2412	6623	Asked why did CGG not model noise impacts on kooyang, specifically? Requested that CGG add this specific analysis to its noise and seismic studies reports in the EP and provide it to them for further consideration at a consultation meeting.	Event ID 6859 - The Regia team responded that the noise modelling conducted by CGG assessed the impacts from sound to fish under three subcategories. These include fish with a swim bladder, fish without a swim bladder, and fish eggs and larvae. Fish susceptibility to injury from noise exposure varies depending on the species and the presence and possible role of a swim bladder in hearing. Thus, different thresholds were proposed for fish without a swim bladder, fish with a swim bladder not used for hearing, and fish that use their swim bladders for hearing. The latter two categories representing a further level of complexity applied to the modelling categories for fish. For context, CGG has grouped kooyang with fish containing swim bladders when assessing seismic effect studies. Therefore, CGG does not agree that the results from the noise modelling were necessarily a "broad evaluation", but an appropriately categorised one. Standard modelling methodology models for receptors based on hearing group, not species. As this relates to fish, the presence/absence of a swim bladder remains the most suitable parameter for grouping fish in modelling for impacts from sound, therefore justifying CGGs reasoning behind not conducting species-specific modelling for kooyang, nor any other fish, bird, marine mammal, or turtle species.
2413	6623	Asked if CGG assessed whether adult and juvenile kooyang would be able to move away from the sound of the seismic survey with sufficient speed to mitigate potential harms?	Event ID 6859 - The Regia team responded that CGG has considered a study by Koster et al. (2021). Adult Short-finned Eels tagged and released from Hopkins River Mouth, Killarney Beach and Warrnambool Harbour, locations in shore of the Operational Area showed that they migrated to access deep water via two main routes: directly east via Bass Strait or southeast around Tasmania (Koster et al 2021). While migrating through the shelf area where the Operational Area is located adult eels achieved an average speed of 30.8 ± 7.3 km/day with one eel swimming at 80 km/day so it is feasible that they can swim away from a sound source (Koster et al 2021). CGGs implementation of the Fauna Management System requires the seismic source to be slowly ramped up to full power over 30 minutes. This would allow eels to move away from the source before it is at full power, and once the source passes, animals will be free to move back into the habitat that they departed from. Thus, injury impacts that may occur if the seismic array commences at full power adjacent to migrating eels has been mitigated for.
2414	6623	Does CGG account for the difference in size and speed of adult and juvenile (for example, glass eels) kooyang in this analysis?	Event ID 6859 - The Regia team responded that this point had been addressed in Appendix E3, where the following information can be found: "Glass eels, which are between 50-60 mm in length, actively swim toward and into the embayments and estuaries of the eastern Australian continent (VFA 2017). Though they are unlikely to achieve speeds reached be adult eels they can actively swim away from the sound source."

2415	6623	Does CGG contemplate whether the sound from the seismic survey could itself affect kooyang swimming speeds (for example if the noise stuns, injures or confuses kooyang so they are unable to swim away)?	Event ID 6859 - The Regia team responded that the following predicted impact has been included in Appendix E3 by CGG: "Injury impacts may occur if the seismic array commences at full power adjacent to migrating eels. However, the implementation of the Fauna Management System requires the seismic source to be slowly ramped up to full power over 30 minutes. This would allow eels to move away from the source before it is at full power." Therefore, CGG predicts that this control measure will provide kooyang with an opportunity to actively move away from the sound source prior to exposure levels that could result in injury.
2416	6623	Does CGG assess the individual and population level impacts of the predicted behavioural change of kooyang swimming away from the sound source, particularly given that the sound source is proposed to occur in an area of the Otway Basin where kooyang migrate through as part of their life cycle. This includes how impacts to kooyang migration (via behavioural changes) as a result of the seismic survey could affect their reproduction and population. How does the predicted behavioural change of swimming away from the seismic survey sound mitigate harm from the seismic survey?	Event ID 6859 - The Regia team responded that the predicted level of impact to kooyang can be found in Appendix E3.The predicted effect level to these species is assessed as minor as impacts are predicted to have some effect on eels, but the effect is not considered significant or at a level to affect the population. CGG's intention to implement the Fauna Management Plan, including the slow ramp-up of the sound source, is based on CGG's prediction that this measure would result in eels moving away from the source to avoid injury. However, once the source passes, animals will be free to move back into the habitat that they departed from. Therefore, due to the temporary nature of the sound source, and the robust abilities of eels to migrate such extensive distances as part of their life cycle, neither the effects of the sound source, nor any temporary displacement of these species, have considered to be significant. Given the extended and volatile timing of migration from estuaries and the high mobility of individual animals CGG does not anticipate any critical effects to the local populations of eels from the Regia MSS. The predicted behavioural change of swimming away from the seismic survey sound is expected to mitigate potential injury to kooyang from the sound source, because increasing distance reduces exposure to more intense sound pressure levels closer to the source that are consistent with potential injury.
2417	6623	Given that CGG appears to recommend that its seismic survey should occur during the period when kooyang are returning to river systems, why has CGG not incorporated an analysis of the impacts of the seismic survey on glass eels and larvae in the EP?	Event ID 6859 - The Regia team responded that CGG has conducted a further assessment on Glass Eels in Appendix F3 – "Further Assessment of Key Values and Sensitivities" which assesses kooyang both during its larval and glass eel life cycle stages. The outcome of this further assessment concluded that CGG is satisfied through implementation of mitigation measures, impacts have been reduced to below acceptable levels and no further assessment or mitigation is recommended.

2418	6623	Asked how can the sound modelling within the EP show potential significant impacts and the Acceptable Levels Assessment show no population level impacts and otherwise reversible, small-scale, or recoverable impacts given these significantly elevated noise levels?	Event ID 6859 - The Regia team responded that the acoustic modelling study on underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) was conducted to assist in understanding the potential acoustic impacts on key regional receptors including marine mammals. The potential impacts presented in these studies do not incorporate/consider any mitigation/control measures in the methodology, therefore presenting the predicted impacts associated with behavioural response, TTS and PTS without mitigation. These acoustic modelling studies therefore served as a tool to assist CGG in designing and setting baseline parameters associated with the Regia MSS, including highlighting the most sensitive marine receptors and setting minimum shutdown distances. The results of the Acceptable Levels Assessment are as such, because of activity limitations and some additional management measures CGG has committed to implementing where required. Without mitigation, predicted impacts to some marine mammals from the Regia MSS would not be below the defined acceptable levels.
2419	6623	Asked for clarification about the discrepancy in model results between CGG and another titleholder?	Event ID 6859 - CGG does not believe it is appropriate to comment on the aspects of another titleholders EP as it relates to the Regia MSS. Input parameters other than location, such as information relating to bathymetry, sound speed profiling, and geoacoustics being some of the many required as part of the methodology associated with acoustic modelling, with levels of complexity exceeding those capable for simplification and explanation in plain language. The acoustic modelling reports were commissioned by CGG and conducted by an independent third party who CGG are confident provided industry-standard, reliable, and accurate acoustic modelling services. The TGS survey was much larger than the Regia survey and going to be undertaken in deeper waters with different bathymetry and substrate which may lead to different TTS distances, thus the TGS and Regia modelling reports are not comparable.
2420	6623	Asked in circumstances where seismic survey blasts occur every 6-20 seconds continuously, why does the EP not analyse the increase in ambient noise in the area nor the effects from chronic noise exposure?	Event ID 6859 - The Regia team responded that CGG acknowledges that an assessment of the ambient noise in the proposed region of the Regia MSS may be required to provide sufficient context that informs the impact assessment of underwater sound on relevant receptors. CGG will be providing additional information in the EP on ambient noise in the Otway region.
2421	6623	Asked if CGG estimated changes to ambient noise levels as part of its analysis? If it did, why have chronic noise impacts been ignored within the Environmental Planning Area and beyond, given the duration of the project?	Event ID 6859 - The Regia team responded that CGG would be providing additional information in the EP on ambient noise in the Otway region.

2422	6541	The relevant person asked if the Regia team had access to the articles/reports related to Middle Island little penguins populations.	Event ID 6538 - The Regia team responded that they had accessed the latest reports from the Middle Island project and contacted various organisations involved with the Victorian colonies.
2423	6880	The relevant person asked what the consultation process was after the 14/02/25 meeting with the Regia team.	Event ID 6880 - The Regia team responded in-meeting and discussed co-design for the ongoing consultation process and stated they were happy to be guided on the relevant person's preferred method of consultation.
2424	6880	The relevant person asked what are the improved outcomes regarding blue whales and southern right whales.	Event ID 6880 -The Regia team responded in-meeting that they were looking at technology advancements regarding detection. Explained that previously, there were plane surveys, marine fauna observers on the seismic vessel and a separate detection vessel dedicated to whales. In relation to improvements, the Regia team explained they had developed a new PAMS technology. Discussed tethered buoys and their purpose to detect whales. Explained that they were running an experiment prior to the survey with the test buoy. Explained that it detects underwater sound and can hear 24 hours a day and, if successful, they had committed to deploying more during the survey.
2425	6880	The relevant person asked who the Regia team are getting advice from regarding where to deploy PAMS technology.	Event ID 6880 -The Regia team responded in-meeting that they would seek advice from whale experts and people from university's who study SRW.
2426	6880	The relevant person requested clarification regarding the 90 days of the activity and the 2025-2028 dates.	Event ID 6880 -The Regia team responded in-meeting that once the vessel arrived, it must leave at the end of the 90 day period.
2427	6880	The relevant person asked if they could be notified when the vessel arrived to carry out the activity.	Event ID 6880 -The Regia team responded in-meeting that they were happy to notify the relevant person.
2428	6880	The relevant person asked if the Regia team would observe animals before, during and after the activity and if they would be notified about the health of the animals.	Event ID 6880 -The Regia team responded in-meeting that when they are talking about seismic, there is a 60-day limitation. It is also intermittent as there are many factors meaning that they would have to stop. In relation to observations, tje Regia team stated that they had committed to pre-start observations and would also have spotter vessels moving ahead of the seismic vessel prior to the activity. They said that if the relevant person wanted notification of the data/images, all they needed to do is ask as the Regia team were happy to share.
2429	6880	The relevant person asked who the Regia team were asking for permissions and licensing from.	Event ID 6880 -The Regia team responded in-meeting that they have to prepare the EP and send to a federal government regulator – NOPSEMA. Explained regulation process and stated they were in the middle of that process and had just received an RFWI request from NOPSEMA.
2430	6880	The relevant person asked if the Regia team would be going out on the seismic vessels and, if not, could they rely on the feedback?	Event ID 6880 - The Regia team responded that it is possible that team members would go out on a vessel. They explained that they could guarantee the on-vessel feedback and that they have several communication arrangements for operation, safety and the environment.

2431	6880	The relevant person asked if the Regia team could provide a video demonstration of seismic.	Event ID 6880 - The Regia team responded in-meeting that they would send video clips. Committed to sending a video of an experiment conducted in the North on snapper. In Event ID 6859, the Regia team provided links: - Geoscience Australia - Marine seismic surveys and the environment: https://www.youtube.com/watch?v=TlyzHW5x1HE&t=5s - Marine acoustic source: https://www.youtube.com/watch?v=s68vb0TQxK8 - Australian Insitute of Marine Science - Marine Noise - Northwest Shoals to Shore Research Program: https://www.youtube.com/watch?v=D0uLK_m57VY
2432	6880	The relevant person asked about impulse sound if the Regia team had a legal requirement to know what was going on inside and outside the areas.	Event ID 6880 - The Regia team explained the amount of sound created and the received levels to the species. Stated that it is how each species receives sound.
2433	6880	The relevant person asked who are CGG funding and who are the interests going to.	Event ID 6880 - The Regia team responded in-meeting with an explanation of who CGG are, what they do, and that they are in discussions with ConocoPhillips and the provisions of data. Clarified that CGG and ConocoPhillips activities are not contingent on each other. Discussed confidentiality and intellectual property requirements. Explained sensitive information requirement and our obligation to make it private. Explained we have to submit it to regulator but it will fall under the SIR. We do not know what is sensitive until we are told. Explained the EP is published and made publicly available. If the information is reasonably publicly known, that information would be made public.
2434	6880	The relevant person asked who gets the bill for consultations.	Event ID 6880 - The Regia team responded in-meeting that CGG receive the bill. Explained there was a public comment period and the NOPSEMA assessment process.
2435	6880	The relevant person asked if the Regia team could provide information to the Gunditjmara people prior to future meetings.	Event ID 6880 - The Reiga team responded that they had been working with the organisation to prepare the materials and that the request for information prior to meetings would not be a problem. Explained consultation with the organisation and explained what CGG had done to gather information on Sea Country.
2436	6880	The relevant person asked what the Sea Country Protection Plan protects against?	Event ID 6880 - The Regia team responded in-meeting that the SCPP protects against impacts and risks that arise from the proposed activity.
2437	6880	The relevant person asked about the previous surveys in the region.	Event ID 6880 - The Regia team responded in-meeting and discussed the historical surveys in the Otway Region.
2438	6880	The relevant person asked if the health of the Otway region had been researched.	Event ID 6880 - The Regia team confirmed in-meeting that the Otway region had been studied and researched.

2439	6880	The relevant person asked if the Regia team had already developed the EP.	Event ID 6880 - The Regia team responded in-meeting that they had developed the EP but that it was not a static document. They discussed getting more input into the process to improve the quality oif the document. Explained that the Regia team had previously attempted consultation with the organisation and that they were looking to improve the protections already in there with consultation.
2440	6880	The relevant person asked if the EP had been accepted by NOPSEMA.	Event ID 6880 - The Regia team responded in-meeting that the Regia team had written an EP but NOPSEMA had not accepted it yet. Explained that the EP was with NOPSEMA for assessment.
2441	6880	The relevant person asked if consultation with their organisation change the document?	Event ID 6880 - The Regia team responded in-meeting that the NOPSEMA assessment is a point in time assessment. Explained that the nature of the environment and environmental mansgement is that things always change and that this was reflected in the document.
2442	6880	The relevant person asked about data sharing, IP rights, and if CGG could profit from their information.	Event ID 6880 - The Regia team explained in-meeting that if the relevant person tells them the information they provide is sensitive, CGG and NOPSEMA are not allowed to publish it. The Regia team stated that the data licensed by CGG is only sub-surface data/scientific data from the survey.
2443	6880	The relevant person asked if CGG would pay their organisation funds to have dedicated resources devoted to consultation work.	Event ID 6880 - The Regia team responded in-meeting that they would look into it but could not make any commitments.
2444	6880	The relevant person asked if the EP had come back from NOPSEMA.	Event ID 6880 - The Regia team responded that the EP had come back from NOPSEMA with a letter to modify and re-submit. They explained that the team needed to redact the letter but that it would soon be published.
2445	6880	The relevant person asked if there would be compensations in place for the coercive and predicative conditions and if there were CGG share options abvailable.	Event ID 6880 - The Regia team responded in-meeting that this was a topic of discussion within future consultation with the organisation.
2446	6880	The relevant person asked if they could see the results from the previous surveys in the area.	Event ID 6880 - The Regia team responded in-meeting that they could. They explained a multi-climate and proprietary survey and the timeframes for data release.
2447	6880	The relevant person asked what reasonable consultation looks like for CGG.	Event ID 6880 - The Regia team responded in-meeting that they approach consultation with an open mind and that it is never assumed how somebody can be affected. They stated that they want to ensure there is a back and forth conversation and that they should er on the side of transparency.
2448	6880	The relevant person asked about the SCPP.	Event ID 6880 - The Regia team responded in-meeting with an outine of the proposed SCPP and provided key features that could be put in place i.e MFO training, pre-survey ceremony. Asked for feedback and that it is to be an initiative led by TO's and facilitate partnership. Explained that if the relevant person does not want SCPP, they can suggest something else.

2449	6580	The relevant person requested the Regia team call them to arrange a meeting time.	Event ID 6799 - The Regia team responded during an incoming telephone call. The relevant person explained that they do not think they are a relevant person anymore to the project and did not have time to meet. The Regia team explained they would like to keep in touch to develop SIMOPs with rec divers.
2450	6624	The relevant person asked if the seismic survey had been approved and, if so, whether there are any restrictions in regardings to timing that will mitigate impacts to Kontapool.	Event ID 6878 - The Regia team provided an overview of the Regia seismic survey and timings ,and that they were notional dates as there are criteria for whale detections. Explained that there were multiple lines of evidence approach in relation to fauna management. Also discussed the tethered buoy expriment and that they were taking advice for the best location to maximise results.
2451	6867	The relevant person asked the Regia team to advise on the status of the NOPSEMA decision and if they were working towards a new decision date for the project.	Event ID 6626 - The Regia team responded they they were yet to receive a decision from NOPSEMA and were expecting a letter later that day.
2452	6631	The relevant person requested that the Regia team inform them when requested documents had been added to share folder.	Event ID 6634 - The Regia team apologised for uploading issues and confirmed the requested documents had been uploaded. They provided a screenshot of the requested documents within the sharefolder.
2453	6630	Requested that materials provided to date should be updated to allow for each meeting agenda item having at least one dedicated slide.	Event ID 6625 - The Regia team proposed that CGG provide a project update before the previously agreed items to ensure that all attendees have the latest information about the project. On the assumption that the organisation would agree to this practical amendment the Regia team made the associated changes in slide order. CGG made the amendments to the presentation as requested, offered a preliminary view on certain agenda items, with the summary information provided. They stated that the brevity necessary to condense their view into text on a slide risks misinterpretation and missing nuance that a meaningful discussion might reveal.
2454	6630	Requested information on CGG's views and response to the Protocols vis-à-vis the Consultation Framework workflow/document.	Event ID 6625 - The Regia team responded that CGG had made the amendments to the presentation as requested and offered a preliminary view on certain agenda items, with the summary information provided. They stated that the brevity necessary to condense their view into text on a slide risks misinterpretation and missing nuance that a meaningful discussion might reveal.
2455	6630	Requested information on how CGG wished to co-design the consultation process, including timeframes, milestones, and views on the proposed strategic regional environmental and cultural assessment.	Event ID 6625 - The Regia team responded that CGG had made the amendments to the presentation as requested and offered a preliminary view on certain agenda items, with the summary information provided. They stated that the brevity necessary to condense their view into text on a slide risks misinterpretation and missing nuance that a meaningful discussion might reveal.

2456	6630	Requested iinformation on the SCPP.	Event ID 6625 - The Regia team responded that CGG had made the amendments to the presentation as requested and offered a preliminary view on certain agenda items, with the summary information provided. They stated that the brevity necessary to condense their view into text on a slide risks misinterpretation and missing nuance that a meaningful discussion might reveal.
2457	6630	Requested information on CGG's legal obligations in relation to intellectual property and company policy in respect of dealing with sensitive information in Environment Plans.	Event ID 6625 - The Regia team responded that CGG had prepared the PowerPoint slide deck in such a way that the slide content, when printed, would form the requested information sheet.
2458	6630	Requested that information sheets be provided as soon as possible	Event ID 6625 - The Regia team responded that CGG had made the amendments to the presentation as requested and offered a preliminary view on certain agenda items, with the summary information provided. They stated that the brevity necessary to condense their view into text on a slide risks misinterpretation and missing nuance that a meaningful discussion might reveal.
2459	6630	Requested for 50 copies of the consultation material provided for attended meeting.	Event ID 6625 - The Regia team responded that CGG would print and have available 50 copies of the documents as requested.
2460	6870	Requested information on the tethered buoy whale monistoring testing activity.	Event ID 6861 - The Regia team responded that the initial stage would be the deployment of two buoys, with attached hydrophones, in the area adjacent to VIC/P44, for a maximum of 90 days. This would hopefully be around late April to late June. They said that they hoped that the test shows that blue whale calls can be recorded and identified, meaning that we can detect blue whale before they have entered an operational area. They would then want to use them for our proposed marine seismic survey (Regia). To detect whales before they enter the operational area, the buoys would potentially need to be deployed outside of the survey area.
2461	6870	Asked what the proposed tethered buoy activity involves.	Event ID 6862 - The Regia team responded that the proposed activity involves deployment of two buoys, with attached hydrophones.
2462	6870	Asked for information about the scale of the proposed tethered buoy activity.	Event ID 6862 - The Regia team responded that there would be 2 buoys.
2463	6870	Asked what the objective of the proposed tethered buoy activity is.	Event ID 6862 - The Regia team responded that the objective of the proposed activity is to record whale calls in order to identify blue whales.
2464	6870	Asked when the tethered buoy activity is proposed to occur and its duration.	Event ID 6862 - The Regia team responded that testing would begin in late April 2025 to June 2025 for a maximum of 90 days.
2465	6870	Asked if there are existing petroleum or greenhouse gas titles over the area of the proposed tethered buoy activity.	Event ID 6862 - The Regia team responded that there are no petroleum or greenhouse gas titles over the area of the proposed activity, but it is adjacent to VIC/P44.
2466	6871	Requested answer to questions sent in previous	Event ID 6862 - The Regia team provided answers to questions previously raised by the relevant person as requested.

		correspondence about the tethered buoy activity.	
2467	6839	Requested CGG's invoicing information for its attendance at the native title meeting.	Event ID 6838 - The Regia team provided their updated invoicing information as requested.
2468	6690	Requested that the Regia team share the feedback provided by NOPSEMA regarding the proposed environment plan.	Event ID 6794 - The Regia team responded that at the start of consultation on the Regia MSS, CGG recognised the need for transparency in order to build trust with relevant persons. One aspect of this has been to publish the NOPSEMA assessment letters, which they had done on the web site and notified relevant persons via a project update. They stated that as this is not something that other titleholders do, and as the letter is essentially private correspondence meant for the addressee (CGG) only, there is a process that has to be undertaken before we publish the correspondence.Once the correspondence was ready to be published, the Regia team would notify relevant persons via a project update, as they had done previously.
2469	6879	Asked if the Regia team were looking to present to the council again?	Event ID 6879 - The Regia team responded in-meeting that they were happy to present again if the council would allow. Extended offer to present in person or onling.
2470	6879	Asked for information about plankton and their role in the activity.	Event ID 6879 - The Regia team responded in-meeting that plankton are the foundation of the food well. Discussed the Bonney Upwelling.
2471	6879	Requested to continue to receive project updates and add another council member to correspondence.	Event ID 6879 - The Regia team responded in-meeting that they would continue to receive project updates.
2472	6878	Question regarding calving interval stretching and that papers regarding reproduction rate need to be revisted.	Event ID 6878 - The Regia team responded in meeting sharing information being built from other proponents ongoing aerial surveillance programs and shared speculation about movement along Tasmania as a migration corridor.
2473	6878	Questioned the uncertainty around the SRW migratory corridor and timing of the Regia survey.	Event ID 6878 - The Regia team responded in-meeting and explained observations in previous surveys and discussed migratory routes along Tasmania. They also explained that there were multiple lines of evidence approach in relation to fauna management. Discussed that the Regia team were doing the most any titleholder had previously done for a seismic survey. Stated that there would be at least one aerial flight survey and that there would be a secondary spotter vessel. Discussed the tethered buoy experiment and that the Regia team were taking advice on what the best location would be to maximise results.
2474	6878	Question about the importance of surveying SRW's from the air.	Event ID 6878 - The Regia team responded in-meeting and explained that they were completing aerial surveys. They also stated that they had satellite mapping which could provide SRW locations.

2475	6878	Asked how the Regia team were completing whale detections. Provided example of aerial surveys?	Event ID 6878 - The Regia team explained in-meeting that there were multiple lines of evidence approach in relation to fauna management. Discussed that the Regia team were doing the most any titleholder had previously done for a seismic survey. Stated that there would be at least one aerial flight survey and that there would be a secondary spotter vessel. Discussed the tethered buoy experiment and that the Regia team were taking advice on what the best location would be to maximise results.
2476	6878	Asked if the secondary spotter vessel moved in front of the seismic vessel?	Event ID 6878 - The Regia team responded in-meeting that the secondary spotter vessel would move in front of the seismic vessel but that pre-start tasking may be different.
2477	6878	Asked how far the survey was from Warrnambool?	Event ID 6878 - The Regia team responded in-meeting that the survey was 20km from the nearest point.
2478	6878	Asked for information about noise modelling.	Event ID 6878 - The Regia team responded in-meeting with a discussion about TTS and PTS. Stated that the main issue being managed was migration. Discussed that there would be a whale expert panel and data could be made available.
2479	6890	Provide a written response to stakeholders' work	Event ID 6815 - provided comprehensive review of stakeholders work
2480	6886	Relevant person requested results of PAM system being trialled by the Regia team	Event ID 6897 - The Regia team committed to sharing some data after the PAM buoy trial when it becomes available. Explained that they were optimistic they would detect whales and that the buoy had been specificlly altered to detect blue whale and SRW calls.
2494	6748	Relevant person requested response to initial enquiry	Event 6722 - Responded to relevant person clarifying the commitment to investigate the matter and advised the work on this was still ongoing a nd requested patience. Provided brief update on search for additional research that supports the FRDC findings and requested if the relevant person was able to access/ provide any other peer reviewed literature to support the claim
2495	6875	Requested information on why fisheries would not answer questions about long-term catchability when the data is available.	Event iD 6875 - The Regia team responded in-meeting that the issue was not resolved but that they were only presenting an interpretation of the data set. The Regia team offered to re-run their analysis based on new data provided by fishers.
2496	6876	Relevant person requested information about the Regia activity maps.	Event ID 6876 - The Regia team responded in-meeting and explained that there was a buffer around Deen Maar for sea lion protection and traditional owner values.
2497	6876	Relevant person asked about operation during poor weather conditions.	Event ID 6876 - The Regia team responded in-meeting and stated that they would not be able to operate in +5m swells. Also explained that they could bring in other vessels to negotiate poor weather conditions.

2498	6876	Requested information on what the Regia team heard during consultation on the adjustment protocol.	Event ID 6876 - The Regia team responded in-meeting and discussed the main concerns raised during consultation: : long term catchability, displacement, claim process, further information and socio-economic. Discussed displacement and communications protocols in place to avoid displacement. Provided details of where to locate claims form and the updated adjustment protocol. Explained that there is currently a test claim form that fishers can use. Explained that a fisher can delegate to a titleholder representative and via a nominated claims assessor.
2499	6876	Requested details about what data was used by the Regia team in their long-term catchability analysis.	Event ID 6876 - The Regia team responded in-meeting and went through their box plot analysis. Explained that the data used was landed catch data each month from 2016 - 2023. Also went through CPUE data set and stated that the analysis showed although landed catch was lower, CPUE was still in range in 2020.
2500	6876	Relevant person asked where the Environment Plan information comes from?	Event ID 6876 - The Regia team responded in-meeting that EP information comes from peer review, scientific literature.
2501	6876	Requested information about what happens 5-7 years after a seismic activity to lobster populations.	Event ID 6876 - The Regia team responded in-meeting and discussed seagrass and adult lobster populations. Explained that there were too many variables in the marine evironment.
2502	6876	Relevant person asked why they had lost quota.	Event ID 6876 - The Regia team responded in-meeting that larvae are coming in from South Australia. Explained that egg production was probably getting sucked into the Bass Straight.
2503	6876	Relevant person asked about short-term catchability assessment on Western Rock Lobster in WA.	Event ID 6876 - The Regia team responded in-meeting that the assessment showed a short-term effect over 30 days in the study. Explained that fishers can make a CPUE claim 30 days after the survey.
2504	6876	Asked about the level of damage of a seismic survey on rock lobsters.	Event ID 6876 - The Regia team responded in-meeting that seismic activity can cause a delayed righting reflex.
2505	6876	Asked for information about the effect of the proposed seismic survey on crab.	Event ID 6876 - The Regia team responded in-meeting that seismic can cause a physiological reaction in crab - delayed righting. Discussed that they will only go to 200m.
2506	6876	Asked about the number of blasts during the activity.	Event ID 6876 - The Regia team responded in-meeting that there will be 1 every 18 seconds. Explained that they had made allowance for 60 days of activity.
2507	6876	Asked what would happen if they went out, dropped a pot and did not catch any lobster.	Event ID 6876 - The Regia team responded in-meeting that the fisher could apply for a CPUE adjustment and explained that they will be paid compensation based on gaps in their fishing data under normal fishing operations.
2508	6876	Asked how the Regia team landed on the compensation protocol?	Event ID 6786 - The Regia team responded in-meeting and stated they had spoken with SIV and explained why retirement of quota is not the right way to pay compensation. Explained that the quota holder is not always the fisher and that it was the Regia team's position that the person on the water should be compensated. The Regia team also discussed anti-rivalry laws.

2509	6876	Relevant person requested their copy consultation records.	This was supplied to the stakeholder in Event ID 7025
2510	6876	Fisher requested information about fishers who are displaced by the drilling activity and the indirect impact this displacement has on other fishers operating in the same area.	Event ID 6786 - The Regia team responded in-meeting that compensation can be claimed via the OMICC Adjustment Protocol for the displacement of the displaced fisher and, if a indirectly affected fisher believes they have a CPUE claim, their claim can be affected on a case-by case basis. It was stated that the OMICC Adjustment Protocol will be updated to reflect this feedback
2511	6876	Fisher asked what happens if someone without a history of fishing offshore? Would they receive the same compensation as other fishers? How do they demonstrate a loss of catch?	Event ID 6786 - The Regia team responded in-meeting that the OMICC protocol has a case-by-case provision.
2512	6876	Fisher asked about the potential of oil spills.	Event ID 6786 - The Regia team responded in-meeting that CGG had commissioned a detail analysis of all the oil spill models completed in the Otway region and and stated that an oil spill was unlikely.
2514	6970	Asked how to make a claim for King George Whiting impacts?	Event ID 6989 - Titleholder responded that they had produced a presentation which showed how to make a claim and provided a link to the OMICC website (https://www.klarite.online/omicc/otway-adjustment-protocol). Also stated that they could offer support in submitting a claim as captured in the protocol.
2515	6988	Requested help with online test claim form.	Event ID 6990 - Titleholder responded with a copy adjustment protocol which had hard copy claim forms attached. The Titleholder also provided the stakeholder with login details to access the online test claim form and supplied a step-by-step screenshot guide for how to log in.
2516	6966	Requested a response to matters raised in their letter within 21 day time frame provided by relevant person.	Titleholder responded within timeframe (Event ID 7022)
2517	6966	Requested that materials provided by CGG are translated into plain non-technical language and that text is condenced without losing key messaging.	CGG requested further clarity from GMTOAC regarding the format and expectations for future responses, particularly when technical questions are involved. CGG also noted its efforts to balance brevity and substance in the information sheets, aiming to be respectful while avoiding oversimplification that could appear dismissive. CGG asked for confirmation on the intended audience and purpose of the materials to tailor future content accordingly (Event ID 7022)

2518	6966	Requested that responses to requests for information prepared by CGG are turned into a PowerPoint presentation or transferred to information sheets.	CGG clarified that Annexure A contained direct responses, with references provided due to the technical nature of the queries. CGG requested further clarity from GMTOAC regarding the format and expectations for future responses, particularly when technical questions are involved. CGG also noted its efforts to balance brevity and substance in the information sheets, aiming to be respectful while avoiding oversimplification that could appear dismissive. CGG asked for confirmation on the intended audience and purpose of the materials to tailor future content accordingly (Event ID 7022)
2519	6892	Regia team to provide additional written information on the tethered buoy activities and dataset usage, along with their position considering section 19.	In Event ID 7029, CGG clarified the spatial scope of the Regia Marine Seismic Survey (MSS), stating the defined petroleum activity area aligns with the petroleum title and the seismic source discharge zone, encompassing all operations under existing and future titles. Two supporting operations outside this boundary—a marine fauna spotter vessel and acoustic monitoring buoys—are included in the Environment Plan (EP) as essential control measures to mitigate environmental impact. These do not require separate titles and are not for exploration purposes, so they fall outside the extended meaning of “explore” under the OPGGS Act. Additionally, a separate technology trial will occur independently of the Regia MSS. It is unrelated to any petroleum title or the MSS and is not exploration-related. Therefore, it is not considered a petroleum activity and is being managed separately from the EP.

EPBC Act Listed Species within the Operational Area Relevant to Release of Materials or Waste Overboard 45

1 Introduction

Accidental release of material and waste overboard was identified through the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) as an aspect needing further assessment. Hence, this document presents a detailed examination of **Accidental Release of Materials and Waste Overboard** as a risk pathway between the Regia Marine Seismic Survey (**Regia MSS**) and the existing environment that may be affected by that aspect.

1.1 Purpose and Scope

The purpose of this document is to assess all relevant sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

Any measures adopted, either through consultation or because of the assessment will be carried through to stage three of the overall process when the ALARP assessment occurs. Recommendations will be made if there is any further assessment required in the third stage.

1.2 Consultation in Preparation of the EP

This document was first published in draft form to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (EP) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

2 Aspect – Accidental Release of Materials or Waste Overboard

2.1 How the Aspect Occurs

An accidental release of materials or waste may occur from the seismic and support vessels.

No materials or solid wastes will be disposed at sea from vessels undertaking the Regia MSS.

2.2 Extent and Duration of the Aspect

Duration: 90 days

Extent: Operational Area

The extent of the area where the risk of an accidental release of materials or waste may occur is within the Operational Area and the risk could occur while the activity is undertaken.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for an accidental release of materials or waste for the following environmental components and their social, cultural, and economic features:

- Water quality
- Benthic assemblages
- Birds
- Sharks
- Marine reptiles
- Marine mammals
- Coastal developments
- Commercial fishing and aquaculture
- People and communities
- Marine protected areas
- Marine industries

The PEIRA identified that risk of an accidental release of materials or waste to the following environment components was ranked as having a negligible level of effect and are not assessed further in this section:

- Water quality
- Benthic assemblages

There is the potential for materials or waste to be accidentally released overboard due to open bins, crane operator error or improper storage or handling. Materials or wastes that could potentially be released overboard are typically inert such as paper, cardboard, foam (earplugs) and plastics (wrapping material, hard hats). These materials or waste could pose a risk marine fauna via ingestion or entanglement. They may also result in visual pollution in the ocean and on shorelines impacting the values of coastal developments, indigenous culture, and marine protected areas.

Larger dropped objects may also occur such as loss of towed equipment (streamers, acoustic sources, paravanes for streamer steering) and sea containers. These may pose a navigational or entanglement hazard to commercial fishers and other marine users.

4 Description of the Existing Environment that May be Affected by the Activity

As detailed in Section 2.2, the Operational Area has been adopted as the extent of the area wherein an accidental release of materials or waste may occur.

To identify the presence of those species that may be at risk of ingestion or entanglement with materials or waste accidentally released overboard (birds, dolphins, pinnipeds, sharks, turtles, whales) a Protected Matters Search (PMST) was undertaken for the Operational Area with the report available in Appendix B5. Annex 3 details those species identified, any biologically important areas and conservation advice or management plans.

PMST searches were run again prior to resubmission to ensure any changes to species or listings were identified to control for passage of time. Conservation Advice has also been updated for several species and subsequent changes throughout the EP have been made to account for these updates. Changes relevant to the assessment of an accidental release of material or waste include:

- Changes to EPBC Act status of several bird species
  - Red Knot is listed as Vulnerable (previously Endangered)
  - Sharp-tailed Sandpiper is listed as Vulnerable (previously not listed as threatened)
  - Sooty Shearwater is listed as Vulnerable (previously not listed as threatened)
- Updates to conservation advice for several bird species
  - Conservation Advice for *Calidris canutus* (Red Knot) (DCCEEW 2024)
  - Conservation Advice for *Calidris acuminata* (Sharp-tailed Sandpiper) (DCCEEW 2024a)
  - Conservation Advice for *Ardenna grisea* (Sooty Shearwater) (DCCEEW 2023i)
  - Conservation Advice for *Calidris ferruginea* (Curlew Sandpiper) (DCCEEW 2023m)
  - Conservation Advice for *Numenius madagascariensis* (Far Eastern Curlew) (DCCEEW 2023n)

These changes have been incorporated throughout the EP and the risk assessment has been revised accordingly. [Section added in response to Matters: I16 and I17]

Information is provided for those species undertaking biologically important behaviour within the Operational Area as these species are more likely to be at risk from ingestion or entanglement with materials or waste accidentally released overboard.

4.1 Birds

The PMST Report identified multiple bird species or species habitat within the Operational Area. provides a summary of the PMST Report. Several of these bird species were identified to be undertaking biologically important behaviours and/or have BIAs within the Operational Area. No habitats critical to the survival of the bird species were identified within the Operational Area.

The orange-bellied parrot, which is critically endangered is likely to migrate through the Operational Area, however, it does not land at sea or use coastal areas as habitat so risks to this species are not predicted from marine debris.

Seabirds that forage at sea are more likely to encounter marine debris and hence are discussed further in this section.

Several albatross species were identified as foraging behaviour likely within the Operational Area with the White-capped Albatross identified as foraging behaviour known to occur. In addition, the following albatross species have foraging BIAs within the Operational Area:

- Antipodean (*Diomedea antipodensis*) – Appendix B12 MAP-REG-EPM-059
- Black-browed (*Thalassarche melanophris*) - Appendix B12 MAP-REG-EPM-060
- Buller's (*Thalassarche bulleri*) - Appendix B12 MAP-REG-EPM-071
- Campbell (*Thalassarche impavida*) - Appendix B12 MAP-REG-EPM-061
- Indian Yellow-nosed (*Thalassarche carteri*) - Appendix B12 MAP-REG-EPM-063
- Shy (*Thalassarche cauta*) - Appendix B12 MAP-REG-EPM-066
- Wandering (*Diomedea exulans*) - Appendix B12 MAP-REG-EPM-072

These BIAs cover either most or all the South-east Marine Region (CoA 2015a).

Albatrosses and petrels are among the most oceanic of all seabirds and seldom come to land unless breeding (CoA 2022). Albatross and petrel species exhibit a broad range of diets and foraging behaviours, and hence at-sea distributions are diverse. Combined with their ability to cover vast oceanic distances, all waters within Australian jurisdiction can be considered foraging habitat, however the most critical foraging habitat is those waters south of 25° where many species spend most of their foraging time (CoA 2022).

Albatrosses have a widespread distribution throughout the southern hemisphere. They feed mainly on cephalopods, fish and crustaceans, using surface feeding or plunge diving to seize their prey (ACAP 2020). Albatrosses are colonial, usually nesting on isolated islands and foraging across oceans in the winter months with most observations along the edge of the continental shelf (CoA 2022).

The Flesh-footed Shearwater and Northern Giant Petrel were also identified as foraging behaviour likely within the Operational Area. No BIAs for these species occur within the Operational Area. The Common Diving-petrel (Appendix B12 MAP-REG-EPM-062), Short Tailed Shearwater (Appendix B12 MAP-REG-EPM-065) and Wedge-tailed Shearwater (Appendix B12 MAP-REG-EPM-067) were identified as having foraging BIAs within the Operational Area.

Petrels are oceanic and have a widespread distribution throughout the southern hemisphere. They are colonial and breed on sub-Antarctic and Antarctic islands in a circumpolar band generally between 40°S and 60°S. Petrel species feed on small fish, cephalopods (octopus, squid and cuttlefish) and crustaceans along the edge of the continental shelf and open waters (CoA 2022).

The Australasian Gannet was also identified as having a foraging BIA within the Operational Area (Appendix B12 MAP-REG-EPM-073). The Australasian Gannet generally feeds over the continental shelf or inshore waters. Their diet is comprised mainly of pelagic fish, but also squid and garfish. Prey is caught mainly by plunge-diving, but it is also seen regularly attending trawlers (CoA 2015a).

Several shorebirds were identified from the PMST Report as being present in the Operational Area with the Australian Fairy Tern and White-fronted Tern identified as foraging behaviour likely within the Operational Area. Threatened shorebirds that may occur within the Operational Area are the Australian Fairy Tern, Curlew Sandpiper, Eastern Curlew, Red Knot and Sharp-tailed Sandpiper. These species are commonly found on coastal shores including beaches and rocky shores and either feed at low tide on worms, crustaceans and molluscs or fish species or feed on aquatic biota. Many of the wader species are migratory travelling from the Northern Hemisphere in non-breeding months. Most inhabit intertidal mudflats, rocky islets, sand beaches, mangroves, rocky coastline, and coral reefs. Roosting occurs in similar habitats and species are found feeding on fish, crustaceans, aquatic insects, as well as plants and seeds (Higgins & Davies 1996).

4.2 Pinnipeds

The PMST Report identified the Australian Fur-seal (*Arctocephalus pusillus*) as likely to occur within the Operational Area, while the Australian Sea-lion (*Neophoca cinerea*) and the New Zealand Fur-seal (*Arctocephalus forsteri*) may occur. No biologically important behaviours or BIAs were identified within the Operational Area for these species.

4.3 Sharks

The PMST Report identified five shark species, that may (School - *Galeorhinus galeus*), are likely (Porbeagle - *Lamna nasus*, Mako - *Isurus oxyrinchus*, Little Gulper - *Centrophorus uyato*) or are known (White - *Carcharodon carcharias*) to occur within the Operational Area. A foraging BIA was identified for the White Shark only (Appendix B12 MAP-REG-EPM-027).

The White Shark is listed as Vulnerable. White Sharks are long-lived, living for 30 years or more (Bruce and Bradford 2008), and are found throughout temperate and sub-tropical regions in the northern and southern hemispheres (Last & Stephens 2009). The species is also commonly found in inshore waters in the vicinity of islands, and often near seal colonies (Malcolm et al. 2001). The foraging BIA that is within the Operational Area is centred on Lady Julia Percy Island which is a known seal breeding colony.

4.4 Turtles

The PMST Report identified three turtle species, that may (*Chelonia mydas* - green) or are likely (*Dermochelys coriacea* - leatherback and *Caretta caretta* - loggerhead) to occur within the Operational Area. No BIAs or habitat critical to the survival of the species were identified.

4.5 Dolphins and Whales

The PMST Report identified several dolphin and whale species that are known, likely or may occur within the Operational Area. Table D1-1 details those species that have biologically important areas or biologically important behaviours identified within the Operational Area.

Table D1-1: Cetacean Species Biologically Important Behaviours and/or BIAs within the Operational Area

Receptor	Biologically Important Behaviour
Blue Whale	Foraging, feeding or related behaviour known to occur within area
	Foraging (annual high use area) BIA (Appendix B12 MAP-REG-EPM-016)
Fin Whale	Foraging, feeding or related behaviour known to occur within area
Pygmy Right Whale	Foraging, feeding or related behaviour likely to occur within area
Sei Whale	Foraging, feeding or related behaviour known to occur within area
Southern Right Whale	Breeding known to occur within area
	Migration BIA (Appendix B12 MAP-REG-EPM-085)

4.5.1 Blue whale

The Blue Whale (*Balaenoptera musculus*) is listed as an endangered species under the EPBC Act. There are two subspecies of blue whales that use Australian waters (including Australian Antarctic waters), the Pygmy Blue Whale (*B. m. brevicauda*) and the Antarctic Blue Whale (*B. m. intermedia*). The Otway region, where the Operational Area is located, is an important migratory and foraging area for Blue Whales, as shown by passive acoustic monitoring and aerial surveys (Gavrilov 2012, McCauley et al. 2018, Gill et al. 2011). Underwater acoustic monitoring programs have detected Antarctic and Pygmy Blue Whale calls in the Otway Region (McCauley et al. 2018).

Important foraging grounds for Blue Whales include the Great Australian Bight, South Australia, and off Portland Victoria. Research to date has found that Pygmy Blue Whales occupy the western area of the Bonney Upwelling system in the Eastern Great Australian Bight and adjacent to the Kangaroo Island canyons from November and December (DoE 2015c). Pygmy Blue Whales then move south-east to the Bonney Upwelling system off eastern South Australia and Victoria (e.g., between Robe, SA and Cape Otway, Vic). This occurs predominately between January to April (DoE 2015c).

The Blue Whale was extremely abundant until the early 20th century when they were hunted to near extinction. Approximately 341,830 Blue Whale takes were recorded by commercial whaling in the

Antarctic and sub-Antarctic in the 20th century, of which 12,618 were identified as Pygmy Blue Whales (Branch et al. 2004). The current global population of Blue Whales is uncertain but is plausibly in the range of 10,000 to 25,000, corresponding to about 3-11% of the 1911 estimated population size (Reilly et al. 2008).

The Operational Area is within the foraging (annual high use) BIA where Pygmy Blue Whales predominately occur between January to April (DoE 2015c) (Appendix B12 MAP-REG-EPM-068).

4.5.2 Fin whale

The Fin Whale (*Balaenoptera physalus*) is a cosmopolitan migratory species that is listed as vulnerable and occurs from polar to tropical waters but is rarely sighted in inshore waters. Fin Whales show well defined migratory movements between polar, temperate, and tropical waters which are essentially north–south with little longitudinal dispersion.

While Australian Antarctic waters are important feeding grounds for Fin Whales, the species also feeds in the Bonney Upwelling during summer/autumn sometimes in the company of Blue and Sei Whales (DCCEEW 2023b). Areas of upwelling and interfaces with mixed and stratified waters may be an important feature of Fin Whale feeding habitat with the species feeding on planktonic crustacea, krill, some fish, and cephalopods (DCCEEW 2023b). Fin Whales frequently lunge or skim feed at or near the surface and they are known to dive to 230 m to feed.

There are no BIAs for the Fin Whale within Australian waters. Fin Whales are likely to be foraging in the Operational Area at similar time as Blue Whales, predominately occur between January to April.

4.5.3 Pygmy Right Whale

The Pygmy Right Whale (*Caperea marginata*) is a little-studied baleen whale species that is found in temperate and sub-Antarctic waters in oceanic and inshore locations. No population estimates are available for Pygmy Right Whales globally, or in Australian waters (DCCEEW 2023p). The species has never been hunted commercially and is listed as a migratory species under the EPBC Act.

Species distribution in Australia is found close to coastal upwellings and the Subtropical Convergence may be important for regulating distribution (Bannister et al. 1996). Key locations include south-east Tasmania, Kangaroo Island (SA) and southern Eyre Peninsula (SA) close to upwelling habitats rich in marine life and zooplankton upon which it feeds (Bannister et al. 1996).

There are no BIAs for the Pygmy Right Whale within Australian waters. Pygmy Right Whales are likely to be foraging in the Operational Area at similar time as Blue Whales, predominately occur between January to April.

4.5.4 Sei Whale

The Sei Whale (*Balaenoptera borealis*) is listed as vulnerable under the EPBC Act. Sei Whales are considered a cosmopolitan species, ranging from polar to tropical waters, but tend to be found more offshore than other species of large whales. Sei Whales move between Australian waters and Antarctic feeding areas; subantarctic feeding areas (e.g. Subtropical Front); and tropical and subtropical breeding areas. The proportion of the global population in Australian waters is unknown as there are no estimates for Sei Whales in Australian waters.

In Australia, Sei Whales occur within Australian Antarctic Territory waters and Commonwealth waters, and have been infrequently recorded off Tasmania, NSW, Queensland, the Great Australian Bight, Northern Territory and Western Australia (Parker 1978, Bannister et al. 1996, Thiele et al. 2000, Chatto and Warneke 2000, Bannister 2008).

Sightings of Sei Whales within Australian waters includes areas such as the Bonney coast upwelling (Miller et al. 2012), where opportunistic feeding has been observed between November and May (Gill et al. 2015).

There are no BIAs for the Sei Whale within Australian waters. Sei Whales are likely to be foraging in the Operational Area at similar time as Blue Whales, predominately occur between January to April.

4.5.5 Southern Right Whale

The Southern Right Whale (*Eubalaena australis*) is listed as endangered under the EPBC Act. Southern Right Whales were depleted to less than 300 individuals globally due to commercial whaling in the 19th and 20th centuries (Tormosov et al. 1998). They were protected from whaling in 1935 however, due to illegal whaling in the 1970s and because Southern Right Whales have a slow rate of increase (7% per annum) compared to other marine mammals, their numbers remain low (IWC 2013). Global abundance estimates are 13,000 for the species, across key wintering grounds in South Africa, Argentina, Australia, and New Zealand.

Southern Right Whales are distributed in the Southern Hemisphere with a circumpolar distribution between latitudes of 16°S and at least 65°S. They migrate from southern feeding grounds in sub-Antarctic waters to Australia in between May and November to calve, mate and rest (Bannister et al. 1996, DCCEEW 2022). In Australian coastal waters, they occur along the southern coastline of the mainland and Tasmania and generally extend as far north as Sydney on the east coast and Perth on the west coast (CoA 2012). There are occasional sightings further north, with the extremities of their range recorded at Hervey Bay and Exmouth (CoA 2012).

The largest established calving areas in Australia include Head of Bight in SA, and Doubtful Island Bay and Israelite Bay in WA. Smaller but established aggregation areas regularly occupied by Southern Right Whales include Yokinup Bay in WA, Fowlers Bay in SA and the Warrnambool and Portland in Victoria. Emerging aggregation areas include Flinders Bay, Hassell Beach, Cheyne/Wray Bays, and Twilight Cove in WA, and sporadically occupied areas include Encounter Bay in SA. Southern Right Whales generally occupy shallow sheltered bays within 2 km of shore and within water depths of less than 20 m (Charlton et al. 2017).

The Operational Area overlaps the Southern Right Whale Migration BIA where the whales are present between April and October (AMSIS 2025, formerly National Conservation Values Atlas (NCVA)) (Appendix B12 MAP-REG-EPM-085).

4.6 Coastal Developments

No coastal developments are within the Operational Area. The closest coastal developments to the Operational Area are the towns of Port Campbell, Port Fairy, and Warrnambool. The Great Ocean Road, a major tourist draw card is popular for its pristine beaches. The nearest coastline is ~ 7 km from the Operational Area.

4.7 Commercial Fishing and Aquaculture

No aquaculture is undertaken within the Operational Area.

Based on the Commercial Fisheries Analysis report (Appendix B6), the Operational Area overlaps the following commercial fisheries that have catch effort:

- Commonwealth
    - Southern and Eastern Scalefish and Shark Fishery following sectors:
    - Shark Gillnet sector
    - Trawl – otter board
    - Southern Squid Jig Fishery

    - Giant Crab
    - Multi-species Ocean

- Octopus
- Southern Rock Lobster
- Wrasse

4.7.1 Commonwealth Fisheries

4.7.1.1 Southern and Eastern Scalefish and Shark Fishery (SESSF)

The Southern and Eastern Scalefish and Shark Fishery (SESSF) stretches south from Fraser Island in southern Queensland, around Tasmania, to Cape Leeuwin in southern Western Australia. Information on the Shark Gillnet Sector and Commonwealth Trawl Sector are from the Fishery Status Reports (Patterson et al. 2022).

The Shark Gillnet Sector is part of the Gillnet, Hook and Trap Sector of the SESSF. Most fishing in the sector using nets occurs in Bass Strait targeting Elephantfish, Gummy Shark, Sawsharks and School Shark. Fishing is generally concentrated east of King Island. In the 2021-22 fishing season there were 32 active trawl vessels.

The Commonwealth Trawl Sector of the SESSF extends south from Barrenjoey Point in northern New South Wales to east of Kangaroo Island off South Australia. The Commonwealth Trawl Sector is a multispecies fishery, targeting a variety of fish and shark species. Effort in the fishery is widely distributed. However, since 2007 – after the closure to trawling of most SESSF waters deeper than 700 m – effort has become increasingly concentrated on the shelf (to 200 m) rather than on the slope. In the 2021-22 fishing season there were 27 active gillnet vessels.

4.7.1.2 Southern Squid Jig Fishery

A single species fishery targeting Gould's Squid (*Nototodarus gouldi*) that operates year-round. Portland and Queenscliff are the major Victorian landing ports. Jigging typically occurs midwater at depths between 50 and 100 m at night using large lights that illuminate the waters around a boat. In 2021 there were eight active vessels in the fishery with the landing ports being Triabunna (Tasmania); Queenscliff and Apollo Bay (Victoria) (Patterson et al. 2022).

4.7.2 Victorian Fisheries

4.7.2.1 Giant Crab

A small fishery operating in western Victoria and closely linked with the Rock Lobster Fishery. Most vessels are used primarily for rock lobster fishing with giant crab taken as by-product. Fishing effort is concentrated on continental shelf edge (~200 m deep). Giant crabs (*Pseudocarcinus gigas*) inhabit the continental slope at approximately 200 m depth and are most abundant along the narrow band of the shelf edge. Closed seasons operate for male (15 September to 15 November) and female (1 June to 15 November) giant crabs. Data for 2020/21 is not available due to insufficient data to report because there are less than five licence holders (policy requirement to protect commercial confidentiality of data) (VFA 2021).

4.7.2.2 Multi-species Ocean

The wrasse, inshore trawl, southern rock lobster and giant crab Victorian fisheries can catch gummy shark and school sharks as part of their fishery. Snapper is caught using lines, nets and haul seine. Over 90% of the catch is from Port Phillip Bay, and around 5% from coastal waters. In 2020/21, 45 tonnes were landed but a value could not be provided as there is insufficient data to report because there are less than five licence holders (policy requirement to protect commercial confidentiality of data) (VFA 2021).

4.7.2.3 Octopus

The octopus fishery is a new fishery harvesting mainly pale octopus (*Octopus pallidus*) in East Gippsland. The fishery may also catch maori octopus (*Macroctopus maorum*) and gloomy octopus (*Octopus tetricus*). Octopus are caught using purpose-built unbaited traps. The fishery commenced on 1st August 2020. Three zones have been established for the management of commercial octopus fishing in Victoria. Octopus Fishery Access Licences authorise commercial take of octopus from the

eastern octopus zone where the majority of commercial octopus fishing in Victoria has occurred to date (VFA 2023). The Operational Area is within the western zone where fishing is less established and being managed by the Victorian Fishing Authority through exploratory, temporary permits.

4.7.2.4 Southern Rock Lobster

Victoria's second most valuable fishery with a production value of A$13.6 million in 2020/21 (VFA 2021). Since 2009/10, annual quotas for the western zone that overlaps the Operational Area have been set at between 230 and 260 tonnes and have been fully caught each year (VFA 2023a). In the western zone, most catch is landed through Portland, Port Fairy, Warrnambool, Port Campbell and Apollo Bay. Closed seasons operate for male (15 September to 15 November) and female (1 June to 15 November) lobsters. Southern rock lobsters (*Jasus edwardsii*) are found to depths of 150 m, with most of the catch coming from inshore waters less than 100 m deep (VFA 2023a).

4.7.2.5 Wrasse

The fishery extends the length of the Victorian coastline from high tide mark to 20 nm offshore (VFA 2023b). Fishers mostly use hook and line. Limited entry fishery with 22 current licences. Total annual catch in 2019/20 was 21.5 tonnes (VFA 2023b).

4.8 People and Communities

4.8.1 Social and Economic Features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of increased rubbish washing up on local beaches, impacts on commercial fishing and the ecosystem in general, which may impact tourism and local enjoyment of the area.

4.8.2 Cultural Features

Native Title (see Appendix F3, section 3.16) has not been identified to occur within the Operational Area. However, the Operational Area is adjacent to Eastern Maar and Gunditjmara Native Title determinations, including Deen Maar (Appendix B12 MAP-REG-EPM-076) and the currently under consultation Nyamat Mirring IPA (GMTOAC, 2023). Deen Maar is culturally significant to both the Gunditjmara and Eastern Maar (Appendix F3, Section 3.16.1). For the Gunditjmara people, Native Title also includes culturally significant sites such as the 'Convincing Ground' (Appendix F3, Section 3.16.1). The Registered Aboriginal Parties (RAPs) with overlap within the Environmental Planning Area are Bunurong Land Council Aboriginal Corporation and Wadawurrung Traditional Owners Aboriginal Corporation.

On its northeastern side, the Environmental Planning Area overlaps the tip of the Mornington Peninsula. The peninsula, particularly Point Nepean located at the tip, holds cultural values for the Bunurong people, including story and song (Appendix F3, Section 3.16.1).

Short-tailed shearwaters (mutton birds) are identified as being culturally significant to the Gunditjmara People and are used in harvesting practice (GMTOAC, 2023). Shearwaters are also identified as culturally significant species to the Eastern Maar people, along with gannets and Little Penguins (Appendix F3, Section 3.16.1).

During consultation, the cultural significance of marine flora and fauna, such as the Southern Right Whale, Blue Whale, Killer Whale, dolphins, seals, sea lions and kelp, were highlighted, with connections to songlines, totemic value and kinship, and cultural practices. Other coastal resources, such as shell middens, along with waterways, including estuaries, also hold cultural significance. (Appendix F3, Section 3.16.1). The Bonney Upwelling was also identified as having cultural significance with its current bringing cold nutrient-rich waters that support marine species such as phytoplankton, fish, squid, seals, dolphins, whales, penguins, gannets and other sea birds (GMTOAC, 2023).

The National Recovery Plan for the Southern Right Whale (DCCEEW 2024) provides information on the cultural significance of southern right whales to Indigenous Australians. The plan details:

In Victoria, Koontapool (southern right whales) occur along the coastlines of south-west Victoria in Gunditjmara Sea Country to feed and birth. These Koontapool Woorrkngan Yakeen (Whale Birthing Dreaming Sites), are in coastal bay areas from Port Campbell to Portland, including Warrnambool. These places on Gunditjmara Country are known resting and feeding sites for mothers and calves and are directly related to Gunditjmara Neeyn (midwives), explaining why Gunditjmara is a Matrilineal Nation.

4.9 Marine Protected Areas

No marine protected areas are within the Operational Area (Appendix B12 MAP-REG-EPM-078 and MAP-REG-EPM-079).

The closest Australian Marine Parks (AMPs) are the Zeehan Marine Park which is ~49 km and the Apollo Marine Park which is ~36 km from the Operational Area (Appendix B12 MAP-REG-EPM-078).

The Operational Area is ~6 km from the Victorian Twelve Apostles Marine National Park (Appendix B12 MAP-REG-EPM-079). The Twelve Apostles Marine Park is managed in conjunction with the Arches Marine Sanctuary under the Management Plan for Twelve Apostles Marine National Park and The Arches Marine Sanctuary (Parks Victoria 2006b) and is classified as IUCN II. The Plan describes the key environmental, cultural, and social values as:

- Unique limestone rock formations, including the Twelve Apostles.
- Range of marine habitats representative of the Otway marine bioregion.
- Indigenous culture based on spiritual connection to sea country and a history of marine resource use.
- Wreck of the Loch Ard (shipwreck).
- Underwater limestone formations of arches and canyons.
- Diverse range of encrusting invertebrates.
- Spectacular dive site.

4.10 Marine Industries

Marine industries within the Operational Area that could be impacted by an accidental release of materials or waste are the offshore energy and shipping.

4.10.1 Offshore Energy

Within the Operational Area is the Beach Energy Otway Development consisting of subsea infrastructure and the Thylacine-A unmanned platform and the Cooper Energy Casino Henry Netherby Development consisting of subsea infrastructure. During the Regia MSS design envelope (1 November 2023 to 31 December 2028) there is the potential for exploration and development activities such as infrastructure inspection, maintenance and repairs campaigns, seabed surveys, seismic surveys, drilling, and infrastructure installation to be undertaken with vessels and drill rigs to support the ongoing energy supply of oil and gas and potentially renewables within the Otway Basin.

4.10.2 Shipping

The South East Marine Region is one of the busiest shipping regions in Australia and Bass Strait is one of Australia's busiest shipping routes. Commercial vessels use the route when transiting between ports on the east, south and west coasts of Australia, and there are regular passenger and cargo services between mainland Australia and Tasmania. Ports Australia provide statistics for port operations throughout Australia's main commercial ports. Based on the latest information (2021) the majority of commercial shipping traffic transiting to and from Victorian ports were container (3,682), general cargo (2,663), bulk liquid carriers (2,019), dry bulk (1,715), car carrier (1,342), bulk gas (220), other cargo (47) and livestock (9).

5 Relevant Legislative and Other Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans that apply to an accidental release of materials or waste, (see Appendix B2).

Measures that will be adopted to demonstrate how these requirements will be met are as follows:

- CGG Marine Assurance System to ensure no waste material is disposed of overboard and that vessels meet all legislative requirements including the International Convention for the Prevention of Pollution from Ships.
- CGG Marine Assurance System to ensure no waste material is disposed of overboard and that vessels have a Garbage Management Plans and Garbage Record Book.
- CGG Marine Assurance System to ensure that in the event of an accidental release of materials or waste the support vessels will search for and retrieve the material or waste where possible and safe to do so
- CGG Marine Assurance System to ensure no waste material is disposed of overboard and that vessels have a Garbage Management Plan and Garbage Record Book, and covered containers for waste that has the potential to be blown overboard.

6 Defining Acceptable Levels of Risk

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table D1-2 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This enables more relevant and targeted comparisons later in this assessment.

Table D1-2 - General and Aspect Specific Defined Acceptable Levels

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Prevent any accidental release of materials or waste overboard. Recover any accidental release of materials or waste overboard.	This acceptable level will ensure no accidental release of waste or materials will also ensure CGG is compliant with the relevant legislation regarding waste management.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		In the unlikely event of an accidental release of materials or waste overboard plans and measures are in place to prevent any injury or death to threatened species and will also ensure CGG is compliant with the relevant legislation regarding waste management.
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Specific)	Rationale
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Predicted levels of impact for species that have social, cultural and economic values will be assessed on a receptor level.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	
Company	All reasonably practicable measures have been adopted to reduce environmental impacts and risks. Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below. The implementation strategy includes specific measures to ensure that measures adopted continue to be effective in managing the impact or risk.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Risks Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of risk could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of release of materials or waste overboard, elimination involves removing or reducing the factors that could lead to this loss of materials or waste. No elimination-based activity limitations were required in this case, as other measures applied were sufficient to reduce the identified risk to an acceptable level.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the risk. No substitution-based activity limitations were required in this case, as other measures applied were sufficient to reduce the identified risk to an acceptable level. One measure was explored as a preventive approach but was not adopted:

Use of biodegradable materials for consumables used offshore

This would reduce long-term harm in the event of accidental loss. However, the feasibility depends on supply chain availability and compatibility with operational requirements. This substitution was not adopted at this time due to uncertainty about its effectiveness and readiness across all vessel types. Biodegradability may help reduce the consequences and it is better to focus efforts on prevention.

9 Predicted Levels of Risk

9.1 Change to physical condition

An accidental release of materials or waste may pose a risk to marine fauna through ingestion and entanglement. Marine fauna such as birds, pinnipeds, sharks, turtles, dolphins and whales can be severely injured or die from entanglement in marine debris, causing restricted mobility, starvation, infection, amputation, drowning and smothering (DoEE 2018). Seabirds entangled in plastic packing straps or other marine debris may lose their ability to move quickly through the water, reducing their ability to catch prey and avoid predators, or they may suffer constricted circulation, leading to asphyxiation and death. In marine mammals and turtles, this debris may lead to infection or the amputation of flippers, tails, or flukes (DoEE 2018).

Fishing gear (ropes and nets made from synthetic fibres), balloons and plastic bags are the biggest entanglement threat to marine fauna, and plastic bags and utensils are the biggest ingestion risk for seabirds, turtles, and marine mammals (Wilcox et al. 2016). Studies published between 1985 and 2012 identified general plastic as the main debris ingested by marine turtles, followed by soft plastic, rope and styrofoam (Schuyler et al. 2014).

Australia is party to Annex V of the International Convention for the Prevention of Pollution from Ships (MARPOL), which regulates garbage pollution from ships. The discharge of plastic into the sea has been prohibited under MARPOL Annex V since 1988; the discharge of all types of garbage into the sea, with very limited exceptions (not related to plastics), has been prohibited since 2013. All vessels used for the Regia MSS will comply with the MARPOL requirements with no discharge of solid waste to the marine environment (CGG Marine Assurance System). In addition, waste with the potential to be windblown shall be stored in covered containers (CGG Marine Assurance System) reducing the potential for solid waste to be lost overboard.

If a loss of equipment or streamer occurred, they would not result in an entanglement risk to fauna as they are not flexible enough for fauna to become entangled.

The predicted level of consequence to marine fauna from an accidental release of materials or waste is assessed as minor (consequence may occur to an individual but is unlikely to affect species, populations, or ecosystems) with a likelihood of unlikely (event is possible but not expected to occur under normal circumstances) and the predicted level of risk is assessed as medium.

9.2 Changes to the functions, interests, or activities of other users

In the event of an accidental release of equipment or a streamer which cannot be recovered, if the object was buoyant, it may present a navigation or entanglement hazard to commercial fishers and other marine users. In addition, buoyant objects may become non-buoyant overtime and sink to the seabed, where it may present a snagging hazard for commercial trawling activities and create a potential risk to vessel safety and damage fishing equipment or may require commercial fishers to avoid a localised area for a period to avoid interaction.

Shipments to and from the survey vessel will be stored in containers (~ 10ft). These will be lifted onboard the seismic vessel, emptied, and returned to supply vessel. All containers will be secured on deck. In the unlikely event these are lost overboard, closed container will typically float while open top containers will sink. The loss of equipment or streamers could result in entanglement with other marine user's infrastructure or equipment (i.e., fishing gear, propellers) or damage to fishing, shipping, or other marine industry vessels if hit.

In the event of an accidental release of equipment or a streamer which cannot be recovered, the vessel would notify any known vessels in the area and notify Australian Safety Marine Authority who would provide any navigation warnings if required.

Historically there has been a report that a seismic streamer contacted a production platform. This occurred during extreme weather conditions and the vessel was not undertaking acquisition at the

time. As detailed in the Section 4.10.1: Offshore Energy, the Beach Energy Thylacine-A unmanned platform is within the Operational Area. The platform has a 500 m Petroleum Safety Zone which unauthorised vessels cannot enter. In addition, if due to acquisition requirements any equipment is required to enter the 500 m Petroleum Safety Zone a Simultaneous Operations Plan will be implemented.

The predicted level of consequence to the functions, interests, or activities of other users from an accidental release of materials or waste is assessed as minor (consequences would be minor and temporary (days) but vessels or fishing gear may require some level of repair or replacement) with a likelihood of unlikely (event is possible but not expected to occur under normal circumstances) and the predicted level of risk is assessed as medium.

9.3 Change in aesthetic, social and cultural value

An accidental release of materials or waste may result in visual pollution changing the aesthetic, social and cultural values of coastal developments, marine protected areas such as marine parks, Native Title determined areas and sea country. As detailed in the existing environment though there are no coastal developments or marine protected areas within the Operational Area, materials or waste could move from the offshore area to coastal areas or marine protected areas via wind and currents. The Great Ocean Road, Victorian Twelve Apostles Marine National Park and the towns of Port Campbell, Port Fairy and Warrnambool are along the coast adjacent to the Operational Area. These areas are major tourist draw cards and known for their pristine beaches. Adjacent to the operational area are Native Title determinations for Eastern Maar and Gunditjmara. Native title rights and interests include the non-exclusive rights to access, enter and remain on the land and waters, to camp on areas above the high-water mark, to use and enjoy the land and waters, to protect culturally important places, and to take resources from the land and waters. Bunurong Land Council Aboriginal Corporation is the Registered Aboriginal Party (RAP) for Point Nepean and the Mornington Peninsula, located in the northeastern extent of the Environmental Planning Area. Wadawurrung Traditional Owners Aboriginal Corporation is the Registered Aboriginal Party (RAP) for Wadawurrung Traditional Owners, whose RAP area includes the coastal area from Aireys Inlet to Queenscliff, overlapping with the northeastern extent of the Environmental Planning Area.

As detailed in the assessment of an accidental release of materials or waste to fauna, Australia is party to Annex V of the International Convention for the Prevention of Pollution from Ships (MARPOL), which regulates garbage pollution from ships. The discharge of plastic into the sea has been prohibited under MARPOL Annex V since 1988; the discharge of all types of garbage into the sea, with very limited exceptions (not related to plastics), has been prohibited since 2013. All vessels used for the Regia MSS will comply with the MARPOL requirements with no discharge of solid waste to the marine environment (CGG Marine Assurance System). In addition, waste with the potential to be windblown shall be stored in covered containers reducing the potential for solid waste to be lost overboard.

It is unlikely that an accidental release of materials or waste would occur and if it did occur it would be a one-off event that is not predicted to pose a risk to the values of the coastal developments, tourism, marine protected areas, Native Title rights and interests, RAP area or sea country.

9.4 Measures Adopted to Manage Environmental Risks

The following measures have been adopted to ensure that the risks associated with potential release of materials or waste overboard from the survey and support vessels will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
CGG Marine Assurance System	System	The CGG Marine Assurance System ensure compliance of contract vessels with legislative requirements including the Navigation Act, MARPOL, COLREGS and Marine Orders.
Garbage Management System	System	Australia is party to Annex V of the International Convention for the Prevention of Pollution from Ships (MARPOL), which regulates garbage pollution from ships. The discharge of plastic into the sea has been prohibited under MARPOL Annex V since 1988; the discharge of all types of garbage into the sea, with very limited exceptions (not related to plastics), has been prohibited since 2013.
Garbage Management Plan	Resource	Vessels 100 gross tonnes (or certified for 15 persons on-board) will have a Garbage Management Plan.
Garbage Record Book	Resource	Vessels ≥400 gross tonnes (or certified for 15 persons on-board) will have a garbage record book.
Support Vessel	Item of Equipment	Throughout the seismic survey, at least one support vessel will be in constant attendance. When safe, assist in the recovery of lost equipment or unintentional garbage discharges.
Streamer Recovery Units	Item of Equipment	Streamers will have recovery units fitted to prevent benthic disturbance and injury to marine fauna in the event of loss.
Consultation Management System	System	If any waste or materials are lost overboard then other marine users should be notified.
Petroleum SIMOPS Plan	Resource	A simultaneous operations plan will be developed if the seismic vessels or any equipment will enter the 500 m Petroleum Safety Zone of the Thylacine-A platform.
OVID Style Inspection	Practice	OVID-Style inspections confirm that the seismic vessel has procedures for streamer inspection, maintenance, deployment, and retrieval.

10 Demonstration Risks Will Be of an Acceptable Level

10.1 Discussion on Principles of ESD

Temporary, Reversible, Small Scale and Natural variation

The risk of accidental release of materials or waste overboard from the petroleum activity is mitigated through stringent industry best practices, such as spill response plans, waste management protocols, and containment procedures. Any accidental release would be managed promptly and effectively, ensuring that the environmental impact remains temporary, reversible, small-scale, and low intensity. This aligns with the principle that the activity will not cause lasting environmental harm.

Based on sufficient information

The impact and risk assessment process is informed by relevant industry guidelines, historical data, and scientific studies on material and waste handling at sea. The process ensures that there is a clear understanding of potential risks and that unplanned releases will be addressed in a timely manner. The precautionary principle is applied where uncertainty exists, ensuring that environmental harm is minimised.

Activity not inconsistent with EPBC Act

The risk management strategies implemented by the petroleum activity comply with the Environmental Protection and Biodiversity Conservation (EPBC) Act and its recovery plans for marine environments. The activity's spill response plans and waste management procedures are aligned with these national frameworks, ensuring that no inconsistency arises between the activity and the EPBC Act.

10.2 Biological and Ecological Categories

The release of materials or waste overboard could have potential biological impacts on marine species and ecosystems, such as contamination or disruption of habitat. However, the risk is considered low due to the proactive measures in place to prevent or mitigate such releases. Should an accidental release occur, it is anticipated to cause only temporary and reversible damage at the population level, with no significant disruption to biodiversity or ecosystem health. The containment and recovery protocols will ensure that the environmental impact is small-scale and recoverable.

10.3 Discussion on Economic, Cultural and Social Categories

The accidental release of materials or waste overboard could impact industries reliant on clean marine environments, such as commercial fisheries, aquaculture, and tourism. However, the likelihood of such releases is minimized by robust waste management practices. Furthermore, any potential impacts are expected to be temporary, and mitigation measures ensure that industries, livelihoods, and cultural practices continue without significant disruption. For species with cultural, social, or economic value, the potential impacts of the release are considered low, with no long-term harm anticipated to these key resources or their associated industries.

10.4 Discussion on Consistency with Company Processes

The environmental management strategies adopted by CGG are consistent with the company's internal impact and risk assessment processes. The company has a strong operational history of managing environmental risks, including those related to waste releases. Spill response plans and waste management practices are aligned with national and international standards, ensuring minimal impact on the marine environment. The application of CGG's impact and risk matrix provides a conservative and reliable evaluation of potential risks, ensuring that any risks associated with accidental releases are kept to an acceptable level. The effectiveness of these strategies will continue to be monitored and adjusted to ensure that they remain effective in managing the risks associated with waste disposal.

This risk assessment has demonstrated that an accidental release of materials or waste causing a change to marine fauna and functions, interests, or activities of other users has a:

- **Predicted level of consequence is minor (2).**
- **Likelihood of an event is unlikely (2).**
- **Predicted level of risk is medium (4).**

11 Environmental Performance Outcomes

Defined Acceptable Level (From Section 6)	Environmental Performance Outcome	Rationale
Prevent any accidental release of materials or waste overboard.	No loss of materials or wastes overboard.	Robust waste management protocols and containment procedures reduce the likelihood of any waste entering the marine environment. In the unlikely event of a release, these controls ensure that it is detected and prevented from spreading, thereby avoiding environmental contamination.
Recover any accidental release of materials or waste overboard	No death or injury to fauna, including listed threatened or migratory species, from the activity.	Prompt and effective recovery actions following an accidental release minimise exposure of marine fauna to harmful substances. These measures protect the health and safety of marine species, reducing the potential for physical harm, ingestion, or habitat disruption, particularly for sensitive or threatened species.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Social, cultural, and economic features are protected, sustaining their value for people and communities.	Effective control and management of waste releases helps maintain healthy marine ecosystems, which are essential to supporting economic activities, cultural practices, and public use of marine areas.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		

12 Recommendations

The predicted level of risk is medium and below pre-defined acceptable levels. The mitigation and management measures in place provide a reliable prevention mechanism to ensure confidence in the predicted likelihood levels, thus there are no further recommendations.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table D1-3 shows how this feedback has been incorporated into the environmental assessments.

Table D1-3 - Public comment input since the beginning of the public comment period starting 25 January 2024.

Matter	Matter ID	Changes made arising from public comment
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table D1-4. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table D1-4 – Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4043	Concern about increased rubbish washing up on beaches due to activities at sea.	This risk has been thoroughly assessed in D1 and determined to be of a medium risk. There are a number of measures in place to retain garage onboard and crew training in place to lessen the likelihood of waste being accidentally lost overboard.	832
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4103	Expresses strong opposition to the proposed plans for potential oil spills, highlighting significant concern for environmental risks in the area. The individual identifies as a local resident.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. This includes an assessment of all risks associated with marine spills. There is a comprehensive Oil Pollution Emergency Plan and management and mitigation plans for accidental release of materials or waste overboard.	1022
4104	Feedback expresses that the proposed drilling is close to a marine park, threatening this area. An oil spill could cause irreversible damage, similar to the harm already experienced along much of the coast.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. This includes an assessment of all risks associated with marine spills. There is a comprehensive Oil Pollution Emergency Plan and management, and mitigation plans for accidental release of materials or waste overboard. Regia MSS is a seismic program not a drilling one.	1022
4128	Lack of adequate monitoring of species present or likely to be impacted.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions regarding species that may be affected by the Regia MSS. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	3237
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4166	Risk to the marine environment with the plan.	Titleholder has conducted a series of thorough risk assessments including the following aspects: Accidentl release of waste (D1), Fauna Interactions (D2), Invasive Marine Species (D3) and Accidental release of fuel (D4), wherin which relevant receptors have been assessed.	2677
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	3343

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	3343
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2963
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	2886
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4253	The possible effects to marine life and ecosystems is my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publically responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4291	The stakeholder raised a significant concern regarding the claimed accumulation of debris, including 3 to 4 tons of seismic tubes and electrical wire left behind over the last 20 years, indicating frustration with the environmental impact of past activities.	CGG has completd an assessment of the risks arising from the loss of waste and materials overboard. CGG has made a commitment to recover streamers that become detached and has streamer recovery units fitted to enable a support vessel to recover the equipment.	5189
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4315	The statement suggest that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	"A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments are covered below in response to concern 6."	2886

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4487	Claims that CGG's proposed activities are inconsistent with the Recovery Plans made under the EPBC Act, the Southern Right Whale Recovery Plan and the Blue Whale Recovery Plan. GMTOAC states that these activities pose known physical and behavioural risks to the Eastern Population of Southern Right Whales and to Pygmy Blue Whales. These risks include impacts from anthropogenic underwater noise, particularly seismic noise, vessel strikes, climate-driven changes in prey availability, and the cumulative effects of these pressures, all of which have the potential to injure or kill individuals and affect populations. GMTOAC notes that under the EPBC Act Program and NOPSEMA's decision-making guidelines, an Environment Plan cannot be accepted if it is inconsistent with a recovery plan. It emphasises that both Recovery Plans contain "Very High" importance actions requiring that Blue Whales and Southern Right Whales must be able to continue using their Biologically Important Areas (BIAs) without auditory impairment, injury, or displacement. The plans also call for preventing disruption and displacement of Karntubul (Southern Right Whales) from BIAs due to anthropogenic noise such as seismic surveys.	CGG maintains that its approach aligns with statutory obligations and industry best practice. It asserts that all regulatory requirements under Regulation 34 have been met, and that its environmental performance outcomes and control measures are grounded in the best available science and tailored to the ecological and cultural sensitivities revealed through consultation. The Regia MSS Environment Plan (EP) was designed to ensure impacts and risks are reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. Regarding whale protection, CGG highlights that the EP includes specific mitigation measures for culturally and ecologically significant marine fauna, including species noted in relevant Recovery Plans. Early correspondence in February 2023 identified Southern Right Whales and Pygmy Blue Whales as key sensitivities, and the EP commits to spatial and temporal avoidance measures, sound-source shutdowns, and exclusion zones to protect them. These measures explicitly consider cultural significance, such as timing restrictions to avoid the Karntubul (Southern Right Whale) birthing period. The whales, Karntubul and Wuuloc, are identified in the EP as sensitive receptors with dedicated protective measures. CGG confirms that these cultural and ecological sensitivities were incorporated into the environmental assessment. The EP acknowledges the sacred cultural status of Koontapool (Southern Right Whale) and Wuuloc (Pygmy Blue Whale) for the Gunditjmara people and includes them in impact and cumulative risk assessments. Appendix F3 references the Nyamat Mirring Plan 2023–2033 and recognises Gunditjmara spiritual connections, including to Karntubul. CGG substantively addresses the relevant issues, including underwater noise, vessel interactions, and cumulative effects. The EP sets out noise-management frameworks, timing restrictions, and cumulative impact analyses consistent with the concerns raised.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4493	Claims that CGG's proposed seismic activities contribute both directly and indirectly to broader threats faced by Southern Right Whales, including industrialisation of the marine environment, climate change, and pollution or contamination from vessel discharges.	Broader threats such as climate change and industrialisation fall outside the scope of the Environment Plan, as outlined in the response to Statements 156–166. The EP assesses only the environmental risks directly associated with the proposed activity. These risks are evaluated in the D Appendices, which demonstrate that any residual risks have been reduced to an acceptable level.	EVT352

Annex 3

EPBC Act Listed Species within the Operational Area Relevant to Release of Materials or Waste Overboard

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Birds - Seabirds							
Antipodean Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	Foraging Whole South-east Marine Region	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Black-browed Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	Foraging Whole South-east Marine Region	National Recovery Plan for Albatrosses and Petrels (CoA 2022) Commonwealth Listing Advice on Black-browed Albatross (*Thalassarche melanopris*) (TSSC 2005)
Blue Petrel	Species or species habitat may occur within area	Vulnerable			Listed	None identified	Conservation Advice *Halobaena caerulea* Blue Petrel (TSS 2015)
Buller's Albatross, Pacific Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	Foraging	National Recovery Plan for Albatrosses and Petrels (CoA 2022)

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Campbell Albatross, Campbell Black-browed Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	Foraging Whole South-east Marine Region	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Common Diving-petrel						Foraging: year round Breeding: July – January Buffer around Tasmania and Victoria	None identified
Fairy Prion	Species or species habitat may occur within area				Listed	None identified	Wildlife Conservation Plan for Seabirds (CoA 2020a)
Fairy Prion (southern)	Species or species habitat may occur within area	Vulnerable				None identified	Conservation Advice *Pachyptila turtur subantarctica* fair y prion (southern) (TSSC 2015e)
Flesh-footed Shearwater, Fleshy-footed Shearwater	Foraging, feeding or related behaviour likely to occur within area		Migratory	Migratory Marine Birds	Listed (as *Puffinus carneipes*)	None identified	Wildlife Conservation Plan for Seabirds (CoA 2020a) Commonwealth Listing Advice on *Ardenna carneipes* (Flesh-footed Shearwater) (TSSC 2014)

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Gould's Petrel, Australian Gould's Petrel	Species or species habitat may occur within area	Endangered				None identified	Gould's Petrel (*Pterodroma leucoptera leucoptera*) Recovery Plan (DEC NSW 2006)
Grey-headed Albatross	Species or species habitat may occur within area	Endangered	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022) Approved Conservation Advice for *Thalassarche chrysostoma* (Grey-headed Albatross) (DEWHA 2009)
Indian Yellow-nosed Albatross	Species or species habitat likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	Foraging Most of the South-east Marine Region	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Northern Buller's Albatross, Pacific Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable			Listed (as *Thalassarche sp. nov.)*	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Northern Giant Petrel	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022) Commonwealth Listing Advice on *Macronectes halli*

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
							(Northern Giant-Petrel) (TSSC 2001)
Northern Royal Albatross	Foraging, feeding or related behaviour likely to occur within area	Endangered	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Salvin's Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Shy Albatross	Foraging, feeding or related behaviour likely to occur within area	Endangered	Migratory	Migratory Marine Birds	Listed	Foraging Whole South-east Marine Region	National Recovery Plan for Albatrosses and Petrels (CoA 2022)) Conservation Advice *Thalassarche cauta* Shy Albatross (TSS 2020)
Soft-plumaged Petrel	Species or species habitat may occur within area	Vulnerable			Listed	None identified	Conservation Advice *Pterodroma Mollis* Soft-plumaged Petrel (TSS 2015a)

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Sooty Albatross	Species or species habitat likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Sooty Shearwater	Species or species habitat may occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed (as *Puffinus griseus*)	None identified	Wildlife Conservation Plan for Seabirds (CoA 2020a) Conservation Advice for *Ardenna grisea* (Sooty Shearwater) (DCCEEW 2023i)
Southern Giant-Petrel, Southern Giant Petrel	Species or species habitat may occur within area	Endangered	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022) Commonwealth Listing Advice on *Macronectes giganteus* (Southern Giant-Petrel) (TSSC 2001a)
Southern Royal Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Wandering Albatross	Foraging, feeding or related behaviour likely to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
White-capped Albatross	Foraging, feeding or related behaviour known to occur within area	Vulnerable	Migratory	Migratory Marine Birds	Listed	None identified	National Recovery Plan for Albatrosses and Petrels (CoA 2022)
Birds - Shorebirds							
Australian Fairy Tern	Foraging, feeding or related behaviour likely to occur within area	Vulnerable				None identified	Approved Conservation Advice for *Sternula nereis nereis* (Fairy Tern) (DSEWPaC. 2011) National Recovery Plan for the Australian Fairy Tern (*Sternula nereis nereis*) (DAWE 2020)
Brown Skua	Species or species habitat may occur within area		Migratory	Migratory Wetlands Species	Listed	None identified	Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015)
Common Sandpiper	Species or species habitat may occur within area		Migratory	Migratory Wetlands Species	Listed	None identified	Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015)

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Curlew Sandpiper	Species or species habitat may occur within area	Critically Endangered	Migratory	Migratory Wetlands Species	Listed - overfly marine area	None identified	Conservation Advice for Calidris ferruginea Curlew Sandpiper (DCCEEW 2023m)
Eastern Curlew, Far Eastern Curlew	Species or species habitat may occur within area	Critically Endangered	Migratory	Migratory Wetlands Species	Listed	None identified	Conservation Advice for *Numenius madagascariensis* (Far Eastern Curlew) (DCCEEW 2023n)
Fork-tailed Swift	Species or species habitat likely to occur within area		Migratory	Migratory Marine Birds	Listed - overfly marine area	None identified	None identified
Orange-bellied Parrot	Migration route likely to occur within area	Critically Endangered			Listed - overfly marine area	None identified	Commonwealth Listing Advice on *Neophema chrysogaster* (TSSC 2006). National Recovery Plan for the Orange-bellied Parrot, *Neophema chrysogaster* (DEWLP 2016)
Pectoral Sandpiper	Species or species habitat may occur within area		Migratory	Migratory Wetlands Species	Listed - overfly marine area	None identified	Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015)

1 Introduction

Collisions with marine fauna was identified through the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) as an aspect needing further assessment. Hence, this document presents a detailed examination of **Collisions with Marine Fauna** as a risk pathway between the Regia Marine Seismic Survey (**Regia MSS**) and the existing environment that may be affected by that aspect.

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was first published in draft form to the Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (**EP**) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

2 Aspect – Collisions with Fauna

2.1 How the Aspect Occurs

The presence of the seismic and support vessels and towed equipment provides a risk of collision or entrapment of marine fauna potentially causing injury or mortality.

2.2 Extent and Duration of the Aspect

Duration: 90 days

Extent: Operational Area

The extent of the area where the risk of a vessel collision with marine fauna may occur is within the Operational Area and the risk could occur while the activity is undertaken.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for collisions with fauna for the following environmental components and their social, cultural, and economic features:

- Marine reptiles
- Marine mammals
- Fish
- People and communities

There have been no reported cases of marine fauna becoming entangled in seismic survey streamers in Australian waters. As the streamers are towed, they have a level of tautness that would not result in entanglement of fauna. Thus, there is no cause-effect pathway for entanglement of fauna in streamers.

Historically, turtles have been recorded as becoming trapped in the streamer tail buoys. Tail buoys are now of a design that does not represent an entrapment risk to turtles. In addition, where a tail buoy is not of the newer design, turtle guards are used as standard equipment. Thus, there is no cause-effect pathway for entrapment of turtles in streamer buoys.

The National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna (CoA 2017a) identifies cetaceans, dugong, marine turtles, and whale sharks as being vulnerable to vessel collisions. Though vessel collisions with marine fauna occur within Australia they have not been reported during seismic surveys.

The National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna did not identify pinnipeds as vulnerable to vessel collisions, and there were no BIAs for pinnipeds identified in the PMST searches. As a result, pinnipeds are not assessed further.

Fish being identified as vulnerable to vessel collisions is specifically related to Whale Sharks who fit a similar collision profile to cetaceans. However, the PMST report verified whale sharks are not found in this region, so fish are not assessed further.

4 Description of the Existing Environment that May be Affected by the Activity

As detailed in the Section Extent and Duration of the Aspect, the Operational Area has been adopted as the extent of the area within which a collision with marine fauna may occur. To identify the presence of those species that may be at risk of vessel collision (cetaceans, dugong, marine turtles, and whale sharks) a Protected Matters Search (PMST) was undertaken for the Operational Area with the report available in Appendix B5.

The PMST Report identified that cetaceans and marine turtles may be present within the Operational Area while dugongs and whale sharks will not. Annex 3 details those species and identifies any biologically important areas and conservation advice or management plans.

PMST searches were run again prior to resubmission to ensure any changes to species or listings were identified to control for passage of time. There are no changes to protected matters information for species that may be at risk of vessel collision [Section added in response to Matters: I16 and I17].

4.1 Turtles

The PMST Report identified three turtle species, which may (*Chelonia mydas* - green) or are likely (*Dermochelys coriacea* - leatherback and *Caretta caretta* - loggerhead) to occur within the Operational Area. No BIAs or habitat critical to the survival of the species were identified.

4.2 Marine Mammals

4.2.1 Cetaceans

The PMST Report identified several cetacean (whales and dolphin) species that are known or are likely to occur within the Operational Area. Table D2-1 details those species that were identified as having biologically important areas or biologically important behaviours identified within the Operational Area.

Table D2-1 - Cetacean Species Biologically Important Behaviours and/or BIAs within the Operational Area.

Receptor	Biologically Important Behaviour
Blue Whale	Foraging, feeding or related behaviour known to occur within area
	Foraging (annual high use area) BIA (Appendix B12 MAP-REG-EPM-068)
Fin Whale	Foraging, feeding or related behaviour known to occur within area
Pygmy Right Whale	Foraging, feeding or related behaviour likely to occur within area
Sei Whale	Foraging, feeding or related behaviour known to occur within area
Southern Right Whale	Breeding known to occur
	Migration BIA (Appendix B12 MAP-REG-EPM-069)

4.2.1.1 Blue Whale

The Blue Whale (*Balaenoptera musculus*) is listed as an endangered species under the EPBC Act. There are two subspecies of blue whales that use Australian waters (including Australian Antarctic waters), the Pygmy Blue Whale (*B. m. brevicauda*) and the Antarctic Blue Whale (*B. m. intermedia*). The Otway region, where the Operational Area is located, is an important migratory and foraging area for Blue Whales, as shown by passive acoustic monitoring and aerial surveys (Gavrilov 2012, McCauley et al. 2018, Gill et al. 2011). Underwater acoustic monitoring programs have detected Antarctic and Pygmy Blue Whale calls in the Otway Region (McCauley et al. 2018).

Important foraging grounds for Blue Whales include the Great Australian Bight, South Australia, and off Portland, Victoria. Research to date has found that Pygmy Blue Whales occupy the western area of the Bonney Upwelling system in the Eastern Great Australian Bight and adjacent to the Kangaroo Island canyons from November and December (DoE 2015c). Pygmy Blue Whales then move south-east to the Bonney Upwelling system off eastern South Australia and Victoria (e.g., between Robe, SA and Cape Otway, Vic). This occurs predominately between January to April (DoE 2015c).

The Blue Whale was extremely abundant until the early 20th century when they were hunted to near extinction. Approximately 341,830 Blue Whale takes were recorded by commercial whaling in the Antarctic and sub-Antarctic in the 20th century, of which 12,618 were identified as Pygmy Blue Whales (Branch et al. 2004). The current global population of Blue Whales is uncertain but is plausibly in the range of 10,000 to 25,000, corresponding to about 3-11% of the 1911 estimated population size (Reilly et al. 2008).

The Operational Area is within the foraging (annual high use) BIA where blue whales predominately occur between January to April (DoE 2015c) (Appendix B12 MAP-REG-EPM-068).

4.2.1.2 Fin Whale

The Fin Whale (*Balaenoptera physalus*) is a cosmopolitan migratory species that is listed as vulnerable and occurs from polar to tropical waters but is rarely sighted in inshore waters. Fin Whales show well defined migratory movements between polar, temperate and tropical waters which are essentially north–south with little longitudinal dispersion.

While Australian Antarctic waters are important feeding grounds for Fin Whales, the species also feeds in the Bonney Upwelling during summer/autumn sometimes in the company of Blue and Sei Whales (DCCEEW 2023b). Areas of upwelling and interfaces with mixed and stratified waters may be an important feature of Fin Whale feeding habitat with the species feeding on planktonic crustacea, krill, some fish and cephalopods (DCCEEW 2023b). Fin Whales frequently lunge or skim feed at or near the surface and they are known to dive to 230 m to feed.

There are no BIAs for the Fin Whale within Australian waters. Fin Whales are likely to be foraging in the Operational Area at similar time as Blue Whales, predominately occur between January to April.

4.2.1.3 Pygmy Right Whale

The Pygmy Right Whale (*Caperea marginata*) is a little-studied baleen whale species that is found in temperate and sub-Antarctic waters in oceanic and inshore locations. No population estimates are available for Pygmy Right Whales globally, or in Australian waters (DCCEEW 2012c). The species has never been hunted commercially and is listed as a migratory species under the EPBC Act.

Species distribution in Australia is found close to coastal upwellings and the Subtropical Convergence may be important for regulating distribution (Bannister et al. 1996). Key locations include south-east Tasmania, Kangaroo Island (SA) and southern Eyre Peninsula (SA) close to upwelling habitats rich in marine life and zooplankton upon which it feeds (Bannister et al. 1996).

There are no BIAs for the Pygmy Right Whale within Australian waters. Pygmy Right Whales are likely to be foraging in the Operational Area at similar time as Blue Whales, predominately occur between January to April.

4.2.1.4 Sei Whale

The Sei Whale (*Balaenoptera borealis*) is listed as vulnerable under the EPBC Act. Sei Whales are considered a cosmopolitan species, ranging from polar to tropical waters, but tend to be found more offshore than other species of large whales. Sei Whales move between Australian waters and Antarctic feeding areas; subantarctic feeding areas (e.g. Subtropical Front); and tropical and subtropical breeding areas. The proportion of the global population in Australian waters is unknown as there are no estimates for Sei Whales in Australian waters.

In Australia, Sei Whales occur within Australian Antarctic Territory waters and Commonwealth waters, and have been infrequently recorded off Tasmania, NSW, Queensland, the Great Australian Bight, Northern Territory and Western Australia (Parker 1978, Bannister et al. 1996, Thiele et al. 2000, Chatto and Warneke 2000, Bannister 2008).

Sightings of Sei Whales within Australian waters includes areas such as the Bonney coast upwelling off South Australia (Miller et al. 2012), where opportunistic feeding has been observed between November and May (Gill et al. 2015).

There are no BIAs for the Sei Whale within Australian waters. Sei Whales are likely to be foraging in the Operational Area at similar time as Blue Whales, predominately occur between January to April.

4.2.1.5 Southern Right Whale

The Southern Right Whale (*Eubalaena australis*) is listed as endangered under the EPBC Act. Southern Right Whales were depleted to less than 300 individuals globally due to commercial whaling in the 19th and 20th centuries (Tormosov et al. 1998). They were protected from whaling in 1935 however, due to illegal whaling in the 1970s and because Southern Right Whales have a slow rate of increase (7% per annum) compared to other marine mammals, their numbers remain low (IWC 2013). Global abundance estimates are 13,000 for the species, across key wintering grounds in South Africa, Argentina, Australia and New Zealand.

Southern Right Whales are distributed in the Southern Hemisphere with a circumpolar distribution between latitudes of 16°S and at least 65°S. They migrate from southern feeding grounds in sub-Antarctic waters to Australia in between May and November to calve, mate and rest (Bannister et al. 1996, DCCEEW 2024). They are distributed across thirteen primary aggregation areas along the southern coast of Australia. In Australian coastal waters, they occur along the southern coastline of the mainland and Tasmania and generally extend as far north as Sydney on the east coast and Perth on the west coast (CoA 2012). There are occasional sightings further north, with the extremities of their range recorded at Hervey Bay and Exmouth (CoA 2012).

The largest established calving areas in Australia include Head of Bight in SA, and Doubtful Island Bay and Israelite Bay in WA. Smaller but established aggregation areas regularly occupied by Southern Right Whales include Yokinup Bay in WA, Fowlers Bay in SA and the Warrnambool and Portland in Victoria. Emerging aggregation areas include Flinders Bay, Hassell Beach, Cheyne/Wray Bays, and Twilight Cove in WA, and sporadically occupied areas include Encounter Bay in SA (CoA 2012). Southern Right Whales generally occupy shallow sheltered bays within 2 km of shore and within water depths of less than 20 m (Charlton et al. 2017).

The Operational Area overlaps the Southern Right Whale Migration BIA where the whales are present between April and October (AMSIS 2025, formerly National Conservation Values Atlas (NCVA)) (Appendix B12 MAP-REG-EPM-069).

4.3 People and Communities

4.3.1 Social and Economic Features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local fauna, which may impact tourism and local enjoyment of the area, including whale and their habitat.

4.3.2 Cultural Features

During consultation, the cultural significance of marine mammals, such as the Southern Right Whale, Blue Whale, Killer Whale, seals, sea lions and dolphins were highlighted, with connections to songlines, totemic value and kinship, and cultural practices (Appendix F3, Section 3.16.1).

5 Relevant Legislative and Other Requirements

CGG has considered all the relevant legislative requirements, which apply to collisions with marine fauna (see Appendix B2). Measures that will be adopted to demonstrate how these requirements will be met are as follows:

- The procedures in the Fauna Management Plan details how the requirements of EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with Cetaceans and EPBC Act Policy Statement 2.1 will be met. These measures include:
  - A 300 m caution zone for whales.
  - A 150 m caution zone for dolphins (except for those bow riding).
  - A 150 m caution zone will also be applied to pinnipeds, as it is feasible that they can be detected by MFOs at 150 m.
  - A 150 m caution zone will also be applied to turtles as it is feasible that they can be detected by MFOs at 150 m.
- Whale and vessel strike incidents will be reported in the National Ship Strike Database Reporting as detailed in Appendix B3 Implementation Strategy.

6 Defining Acceptable Levels of Risk

Category	Defined Acceptable Level (General)	Defined Acceptable Level (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Prevent collisions with marine fauna. Prevent entrapment of turtles. Prevent collisions with Blue Whales.	Under the EPBC Act it is an offence to intentionally kill or harm a listed species. Prevention of collisions will satisfy this criterion.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it

Category	Defined Acceptable Level (General)	Defined Acceptable Level (Aspect Specific)	Rationale
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Predicted levels of impact for species that have social, cultural and economic values will be assessed on a receptor level.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Risks Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of risk could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of marine fauna collisions, elimination involves removing or reducing the factors that could lead to vessel strikes. One main option was considered and subsequently adopted:

The seismic vessel will operate at no more than 6 knots speed over ground during acquisition

Eliminating higher vessel speeds is intended to significantly reduce the risk of collisions with marine fauna. By operating at slower speeds, this approach ensures safer and more environmentally friendly operations. This measure has been accepted by CGG as a key component of the activity design to prevent potential harm to vulnerable species.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the risk. One main option was considered and subsequently adopted:

If the survey occurs in September, October, November, or December, the acquisition lines will be acquired working from the deepest lines first

This option is likely to minimise the disturbance to sensitive ecosystems, particularly during breeding or migration periods of marine species. By starting with the deepest lines, the risk of disturbing more sensitive coastal or shallow areas is reduced, such as the Southern Right Whale when in its coastal reproduction BIA. Similarly, acquiring the deepest lines first means the survey will be closer to the coast at the time the survey would overlap with the early arrival of Blue Whales.

9 Predicted Levels of Risks

Though vessel collisions with marine fauna occur within Australia they have not been reported during seismic surveys. The extent of the area where the risk of a vessel collision with marine fauna may occur is within the Operational Area and the risk could occur while the activity is underway. The worst potential outcome from vessel collision would be mortality or serious injury of an individual.

9.1 Change in Physical Condition

9.1.1 Turtles

No habitat critical to the survival of marine turtles or biologically important areas have been identified within the Operational Area, from the Recovery Plan for Marine Turtles in Australia (DoEE 2017) or PMST Report (Appendix B5). Thus, it is likely that the three marine turtle species identified in the PMST Report (Green, Leatherback and Loggerhead) may be present in low numbers within the Operational Area.

The Recovery Plan for Marine Turtles in Australia (DoEE 2017) details that impact from vessels can cause serious injury and/or death to individual marine turtles and is particularly an issue in shallow coastal foraging habitats and inter-nesting areas where there are high numbers of recreational and commercial craft, and in areas of marine development. Although the outcome can be fatal for individual turtles, boat strike (as a standalone threat) has not been shown to cause stock level declines.

The National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna (CoA 2017c) found speed to be a critical factor in determining a flee response in marine turtles being approached by vessels. The proportion of flee responses decreased significantly with increasing speed, particularly with close encounters. While speed is a particularly important factor, so too is the movement patterns of the vessel for example, whether a vessel is transiting a dedicated route or is a recreational boat that is moving erratically.

The predicted level of consequence to marine turtles from a vessel collision is assessed as major (injury or death of individuals of a protected species) with a likelihood of rare (almost impossible / unheard of in the industry) with a predicted level of risk of medium, based on:

- Though vessel collisions with marine fauna occur within Australia they have not been reported during seismic surveys.
- There is no habitat critical to the survival of marine turtles or BIAs within Operational Area.
- There are no shallow coastal marine turtle foraging habitats or inter-nesting areas within the Operational Area.
- The seismic and support vessels will operate at a speed of no more than 6 knots during acquisition (Activity Limitation).
- The seismic survey is undertaken by following a set racetrack pattern (see the Description of Activity in Appendix A2) and not moving erratically.
- Marine fauna observers will be on the seismic vessel watching for fauna (Fauna Management System).
- If an incident occurred, it would be restricted to individual marine turtles and will not affect turtle species at a population level

9.1.2 Cetaceans

Twenty-three whale/dolphin species (or species habitat) may occur within the Operational Area. Foraging behaviours were identified for the Blue, Fin, Pygmy Right and Sei Whale and breeding for the Southern Right Whale. The Operational Area overlaps Southern Right Whale migration BIA and

the Pygmy Blue Whale foraging (annual high use area) BIA. Other whale/dolphin species identified are transient within the Operational Area.

The Conservation Management Plan for the Blue Whale (DoE 2015c) details that collisions will impede recovery of blue whale populations if enough individuals in the population lose reproductive fitness or are killed. Although all forms of vessels can collide with whales, severe or lethal injuries are more likely to occur by larger or faster vessels. Blue Whales in the Bonney Upwelling region regularly feed at the surface on krill aggregations and are likely to be more vulnerable to ship strike.

The Conservation Management Plan for the Blue Whale (DoE 2015c) assesses the threat of vessel collision to Antarctic and Pygmy Blue Whales as having a moderate consequence (population recovery stalls or reduces) with a possible likelihood (might occur at some time) giving an overall rating of high. Relevant actions from the recovery plan are ensure the risk of vessel strikes on blue whales is considered when assessing actions that increase vessel traffic in areas where blue whales occur and, if required, appropriate mitigation measures are implemented.

The National Recovery Plan for the Southern Right Whale (DCCEEW 2024) details that in Australia, Southern Right Whales are the second most common species involved in Australian vessel strikes, which is consistent with worldwide data. At present, there have been ten vessel strike reports of Southern Right Whales in Australian waters between 1997 and 2015, with at least four mortalities including mother-calf pairs in the region of the eastern population.

The Conservation Management Plan for the Southern Right Whale (DCCEEW 2022) assesses the threat of vessel collision as having a major consequence (population declines) with an almost certain likelihood (expected to occur every year) giving an overall rating of very high. Relevant actions from the recovery plan are ensure environmental impact assessments and associated plans consider and quantify the risk of vessel strike and associated potential cumulative risks in BIAs.

The National Recovery Plan for the Southern Right Whale (DCCEEW 2024) details that proven effective mitigation measures for addressing vessel strike are to reduce co-occurrence of vessels with whales through separation of vessels from areas with high concentrations of whales and to reduce vessel speeds. Mitigation actions to prevent injury and minimise disturbance from vessels to Southern Right Whales include seasonal or temporary area restrictions/exclusions and speed restrictions in biologically important areas and habitat critical for survival.

The Conservation Advice for the Sei Whale (TSSC 2015c) and Fin Whale (TSSC 2015b) lists vessel strike as a threat with a minor consequence rating.

The National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna (CoA 2017c) details that speed is a concern when considering collision risk and the outcome. Vanderlaan and Taggart (2007) observed that an escalation in speed of the vessel caused an increase in the severity of injury to large cetaceans. Slower moving vessels provide greater opportunity for both fauna and vessel to avoid collision.

Large, high-speed vessels have become a major concern as they can travel at speeds of up to 35 to 40 knots, which correlates to an increase in collisions (Weinrich 2004, Ritter 2010). According to Laist et al. (2001), 89 per cent of incidences where the whale was severely hurt or killed occurred at vessel travelling speeds greater than 14 knots and were most serious in large vessels (> 80 m). Furthermore, the chance of an injury being lethal increases significantly as vessel speed increases up to 13-15 knots (Vanderlaan and Taggart 2007).

The predicted level of consequence to cetaceans from a vessel collision is assessed as major (injury or death of individuals of a protected species) with a likelihood of rare (almost impossible / unheard of in the industry) with a predicted level of risk of medium, based on:

- Though vessel collisions with marine fauna occur within Australia they have not been reported during seismic surveys.
- The seismic and support vessels will operate at low speed of no more than 6 knots during acquisition (Activity Limitation).

- Separation distances will be applied to cetaceans as per the EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans (Fauna Management System)
- Marine fauna observers will be on the seismic vessel watching for fauna (Fauna Management System).
- If an incident occurred, it would be restricted to individual whales or dolphins and will not affect the species at a population level.

9.2 Measures Adopted to Manage Environmental Risks

The following measures have been adopted to ensure that the risks associated with potential collisions with marine fauna from the survey and support vessels will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Table D2-2 - Measures adopted to manage collisions with marine fauna.

Measure	Measure Type	Details and Justification
Streamer Design Modification or Turtle Guards	Item of Equipment	Streamer tail buoys will be of a design that does not represent an entrapment risk to turtles or in the case of older models then turtle guards will be used.
Fauna Management Plan	Resource	The Fauna Management System (Appendix G2) provides details about how the Regia MSS will be carried out in a way the environmental impacts from collisions to marine fauna will be compliant with EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with Cetaceans. The requirements of the EPBC Regulations set out measures to reduce vessel speed to decrease probability of contact with approaching cetaceans.
Operational Procedures	Procedure	Implementation of EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with Cetaceans to reduce the risk of collision with marine fauna during the activity. This procedure always applies to all vessels.

10 Demonstration Risks Will Be of An Acceptable Level

10.1 Discussion on Principles of ESD

Temporary, Reversible, Small Scale and Natural variation

The petroleum activity incorporates measures such as real-time monitoring, vessel strike avoidance protocols, and mitigation strategies to prevent collisions with marine fauna, including turtles and Blue Whales. These strategies ensure that any risk of collision is minimized and that any potential impacts are temporary, reversible, and small-scale in nature. This approach is aligned with the principles of Ecologically Sustainable Development (ESD), where the environmental damage is minimal, and any harm caused is temporary and recoverable.

Based on sufficient information

The risk assessment is based on comprehensive data, including scientific literature, species distribution information, and relevant management plans under the EPBC Act. The use of real-time monitoring and avoidance protocols ensures that risks to marine fauna are well understood and effectively managed. The precautionary principle is applied in cases where uncertainty exists regarding the potential risks, further ensuring that impacts on marine fauna are minimised.

Activity not inconsistent with EPBC Act

The environmental management strategies for the activity align with the management plans and recovery plans outlined in the EPBC Act. By adhering to these guidelines and incorporating species-specific mitigation strategies, the activity ensures that it is consistent with the EPBC Act's requirements for protecting marine fauna, particularly for vulnerable species such as turtles and Blue Whales.

10.2 Biological and Ecological Categories

The risk of collisions with marine fauna, including turtles and Blue Whales, is mitigated by implementing vessel strike avoidance protocols, real-time monitoring, and other industry-standard measures. These efforts ensure that any biological impacts are temporary, reversible, and of low intensity. The activity is not expected to result in significant harm to population levels, and marine fauna are expected to continue functioning in their ecosystems without disruption. The measures in place also reduce the risk of any lasting ecological damage, ensuring that the health, diversity, and functioning of the ecosystem remain intact.

10.3 Discussion on Economic, Cultural and Social Categories

Collisions with marine fauna could impact industries such as fishing, tourism, and marine-based recreation, especially those that rely on the presence of species like turtles and Blue Whales. However, the preventive measures in place, including vessel strike avoidance and mitigation protocols, ensure that these industries are protected from significant operational or financial consequences. Additionally, the activity poses no long-term disruption to cultural practices or communities that rely on marine fauna. The activity maintains the viability of social, cultural, and economic activities by minimizing potential harm to species with social, economic, or cultural value.

10.4 Discussion on Consistency with Company Processes

CGG's approach to managing the risks of collisions with marine fauna is consistent with its internal environmental risk framework. The company's global operational history, particularly in managing seismic sound effects on the marine environment, supports the reliability of its risk management

processes. The use of CGG's impact and risk matrix ensures that environmental impacts are conservatively assessed, and mitigation measures are implemented effectively to avoid unacceptable outcomes. The company's established processes have consistently resulted in successful environmental outcomes, demonstrating the effectiveness and reliability of its approach to managing risks associated with marine fauna collisions.

This risk assessment has demonstrated that collision between marine fauna and the survey vessels has a:

- **Predicted level of consequence of major (4).**
- **Likelihood of occurrence as rare (1).**
- **Predicted level of risk of medium (5).**

11 Environmental Performance Outcomes

Defined Acceptable Level (From Section 6)	Environmental Performance Outcome	Rationale
Prevent collisions with marine fauna.	No death or injury to fauna, including listed threatened or migratory species, from the activity.	The implementation of vessel speed restrictions, real-time marine fauna observations, and avoidance protocols ensures the activity does not result in collisions, entrapment, or injury to marine species, including listed threatened or migratory fauna such as turtles and Blue Whales.
Prevent entrapment of turtles.		
Prevent collisions with Blue Whales.		
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Social, cultural, and economic features are protected, sustaining their value for people and communities.	The prevention of harmful interactions with marine fauna ensures that the ecological balance and species populations remain stable, which in turn supports the continuity of marine-based industries, community practices, and cultural relationships tied to the marine environment.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		

12 Recommendations

The predicted level of risk is medium and below pre-defined acceptable levels. The mitigation and management measures in place provide a reliable prevention mechanism to ensure confidence in the predicted likelihood levels, thus there are no further recommendations.

13 Document Control

Date	Revision	Update
6 July 2023	A	Draft prepared for initial comment
23 August 2023	B	Update based on comments and relevant person feedback
11 Sept 2023	0	Approved for release on Regia MSS website
20 Dec 2023	1	EP submission to NOPSEMA
14 May 2024	2	Updated following public comment, update to PMST searches, and updated literature.
21 October 2024	3	Updated following NOPSEMA assessment
16 April 2025	4	Updated following NOPSEMA OMR 1 Letter
5 December	5	Updated following NOPSEMA OMR 2 Letter

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table D2-3 shows how this feedback has been incorporated into the environmental assessments.

Table D2-3 - Public comment input

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Appendices E2 -E7, F1 and F3 to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Effectiveness of mitigation measures	E08	EP Appendices D2 and E5 have been updated to include existing mitigation and management measures that will reduce the likelihood of injury associated with vessel collision and underwater sound including implementing the EPBC Act Policy Statement 2.1 - Interaction between offshore seismic activities and whales (Soft-start Procedure), which provides for marine turtles to move away from the activity before the airguns reach full power.
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table D2-4. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table D2-4 – Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4128	Lack of adequate monitoring of species present or likely to be impacted.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions regarding species that may be affected by the Regia MSS. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	3237

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4166	Risk to the marine environment with the plan.	Titleholder has conducted a series of thorough risk assessments including the following aspects: Accidental release of waste (D1), Fauna Interactions (D2), Invasive Marine Species (D3) and Accidental release of fuel (D4), wherein which relevant receptors have been assessed.	2677
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4186	Stakeholder expressed concern about the destruction and	Petroleum activities do not operate to a no-impact standard. Instead, the Regia	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	depletion of the ocean due to the activity.	MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and	1659

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work	1665

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4338	Concerned that whales in the southwest will no longer return to birth and nurture calves	Titleholder responded to the stakeholder, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1255
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	"A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6."	2886
4487	Claims that CGG's proposed activities are inconsistent with the Recovery Plans made under the EPBC Act, the Southern Right Whale Recovery Plan and the Blue Whale Recovery Plan. GMTOAC states that these activities pose known physical and behavioural risks to the Eastern Population of Southern Right Whales and to Pygmy Blue Whales. These risks include impacts from anthropogenic underwater noise, particularly seismic noise, vessel strikes, climate-driven changes in prey availability, and the cumulative effects of these pressures, all of which have the potential to injure or kill individuals and affect populations. GMTOAC notes that under the EPBC Act Program and NOPSEMA's decision-making guidelines, an Environment Plan cannot be accepted if it is inconsistent with a recovery plan. It emphasises that both Recovery Plans contain "Very High" importance actions requiring that Blue Whales and Southern Right Whales must be able to continue	CGG maintains that its approach aligns with statutory obligations and industry best practice. It asserts that all regulatory requirements under Regulation 34 have been met, and that its environmental performance outcomes and control measures are grounded in the best available science and tailored to the ecological and cultural sensitivities revealed through consultation. The Regia MSS Environment Plan (EP) was designed to ensure impacts and risks are reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. Regarding whale protection, CGG highlights that the EP includes specific mitigation measures for culturally and ecologically significant marine fauna, including species noted in relevant Recovery Plans. Early correspondence in February 2023 identified Southern Right Whales and Pygmy Blue Whales as key sensitivities, and the EP commits to spatial and temporal avoidance measures, sound-source shutdowns, and exclusion zones to protect them. These measures explicitly consider cultural significance, such as timing restrictions to avoid the Karntubul (Southern Right Whale) birthing period.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	using their Biologically Important Areas (BIAs) without auditory impairment, injury, or displacement. The plans also call for preventing disruption and displacement of Karntubul (Southern Right Whales) from BIAs due to anthropogenic noise such as seismic surveys.	The whales, Karntubul and Wuuloc, are identified in the EP as sensitive receptors with dedicated protective measures. CGG confirms that these cultural and ecological sensitivities were incorporated into the environmental assessment. The EP acknowledges the sacred cultural status of Koontapool (Southern Right Whale) and Wuuloc (Pygmy Blue Whale) for the Gunditjmara people and includes them in impact and cumulative risk assessments. Appendix F3 references the Nyamat Mirring Plan 2023–2033 and recognises Gunditjmara spiritual connections, including to Karntubul. CGG substantively addresses the relevant issues, including underwater noise, vessel interactions, and cumulative effects. The EP sets out noise-management frameworks, timing restrictions, and cumulative impact analyses consistent with the concerns raised.	
4491	Claims about the SRW and BW BIAs. States proposed activity will cause unacceptable impacts to all Karntubul species, including temporary & permanent hearing loss, displacement from BIAs, vessel strike, prey depletion during peak feeding/migration period, calving interruption, and impact to ecosystems and cultural landscapes as a result of the cumulative impact of these.	CGG has identified all Biologically Important Areas (BIAs) relevant to blue whales (BWs) and southern right whales (SRWs) and incorporated seasonal BIA use into the survey design through substantial temporal and spatial restrictions detailed in the EP. Predicted underwater-sound impacts on these Karntubul species, along with mitigation measures presented in Appendices E7 and F3, demonstrate impacts will remain acceptable and will avoid auditory impairment or displacement from BIAs or Habitats Critical to Survival (HCTS). CGG further notes that vessel-strike risk is already extremely low during seismic surveys and that additional controls in Appendix D2 ensure this risk is prevented and acceptable. It concludes that no changes to ecosystem structure, diversity, or function are expected from the one-off survey, with sound exposure too limited in extent and duration to affect prey, food webs, or predator–prey relationships. A cumulative impact assessment found residual cumulative effects to be low, reduced to ALARP, and acceptable, with no impacts predicted for regional marine parks. CGG also asserts consistency with the National Recovery Plan for Southern Right Whales and the Blue Whale Conservation Management Plan, stating that their objectives and recommended measures have been incorporated. Finally, CGG maintains that all marine mammal species likely to occur in the region have been adequately assessed	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		using up-to-date EPBC Protected Matters data, and that mitigation measures ensure impacts to all listed species will remain acceptable and not inconsistent with EPBC Act protection provisions.	
4492	Claims that the eastern population of the Southern Right Whale, estimated at only 200–300 individuals, is at particularly high risk because its migration and reproduction Biologically Important Areas (BIAs) overlap directly with CGG's Operational Area and sound propagation footprint. According to the Southern Right Whale Recovery Plan, these whales use the affected region for reproduction between May and September and for migration between April and October. The Recovery Plan also notes that Southern Right Whales do not feed in coastal waters but are expected to feed, and possibly conceive, within the Australian Whale Sanctuary—an area entirely overlapped by the proposed Regia MSS activity. As a result, the seismic survey could occur within, or affect, conceiving, calving, and feeding grounds for this critically endangered sub-population. The species is particularly vulnerable to human impacts due to its low reproductive rate, long lifespan, and strong site fidelity to key habitats. The submission therefore emphasises the relevance of underwater noise, habitat degradation, and vessel-strike risks in the context of the proposed seismic activities.	The Recovery Plan explains that BIAs can be designated for key behaviours such as reproduction, foraging, migration, and resting. While Southern Right Whale BIAs in the Plan cover reproduction and migration, the Plan notes that foraging occurs across a much broader offshore latitudinal range (30°S–65°S) and is not linked to these BIAs. Because the Regia MSS is not located in Antarctic waters, it will not affect cetaceans that forage there. CGG states the survey will avoid peak SRW abundance in the mapped BIA and apply mitigation measures to ensure no SRWs are harmed, injured, or interfered with.	EVT352
4493	Claims that CGG's proposed seismic activities contribute both directly and indirectly to broader threats faced by Southern Right Whales, including industrialisation of the marine environment, climate change, and pollution or contamination from vessel discharges.	Broader threats such as climate change and industrialisation fall outside the scope of the Environment Plan, as outlined in the response to Statements 156–166. The EP assesses only the environmental risks directly associated with the proposed activity. These risks are evaluated in the D Appendices, which demonstrate that any residual risks have been reduced to an acceptable level.	EVT352
4495	GMTOAC claims CGG's assertion that vessel strikes are "rare" or "almost impossible," noting that the absence of recorded collisions involving seismic vessels does not demonstrate that such events have not occurred. They highlight that smaller support vessels, also part of CGG's activity, are far less	CGG disagrees that they have underestimated vessel-strike risk; the survey incorporates the highest practicable controls, including limiting vessel speed to 5 knots, commencing acquisition on deep lines during sensitive months, adhering to EPBC separation distances, and using both trained observers and autonomous PAM	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	represented in AIS datasets, meaning collisions involving them are likely underreported. Citing recent research, GMTOAC notes that small vessels were responsible for 67% of humpback whale strikes in Moreton Bay and that the waters around Portland, where CGG intends to operate, have been identified by government agencies as a particular vessel-strike risk area for the critically endangered eastern population of Southern Right Whales. GMTOAC requests clarification on how CGG concluded that vessel-strike likelihood is minimal, arguing that for species with very low population numbers, such as the eastern Southern Right Whale, even a single mortality could have severe population-level consequences. They further argue that CGG has underestimated vessel-strike risk by excluding transiting vessels, used for mobilisation, demobilisation, port calls, crew changes, and maintenance, from its assessment. GMTOAC maintains that these vessel movements are an inherent part of the proposed activity and should have been assessed for their potential environmental impacts.	technologies proven to reduce strike risk. CGG maintains that these combined measures minimise spatial and temporal overlap with sensitive whale habitats and greatly improve detection capacity, resulting in a vessel-strike likelihood rated as rare. The company emphasises that its conclusion is based on operational design, low vessel speeds, continuous real-time monitoring, and mandatory separation measures, not merely on AIS data or a lack of past seismic-related strikes. CGG concludes that the overall suite of controls reduces vessel-strike risk to ALARP and provides a defensible basis for determining that the likelihood of a strike is minimal.	
4496	GMTOAC objects to CGG removing a previous control measure limiting seismic discharge in the Pygmy Blue Whale foraging BIA during periods of low whale presence, replacing it with a vague condition requiring CGG to determine whether whale presence is “compatible” with proceeding. GMTOAC argues this new measure lacks detail on how whale presence or “unacceptable disturbance” will be assessed, and that it fails to reference Recovery Plans which define unacceptable impacts. GMTOAC warns that the proposed survey timing (April–June 2026) coincides with peak Pygmy Blue Whale foraging season and Southern Right Whale migration and calving periods, meaning the seismic survey is likely to occur when both species are using their BIAs. Preventing whales from accessing these areas, or exposing them to injury while they remain, would constitute unacceptable impacts inconsistent with Recovery Plan objectives.	CGG has further reduced the likelihood of interactions with marine mammals by excluding the April–June period and commencing the survey only after 15 September. Because blue whales typically do not arrive from Western Australia until November, CGG argues that most of the survey will occur when blue whales are absent from the area. It adds that sighting data show very few blue whales in November and December, with peak abundance occurring later, from January to March during the Bonney Upwelling.	EVT352

Annex 3

EPBC Act Listed Species within the Operational Area Relevant to Collison

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Turtles							
Green Turtle	Species or species habitat may occur within area	Vulnerable	Migratory	Migratory Marine Species	Listed	None identified	Recovery Plan for Marine Turtles (DoEE 2017)
Leatherback Turtle, Leathery Turtle	Species or species habitat likely to occur within area	Endangered	Migratory	Migratory Marine Species	Listed	None identified	Recovery Plan for Marine Turtles (DoEE 2017) Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle*)* (DEWHA 2008)
Loggerhead Turtle	Species or species habitat likely to occur within area	Endangered	Migratory	Migratory Marine Species	Listed	None identified	Recovery Plan for Marine Turtles (DoEE 2017)
Dolphins							
Bottlenose Dolphin	Species or species habitat may occur within area					None identified	None identified
Common Dolphin, Short-beaked Common Dolphin	Species or species habitat may occur within area					None identified	None identified

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Dusky Dolphin	Species or species habitat likely to occur within area		Migratory	Migratory Marine Species		None identified	None identified
Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin	Species or species habitat likely to occur within area					None identified	None identified
Risso's Dolphin, Grampus	Species or species habitat may occur within area					None identified	None identified
Southern Right Whale Dolphin	Species or species habitat may occur within area					None identified	None identified
Whales							
Andrew's Beaked Whale	Species or species habitat may occur within area					None identified	None identified
Antarctic Minke Whale, Dark-shoulder Minke Whale	Species or species habitat likely to occur within area		Migratory	Migratory Marine Species		None identified	None identified

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Arnoux's Beaked Whale	Species or species habitat may occur within area					None identified	None identified

1 Introduction

The introduction of invasive marine species was identified through the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) as an aspect needing further assessment. Hence, this document presents a detailed examination of **Invasive Marine Species** as a risk pathway between the Regia Marine Seismic Survey (**Regia MSS**) and the existing environment that may be affected by that aspect.

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was first published in draft form to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (EP) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

2 Aspect – Introduction of Marine Pest Species

2.1 How the Aspect Occurs

The introduction of marine pests could occur from vessels used for the Regia MSS because of:

- Discharge of ballast water containing foreign species.
- Translocation of species through biofouling of the vessel hull and/or niches (e.g., sea chests, bilges, and strainers) or in-water equipment (e.g., source array and streamers).

2.2 Extent and Duration of the Aspect

Duration: 90 days

Extent: Operational Area

The extent of the area where the risk of an introduction of marine pest species may occur is within the Operational Area and the risk could occur while the activity is undertaken.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for marine pests for the following environmental components and their social, cultural, and economic features:

- Benthic assemblages.
- Invertebrates.
- Commercial Fishing and Aquaculture.
- Diving.
- Recreational fishing.
- People and communities.

No cause-effect pathway for marine pests and marine protected areas such as Australian and Victorian marine parks was identified as the closest Australian Marine Park (Apollo) is ~36 km from the Operational Areas (Appendix B12 MAP-REG-EPM-078). The Victorian Twelve Apostles Marine National Park was identified to abut the previous Activity Planning Area and to reduce the risk of IMS translocation into the park a 5 km buffer was put in place for the final Operational Area making the distance to the park from the Operational Area ~ 6 km (Appendix B12 MAP-REG-EPM-079).

Marine pests may become established where conditions are suitable, and these species may have impacts on local ecological and economic values. However, establishment of introduced marine species is mostly likely to occur in shallow waters in areas where large numbers of vessels are present and are stationary for an extended period.

Successful marine pest establishment requires the following three steps (Marine Pest Sectoral Committee 2018):

- Colonisation and establishment of the marine pest on a vector (e.g., vessel hull) in a donor region (e.g., home port).
- Survival of the settled marine species on the vector during the voyage from the donor to the recipient region (e.g., Operational Area).
- Colonisation (e.g., dislodgement or reproduction) of the marine species in the recipient region, followed by successful establishment of a viable new local population.

The Australian Government Bureau of Resource Sciences (BRS) established that the relative risk of a marine pest incursion around the Australian coastline decreases with distance from the shoreline. Modelling conducted by BRS (2007) estimates:

- 33% chance of colonisation at 3 nm.
- 8% chance at 12 nm.
- 2% chance at 24 nm.

If the risk of establishment of IMS is realised, the following known and potential environmental impacts may occur:

- Change in ecosystem dynamics.
- Changes to the functions, interests, or activities of other users.

Change in ecosystem dynamics may include reduction in native marine species diversity and abundance, displacement of native marine species, socio-economic impacts on commercial fisheries, and changes to conservation values of protected area.

4 Description of the Existing Environment that May be Affected by the Activity

As detailed in Section 2.2, the Operational Area has been adopted as the extent of the area wherein marine pest translocation could occur from Regia MSS vessels.

As detailed in the PMST Report for the Operational Area (Appendix B5) there are no marine protected areas within the Operational Area. The Operational Area overlaps the West Tasmanian Canyons Key Ecological Feature (KEF) and the Giant Kelp Marine Forests of Southeast Australia Threatened Ecological Community (TEC). However, giant kelp requires clear, shallow water no deeper than approximately 35 m deep (TSSC 2012) which is outside the water depths for the Regia MSS Operational Area (40 to 1,400 m) and thus it is not assessed further.

PMST searches were run again prior to resubmission to ensure any changes to species or listings were identified to control for passage of time. There are no changes to protected matters information for receptors that may be impacted by an introduction of marine pests [Section added in response to Matters: I16 and I17]

4.1 Marine Pests

In the South-east Marine Region, 115 marine pest species have been introduced and an additional 84 have been identified as possible introductions, or 'cryptogenic' species (NOO 2002). Several introduced species have become pests either by displacing native species, dominating habitats or causing algal blooms.

Marine pests in Victoria marine waters according to Parks Victoria (No date) and Agriculture Victoria (2023) are:

- Asian date mussel (*Musculista senhousia*) – prefers soft sediments in waters up to 20 m deep, forming mats and altering food availability for marine fauna. Found in Port Phillip and Western Port, including Yaringa and French Island Marine National Parks; some records from eastern Victoria, particularly the Gippsland Lakes.
- Asian shore crab (*Hemigrapsus sanguineus*) - found on hard surfaces like under rocks, shells, debris or artificial structures (marinas, moorings, etc.) in exposed rocky coasts, estuaries, tidal flats and shallow waters. Currently present in Port Phillip Bay.
- Cord grass (*Spartina anglica* and *Spartina x townsendii* sp) – found at the mouth of Bass River and in drain outlets near Tooradin in Westernport. Widespread in South Gippsland including Anderson's Inlet and Corner Inlet. Invades native saltmarsh, mangroves and mudflats, altering the mud habitat and excluding other species.
- Dead man's fingers (*Codium fragile* ssp. fragile) – widespread in Port Phillip and known to inhabit San Remo and Newhaven in Westernport. It grows rapidly to shade out native vegetation and can regenerate from a broken fragment enabling easy transfer from one area to another. Attaches to subtidal rocky reef and other hard surfaces.
- European fan worm (*Sabella spallanzanii*) - found at depths down to 30 m and is found in nutrient-rich waters in sheltered locations where there are no strong currents and little wave action. It is a filter feeder and grows on soft sediments or anchors itself to rocks, mollusc shells, jetties, pontoons or other solid surfaces. Well established in Port Phillip and some other local ports but not yet observed in Western Port or elsewhere.
- Green Shore Crab (*Carcinus maenas*) - voracious and aggressive predator with a broad diet, it out-competes native crabs for food and habitat. It is a major cause of mortality of native crabs and mollusc populations. Widespread across Victoria and common in Port Phillip and Western Port. This crab has been present in Victoria since the 1800s
- New Zealand screw shell (*Maoricolpus roseus*) – lies on or partially buried in sand, mud or gravel in waters up to 130 m deep. It can densely blanket the sea floor with live and dead shells and compete with native scallops and other shellfish for food. This species is widespread in coastal areas of Eastern Victoria, including Corner Inlet and has been found

west of Wilsons Promontory in Waratah Bay and Shallow Inlet. Its range is slowly expanding westward. Not currently known in Port Phillip or Western Port.

- Northern pacific seastar (*Asterias amurensis*) – prefer soft sediment habitat, but also use artificial structures and rocky reefs, living in water depths usually less than 25 m but up to 200 m water depths. It is thought to have been introduced in 1995 through ballast water from Japan.
- Pacific Oyster (*Crassostrea gigas*) - alter habitats by covering substrates, forming reefs and over growing native species. It is fast growing and is a filter feeder, competing with native species for food. Known pest in Western Port. Also observed in Port Phillip, Tidal River, Corner Inlet and Nooramunga Marine and Coastal Park however not considered a pest in these locations.
- Red Algae (*Grateloupia turuturu*) - large size of the plant shades out native algae on the reef. It grows rapidly in summer and dies back in winter causing large change in the availability of food for grazers such as snails. Widespread in northern Port Phillip.
- Wakame (*Undaria pinnatifida*) - grows rapidly and forms dense underwater forests, outcompeting native kelp and algae for light and space, then dies back in summer, changing kelp habitat. Well established in Port Phillip but currently not present in other Victorian locations, apart from Apollo Bay Harbour.

The National Introduced Marine Pests Information System (NIMPIS 2023) indicates that Portland, a potential port for mobilisation, harbours the following marine pests:

- Bryozoan (*Bugula neritina*) - most abundant bryozoans in ports and harbours and an important member of the fouling community. They grow well on pier piles, vessel hulls, buoys, and similar submerged surfaces.
- Bryozoan (*Cryptosula pallasiana*) - typical habitats include seagrasses, drift algae, oyster reef, artificial structures such as piers and breakwaters, man-made debris, rock, shells, ascidians, glass and vessel hulls. It has been reported from depths down to 35 m.
- Dead man's fingers (*Codium fragile* ssp. fragile) - as per Victorian waters.
- East Asian bivalve (*Theora lubrica*) - typically lives in muddy sediments from the low tide mark to 50 m, however it has been found at 100 m.
- European clam (*Varicorbula gibba* - inhabits the shallow sublittoral zone to depths of around 140 m, where it is a shallow burrower in thick muddy sand with coarse elements.
- European fan worm (*Sabella spallanzanii*) - as per Victorian waters.
- Fanworm (*Euchone limnicola*) - burrows into soft sediments, secreting a mucous layer to enable it to build firm burrow walls.
- Solitary ascidian (*Ascidiella aspersa*) - found from intertidal to shallow subtidal waters to 50 m depth attached to clay, stones, rocks, algae and wharf piles, where it can be the dominant fouling species.
- Toxic dinoflagellate (*Alexandrium tamarense*) - found in the photic zone; 1-20 m depth inshore; possibly deeper offshore.
- Toxic dinoflagellate (*Alexandrium minutum*) - found to a depth of 20 m in inshore waters but may also be found deeper offshore.
- Wakame (*Undaria pinnatifida*) – as per Victorian waters.
- White bushy bryozoan (*Amathia distans*) - Usually found in sheltered, often turbid, waters. Rocks, rock reef, oyster reef, docks, pilings, breakwaters, buoys, pontoons, man-made debris, and drift algae are all good substrates for this species.

The National Introduced Marine Pests Information System (NIMPIS 2023) indicates that other ports which may be used for the survey, Warrnambool, Apollo Bay or Port Fairy do not currently harbour any marine pests.

4.2 Benthic Assemblages

Benthic assemblages are biological communities that live in or on the seabed. They typically contain light-dependent taxa such as algae, seagrass and corals, which obtain energy primarily from

photosynthesis, and/or animals such as molluscs, sponges and worms. Benthic habitats are the seabed substrates that benthic communities grow on or in; these can range from unconsolidated sand to hard substrates (e.g., limestone) and occur either singly or in combination.

Rocky reefs and hard grounds are in all areas of the South-east Marine Region continental shelf including Bass Strait, from the sub-tidal zone shore to the continental shelf break. On the continental shelf, rocky reefs and hard grounds provide attachment sites for macroalgae and sessile invertebrates, increasing the structural diversity of shelf ecosystems. The reefs provide habitat and shelter for fish and are important for aggregations of biodiversity and enhanced productivity. The shallowest depth at which the rocky reefs occur in Commonwealth waters is approximately 50 m (CoE 2015a).

Corals do not occur as a dominant habitat type within the Environmental Planning Area. Reef development by hard corals does not occur further south than Queensland (Tzioumis and Keable, 2007). Soft corals are typically present in deeper waters throughout the continental shelf, slope and off-slope regions, to well below the limit of light penetration (BBG 2003, Boreen et al. 1993). Gorgonian corals (soft corals) were identified during seabed surveys of the Beach Otway Development area within the Environmental Planning Area (Ramboll 2020).

James et al (2013) undertook extensive surveys of macroalgal communities along the Otway Shelf from Warrnambool to Portland in south-west Victoria. Sites were adjacent to shore or on offshore rocky reefs covering a depth range of 0 to 36 meters water depth. These surveys did not locate giant kelp at any site but identified that other brown algae species (*Durvillaea, Ecklonia, Phyllospora, Cystophora*, and *Sargassum*) are prolific to around 20 m water depth. Brown algae tend to be replaced by red algae in deeper waters.

4.3 Invertebrates

Studies by the Museum of Victoria found that invertebrate diversity was high in southern Australian waters although the distribution of species was patchy, with little evidence of any distinct biogeographic regions (Wilson and Poore 1987). Results of sampling in shallower inshore sediments reported high diversity and patchy distribution (Parry et al. 1990). In these areas, crustaceans, polychaetes, and molluscs were dominant.

Throughout the region, a variety of seabed habits support a range of animal communities such as sparse sponges to extensive 'thickets" of lace corals and sponges, polychaete worms and filter feeders (DNP 2013). Echinoderms, such as sea stars, sea urchins and sea cucumbers are also an important fauna species of the southern Australian and Tasmanian waters, with several species at risk of extinction (DPIPWE 2020).

4.4 West Tasmanian Canyons Key Ecological Feature

The West Tasmanian Canyons are located on the relatively narrow and steep continental slope west of Tasmania. This location has the greatest density of canyons within Australian waters where 72 submarine canyons have incised a 500 km-long section of slope (Heap & Harris 2008).

The Operational Area overlaps a small portion of the West Tasmanian Canyons KEF (Appendix B12 MAP-REG-EPM-004).

Submarine canyons modify local circulation patterns by interrupting, accelerating, or redirecting current flows that are generally parallel with depth contours. Their size, complexity and configuration of features determine the degree to which the currents are modified and hence their significant influence on local nutrients, prey, dispersal of eggs, larvae and juveniles and benthic diversity with subsequent effects which extend up the food chain.

Eight submarine canyons surveyed in Tasmania, Australia, by Williams et al (2009) displayed depth-related patterns with regard to benthic fauna, in which the percentage occurrence of faunal coverage

visible in underwater video peaked at 200-300 m water depth, with averages of over 40% faunal coverage. Coverage was reduced to less than 10% below 400 m depth. Species present consisted of low-relief bryozoan thicket and diverse sponge communities containing rare but small species in 150 to 300 m water depth.

Sponges are concentrated near the canyon heads, with the greatest diversity between 200 m and 350 m depth. Sponges are associated with abundance of fishes and the canyons support a diversity of sponges comparable to that of seamounts. Based upon this enhanced productivity, the West Tasmanian Canyon system includes fish nurseries (blue wahoo and ocean perch), foraging seabirds (albatross and petrels), white shark and foraging blue and humpback whales (CoA 2015a).

4.5 Commercial and Recreational Fishing and Aquaculture

As detailed in the Commercial Fisheries Analysis Report (Appendix B6), the Operational Area overlaps the following fisheries that have catch effort:

- Commonwealth:
  - Southern and Eastern Scalefish and Shark (SESS) Fishery SESSF following sectors:
    - Scalefish Hook
    - Shark Gillnet sector
  - Trawl – otter board
  - Southern Squid Jig Fishery
- Victorian:
  - Giant Crab
  - Multi-species Ocean
  - Octopus
  - Southern Rock Lobster
  - Wrasse

Recreational fishing may occur within the Operational Area but there are no known popular areas.

No aquaculture sites have been identified within the Operational Area and thus it is not assessed further.

4.6 Diving

No dive sites have been identified within the Operational Area and thus it is not assessed further.

4.7 People and Communities

4.7.1 Social and Economic Features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local flora and fauna, which may impact tourism and local enjoyment of the area. The commercial fisheries that overlap the Operational Area and have catch effort are described in Section 4.5.

4.7.2 Cultural Features

Kelp forests, home to giant and bull kelps, are identified as culturally significant to the Wadawurrung People as habitats and food sources for numerous animals, including rock lobster and abalone and their ability to be used to create water carriers (WTOAC, 2020) (Appendix F3, Section 3.16.1).

Several invertebrate species including torbos, pipis, abalone, limpets, mussels, elephant snails, crayfish/lobster, crabs and squid are identified as culturally significant to the Gunditjmara People as both a resource and in harvesting as a cultural practice (GMTOAC, 2023). Barnabeel (oyster), murrabal (mussel), bam bam (crayfish), abalone and pipi are also culturally important resources to the Wadawurrung People (WTOAC, 2020). Invertebrate species are an important traditional, social and economic resource for the Eastern Maar People. Abalone, cockles and crayfish are collected as tucker along the coast (EMAC, 2015) (Appendix F3, Section 3.16.1).

5 Relevant Legislative and Other Requirements

CGG has considered all the relevant legislative requirements, that apply to the risk of the introduction of invasive marine species (see Appendix B2). Measures that will be adopted to demonstrate how these requirements will be met are as follows:

- CGG Marine Assurance System which includes a vessel contractor pre-qualification assessment and OVID-Style Inspections prior to the activity starting that:
  - Checks that vessels used have met the following requirements before being deployed for the survey:
    - Biosecurity Act 2015
    - Biosecurity Regulations 2016
    - Biosecurity Amendment (Biofouling Management) Regulations 2021
    - Marine Order 98 - Marine pollution prevention - antifouling systems
    - Australian Ballast Water Management Requirements
    - Australia Biofouling Management Requirements
    - Guidelines for the Control and Management of Ships' Biofouling to Minimize the Transfer of Invasive Aquatic Species (Biofouling Guidelines)
    - Marine Pest Plan 2018–2023: National Strategic Plan for Marine Pest Biosecurity
    - National Biofouling Management Guidance for the Petroleum Production and Exploration Industry 2009.
  - Check the vessel Anti-Fouling System.

6 Defining Acceptable Levels of Risk

Category	Defined Acceptable Level (General)	Defined Acceptable Level (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Prevent the introduction of any invasive marine pest species.	Australia is a party to the MARPOL convention and the International Convention on the Control of Harmful Anti-fouling Systems, which requires prevention of marine environmental pollution from shipping. Prevention of IMS will ensure the Regia MSS is compliant with the relevant legislation.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	

Category	Defined Acceptable Level (General)	Defined Acceptable Level (Aspect Specific)	Rationale
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	are key for maintaining their social, economic and cultural roles. Predicted levels of impact for species that have social, cultural and economic values will be assessed on a receptor level.
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Risks Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of risk could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of invasive marine species introduction, elimination involves removing or reducing the factors that could lead to this introduction. Two main options were considered and subsequently adopted:

No vessel movements within 5 km of the Twelve Apostles State Marine Park

This measure removes the possibility of transporting biofouling organisms in proximity to a sensitive marine environment. This measure was adopted because of consultation with Marine Parks Victoria who were concerned about IMS risks. It is also protective of cultural values of the marine park and Southern Rock Lobsters which are also a key value.

Ballast water exchange activities will be conducted outside of Marine Protected Areas

By ensuring that these activities occur well outside MPAs, the potential for releasing non-native organisms into highly sensitive and ecologically valuable environments is effectively removed. This approach supports the complete avoidance of invasive species risks in the most vulnerable areas.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the risk. No substitution-based limitations were required in this case, as the elimination measures applied were sufficient (when applied with other measure types) to reduce the identified risk to an acceptable level.

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2. These limitations were evaluated to determine whether the source of risk could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

9 Predicted Levels of Risk

9.1 Change in ecosystem dynamics and social and cultural value

The introduction and subsequent establishment and spread of a marine pest may result in the reduction in native marine species diversity and abundance, displacement of native marine species, changes to conservation values of protected areas and culturally important species. The extent of the initial risk to benthic assemblages are likely to be localised (isolated locations if there is no spread) but may become widespread if establishment and spread occurs.

Receptors which may occur within the Operational Area and are at risk from marine pest introduction are:

- Benthic Assemblages (sponges, bryozoans etc.)
- West Tasmania Canyons KEF
- Invertebrates

Only a small proportion of marine pests become invasive (Wells 2018) with the risk of a marine pest being able to successfully establish itself depending on depth, distance from the coast, water movement and latitude. Survival is not expected in deep oceanic waters (>90 m depth) with establishments more likely within shallower waters (<50m), where vessels are stationary for extended periods of time.

The Regia MSS vessels will not be stationary within the Operational Area and no anchoring will take place further reducing the risk of translocating a marine pest to the seabed. All subsea survey equipment is stored on the vessel so a marine pest would not be able to survive on equipment in these exposed dry conditions. Support vessels will generally not be alongside the survey vessel for more than two hours during support operations, so a cross transfer of a marine pest is highly unlikely.

As the Operational Area at its nearest point is ~7 km from the Victorian coast, BRS (2007) estimates indicate that the chance of colonisation of a marine pest is 33%. However, as detailed in the Existing Environment Section, marine pests which are known to occur in the Bass Strait are limited to either sheltered areas or shallow waters which are not present in the exposed well mixed waters of the Operational Area where water depths range from 40 to 1,400 m.

The CGG Marine Pest Risk Assessment Process ensures contracted vessels meet ballast water and biofouling legislative requirements to prevent the introduction of marine pests.

Values for the West Tasmania Canyons KEF includes sponges that are associated with abundance of fishes and a diversity, greatest between 200 and 350 m, comparable to that of seamounts (DCCEEW 2020d). At the water depths of these values the possibility of a marine pest becoming established is negligible.

No EPBC listed invertebrate species were identified from the PMST Report for the Operational Area (Appendix B5).

The predicted level of consequence of introducing a marine pest causing a change in ecosystem dynamics, and therefore a change to social and cultural value, is assessed as major as there is the potential to alter ecosystem processes and reduce biodiversity. However, the likelihood of a marine pest being present on a Regia MSS vessel and becoming established is assessed as rare due to the implementation of ballast and biofouling management requirements and that a marine pest would be unable to colonize the benthic substrate due to the deep and well mixed waters within the Operational Area. The predicted level of risk is assessed as low.

9.2 Changes to the functions, interests, or activities of other users

The introduction of a marine pest may result in the reduction in native marine species diversity and abundance, displacement of native marine species which could result in changes to commercial fish

species diversity and abundance. The extent of the initial risk to commercial fisheries is likely to be localised if a marine pest introduction occurred and did not spread but may become more widespread if colonisation and spread occurs.

As detailed in the assessment of a change in ecosystem dynamics, the introduction of a marine pest in the Operational Area is unlikely to impact on fisheries within the region as colonisation and spread is unlikely based on the Operational Area water depth and distance from shore which BRS (2007) estimates indicate that the chance of colonisation of a marine pest is 33%. In addition, the low light levels (water depth of 40 to 1,400 m) and well mixed marine environment is not conducive to the establishment of marine pests.

The CGG Marine Assurance System ensures contracted vessels meet ballast water and biofouling legislative requirements to prevent the introduction of marine pests. Thus, it is highly unlikely that marine pests would be present on vessels.

None of the fisheries identified as being active in the Operational Area identified marine pests as a threat. Whilst Southern Rock lobster is suspectable to tail fan necrosis, caused by combination of several bacteria and fishing practices such as live holding (Musgrove et al. 2005) and both crab and lobster can be susceptible to paralytic shellfish toxin, none are related to the introduction of marine pests.

The predicted consequence of introducing a marine pest causing a change to the functions, interests or activities of commercial fisheries is assessed as major as there is the potential to alter ecosystem processes and reduce biodiversity, however, the likelihood of a marine pest being present on a Regia MSS vessel and becoming established is assessed as rare due to the implementation of ballast and biofouling management requirements and that a marine pest would be unable to colonize the benthic substrate due to the deep and well mixed waters within the Operational Area. The predicted level of risk is assessed as low.

9.3 Measures Adopted to Manage Environmental Impact

The following measures have been adopted to ensure that the risks associated with potential introduction of invasive marine species from the survey and support vessels will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
Vessel contractor pre-qualification assessment	Practice	CGG undertakes this assessment in accordance with its Marine Risk Management Standard (GM-STD-MA-003) to ensure vessel biofouling controls meet these EP requirements.
OVID-Style Inspections	Practice	Confirm that all contracted vessels conduct pre-port entry checks using the National Introduced Marine Pest Information System database and assess changes in known invasive species. Confirm that the sound source and towed streamers will be inspected and cleaned (where required) prior to deployment.
Anti-Fouling Systems	System	Anti-fouling systems are essential for maritime vessels to prevent the accumulation of marine organisms like barnacles, algae, and mussels on the hull. All contracted vessels must have anti-foulant systems that are properly maintained and in compliance with the International Convention on the Control of Harmful Anti-Fouling Systems on Ships.

Measure	Measure Type	Details and Justification
IMS Risk Assessment Procedure	Procedure	A procedure which mandates an IMS risk assessment be conducted on vessels and immersible equipment. The CGG IMS Risk Assessment Procedure aligns with national standards for IMS management. This procedure assures CGG's adherence to the International Convention for the Control and Management of Ship's Ballast Water and Sediments 2004 and the Australian Ballast Water Management Requirements. The IMS risk assessment procedure requires a qualified IMS inspector to, prior to mobilisation into the region, evaluate the vessels operational history, inspection results, and biofouling management measures to determine risk levels before mobilisation. If a vessel or facility presents a low biofouling risk, it may proceed with offshore activities, while moderate or high-risk cases may require actions such as cleaning, antifouling treatments, or operational restrictions depending on the findings to ensure all vessels used during the activity have a 'low-risk' rating. Biofouling management plans and record-keeping align with IMO Guidelines (2011), ensuring vessels maintain effective biosecurity controls, including inspections, maintenance logs, and marine growth prevention systems. Vessels moving between regions will be assessed for prior exposure to high-risk areas.

10 Demonstration Risks Will Be of An Acceptable Level

10.1 Discussion on Principles of ESD

Temporary, Reversible, Small Scale and Natural variation

The risk of introducing marine pests from the petroleum activity is assessed as rare due to the application of stringent biosecurity measures, such as vessel inspections, ballast water management, and compliance with national guidelines. Any residual risk is considered localized, and any potential impacts are expected to be temporary, reversible, and of low intensity, with minimal long-term or widespread environmental consequences. Marine pests are unlikely to establish or spread due to the proactive and robust risk mitigation measures.

Based on Sufficient Information

The risk assessment is informed by peer-reviewed literature, government marine pest databases, and relevant management plans. Expert judgment, alongside an understanding of vessel origin, operational logistics, and known marine pest distribution, supports the conclusion that the risk of pest introduction is low. The assessment incorporates all available data to ensure a conservative and scientifically grounded evaluation of potential risks.

Activity not inconsistent with EPBC Act

The activity is in full compliance with EPBC Act-listed species recovery plans, as well as biosecurity and marine pest management frameworks. The measures in place align with national ballast water management standards and broader marine biosecurity protocols, ensuring no inconsistency with the statutory obligations under the EPBC Act.

10.2 Biological and Ecological Categories

Marine pests are known to cause significant ecological consequences, such as species displacement, loss of biodiversity, and disruption of ecosystem functions. However, the likelihood of marine pest establishment is very low due to the rigorous biosecurity procedures in place. As a result, no significant biological or ecological impacts are predicted. Ecosystem function, biodiversity, and the health of marine habitats are expected to remain intact, with no adverse long-term effects on species composition or ecological processes.

10.3 Discussion on Economic, Cultural and Social Categories

Marine pests have the potential to impact commercial fisheries, aquaculture, and culturally significant marine species. However, the likelihood of pest establishment is minimal, and the application of preventive measures such as biosecurity protocols ensures that the economic, cultural, and social fabric tied to these species remains protected. No long-term disruption to economic activities, including fishing industries or recreational use, is expected. The continuation of traditional and culturally important practices, such as fishing for specific species, will not be hindered. Communities will maintain ongoing access to marine resources and heritage values without experiencing significant or irreversible disruption.

10.4 Discussion on Consistency with Company Processes

The risk assessment process was conducted in line with CGG's internal environmental risk framework, employing a conservative threshold for biosecurity risks. All measures for vessel and equipment mobilization followed national and international best practices for marine pest prevention. The risk of marine pest introduction is considered rare, and there have been no recorded introductions in past company operations. The mitigation strategies implemented by CGG align with industry standards and reflect a commitment to maintaining environmental integrity throughout the project. This consistency with company processes ensures that the activity complies with all relevant environmental regulations and has no adverse long-term effects.

This risk assessment has demonstrated that the introduction of marine pests causing a change to both ecosystem dynamics and to the functions, interests or activities of commercial fisheries has a:

- Predicted level of consequence of major.
- Likelihood of rare.
- Predicted level of risk of medium.

11 Environmental Performance Outcomes

Defined Acceptable Level (From Section 6)	Environmental Performance Outcome	Rationale
Prevent the introduction of any invasive marine pest species.	No introduction of a known or potential invasive marine species.	Biosecurity controls such as vessel inspections, ballast water management, and adherence to national guidelines significantly reduce the risk of marine pest introduction, preserving ecosystem integrity.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Social, cultural, and economic features are protected, sustaining their value for people and communities.	Protecting native marine species and preventing the establishment of invasive pests maintains ecological balance, which in turn supports the ongoing viability of industries, cultural practices, and recreational use of the marine environment.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		

12 Recommendations

The predicted level of risk level is medium; thus, good industry practice (including legislation and standards) has been applied. Risks are of an acceptable level without further recommendations being required.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table D3- 1 shows how this feedback has been incorporated into the environmental assessments.

Table D3- 1 - Public comment input since the beginning of the public comment period starting 25 January 2024.

Matter	Matter ID	Changes made arising from public comment
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table D3-2. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table D3-2 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4128	Lack of adequate monitoring of species present or likely to be impacted.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions regarding species that may be affected by the Regia MSS. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	3237
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise	4808

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		adverse impacts on marine life are outlined in the EP in G1.	
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4166	Risk to the marine environment with the plan.	Titleholder has conducted a series of thorough risk assessments including the following aspects: Accidentl release of waste (D1), Fauna Interactions (D2), Invasive Marine Species (D3) and Accidental release of fuel (D4), wherin which relevant receptors have been assessed.	2677
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	3343
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the	1661

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptable levels and is presented in the Environment Plan	
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4253	The possible effects to marine life and ecosystmens is my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publically responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	future of herself, other people of Port Fairy and the greater community.	used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4315	The statement suggest that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times	786

		activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	"A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments are covered below in response to concern 6."	2886
4493	Claims that CGG's proposed seismic activities contribute both directly and indirectly to broader threats faced by Southern Right Whales, including industrialisation of the marine environment, climate change, and pollution or contamination from vessel discharges.	Broader threats such as climate change and industrialisation fall outside the scope of the Environment Plan, as outlined in the response to Statements 156–166. The EP assesses only the environmental risks directly associated with the proposed activity. These risks are evaluated in the D Appendices, which demonstrate that any residual risks have been reduced to an acceptable level.	EVT352

Loss of Containment Sensitive Species 109

1 Introduction

Accidental release of fuel was identified through the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) as an aspect needing further assessment. Hence, this document presents a detailed examination of **Accidental Release of Fuel** as a risk pathway between the Regia Marine Seismic Survey (**Regia MSS**) and the existing environment that may be affected by that aspect.

This document also uses information in two preceding study:

1. PEIRA
2. Oil Spill Modelling Analysis (Appendix B11)

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was first published in draft form to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (EP) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

2 Aspect – Accidental Release of Fuel

2.1 How the Aspect Occurs

The following hydrocarbons and chemicals will be present on the seismic vessel and support vessels:

- Marine diesel oil (MDO) used as fuel for the vessels.
- Hydraulic fluids such as engine and synthetic oils required for equipment and engine use.
- Chemicals for cleaning and maintenance purposes.

Hydrocarbons and chemicals are stored in contained areas but there is the potential for a loss of containment to occur resulting in a release of hydrocarbons or chemicals to the marine environment. Loss of containment scenarios are details in Table D4-1.

Table D4-1: Accidental Release of Fuel Scenarios

Scenario	Material and Potential Volume	Description
Vessel fuel tank rupture	257.4 m^3 MDO	A collision between the survey vessel, support vessel or a third-party vessel has the potential to result in the breach of the vessel hull and subsequent rupture of a fuel tank. A spill to sea because of vessel collision/grounding is only likely to occur under exceptional circumstances where these conditions resulted in significant damage to one or more of the fuel tanks in the hull of the vessel. These may include: • Navigational error • Vessel loss of power • Floundering due to weather. If a collision/grounding involving the seismic vessel occurred, the worst-case credible scenario would be the loss of the largest single fuel tank volume (consistent with AMSA (2015) guidelines), which is 257.4 m^3 of MDO. Vessel fuel tank inventory will be limited to 250m^3 to align with the modelling report.
Vessel refuelling failure	1.2 m^3 to 25 m^3 of MDO	A vessel refuelling failure may result in the release of MDO to the marine environment. Using dry-break couplings (which provide an automatic mechanism to seal off both the hose and the fixed pipe end when the hose is disconnected), the maximum credible spill volume from a refuelling failure is the maximum typical volume of a transfer hose (1.2 m^3). In the event dry break couplings fail, guidelines indicate the maximum credible spill volume from a refuelling incident with continuous supervision is equivalent to the volume of MDO transferred within a 15-minute period (AMSA 2053), which represent the estimated time required to shut down refuelling operations following discovery of a spill. Based on a transfer volume of 100 m^3/hr, this may result in a spill volume of 25 m^3.
Loss of containment overboard	1 m^3 of hydraulic fluid, lubricating fluids, or chemicals	A loss of containment may occur because of mechanical/ structural failure, human error, or poor housekeeping. Should a spill occur on a vessel deck, controls such as equipment bunds, scupper plugs and on-board clean up should prevent the spilt material reaching the marine environment.

Scenario	Material and Potential Volume	Description
		However, in the event these controls fail, or are not implemented, spill volumes released to the environment are likely to be less than 1 m^3 based on the inventory typically used on deck.

2.2 Extent and Duration of the Aspect

Duration: 90 days survey duration +30 days

A loss of containment could occur at any time during the activity (90 days). If there were a loss of containment the consequences of the largest release (fuel tank rupture of MDO) may persist for up to 30 days post-incident before water quality was below acceptable thresholds again.

Extent: Environmental Planning Area

If there were an accidental release of fuel it could potentially disperse 150 km from the location of the vessel. An additional 5 km was added to this range to ensure that coastal sensitivities were included in the search ranges for environmental values and sensitivities to inform the description of environment. This area is the Environmental Planning Area (Appendix B12 MAP-REG-EPM-083).

The 150 km is based on the NERA Reference Case: Consequences analysis of an accidental release of MDO (NERA 2018) that found that MDO spills under 700m^3 were reliably predicted to disperse within 150 km from the source of the spill. However, this reference case was based on exposure values that are higher than the current commonly used exposure values for oil spill modelling (NOPSEMA 2019) that are selected to approximate the spatial extent and variability of the receiving environment's contact with oil and subsequently inform risk evaluation and planning for oil spill response and monitoring. Thus, to validate that 150 km was sufficiently conservative a review was undertaken to identify oil spill modelling that has been undertaken in the Otway area since the NOPSEMA Oil Spill Modelling Environment Bulletin was published in April 2019. The review, provided in Oil Spill Modelling Analysis (Appendix B11), confirmed that 150 km was sufficiently conservative to approximate the spatial extent and variability of the receiving environment's contact with oil and subsequently inform risk evaluation and planning for oil spill response and monitoring for a spill up to 250 m^3 of MDO within the Regia MSS Operational Area.

2.2.1 Analysis of Low Threshold Exposure Ranges

As acknowledged above, the NERA Reference Case (NERA 2018) was prepared before NOPSEMA clarified its expectations for exposure values from modelling to conform to 10 parts per billions (ppb) thresholds for entrained hydrocarbons. Whilst the analysis presented in Appendix B11 did consider the higher thresholds in the NOPSEMA Oil Spill Modelling Environment Bulletin (April 2019), the highest distances in this analysis exceed the Environmental Planning Area distance.

The analysis is reasonable to apply to the Regia MSS for the reasons provided in Appendix B11 and because:

- An accidental release of hydrocarbons from vessel collisions with seismic survey operations has never occurred in Australia.
- A volume of 250m^3 has been used as the worst-case release rather than 257.4m^3 because fuel tanks are rarely topped out and hydrostatic pressure and/or ballasting can prevent release of the full inventory. The difference of 7.4m^3 in predicting the level of risk is immaterial to the analysis.
- The most likely accidental release of hydrocarbons would occur from an accident whilst bunkering which would be a release orders of magnitude less than the predicted loss of 250m^3.

- The consequence analysis undertaken relies on modelled results from multiple thousands of modelled runs rather than the typical range of 100 – 300 model runs in a single analysis.

The consequence analysis presented covers all months of the year and the sea states in the operational months September – December will:

- Enhance the natural degradation of entrained hydrocarbons; and
- Significantly limit the spread of entrained hydrocarbons.

If entrained hydrocarbons did exceed the Environmental Planning Area distance:

- The only part of the environment that may be affected by entrained hydrocarbons is water quality and the description of water quality in the bioregion is the same as that provided in Section 4.
- The predicted impacts in an area beyond the environmental planning area remain unchanged.

Whilst the effect range at 10-ppb may be larger, the operational and scientific monitoring plan (OMSP) and arrangements are sufficient to detect exceedances of thresholds noting that:

- Water quality monitoring at sea in the months in which the activity is being carried out is unlikely to be effective, limiting detection options to coastal locations.
- The Otway coastline is known as being one of the highest energy coastlines around Australia further improving natural degradation and limiting the spread of entrained hydrocarbons.

3 Cause-Effect Pathway

The PEIRA identified a cause-effect pathway for an accidental release of fuel for the following environmental components and their social, cultural, and economic features:

- Water quality
- Sediment quality
- Benthic assemblages
- Coastal habitats and communities
- Plankton
- Invertebrates
- Fish
- Birds
- Marine reptiles
- Marine mammals
- Coastal development
- Indigenous culture
- Commercial fishing and aquaculture
- Marine industries
- Marine Tourism
- Diving
- Recreational Fishing
- Marine Protected Areas

Hydraulic fluids and lubricating fluids behave similarly to MDO when spilt in the marine environment. Hydraulic fluids are oils of light to moderate viscosity and have a relatively rapid spreading rate. Like MDO, they will dissipate quickly, particularly in high sea states, although lubricating oils are more viscous and so the spreading rate of a spill of these oils would be slightly slower.

Impacts associated with a spill of chemicals to the marine environment will depend on the nature of the liquid released, the volume and its behaviour in the marine environment (whether it sinks, floats, disperses, etc.). In the event of a spill to the marine environment, these liquids would be subjected to rapid dispersion and dilution by the open ocean water conditions and prevailing currents and would remain within the surface waters.

Potential impacts from minor spills of hydraulic fluids, lubricating fluids or chemicals include a temporary and highly localised decline in water quality. This would have limited potential for toxicity to marine fauna or impact socio-economic receptors, due to the short duration of exposure and rapid dilution of the released liquids in the marine environment. As there is no likely cause-effect pathway to impact fauna or socio-economic receptors and impacts to water quality is predicted to be negligible no further assessment is required.

MDO is a light, refined petroleum product that when spilled on water, most of the oil evaporates or naturally disperses quickly (hours to days). However, the rates differ with both water and air temperature, more so with wind speed (and wave energy).

MDO is much lighter than water, so it is not possible for MDO to sink and accumulate on the seabed as pooled or free oil.

Dispersion into the sea by the action of wind and waves can result in 25–50% of the loss of hydrocarbons from surface slicks and dissolution (solubility of hydrocarbons) can account for 1-10% loss from the surface. While the majority of the MDO evaporates quickly, it is common for the residues of MDO spills after weathering to contain n-alkanes, iso-alkanes and naphthenic hydrocarbons.

Spilled MDO can affect biological receptors via direct contact or through inhalation of vapours as the MDO as it disperses. Visual slicks or oil shoreline oil can have impacts on socio-economic and cultural receptors especially where there is commercial, recreational, and traditional fishing, coastal activities, and tourism.

The known and potential environmental risks of a MDO spill are:

- Change in water quality
- Change in sediment quality
- Change in ecosystem dynamics
- Change in physical condition
- Change in fauna behaviour
- Changes to the functions, interests, or activities of other users (e.g., commercial fisheries, shipping).
- Change in aesthetic value

4 Description of the Existing Environment that may be Affected by the Activity

As detailed in Section 2.2, the Environmental Planning Area has been adopted as the areal extent within which receptors could be exposed to oil from a MDO spill.

To identify key values and sensitivities that may be at risk from an accidental release of marine diesel oil within the Environmental Planning Area a PMST search was undertaken using the Environmental Planning Area, with the PMST Report available in Appendix B5: PMST Search Reports. A summary of the values and sensitivities protected under the EPBC Act relevant to a loss of containment is detailed in within this document. The summary also identifies any relevant conservation advice or recovery plans.

The identified Cultural Features values and sensitivities (refer to section 3.16, Appendix F3), were also reviewed to assess potential risks from an accidental release of fuel.

In addition, a review was undertaken of commercial fisheries that may fish within the Environmental Planning Area and is documented in the Commercial Fisheries Analysis Report (Appendix B6).

A description of the existing environment that may be affected by an accidental release of fuel is provided for each environmental component in Section 9.

PMST searches were run again prior to resubmission (Rev 2) to ensure any changes to species or listings were identified to control for passage of time. Conservation Advice has also been updated for several species and subsequent changes have been made to Annex 3. Changes relevant to the assessment of an accidental release of fuel include:

- Changes to EPBC Act status of several species
    - Red Knot is listed as Vulnerable (previously Endangered)
    - Sharp-tailed Sandpiper is listed as Vulnerable (previously not listed as threatened)
    - Sooty Shearwater is listed as Vulnerable (previously not listed as threatened)
    - Great Knot is listed as Vulnerable (previously Critically Endangered)
    - Western Alaskan Bar-tailed Godwit is listed as Endangered (previously Vulnerable)
    - Common Greenshank is listed as Endangered (previously not listed as threatened)
    - Ruddy Turnstone is listed as Vulnerable (previously not listed as threatened)
    - Latham's Snipe is listed as Vulnerable (previously not listed as threatened)
    - Terek Sandpiper is listed as Vulnerable (previously not listed as threatened)
    - Grey Plover is listed as Vulnerable (previously not listed as threatened)
    - Eastern Dwarf Galaxias is listed as Endangered (previously Vulnerable)
    - Yarra Pygmy Perch is listed as Endangered (previously Vulnerable)
    - Blue-winged Parrot is listed as Vulnerable (previously not listed as threatened)
- Updates to conservation advice for several species
    - Conservation Advice for *Calidris canutus* (Red Knot) (DCCEEW 2024)
    - Conservation Advice for *Calidris acuminata* (Sharp-tailed Sandpiper) (DCCEEW 2024a)
    - Conservation Advice for *Ardenna grisea* (Sooty Shearwater) (DCCEEW 2023i)
    - Conservation Advice for *Calidris tenuirostris* (Great Knot) (DCCEEW 2024f)
    - Conservation Advice for *Limosa lapponica baueri* (Bar-tailed Godwit western Alaskan) (DCCEEW 2024b)
    - Conservation Advice for *Tringa nebularia* (Common Greenshank) (DCCEEW 2024e
    - Conservation Advice for *Arenaria interpres* (Ruddy Turnstone) (DCCEEW 2024c)
    - Conservation Advice for *Gallinago hardwickii* (Latham's snipe) (DCCEEW 2024d)
    - Conservation Advice for *Xenus cinereus* (Terek Sandpiper) (DCCEEW 2024g)

  - Conservation Advice for *Pluvialis squatarola* (Grey Plover) (DCCEEW 2024h)
  - Conservation Advice for *Neophema chrysostoma* (Blue-winged Parrot) (DCCEEW 2023l)
  - Conservation Advice for *Calidris ferruginea* (Curlew Sandpiper) (DCCEEW 2023m)
  - Conservation Advice for *Numenius madagascariensis* (Far Eastern Curlew) (DCCEEW 2023n)
  - Conservation Advice for *Charadrius leschenaultii* (Greater Sand Plover) (DCCEEW 2023o)
  - Conservation Advice for *Galaxiella pusilla* (Dwarf Galaxias) (DCCEEW 2023j)
  - Conservation Advice for *Nannoperca obscura* (Yarra Pygmy Perch) (DCCEEW 2023k
- Removal of bird species, Broad-billed Sandpiper (species no longer appears in PMST).
- Removal of National Heritage place, 'Quarantine Station and Surrounds' (doesn't overlap with the Environmental Planning Area).

These changes have been incorporated throughout the EP and the risk assessment has been revised accordingly [Section added in response to Matters: I16 and I17].

All changes listed above remain relevant after the PMST searches were rerun prior to resubmission of Rev 3, with two exceptions:

- The National Heritage place 'Quarantine Station and Surrounds' which now overlaps with the Environmental Planning Area again.
- Southern Bluefin Tuna (*Thunnus maccoyii*) also has been removed from the February 2025 PMST reports for all areas searched, as it is no longer listed as a threatened species under the EPBC Act (DCCEEW 2024k). This species remains to be discussed here for a number of reasons including the view that a precautionary approach remains appropriate to assess this species that was only recently delisted, the species known relevance to regional fisheries, and to accurately reflect the passage of time over which this EP has been constructed.

Additional changes from the most recent PMST searches relevant to the assessment of an accidental release of fuel include:

- Changes to Biologically Important Areas
  - Pygmy Blue Whale Distribution BIA has been removed (from all areas searched).
  - Distribution BIAs for White Shark have been removed (from all areas searched).
  - Breeding BIA added for Short-tailed Shearwater to three areas searched (Light EMBA, and Underwater Sound EMBAs for Birds and LF cetaceans).
  - Breeding BIA added for White-faced storm-petrel to the EPA.
- Additional Species detected
  - Grey Nurse Shark (*Carcharias taurus*) appears in searches for all areas as 'Species or species habitat may occur within area'.
- Additional Listed Threatened Ecological Community
  - King Island Scrub Complex overlaps the Environmental Planning Area.
- National Heritage place 'Budj Bim National Heritage Landscape – Tyrendarra Area' was present in one additional search area and now overlaps with the Environmental Planning Area.
- World Heritage Property – 'Budj Bim Cultural Landscape' was present in one additional search area and now overlaps with the Environmental Planning Area.

These changes have been incorporated throughout the EP and the risk assessment has been revised accordingly.

5 Relevant Legislative and Other Requirements

CGG has considered all the relevant legislative requirements, that apply to the risk of accidental release of fuel (see Appendix B2). Measures that will be adopted to demonstrate how these requirements will be meet are as follows:

- CGG Marine Assurance System which ensures compliance of contract vessels with Navigation Act, MARPOL, COLREGS and Marine Orders.
- Oil Spill Response Plans where the NOPSEMA Accepted OPEP details the role of the vessel operator, CGG and AMSA in the event of an oil spill.
- Consultation Management System which details notification requirements to the AHO and AMSA and to relevant stakeholders as required.

6 Defining Acceptable Levels of Risk

Category	Defined Acceptable Level (General)	Defined Acceptable Level (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Prevent any accidental release of fuel to the marine environment. Have comprehensive emergency response plans, aligned with the National Plan for Maritime Environmental Emergencies, in place to mitigate consequences. Have an Operational and Scientific Monitoring Plan in place to monitor the effects of a release of fuel to the marine environment.	No accidental release of fuel to the marine environment. Maintain arrangements to respond to an unplanned release of fuel in accordance with the OPEP. Maintain arrangements to monitor the effects of a release of fuel to the marine environment in accordance with the OSMP.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the

Category	Defined Acceptable Level (General)	Defined Acceptable Level (Aspect Specific)	Rationale
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Predicted levels of impact for species that have social, cultural and economic values will be assessed on a receptor level.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	
	The views of public have been considered in the impact and risk assessment.		
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in

Annex 2.

8 Minimisation of Risks Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of risk could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of accidental release of fuel, elimination involves removing or reducing the factors that could lead to this risk occurring. One main option was considered and subsequently adopted:

Bunkering operations will not occur within 50 km of a Commonwealth or State marine park

Even though spills from collisions and bunkering are extremely unlikely this measure adds a precautionary measure because diesel releases are not expected to travel more than 50 km from the source of the release given the prevailing conditions in the region.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the risk. No substitution-based activity limitations were required in this case, as other measures applied were sufficient to reduce the identified risk to an acceptable level.

9 Predicted Levels of Risk

Based upon an understanding of the cause/effect pathway, an accidental release of fuel releases 250 m^3 of MDO is used to predict the level of risk to receptors as this is the largest loss of containment scenario.

Table D4-2 provides the criteria used to determine the sensitivity of receptors within the Environmental Planning Area with the following tables assessing each receptor identified within the Environmental Planning Area having regard to the legislative and other requirement.

Table D4-2 - Receptor Sensitivity Criteria.

Sensitivity	Protected Areas	Species Status	BIA	Coastal Habitat Sensitivity	Relevant Receptors
Low	State - no marine protected areas. Commonwealth - multiple use zones are the dominant component of the protected area.	Species not threatened (or limited to only a few species of a particular faunal grouping). Present in the Environmental Planning Area only occasionally or as vagrants. Populations known to recover rapidly from disturbance.	No BIA (or limited to only a few species of a particular faunal grouping).	Low sensitivity habitat, such as fine-grained beaches, exposed wave-cut platform and exposed rocky shores, with rapid recovery from oiling (~ 1 year or less). Public recreation beaches not present or not widely used. No harbours or marinas.	Sediment quality Plankton Invertebrates Fish Marine protected areas
Medium	State – no marine protected area. Commonwealth -little to no special purpose zonation.	Species may be threatened (or some species of a particular faunal grouping). Species may or may not be present at time of activity. Some susceptibility to oiling. Populations may take a moderate time to recover from oiling.	Some intersection with one or more BIAs, generally for distribution or migration rather than breeding.	Moderately sensitive habitat present, such as sheltered rocky rubble coasts, exposed tidal flats, gravel beaches, mixed sand and gravel beaches, with a medium recovery period from oiling (~2-5 years). Public recreation beaches present but not often used. No harbours or marinas	Water quality Benthic assemblages Coastal habitats and communities Seabirds Marine reptiles Marine mammals Commercial fisheries and aquaculture Marine industries Marine protected areas
High	State - marine protected area present. Commonwealth -special purposes zones are the dominant component of the protected area.	Species are threatened (or most species of a particular faunal grouping). Species known to be present at time of activity. Known to be susceptible to oiling. Populations may take a long time to recover from oiling.	Significant intersection with one or more BIAs, particularly with regard to foraging or breeding.	Sensitive habitat present, such as mangrove, salt marshes, and sheltered tidal flats, with long recovery periods from oiling (> 5 years). Public recreation beaches present that are widely used. Busy harbours or marinas.	Coastal developments Aquatic birds Shorebirds Diving Indigenous culture Marine Tourism Marine protected areas Recreational fishing

9.1 Change in Water Quality

9.1.1 Water Quality

Water Quality	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
Water quality within the Environmental Planning Area is expected to be typical of offshore waters of southern Australia. Water sampling undertaken for the Beach Otway Development area within the Environmental Planning Area (Ramboll 2020) detailed that the water quality at survey areas indicated an undisturbed mid-depth environment.	
Predicted Level of Risk	
The Environmental Planning Area is based on the following thresholds where water quality could be potentially at risk: The low threshold to assess the potential for floating oil exposure of 1 g/m^2 equates to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (AMSA 2014). This threshold is used to establish the planning area for scientific monitoring. The low threshold of 10 ppb to assess the potential for dissolved and entrained oil exposure represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. This threshold is used to establish the planning area for scientific monitoring. A summary of the mass balance of a MDO spill within the Environmental Planning Area (RPS 2022) showed: Under a constant 5 knot (~2.5 m/s) wind, 40.3% of the oil is predicted to evaporate within 24 hours. Under calm conditions, most of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation shall cease when the residual compounds remain, and they will be subject to more gradual decay through biological and photochemical processes. Under a variable-wind where the winds are of greater strength on average, entrainment of MDO into the water column is predicted to increase. Approximately 24 hours after the spill, 60.1% of the oil mass is forecast to have entrained and a further 38.4% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<0.1%). The increased level of entrainment in the variable-wind case result in a higher percentage decaying at an approximate rate of 1.5% per day with or ~10.5% after 7 days, compared to <0.1% per day and a total of 0.9% after 7 days for the constant-wind case. Given the proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks. Based on the weathering properties of MDO water quality within the Environmental Planning Area, 40% of a 250 m^3 MDO spill will evaporate within 24 hours with the remaining oil to becoming entrained in the water column where it will decay below threshold levels within 30 days.	

Water Quality
Thus, the predicted level of consequence to water quality from a 250 m^3 MDO spill is assessed as minor as any consequences will be short-term (< 30 days for oil to decay below low thresholds) within a localised area with full recovery, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.

9.2 Change in Sediment Quality

9.2.1 Sediment Quality

Sediment Quality	
Sensitivity Rating	**Low**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
Sediment quality within the Environmental Planning Area is expected to be typical of coastal and nearshore area of southern Australia. Water sampling undertaken for the Beach Otway Development area within the Environmental Planning Area (Ramboll 2020) detailed that the sediment quality at survey areas had a high oxidation reduction potential and low or undetectable levels of toxicants indicating an unmodified seabed environment.	
Predicted Level of Risk	
In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m2 shoreline accumulation threshold has been selected to define the zone of potential "low shoreline accumulation". As detailed in the assessment of water quality, the majority of surface oil will have evaporated or entrained in the water column within ~ 24 hours, thus only a small proportion is likely to move to shoreline areas above the low threshold. Furthermore, wave action in shoreline areas will further breakdown the remaining oil. Thus, the predicted level of consequence to sediment quality from a 250 m^3 MDO spill is assessed as minor as consequences will be short-term (< 30 days) within a localised area with full recovery, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.	

9.3 Change in Fauna Behaviour and Physical Condition

9.3.1 Plankton

Plankton	
Sensitivity Rating	**Low**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	

Plankton is a key component in oceanic food chains and support nearly all marine life. Plankton is divided into two groups, namely phytoplankton (microscopic plants) and zooplankton (microscopic animals). Plankton is the dominant biomass of marine ecosystems (CSIRO 2015).

Copepods are the most common zooplankton and are some of the most abundant animals on earth. Plankton communities are highly diverse, with members from almost all phyla. Phytoplankton are photosynthetic organisms that drift with ocean currents and are mostly microscopic; however, some gelatinous plankton can be up to 2 m in diameter. Phytoplankton is grazed by zooplankton such as small protozoa, copepods, decapods, krill and gelatinous zooplankton.

The carrying capacity of marine ecosystems (the mass of fish resources) and recruitment of individual stocks is strongly related to plankton abundance, timing and composition. In the Environmental Planning Area, the seasonal Bonney coast upwelling is a productivity hotspot, with high densities of zooplankton and are important for fish and whales, including culturally significant species (see Appendix F3, section 3.16.1). The primary ecological importance of the Bonney coast upwelling is as a feeding area for the Pygmy Blue Whale (PBW) (*Balaenoptera musculus brevicauda*). The upwelled nutrient-rich water promotes blooms of coastal krill (*Nyctiphanes australis*), which in turn attracts PBW to the region to feed. The upwelling is one of only three identified feeding areas consistently used by PBW in Australian coastal waters (Butler et al. 2002). The upwelling occurs when strong south-easterly surface winds induce warm, nutrient-deficient surface waters away from the coastline. This leads to surface upwellings bringing cool, nutrient-rich deep waters closer to the surface where there is enough sunlight for primary production among planktonic organisms to take place (Hosack and Dambacher 2012).

Plankton distribution from the upwelling area is dependent upon prevailing ocean currents including the Leeuwin Current, East Australia Current, flows into and from Bass Strait and Southern Ocean water masses. Populations are thought to be highly variable both spatially and temporally and are likely to comprise characteristics of tropical, southern Australian, central Bass Strait and Tasman Sea populations.

A detailed analysis of satellite-derived ocean data (chlorophyll a levels) for the periods 1998-2000 and 2005- 2014 suggests that the western Tasmanian shelf also accommodates a productive ecosystem. Based upon the Kampf (2015) study, this region forms part of the Great South Australian Coastal Upwelling System and experiences two phytoplankton blooms per annum:

The first and larger bloom – occurs in the late austral summer months (typically February-April) resulting from favourable winds that occur between December-April. Stronger upwelling winds do not always create phytoplankton blooms.

The second smaller bloom – occurs in spring (October) coincident with the onset of spring bloom in the western Tasman Sea. The mechanism for this smaller bloom remains unclear.

Plankton
Kampf (2015) identifies that the accuracy of satellite data cannot be used to identify upwelling jets however would suggest the existence of upwelling jets on the western Tasmanian shelf. The significance of these jets is that they operate to disperse nutrient-rich water northwards along the shelf and possibly into western Bass Strait. This advective process would explain elevated chlorophyll a level in western Bass Strait – a typical feature of the region during austral summer months. The western Tasmanian upwelling system lies to the west of the Tasmanian mainland and at least 130 km southeast of the acquisition area.
Predicted Level of Risk
Plankton are likely to be exposed to oil within the upper 10 m of the water column in areas close to the spill source where oil concentrations are the highest. Phytoplankton is typically not sensitive to the impacts of oil, though they do accumulate it rapidly due to their small size and high surface area to volume ratio (Hook et al. 2016). If phytoplankton is exposed to hydrocarbons at the sea surface, this may directly affect their ability to photosynthesize via smothering and would have implications for the next trophic level in the food chain (e.g., small fish) (Hook et al. 2016). In addition, the presence of surface hydrocarbons may result in a reduction of light penetrating the water column, which may affect the rate of photosynthesis, particularly in instances where there is prolonged presence of surface hydrocarbons over an extensive area such that the phytoplankton was restricted from light exposure, in turn affecting the rate of photosynthesis and inhibiting growth, depending on the concentration range. For example, photosynthesis is stimulated by low concentrations of oil in the water column (10-30 ppb) but become progressively inhibited above 50 ppb. Conversely, photosynthesis can be stimulated below 100 ppb for exposure to weathered oil (Volkman et al. 2004). Zooplankton (microscopic animals such as rotifers, copepods and krill that feed on phytoplankton) are vulnerable to hydrocarbons due to their small size and high surface area to volume ratio, along with (in many cases) their high lipid content (that facilitates hydrocarbon uptake and bioaccumulation) (Hook et al. 2016). Water column organisms that come into contact with oil risk exposure through ingestion, inhalation, and dermal contact (NRDA 2012), which can cause immediate mortality or declines in egg production and hatching rates along with a decline in swimming speeds (Hook et al. 2016). Plankton is generally abundant in the upper layers of the water column and acts as the basis for the marine food web, meaning that a MDO spill in any one location is unlikely to have long-lasting impacts on plankton populations at a regional level. Variations in the temporal scale of oceanographic processes typical of the ecosystem have a greater influence on plankton communities than the direct effect of spilt hydrocarbons. This is because reproduction by survivors or migration from unaffected areas would be likely to rapidly replenish any losses from permanent zooplankton (Volkman et al. 2004). Field observations from oil spills show minimal or transient effects on marine plankton (Volkman et al. 2004). Once background water quality conditions have re-established, the plankton community will take weeks to months to recover (ITOPF 2011), allowing for seasonal influences on the assemblage characteristics. Thus, the predicted level of consequence to plankton from a 250 m^3 MDO spill is assessed as minor as consequences will be short-term (days to weeks to months), recoverable and affect a small portion of the plankton population that is widely representative of the region and would be unlikely to impede associated food chains within the region, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.

9.3.2 Invertebrates

Invertebrates	
Sensitivity Rating	**Low**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
Studies by the Museum of Victoria found that invertebrate diversity was high in southern Australian waters although the distribution of species was patchy, with little evidence of any distinct biogeographic regions (Wilson and Poore 1987). Results of sampling in shallower inshore sediments reported high diversity and patchy distribution (Parry et al. 1990). In these areas, crustaceans, polychaetes, and molluscs were dominant. Throughout the region, a variety of seabed habits support a range of animal communities such as sparse sponges to extensive 'thickets" of lace corals and sponges, polychaete worms and filter feeders (DNP 2013). Echinoderms, such as sea stars, sea urchins and sea cucumbers are also an important fauna species of the southern Australian and Tasmanian waters, with several species at risk of extinction (DPIPWE 2020). Rock lobster, giant grab, scallops, abalone, and octopus are fished by commercial and recreational fishers in the Environmental Planning Area. Risks to these fisheries are assessed in the section on commercial fishing. Several invertebrate species including torbos, pipis, abalone, limpets, mussels, elephant snails, crayfish/lobster, crabs and squid are identified as culturally significant to the Gunditjmara People as both a resource and in harvesting as a cultural practice (GMTOAC, 2023). Barnabeel (oyster), murrabal (mussel), bam bam (crayfish), abalone and pipi are also culturally important resources to the Wadawurrung People (WTOAC, 2020). Invertebrate species are an important traditional, social and economic resource for the Eastern Maar People. Abalone, cockles and crayfish are collected as tucker along the coast (EMAC, 2015) (Appendix F3, Section 3.16.1).	
Predicted Level of Risk	
The primary modes of exposure for benthic invertebrate communities for a surface oil spill are: Direct exposure to oil within the water column to a depth of 10 m (RPS 2019a). Direct exposure to oil on shoreline or within sediment within 10 m water depth. Indirect exposure to oil through the food web via uptake of oiled plankton, detritus, prey, etc. (NRDA 2012). Acute or chronic exposure, through surface contact, and/or ingestion can result in toxicological risks. Entrained and dissolved hydrocarbons can have negative impacts on marine invertebrates and associated larval forms. Impacts to some adult species (e.g. crustaceans) is reduced as a result of the presence of an exoskeleton, while other invertebrates with no exoskeleton and larval forms may be more prone to impacts from pelagic hydrocarbons.	

Invertebrates
Localised impacts to larval stages may occur which could impact on population recruitment. If invertebrates are contaminated by hydrocarbons, tissue taint can remain for several months, although taint may eventually be lost. For example, it has been demonstrated that it took 2-5 months for lobsters to lose their taint when exposed to a light hydrocarbon (NOAA 2002) (see Commercial Fisheries' assessment). Exposure to microscopic oil droplets may also impact aquatic biota either mechanically (especially filter feeders) or act as a conduit for exposure to semi-soluble hydrocarbons (that might be taken up by the gills or digestive tract) (McCay-French 2009). Toxicity is primarily attributed to water soluble PAHs, specifically the substituted naphthalene (C2 and C3) as the higher C-ring compounds become insoluble and are not bioavailable. ANZECC/ARMCANZ (2000) identifies the following 96-hr LC50 concentrations for naphthalene (a key PAH dissolved phase toxicant in crude oils): For the bivalve mollusc, *Katelysia opima*, a concentration of 57,000 ppb For six species of marine crustaceans, a concentration between 850 and 5,700 ppb. Other possible impacts from the presence of dispersed and non-dispersed oil include effects of oxygen depletion in bottom waters due to bacterial metabolism of oil (and/or dispersants), and light deprivation under surface oil (NRDA 2012). Water quality in benthic habitats exposed to entrained hydrocarbons would be expected to return to background conditions within < 30 day. Several studies have indicated that rapid recovery rates may occur even in cases of heavy oiling (Committee on Oil in the Sea 2003). Due to the low concentrations and physical properties of the MDO, and the exposed nature of shoreline and well- mixed nature of the waters in the Environmental Planning Area coating of invertebrates and prolonged exposure to hydrocarbons is considered highly unlikely. Thus, the predicted level of consequence to invertebrates from a 250 m^3 MDO spill is assessed as minor as consequences will be short-term (days to weeks), recoverable and affect a small portion of the invertebrate population would be unlikely to impede associated food chains within the region the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.

9.3.3 Fish

Fish	
Sensitivity Rating	**Low**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
The PMST Report (Appendix B5) identified multiple fish species or species habitat within the Environmental Planning Area as detailed in Annex 3 of this document. None of these fish species were identified to be undertaking biologically important behaviours or have BIAs or habitat critical to the survival of the fish species. The Dwarf Galaxias is a freshwater species (Saddler et al. 2010) and the Yarra Pygmy Perch occurs in lakes, ponds, and slow flowing rivers (Sadler and Hammer 2010) which are outside the Environmental Planning Area. The Australian Grayling is a small to medium-sized, slender, silvery fish with soft-rayed fins lacking any spines. It is endemic to south-eastern Australia, including Victoria, Tasmania, and New South Wales, and is a migratory species that inhabits estuarine waters and coastal seas as larvae/juveniles, and freshwater rivers and streams as adults (Backhouse et al. 2008). The Blue Warehou is a medium-sized, deep-bodied fish, reaching a maximum total length of 90 cm and a maximum weight of 7 kg (TSSC 2015). Globally, the Blue Warehou is confined to Australian and New Zealand waters predominantly in coastal shelf, upper continental slope, and seamount waters offshore from New South Wales, Tasmania, Victoria and South Australia (TSSC 2015). Blue Warehou is a target species for the Tasmania Scalefish Fishery. The eastern population of Gemfish (Eastern Gemfish) is taken as bycatch in commercial fisheries. The largest proportion of catch of the species is taken in the South East Trawl sector of the Commonwealth Southern and Eastern Scalefish and Shark Fishery (SESSF), where it is caught primarily in deepwater trawl nets that are targeting multiple species that are found on the continental shelf. Eastern Gemfish are mesopelagic and inhabit deeper continental shelf habitats and upper slope waters from 100 m to 700 m (down to 1254 m) but are generally found in waters about 250 to 500 m deep (TSSC 2009). The Orange Roughy is a demersal fish targeted by the Southern and Eastern Scalefish and Shark Fishery. They are widely distributed throughout the world and forms dense spawning and feeding aggregations on or near topographic features such as seamounts, canyons, and plateaus (DCCEEW 2023). No spawning or feeding aggregation areas have been identified in the Environmental Planning Area. Southern Bluefin Tuna can grow to 225 cm in length and 200 kg in weight (TSSC 2010). They are a highly migratory species that occurs globally in waters between 30°S and 50°S forming on single global population (TSSC 2010). In Australian waters, they range from northern Western Australia, around the southern region of the continent, to northern New South Wales (TSSC 2010). Southern Bluefin Tuna are a target species for the Southern Bluefin Tuna Fishery. Most of the listed marine ray-finned fish species identified in the PMST Report for the Environmental Planning Area are syngnathids, which includes seahorses and their relatives (sea dragon, pipehorse and pipefish). The majority of these species are associated with seagrass meadows, macroalgal seabed habitats, rocky reefs and sponge gardens located in shallow, inshore waters (e.g., protected coastal bays, harbours and jetties) less than 50 m deep (Fishes of Australia 2015). They are sometimes recorded in deeper offshore waters, where they depend on the protection of sponges and rafts of floating seaweed such as sargassum. The PMST Report (Appendix B5) identified six shark species with the White Shark having foraging or feeding related behaviour and a foraging BIA as detailed in Annex 3 of this document.	

Fish
The east coast population of the Grey Nurse Shark covers a range of approximately 2700 km and extends from the Capricornia coast (central Queensland) to Narooma in southern New South Wales. Sightings data from the New South Wales Department of Primary Industries (NSW DPI) includes sightings as far south as the NSW/Victoria border (CoA 2014). Grey Nurse Sharks tend to live in shallow inshore waters, with their preferred habitats have sandy-bottomed gutters or rocky caves and are close to inshore rocky reefs or islands (DCCEEW 2021). Gulpener Sharks are targeted by the Southern and Eastern Scalefish and Shark Fishery. There are endemic to Australia in habitats on the upper-slope and are mainly demersal (bottom dwelling) between 180 m to 900 m (Williams et al. 2012) of the southern continental shelf. The Porbeagle occurs in waters from southern Queensland to south-west Australia (Last & Stevens 2009). Animals typically occur in oceanic waters off the continental shelf, although they occasionally enter coastal waters (Francis et al. 2002). The Porbeagle is known to undertake seasonal migrations, although the timing and details of these migratory movements are not well-understood (Saunders et al. 2011). Individuals have been tracked moving large distances (i.e. 1500-1800 km along continental shelves and crossing the Atlantic Ocean between Europe and North America) (Francis et al. 2002). School Shark appears to have undergone a significant reduction in numbers as the result of commercial fishing in south eastern Australian waters (TSSC 2009a). School Shark is primarily a deep water demersal (bottom-dwelling) species, although individuals have been recorded undertaking daily vertical migrations, remaining at depths of around 500 m during the day and moving up to around 100 m at night (McLoughlin, 2007). Females and juveniles utilise inshore coastal areas around Victoria, Tasmania and parts of South Australia for nursery areas (Pogonoski et al., 2002). The Shortfin Mako is a large pelagic shark with a circum-global distribution inhabiting tropical and temperate waters. It is rarely encountered in waters with temperatures below 16°C (Last and Stevens 2009). In Australian waters, the shortfin mako has been recorded in offshore waters all around the continent's coastline except for the Arafura Sea, Gulf of Carpentaria, and Torres Strait. The species primarily occurs in offshore, oceanic waters and is pelagic (has no habitat associations with the seafloor) (Last and Stevens 2009). The White Shark is listed as Vulnerable. White Sharks are long-lived, living for 30 years or more (Bruce 2008), and are found throughout temperate and sub-tropical regions in the northern and southern hemispheres (Last & Stephens 2009). The species is also commonly found in inshore waters in the vicinity of islands, and often near seal colonies (Malcolm et al. 2001). The foraging BIA that is within the Environmental Planning Area is centred on Lady Julia Percy Island which is a known seal breeding colony (Appendix B12 MAP-REG-EPM-027). The Environmental Planning Area also overlaps the distribution BIA that covers Australian waters from Barrow Island/Montebello Islands, WA to Yeppoon/Swains Reef, Qld. In addition to protected fish species, commercial fish and shark species such as mackerel, salmon, sardines, snapper, sawsharks, whiting and wrasse are likely to be present in the Environmental Planning Area. Short finned eels, known as Kooyang, are an important Indigenous cultural value, and may migrate through the Environmental Planning Area (GMTOAC, 2023; WTOAC, 2020; EMAC, 2015). The Environmental Planning Area does not overlap any freshwater or estuaries where eels spend most of their life cycle (VFA 2022) or where Indigenous eel traps are present. Perch, and Blackfish species also hold Indigenous cultural value in traditional, social and economic practices (GMTOAC, 2023; WTOAC, 2020; EMAC, 2015). Blackfish are an inland river fish (VFA 2024b) and therefore outside of the Operational and Planning Areas (Appendix F3, Section 3.16.1).
Predicted Level of Risk
Fish are exposed to in-water hydrocarbon (entrained and dissolved) through a variety of pathways, including: Direct dermal contact such as swimming through oil or waters with elevated dissolved hydrocarbon concentrations and other constituents, with diffusion across their gills (Hook et al. 2016).

Fish
Ingestion either directly or via food base, fish that have recently ingested contaminated prey may themselves be a source of contamination for their predators.
Inhalation where elevated dissolved contaminant concentrations in water pass over the gills.
Exposure to hydrocarbons entrained or dissolved in the water column can be toxic to fish. Studies have shown a range of impacts including changes in abundance, decreased size, inhibited swimming ability, changes to oxygen consumption and respiration, changes to reproduction, immune system responses, DNA damage, visible skin and organ lesions, and increased parasitism. However, many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation of contaminants in the food web and human exposure to contaminants through the consumption of seafood (NRDA 2012).
Sub-lethal impacts in adult fish include altered heart and respiratory rates, gill hyperplasia, enlarged liver, reduced growth, fin erosion, impaired endocrine systems, behavioural modifications and alterations in feeding, migration, reproduction, swimming, schooling, and burrowing behaviour (Kennish 1996). However, fish are highly mobile and unlikely to remain in the area of a spill for long enough to be exposed to sub-lethal doses of hydrocarbons.
The toxicity of dissolved hydrocarbons and dispersed oil to fish species has been the subject of a number of laboratory studies (AMSA 1998). Generally, concentrations in the range of 0.1–0.4 mg/L dispersed oil have been shown to cause fish deaths in laboratory experiments (96-hour LC50). No reported studies of the impacts of oil spills on cartilaginous fish (including sharks, rays and sawfish) were found in the literature.
The assessment of effects on fish species in the Timor Sea as a result of the Montara well blowout (a light gas condensate), conducted from November 2009 to November 2010 undertaken by Gagnon & Rawson (2011), found that of the species studied (mostly Goldband Snapper Pristipomoides multidens, Red Emperor Lutjanus sebae, Rainbow Runner Elegatis bipinnulata and Spanish Mackerel Scomberomorus commerson), all 781 specimens were in good physical health at all sites. Results show that:
Phase 1 study (November 2009, immediately after the blowout ceased) - indicated that in the short-term, fish were exposed to and metabolised petroleum hydrocarbons, however no consistent adverse effects on fish health or their reproductive activity were detected.
Phase 2 study (March 2010, 5 months after the blowout ceased) – indicated continuing exposure to petroleum hydrocarbons, as detected by elevated liver detoxification enzymes and PAH biliary metabolites in three out of four species collected close to the spill site, and elevated oxidative DNA damage.
Phase 3 study (November 2010, 12 months after the blowout ceased) – showed a trend towards a return to reference levels with often, but not always, comparable biomarker levels in fish collected from reference and impacted sites. This evidence of exposure to petroleum hydrocarbons at sites close to the spill location suggest an ongoing trend toward a return to normal biochemistry/physiology (Gagnon & Rawson 2011).
The main finding of the Gagnon & Rawson (2011) study concluded that there were no detectable petroleum hydrocarbons found in the fish muscle samples, limited ill effects were detected in a small number of individual fish, and no consistent adverse effects of exposure on fish health could be detected within two weeks following the end of the well release. Notwithstanding, fishes from close to the Montara well, collected seven months after the discharge began, showed continuing exposure to hydrocarbons in terms of biomarker responses. Two years after the discharge, biomarker levels in fishes had mostly returned to reference levels, except for liver size. However, this was potentially attributed to local nutrient enrichment, or to past exposure to hydrocarbons. Fishes near Heyward Shoal, approximately 100 km southwest of the Montara well, had elevated biomarker responses indicating exposure to hydrocarbons, but were collected close to the Cornea natural hydrocarbon seep. Studies on the Montara discharge have shown recovery in terms of the abundance and composition of fishes, and toxicological and physiological responses of fishes.
No reports of oil spills in open waters have been reported to cause fish kills (though mortality in aquaculture pens has), which is likely to be because vertebrates can rapidly metabolise and excrete hydrocarbons (Hook et al. 2016).
Recovery of fish assemblages depends on the intensity and duration of an unplanned discharge, the composition of the discharge and whether dispersants are used, as each of these factors influences the level of exposure to potential toxicants. Recovery would also depend on the life cycle attributes of fishes. Species that are abundant,

Fish
short-lived and highly fecund may recover rapidly. However less abundant, long-lived species may take longer to recover. The range of movement of fishes will also influence recovery. The nature of the receiving environment would influence the level of impact on fishes. None of the conservation advices or recovery plans for fish or sharks identify oil spill as a threat. The syngnathid species are most likely to be present in the top 10 m of the water column where oil may be present. The other fish and shark species are either demersal species (bottom dwelling) or pelagic species which swim large distances and hence these species are unlikely to be affected by oil from a diesel spill. Impacts to syngnathid species are more likely close to the spill location which oil concentrations would be highest, however as there are no reef or seagrass areas in the Operational Areas it is unlikely, they would be present in significant numbers. Thus, the predicted level of consequence to fish from a 250 m^3 MDO spill is assessed as minor as consequences will be short-term (days to weeks), recoverable and affect a small portion of the fish population would be unlikely to impede associated food chains within the region, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.

9.3.4 Birds

Birds	
Sensitivity Rating	**Medium– seabirds**
	High - aquatic birds, shorebirds
Predicted Level of Risk	**Low – seabirds, aquatic birds**
	Medium - shorebirds
Environmental Planning Area Existing Environment	
The PMST Report (Appendix B5) identified multiple bird species or species habitat within the Environmental Planning Area as detailed in Annex 3 of this document. Several of these bird species were identified to be undertaking biologically important behaviours and/or have BIAs within the Environmental Planning Area. No habitat critical to the survival of the bird species were identified within the Environmental Planning Area. The orange-bellied parrot, which is critically endangered is known to migrate through the Environmental Planning Area, however, it does not land at sea or use coastal areas as habitat so impacts to this species are not predicted. A number of albatross and two petrel species were identified as foraging behaviour known or likely within the Environmental Planning Area as detailed in Annex 3 of this document. Of these the following have foraging BIAs: Antipodean Albatross (Appendix B12 MAP-REG-EPM-059) Black-browed Albatross (Appendix B12 MAP-REG-EPM-060 Buller's Albatross (Appendix B12 MAP-REG-EPM-071) Campbell Albatross (Appendix B12 MAP-REG-EPM-061) Indian Yellow-nosed Albatross (Appendix B12 MAP-REG-EPM-063) Shy Albatross (Appendix B12 MAP-REG-EPM-066) Wandering Albatross (Appendix B12 MAP-REG-EPM-072) Common Diving Petrel (Appendix B12 MAP-REG-EPM-062) White-face Storm Petrel (Appendix B12 MAP-REG-EPM-075 These BIAs cover either most or all the South-east Marine Region (CoA 2015a). In addition, the Common Diving Petrel has a breeding BIA on Lady Julia Percy Island which is within the Environmental Planning Area (Appendix B12 MAP-REG-EPM-062). A breeding BIA was also identified for the White-faced Storm Petrel within the Environmental Planning Area.	

Birds
Albatrosses and petrels are among the most oceanic of all seabirds, and seldom come to land unless breeding (CoA 2022). Albatross and petrel species exhibit a broad range of diets and foraging behaviours, and hence at-sea distributions are diverse. Combined with their ability to cover vast oceanic distances, all waters within Australian jurisdiction can be considered foraging habitat, however the most critical foraging habitat is those waters south of 25° where many species spend the majority of their foraging time (CoA 2022). Albatrosses have a widespread distribution throughout the southern hemisphere. They feed mainly on cephalopods, fish, and crustaceans, using surface feeding or plunge diving to seize their prey (ACAP 2020). Albatrosses are colonial, usually nesting on isolated islands and foraging across oceans in the winter months with most observations along the edge of the continental shelf (CoA 2022). Petrels are oceanic and have a widespread distribution throughout the southern hemisphere. They are colonial and breed on sub-Antarctic and Antarctic islands in a circumpolar band generally between 40°S and 60°S. Petrel species feed on small fish, cephalopods (octopus, squid, and cuttlefish) and crustaceans along the edge of the continental shelf and open waters (CoA 2022). Within the Environmental Planning Area Little Penguin breeding and foraging BIAs occur at Black Pyramid, Christmas Island and Councillor Island in Tasmanian waters (Appendix B12 MAP-REG-EPM-064). A small breeding colony also occurs at Middle Island off Victoria. Breeding typically occurs from September to February, but some birds reside at the colony all year round. The Bass Strait supports approximately 60% of the known breeding population, with additional breeding BIAs outside of the Environmental Planning Area located at Albatross Island (Tasmania), Egg Island (Tasmania), Hunter Island (Tasmania), Phillip Island (Victoria), Sisters Island (Tasmania) and Three Hummock Island (Tasmania). The Little Tern and Short-tailed Shearwater (migratory marine birds) were identified as breeding known to occur in the Environmental Planning Area with a proportion of the Short-tailed Shearwater breeding and foraging BIAs overlapping the Environmental Planning Area (Appendix B12 MAP-REG-EPM-065). Birds are typically present between September to May. The Environmental Planning Area also overlaps breeding and foraging BIAs for the Wedge-tailed Shearwater (Appendix B12 MAP-REG-EPM-067) that covers an area 160 km from Mutton bird Island where birds may be present between August and May. Short-tailed shearwaters (mutton birds) are identified as being culturally significant to the Gunditjmara People and are used in harvesting practice (GMTOAC, 2023). Shearwaters are also identified as culturally significant species to the Eastern Maar people, along with gannets and Little Penguins (Appendix F3, Section 3.16.1). The Black-faced Cormorant has two foraging/breeding BIAs within the Environmental Planning Area, at Christmas Island and Councillor Island just off King Island (Appendix B12 MAP-REG-EPM-074). Breeding usually occurs on rocky islands, but also on stacks, slopes, and sea cliffs in colonies of up to 2,500 individuals (del Hoyo et al. 1992). It feeds in coastal waters, sometimes in sheltered places such as bays and islets and can be found entering rivers along the coast (CoA. 2020a). The Australasian Gannet was identified as having a foraging BIA within the Environmental Planning Area (Appendix B12 MAP-REG-EPM-073). The Australasian Gannet generally feeds over the continental shelf or inshore waters. Their diet is comprised mainly of pelagic fish, but also squid and garfish. Prey is caught mainly by plunge-diving, but it is also seen regularly attending trawlers (CoA 2015a). Several shorebirds were identified from the PMST Report as being present in the Environmental Planning Area with the threatened species, Black-tailed Godwit, Great Knot, Grey Plover, Lesser Sand Plover, Sharp-tailed Sandpiper, Ruddy Turnstone and Terek Sandpiper identified as roosting in the area. No BIAs for shorebirds were identified. Other threatened shorebirds that are known to occur within the Environmental Planning Area are the Australian Painted Snipe, Blue-winged Parrot, Common Greenshank, Curlew Sandpiper, Eastern Curlew, Eastern Hooded Plover, Greater Sand Plover, Latham's Snipe, Red Knot and Western Alaskan Bar-tailed Godwit. These species are commonly found on coastal shores including beaches and rocky shores and either feed at low tide on worms, crustaceans and molluscs or fish species or feed on aquatic biota. Many of the wader species are migratory travelling from the Northern Hemisphere in non-breeding months. Most inhabit intertidal mudflats, rocky islets, sand beaches, mangroves, rocky coastline and coral reefs. Roosting occurs in similar habitats and species are found feeding on fish, crustaceans, aquatic insects, as well as plants and seeds (Higgins & Davies 1996).

Birds
Important coastal habitat where shorebirds are likely to be present within the Environmental Planning Area and have a marine interface are wetlands and shorelines. Impacts to these areas are assessed in the respective sections. The King Island Important Bird Area (IBA) is within the Environmental Planning Area. Birdlife International (2008) detail the following regarding the IBA. The IBA includes the entire coastline of King Island, which supports significant numbers of Hooded Plovers; Lavinia State Reserve, which supports the critically endangered Orange-bellied Parrot and endemic subspecies of bush birds; and three inshore islands which support large numbers of nesting seabirds. These islands are Christmas Island (a 63 ha Nature Reserve), New Year Island (a 98 ha Game Reserve, on which harvesting of shearwaters is allowed) and Councillor Island (11 ha of Crown Land). The coastline is a mixture of rocky outcrops and long sandy beaches with beach-washed kelp. The IBA is defined as the coastal strip extending from the low water mark to 1 km inland of the high-water mark around the entire island; this is intended to capture most significant habitat for shorebirds and Orange-bellied Parrots. Two other IBAs within the Environmental Planning Area are Lawrence Rocks Wildlife Reserve, which consists of two rocky islets off the coast from Portland with a resident Australasian Gannett population, and the Discovery Bay Coast through to Picaninnie Ponds in South Australia with resident populations of Australasian Bittern, Hooded Plover, Rufous Bristlebird and Striated Fieldwren, and non-breeding Orange-bellied Parrot (Parks Victoria 2015).
Predicted Level of Risk
Seabirds, shorebirds, and aquatic birds are sensitive to the impacts of oiling, with their vulnerability arising from the fact that they cross the air-water interface to feed, while their shoreline habitats may also be oiled (Hook et al. 2016). Species that raft together in large flocks on the sea surface are particularly at risk (ITOPF 2011). Toxic effects of hydrocarbons on birds may result where the oil is ingested as the bird attempts to preen its feathers, and the preening process may spread the oil over otherwise clean areas of the body (ITOPF 2011). Whether this toxicity ultimately results in mortality will depend on the amount of hydrocarbons consumed and other factors relating to the health and sensitivity of the bird. Birds that are coated in oil also suffer from damage to external tissues including skin and eyes, as well as internal tissue irritation in their lungs and stomachs. Breeding seabirds may be directly exposed to oil via a number of potential pathways. Any direct impact of oil on terrestrial habitats has the potential to contaminate birds present at the breeding sites (Clarke 2010). Bird eggs may also be damaged if an oiled adult sits on the nest. Fresh crude was shown to be more toxic than weathered crude, which had a medial lethal dose of 21.3 mg/egg (Clarke 2010). Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos. Engelhardt (1983), Clark (1984), Geraci & St Aubin (1988) and Jenssen (1994) indicated that the threshold thickness of oil that could impart a lethal dose to some intersecting wildlife individual is 10 µm (~10 g/m^2). Scholten et al (1996) indicates that a layer 25 µm thick would be harmful for most birds that contact the slick. *Seabirds* Birds foraging at sea have the potential to directly interact with oil on the sea surface some considerable distance from breeding sites in the course of normal foraging activities. Species most at risk include those that readily rest on the sea surface such as shearwaters and surface plunging species such as terns and boobies. As seabirds are top order predators, any impact on other marine life (e.g., pelagic fish) may disrupt and limit food supply both for the maintenance of adults and the provisioning of young. In the case of seabirds, direct contact with hydrocarbons is likely to foul plumage, which may result in hypothermia due to a reduction in the ability of the bird to thermo-regulate and impair waterproofing (ITOPF 2011). A bird suffering from cold, exhaustion and a loss of buoyancy resulting from fouling of plumage may dehydrate, drown, or starve (ITOPF 2011, DSEWPC 2011). It may also result in impaired navigation and flight performance (Hook et al. 2016). Increased heat loss as a result of a loss of water-proofing results in an increased metabolism of food reserves in the body, which is not countered by a corresponding increase in food intake and may lead to emaciation (DSEPWC 2011). The greatest vulnerability in this case occurs when birds are feeding or resting at the sea surface (Peakall et al. 1987). In a review of 45 marine hydrocarbon spills, there was no correlation between the numbers of bird deaths and the volume of the spill (Burger 1993). Most of the seabird species that are likely to occur in the Environmental Planning Area forage over an extensive area and are distributed over a wide geographic range. Seabirds plunge diving through the sea surface for prey are most likely to encounter the low concentration of hydrocarbons due to its broader extent than moderate and

Birds
high concentrations. Seabirds rafting, resting, diving or feeding at sea have the potential to come into contact with oil. However, the low threshold level of exposure is not expected to result in the lethal impacts or feather matting and hypothermia. However, contact at the high threshold is expected to impart toxicity and ecological impacts. Though, oil at high thresholds is only predicted within a small area around the spill location and for a short duration (days). The extensive ocean foraging habitat available to species such as albatrosses, petrels, shearwaters and terns and the small area and temporary nature of the hydrocarbon release on the sea surface (~ 24 hours) makes it unlikely that a spill will limit their ability to forage for unaffected prey, nor will the unlikely event of exposure at the sea surface result in permanent injury or mortality. The area where dissolved hydrocarbons would exceed the moderate threshold or entrained hydrocarbons exceed the high threshold during an MDO spill would be relatively small in comparison to the Bass Strait and Otway region where seabirds forage. It is these small areas where sub-lethal or toxic effects to birds may occur. There is a low probability that seabirds would be feeding exclusively or predominantly on fish found in areas of higher hydrocarbon thresholds, thus there is low probability of seabirds experiencing sub-lethal or toxic impacts as a result of consuming hydrocarbon-tainted fish. Seabird interactions with shorelines is expected to be largely during periods of rest and breeding activities. Most seabirds are oceanic and seldom come to land unless breeding in areas associated with burrows on sloping ground in coastal forest, scrubland, shrubland or grassland. As detailed in the assessment of coastal habitats and communities due to the exposed nature of the coastal areas within the Environmental Planning Area and the nature of MDO, long-term toxicity or smothering effects in areas of moderate or high MDO are not expected. The predicted level of consequence to seabirds from a 250 m^3 MDO spill is assessed as minor as consequences are unlikely to occur at thresholds levels where oiling of birds or tainting of food would occur, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low. *Shorebirds* Shorebirds are likely to be exposed to oil when it directly impacts their intertidal feeding habitat. Shorebird species foraging for invertebrates on exposed sand and mud flats at lower tides will be at potential risk of both direct impacts through contamination of individual birds (ingestion or soiling of feathers) and indirect impacts through the contamination of foraging areas that may result in a reduction in available prey items (Clarke 2010). Shorebird species (e.g., plovers, godwits, curlews, etc.) prefer varying habitats including tidal flats, open saltmarsh, freshwater wetlands, open grasslands and sandy beaches. These habitats on the Victorian coastline inshore of the Operational Area could be exposed to moderate or high threshold shoreline oil due that has not yet evaporated or entrained. Exposure to moderate or high threshold shoreline oil at King Island and the King Island IBA is less likely due to the distance from the Operational Area. Due to the proximity to the Victorian coastline, the predicted level of consequence to shorebirds from a 250 m^3 MDO spill is assessed as moderate as consequences could be longer lasting (> 30 days) if shorebirds are exposure to oil above low threshold, though if consequences occurred, they are likely to only affect a small portion of the shorebird population due to the low volume of oil that would come onshore, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium. *Aquatic birds* Penguins may be especially vulnerable to oil because they spend a high portion of their time in the water and readily lose insulation and buoyancy if their feathers are oiled (Hook et al. 2016). The Iron Baron vessel spill (325 tonnes of bunker fuel in Tasmania in 1995) is estimated to have resulted in the death of up to 20,000 penguins (Hook et al. 2016). As characteristic of aquatic birds, Little Penguins forage while swimming and often forage for extended periods of time (dawn to dusk) and may forage up to 50 km from the colony. As such Little Penguins are most at risk of direct contact, ingestion or inhalation while feeding at sea. Little Penguins are most likely to encounter the low concentration of hydrocarbons due to its broader extent than moderate and high concentrations. However, the low threshold level of exposure is not expected to result in

Birds
the lethal impacts of feather matting and hypothermia. The high threshold is expected to impart toxicity and ecological impacts. Given the offshore location of the spill volume, the small area of exposure and temporary nature of the hydrocarbon release on the sea surface (~ 24 hrs) it is unlikely that a spill would limit Little Penguins ability to forage for unaffected prey, nor will the unlikely event of exposure at the sea surface result in permanent injury or mortality. The area of exposure to dissolved hydrocarbons above the moderate threshold and entrained hydrocarbons above the high threshold during an MDO spill are relatively small in comparison to the Bass Strait and Otway region. It is these small areas where sub-lethal or toxic effects may occur. There is a low probability that Little Penguins would be feeding exclusively or predominantly on fish found in areas of higher hydrocarbon thresholds, thus there is low probability of Little Penguins experiencing sub-lethal or toxic impacts as a result of consuming hydrocarbon-tainted fish. The Little Penguin foraging/breeding BIAs on Black Pyramid Island off Tasmania and Christmas Island and Councillor Island off King Island are unlikely to be exposed to oil above the low threshold due to the distance from the Operational Area and low volume of MDO that could be spilt. The predicted level of consequence to aquatic birds (Little Penguins) from a 250 m^3 MDO spill is assessed as minor as consequences are unlikely to occur at thresholds levels where oiling of birds, next or tainting of food would occur, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low

9.3.5 Marine Reptiles

Marine Reptiles	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
The PMST Report (Appendix B5) identified three turtle species within the Environmental Planning Area, green, leatherback and loggerhead turtle. No BIAs or habitat critical to the survival of the species were identified. The PMST Report also identified foraging, feeding or related behaviour known to occur within area for the leatherback and loggerhead turtle as detailed in Annex 3 of this document. Green turtles' nest, forage and migrate across tropical northern Australia. Green turtles spend their first 5-10 years drifting on ocean currents. Green turtles are predominantly found in Australian waters off the Northern Territory, Queensland, and Western Australian coastlines, with limited numbers in NSW, Victoria, and South Australia (DoEE 2017). Small numbers of leatherback turtles' nest on the Cobourg Peninsula (NT) and there are unconfirmed accounts of leatherback turtles nesting in Western Australia. Leatherback turtles are more commonly found foraging in Australian waters along the east coast and in Bass Strait. The southern waters of Australia are one of five identified foraging sites (where area restricted behaviour occurs) for Leatherback turtles (DoEE 2017). There are two genetically distinct stocks of loggerhead turtles nesting in Australia, one in Queensland (known as the south-west Pacific stock) and one in Western Australia. Loggerhead turtles forage in all coastal states and the Northern Territory, but are uncommon in South Australia, Victoria, and Tasmania (DoEE 2017).	
Predicted Level of Risk	
The Recovery Plan for Marine Turtles (DoEE 2017) identifies oil spill as a threat detailing that there is well documented evidence of the detrimental effects from encountering oil either via external contact, ingestion, or inhalation, resulting in breathing, sight or gastro-intestinal injuries. Sea turtles are vulnerable to the effects of oil at all life stages—eggs, post-hatchlings, juveniles, and adults in nearshore waters. Several aspects of sea turtle biology and behaviour place them at particular risk, including a lack of avoidance behaviour, indiscriminate feeding in convergence zones, and large pre-dive inhalations. Effects of oil on turtles include increased egg mortality and developmental defects, direct mortality due to oiling in hatchlings, juveniles and adults, and negative impacts to the skin, blood, digestive and immune systems and salt glands. Oil exposure affects different turtle life stages in different ways. Thus, information on oil toxicity needs to be organised by life stage. Turtles may be exposed to chemicals in oil in two ways: Internally – eating or swallowing oil, consuming prey containing oil-based chemicals, or inhaling of volatile oil related compounds; and Externally – swimming in oil or dispersants, or oil or dispersants on skin and body. Records of oiled wildlife during spills rarely include marine turtles, even from areas where they are known to be relatively abundant (Short 2011). An exception to this was the large number of marine turtles collected (613 dead and 536 live) during the Macondo spill in the Gulf of Mexico, although many of these animals did not show any sign of oil exposure (NOAA 2013). Of the dead turtles found, 3.4% were visibly oiled and 85% of the live turtles found were oiled (NOAA 2013). Of the captured animals, 88% of the live turtles were later released, suggesting that oiling does not inevitably lead to mortality.	

Marine Reptiles
There is potential for contamination of turtle eggs to result in similar toxic impacts to developing embryos as has been observed in birds. Studies on freshwater snapping turtles showed uptake of PAHs from contaminated nest sediments, but no impacts on hatching success or juvenile health following exposure of eggs to dispersed weathered light crude (Rowe et al. 2009). However, other studies found evidence that exposure of freshwater turtle embryos to PAHs results in deformities (Bell et al. 2006, Van Meter et al. 2006). Turtles may experience oiling impacts on nesting beaches and eggs through chemical exposure, resulting in decreased survival to hatching and developmental defects in hatchlings. Turtle hatchlings may be more vulnerable to smothering as they emerge from the nests and make their way over the intertidal area to the open water (AMSA 1998). Hatchlings that contact oil residues while crossing a beach can exhibit a range of effects including impaired movement and bodily functions (Shigenaka 2003). Hatchlings sticky with oily residues may also have more difficulty crawling and swimming, rendering them more vulnerable to predation. Ingested oil may cause harm to the internal organs of turtles. Oil covering their bodies may interfere with breathing because they inhale large volumes of air to dive. Oil can enter cavities such as the eyes, nostrils, or mouth. Turtles may experience oiling impacts on nesting beaches when they come ashore to lay their eggs, and their eggs may be exposed during incubation, potentially resulting in increased egg mortality and/or possibly developmental defects in hatchlings. There are no turtle nesting sites within the Environmental Planning Area thus impacts to turtling eggs, post-hatchlings and juveniles are not predicted. Turtle interaction with surface oil is likely to include direct contact due to resting behaviours floating on the sea surface and through inhalation of volatile compounds in the vicinity of unweathered MDO. At moderate and high concentrations, toxicity impacts may occur including sub-lethal irritation of skin or cavities. However, due to the absence of turtle BIAs and nesting locations in the Environmental Planning Area. As low numbers of turtles forage or migrate through the Otway area, individual marine reptiles may come into contact with hydrocarbons on the sea surface or within the water column. This is most likely to be at the low threshold levels as exposure levels above the low thresholds would be within a small area of the spill location for a short period of time (~24 hours). Thus, the predicted level of consequence to marine turtles from a 250 m^3 MDO spill is assessed as minor as consequences will be short-term (days to weeks), recoverable and affect a small portion of the marine turtle population the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.

9.3.6 Marine Mammals

Marine Mammals	
Sensitivity Rating	Medium
Predicted Level of Risk	Medium
Environmental Planning Area Existing Environment	
The PMST Report for the Environmental Planning Area (Appendix B5) identified the following for marine mammals: Three species (Blue, Fin and Sei whales) with foraging, feeding or related behaviour known to occur within area. Pygmy blue whale foraging (annual high use area) BIA and known foraging area BIA. Southern Right Whale breeding and migration known to occur within area. Australian Fur-seal breeding known to occur within area. New Zealand Fur-seal and Australian Sea-lion may occur in the area. Six dolphin species likely or may occur in the area. 25 whale species likely or may occur in the area. In addition, the Environmental Planning Area overlaps the Southern Right Whale BIAs for reproduction and migration. During consultation, the cultural significance of marine mammals, such as the Southern Right Whale, Blue Whale, Killer Whale, dolphins, seals, and sea lions were highlighted, with connections to songlines, totemic value and kinship, and cultural practices (Appendix F3, Section 3.16.1). The National Recovery Plan for Southern Right whale describes Whale Birthing Dreaming Sites being in coastal bay areas from Port Campbell to Portland, including Warrnambool. These places on Gunditjmara Country are known resting and feeding sites for mothers and calves and are directly related to Gunditjmara Neeyn (midwives), explaining why Gunditjmara is a Matrilineal Nation. (DCCEEW, 2024) More information is provided on those species undertaking biologically important behaviour within the Environmental Planning Area. Australian Fur-seal Australian fur-seals (*Arctocephalus pusillus*) breed on islands of the Bass Strait but range throughout waters off the coasts of South Australia, Tasmania, Victoria and NSW. Numbers of this species are believed to be increasing as the population recovers from historic hunting (Hofmeyr et al. 2008). The species is endemic to south-eastern Australian waters. In Victorian waters they breed on offshore islands, including Lady Julia Percy Island, Seal Rocks in Westernport Bay, Kanowna and Rag Islands off the coast of Wilson's Promontory and The Skerries off Wingan Inlet in Gippsland. In Tasmanian waters they breed on Reid Rocks. There are important breeding sites on Lady Julia Percy Island	

Marine Mammals
and Seal Rocks, with 25% of the population occurring at each of these islands. Their preferred breeding habitat is a rocky island with boulder or pebble beaches and gradually sloping rocky ledges. Haul out sites with occasional pup births are located at Cape Bridgewater, at Moonlight Head, on various small islands off Wilsons Promontory and Marengo Reef near Apollo Bay. Australian fur-seals are present in the region all year, with breeding taking place during November and December. Research being undertaken at Lady Julia Percy Island indicates that adult females feed extensively in the waters between Portland and Cape Otway, out to the 200 m bathymetric contour. Seal numbers on the island reach a maximum during the breeding season in late October to late December. By early December, large numbers of lactating females are leaving for short feeding trips at sea and in late December there is an exodus of adult males. Thereafter, lactating females continue to alternate between feeding trips at sea and periods ashore to suckle their pups. Even after pups begin to venture to sea, the island remains a focus, and at any time during the year groups may be seen ashore resting (Robinson et al. 2008, Hume et al. 2004, Arnould & Kirkwood 2007). Lady Julia Percy Island and Reid Rocks are within the Environmental Planning Area as is the haul out area at Cape Bridgewater. Blue whale The Blue Whale (*Balaenoptera musculus*) is listed as an endangered species under the EPBC Act. There are two subspecies of blue whales that use Australian waters (including Australian Antarctic waters), the Pygmy Blue Whale (*B. m. brevicauda*) and the Antarctic Blue Whale (*B. m. intermedia*). The Otway region, where the Operational Area is located, is an important migratory and foraging area for Blue Whales, as shown by passive acoustic monitoring and aerial surveys (Gavrilov 2012, McCauley et al. 2018, Gill et al. 2011). Underwater acoustic monitoring programs have detected Antarctic and Pygmy Blue Whale calls in the Otway Region (McCauley et al. 2018). Important foraging grounds for Blue Whales include the Great Australian Bight, South Australia, and off Portland Victoria. Research to date has found that Pygmy Blue Whales occupy the western area of the Bonney Upwelling system in the Eastern Great Australian Bight and adjacent to the Kangaroo Island canyons from November and December (DoE 2015c). Pygmy Blue Whales then move south-east to the Bonney Upwelling system off eastern South Australia and Victoria (e.g., between Robe, SA and Cape Otway, Vic). This occurs predominately between January to April (DoE 2015). The Blue Whale was extremely abundant until the early 20th century when they were hunted to near extinction. Approximately 341,830 Blue Whale takes were recorded by commercial whaling in the Antarctic and sub-Antarctic in the 20th century, of which 12,618 were identified as Pygmy Blue Whales (Branch et al. 2004). The current global population of Blue Whales is uncertain but is plausibly in the range of 10,000 to 25,000, corresponding to about 3-11% of the 1911 estimated population size (Reilly et al. 2008). The Environmental Planning Area is within the foraging (annual high use) and known foraging area BIA where blue whales predominately occur between January to April (DoE 2015) (Appendix B12 MAP-REG-EPM-068). Fin whale The Fin Whale is a cosmopolitan migratory species that is listed as vulnerable and occurs from polar to tropical waters but is rarely sighted in inshore waters. Fin Whales show well defined migratory movements between polar, temperate and tropical waters which are essentially north–south with little longitudinal dispersion. While Australian Antarctic waters are important feeding grounds for Fin Whales, the species also feeds in the Bonney Upwelling during summer/autumn sometimes in the company of Blue and Sei Whales (DCCEEW 2023b). Areas of upwelling and interfaces with mixed and stratified waters may be an important feature of Fin Whale feeding habitat with the species feeding on planktonic crustacea, krill, some fish, and cephalopods (DCCEEW 2023b). Fin Whales frequently lunge or skim feed at or near the surface and they are known to dive to 230 m to feed. There are no BIAs for the Fin Whale within Australian waters. Fin Whales are likely to be foraging in the Environmental Planning Area at similar time as Blue Whales, predominately occur between January to April.

Marine Mammals
Sei Whale The Sei Whale is listed as vulnerable under the EPBC Act. Sei Whales are considered a cosmopolitan species, ranging from polar to tropical waters, but tend to be found more offshore than other species of large whales. Sei Whales move between Australian waters and Antarctic feeding areas; subantarctic feeding areas (e.g. Subtropical Front); and tropical and subtropical breeding areas. The proportion of the global population in Australian waters is unknown as there are no estimates for Sei Whales in Australian waters. In Australia, Sei Whales occur within Australian Antarctic Territory waters and Commonwealth waters, and have been infrequently recorded off Tasmania, NSW, Queensland, the Great Australian Bight, Northern Territory and Western Australia (Parker 1978, Bannister et al. 1996, Thiele et al. 2000, Chatto and Warneke 2000, Bannister 2008). Sightings of Sei Whales within Australian waters includes areas such as the Bonney coast upwelling off South Australia (Miller et al. 2012), where opportunistic feeding has been observed between November and May (Gill et al. 2015). There are no BIAs for the Sei Whale within Australian waters. Sei Whales are likely to be foraging in the Environmental Planning Area at similar time as Blue Whales, predominately occur between January to April. Southern Right Whale The Southern Right Whale (*Eubalaena australis*) is listed as endangered under the EPBC Act. Southern Right Whales were depleted to less than 300 individuals globally due to commercial whaling in the 19th and 20th centuries (Tormosov et al. 1998). They were protected from whaling in 1935 however, due to illegal whaling in the 1970s and because Southern Right Whales have a slow rate of increase (7% per annum) compared to other marine mammals, their numbers remain low (IWC 2013). Global abundance estimates are 13,000 for the species, across key wintering grounds in South Africa, Argentina, Australia, and New Zealand. Southern Right Whales are distributed in the Southern Hemisphere with a circumpolar distribution between latitudes of 16°S and at least 65°S. They migrate from southern feeding grounds in sub-Antarctic waters to Australia in between May and November to calve, mate and rest (Bannister et al. 1996, DCCEEW 2024). They are distributed across thirteen primary aggregation areas along the southern coast of Australia. In Australian coastal waters, they occur along the southern coastline of the mainland and Tasmania and generally extend as far north as Sydney on the east coast and Perth on the west coast (CoA 2012). There are occasional sightings further north, with the extremities of their range recorded at Hervey Bay and Exmouth (CoA 2012). The peak period for Southern Right Whale mating is from mid-July through to August (CoA 2012). Pregnant females generally arrive during late May/early June and depart with calves in September to October however the general time of arrivals and departures varies on an inter-annual basis. Calving females are known to have high site fidelity and a 3 to 4-year calving interval. Other population classes stay for shorter and variable periods undertaking coastal movements and departing the coast earlier than female-calf pairs (CoA 2012). The Environmental Planning Area overlaps the Southern Right Whale reproduction and migration BIAs (Appendix B12 MAP-REG-EPM-069).
Predicted Level of Risk
Marine mammals may be exposed to the chemicals in oil through: • Internal exposure by consuming oil or contaminated prey. • Inhaling volatile oil compounds when surfacing to breathe. • Dermal contact, by swimming in oil and having oil directly on the skin and body (NRDA 2012, Hook et al. 2016). The effects of this exposure include:

Marine Mammals
• Maternal transfer of contaminants to embryos. • Hypothermia due to conductance changes in skin, resulting in metabolic shock (expected to be more problematic for non-cetaceans in colder waters). • Toxic effects and secondary organ dysfunction due to ingestion of oil. • Congested lungs. • Damaged airways. • Interstitial emphysema due to inhalation of oil droplets and vapour. • Gastrointestinal ulceration and haemorrhaging due to ingestion of oil during grooming and feeding. • Eye and skin lesions from continuous exposure to oil. • Decreased body mass due to restricted diet. • Stress due to oil exposure and behavioural changes. Whales and Dolphins French-McCay (2009) identifies that a 10–25 µm oil thickness threshold has the potential to impart a lethal dose on marine species, however, they also estimate a probability of 0.1% mortality to cetaceans if they encounter these thresholds based on the proportion of the time spent at surface. Direct surface oil contact with hydrocarbons is considered to have little deleterious effect on whales, possibly due to the skin's effectiveness as a barrier to toxicity, as such effect of oil on cetacean skin is probably minor and temporary (Geraci & St Aubin 1988). Cetaceans in particular have mostly smooth skins with limited areas of pelage (hair covered skin) or rough surfaces such as barnacled skin. Oil tends to adhere to rough surfaces, hair, or calluses of animals, so contact with hydrocarbons by cetaceans is expected to cause only minor hydrocarbon adherence. The physical impacts from ingested hydrocarbon with subsequent lethal or sub-lethal impacts are both applicable to entrained oil. However, the susceptibility of cetaceans varies with feeding habits. Baleen whales (such as blue, fin, humpback and sei whales) are not particularly susceptible to ingestion of oil in the water column but are susceptible to oil at the sea surface as they feed by skimming the surface. Oil may stick to the baleen while they 'filter feed' near slicks. Sticky, tar-like residues are particularly likely to foul the baleen plates. The inhalation of oil droplets, vapours and fumes is a distinct possibility if whales surface in slicks to breathe. Exposure to hydrocarbons in this way could damage mucous membranes, damage airways, or even cause death. Toothed whales and dolphins may be susceptible to ingestion of dissolved and entrained oil as they gulp feed at depth. There are reports of declines in the health of individual pods of killer whales (a toothed whale species), though not the population as a whole, in Prince William Sound after the Exxon Valdez vessel spill (heavy oil) (Hook et al. 2016). It has been stated that pelagic species will avoid hydrocarbon, mainly because of its noxious odours, but this has not been proven. The strong attraction to specific areas for breeding or feeding (e.g., use of the Warrnambool coastline as a nursery area for southern right whales) may override any tendency for cetaceans to avoid the noxious presence of hydrocarbons. So weathered or tar-like oil residues can still present a problem by fouling baleen whales feeding systems. Dolphin populations from Barataria Bay, Louisiana, USA, which were exposed to prolonged and continuous oiling from the Macondo oil spill in 2010, had higher incidences of lung and kidney disease than those in the other urbanised environments (Hook et al. 2016). The spill may have also contributed to unusually high perinatal mortality in bottlenose dolphins (Hook et al. 2016).

Marine Mammals
There is the potential for the survey to occur when blue, fin and sei whales are foraging in the areas If present, these species may be exposed to oil externally and via ingestion whilst feeding. If large quantities of zooplankton exposed to the spill were ingested, chronic toxicity impacts may occur. However, as oil exposure above low thresholds will only occur within a small area at the spill source and for ~24 hours biological consequences of physical contact with localised areas of low concentrations of hydrocarbons are unlikely to lead to any long-term population impacts, with temporary skin irritation and very light fouling/matting of baleen plates likely to occur.
Southern Right Whales may also be present in the area of oil exposure and they and their calves could be exposed to oil. However, as oil exposure above low thresholds will only occur within a small area at the spill source and for ~ 24 hours biological consequences of physical contact with localised areas of low concentrations of hydrocarbons are unlikely to lead to any long-term population impacts.
It is unlikely that highly mobile and transient species that are not undertaking biologically important behaviour would be affected by exposure to oil within the relatively small area of the Environmental Planning Area and that oil exposure above low thresholds will only occur within a small area at the spill source.
The predicted levels of consequence to whales and dolphins from a 250 m^3 MDO spill is assessed as moderate as exposure to oil above low thresholds could occur to whales undertaking biologically important behaviours (feeding, reproduction), though if consequences occurred, they are likely to only affect a small portion of the population due to the low spill volume and short duration of any exposure the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.
Pinnipeds
Pinnipeds are vulnerable to sea surface exposures given they spend much of their time on or near the surface of the water as they need to surface every few minutes to breathe and regularly haul out on to beaches. Pinnipeds are also sensitive as they will stay near established colonies and haul-out areas, meaning they are less likely to practice avoidance behaviours. This is corroborated by Geraci & St. Aubin (1988) who suggest seals, sea- lions and fur-seals have been observed swimming in oil slicks during a number of documented spills.
Exposure to surface oil can result in skin and eye irritations and disruptions to thermal regulation. As a result of exposure to surface oils, pinnipeds, with their relatively large, protruding eyes are particularly vulnerable to effects such as irritation to mucous membranes that surround the eyes and line the oral cavity, respiratory surfaces, and anal and urogenital orifices. Hook et al (2016) reports that seals appear not to be very sensitive to contact with oil, but instead to the toxic impacts from the inhalation of volatile components.
For some pinnipeds, fur is an effective thermal barrier because it traps air and repels water. Petroleum stuck to fur reduces its insulative value by removing natural oils that waterproof the pelage. Consequently, the rate of heat transfer through fur seal pelts can double after oiling (Geraci & St. Aubin 1988), adding an energetic burden to the animal. Kooyman et al (1976) suggest that in fact, fouling of approximately one-third of the body surface resulted in 50% greater heat loss in fur seals immersed in water at various temperatures. Fur-seals are particularly vulnerable due to the likelihood of oil adhering to fur. Heavy oil coating and tar deposits on fur-seals may result in reduced swimming ability and lack of mobility out of the water. Davis and Anderson (1976) observed two Gray Seal pups drowning, their "flippers stuck to the sides of their bodies such that they were unable to swim".
However, pinnipeds other than Fur-seals are less threatened by thermal effects of fouling, if at all. Oil has no effect on the relatively poor insulative capacity of sea-lion and bearded and ringed seal pelts; oiled Weddell seal samples show some increase in conductance (Oritsland 1975, Kooyman et al. 1976, 1977). ITOPF (2011) documents impacts on species that rely on fur to regulate their body temperature (such as fur-seals), demonstrating these species are most vulnerable to oil as the animals may die from hypothermia or overheating, depending on the season, if the fur becomes matted with oil.

Marine Mammals
It is reported that most pinnipeds scratch themselves vigorously with their flippers and do not lick or groom themselves, so are less likely to ingest oil from skin surfaces (Geraci & St. Aubin 1988). However, mothers trying to clean an oiled pup may ingest oil. All pinnipeds examined to date have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt 1982, Addison and Brodie 1984, Addison et al. 1986). Ingested hydrocarbons can irritate or destroy epithelial cells that line the stomach and intestine, thereby affecting motility, digestion and absorption. However, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt 1982, Addison & Brodie 1984, Addison et al. 1986). Geraci & St. Aubin (1988) suggest that a small phocid weighing 50 kg might have to ingest approximately 1 litre of oil to be at risk. Volkman et al (1994) report that benzene and naphthalene ingested by seals is quickly absorbed into the blood through the gut, causing acute stress, with damage to the liver considered likely. If ingested in large volumes, hydrocarbon, may not be completely metabolised, which may result in death. Breeding colonies (used to birth and nurse until pups are weaned) are particularly sensitive to hydrocarbon spills (Higgins & Gass 1993). Pinnipeds also appear to rely on scent to establish a motherpup bond (Sandegren 1970, Fogden 1971), and consequently oil-coated pups may not be recognisable to their mothers. This is only theorised, with studies and research indicating interaction between mothers and oiled pups were normal (Davis and Anderson 1976, Davies 1949, Shaughnessy & Chapman 1984). The long-term Environmental Impact and Recovery report for the Iron Barren oil spill (in Tasmania, 1995) concluded that “The number of seal pups born at Tenth Island in 1995 was reduced when compared to previous years. There was a strong relationship between the productivity of the seal colonies and the proximity of the islands to the oil spill wherein the islands close to the spill showed reduced pup production and those islands more distant to the oil spill did not” (Tasmanian SMPC 1999). Australian sea-lions have ‘naturally poor recovery abilities’ due to ‘unusual reproductive biology and life history’ (TSSC 2005). Due to the extreme philopatry of females and limited dispersal of males between breeding colonies, the removal of only a few individuals annually may increase the likelihood of decline and potentially lead to the extinction of some of the smaller colonies. Extinction of breeding colonies has the potential to further reduce genetic diversity and the already limited genetic flow between colonies. This, in turn, may weaken the genetic resilience of the species and impact on its ability to cope with other natural or anthropogenic impacts. In addition, the extreme philopatry of females suggests that extinction of breeding colonies may lead to a contraction of the range of the species as re-colonisation of breeding sites via immigration is limited. For the reasons outlined above, small breeding colonies are under particular pressure of survival from even low levels of anthropogenic mortality. As highly mobile species, in general it is very unlikely that marine mammals will be constantly exposed to concentrations of hydrocarbons in the water column for continuous durations (e.g., >96 hours) that would lead to chronic toxicity effects. There is the potential for Lady Julia Percy Island and Cape Bridgewater to be exposed to oil above the low threshold levels, though unlikely for Reid Rocks due to the distance from the Operational Area. Thus, seals at Lady Julia Percy Island and Cape Bridgewater could be exposed to oil at levels that could result in some level of impact. As diesel is a light fuel and readily evaporates matting and heavy coating of fur is not predicted. Impacts from inhalation of vapours is more likely as the diesel evaporates resulting in irritations to mucous membranes. Ingestion and tainting of prey are less likely as pinnipeds have large foraging ranges and are less likely to be exposed to oil above low thresholds in the water column. The predicted level of consequence to pinnipeds from a 250 m^3 MDO spill is assessed as moderate as exposure to oil above low thresholds could occur to breeding and haul out locations, though if consequences occurred, they are likely to only affect a small portion of the population due to the low spill volume and short duration of any exposure the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.4 Change in Ecosystem Dynamics

9.4.1 Benthic Assemblages

Benthic Assemblages	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	
Benthic assemblages are biological communities that live in or on the seabed. They typically contain light-dependent taxa such as algae, seagrass and corals, which obtain energy primarily from photosynthesis, and/or animals such as molluscs, sponges and worms. Benthic habitats are the seabed substrates that benthic communities grow on or in; these can range from unconsolidated sand to hard substrates (e.g., limestone) and occur either singly or in combination. Given that MDO would only be present on the sea surface or within the water column to a depth of 10 m (RPS 2019a) the existing environment covers those benthic assemblages along the Victorian, South Australian and King Island coastlines within the Environmental Planning Area. Rocky reefs and hard grounds are located in all areas of the South-east Marine Region continental shelf including Bass Strait, from the sub-tidal zone shore to the continental shelf break. On the continental shelf, rocky reefs and hard grounds provide attachment sites for macroalgae and sessile invertebrates, increasing the structural diversity of shelf ecosystems. The reefs provide habitat and shelter for fish and are important for aggregations of biodiversity and enhanced productivity. The shallowest depth at which the rocky reefs occur in Commonwealth waters is approximately 50 m (CoE 2015a). Corals do not occur as a dominant habitat type within the Environmental Planning Area. Reef development by hard corals does not occur further south than Queensland (Tzioumis and Keable, 2007). Soft corals are typically present in deeper waters throughout the continental shelf, slope and off-slope regions, to well below the limit of light penetration (BBG 2003, Boreen et al. 1993). Gorgonian corals (soft corals) were identified during seabed surveys of the Beach Otway Development area within the Environmental Planning Area (Ramboll 2020). James et al (2013) undertook extensive surveys of macroalgal communities along the Otway Shelf from Warrnambool to Portland in south-west Victoria. Sites were adjacent to shore or on offshore rocky reefs covering a depth range of 0 to 36 meters water depth. These surveys did not locate giant kelp at any site but identified that other brown algae species (Durvillaea, Ecklonia, Phyllospora, Cystophora, and Sargassum) are prolific to around 20 m water depth. Brown algae tend to be replaced by red algae in deeper waters. Bull kelp or southern bull kelp (Durvillaea potatorum) is a fast-growing brown macroalgae (seaweed) with large dark brown and leathery strap-like blades. It consists of a body, called the thallus, with a stipe connecting the blades to the holdfast (a structure adhering the bull kelp to the seafloor. Offshore Victoria and Tasmania there are two main species of Durvillaea, these are D. potatorum and D. amatheiae. The approximate distribution of the species is shown in Figure D4-1 with locations within the Environmental Planning Area. Bull kelp is a significant habitat. The holdfast can be inhabited by a diverse array of epifauna and infauna invertebrates. These burrow into the holdfast creating holes that can be used by a wide variety of animals. In addition, bull kelp grows in large groups or forests that can become important nursery areas and sanctuary areas for fish, crustaceans and other fauna. Bull kelp has a long history of use by First Nations in Australia, New Zealand, and Chile. In Australia this reportedly dates back 65,000 years	

Benthic Assemblages
(Thurstan et al. 2018). First Nation people in Tasmania used dried bull kelp to transport water and food. The species name came from this use: potatorum means 'to drink' in Latin (Govt of SA 2023). Wadawurrung Traditional Owners Aboriginal Corporation describe in their Country Plan how kelp forests, with their giant and bull kelps, serve as a habitat for numerous native species, as well as being used to create water carriers (WTOAC 2020). Thurstan et al. (2018) details several First Nations historical references for bull kelp including: Cultural activities and cultural history –mythology and sacred songs. Ceremonial activities –being burned or being used during smoking ceremonies. Medicinal use –bandages and medicinal poultice. Clothing – cloaks and shoes. Diet – raw, jelly, dried and roasted (preserving for several months). Fishing – ropes and fishing nets / traps, traps for short-finned eels, also used to assist during diving for crayfish. Shelter – waterproofing, wind proofing and carpeting. Bulk kelp is also collected by the seaweed industry as described in the assessment of Commercial fishing and aquaculture.

Benthic Assemblages

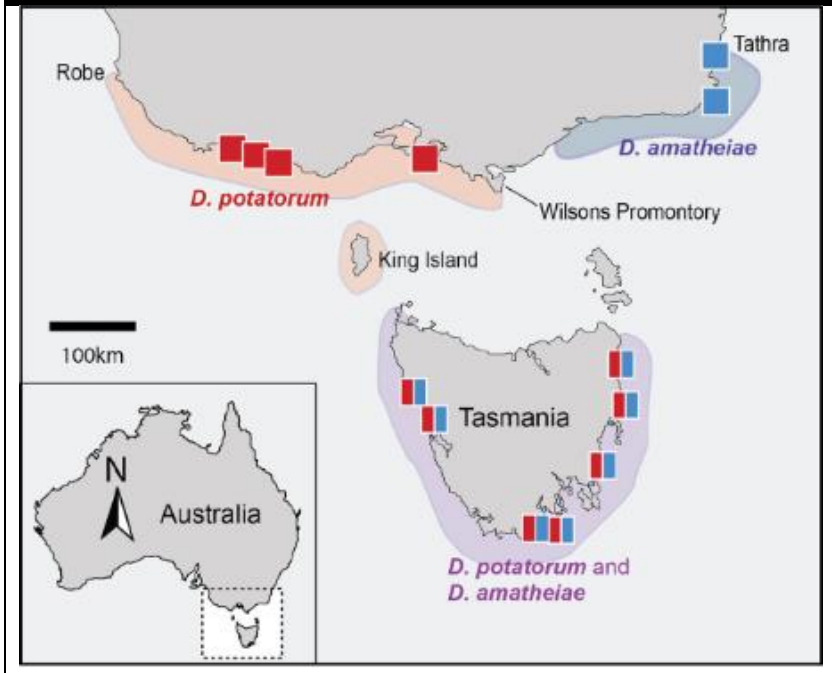

Figure D4-1 - Distribution of bull kelp off Victoria and Tasmania (Velasquez et al. 2029)

The PMST Report (Appendix B5) for the Environmental Planning Area did not identify any Key Ecological Features with benthic habitats in water depths > 10 m.

The PMST Report (Appendix B5) for the Environmental Planning Area did identify the Giant Kelp Marine Forests of South East Australia threatened ecological community. The Giant Kelp Forests of South East Australia ecological community is defined as giant kelp growing typically at depths greater than eight metres below sea level and forming a closed or semi-closed surface or sub-surface canopy (TSSC 2012). The ecological community is characterised by a closed to semi-closed surface or subsurface canopy of Macrocystis pyrifera which is the only species of kelp able to provide this three-dimensional structure from the sea floor to the sea surface, so if giant kelp plants are lost or removed, the ecological community no longer exists (TSSC 2012). The giant kelp forests provide habitat for other marine flora such as seaweeds and marine fauna including fish, molluscs (sea snails), bryozoans (lace corals), polychaetes (worms), crustaceans (crabs, isopods, amphipods), echinoderms (sea urchins, seastars) and sponges (TSSC 2012). There distribution is restricted to waters off the coast of Tasmania particularly in the Bruny, Freycinet and Davey bioregions, but also the Boags and Franklin, Flinders and Otway bioregions, the coast of South Australia in the Otway and Coorong bioregions as far west as Margaret Bock Reef and the coast of Victoria in the Otway, Flinders, Central Victoria and Twofold Shelf bioregions as far east as Gabo Island.

Benthic Assemblages
Predicted Level of Risk
Studies of offshore benthic seaweeds in the northwest Gulf of Mexico prior to and after the Macondo well blowout at Sackett and Ewing banks (in water depths of 55–75 m) found a dramatic die-off of seaweeds after the spill (60 species pre-spill compared with 10 species post-spill) (Felder et al. 2014). Benthic decapod assemblages (crabs, lobsters, prawns) associated with the seaweeds and benthic substrate also showed a strong decline in abundance at both banks post-spill (species richness on Ewing Bank reduced by 42% and on Sackett Bank by 29%), though it is noted that these banks are exposed to influences from Mississippi River discharges that vary year to year, so definitive links to the oil spill are not possible. It is noted, however, that petroleum residues were observed on Ewing Bank, and it is possible that this may have caused localised mortalities, reduced the fecundity of surviving female decapods or reduced recruitment (Felder et al. 2014). Felder et al (2014) also notes that freshly caught soft-sediment decapod samples caught in early and mid-2011 near the spill site exhibited lesions that were severe enough to cause appendage loss and mortality. Water quality in benthic habitats exposed to entrained hydrocarbons would be expected to return to background conditions within weeks to months of contact. Several studies have indicated that rapid recovery rates may occur even in cases of heavy oiling (Committee on Oil in the Sea 2003). Studies undertaken after the Montara oil spill incident included diver surveys to assess the status of Ashmore, Cartier and Seringapatam coral reefs. These found that other than a region-wide coral bleaching event caused by thermal stress (i.e. caused by sea water exceeding 32°C), the condition of the reefs was consistent with previous surveys, suggesting that any effects of oil reaching these reefs was minor, transitory, or sub-lethal and not detectable (Heyward et al. 2010). This is despite AMSA observations of surface slicks or sheen nears these shallow reefs during the spill (Heyward et al. 2010). Surveys in 2011 indicated that the corals exhibiting bleaching in 2010 had largely survived and recovered (Heyward et al. 2012), indicating that potential exposure to hydrocarbons while in an already stressed state did not have any impact on the healthy recovery of the coral. Macroalgae are generally limited to growing on intertidal and subtidal hard substrata in shallow waters within the photic zone. As such, they may be exposed to subsurface and entrained and dissolved hydrocarbons, however, are susceptible to surface hydrocarbon exposure more so in intertidal habitats as opposed to subtidal habitats. Smothering, fouling, and asphyxiation are some of the physical effects that have been documented from oil contamination in marine plants (Blumer 1971, Cintron et al. 1981). In macroalgae, oil can act as a physical barrier for the diffusion of CO_2 across cell walls (O'Brian & Dixon 1976). The effect of hydrocarbons, however, is largely dependent on the degree of direct exposure and how much of the hydrocarbon adheres to algae, which will vary depending on the oils physical state and relative 'stickiness'. The morphological features of macroalgae, such as the presence of a mucilage layer or the presence of fine 'hairs' will influence the amount of hydrocarbon that will adhere to the algae. A review of field studies conducted after spill events by Connell et al (1981) indicated a high degree of variability in the level of impact, but in all instances, the algae appeared to be able to recover rapidly from even very heavy oiling. The rapid recovery of algae was attributed to the fact that for most algae, new growth is produced from near the base of the plant while the distal parts (which would be exposed to the oil contamination) are continually lost. Other studies have indicated that kelp beds oiled by crude oil had a 90% recovery within 3-4 years of impact, however full recovery to pre-spill diversity may not occur for long periods after the spill (French- McCay 2004). Intertidal macroalgal beds are more prone to oil spills than subtidal beds because, although the mucous coating prevents oil adherence, oil that is trapped in the upper canopy can increase the persistence of the oil, which impacts upon site-attached species. Additionally, when oil sticks to dry fronds on the shore, they can become overweight and break as a result of wave action (IPIECA 2002). The toxicity of hydrocarbons to macroalgae varies for the different macroalgal life stages, with water-soluble hydrocarbons more toxic (Van Overbeek and Blondeau 1954, Kauss et al. 1973 cited in O'Brien and Dixon, 1976). Toxic effect concentrations for hydrocarbons and algae have varied greatly among species and studies, ranging 0.002–10,000 ppm (Lewis & Pryor 2013). The sensitivity of gametes, larva and zygote stages however have all proven more responsive to petroleum oil exposure than adult growth stages (Thursby and Steele 2004, Lewis & Pryor 2013).

Benthic Assemblages
Macrophytes, including seagrasses and macroalgae, require light to photosynthesise. So, in addition to the potential impacts from direct smothering or exposure to entrained and dissolved hydrocarbons, the presence of entrained hydrocarbon within the water column can affect light qualities and the ability of macrophytes to photosynthesise. Experiments verified the susceptibility *of Nereocystis luetkeana* (bull kelp – North America) tissue to the direct exposure to several petroleum types. Antrim et al (1995) showed that petroleum treatments resulted in visible tissue damage, with a distinct bleached line being the most visible indication of plant contact with the petroleum. Moderate to heavy colour loss, which was generally followed by rapid decay of tissue, was most pronounced in 24 h exposures to unweathered and weathered diesel. Due to the exposed nature of the coastal areas within the Environmental Planning Area and the nature of MDO, long-term effects in areas of moderate MDO exposure are not expected and natural weathering should result in rapid recovery of communities. MDO shoreline loading at the high threshold is not predicted due to the low spill volume. Consequently, impacts resulting in the loss of coastal seaweed to the extent that coastal erosion could be affected are not predicted. [Paragraph added in response to Matter: E14]. The predicted level of consequence to benthic assemblages from a 250 m^3 MDO spill is assessed as moderate as the consequences could be longer lasting (> 30 days) if kelp and other macroalgal areas are exposure to oil above the low threshold level, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.4.2 Coastal Habitats and Coastal Communities

Coastal Habitats and Communities	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	
The Environmental Planning Area overlaps a wide variety of shorelines along Victoria, South Australia, and King Island. Coastal habitats which have the potential to be contacted by MDO spill include sandy shorelines, rocky shorelines, and saltmarsh. Mangroves are not present along the west coast of Victoria or King Island where the Environmental Planning Area. Coastal resources, specifically shell middens and flint, have been identified as having cultural value to the Gunditjmara and Eastern Maar people (Appendix F3, Section 3.16.1). Sandy and rocky shorelines are the dominant the coastal habitats within the Environmental Planning Area. The PMST Report (Appendix B5) for the Environmental Planning Area identified the following Threatened Ecological Communities that are present on the shoreline: • Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community. • Subtropical and Temperate Coastal Saltmarsh. • King Island Scrub Complex The Subtropical and Temperate Coastal Saltmarsh TEC occurs in a relatively narrow strip along the Australian coast, within the boundary along 23°37' latitude along the east coast and south from Shark Bay on the west coast of WA (TSSC 2013). The community is found in coastal areas which have an intermittent or regular tidal influence. The coastal saltmarsh community consists mainly of salt-tolerant vegetation including grasses, herbs, sedges, rushes and shrubs. Succulent herbs, shrubs and grasses generally dominate, and vegetation is generally less than 0.5 m in height (Adam 1990). In Australia, the vascular saltmarsh flora may include many species, but is dominated by relatively few families, with a high level of endism at the species level. The saltmarsh community is inhabited by a wide range of infaunal and epifaunal invertebrates and low and high tide visitors such as fish, birds and prawns (Adam 1990). It is often important nursery habitat for fish and prawn species. Insects are also abundance and an important food source for other fauna. The dominant marine residents are benthic invertebrates, including molluscs and crabs (Ross et al. 2009). Saltmarsh communities are threatened by clearing and fragmentation, land reclamation, altered hydrology and tidal restriction, invasive species, climate change, mangrove encroachment, recreation, eutrophication, grazing, insect control and inappropriate fire regimes (TSSC 2013). The coastal saltmarsh community provides extensive ecosystem services such as the filtering of surface water, coastal productivity and the provision of food and nutrients for a wide range of adjacent marine and estuarine communities and stabilising the coastline and providing a buffer from waves and storms. Most importantly, the saltmarshes are one of the most efficient ecosystems globally in sequestering carbon, due to the biogeochemical conditions in the tidal wetlands being conducive to long-term carbon retention. A concern with the loss of saltmarsh habitat is that it could release the huge pool of stored carbon to the atmosphere. The Assemblages of species associated with open-coast salt-wedge estuaries of western and central KEF are an assemblage of native plants, animals and micro-organisms associated with the dynamic salt-wedge estuary systems that occur within the temperate climate, microtidal regime (< 2 m), high wave energy coastline of western and	

Coastal Habitats and Communities
central Victoria. The ecological community currently encompasses 25 estuaries in the region defined by the border between South Australia and Victoria and the most southerly point of Wilsons Promontory (DoEE 2018a). Salt-wedge estuaries are usually highly stratified, with saline bottom waters forming a 'salt-wedge' below the inflowing freshwater layer of riverine waters. The dynamic nature of salt-wedge estuaries has important implications for their inherent physical and chemical parameters, and ultimately for their biological structure and ecological functioning. Some assemblages of biota are dependent on the dynamics of these salt-wedge estuaries for their existence, refuge, increased productivity and reproductive success. The ecological community is characterised by a core component of obligate estuarine taxa, with associated components of coastal, estuarine, brackish and freshwater taxa that may reside in the estuary for periods of time and/or utilise the estuary for specific purposes (e.g. reproduction, feeding, refuge, migration) (DoEE 2018a). The King Island Scrub Complex threatened ecological community is listed as endangered, and is the assemblage of plants, animals and other organisms associated with a type of scrub or tall shrubland that is found on King Island, Tasmania. At the time of listing, the King Island scrub complex occurs in the Cradle Coast Natural Resource Management (NRM) region. King Island scrub complex typically occurs on acidic sandy soils (with or without an organic rich A-horizon) on flats or undulating plains in the north-east, central and south-east coast, and centre of the island, with significant occurrences also in the far south-west of the island, where it lies between the New Dunes and the more fertile plateau country to the east (DCCEEW 2024j). The Conservation Advice for this threatened community also mentions the Sea Elephant Conservation Area as a relevant listed ecological community on King Island, and is described as providing a suitable habitat for a range of threatened flora and fauna species including the critically endangered Orange-bellied Parrot and endemic subspecies of bush birds. Southern Elephant Seals (*Mirounga leonine*) once bred on King Island but were wiped out because of the sealing industry in the 19th century. The closest breeding area for the Southern Elephant Seals (listed as vulnerable) to the EPA is Macquarie Island (TSSC 2016c). Oil is listed in this species recovery plan as a potential threat, but no known colonies currently live on King Island, thus impacts to this species and its habitat from oil are not predicted (DEH 2003b).
Predicted Level of Risk
Sandy beaches are regularly exposed to wave action and have low sediment total organic carbon and therefore generally a low abundance of marine life (Hook et al. 2016). The low concentration of total organic carbon and large particle size of sand means that any MDO deposited on the beach would not be retained. However, sandy beaches are important socio-economically, so an MDO spill reaching this type of shoreline may attract attention that is disproportionate to its sensitivity (Hook et al. 2016). Depth of penetration in sandy sediment is influenced by: • Particle size – penetration is great in coarser sediments (such as beach sand) compared to mud (in estuaries and tidal flats). • Oil viscosity – MDO quickly penetrates sandy sediments. • Drainage – coarse beach sands allow for rapid drainage (it may reach depths greater than one metre in coarse well-drained sediments). • Animal burrows and root pores – penetration into fine sediments is increased if there are burrows of animals such as worms, or pores left where plant roots have decayed. Areas of heavy oiling (>1,000 g/m^2 threshold) would likely result in acute toxicity, and death, of many invertebrate communities, especially where oil penetrates sediments through animal burrows (IPIECA 1999). However, these communities would be likely to rapidly recover (recruitment from unaffected individuals and recruitment from nearby areas) as oil is removed from the environment. The results of exposure to oil may be acute (e.g., die off of amphipods and replacement by more tolerant species such as worms or chronic (i.e., gradual accumulation of oil and genetic damage) (Hook et al. 2016).

Coastal Habitats and Communities
Cracks and crevices, rock pools, overhangs and other shaded areas provide habitat for soft bodied animals such as sea anemones, sponges, and sea- squirts, and become places where hydrocarbons can become concentrated as it strands ashore. The same is true on stable boulder shores where the rich animal communities underneath the rocks are also the most vulnerable to hydrocarbon pollution. The vulnerability of a rocky shoreline to oiling is dependent on its topography and composition as well as its position. A vertical rock wall on a wave- exposed coast is likely to remain unoiled if an oil slick is held back by the action of the reflected waves (IPIECA-IOGP 2016). At the other extreme, a gradually sloping boulder shore in a calm backwater of a sheltered inlet can trap enormous amounts of hydrocarbons, which may penetrate deep down through the substratum. The complex patterns of water movement close to rocky coasts also tend to concentrate oil in certain areas. Some shores are well known to act as natural collection sites for litter and detached algae and oil is carried there in the same way. As on all types of shorelines, most of the oil is concentrated along the high tide mark while the lower parts are often untouched. As MDO is less sticky than other oils it is less likely to adhere to rocky shorelines and creates stains. Saltmarshes are considered to have a high sensitivity to hydrocarbon exposure. Saltmarsh vegetation offers a large surface area for oil absorption and tends to trap oil. Evidence from case histories and experiments shows that the damage resulting from oiling, and recovery times of oiled marsh vegetation, are very variable. In areas of light to moderate oiling where oil is mainly on perennial vegetation with little penetration of sediment, the shoots of the plants may be killed but recovery can take place from the underground systems. However, many case studies have shown good recruitment of annual species in the year following a spill (IPIECA-IOGP 2016). Sections of the King Island Scrub Complex community and the Sea Elephant Conservation Area occur on the shorelines along the eastern side of King Island, indicating that a small area of this community is at risk of impact from a worst-case scenario hydrocarbon spill. The majority of this community is located inland within terrestrial ecosystems and is not expected to be impacted by hydrocarbons in the event of a spill. No key threats were identified for these communities as relevant to the proposed activity. The distance to the nearest King Island (western) coastal areas from the Operational Area is ~ 70 km, and the coastal elements of these communities are located on the east coast of King Island, thus, impacts to these communities are not predicted. Due to the exposed nature of the coastal areas within the Environmental Planning Area and the nature of MDO, long-term toxicity or smothering effects in areas of moderate MDO exposure are not expected and natural weathering should result in rapid recovery of communities. MDO shoreline loading at the high threshold is not predicted due to the low spill volume. Potential risks arising from a MDO spill on socio-economic receptors (tourism, cultural and/or other social values) are more likely to occur as a result of visual/ aesthetic impacts, rather than ecological impacts. The predicted level of consequence to coastal habitats and communities from a 250 m^3 MDO spill is assessed as moderate as consequences could be longer lasting (> 30 days) if saltmarsh communities are exposure to oil above the low threshold level the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.5 Changes to Functions, Interests and Activities and Change in Aesthetic Value

9.5.1 Commercial Fisheries

Commercial Fisheries	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	

The Environmental Planning Area overlaps the following fisheries that have catch effort. A description of these fisheries is provided in the Regia MSS Commercial Fishery Review in Appendix B6.
Commonwealth:
• Bass Strait Central Zone Scallop Fishery
• Eastern Tuna and Billfish Fishery
• Small Pelagic Fishery (Western sub-area)
• Southern and Eastern Scalefish and Shark (SESS) Fishery SESSF following sectors:
  ○ Shark Gillnet and Hook
  ○ Scalefish Hook
  ○ Trawl – otter board
• Southern Squid Jig Fishery
• Western Tuna and Billfish Fishery
Victorian:
• Abalone
• Giant Crab
• Multi-species Ocean
• Octopus
• Rock Lobster	

Commercial Fisheries
• Wrasse Tasmanian: • Abalone • Giant Crab • Octopus • Rock Lobster South Australian: • Abalone • Charter Boat • Giant Crab • Marine Scalefish Fishery • Rock Lobster
Predicted Level of Risk
Commercial fishing has the potential to be impacted through exclusion zones associated with the spill, the spill response and subsequent reduction in fishing effort. Exclusion zones may impede access to commercial fishing areas, for a short period of time, and nets and lines may become oiled. The impacts to commercial fishing from a public perception, however, may be much more significant and longer term than the spill itself. Fishing areas may be closed for fishing for shorter or longer periods because of the risks of the catch being tainted by oil. Concentrations of petroleum contaminants in fish and crustacean and mollusc tissues could pose a significant potential for adverse human health effects, and until these products have been cleared by the health authorities, they could be restricted for sale and human consumption. Toxicity in adult fish has been reported in response to crude oils, HFO and diesel (Holdway 2002, Shigenaka 2011). Uptake of hydrocarbons has been demonstrated in bony fish after exposure to water-accommodated fraction hydrocarbons of between 24 and 48 hours. Davis et al (2002) report detectable tainting of fish flesh after a 24-hour exposure at crude concentrations of 0.1 ppm, marine fuel oil concentrations of 0.33 ppm and diesel concentrations of 0.25 ppm. The majority of studies, either from laboratory trials or of fish collected after spill events (including the Hebei Spirit, Macondo, and Sea Empress) find evidence of elimination of PAHs in fish tissues returning to reference levels within two months of exposure (Challenger and Mauseth 2011, Davis et al. 2002, Gagnon & Rawson 2011, Gohlke et al. 2011, Jung 2011, Law 1997, Rawson et al. 2011). Should there be impacts to fish stocks associated with impacts to plankton life phase there is the potential for reduction in profits for commercial fisheries over a longer period of time, and potential for reduced fishing quotas or exclusion zones exclude fishing effort, associated with sustainable fisheries management. The Montara spill of a light gas condensate, (as the most recent [2009] example of a large hydrocarbon spill in Australian waters) occurred over an area fished by the Northern Demersal Scalefish Managed Fishery (with 11 licences held by 7 operators), with Goldband Snapper, Red Emperor, Saddletail Snapper and Yellow Spotted Rockcod being the key species fished (PTTEP 2013). As a precautionary measure, the WA Department of Fisheries advised the commercial fishing fleet to avoid fishing in oil-affected waters. Testing of fish caught in areas of visible oil slick (November 2009) found that there were no detectable petroleum hydrocarbons in fish muscle samples, suggesting fish were safe for human consumption. In the short-term, fish had metabolised petroleum hydrocarbons. Limited ill effects were detected in a small number of individual fish only

Commercial Fisheries
(PTTEP 2013). No consistent effects of exposure on fish health could be detected within two weeks following the end of the well release. Follow up sampling in areas affected by the spill during 2010 and 2011 (PTTEP 2013) found negligible ongoing environmental impacts from the spill. Similarly, the Macondo well blowout in the Gulf of Mexico (2010), began testing a month after the event showing levels of oil contamination residue in seafood consistently tested 100 to 1,000 times lower than safety thresholds established by the USA FDA, and every sample tested was found to be far below the FDA's safety threshold for dispersant compounds (BP 2015). FDA testing of oysters found oil contamination residues to be 10 to 100 times below safety thresholds (BP 2014). Sampling data shows that post-spill fish populations in the Gulf of Mexico since 2011 were generally consistent with pre-spill ranges and for many shellfish species, commercial landings in the Gulf of Mexico in 2011 were comparable to pre-spill levels. In 2012, shrimp (prawn) and blue crab landings were within 2.0% of 2007-09 landings. In the event of a MDO spill, a temporary fisheries closure may be put in place by the fishing authority or voluntarily by the fishers themselves. A temporary fisheries closure, combined with oil tainting of target species (actual or perceived), may lead to financial losses to fisheries and economic losses for individual licence holders. Fisheries closures and the flow on losses from the lack of income derived from these fisheries are likely to have short-term but potentially widespread socio-economic consequences, such as reduced employment in the fisheries and fisheries service industries, such as tackle and bait supplies, fuel, marine mechanical services, accommodation and so forth. Oiling of fishing vessel hull and fishing equipment is not predicted given the light nature of MDO and that surface oil is predicted to have evaporated or entrained with 24 hours. A spill event may result in a short-term fishing exclusion zone (days to weeks) being implemented by the appropriate fishing authority. Areas of moderate dissolved and high entrained exposure thresholds are expected to be very small as MDO is predicted to weather quickly and the area would return to pre-spill conditions rapidly. MDO is not predicted to accumulate among benthic sediments due to the significant mixing of waters and dilution of the low concentration of hydrocarbons in the water column, as such reducing impacts to habitats in 10 m depth, which are likely slower to recover. The predicted level of consequence to commercial fisheries from a 250 m^3 MDO spill is assessed as moderate as consequences could be longer lasting (> 30 days) if fishery closures and public perception of fishing tainting occur, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.5.2 Marine Industries

Marine Industry	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
Marine industries identified within the Environmental Planning Area are: Defence A defence practice area is located within the Environmental Planning Area. There is also a number of potential unexploded ordnance areas, however, these are not predicted to be impacted by oil exposure and is not assessed further. Desalination Plant The Victorian Desalination Plant, located at Wonthaggi, is outside of the Environmental Planning Area. Offshore Energy Within the Environmental Planning Area there is the Beach Energy Otway Development consisting of subsea infrastructure and an unmanned platform and the Cooper Energy Casino Henry Netherby Development consisting of subsea infrastructure. During the Regia MSS design envelope (1 April 2024 to 31 December 2028) there is the potential for exploration and development activities such as infrastructure inspection, maintenance and repairs campaigns, seabed surveys, seismic surveys, drilling and infrastructure installation to be undertaken with vessels and drill rigs to support the ongoing energy supply of oil and gas and potentially renewables within the Otway Basin. Shipping The South East Marine Region is one of the busiest shipping regions in Australia and Bass Strait is one of Australia's busiest shipping routes. Commercial vessels use the route when transiting between ports on the east, south and west coasts of Australia, and there are regular passenger and cargo services between mainland Australia and Tasmania. Ports Australia provide statistics for port operations throughout Australia's main commercial ports. Based on the latest information (2021) the majority of commercial shipping traffic transiting to and from Victorian ports were container (3,682), general cargo (2,663), bulk liquid carriers (2,019), dry bulk (1,715), car carrier (1,342), bulk gas (220), other cargo (47) and livestock (9). Submarine cables INDIGO-Central submarine cable which at a depths greater than 100 m is not predicted to be affected by oil exposure and is not assessed further.	
Predicted Level of Risk	
Marine industries have the potential to be impacted through exclusion zones associated with the spill and the spill response. Exclusion zones may impede access to shipping lanes, defence practice areas and offshore energy infrastructure, for a short period of time. Oiling of vessel hulls or the Thylacine-A platform is not predicted given the light nature of MDO and that surface oil is predicted to have evaporated or entrained with 24 hours.	

Marine Industry
Thus, the predicted level of consequence to seaweed industries from a 250 m^3 MDO spill is assessed as minor as exposure is likely to be below low thresholds and any consequences would be short-term (days to weeks), recoverable and affect a small portion of marine industries, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.

9.5.3 Coastal Developments

Coastal Developments	
Sensitivity Rating	**High**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	
Local government areas within the Environmental Planning Area are detailed below. Victoria *Mornington Peninsula Shire* Mornington Peninsula Shire coastal areas within the environmental planning area are St Andrews Beach, Rye, Blairgowrie, Sorrento, and Portsea. These towns are popular tourist areas with a variety of beaches and tourist attractions. The area was originally home to the Mayone-bulluk and Boonwurrung-Balluk clans and formed part of the Boonwurrung nation's territory prior to European settlement. *Greater Geelong City* Greater Geelong City coastal areas within the environmental planning area are St Leonards, Swan Bay, Point Lonsdale, Ocean Grove, Barwon Heads, Connewarre, and Breamlea. The largest of these towns is Ocean Grove with a population of 14,714 (ABS 2021). These towns are popular tourist areas with a variety of beaches and access to Port Phillip Bay. *Surf Coast Shore* Within the environmental planning area are the world-famous surfing beaches Bells Beach and Torquay Beach. In addition, the Great Ocean Road follows the coast from Anglesea past Lorne. *Colac Otway Shire* Within the environmental planning area, the Great Ocean Road follows the coast past Apollo Bay and then goes inland at Marengo. The Great Otway National Park coastal areas, including the Aire River outlet, which is a popular campaign area, are within the environmental planning area. The Apollo Bay Port is home to a local fishing industry and commercial fleet which employs more than 70 people and boasts 16 boats, including trawlers, crayfish, and charter boats (Colac Otway Shire 2023). *Corangamite Shire* The main Corangamite Shire coastal areas within the environmental planning area are Princetown and Port Campbell. The Great Ocean Road follows the coast within the shire and the Twelve Apostles Marine National Park abouts the coastal area. Port Campbell is one of the main ports for the Eastern Zone Rock Lobster Fishery (VFA 2023). *Moyne Shire* The main Corangamite Shire coastal areas within the environmental planning area are Peterborough, Warrnambool, and Port Fairy. The three towns are on the Great Ocean Road and are popular tourist areas for sightseeing, beaches and whale watching.	

Coastal Developments
Glenelg Shire Within the Glenelg Shire the main coastal town is Portland which is the oldest European settlement in Victoria. In 2021, the population was 10,016 (ABS 2021). The Great South West Walk, a 250 km walking track, begins in Portland. Portland has become known as 'Tuna Town' because of its reliable tuna fishing and the importance of the species to the tourist economy (VFA 2023a). Portland harbour exists for commercial boats and ships that support export industries and doubles as a first-class boating facility. South Australia *District Council of Grant* The area along the South Australian coast of the environmental planning area is known as the limestone coast. The main town is Port MacDonnell, originally known as *Ngaranga,* which is the southernmost town in South Australia. The area was originally inhabited by the Bungandidj Aboriginal people. The 2021 Census reports that the locality of Port MacDonnell had a population of 859 (ABS 2021). Once a busy shipping port, the town now relies heavily on its fishing and summer tourism industries, particularly rock lobster harvest industry, proclaiming itself "Australia's Southern Rock Lobster Capital". Tasmania *King Island Council* King Island is at the western entrance to Bass Strait and is 64 km long by 27 km wide. The 2021 Census reports that the King Island had a population of 1,617 (ABS 2021). King Island was originally part of a land bridge linking Tasmania with the Australian mainland, which was submerged around 12,000 years ago due to rising sea levels. A human skeleton was discovered in a cave on the island in 1989, which was dated to approximately 14,000 years ago. However, previous examinations had revealed no "shell heaps, bones, charcoal or other remains which might indicate Aboriginal occupation", suggesting that the area was passed through by the ancestors of Aboriginal Tasmanians but not permanently inhabited (Sim 1990). The island is a popular tourist location and produces cheese, lobsters, kelp, and beef.
Predicted Level of Risk
Due to the distance to the South Australian and King Island coastal areas from the Operational Area (~130 km and ~ 70 km respectively) impacts to coastal areas above the low thresholds are not predicted. As the Operational Area is as close as ~7 km to the Victorian coast, there is the potential for diesel above the low threshold to be visible on the ocean surface in coastal waters and as a sheen on shoreline areas. Most of the diesel will be concentrated along the high tide mark while the lower/upper parts are often untouched (IPIECA 1995) and expected to be visible. Visible nearshore and shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities this can have a knock-on effect to local businesses if beaches are required to be closed to allow for the clean-up of any oil. Due to the low volumes, light nature of marine diesel and substantial wave action with the nearshore area's impacts are likely to be short term and not require intrusive clean-up response. The predicted level of consequence to coastal developments from a 250 m^3 MDO spill is assessed as moderate as exposure to oil above low thresholds could occur areas nearshore of the Operational Area, though if consequences occurred, they are likely to only affect a small portion of the coastal area for a short duration (hours to days) due to the low spill volume and short duration of any exposure, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.5.4 Indigenous Culture

Indigenous Culture	
Sensitivity Rating	**High**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	
The information provided below has been sourced from publicly available information and from consultation undertaken in preparing the EP. Within the Environmental Planning Area key values and sensitivities in relation to First Nations have been identified and described, through consultation and desktop research, documented in Appendix F3, Section 3.16. These include both tangible and intangibles, for example, Nyamat Mirring Indigenous Protected Area [currently under consultation], Deen Maar, Point Nepean & Mornington Peninsula, Southern Right Whales, Glass Eel, kelp and songlines. The relevant section of this document concerning the value is outlined in the Cultural Features Table, located in Appendix F3, Section 3.16.1. The Environmental Planning Area overlaps King Island which was part of a land bridge linking Tasmania with the Australian Mainland and was submerged around 12,000 years ago with rising sea levels. While uninhabited at the time of European discovery by Captain Reed in 1799 the first Tasmanians were a very mobile people, especially by water. They had a wide-ranging territory, travelling in season for hunting, gathering and ceremonial purposes. They built and used several different types of seaworthy boats and research suggests that they passed through but did not permanently inhabit King Island (KIC 2023). The Environmental Planning Area overlaps with the following Native Title determinations (Appendix B12 MAP-REG-EPM-92_A): Gunditj Mirring Traditional Owners Aboriginal Corporation (GMTOAC) on behalf of the Gunditjmara people. Eastern Maar Aboriginal Corporation (EMAC) on behalf of the Eastern Maar people. The Environmental Planning Area overlaps with the following Registered Aboriginal Parties' coastal areas in Victoria: Wadawurrung Traditional Owners Aboriginal Corporation (WTOAC) on behalf of the Wadawurrung people. Bunurong Land Council Aboriginal Corporation (BLCAC) on behalf of the Bunurong people. Non-exclusive rights linked to Native Title determinations, include access to the land and waters and resources therein, the use and enjoyment of lands and waters, camping, and the protection of areas of importance, such as the 'Convincing Grounds; (Appendix F3, Section 3.16.1). As per the Offshore Petroleum and Greenhouse Gas Storage Act 2006, Section 280, Requirement 2(e), offshore activities must carry out the activities in a manner that does not interfere with the enjoyment of native title rights and interests beyond what is necessary for the reasonable exercise of the rights granted under exploration titles.	

Indigenous Culture
Predicted Level of Risk
Due to the distance to the South Australian and King Island coastal areas from the Operational Area (~130 km and ~ 70 km respectively) impacts to coastal areas above the low thresholds are not predicted. As the Operational Area is as close as ~7 km to the Victorian coast, there is the potential for diesel above the low threshold to be visible on the ocean surface in coastal waters and as a sheen on shoreline areas. Most of the diesel will be concentrated along the high tide mark while the lower/upper parts are often untouched (IPIECA 1995) and expected to be visible. Visible nearshore and shoreline hydrocarbons have the potential to reduce the visual amenity of the area but impacts to cultural values are not predicted due to the low volumes, light nature of marine diesel and substantial wave action with the nearshore areas impacts are likely to be short term and not require intrusive clean-up response, with access, enjoyment and use of Native Title land and waters able to continue. The predicted level of consequence to coastal developments from a 250 m^3 MDO spill is assessed as moderate as exposure to oil above low thresholds could occur areas nearshore of the Operational Area, though if consequences occurred, they are likely to only affect a small portion of the coastal area for a short duration (hours to days) due to the low spill volume and short duration of any exposure, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.5.5 Protected Areas

Protected Areas	
Sensitivity Rating	**High**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	

There is one World Heritage Property adjacent to the Environmental Planning Area:

Budj Bim Cultural Landscape

The Budj Bim Cultural Landscape, located in the traditional Country of the Gunditjmara Aboriginal people in south-eastern Australia, is recognized for its world heritage values due to its ancient and sophisticated aquaculture systems. The Budj Bim lava flow is recognised as an attribute contributing to the Outstanding Universal Value of the Budj Bim World Heritage Site which extends into Portland Bay (Wheeler et al., 2023). The Gunditjmara people utilized the lava flows from the Budj Bim volcano to create an extensive network of channels, weirs, and dams. This network was designed to manage water flow for the systematic trapping, storing, and harvesting of Kooyang (short-finned eel - *Anguilla australis*), providing a sustainable economic and social base for their society over millennia. The Budj Bim Cultural Landscape connects to the coast through waterways and hence these waterways could theoretically be affected by surface oil. Surface oils are not however expected to travel upstream, nor be transported far enough inland to have an impact on the landscape. The coastal waterway that has the potential to be associated with oiling on a small scale is not predicted to impact the cultural values of this World Heritage Property.

The PMST Report for the Environmental Planning Area (Appendix B5) identified the following for protected areas.

National Heritage Places

Four places of National Heritage were identified in the Environmental Planning Area:

Great Ocean Road and Scenic Environs (Historic)

Point Nepean Defence Sites and Quarantine Station Area (Historic)

Quarantine Station and Surrounds (Historic)

Budj Bim National Heritage Landscape – Tyrendarra Area (Indigenous)

The Point Nepean Defence Sites and Quarantine Station Area is above the shoreline and hence would not be directly affected by oil. It is on the bay side of the Mornington Peninsula which is not predicted to be impacted by a spill.

The Quarantine Station and Surrounds is located towards the western end of the Nepean Peninsula on the shore of Port Phillip Bay. The building is on the bay side of the Mornington Peninsula which is not predicted to be impacted by a spill. To the east and south of the main building area the land rises to a height of about 40 metres which is not predicted to be impacted by a spill.The Tyrendarra Area of the Budj Bim Cultural Landscape in Western Victoria contains the remains of a complex system of natural and artificially created wetlands, channels, the stone bases of weirs and stone fish traps that were used by Gunditj Mara people to grow and harvest eels and fish. The remains on Tyrendarra are part of the same system as the remains in the Mt Eccles/Lake Condah area. The Budj Bim Cultural Landscape connects to the coast through waterways and hence these waterways could theoretically be affected by surface oil. Surface oils are not however expected to travel upstream, nor be transported far enough

Protected Areas
inland to have an impact on the landscape. The coastal waterway that has the potential to be associated with oiling on a small scale is not predicted to impact the cultural values of this World Heritage Property. The Great Ocean Road and Scenic Environs is above the shoreline and hence would not be directly affected by oil. However, the scenic environs could be impacted by surface or shoreline oil. The Australian Heritage Council found the Great Ocean Road and its scenic environs road from Torquay to Allansford, a journey of 242 kms, as a place of outstanding national heritage significance. Constructed by workers, including more than 3000 returned servicemen, as a memorial to First World War servicemen, the Great Ocean Road is a significant reminder of the participation of Australian servicemen in the First World War, the Australian community's appreciation of their service, and the support provided for the welfare of servicemen and women upon returning to Australia. The scenic environs include all views from the Great Ocean Road and Great Ocean Walk, including the Twelve Apostles, the Bay of Islands and Bay of Martyrs. The coastline from Lorne to Kennett River is among the world's most dramatic cliff and ocean scenery able to be viewed from a vehicle. Along the length of the Great Ocean Road, the pullover points and lookouts beside or nearby the road provide travellers with spectacular views of the coastline, hinterland, and Bass Strait seascape, framed only by cliffs, lighthouses and unencumbered by intrusive built structures. The place is also listed for its; outstanding rocky coastline, dinosaur fossil sites, geomorphological monitoring sites, its association with the pioneering landscape architect Edna Walling, and for the significance of Bells Beach to surfing. Commonwealth Heritage Places Six places of National Heritage were identified in the Environmental Planning Area Cape Northumberland Lighthouse SA (Historic, Listed place) Cape Wickham Lighthouse TAS (Historic, Listed place) Fort Queenscliff VIC (Historic, Listed place) Sorrento Post Office VIC (Historic, Listed place) Swan Island Defence Precinct VIC (Historic, Listed place) Swan Island and Naval Waters VIC (Natural, Listed place) Only the Swan Island and Naval Waters includes coastal areas within the Environmental Planning Area and is described. Swan Island is the largest emergent sand accumulation feature in Port Phillip Bay. The island, which has been built principally by wave actions rather than by aeolian forces, has played a major role in determining the pattern of sedimentation in Swan Bay and preserves geomorphological evidence of changing Quaternary sea levels. The eastern and northern shores of the eastern arm of Swan Island are of regional significance as an example of active coastal depositional and erosional processes (DCCEEW 2023c). Swan Island and adjacent naval waters provide important habitat for 46 water bird species, of which 26 species are listed under the Japan-Australia and China-Australia migratory bird agreements, and 8 species are listed under the Bonn Convention on Migratory Species (DCCEEW 2023c). During the migration season Swan Bay supports internationally significant populations of the Eastern Curlew, Ruddy Turnstone, Red-necked Stint, Sharp-tailed Sandpiper, Curlew Sandpiper, and Grey Plover (DCCEEW 2023c). Nationally significant populations of the Greenshank, Pacific Golden Plover, Double-banded Plover, and Lesser Sand Plover also occur (DCCEEW 2023c). Sand Island is the most important high tide roosting area in Swan Bay and at high tide regularly supports half of the shorebirds in the Swan Bay - Mud Islands complex.

Protected Areas
Ramsar Wetlands Four Ramsar Wetlands were identified in the Environmental Planning Area. Glenelg Estuary and Discovery Bay Key features of the site (DCCEEW 2023d): The Glenelg Estuary and Discovery Bay Ramsar Site is situated in western Victoria. It covers approximately 22,289 hectares and comprises portions of the Lower Glenelg National Park, the Discovery Bay Coastal Park and the Nelson Streamside Reserve. The Glenelg River estuary is the longest in the bioregion, extending 75 kilometres. The Ramsar site comprises three broad systems that support different wetland types: freshwater wetlands, the Glenelg Estuary and the beach and dune system. The site contains several regionally (and internationally) rare wetland types: intact fen peatlands and a humid dune slack system. The site: Supports the nationally vulnerable coastal saltmarsh ecological community and eight nationally / internationally listed threatened flora and fauna species. Provides habitat for 95 waterbird species including 24 species listed under international agreements. Beach nesting birds such as Hooded Plover (*Thinornis rubricollis*) and Red-capped Plover (*Charadrius ruficapillus*) are regularly recorded nesting on the dunes of the Discovery Bay Coastal Park. Supports 14 species of native fish which are diadromous, migrating between habitats for part of their lifecycle by providing food, spawning grounds and nurseries. It also acts as a migration path on which diadromous fishes of the region depend. Provides habitat for obligate aquatic species in the permanent wetlands of the Long Swamp complex and Bridgewater Lakes when the surrounding landscape is dry and during drought conditions. Supports > 1% of the population of the wetland dependent invertebrate species the Ancient Greenling (*Hemiphlebia mirabilis*) in the Baumea sedgelands. The area is popular for recreational and tourism activities, including sightseeing, walking, camping, and recreational fishing. Importantly, the Gunditjmara Indigenous people have a living association with the Ramsar site, which has great cultural significance for them, as it is part of their Koonang (sea) and Bocara Woorrowarook (river forest) country. Lavinia Key features of the site (DCCEEW 2023e): The Lavinia Ramsar site is located on the north-east coast of King Island, Tasmania. The boundary of the site forms the Lavinia State Reserve, with major wetlands in the reserve including the Sea Elephant River estuary area, Lake Martha Lavinia, Penny's Lagoon, and the Nook Swamps. The shifting sands of the Sea Elephant River's mouth have caused a large back-up of brackish water in the site, creating the saltmarsh which extends up to five kilometres inland. The present landscape is the result of several distinct periods of dune formation. The extensive Nook Swamps, which run roughly parallel to the coast, occupy a flat depression between the newer parallel dunes to the east of the site and the older dunes further inland. Water flows into the wetlands from the catchment through surface channels and groundwater and leaves mainly from the bar at the mouth of the Sea Elephant River and seepage through the young dune systems emerging as beach springs.

Protected Areas
The Lavinia State Reserve is one of the few largely unaltered areas of the island and contains much of the remaining native vegetation on King Island. The vegetation communities present on the site include Succulent Saline Herbland, Coastal Grass and Herbfield, Coastal Scrub and King Island Eucalyptus globulus Woodland. The freshwater areas of the Nook Swamps are dominated by swamp forest. Nook Swamps and the surrounding wetlands contain extensive peatlands. The site is an important refuge for a collection of regional and nationally threatened species, including the nationally endangered Orange-bellied Parrot. This parrot is heavily dependent upon the samphire plant, which occurs in the saltmarsh, for food during migration. They also roost at night in the trees and scrub surrounding the Sea Elephant River estuary. Several species of birds which use the reserve are rarely observed on the Tasmanian mainland, including the Dusky Moorhen, Nankeen Kestrel, Rufous Night Heron and the Golden-headed Cisticola. The site is currently used for conservation and recreation, including boating, fishing, camping and off-road driving. There are artefacts of Indigenous Australian occupation on King Island that date back to the last ice age when the island was connected to Tasmania and mainland Australia via the Bassian Plains. Piccaninnie Ponds Karst Key features of the site (DCCEEW 2023f): The Piccaninnie Ponds Karst Wetlands Ramsar Site is located in south-east South Australia, near Mount Gambier. It is an exceptional example of karst spring wetlands, with the largest and deepest of the springs reaching a depth of more than 110 m. The majority of the water comes from an unconfined regional aquifer and is consistently 14-15 degrees Celsius. The karst springs support unique macrophyte and algal associations, with macrophyte growth extending to 15 m below the surface as a result of exceptional water clarity. A number of different wetland types exist on the site, including a large area of peat fens. There are four distinct areas of the Ramsar site. Piccaninnie Ponds (also known as Main Ponds) consists of three interconnected bodies of water - First Pond, The Chasm and Turtle Pond - rounded by an area of shrub dominated swamp. Western Wetland consists of dense closed tea-tree and paperbark shrubland over shallow dark clay on limestone soils. Eastern Wetland includes the spring-fed Hammerhead Pond. Pick Swamp, on the extreme west of the site, includes areas of fen, marshes and sedgelands as well as the spring-fed Crescent Pond on peat soils. The system is an important remnant of an extensive system of wetlands that once occupied much of the south-east of South Australia. The major groundwater discharge points are Main Ponds, Hammerhead Pond and Crescent Pond. Water principally leaves the site via Outlet Creek and the Pick Swamp drain outlet, which connect the site to the sea. There are a number of fresh groundwater beach springs located on the site. The geomorphic and hydrological features of the site produce a complex and biologically diverse ecosystem which supports considerable biodiversity, including a significant number of species of national and/or international conservation value. These include the orange-bellied parrot, Australasian bittern and Yarra pygmy perch. The site attracts 20,000 visitors annually for cave diving, snorkelling, bushwalking, educational activities and birdwatching. The site also has spiritual and cultural value. The Traditional Owners of the land, the Bunganditj (Boandik) and local Indigenous people have a strong connection with the site. Traditionally the site provided a good source of food and fresh water, and evidence of previous occupation still exists. Port Phillip Bay (Western Shoreline) and Bellarine Peninsula Key features of the site (DCCEEW 2023g): The Port Phillip Bay (Western Shoreline) and Bellarine Peninsula Ramsar site is located in the western portion of Port Phillip Bay, near the city of Geelong in Victoria. The site comprises six distinct areas that include Point Cook/Cheetham, Werribee/Avalon, Point Wilson/Limeburners Bay, Swan Bay, Mud Islands, and the Lake Connewarre Complex.

Protected Areas
The Ramsar site is a low-lying area and a natural discharge point for the rivers draining southern central Victoria. The tidal amplitude within the bay is reduced compared with Bass Strait due to the narrow opening of the Bay (Port Phillip Heads). Port Phillip Bay (Western Shoreline) and Bellarine Peninsula support a variety of wetland types ranging from shallow marine waters to seasonal freshwater swamps and extensive sewage ponds. Wetland areas include freshwater lakes, estuaries, some with White Mangrove, saltmarshes, intertidal mudflats and seagrass beds. The Ramsar site supports some plants species threatened in Victoria, such as Small Scurf-pea and Rare Bitter-bush. This Ramsar site is the sixth most important area in Australia for migratory waders and the most important in Victoria. Large numbers of bird species including Pied Oystercatchers, Banded Stilts, Red-necked Stint, Sharp-tailed Sandpiper, Fairy Tern, Australasian Shoveler, Red-necked Avocets, Blue-billed Duck, and Freckled Duck, have been recorded at the site. Furthermore, the Melbourne Water Corporation Sewage Farm and Western Treatment Plant at Werribee support many waterbirds on its retention ponds. Port Phillip Bay (Western Shoreline) and Bellarine Peninsula provides important habitat for threatened species such as the Little Tern and Striped Legless Lizard. In particular, large numbers of the nationally threatened Orange-bellied Parrot utilise Port Phillip Bay during the winter after their summer migration to Tasmania to breed. Swan Bay and Limeburners Lagoon are also valuable fish breeding grounds for many of the commercial species caught in Port Phillip Bay. There are a number of important indigenous sites within the wetlands, including burial sites, middens and artefacts, with the oldest midden in the area being at least 5000 years old. Currently over three million people live around Port Phillip Bay, which is used intensively for recreation, nature conservation, sewage treatment, aquaculture, fishing, and salt production. Nationally Important Wetlands Information on Nationally Important Wetlands is from the DCCEEW Directory of Important Wetlands. The following wetlands have a coastal intersect. Aire River and Lower Aire River The Aire River is located in south-western Victoria. The Aire River reach is of high value for its flora and fauna which is of national and state significance, particularly its large continuous stands of cool temperate rainforest. There are fourteen threatened flora species within the Aire reach and its associated corridor of which two are listed nationally. There are twenty-seven threatened fauna species within the Aire River reach and its associated corridor of which five are listed nationally. Significant fauna species in the reach are the Cape Barren Goose, Ground Parrot, Rufous Bristlebird, Eastern Barred Bandicoot, and the Australian Grayling. Social values are trout fishing, picnicking, camping, and scenic driving are. Hopetoun Falls Scenic reserve is the most popular area for sight-seeing along the reach. There are approximately eighteen archaeological sites in the area, most of which are Aboriginal shell middens. The area also contains the site of the 1848 Katabanuut Aboriginal massacre. Glenelg River and Estuary The Glenelg River reach begins at Dartmoor, on the southern side of the Grampians National Park, and flows through the Lower Glenelg National Park to the sea at Nelson, near the Discovery Bay Coastal Park. There are 25 threatened flora species found within the Glenelg River reach and its associated corridor of which ten are listed nationally. The river reach provides an important habitat link between the inland woodland environments and coastal environments. There are seventy-two threatened flora species found within the Glenelg River reach and its associated corridor of which 12 are listed nationally. The river was a source a food supplies for the Dhauwurd Wurrung Aboriginal Group. Shell middens and surface scatters as well as isolated artefacts and a scarred tree around the coastal dunes have been found just outside the river reach. The Princess Margaret Rose Caves are of significant historical values and are listed as an historic place

Protected Areas
of regional significance. Patterson's Canoe Camp recreation area is also of regional significance. Tourism in the river reach is increasing in Nelson and the caves. Other attractions are bushwalking such as the Great South West Walk, camping, sight-seeing, picnicking, canoeing, fishing, motor-boating, house-boating and water-skiing. Lavinia Nature Reserve – see Lavinia Ramsar Wetland Description above. Lower Merri River The Lower Merri River Wetlands consist of two connected wetlands developed in a swale between calcareous dune ridges and fed by the Merri River. Lower Merri River Wetland is of high value for its avifauna. There are large areas of Common Reed Phragmites australis with Spiky Club-sedge, saltmarsh and mudflats. Also, of high value for its geomorphology and are a well-preserved example of interdunal wetlands fed by a small drainage system. The wetlands are used for hunting, walking and bird watching. The Mahogany Trail follows the edge of these wetlands. The Mahogany Ship is reputed to be buried under sand dunes adjacent to Saltwater Swamp. Surface scatters exist at Kelly Swamp indicating a history of Aboriginal occupation. Princetown Wetlands These wetlands consist of swamps of varying salinity on the floodplains of the Gellibrand River and its tributary, the Serpentine (Latrobe) Creek. Wetlands types present are a deep freshwater marsh, semi- permanent saline marshes and a shallow freshwater marsh. The Princetown Wetlands have extensive beds of Common Reed (Phragmites australis) and meadows dominated by Beaded Glasswort which can support large numbers of waterbirds. The saltmarsh habitat surrounding these swamps is likely to be important for migration of the Orange-bellied Parrot. Australasian Bittern and Lewin's Rail have been recorded. Camping, fishing, boating, and duck hunting occur within the wetlands. Swan Bay Swan Bay is a shallow marine embayment partly enclosed by spits and barrier islands such as Swan Island. It is generally <2 m in depth, with 700-1,000 ha of mudflats exposed at low tide, and has extensive seagrass beds. The bay is fringed with saltmarsh including some extensive flats and there are some stands of remnant woodland. The bay is of high value for its avifauna and flora. It is very productive for birds, molluscs, and fish. The saltmarsh and intertidal seagrass meadows are regionally significant. The avifauna is particularly diverse, with 190 bird species recorded. Swan Bay is a high value wetland for its ecological, recreational, and educational features. Swan Bay is an unusual shallow embayment with a mixture of seagrass species which is relatively undisturbed and in good ecological condition. Australian Marine Parks Four Australian Marine Parks (AMPs) were identified in the Environmental Planning Area (Appendix B12 MAP-REG-EPM-078). No direct impacts were predicted for any marine park, with the risk of accidental release of fuel being the only cause-effect pathway identified for these parks. Apollo The Apollo AMP is located off Apollo Bay on Victoria's west coast in waters 80 m to 120 m deep on the continental shelf. The reserve covers 1,184 km2 (DNP 2013). The reserve encompasses the continental shelf ecosystem of the major biological zone that extends from South Australia to the west of Tasmania. The area includes the Otway Depression, an undersea valley that joins the Bass Basin to the open ocean. Apollo AMP is a relatively shallow reserve with big waves and strong tidal flows; the rough seas provide habitats for fur seals and school sharks (DNP 2013). The major conservation values of the Apollo AMP (DNP 2013) are:

Protected Areas
Ecosystems, habitats, and communities associated with the Western Bass Strait Shelf Transition and the Bass Strait Shelf Province and associated with the seafloor features: deep/hole/valley and shelf. Important migration area for blue, fin, sei and humpback whales. Important foraging area for black-browed and shy albatross, Australasian gannet, short-tailed shearwater and crested tern. Cultural and heritage site - wreck of the MV City of Rayville. Franklin The Franklin AMP covers an area of 671 km2 west of the north-western corner of Tasmania and south-east of King Island (DNP 2013). At its northern end, the waters are only 40 m deep, and in much of the reserve the sea floor slopes gently and is covered by fine and coarse sediments. At the southern end of the reserve there is a valley where the water is up to 150 m deep. The major conservation values for the Franklin AMP (DNP 2013) are: Examples of ecosystems, habitats and communities associated with the Tasmanian Shelf Province and Western Bass Strait Shelf Transition and associated with sea-floor features shelf, deep/hole/valley, escarpment and plateau. Important foraging area for Shy Albatross, Short-tailed Shearwater, Australasian Gannet, Fairy Prion, Little Penguin, Common Diving petrel, Black-faced Cormorant and Silver Gull. Black Pyramid Rock, 6 km north of the reserve supports the largest breeding colony of the Australasian gannet in Tasmania, and one of only eight breeding sites for this species in Australia. White shark also forages in the reserve. Nelson The Nelson AMP spans the deepwater ecosystems (greater than 3,000 m depth) extending from South Australia to the west of Tasmania (DNP 2013). The reserve spans a range of geological features including plateaus, knolls, canyons and the abyssal plain (a large area of extremely flat or gently sloping ocean floor just offshore from the continent). The knoll features provide a rocky substrate above the abyssal plain. Little is known about the benthic biodiversity of this reserve; however, marine mammals are known to occur here. The major conservation values of the Nelson AMP (DNP 2013) are: Examples of ecosystems, habitats and communities associated with the West Tasmanian Transition and associated with the seafloor features including the abyssal plain/deep ocean floor, canyon, knoll/abyssal hill, plateau, and slope. Important migration area for Blue, Fin, Humpback and Sei whales. Zeehan The Zeehan AMP covers an area of 19,897 km2 to the west and south-west of King Island in Commonwealth waters surrounding north-western Tasmania (DNP 2013). It covers a broad depth range from the shallow continental shelf depth of 50 m to the abyssal plain which is over 3,000 m deep. The reserve spans the continental shelf, continental slope and deeper water ecosystems of the major biological zone that extends from South Australia to the west of Tasmania. Four submarine canyons incise the continental slope, extending from the shelf edge to the abyssal plains. A rich community made up of large sponges and other permanently attached or fixed invertebrates is present on the continental shelf, including Giant Crab. Concentrations of larval Blue Wahoo and Ocean Perch demonstrate the role of the area as a nursery ground.

Protected Areas
Rocky limestone banks provide important seabed habitats for a variety of commercial fish and crustacean species including the Giant Crab. The area is also a foraging area for a variety of seabirds such as Fairy Prion, Shy Albatross, Silver Gull, and Short Tail Shearwater (DNP 2013).
The major conservation values for the Zeehan AMP (DNP 2013) are:
Examples of ecosystems, habitats and communities associated with the Tasmania Province, the West Tasmania Transition and the Western Bass Strait Shelf Transition and associated with the seafloor features: abyssal plain/deep ocean floor, canyon, deep/hole/valley, knoll/abyssal hill, shelf and slope.
Important migration area for Blue and Humpback whales.
Important foraging habitat for Black-browed, Shy and Wandering albatrosses, and Great-winged and Cape Petrels.
Victorian Marine Parks and Sanctuaries
Four Victorian Marine National Parks (Appendix B12 MAP-REG-EPM-079) and six Marine Sanctuaries were identified in the Environmental Planning Area. In addition, two Conservation Parks, two Wildlife Reserves and three National Parks were identified as having coastal areas within the Environmental Planning Area.
The Narrwong Coastal Reserve and Yambuck Coastal Reserve are long stretches of beach between Narrawong and Porty Fairy, however, no information on the reserves could be found.
Barwon Bluff Marine Sanctuary
Barwon Bluff Marine Sanctuary (17 ha) is located at Barwon Heads, approximately 100 km south-west of Melbourne. The Barwon Bluff Marine Sanctuary Management Plan (Parks Victoria 2007a) identifies the environmental, cultural and social values as:
Intertidal reef platforms with a high diversity of invertebrate fauna and flora.
Subtidal reefs that support diverse and abundant flora, including kelps, other brown algae, and green and red algae.
Calcarenite and basalt reefs extending from The Bluff that are of regional geological significance.
Intertidal habitats that support resident and migratory shorebirds, including threatened species.
Subtidal habitats that support sedentary and mobile fish and are also used by migratory marine mammals.
Marine habitats and species that are of scientific interest and valuable for marine education.
Underwater recreation, including visits to subtidal communities that are easily accessible from the shore.
Coastal vistas, seascapes and underwater scenery.
Important landmark and area for gathering fish and shellfish for the Wathaurong people.
Strong historic and ongoing connection with marine education.
Remnants from the Earl of Charlemont, a heritage-listed shipwreck.
Bay of Islands Conservation Park

Protected Areas
This coastal park has outstanding ocean views and geological features and covers an extensive area of the coastline (~32 km in length and 950 ha), stretching east from Warrnambool to Peterborough. Sheer cliffs and rock stacks dominate the bays, and the heathlands contain wildflowers. Beaches are accessible at some points (Parks Victoria 1998). This park protects the terrestrial environment above the low water mark of this coastline. This Coastal Park is managed under the Port Campbell National Park and Bay of Islands Coastal Park Management Plan (Parks Victoria 1998). Discovery Bay Marine National Park and Coastal Park The Discovery Bay Marine National Park is situated 20 km west of Portland and covering 2,770 ha. It covers part of the largest coastal basalt formation in western Victoria. In deep water (30 – 60 m) there are low reefs from ancient shorelines or dunes. There is a rich diversity of marine life within this park due to the cold, nutrient rich waters of the area. The deep calcarenite reefs support diverse sponge gardens whilst the shallower reefs support the brown alga Ecklonia radiata. The offshore waters support a diverse array of invertebrates including southern rock lobster, black-lip abalone, and gorgonians. The waters also support great white sharks and blue whales during the summer breeding season. The Discovery Bay Marine National Park abuts the Discovery Bay Coastal Park which are managed via the Ngootyoong Gunditj Ngootyoong Mara South West Management Plan (Parks Victoria 2015). The Plan describes some key values of the Discovery Bay Marine National Park and Coastal Park, namely: Important shorebird habitat for migratory species listed under international agreements. Two Important Bird Areas, Lawrence Rocks Wildlife Reserve, which consists of two rocky islets off the coast from Portland with a resident Australasian Gannett population, and the Discovery Bay Coast through to Picaninnie Ponds in South Australia with resident populations of Australasian Bittern, Hooded Plover, Rufous Bristlebird and Striated Fieldwren, and non-breeding Orange-bellied Parrot. The Bonney Coast, which extends from Robe in South Australia to Discovery Bay, is a productive area because of a nutrient rich cold water upwelling, known as the Bonney Upwelling. This high productivity provides an important feeding ground for seabirds, fur seals and whales. It also greatly influences primary productivity and maintains commercially important fisheries species such as Blacklip Abalone and Southern Rock Lobster. The continental shelf and the Bonney Upwelling draws close to the coast near the township of Portland, and this makes the area a highly significant recreational fishery for Southern Bluefin Tuna. The Bonney Upwelling is also identified as culturally significant to the Gunditjmara People (Appendix F3, Section 3.16.1), with its current bringing cold nutrient-rich waters that support culturally significant species such as phytoplankton, fish, squid, seals, dolphins, whales, penguins, gannets and other sea birds (GMTOAC, 2023). Subtidal Reefs with six key natural assets – Brown macroalgae dominated beds, large mobile fish including sharks and rays, motile macroinvertebrates, Giant Kelp Forest communities, sessile invertebrate dominated communities such as thick growths of sponges, ascidians, bryozoans and gorgonians, and mixed red algae sessile invertebrate dominated communities. Great Otway National Park The Great Otway National Park (103,185 ha) is located near Cape Otway and stretches from the low water mark inland on an intermittent basis from Princetown to Apollo Bay (approximately 100 km). Landscapes within the park are characterised by tall forests and hilly terrain extending to the sea with cliffs, steep and rocky coasts, coastal terraces, landslips, dunes and bluffs, beaches and river mouths. There is a concentration of archaeological sites along the coast, coastal rivers and reefs. The park contains many sites of international and national geological and geomorphological significance including Dinosaur Cove (internationally significant dinosaur fossil site), Lion Headland and Moonlight Head to Milanesia Beach (internationally significant coastal geology and fossils). The park provides habitats for the conservation of the Rufous Bristlebird, Hooded Plover, White-bellied Sea Eagle, Fairy Tern, Caspian Tern and Lewin's Rail and native fish such as the Australian Grayling.

Protected Areas
The park contains significant Aboriginal cultural sites adjacent to rivers, streams and the coastline including over 100 registered archaeological sites, particularly shell middens along the coast, as well as non-physical aspects such as massacre sites, song lines, family links and stories. The park also contains four sites listed on the Victorian Heritage Register including the Cape Otway Light Station and several shipwreck features along the coast (Parks Victoria and DSE 2009). This park protects the terrestrial environment above the low water mark of this coastline. The Park is protected under the Great Otway National Park and Otway Forest Park Management Plan (Parks Victoria and DSE 2009) and relevant values are: Large area of essentially unmodified coastline, linking the land to marine ecosystems and marine national parks. Diverse range of lifestyle and recreation opportunities for communities adjacent to the parks – for local permanent residents and holiday homeowners Regionally, nationally and internationally. Significant tourist attractions, close to access routes and accommodation, such as spectacular coastal scenery along the Great Ocean Road, access to beautiful beaches, clifftop lookouts, picnic areas, historic sites, waterfalls and walking tracks such as the Great Ocean Walk. Basis for continued growth of nature-based tourism associated with the parks and the region, providing economic opportunities for accommodation providers, food and services providers, and recreation, tourism and education operators. Lady Julia Percy Island Wildlife Reserve Lady Julia Percy Island is off the coast of Victoria 22 km south-west of Port Fairy. It is one of the two largest breeding sites for the Australian fur seal species in Australia (DCCEEW 2023h) and provides habitat to migratory seabirds. Lawrence Rocks Wildlife Reserve Lawrence Rocks Wildlife Reserve consists of two small islets about 6.8 ha and 1.5 ha in area that lie about 2 km offshore from Point Danger and about 6 km south-east of Portland in western Victoria (BirdLife International 2023). The islets are composed of basaltic and tuff rock. The habitat on the islets consists of exposed rock and some patches of exotic grasses and native and exotic herbs. The Australasian Gannet breeds on both islets in the IBA. Lawrence Rocks supports a small population of the Australian Fur Seal. BirdLife International have deemed Lawrence Rocks an Important Bird Area (BirdLife International 2023). Marengo Reefs Marine Sanctuary The Marengo Reefs Marine Sanctuary (12 ha) is in Victorian State waters near Marengo and Apollo Bay, which are on the Great Ocean Road, approximately 220 km south-west of Melbourne. The sanctuary protects two small reefs and a wide variety of microhabitats. Protected conditions on the leeward side of the reefs are unusual on this high wave energy coastline and allow for dense growths of bull kelps and other seaweed. There is an abundance of soft corals, sponges, and other marine invertebrates, and over 56 species of fish have been recorded in and around the sanctuary. Seals rest on the outer island of the reef and there are two shipwrecks (the Grange and Woolamai) in the sanctuary (Parks Victoria 2007). The Marengo Reefs Marine Sanctuary Management Plan (Parks Victoria 2007) identifies the environmental, cultural and social values as: Subtidal soft sediments, subtidal rocky reefs and intertidal reefs. High diversity of algal, invertebrate and fish species. Australian fur seal haul out area. Evidence of a long history of Indigenous use, including many Indigenous places and objects nearby.

Protected Areas
Wrecks of coastal and international trade vessels in the vicinity of the sanctuary.
Spectacular underwater scenery for snorkelling and scuba diving.
Intertidal areas for exploring rock pools.
Opportunities for a range of aquatic recreational activities including seal watching.
Merri Marine Sanctuary
The Merri Marine Sanctuary is on the Victorian south-west coast near Warrnambool, approximately 260 km west of Melbourne. Merri Reefs Marine Sanctuary (25 ha) is located at the mouth of the Merri River, west of Warrnambool Harbour. Merri Marine Sanctuary contains a mixture of habitats, including intertidal reef, sand, shallow reef and rocky overhang. These areas provide a nursery for many fish species and a habitat for many algae species, hardy invertebrates and shorebirds. Bottlenose dolphins and fur seals are regular visitors to the shore (Parks Victoria 2007c).
The Sanctuary is protected with the Merri Marine Sanctuary Management Plan (Parks Victoria, 2007c) identifies the environmental, cultural and social values as:
Culturally significant to indigenous communities that have a long association with the area.
Merri River, wetlands and islands and headlands provide a variety of habitats.
Provision of nursery for many fish species and habitat for algal species, hardy invertebrates and shorebirds.
Mornington Peninsula National Park
Mornington Peninsula National Park is situated about 70 km south of Melbourne. Mornington Peninsula National Park runs along the coast from Point Nepean, at the western tip of the Mornington Peninsula, to Bushrangers Bay, where it turns inland along the Main Creek valley, still as a narrow band, until it joins the more expansive Greens Bush section of the Park. This park protects the terrestrial environment above the low water mark of this coastline. The Park is managed under the Mornington Peninsula National Park and Arthurs Seat State Park Management Plan, which has identified the key environmental, social and cultural values as (Parks Victoria 2016):
Largest and most significant remaining areas of native vegetation on the Mornington Peninsula. Numerous sites and features of geomorphic significance, particularly along the coast (cliffed calcarenite coast sandy forelands and basalt shore platforms).
Only representation in the Victorian conservation reserve system of four land systems formed within the Southern Victorian Coastal Plains and the Southern Victorian Uplands.
Many significant native plants and vegetation communities, especially in Greens Bush and former McKellar Flora Reserve, and the most extensive remnant coastal grassy forest habitat on the Mornington Peninsula.
Highly scenic landscape values along the ocean coast and at Port Phillip heads and the prominent landscape feature of Arthurs Seat.
Many significant fauna species, including populations of the nationally significant hooded plover, over 30 species of State significance and many species of regional significance.
High quality marine and intertidal habitats, with some pristine areas within Point Nepean.
Nationally significant and fascinating historic sites at Point Nepean.
Historic Seawinds Gardens in Arthurs Seat State Park.

Protected Areas
One of the highest recorded densities of Aboriginal archaeological sites along the Victorian Coast
South Channel Fort is an important component of the historic fortification defence system of Port Phillip (and an important bird nesting and roosting site).
Spectacular scenery and popular surf beaches associated with a wild and rugged coastline.
Local and regional economic benefits.
Intensively used recreational nodes, e.g. at Portsea, Sorrento, Cape Schanck and Arthurs Seat.
Point Addis Marine National Park, Point Danger Marine Sanctuary and Eagle Rock Marine Sanctuary
The three protected areas are managed under the Management Plan for Point Addis Marine National Park, Point Danger Marine Sanctuary and Eagle Rock Marine Sanctuary (Parks Victoria 2005).
Point Addis Marine National Park lies east of Anglesea and covers 4,600 hectares. The park protects representative samples of subtidal soft sediments, subtidal rocky reef, rhodolith beds and intertidal rocky reef habitats. The park also provides habitat for a range of invertebrates, fish, algae, birds and wildlife. The world-famous surfing destination of Bells Beach is within the park.
Point Danger Marine Sanctuary is 20 km south-west of Geelong, close to the township of Torquay and nearby Jan Juc and covers 25 ha. It extends from the high-water mark at Point Danger offshore for approximately 600 m east and 400 m south, encompassing an offshore rock platform.
Eagle Rock Marine Sanctuary is about 40 km south-west of Geelong, close to Aireys Inlet and covers 17 ha. The sanctuary extends from high water mark around Split Point between Castle Rock and Sentinel Rock. It extends offshore for about 300 m and includes Eagle Rock and Table Rock. The main habitats protected by the sanctuary include intertidal and subtidal soft sediment, intertidal and subtidal reefs, and the water column.
The management plan identifies the following environmental, cultural, and social values for the parks and sanctuaries:
Sandy beaches, subtidal soft sediments, subtidal rocky reefs, rhodolith beds and intertidal reefs.
High diversity of algal, invertebrate and fish species.
High diversity of sea slugs (opisthobranchs) and other invertebrate communities within Point Danger Marine Sanctuary.
Evidence of a long history of Indigenous use, including many Indigenous places and objects adjacent to the park and sanctuaries near dunes, headlands, estuaries and creeks.
Surf breaks, including those at Bells Beach, which are culturally important to many people associated with surfing.
Coastal seascapes of significance for many who live in the area or visit.
Recreational and tourism values
Spectacular underwater scenery for snorkelling and scuba diving.
Intertidal areas for exploring rock pools.
Opportunities for a range of recreational activities.
Spectacular seascape complementing well-known visitor experiences on the Great Ocean Road.

Protected Areas
Port Campbell National Park
Port Campbell National Park is slightly west of Twelve Apostles Marine National Park and 10 km east of Warrnambool. The park is 1,750 ha that presents an extraordinary collection of wave-sculptured rock formations. Port Campbell National Park is home to various fauna such as the little penguin, short-tailed shearwater, and various whale species (Parks Victoria 1998).
Port Phillip Heads Marine National Park
Port Phillip Heads Marine National Park is an area of 35.8 km2 that is located at the southern end of Port Phillip Bay. Many areas within the Port Phillip Heads Marine National Park are popular for a range of recreational activities. The habitats that are found within the park are seagrass beds, sheltered intertidal mudflats, intertidal sandy beaches and rocky shores, subtidal soft substrate and rocky reefs. The bay has a high diversity and abundance of marine flora and fauna that provides a migratory site for wader birds (Visit Victoria 2019). The land adjacent to the Port Phillip Heads Marine National Park is within the Port Nepean National Park.
Twelve Apostles Marine National Park and The Arches Marine Sanctuary
The Twelve Apostles Marine Park is managed in conjunction with the Arches Marine Sanctuary under the Twelve Apostles Marine National Park and The Arches Marine Sanctuary Management Plan (Parks Victoria 2006).
The Twelve Apostles Marine National Park (7,500 ha) is located south-east of Port Campbell between Broken Head and Pebble Point and extends offshore 3 nautical miles to the limit of Victorian waters (Parks Victoria 2006).
The area is representative of the Otway Bioregion and is characterised by a submarine network of towering canyons, caves, arches, and walls with a large variety of seaweed and sponge gardens plus resident schools of reef fish. The park contains areas of calcarenite reef supporting the highest diversity of intertidal and sub-tidal invertebrates found on that rock type in Victoria (Parks Victoria 2006).
The Arches Marine Sanctuary (45 ha) is approximately 600 m offshore from Port Campbell. It has a spectacular dive site of limestone formations, rocky arches, and canyons. The sanctuary is also ecologically significant, supporting habitats such as kelp forests and a diverse range of sessile invertebrates on the arches and canyons. These habitats support schools of reef fish, seals and a range of invertebrates such as lobster, abalone and sea urchins.
The Twelve Apostles Marine Park is managed in conjunction with the Arches Marine Sanctuary under the Management Plan for Twelve Apostles Marine National Park and The Arches Marine Sanctuary (Parks Victoria 2006b) and is classified as IUCN II. The Plan describes the key environmental, cultural, and social values as:
Unique limestone rock formations, including the Twelve Apostles.
Range of marine habitats representative of the Otway marine bioregion.
Indigenous culture based on spiritual connection to sea country and a history of marine resource use.
Wreck of the Loch Ard (shipwreck).
Underwater limestone formations of arches and canyons.
Diverse range of encrusting invertebrates.
Spectacular dive sites.
South Australian Marine and Coastal Conservation Parks
Lower South East Marine Park

Protected Areas
The Lower South East Marine Park Management Plan 2012 (DEWNR 2012) details the following values:
High diversity of plants and animals, including blue whales, due to the influence of the Bonney coast upwelling, an ocean current that supplies nutrient-rich water to the area.
Diverse range of habitats ranging from high-energy sandy beaches and freshwater springs, various reef types (shore platforms, fringing and limestone),
Kelp forests and algal communities and is strongly influenced by natural processes such as the Bonney coast upwelling.
Spring lakes such as Ewen Ponds and Piccaninnie Ponds (both Wetlands of National Importance) emerge from the beaches and are unusual in South Australia.
Habitat for several threatened or potentially threatened species that require freshwater and marine environments during their lifecycle, including the pouched lamprey, short-headed lamprey and shortfinned eel.
Feeding and resting grounds for migratory and resident shorebirds.
Recreational activities including fishing, diving and snorkelling.
Commercial fisheries including the Southern Zone Abalone Fishery, the Southern Zone Rock Lobster Fishery, the Marine Scalefish Fishery, the Charter Fishery and the Miscellaneous Giant Crab Fishery.
Buandig Aboriginal people have traditional associations with areas of the marine park.
Douglas Point Conservation Park
Douglas Point Conservation Park provides scenic views of the coastline and is home to a rare daisy that is only found in three other sites in Australia. The coastal park features areas of exposed limestone, sea cliffs, small sandy beaches and dense coastal vegetation, and provides for fishing, diving and bushwalking. The park is managed under the Douglas Point Conservation Park Management Plan (DEH 2003a).
Values of the park (DEH 2003) are:
The only reserved population of Sand Ixodia in Australia.
Conserves vulnerable (SA) Rufous Bristlebird and rare (SA) Beautiful Firetail, regionally uncommon coast velvet-bush and drooping velvet-bush.
Nationally endangered Orange-bellied Parrot recorded in the Park.
The Park is located within the traditional lands of the Boandik people. The remains of scattered middens are evidence of Aboriginal habitation in the past.
Shipwrecks.
Nene Valley Conservation Park
Nene Valley Conservation Park preserves an area of vegetation typical of sandy coasts in the south-east of South Australia. This vegetation complex has suffered through the effects of clearing and grazing throughout much of its former range.
Piccaninnie Ponds Conservation Park
The Piccaninnie Pond covers an area of 8.64 km2, that has a wide diversity of fauna and flora with 60 bird species and six vegetation communities. Other vegetation found within the park includes reeds, sedge swamp, open heath and tussock grassland.

Protected Areas
Tasmanian Marine and Coastal Parks and Reserves
Black Pyramid Rock Nature Reserve
Black Pyramid Rock Nature Reserve, situated of Hunter Island has a land mass of 40 ha. Black Pyramid Rock was proclaimed a Wildlife Sanctuary on 30 June 1964 due to it being the largest known breeding ground for Australasian gannets in Australia (DPIWE 2020). The Nature Reserve is managed under the Small Bass Strait Island Reserves Draft Management Plan (DPIWE 2020).
Cape Wickham State Reserve
The Cape Wickham State Reserve is on the northern tip of King Island and contains Cape Wickham lighthouse and the gravesites of the crew of Loch Leven, a ship that was wrecked nearby. It is designated as IUCN Category V which is a protected landscape/seascape.
Christmas Island Nature Reserve
Christmas Island is located off the west coast of King Island. It is designated IUCN 1a which is a strict nature reserve, which allows minimal human use. It is a BIA for both breeding and foraging for the little penguin (Commonwealth of Australia, 2015a). It is also a known nesting site of the Little Tern. Christmas Island Nature Reserve is a priority site for management under the King Island Biodiversity Management Plan (TSS 2012).
Councillor Island Nature Reserve
Councillor Island Nature Reserve is a 10.53 ha granite reserve east of Tasmania approximately 2.5 km off the mainland coastline of Tasmania within the Bass Strait. The island forms part of the King Island Important Bird Area because of its importance for breeding seabirds and waders.
Disappointment Bay State Reserve
The Disappointment Bay State Reserve is located on the north coast of King Island near Cape Wickham.
Lavinia State Reserve
Lavinia State Reserve is located on the north-east coast of King Island. The reserve contains a number of rare birds, including the endangered orange-bellied parrot (DELWP 2016). It includes the Lavinia Ramsar site and two freshwater lakes. Lavinia Beach is a popular location for surfing and fishing. The Lavinia Nature Reserve (Ramsar Site) Management Plan draft (2000) is not available online. The Sea Elephant Estuary which is within the Lavinia State Reserve is a priority site for management under the King Island Biodiversity Management Plan (TSS 2012).
Reid Rock Nature Reserve
Reid Rocks are situated approximately 21.5 km east-south-east of Stokes Point at the southern extremity of King Island in western Bass Strait. The main islet is approximately 500 m long and rises to 13 m above sea level. Reid Rocks became a Nature Reserve on 5 April 1978 due to their importance as an Australian fur seal breeding colony (DPIWE 2020). The Nature Reserve is managed under the Small Bass Strait Island Reserves Draft Management Plan (DPIWE 2020).
Seal Rock State Reserve
Seal Rock State Reserve is located on the south-east coast of King Island. Species and vegetation communities are seabird rookeries, shining dogwood, triggerplants and coastal complex on King Island. Seal Rock State Reserve is a priority site for management under the King Island Biodiversity Management Plan (TSS 2012).
Predicted Level of Risk

Protected Areas
Due to the distance to the South Australian and King Island coastal areas from the Operational Area (~130 km and ~ 70 km respectively) impacts to coastal areas above the low thresholds are not predicted. As the Operational Area is as close as ~7 to the Victorian coast, there is the potential for diesel above the low threshold to be visible on the ocean surface in coastal waters and as a sheen on shoreline areas. Most of the diesel will be concentrated along the high tide mark while the lower/upper parts are often untouched (IPIECA 1995) and expected to be visible. Visible nearshore and shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities within protected areas. Due to the low volumes, light nature of marine diesel and substantial wave action with the nearshore areas impacts are likely to be short term and not require intrusive clean-up response. The predicted level of consequence to protected areas and their values from a 250 m^3 MDO spill is assessed as moderate as exposure to oil above low thresholds could occur in protected areas nearshore of the Operational Area, though if consequences occurred, they are likely to only affect a small portion of coastal areas or marine areas for a short duration (hours to days) due to the low spill volume and short duration of any exposure, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.

9.5.6 Seaweed Industries

Seaweed Industry	
Sensitivity Rating	**Medium**
Predicted Level of Risk	**Low**
Environmental Planning Area Existing Environment	
The Australian seaweed industry is small: currently valued at an estimated GVP of AUD $3 million. Of this, the majority is from one company, Kelp Industries Pty Ltd on King Island in Tasmania, who hand collect plants cast bull kelp (*Durvillea pototorum*) on the beaches from predominantly the west coast of the island, predominantly for export to a large alginate manufacturer and for use in biofertiliser products (Australian Seaweed Institute 2023). Australia Bureau of Statistics (ABS) data shows seaweed exports from Australia are valued at $1.5 million for non-human consumption and it is assumed that this is almost entirely from Kelp Industries exports. Besides Kelp Industries, other seaweed collectors in Tasmania include Kelpomix and TasKelp. There are also licenses for wild harvest of the invasive species of *Undaria* in Tasmania (KaiHo Ocean Treasure) and some in Victoria (Australian Seaweed Institute 2023). The harvesting of native seaweed in Victorian marine waters is prohibited without a permit (s. 112(2) Fisheries Act 1995) and licences enabling seaweed aquaculture are not currently available in Victoria (VFA 2023b). While there are numerous research projects taking place or being planned, currently there are two projects in Tasmania (Australian Seaweed Institute 2023). The first, is a CRC-P project involving collaboration with Tassal, Spring Bay Seafoods and University of Tasmania (UTAS). This project aims to demonstrate the benefits of Kelps as part of an integrated multitrophic aquaculture approach. The second is a research collaboration between UTAS and Huon Aquaculture in Storm Bay that will also yield its first harvest in late 2020. The west coast of King Island where bull kelp is collected is within the Environmental Planning Area.	
Predicted Level of Risk	
Experiments verified the susceptibility of *Nereocystis luetkeana* (bull kelp – north America) tissue to the direct exposure to several petroleum types. Antrim et al (1995) showed that petroleum treatments resulted in visible tissue damage, with a distinct bleached line being the most visible indication of plant contact with the petroleum. Moderate to heavy colour loss, which was generally followed by rapid decay of tissue, was most pronounced in 24 h exposures to unweathered and weathered diesel. The study did not look at how this would affect the productivity of bull kelp. Bull kelp affect by oil would not be suitable for collection and processing which could result in a temporary closure to the industry and a perception of tainting of product. This could lead to financial losses to kelp collection and processing businesses. However, given the distance to King Island from the Operational Area oil exposure above low threshold levels are not predicted and thus impacts are unlikely to be a significant to seaweed collection and associated income. The relatively short duration and low volume means there may be short-term and localised consequences, which are ranked as Moderate. Thus, the predicted level of consequence to seaweed industries from a 250 m^3 MDO spill is assessed as minor as exposure is likely to be below low thresholds and any consequences would be short-term (days to weeks), recoverable and affect a small portion of bull kelp, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of low.	

9.5.7 Tourism Including Diving and Recreational Fishing

Tourism including Diving and Recreational Fishing	
Sensitivity Rating	**High**
Predicted Level of Risk	**Medium**
Environmental Planning Area Existing Environment	
The coastal areas of the Environmental Planning Area offer a wide and diverse range for marine based tourism and recreational activities, including snorkelling, scuba diving, surfing, kayaking, whale, and wildlife watching, sailing and charter boat cruises. Popular tourist destinations in the Environmental Planning Area include Portland, Port Fairy, Warrnambool, the Great Ocean Road, Great Otway National Park, and King Island. The west coast of Victoria from Warrnambool to Portland is known as reliable spots to catch tuna, kingfish, and trevalla in areas such as Lawrence Rock, the North Shore, Lady Julia Percy Island, Killarney, The Crags, Minerva Reef, Julia Reef and the Horseshoe off Cape Bridgewater (VFA 2023a). May, June, and July are reliable months to find schools of bluefin tuna (VFA 2023c). The Arches Marine Sanctuary and Twelve Apostles Marine National are well known locally for excellent scuba diving sites (Parks Victoria 2006) Seal and Dolphin watching occur within Discovery Bay Marine National Park and Deen Maar (Lady Julia Percy Island).	
Predicted Level of Risk	
Due to the distance to the South Australian and King Island coastal areas from the Operational Area (~130 km and ~ 70 km respectively) impacts to coastal areas above the low thresholds are not predicted. As the Operational Area is as close as ~7 km to the Victorian coast, there is the potential for diesel above the low threshold to be visible on the ocean surface in coastal waters and as a sheen on shoreline areas. Most of the diesel will be concentrated along the high tide mark while the lower/upper parts are often untouched (IPIECA 1995) and expected to be visible. Visible nearshore and shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities. Due to the low volumes, light nature of marine diesel and substantial wave action with the nearshore areas impacts are likely to be short term and not require intrusive clean-up response. The predicted level of consequence to tourism and recreation from a 250 m^3 MDO spill is assessed as moderate as exposure to oil above low thresholds could occur in areas nearshore of the Operational, though if consequences occurred, they are likely to only affect a small portion of the coastal area for a short duration (hours to days) due to the low spill volume and short duration of any exposure, the likelihood is assessed as rare (based on the absence of any reported seismic vessel collisions in Australia) resulting in a predicted level of risk of medium.	

Circumstances resulting in a loss of containment of MDO such as a vessel collision and subsequent fuel tank rupture) are low probability events in open ocean areas without restricted navigation. Though shipping activity is relatively high within the Operational Area, modern navigational aids assist in reducing the likelihood of a collision event.

There have been no vessel collisions during a seismic survey in Australia. While undertaking the survey the seismic and support vessels will be moving at a slow speed of up to 10 km/hr and the seismic vessel will always have at least one vessel with it to observe and respond to any vessels that come to close to the seismic vessel, thereby further reducing the risk of collision with third-party vessels. Therefore, the likelihood of a vessel collision resulting in a loss of a full tank of MDO is rare.

9.6 Measures Adopted to Manage Environmental Risks

The following measures have been adopted to ensure that the risks associated with potential accidental release of fuel from the survey and support vessels will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
Consultation Management System	System	CGG will implement the Consultation Management System to ensure that pre and during survey communications will be undertaken so that other marine users know when, where and how the Regia MSS will be undertaken so they can undertake their activities in a manner that avoids any interactions or can engage with CGG so that both parties can plan activities in a manner that minimises potential displacement to each party.
CGG Marine Assurance System	System	The marine assurance system, amongst other requirements, ensures compliance of contract vessels with MARPOL, COLREGS, and Marine Orders 21, 30, 59 70,71,72, 91, 95, 96, 97, 98.
Vessel Bunkering Procedure	Procedure	A procedure which ensures that good practice and industry standards are applied to bunkering operations at sea, including the use of standard bunkering equipment such as dry-break couplings and prior-to-use inspections of bunkering hoses, equipment maintenance records, and certification. The procedure outlines how to undertake a safe transfer (e.g. safety, communication, monitoring, inventory, emergency shut down, spill response and incident reporting).
CGG Technical Operations Manager	Person	CGG will notify any incidents in accordance with the procedures in the OPEP and OSMP and execute the response strategies outlined in the OPEP and OSMP.
OVID Style Inspection	Practice	OVID-Style inspections confirm that the seismic vessel has procedures for streamer inspection, maintenance, deployment, and retrieval.
Petroleum SIMOPS Plan	Resource	A simultaneous operations plan will be developed if the seismic vessels or any equipment will enter the 500 m Petroleum Safety Zone of the Thylacine-A platform.
Oil Pollution Emergency Plan	Resource	The Oil Pollution Emergency Plan (OPEP) for the Regia MSS is a comprehensive document designed to address potential oil spill incidents during operations. This OPEP are crafted to align with the national system for oil spill preparedness and response, ensuring consistency with established protocols and coordination mechanisms. It outlines specific procedures, responsibilities, and resources necessary to respond to any oil spill event promptly and effectively. The OPEP must be submitted as part of the Implementation Strategy and must therefore be accepted by NOPSEMA prior to the activity commencing.
Oil Spill Monitoring Plan	Resource	The Operational and Scientific Monitoring Program (OSMP) for the Regia MSS is a comprehensive document designed to address potential oil spill incidents during operations. This OSMP are crafted to align with the national system for oil spill preparedness and response, ensuring consistency with established protocols and coordination mechanisms. It outlines specific procedures, responsibilities, and resources necessary to respond to any oil spill event promptly and effectively. The OSMP must be submitted as part of the Implementation Strategy and must therefore be accepted by NOPSEMA prior to the activity commencing.

10 Demonstration Risks Will Be of An Acceptable Level

10.1 Discussion on Principles of ESD

Temporary, Reversible, Small Scale and Natural variation

The accidental release of fuel during the petroleum activity is considered highly unlikely due to the presence of robust vessel management systems and stringent operational procedures. In the unlikely event of a release, the environmental consequences are expected to be temporary, reversible, and of low intensity, with the scale of potential impact limited by emergency response measures. The activity includes proactive controls to prevent releases and comprehensive response frameworks to ensure impacts remain small-scale and within acceptable environmental thresholds.

Based on sufficient information

The risk assessment process for fuel release incorporates expert judgment, incident history, and site-specific operational data. Modelling of potential spill scenarios, along with knowledge of fuel behaviour in marine environments, informs the assessment. The application of the precautionary principle and alignment with national planning frameworks ensures the evaluation is both conservative and scientifically valid. Monitoring plans are in place to verify assumptions and measure real-world environmental responses.

Activity not inconsistent with EPBC Act

The planned activity and its response measures are not inconsistent with relevant EPBC Act recovery and management plans. The implementation of a scientifically defensible Operational and Scientific Monitoring Plan (OSMP), as well as alignment with the National Plan for Maritime Environmental Emergencies, ensures compliance with applicable legislation and guidance. These measures support a structured and legally consistent approach to managing environmental risk.

10.2 Biological and Ecological Categories

Accidental fuel release poses a potential risk to marine species and habitats. However, due to comprehensive prevention systems and spill response capabilities, impacts and risks to biological and ecological features are expected to be low. In the event of a release, the affected area would be limited and short-term, with natural recovery likely and no predicted population-level impacts. Ecosystem structure, diversity, and function are expected to remain intact, with no long-term or irreversible ecological consequences.

10.3 Discussion on Economic, Cultural and Social Categories

Fuel spills have the potential to disrupt fishing, tourism, and culturally important marine resources. However, the likelihood of such outcomes is minimal due to CGG's effective control systems and rapid-response plans. Economic activities dependent on the marine environment are not expected to suffer long-term impacts. Culturally significant practices and community access to marine areas will not be interrupted or diminished in their value. The social fabric of coastal communities and stakeholders reliant on the marine environment will remain unaffected in any lasting way.

10.4 Discussion on Consistency with Company Processes

The risk of fuel release has been assessed in line with CGG's internal environmental risk framework, which incorporates global industry best practice and aligns with national emergency response protocols. Fuel management and emergency preparedness are embedded into CGG's standard operations, with no previous record of significant releases. The company's risk matrix, when applied to this activity, confirms the likelihood of unacceptable impacts is very low. CGG's history of operational integrity and environmental performance underpins the credibility of its risk assessments and supports its ability to deliver environmentally responsible operations.

This chapter predicts the levels of risk to environmental receptors within the Environment Planning Area of the Regia MSS. The survey vessels and support vessels will carry an inventory of oils and fuel and though it is unlikely that a spill will occur during operations the risk is part of carrying out the activity. A summary of the outcomes of the risk assessment is provided in Table D4-3.

Table D4-3 - Summary of Risk Assessment Outcome for Accidental Release of Fuel.

Receptor	Sensitivity	Consequence	Likelihood	Predicted Level of Risk
Water Quality	Medium	Minor	Rare	Low
Sediment Quality	Low	Minor	Rare	Low
Benthic Assemblages	Medium	Moderate	Rare	Medium
Coastal Habitats & Communities	Medium	Moderate	Rare	Medium
Plankton	Low	Minor	Rare	Low
Invertebrates	Low	Minor	Rare	Low
Fish	Low	Minor	Rare	Low
Birds	Medium – seabirds	Minor	Rare	Low – seabirds, aquatic birds
	High – aquatic birds, shorebirds	Moderate	Rare	Medium - Shorebirds
Marine Reptiles	Medium	Minor	Rare	Low
Marine Mammals	Medium	Moderate	Rare	Medium
Coastal Developments	High	Moderate	Rare	Medium
Indigenous Culture	High	Moderate	Rare	Medium
Commercial Fisheries	Medium	Moderate	Rare	Medium
Seaweed Industry	Medium	Minor	Rare	Low
Marine Industries	Medium	Minor	Rare	Low
Tourism (inc. Diving and Recreational Fishing	High	Moderate	Rare	Medium
Protected Areas	High	Moderate	Rare	Medium

11 Environmental Performance Outcomes

Defined Acceptable Level (From Section 6)	Environmental Performance Outcome	Rationale
Prevent any accidental release of fuel to the marine environment.	No accidental release of fuel to the marine environment.	Preventing fuel release at the source is the most effective way to protect the marine environment. Implementation of preventative measures, such as robust fuel handling procedures and regular maintenance of equipment, ensures environmental integrity and compliance with relevant legislation.
Have comprehensive emergency response plans, aligned with the National Plan for Maritime Environmental Emergencies, in place to mitigate consequences.	Maintain arrangements to respond to an unplanned release of fuel in accordance with the OPEP.	The development and maintenance of an Oil Pollution Emergency Plan (OPEP) ensures preparedness to manage and contain any unplanned releases. Alignment with the National Plan for Maritime Environmental Emergencies supports a rapid and coordinated response, limiting environmental harm.
Have an Operational and Scientific Monitoring Plan in place to monitor the effects of a release of fuel to the marine environment.	Maintain arrangements to monitor the effects of a release of fuel to the marine environment in accordance with the OSMP. Monitor any accidental release of fuel until termination criteria are met.	Monitoring the environmental impacts of any fuel release allows for evidence-based decision-making and adaptive management. The Operational and Scientific Monitoring Plan (OSMP) supports compliance with regulatory requirements and ensures environmental outcomes are understood and appropriately managed.
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption. **Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.** **Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.**	Social, cultural, and economic features are protected, sustaining their value for people and communities.	Preventing or effectively managing accidental fuel releases protects marine ecosystems and ensures continuity of access to marine resources, which underpin social, cultural, and economic values. By avoiding contamination of culturally significant areas and species, and minimising disruption to fisheries, tourism, and other livelihoods, the measures in place sustain community well-being, cultural heritage, and economic resilience.

12 Recommendations

As demonstrated in this risk assessment, the predicted level of risk to each receptor has either been assessed as medium or low. The predicted levels of risk are clearly below the pre-defined acceptable levels of risk and the mitigation and management measures in place provide reliable prevention to have confidence in the predicted likelihood levels, thus there are no further recommendations.

13 Document Control

Date	Revision	Update
6 July 2023	A	Draft prepared for initial comment
23 August 2023	B	Update based on comments and relevant person feedback
11 Sept 2023	0	Approved for release on Regia MSS website
20 Dec 2023	1	EP submission to NOPSEMA

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table D4-4 shows how this feedback has been incorporated into the environmental assessments.

Table D4-4 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Failure of EP to address coastal erosion due to loss of seaweed	E14	EP Appendix D4 (Accidental Release of Fuel), Section 9.4.1 (Benthic Assemblages) has been updated in response to these claims to reflect that, impacts resulting in the loss of coastal seaweed to the extent that coastal erosion could be affected, are not predicted.
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table D4-5. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table D4-5 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4042	Concern about fuel spillage and its impact on the natural environment.	This has been thoroughly assessed in D4 and the risks determined to be of an acceptable level, with preventative and mitigative measures applied.	832
4168	Risks of oil spills impacting marine life, including endangered species like the Southern Right Whale and the Tasmanian Rock Lobster.	Titleholder has conducted a thorough risk assessment relating to accidental release of fuel (D4), wherein which both receptors of concern mentioned in this feedback have been assessed. An OPEP and OSMP have also been designed and incorporated into the EP to establish a clear and systematic framework for preventing, managing and mitigating oil pollution incidents on the vessels deployed during the Regia MSS (G3).	2278
4307	The stakeholder was concerned about the environmental impact of gas released during seismic testing and production.	No impact assessment relating to the release of hydrocarbons has been conducted by CGG because hydrocarbon release is not an expected aspect of the activity. CGG has however conducted a thorough risk assessment relating to accidental release of fuel (D4). An OPEP and OSMP have also been designed and incorporated into the EP to establish a clear and systematic framework for preventing, managing and mitigating oil pollution incidents on the vessels deployed during the Regia MSS (G3).	2273
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation	1673

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4103	Expresses strong opposition to the proposed plans for potential oil spills, highlighting significant concern for environmental risks in the area. The individual identifies as a local resident.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. This includes an assessment of all risks associated with marine spills. There is a comprehensive Oil Pollution Emergency Plan and management, and mitigation plans for accidental release of materials or waste overboard.	1022
4104	Feedback expresses that the proposed drilling is close to a marine park, threatening this area. An oil spill could cause irreversible damage, similar to the harm already experienced along much of the coast.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. This includes an assessment of all risks associated with marine spills. There is a comprehensive Oil Pollution Emergency Plan and management, and mitigation plans for accidental release of materials or waste overboard. Regia MSS is a seismic program not a drilling one.	1022
4128	Lack of adequate monitoring of species present or likely to be impacted.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions regarding species that may be affected by the Regia MSS. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	3237
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4158	Reference to the destruction and degradation of the marine	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed	2830

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	environment observed during diving trips.	in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	
4163	Request to explicitly consider protection for bird colonies on the north of King Island.	The only effects to the bird colonies on King Island arise from an accidental release of fuel. This has been assessed thoroughly in D4 and consultation with the EPA Tasmania identified protection measures to be adopted for birds on King Island in the event of a spill.	2033
4166	Risk to the marine environment with the plan.	Titleholder has conducted a series of thorough risk assessments including the following aspects: Accidental release of waste (D1), Fauna Interactions (D2), Invasive Marine Species (D3) and Accidental release of fuel (D4), wherein which relevant receptors have been assessed.	2677
4168	Risks of oil spills impacting marine life, including endangered species like the Southern Right Whale and the Tasmanian Rock Lobster.	Titleholder has conducted a thorough risk assessment relating to accidental release of fuel (D4), wherein which both receptors of concern mentioned in this feedback have been assessed. An OPEP and OSMP have also been designed and incorporated into the EP to establish a clear and systematic framework for preventing, managing and mitigating oil pollution incidents on the vessels deployed during the Regia MSS (G3).	2278
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation	1659

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and	1665

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work	2117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and	2107

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	due to its perceived harmful effects on the marine ecosystem.	of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4307	The stakeholder was concerned about the environmental impact of gas released during seismic testing and production.	No impact assessment relating to the release of hydrocarbons has been conducted by CGG because hydrocarbon release is not an expected aspect of the activity. CGG has however conducted a thorough risk assessment	2273

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		relating to accidental release of fuel (D4). An OPEP and OSMP have also been designed and incorporated into the EP to establish a clear and systematic framework for preventing, managing and mitigating oil pollution incidents on the vessels deployed during the Regia MSS (G3).	
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	"A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6."	2886
4452	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	7136
4453	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	EVT070
4487	Claims that CGG's proposed activities are inconsistent with the Recovery Plans made under the EPBC Act, the Southern Right Whale Recovery Plan and the Blue Whale Recovery Plan. GMTOAC states that these activities pose known physical and behavioural risks to the Eastern Population of Southern Right Whales and to	CGG maintains that its approach aligns with statutory obligations and industry best practice. It asserts that all regulatory requirements under Regulation 34 have been met, and that its environmental performance outcomes and control measures are grounded in the best available science and tailored to the ecological and cultural sensitivities revealed through	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	Pygmy Blue Whales. These risks include impacts from anthropogenic underwater noise, particularly seismic noise, vessel strikes, climate-driven changes in prey availability, and the cumulative effects of these pressures, all of which have the potential to injure or kill individuals and affect populations. GMTOAC notes that under the EPBC Act Program and NOPSEMA's decision-making guidelines, an Environment Plan cannot be accepted if it is inconsistent with a recovery plan. It emphasises that both Recovery Plans contain "Very High" importance actions requiring that Blue Whales and Southern Right Whales must be able to continue using their Biologically Important Areas (BIAs) without auditory impairment, injury, or displacement. The plans also call for preventing disruption and displacement of Karntubul (Southern Right Whales) from BIAs due to anthropogenic noise such as seismic surveys.	consultation. The Regia MSS Environment Plan (EP) was designed to ensure impacts and risks are reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. Regarding whale protection, CGG highlights that the EP includes specific mitigation measures for culturally and ecologically significant marine fauna, including species noted in relevant Recovery Plans. Early correspondence in February 2023 identified Southern Right Whales and Pygmy Blue Whales as key sensitivities, and the EP commits to spatial and temporal avoidance measures, sound-source shutdowns, and exclusion zones to protect them. These measures explicitly consider cultural significance, such as timing restrictions to avoid the Karntubul (Southern Right Whale) birthing period. The whales, Karntubul and Wuuloc, are identified in the EP as sensitive receptors with dedicated protective measures. CGG confirms that these cultural and ecological sensitivities were incorporated into the environmental assessment. The EP acknowledges the sacred cultural status of Koontapool (Southern Right Whale) and Wuuloc (Pygmy Blue Whale) for the Gunditjmara people and includes them in impact and cumulative risk assessments. Appendix F3 references the Nyamat Mirring Plan 2023–2033 and recognises Gunditjmara spiritual connections, including to Karntubul. CGG substantively addresses the relevant issues, including underwater noise, vessel interactions, and cumulative effects. The EP sets out noise-management frameworks, timing restrictions, and cumulative impact analyses consistent with the concerns raised.	
4490	CGG has failed to adequately assess the impacts of its proposed activity on the Budj Bim World Heritage Cultural Landscape. GMTOAC further states that CGG did not sufficiently evaluate impacts on Kooyang, a culturally significant species whose lifecycle and migration underpin the world heritage values of the Budj Bim Cultural Landscape and extend well beyond its physical boundaries.	Culturally significant features, including the Budj Bim landscape, were included in both impact and cumulative risk assessments using a methodology that blends scientific evidence with cultural narratives. Regarding Kooyang (Eel), CGG maintains that this culturally important species, whose lifecycle is central to the world heritage values of Budj Bim, was addressed within the EP's impact and cumulative assessments. These assessments include both Kooyang's cultural significance and ecological role. CGG reiterates that its EP is consistent with statutory obligations, based on best-available science, and	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		tailored to the cultural and ecological sensitivities identified. CGG maintains that the Budj Bim Cultural Landscape and Kooyang have been incorporated into the EP and that this inclusion meets regulatory standards for demonstrating ALARP and acceptable levels of impact.	
4493	Claims that CGG's proposed seismic activities contribute both directly and indirectly to broader threats faced by Southern Right Whales, including industrialisation of the marine environment, climate change, and pollution or contamination from vessel discharges.	Broader threats such as climate change and industrialisation fall outside the scope of the Environment Plan, as outlined in the response to Statements 156–166. The EP assesses only the environmental risks directly associated with the proposed activity. These risks are evaluated in the D Appendices, which demonstrate that any residual risks have been reduced to an acceptable level.	EVT352

Annex 3

Loss of Containment Sensitive Species

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice
Fish							
Australian Grayling	Species or species habitat known to occur within area	Vulnerable				None identified	Conservation Advice *Prototroctes maraena* Australian Grayling (TSSC 2021)
Blue Warehou	Species or species habitat known to occur within area	Conservation Dependent				None identified	Commonwealth Listing Advice *Seriolella brama* Blue Warehou (TSSC 2015)
Eastern Dwarf Galaxias, Dwarf Galaxias	Species or species habitat known to occur within area	Endangered				None identified	National Recovery Plan for the Dwarf Galaxias (*Galaxiella pusilla*) (Saddlier et al. 2010) Conservation Advice for *Galaxiella pusilla* (Dwarf Galaxias) (DCCEEW 2023j)
Eastern Gemfish	Species or species habitat known to occur within area	Conservation Dependent				None identified	Commonwealth Listing Advice on *Rexea solandri* (TSSC 2009)
Orange Roughy, Deep-sea Perch, Red Roughy	Species or species habitat likely to occur within area	Conservation Dependent				None identified	None identified
Yarra Pygmy Perch	Species or species habitat known to occur within area	Endangered				None identified	National Recovery Plan for the Yarra Pygmy Perch (*Nannoperca obscura*) (Sadler and Hammer 2010) Conservation Advice for *Nannoperca obscura* (Yarra Pygmy Perch) (DCCEEW 2023k)
Sharks							
Little Gulper Shark	Species or species habitat likely to occur within area	Conservation Dependent (listed as *Centrophorus zeehaani)*				None identified	Commonwealth Listing Advice on *Centrophorus zeeha* (southern dogfish) (TSSC 2013)
Porbeagle, Mackerel Shark	Species or species habitat likely to occur within area		Migratory	Migratory Marine Species		None identified	None identified
School Shark, Eastern School Shark, Snapper Shark, Tope, Soupfin Shark	Species or species habitat likely to occur within area	Conservation Dependent				None identified	Commonwealth Listing Advice on *Galeorhinus galeus (*TSSC 2009a)
Shortfin Mako, Mako Shark	Species or species habitat likely to occur within area		Migratory	Migratory Marine Species		None identified	Listing Advice *Isurus oxyrinchus* shortfin mako shark (TSSC 2014)
White Shark, Great White Shark	Foraging, feeding or related behaviour known to occur within area	Vulnerable	Migratory	Migratory Marine Species		Distribution and foraging	Recovery Plan for the White Shark (*Carcharodon carcharias*). (DSEWPaC 2013b)

1 Introduction

Physical presence of the seismic survey vessel and support vessels was identified through the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) as an environmental aspect needing further assessment. Hence this document presents a detailed examination of **Physical Presence**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental receptor we are collectively calling **Other Marine Users.**

This document also uses information in three preceding studies that should be understood before reading this report.

1. PEIRA.
2. Commercial Fisheries Analysis Report (Appendix B6).
3. Cultural Heritage Assessment Report (Appendix B10).

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was first published in draft form to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (**EP**) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Physical Presence

2.1 How the Aspect Occurs

The physical presence of the survey vessel with the towed sound source and streamers and the support vessels operating in marine waters may interfere with other marine users' activities.

The aspect does not cover the risk of a vessel collision with other marine users as this is assessed in the Accidental Release of Fuel section.

2.2 Extent and Duration of the Aspect

Duration: 90 days

Extent: Operational Area

The extent of the area where the physical presence of vessels and towed equipment will occur is within the Operational Area and the impact (of interference with other marine user's activities) could occur while the activity is undertaken.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for the physical presence of vessels and towed equipment for the following environmental components and their social, cultural, and economic features:

- Commercial fishing and aquaculture
- People and communities
- Marine industries
- Diving
- Marine tourism
- Recreational fishing

Via the relevant person consultation process the Department of Defence confirmed the Operational Area is located outside of any Defence Training Areas and restricted airspace thus interference with defence activities is not assessed further.

Based on relevant person consultation, an activity limitation has been put in place to have no vessel movement within 4 nautical miles of the coast, except in case of emergency**,** to reduce impacts to commercial and recreational fishers, surfers, swimmers, and coastal users. No impacts are therefore predicted from the physical presence of vessels and towed equipment to swimmers and coastal users, and they are not assessed further.

The limited manoeuvrability of the seismic survey vessel while towing the source array and streamers means that other marine users in the same water space will have to avoid the seismic survey vessel and towed equipment while in operation. Commercial fishing vessels may also be asked to remove fishing gear such as traps and lines to avoid interaction with the seismic survey vessel and towed equipment.

4 Description of the Existing Environment that May be Affected by the Activity

As detailed in the Section 2.2, the Operational Area has been adopted as the extent of the area where other marine users' activities may be affected by the physical presence of vessels and towed equipment associated with the Regia MSS.

4.1 Commercial Fishing and Aquaculture

In August 2023 a review of commercial fisheries was undertaken to identify Commonwealth and State (Victorian, Tasmanian, and South Australian) fisheries that fish or potentially fish within the Activity Planning Area and is available in Appendix B6: Commercial Fisheries Analysis Report. In March 2025, a further review was undertaken of the commercial fisheries to include the 2023 Commonwealth fishery data and the updated Operational Area. The outcomes of this latest review are detailed in Table E1-1.

The review identified the following commercial fisheries that have catch-effort, and hence are likely to be fish within the Operational Area:

- Commonwealth
    - Bass Strait Central Zone Scallop Fishery
    - Eastern Tuna and Billfish Fishery
    - Small Pelagic Fishery
    - Southern and Eastern Scalefish and Shark Fishery following sectors:
        - Commonwealth Trawl Sector – Danish Siene
        - Commonwealth Trawl Sector – Otter-board
        - Shark Gillnet Sub-sector
        - Shark Hook Sub-Sector
    - Southern Squid Jig Fishery
    - Western Tuna and Billfish Fishery
- Victorian:
    - Giant Crab
    - Multi-species Ocean
    - Octopus
    - Southern Rock Lobster
    - Wrasse
- Tasmania: No fisheries identified.

A summary of these fisheries is provided in Table E1-1.

For the Commonwealth fisheries ABARES Annual Fishery Status Reports and map data has been used to determine activity within the Operational Area. ABARES Annual Fishery Status Reports Map Data are digital representations of the two thematic components of the maps in the ABARES Fishery Status Reports: relative fishing intensity and the maximum area of waters fished. In Feedback ID 1237, AFMA confirmed the reliability of the ABARES data, stating it uses logbook and other AFMA collected data.

Relative fishing intensity shows areas where five or more fishing vessels operated, and the relative effort expended or the catch. Maximum area fished shows the total area where fishing occurred at a resolution of one degree (approximately 111 x 111 km) the relative effort expended, or the catch is not publicly available for the maximum area fished due to confidentiality associated with four or less vessel.

For the Victorian fisheries, data (2011-2022) from the Victorian Fishing Authority has been used to determine activity within the Operational Area.

Table E1-1 - Summary of Level of Fishing Activity within the Operational Area

Fishery	Activity within the Operational Area	Activity Level
Commonwealth Fisheries		
Bass Strait Central Zone Scallop Fishery (BSCZSF)	The Operational Area overlaps a small area (0.29%) of the fishery where there have been less than 5 fishers during 2010 to 2023. This overlap is due to the grid size used for reporting (111 km × 111 km) as historical and current scallop beds are to the east and north of King Island outside of the Operational Area. See Appendix B12 MAP-REG-EPM-097 and Annex 3 for overlap calculation. As detailed in the Bass Strait and Central Zone Scallop Fishery - 2024 Survey (Koopman and Knuckey 2024) scallop fishing only occurs within commercially viable scallop beds. All beds surveyed since 2015 and new beds in 2024 are to the east and north of King Island. Based on this the likely activity level for the BSCZSF within the Operational Area is assessed as none.	None
Eastern Tuna and Billfish Fishery (ETBF)	The Operational Area overlaps the fishery (0.22%) where there have been less than 5 fishers during 2010 to 2023. See Appendix B12 MAP-REG-EPM-126 and Annex 3 for overlap calculation. Fishery effort is typically concentrated along the NSW coast and southern Queensland coast with some fishing effort in Victoria. See Appendix B12 MAP-REG-EPM-126. The number of active longline vessels in the fishery has decreased substantially in the past 2 decades from around 152 in 1999 to 34 in 2023 (Butler et al. 2024). Primary landing ports are Bermagui, Coffs Harbour and Ulladulla (New South Wales); Cairns, Mooloolaba and Southport (Queensland) (Butler et al. 2024). There is a 12-month season. One fishing reporting grid that the Operational Area overlaps has been fished in 2023 with no other activity within the Operational Area in the last 6 years (2018 – 2023). The grid fished in 2023 is the closest to the SA border and is overlapped by a small area of the Operational Area (See Appendix B12 MAP-REG-EPM-098). Based on there has only been fishing in one grid in one year in the last 6 years within the Operational Area, no landing ports in Victoria and fishing effort is concentration off the east coast of Australia, the likely activity level for the ETBF within the Operational Area is assessed as low.	Low
Small Pelagic Fishery (Western sub-area) (SPF)	The Operational Area overlaps a small area of the fishery (0.12%) where there have been less than 5 fishers during 2010 to 2023. See Appendix B12 MAP-REG-EPM-127, Appendix B12 MAP-REG-EPM-099 and Annex 3 for overlap calculation. In 2023, there were 8 boats active in the fishery (Butler et al. 2024). Midwater trawling has been the primary fishing method in the fishery in more recent years and most effort now occurs off the south coast of New South Wales (Butler et al. 2024). Primary landing ports are Eden and Ulladulla (New South Wales) (Butler et al. 2024). There is a 12-month season. Based on the last year there was active fishing in the fishing reporting grid that overlaps the Operational Area was 2015, no landing ports in Victoria and fishing effort is concentration off the south coast of NSW, the likely activity level for the WTBF within the Operational Area is assessed as low.	Low

Fishery	Activity within the Operational Area	Activity Level
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Commonwealth Trawl Sector, Danish Seine Sub-sector (SCDS)	The Operational Area overlaps the fishery (2.32%) where there have been less than 5 fishers during 2010 to 2023. See Appendix B12 MAP-REG-EPM-132, Appendix B12 MAP-REG-EPM-104 and Annex 3 for overlap calculation. Danish-seine effort has been slowly declining since 2019. In 2023, there were 18 vessels active in the fishery (Butler et al. 2024). Primary landing ports are Eden, Sydney and Ulladulla (New South Wales); Hobart (Tasmania); Lakes Entrance and Portland (Victoria) (Butler et al. 2024). There is a 12-month season. Though only four or less fishers have fished within the Operational Area the relative fishing intensity is not known as it is confidential where there are less than 5 fishers. As the landing port of Portland is within the Otway area (west of King Island to the Vic/SA border) and the relative fishing intensity within the Operational Area is not known the likely activity level for the SCDS within the Operational Area is assessed as high.	High
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Commonwealth Trawl Sector (SCTR)	The Operational Area overlaps the fishery where there have been low, medium and high levels of fishing intensity during 2010 to 2023. See Appendix B12 MAP-REG-EPM-131 and Appendix B12 MAP-REG-EPM-103. The CTS otter-board level of effort has been slowly declining since 2017 and represents around half the effort recorded in the early 2000s. In 2023, there were 24 vessels with 251 fishing days down from 2022 where there were 30 vessels with 380 fishing days (Butler et al. 2024). Primary landing ports are Eden, Sydney and Ulladulla (New South Wales); Hobart (Tasmania); Lakes Entrance and Portland (Victoria) (Butler et al. 2024). There is a 12-month season. Based on the Operational Area overlaps where there has been low, medium and high level of fishing intensity and the landing port of Portland is within the Otway area (west of King Island to the Vic/SA border) the likely activity level for the SCTR within the Operational Area is assessed as high.	High
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Shark Hook Sub-sector (SSKK)	The Operational Area overlaps the fishery where there have been less than 5 fishers during 2010 to 2023. See Appendix B12 MAP-REG-EPM-129 and Appendix B12 MAP-REG-EPM-101. The SSKK primarily targets four shark species (elephantfish, gummy shark, sawsharks and school sharks) using demersal longlines with most fishing occurring off South Australia (Butler et al. 2024). Spatial closures that have been progressively implemented since 2003 have resulted in an increase in hook effort to replace gillnet effort off South Australia (Butler et al. 2024). In 2023, there were 68 active an increase from 57 vessels in 2022 (Butler et al. 2024). Primary landing ports are Lakes Entrance, Port Welshpool, San Remo (Victoria); Adelaide, Port Lincoln, Robe (South Australia); Devonport, Hobart (Tasmania) (Butler et al. 2024). There is a 12-month season. Based on most fishing using demersal longlines is undertaken off South Australia and there are no landing ports in the Otway area (west of King Island to the Vic/SA border) the likely activity level for the SSKK within the Operational Area is assessed as low	Low

Fishery	Activity within the Operational Area	Activity Level
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Shark Gillnet Sub-sector (SSKN)	The Operational Area overlaps the fishery where there has been a low, medium and high levels of fishing intensity during 2010 to 2023. See Appendix B12 MAP-REG-EPM-130 and Appendix B12 MAP-REG-EPM-102. The SSKN primarily targets four shark species (elephantfish, gummy shark, sawsharks and school sharks) using demersal gillnets. Spatial closures that have been progressively implemented since 2003 have resulted in gillnet effort being concentrated in Bass Strait (Butler et al. 2024). In 2023, there were 31 active vessels and in 2022 there were 30 active vessels (Butler et al. 2024). Primary landing ports are Lakes Entrance, Port Welshpool, San Remo (Victoria); Adelaide, Port Lincoln, Robe (South Australia); Devonport, Hobart (Tasmania) (Butler et al. 2024). There is a 12-month season. Though there are no primary landing ports in the Otway area (west of King Island to the Vic/SA border) there has been recorded low, medium and high levels of fishing intensity within the Operational Area, thus the likely activity level for the SSKN within the Operational Area is assessed as high.	High
Southern and Eastern Scalefish and Shark Fishery (SESSF) -Scalefish Hook Sector (SSCK)	The Operational Area overlaps the fishery where there has been a low level of fishing intensity and where there have been less than 5 fishers during 2010 to 2023. See Appendix B12 MAP-REG-EPM-133 and Appendix B12 MAP-REG-EPM-105. The SSCK is a multispecies fishery, targeting a variety of fish and shark species that uses a variety of longline and dropline hook fishing methods (Butler et al. 2024). In 2023, there were 13 active scalefish hook vessels, a decrease from 2022 when there were 21 active vessels (Butler et al. 2024). Primary landing ports are Eden, Sydney and Ulladulla (New South Wales); Hobart (Tasmania); Lakes Entrance and Portland (Victoria) (Butler et al. 2024). There is a 12-month season. Though a low level of fishing intensity has been recorded in the Operational Area, relative fishing intensity is not known as it is confidential where there are less than 5 fishers. As the landing port of Portland is within the Otway area (west of King Island to the Vic/SA border) and the relative fishing intensity within the Operational Area ranges from not known to low the likely activity level for the SCDS within the Operational Area is assessed as high.	High
Southern Squid Jig Fishery (SSJF)	The Operational Area overlaps the fishery where there have been low, medium and high levels of fishing intensity during 2010 to 2023. See Appendix B12 MAP-REG-EPM-134 and Appendix B12 MAP-REG-EMP-106. The SSJF is a single-method (jigging), single-species fishery, targeting Gould's squid. Australian jig vessels typically operate at night in continental-shelf waters between depths of 60 m and 120 m (Butler et al. 2024). In 2023, there were 8 active jig vessels, an increase from 2022 when there were 6 active jig vessels (Butler et al. 2024). Primary landing ports are Portland and Apollo Bay (Victoria), Port Fairy, Queenscliff, Devonport and Triabunna (Tasmania). There is a 12-month season. Based on the Operational Area overlaps where there has been low, medium and high level of fishing intensity and the landing ports of Portland and Apollo Bay are within the Otway area (west of King Island to the Vic/SA border) the likely activity level for the SSJF within the Operational Area is assessed as high.	High

Fishery	Activity within the Operational Area	Activity Level
Western Tuna and Billfish Fishery (WTBF)	The Operational Area overlaps a small area (0.04%) of the fishery where there have been less than 5 fishers during 2010 to 2023. See Appendix B12 MAP-REG-EPM-138, Appendix B12 MAP-REG-EPM-108 and Annex 3 for overlap calculation. In recent years, fishing effort has concentrated off south-west Western Australia, with occasional activity off South Australia (Butler et al. 2024). See Appendix B12 MAP-REG-EPM-138. Effort in the WTBF was relatively low (<20 vessels) from the mid-1980s to the mid-1990s. Effort increased in the late 1990s, peaking at 50 active vessels in 2000, but then declined rapidly. Since 2005, fewer than 5 vessels have been active in the fishery each year. (Butler et al. 2024). Primary landing ports are Fremantle and Geraldton (Western Australia). Based on the last year there was active fishing in the one fishing reporting grid that overlaps the Operational Area was 2014, no landing ports in Victoria and fishing effort is concentration off south-west Australia, the likely activity level for the WTBF within the Operational Area is assessed as low.	Low
Victorian Fisheries		
Abalone Fishery	The Abalone Fishery operates along most of the Victorian shoreline, generally to 30 m depth where abalone are harvested by divers (VFA 2025). This area is outside the Operational Area. See Appendix B12 MAP-REG-EPM-136.	None
Giant Crab Fishery	Giant crabs are fished commercially in western Victoria. The fishery is a small quota managed fishery that is closely linked with the Rock Lobster Fishery. The majority of vessels are used primarily for rock lobster fishing with giant crab taken as by-product (VFA 2025a). Giant crabs inhabit the continental slope at approximately 200 m depth and are most abundant along the narrow band of the shelf edge (VFA 2025a). Closed seasons are: • Male: 15 September to 15 November to protect males during moult. • Female: 1 June to 15 November to protect females while breeding and in berry (with eggs attached). During 2011 to 2022 the maximum number of vessels that fished in a year within the Operational Area was three and the maximum days fished in a year was 28. See Appendix B12 MAP-REG-EPM-110 and Appendix B12 MAP-REG-EPM-096. Based on the closed seasons, giant crab fishing will only overlap with the seismic survey for 15 days in the September and November period noting that the survey operations are for up to 90 days. In addition, up to 3 vessels may be present during this time thus the likely activity level for the giant crab fishery within the Operational Area is assessed as low.	Low

Fishery	Activity within the Operational Area	Activity Level
Multispecies Ocean Fisheries – Ocean General	The wrasse, inshore trawl, southern rock lobster and giant crab fisheries are able to catch gummy shark and school sharks as part of their fishery. Snapper is caught using lines, nets and haul seine. Over 90% of the catch is from Port Phillip Bay, and around 5% from coastal waters. During 2011 to 2022 the maximum number of vessels that fished in a year within the Operational Area was three and the maximum days fished in a year was 16. See Appendix B12 MAP-REG-EPM-115 and Appendix B12 MAP-REG-EPM-114. Based on the low number of fishing vessels annually (3 vessels) and fishing days (maximum 16 days) within the Operational Area, the likely activity level for the Multispecies Ocean Fisheries – Ocean General fishery within the Operational Area is assessed as low.	Low
Octopus Fishery	Victoria's Octopus (Eastern Zone) Fishery harvests mainly pale octopus in East Gippsland using purpose-built unbaited traps. The fishery may also catch Māori octopus and gloomy octopus. The fishery commenced on 1 August 2020 (VFA 2025b). The Operational Area is within the Western Octopus Zone which is less established and is being managed by the VFA through exploratory, temporary permits (VFA 2025b). During 2020 to 2022 the maximum number of vessels that fished in a year within the Operational Area was one and the maximum days fished in a year was one. See Appendix B12 MAP-REG-EPM-119 and Appendix B12 MAP-REG-EPM-118. Based on the low number of fishing vessels annually (1 vessel) and fishing days (maximum 1 day) within the Operational Area, the likely activity level for the Octopus Fishery within the Operational Area is assessed as low.	Low
Rock Lobster Fishery	The Rock Lobster Fishery is Victoria's most valuable fishery and is based on the southern rock lobster (*Jasus edwardsii*). The fishery is quota managed, with a total allowable commercial catch set annually after the status of the stock has been assessed. There are two commercial zones in the fishery that operate along the entire coastline of Victoria (VFA 2025c). The Operational Area overlaps the Portland Region within the Western Zone of the fishery. Fishing for rock lobsters is prohibited during closed seasons: • Female rock lobsters are from 1 June to 15 November and is designed to protect females in berry (with eggs attached) during the spawning period. • Male rock lobsters are from 15 September to 15 November and is designed to protect males during the moulting period when soft shells increase their vulnerability. During 2011 to 2022 the maximum number of vessels that fished in a year within the Operational Area was nine and the maximum days fished in a year was 212. See Appendix B12 MAP-REG-EPM-111 and Appendix B12 MAP-REG-EPM-095. Based on the closed seasons, rock lobster fishing will only overlap with the seismic survey during for 15 days in September and November, and in December noting that the survey operations are for up to 90 days.. Between 1 to 9 vessels may be present during this time and the maximum days fished in a year ranged from 2 to 212 (See Appendix B12 MAP-REG-EPM-095), thus the likely activity level for the rock lobster fishery within the Operational Area is assessed as high.	High

Fishery	Activity within the Operational Area	Activity Level
Wrasse (Ocean) Fishery	The fishery extends along the entire length of the Victorian coastline and out to 20 nm offshore, except for marine reserves (VFA 2025d). Most wrasse is harvested by hook and line, although commercial rock lobster fishers who also hold a commercial wrasse licences can keep those fish that they catch in their rock lobster pots (VFA 2025d). There are currently 22 licences (VFA 2025d). Wrasse inhabit depths up to 160 m, whereas fishers mostly operate in depths shallower than 30 m to reduce their losses due to barotrauma, where the swim bladder expands and damages the fish as it is hauled to the surface (VFA 2025d). The Operational Area overlaps a small proportion of three fishing blocks where during 2011 – 2022 the maximum number of vessels that fished in a year within the Operational Area was four and the maximum days fished in a year was 102 (See Appendix B12 MAP-REG-EPM-123 and Appendix B12 MAP-REG-EPM-122. Based on fishers mostly operate in depths shallower than 30 m which is outside the Operational Area (See Appendix B12 MAP-REG-EPM-136) and the small area of overlap (6.26%) between the fishery area between Port Campbell and just past Portland and the Operational Area (See Appendix B12 MAP-REG-EPM-122 and Annex 3 for overlap calculation) the likely activity level for the wrasse fishery is assessed as low..	Low

4.2 Offshore Energy

There are offshore energy providers within the Operational Area that could be impacted by the physical presence of the survey vessel and towed equipment. Within the Operational Area is the Beach Energy Otway Development consisting of subsea infrastructure and the Thylacine-A unmanned platform and the Cooper Energy Casino Henry Netherby Development consisting of subsea infrastructure (Appendix B12 MAP-REG-EPM-082). During the Regia MSS design envelope (16th September 2025 to 31 December 2028) there is the potential for exploration and development activities such as infrastructure inspection, maintenance and repairs campaigns, seabed surveys, seismic surveys, drilling, and infrastructure installation to be undertaken with vessels and drill rigs to support the ongoing energy supply of gas and potentially renewables within the Otway Basin. In September 2024 the Spinifex offshore wind farm was granted a preliminary feasibility licence, subject to further consultation with First Nations groups. Once a full feasibility licence is granted, they will be able to undertake detailed environmental and technical studies within their project areas which overlaps the Operational Area.

4.3 Commercial Shipping

There are commercial shipping companies transiting adjacent to and within the Operational Area that could be impacted by the physical presence of the survey vessel and towed equipment. The Southeast Marine Region is one of the busiest shipping regions in Australia and Bass Strait is one of Australia's busiest shipping routes. Commercial vessels use the route when transiting between ports on the east, south and west coasts of Australia, and there are regular passenger and cargo services between mainland Australia and Tasmania. Ports Australia provide statistics for port operations throughout Australia's main commercial ports. Based on the latest information (2021) the majority of commercial shipping traffic transiting to and from Victorian ports were container (3,682), general cargo (2,663), bulk liquid carriers (2,019), dry bulk (1,715), car carrier (1,342), bulk gas (220), other cargo (47) and livestock (9).

4.4 Marine Tourism

No areas of marine tourism were identified within the Operational Area. Areas where marine tourism occurs such as Deen Maar (Lady Julia Percy Island), Australian Marine Parks, Victorian Marine Parks, and Sanctuaries are outside of the Operational Area.

4.5 Recreational Fishing

Recreational fishing from vessels including fishing tour operators, may occur within the Operational Area.

Several fishing tour operators operate from coastal towns including Port Fairy, Warrnambool, Portland, and Port Campbell that fish in offshore waters for species such as Blue Fin Tuna, Shark (Gummy, School and Mako), Yellowtail Kingfish and reef species including Snapper, Morwong, Nannygai.

From relevant person consultation undertaken during preparation of the EP, only a single fishing tour operator was identified as occurring within the Operational Area.

4.6 Defence Activities and UXOs

During consultation, the Department of Defence (DoD) confirmed that the Operational Area was located outside of any Defence Training Areas and restricted airspace, therefore no impact on defence activities from the Regia MSS is expected, as such this will not be assessed further.

The Department of Defence also advised that unexploded ordnance (UXO) may be present in the sea floor and issued the following disclaimers:

a. all activities in the area are conducted at its own risk; and

b. the Commonwealth of Australia, represented by the Department of Defence, takes no responsibility for:

i. reporting the location and type of UXO that may be in the areas;

ii. identifying or removing any UXO from these areas; and

iii. any loss or damage suffered or incurred by Regia MSS or any third party arising out of, or directly related to, UXO in the area.

(Event ID 920, Feedback IDs 1522 – 1526).

As per Figure E1-1, a search of the Department of Defence's UXO map shows the following overlaps:

- Survey Acquisition Area – none
- Active Source Area – overlap with 1052 King Island, this site was used during 1954 as an Air-to-Air Firing Range and is UXO category *'Slight Potential'*
- Operational Area - overlap with 1052 King Island, this site was used during 1954 as an Air-to-Air Firing Range and is UXO category *'Slight Potential'* and SDG110 Sea Dumping – Bass Strait, this site is an area used for the dumping at sea of ordnance and other items. This site was used for the dumping at sea of ammunition including 2331 boxes of detonators and 144 boxes of explosives and is UXO category *'Other Sea Dumping Sites'*.

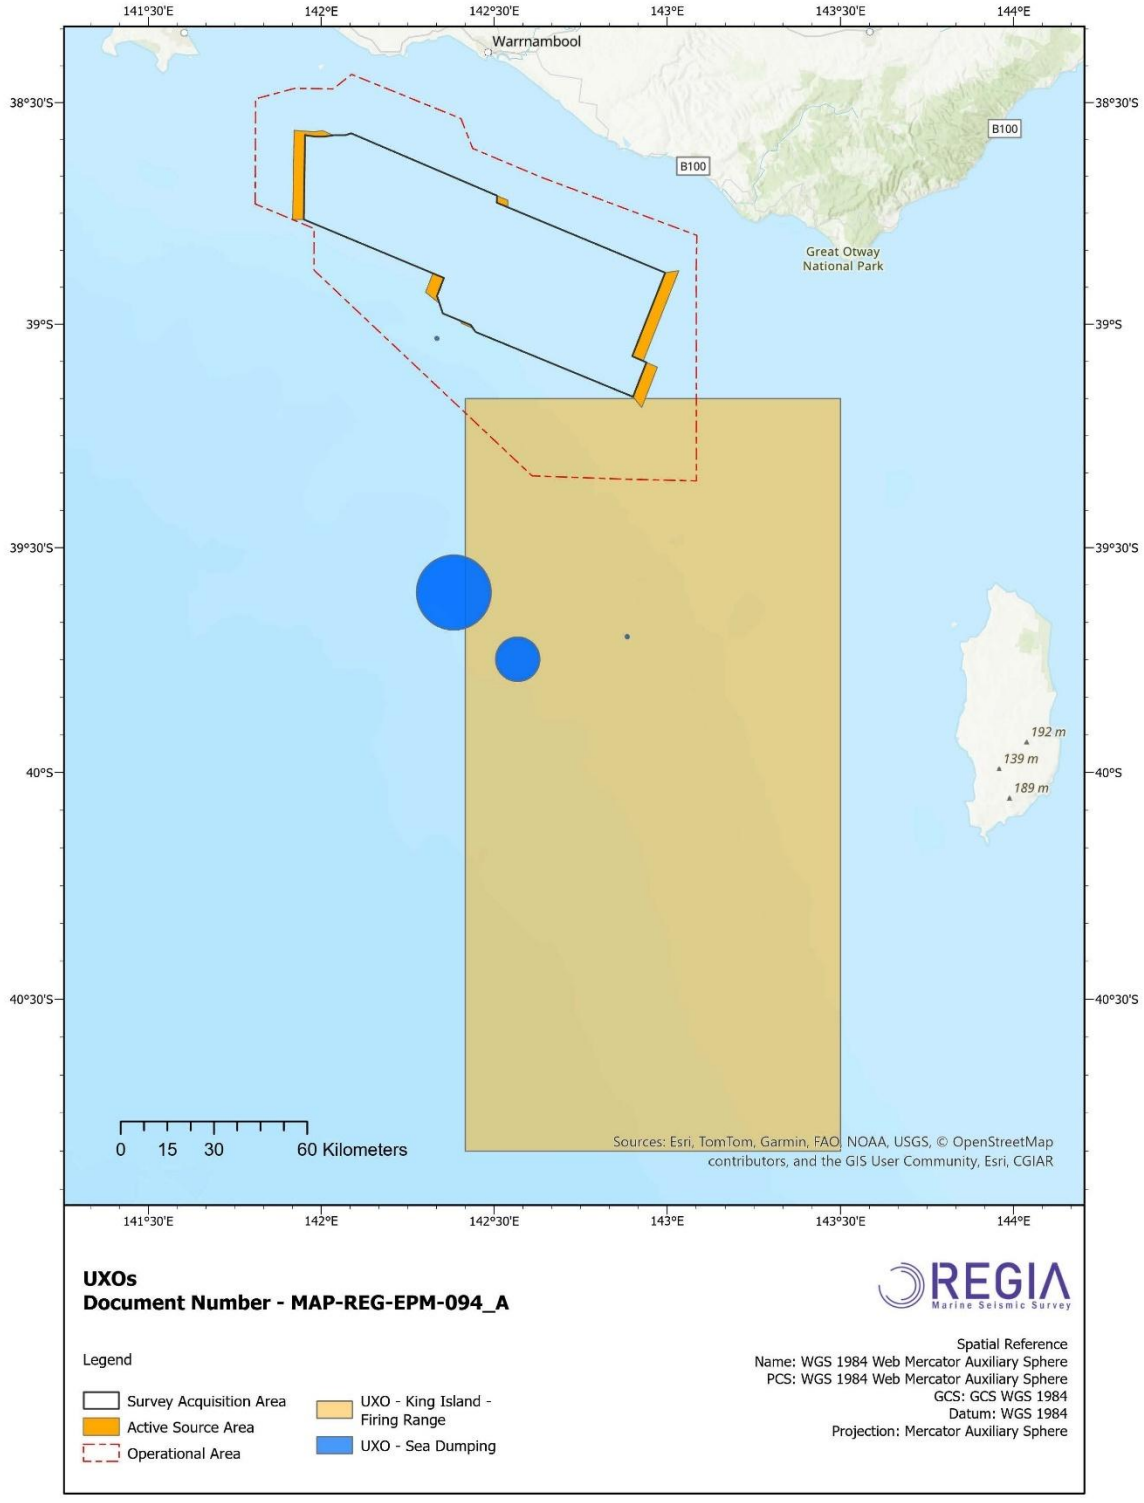

Figure E1-1 – UXOs within the Operational Area

4.7 People and Communities

4.7.1 Social and economic features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local economy and environment, including commercial and recreational fishing and tourism. Commercial fishing and aquaculture, Marine Tourism and Recreational Fishing are described above in sections 4.1, 4.4 and 4.5, respectively.

4.7.2 Cultural features

Biosis Pty Ltd (**Biosis**) was commissioned by ConocoPhillips to undertake a cultural heritage desktop assessment for proposed resource exploration in Bass Strait. ConocoPhillips and Biosis gave permission for CGG to utilise this report given the overlap of the study area with the Regia MSS. The report is provided as part of this EP at Appendix B10, and a short summary is included in this document.

The purpose of the report was to explore cultural heritage and cultural heritage landscapes to understand Country, and Sea Country within and surrounding the project area, to provide the project with a grounding in Aboriginal cultural heritage. The report describes the known cultural environment, include a brief ethnohistory and history, and detailed results of register searches.

The study area includes the proposed permit areas (the location of the exploration zone(s)), where the survey is planned to occur. In general, the permit areas are located south of Port Fairy and the Great Otway National Park, and west of King Island. The study area consists of a large geographical area which did not identify any specific physical indigenous cultural features of the benthic environment. As there is no benthic disturbance pathway and no physical cultural values identified in the Operational Area the physical effect to indigenous features of the benthic environment are not assessed further.

Although Native Title has not been identified to occur within the Operational Area, it is considered possible that there may be interests and rights, and cultural values and sensitivities associated with Eastern Maar and Gunditjmara Native Title determinations (Appendix B12 MAP-REG-EPM-076) adjacent to the Operational Area including the currently under consultation Nyamat Mirring (GMTOAC, 2023).. Native title rights and interests include the non-exclusive rights to access, enter and remain on the land and waters, to camp on areas above the high-water mark, to use and enjoy the land and waters, to protect culturally important places, and to take resources from the land and waters. Deen Maar, also known as Lady Percy Island, is a culturally significant site for both the Gunditjmara and Eastern Maar. For the Gunditjmara people, Native Title also includes culturally significant sites such as the 'Convincing Ground' (Appendix F3, Section 3.16.1). In addition, Wadawurrung and Bunurong Registered Aboriginal Parties coastal areas have overlap with the northeastern extent of the Environmental Planning Area, may be affected (Appendix B12 MAP-REG-EPM-091).

4.7.2.1 Sea Country Values

There is the potential for marine ecosystems to include intangible cultural features. This is one aspect of the broader concept of "sea country", which can be defined as the area of sea over which an Indigenous group has interests, cultural value, connection and use. Country refers to more than just a geographical area: it is shorthand for all the values, places, resources, stories and cultural obligations associated with that geographical area. (Smyth, 2007). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within Sea Country — the seascape which Traditional Custodians view, interact with or hold knowledge of.

The link between environmental protection and cultural heritage protection is illustrated in the Australian Government's Indigenous Protected Areas Program. The Indigenous Protected Areas program provides for "areas of land and sea managed by Indigenous groups as protected areas for biodiversity conservation…IPAs deliver environmental benefits…Managing IPAs also helps Indigenous communities protect the cultural values of their country for future generations…" (IPA Program Evaluation 2024).

Cultural features of coastal areas may include marine species (e.g., whales) that may travel many thousands of kilometres through areas with similar cultural values to multiple Indigenous language groups. For example, Southern Right Whales are a highly mobile migratory species that can travel

thousands of kms between habitats used for these essential life functions (Kenney, 2018) passing Indigenous language groups along the southern and eastern coasts of Australia.

Through consultation and online research, information about cultural features of the environment have been identified, as captured in Appendix F3, section 3.,16. This includes:

- Sacred Sea Country Songlines.
- Sacred Burial grounds of Deen Maar.
- Point Nepean and Mornington Peninsula area of high cultural significance.
- Dreaming and creation stories associated with coast area and sea.
- Connections with the sea and its resources.
- Koontapool (Southern Right Whale):
  - The Gunditjmara's deep connection to Koontapool as a carrier of life and knowledge is emphasized, with the whale being seen as kin, and their survival intertwined with that of the people for millennia.
  - Welcoming Koontapool back to the familiar waters of Sea Country was a significant event for the community, marked by ancient rituals and the first public acknowledgment of this homecoming by the Gunditjmara people.
- Wuulok (Blue Whale).
- Koorn Moorn (Seals).
- Sea Lions.
- Kooyang Short Finned Eels.
- Coastal resources, such as shell middens
- Important birthing and calving grounds at Logan's beach whale nursey.
- A connection to the Koontapool and Sea Country kin.

The scope of advice sought during consultation and research about Sea Country was not limited by reference to any boundaries or limits. These values are of high significance for First Nations groups, including the Gunditjmara, along with the importance of sharing cultural tales in modern times and highlighting the importance of preserving these stories for future generations. CGG also heard about the importance of respecting the past, protecting the present, and ensuring the future.

An impact to marine ecosystems has the potential to impact cultural values where the impact is detectable within Sea Country. CGG considers that impact to cultural values of marine species will be adequately managed in Sea Country, and therefore management of the environmental values will preserve the cultural values of environmental receptors. Management of impacts other than physical presence are found in Appendix E2 to E9.

5 Relevant Legislative and Other Requirements

CGG has considered relevant legislative requirements, that apply to the physical presence of vessels and towed equipment (see Appendix B2). Measures that will be adopted to demonstrate how these requirements will be meet are as follows:

- The CGG Marine Assurance System ensure compliance of contract vessels with Navigation Act, MARPOL, COLREGS and Marine Orders.
- The Communications Management System ensures that survey communications will minimise interference with the activities of the other marine users. This includes mandatory notification of the Australian Hydrographic Service who issue Notices to Mariners.
- An On-Water Communications Plan documents how and when communications with other marine users will occur to minimise interference with their operations and equipment.
- Vessel captains legislated responsibilities to communicate with other marine users and follow the On-Water Communications Plan.

6 Defining Acceptable Levels of Impact

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that aspect specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E1-2 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding aspect specific defined acceptable levels established for this assessment. Defining the acceptable levels is the starting point for the required demonstration that environmental impacts and risks of the activity will be of an acceptable level. The defined acceptable levels found in this section are subsequently carried through the prediction of impacts in this document, to the demonstration found in Section 10.[1]

Table E1-2 - General and Aspect Specific Defined Acceptable Levels

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	The physical presence of vessels does not cause changes in fishing catch patterns that result in measurable effects to the biomass or recruitment of target species.	This acceptable level ensures that any displacement or exclusion of fishing activity caused by the activity does not result in ecological consequences for target fish stocks through increased concentration of fishing in other areas. Preventing population-level effects is consistent with ecosystem-based fisheries management.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they are documented elsewhere, these criteria are not discussed further in this assessment.

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	The activity is carried out in a manner that does not interfere with activities of another person to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the titleholder.	This acceptable level is based on Section 280 of the Offshore Petroleum and Greenhouse Gas Storage Act 2006, which establishes the legal requirement to minimise interference with other marine users. It reflects the principle that petroleum activities must be conducted with consideration for the rights and needs of others, including commercial fishers, shipping operators, and recreational users.
		Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Reflects Commonwealth and State policy objectives for sustainable resource use and protection of ecosystem services.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	This level reflects the principle of maintaining cultural values and heritage as protected under national and state legislation. It ensures that activities do not interfere with traditional practices, spiritual connections, or ongoing access to culturally significant areas.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	This level reflects broader social licence to operate, ensuring that environmental activities do not lead to degradation of public amenity, loss of recreational use, or impacts to non-Indigenous heritage values. It aligns with Commonwealth policies promoting public access, well-being, and sustainable use of the marine environment.
	The views of public have been considered in the impact and risk assessment.		

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic surveys on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of physical presence, this would require removing the vessels from the environment or conducting the survey in a way that does not result in interference with other marine users. Nine main options were considered:

Removal of vessels from the activity

While this may theoretically eliminate interference with other marine users, it is not practically feasible without eliminating the activity itself. Attempting to eliminate the physical presence of vessels would prevent the survey from occurring, which is inconsistent with the objectives of the Regia MSS. Any reduction in interference from the absence of vessels would come at the cost of not achieving the activity's primary purpose, and no viable alternative designs exist that can avoid all physical presence within the marine environment. For these reasons, this option was ultimately discarded.

In addition, CGG has adopted a set of spatial activity limitations that reduce the likelihood of interference with other marine users. These remaining activity limitations described below have subsequently been adopted:

No vessel movement within 4 nautical miles of the coast, except in case of emergency.

This limitation ensures no overlap with local yacht races. In response to consultation MSS is constrained to >50m depth which equates to minimum 25 km or 13.5 nm from the coast.

No sound source discharges within the Orange Roughy research program areas.

During consultation (Event IDs 2002, 3350, 1649, 2003, Feedback IDs 4125, 4305, 4124, 4337) claims were raised by a fishing association to avoid interference with an Orange Roughy Research Program by ensuring there was no data acquisition, or turns, over the sample collection areas, with a buffer between the acquisition and sample areas, with preferred non-acquisition months to be April to October. As shown in map MAP-REG-EPM-050_B (Appendix B12), the activity was reduced to ensure there is no overlap of sampling areas with the active source area, including turns.
There are no specific studies focused on seismic effects on Orange Roughy, however, inferences can be drawn from research on other species. In particular, multiple studies have investigated the impact of seismic surveys on the spawning behaviour of cod, given this is a period in the life cycle when individuals gather in large numbers (Mcqueen et al 2022, Mcqueen et al 2023). Both studies found cod were not significantly disrupted from their spawning behaviour after exposure treatments representative of a full seismic survey at distances ranging from 5-40km. These distances closely align with the proximity between the Regia MSS acquisition area and the Orange Roughy Study central sampling area, 5.27 km at its nearest point (see Appendix B12, map MAP-REG-EPM-050_B). Based on this, we do not anticipate any significant level of disturbance to Orange Roughy in the sampling area. A small portion of the central sampling area overlaps with the operational area; however, this will not have a greater impact than any other vessel transiting the area. Therefore, there is no break to the time series of the data, due to lack of overlap with the active source area. In addition, the Regia MSS is not prohibiting the ability of the research program to catch the fish required for the study to continue uninterrupted, negating the need for exclusionary months.

No seismic acquisition within 17 km of Deen Maar / Lady Percy Julia Island

The cultural heritage desktop assessment (Appendix B12), consultation, and desktop research identified the cultural significance of Deen Maar/Lady Julia Percy Island. The buffer zone was applied

to provide spatial protection for species utilising this ecologically and culturally important area, thereby reducing potential impacts.

This limitation reduced the overlap with most fishing effort in the region and. This is protective for mobile or short ranging fish species that are more likely to be present in water depth < 50 m. The shallow depths are also where most lobster will settle when ready to do so. This measure was adopted via consultation to avoid disturbance to coastal and nearshore invertebrate communities and to prevent elevated acoustic energy in shallow, sensitive environments. This was confirmed during consultation with commercial fishers who agreed that the data was correct and most fishing activities occurred in shallower waters close to ports (Event ID 4107, Feedback ID 1277).

No vessel movements in between Deen Maar/Lady Percy Julia Island and the mainland.

The cultural heritage desktop assessment (Appendix B12), consultation, and desktop research identified the cultural significance of Deen Maar/Lady Julia Percy Island, including the connection with spirits departing the mainland and travelling to Deen Maar (Appendix F3, section 3.16). As such the activity limitation for no vessel movements in between Deen Maar and the mainland was put in place.

No anchoring permitted within the operational area to eliminate benthic disturbance

This activity limitation is in place to prevent physical disturbance to the seafloor and sensitive benthic habitats within the operational area. By prohibiting anchoring, the risk of damaging benthic communities, such as corals, sponges, or other bottom-dwelling organisms, is eliminated, supporting broader environmental protection goals during the seismic survey.

No activities within a designated Australian Marine Park (State and Commonwealth)

This activity limitation has been adopted to ensure compliance with environmental regulations and to protect the ecological, cultural, and social values of designated Australian Marine Parks (both State and Commonwealth). These areas are established to conserve biodiversity and critical habitats, support the recovery of threatened species, and maintain ecosystem health. Prohibiting activities within these zones helps prevent disturbance to sensitive marine environments, avoids potential harm to protected species, and aligns with the legal frameworks governing marine conservation in Australia.

No MSS acquisition beyond 200 m depth contour

Deepwater habitats may support unique and less-studied fish assemblages that could be sensitive to noise and extending the survey beyond this boundary may increase environmental uncertainty and operational risk. The limitation was applied to confine the activity within a well-characterised depth zone and reduce exposure of deepwater species to anthropogenic sound.

No vessel movements within 700 m of fishing blocks G12, G13, H13, and H14

During consultation concerns were raised by a fisher regarding the use of a smaller vessel which the fisher launches from a pier in Port Cambell. This restricts the fisher to access deeper waters and limits the fisher to fishing blocks G12, G13, H13 and H14 exclusively (see MAP -REG-EPM-037_A in Appendix 12). To ensure this fisher was not worse off as a result of the activity, CGG implemented an activity limitation where the Regia MSS would not operate within 700m of Southern Rock Lobster Fishing Blocks G12, G13, H13, and H14. This activity limitation is based on the underwater sound modelling results where 700m is the no effect distance for invertebrates including Southern Rock Lobster, which is the target species fishers in these blocks.

While these measures do not eliminate physical presence entirely, they were incorporated into the survey design to remove vessel interaction from areas of higher marine user density where practicable. These adopted limitations reflect the application of elimination principles through activity design to the extent feasible within the operational and safety requirements of the survey.

A preference for the survey to occur in the April to June period, as this is after main fishing stock operations and has the least potential to impact any early upwelling events, was also received during consultation (Event ID 4370, Feedback ID 1300). While this has been noted, it was also taken into consideration that the survey already has minimal interference with the fishery, Southern Bluefin Tuna (SBT). As noted by the stakeholder, there is no active fishing within the Operational Area (rather a reliance on stocks that transit the region), the survey is limited to the shallow continental shelf, avoiding deep-sea canyons and the peak upwelling period, reducing potential impacts on pre-

spawning adult tuna in the Otway Basin. Therefore, other possible months for the activity have not been discarded for this preference.

The preference for acquisition to be during February to April was expressed during a group meeting with Southern Rock Lobster commercial fishers (Feedback ID 1064). Seismic acquisition will be undertaken in a north-west to south-east direction with acquisition along a line taking a ~6 hours for the shorter lines and ~10 hours for the longer lines. As pots are generally set and hauled once each day relocation maybe required from an area for a period of days. As the majority of the Operational Area has only up to four fishers there is more potential to be able to relocate to an alternative viable area, therefore other possible months for the activity have not been discarded for this preference.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. Five main options were considered:

Seasonal Avoidance of Peak Fishing Overlaps

The first involved avoiding peak fishing seasons by introducing additional seasonal timing restrictions beyond those already in place. While fishing occurs throughout the year in the Operational Area, peak periods are concentrated in summer months, which have already been excluded from the planned timing of the survey. Avoiding additional, less productive fishing periods was considered, but this would require splitting the survey into multiple non-continuous phases or delaying it significantly. This would at least double the duration of the survey, increasing the total time the vessels are present in the environment. The extended duration would in turn elevate overall risks and impacts, including underwater noise, operational emissions, and prolonged displacement of other users. The marginal benefit of avoiding lower levels of fishing activity during less productive times was not considered sufficient to justify the increased environmental footprint. This option was therefore discarded.

Limiting Equipment Deployment and Retrieval to Defined Areas

The second substitution option considered was to restrict deployment and retrieval of streamers and the seismic source to within the defined Operational Area. While this would provide added certainty to other marine users about the spatial boundaries of the activity, it would also introduce higher operational risks. Deploying and retrieving streamers only while within the Operational Area increases the likelihood of entanglement, particularly during vessel turning manoeuvres. Furthermore, certain operational requirements such as weather avoidance or crew changes may necessitate brief movements outside the Operational Area. Maritime law already regulates safe vessel movement and ensures adequate notice is provided to other users, aligning with the environmental objectives of the activity. Given the limited environmental benefit of this option and the elevated risks associated with it, this measure was also discarded.

Further minimisation of potential interference has been achieved through additional activity limitations that substitute higher-risk spatial configurations with lower-risk alternatives. These spatial adjustments were made during the design phase to reduce conflict with other users without introducing unacceptable operational or environmental trade-offs. While not assessed as control measures under the ALARP framework, these decisions demonstrate the application of substitution principles through the deliberate avoidance of sensitive or high-use areas prior to formal risk assessment.

These considerations demonstrate that reasonable substitution options were evaluated as part of the environmental planning process. However, neither were adopted, as each option introduced operational inefficiencies, elevated environmental risks, or disproportionate trade-offs. The residual impacts associated with the physical presence of vessels remain, and these are addressed through further assessment and targeted management measures. **In waters deeper than 200 m, interfere with commercial fishers to no greater extent than is necessary for the efficient completion of the survey.**

In cooperation with fishers, this activity limitation has been adopted so survey vessel movements in water depths of greater than 200 m will avoid trawling activities.

If the survey occurs in September, October, November or December, the acquisition lines will be acquired working from the deepest lines first.

An operational planning preference of acquisition to start in the shallow and then work towards the deeper areas, was received during consultation (Event ID 4370, Feedback ID 1301). In further consultation (Event ID 4365) it was discussed with the stakeholder that acquisition direction (shallow-to-deep or deep-to-shallow) would depend on the time of year of acquisition. Under the Activity Limitations, no petroleum activity will occur between 1 January and 15 September, so the shallow–deep acquisition is no longer relevant. If the survey occurs in September, October, November or December, the acquisition lines will be acquired working from the deepest lines first, as this will assist in minimising impacts on Southern Right Whale (see Appendix E7, section 8.2). As described above in Section 8.1, the potential impact on Southern Bluefin Tuna is already minimal. To therefore summarise, these are some of the relevant reasons for adoption of both of these activity limitations.

The full list of activity limitations can be found in Section 4 of Appendix A2.

9 Predicted Levels of Impact

9.1 Changes to the functions, interests, or activities of other users

The limited manoeuvrability of the seismic survey vessel while towing the source array and streamers means that other marine users may have to avoid the immediate vicinity of the seismic survey vessel and towed equipment.

9.1.1 Commercial Fishing and Aquaculture

As detailed in Table E1-1 there are several Commonwealth and Victorian commercial fisheries that have fishing effort within the Operational Area. The following fisheries were assessed as having or potentially having a high level of activity within the Operational Area as detailed in Table E1-1:

- Commonwealth Southern and Eastern Scalefish and Shark Fishery
  - Commonwealth Trawl Sector.
  - Shark Gillnet Sub-sector.
  - Scalefish Hook Sector.
- Southern Squid Jig Fishery.
- Victorian Rock Lobster Fishery.

Commercial fishers may be impacted by having to avoid a part of the Operational Area while the survey is undertaken. This may be for hours or days depending on the fishing location within the Operational Area and the type of fishing equipment used. Fishers using pots, nets and traps which can become entangled with the seismic survey equipment may need to avoid an area for longer than trawling and squid jigging when acquisition is occurring.

These impacts are less likely for fisheries that were assessed as having a low activity level within the Operational Area (see Table E1-1). Further analysis and evaluation has been undertaken to assess the impacts to the commercial fisheries detailed above that have or potentially have a high level of activity within the Operational Area.

Table E1-2- Impact Assessment for Commercial Fisheries with High Fishing Intensity within the Operational Area

Fishery	Predicted Level of Impact	
Commonwealth Fisheries		
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Commonwealth Trawl Sector, Danish Seine Sub-sector (SCDS)	Impacts have been assessed as moderate based on: • The fishery uses Danish seine trawl where the gear is deployed with one end of a weighted rope attached to an anchor buoy. As the vessel sweeps in a large circle the rope is deployed sinking to the bottom, followed by the Danish seine net and another weighted rope until the vessel returns to the anchor buoy. Once a full circle has been made the gear is towed for approximately 30 minutes until the ropes come together. The towing operation then ceases, and the net is winched back onto the vessel scooping up fish that have been herded into its path by the ropes coming together on the bottom. The operation, called a shot, takes approximately 1 hour and 20 minutes (AFMA 2025). Thus, to minimise interactions and relocations communications prior to the start of the survey, and daily lookahead information will be provided during the survey. • Seismic acquisition will be undertaken in a north-west to south-east direction with acquisition along a line taking a ~6 hours for the shorter lines and ~10 hours for the longer lines. Thus, the Danish seine trawl vessel would be able to utilise this area during this time. • There are potentially up to four or less fishers that may fish within the Operational Area and the Otway area (west of King Island to the Vic/SA border), thus if relocation is required there is more potential to be able to relocate to an alternative viable area that is still within a suitable range of Portland which is the only landing port within the Otway area. See Appendix B12 MAP-REG-EPM-132. • A measure has been adopted such that in cooperation with fishers, survey vessel movements in water depths of greater than 200 m will avoid trawling activities. Thus, relocation of fishers would be unlikely.	Moderate
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Commonwealth Trawl Sector (SCTR)	Impacts have been assessed as moderate based on: • The fishery uses otter board trawling where the trawl nets are towed through the water usually about 3 knots for a period of time, which is highly variable, 4-6 hours but may be shorter or longer dependant on location or target species, before being hauled up toward the vessel (AFMA 2025a). As both the trawl and seismic vessel are mobile, interactions and relocations can be managed by communications prior to the start of the survey, and daily lookahead information provided during the survey. • Seismic acquisition will be undertaken in a north-west to south-east direction with acquisition along a line taking a ~6 hours for the shorter lines and ~10 hours for the longer lines. Thus, the trawl vessel would be able to utilise this area during that time. • The Active Source Area, where acquisition will be undertaken and where the seismic vessel will tow the streamers along the acquisition lines, overlaps a very small proportion (32 km^2 which equates to 0.73%) of the high intensity fishing area within the Otway/SA area (4,399 km^2). See Appendix B12 MAP-REG-EPM-103 High Intensity Area from ~142°5E to 140°15E. • The Operational Area where the surveys vessels are more likely to be able to avoid interactions overlaps a very small proportion (189 km^2 which equates to 4.3%) of the high intensity fishing area within the Otway/SA area (4,399 km^2). See Appendix B12 MAP-REG-EPM-103 High Intensity Area from ~142°5E to 140°15E. • There are potentially more than four fishers that may fish within the Operational Area and the Otway/SA area (defined above), however if relocation is required there is more potential to be able to relocate to an alternative viable area within the high	Moderate

Fishery	Predicted Level of Impact	
	intensity fishing area within the Otway/SA are off Portland which is the only landing port within the Otway/SA area (defined above). As shown in Appendix B12 MAP-REG-EPM-135 the trawl fishery main fishing area is centred on the 200 m bathymetry line, thus fishers are mainly moving along this line. As the Operational Area overlaps a small proportion (0.73% as detailed above) of the high intensity fishing area it is less likely that a fisher who may have to relocate will be displacing another fisher. • A measure has been adopted such that in cooperation with fishers, survey vessel movements in water depths of greater than 200 m will avoid trawling activities. As shown in Appendix B12 MAP-REG-EPM-135 the 200 m bathymetry line is the centre trawl line of the high intensity fishing area. Thus, relocation of fishers would be unlikely.	
Southern and Eastern Scalefish and Shark Fishery (SESSF) - Shark Gillnet Sub-sector (SSKN)	Impacts have been assessed as low based on: • The Active Source Area, where acquisition will be undertaken and where there is a higher likelihood of interaction with static gear such as gillnets, does not overlap the gillnet high intensity fishing area. See Appendix B12 MAP-REG-EPM-102. • Spatial closures progressively implemented since 2003 have resulted in gillnet effort being concentrated in Bass Strait (Butler et al. 2024). See Appendix B12 MAP-REG-EPM-130. In addition, there are no primary landing ports in the Otway area (west of King Island to the Vic/SA border). Based on this information it is unlikely that gillnet fishing is undertaken in the Operational Area. • The Operational Area overlaps where gillnet high, medium and low intensity fishing has occurred within 2010 to 2023, if fishing does occur in the Operational Area interactions and relocations can be managed by communications prior to the start of the survey, and daily lookahead information provided during the survey.	Low
Southern and Eastern Scalefish and Shark Fishery (SESSF) -Scalefish Hook Sector (SSCK)	Impacts have been assessed as moderate based on: • The fishery uses a variety of longline and drop hook methods. Longlines consist of baited hooks attached to the longline by short lines. The longline can be many kilometres long and can carry thousands of hooks. Pelagic longlines are not anchored and are set to drift near the surface of the ocean with a radio beacon attached so the vessel can track them to haul in the catch. Bottom longlines are held in place with anchors (AFMA 2025b). Each line is normally left to 'soak' for around 6 to 8 hours before being hauled onto the vessel (AFMA 2025b). Thus, to minimise interactions and relocations communications prior to the start of the survey, and daily lookahead information will be provided during the survey. • Droplines use a main line with an anchor at one end and a float at the other. Each hook is individually connected to a short 30-50 cm monofilament or cord 'snood' which is then clipped to the mainline (AFMA 2025c). Droplines are normally left to 'soak' for around 6 hours before being hauled (AFMA 2025c). The number of lines a vessel sets each day will depend on the vessel size and number of crew on board. Smaller vessels will often set less than 5 lines per day, whereas larger vessels with more crew can set more than 10 (AFMA 2025). Thus, to minimise interactions and relocations communications prior to the start of the survey, and daily lookahead information will be provided during the survey. • Seismic acquisition will be undertaken in a north-west to south-east direction with acquisition along a line taking a ~6 hours for the shorter lines and ~10 hours for the longer lines. Thus, the longline and dropline fishing would be able to utilise this area during this time. • The depth which droplines are set in varies depending on the target species but generally ranges from 250 to 600m (AFMA	Moderate

Fishery	Predicted Level of Impact	
	2025c). As shown Appendix B12 MAP-REG-EPM-105, approximately 16% of the Operational Area overlaps with water depths >250 m (OA > 250m = 1095 km^2, OA is 6801 km^2). • There have only been up to four fishers within the Operational Area and the Otway area (west of King Island to the Vic/SA border) from 2018/19 to the 2023/2024 season, thus if relocation is required there is more potential to be able to relocate to an alternative viable area within a suitable range of Portland which is the only landing port within the Otway area. See Appendix B12 MAP-REG-EPM-105.	
Southern Squid Jig Fishery (SSJF)	Impacts have been assessed as moderate based on: • The Operational Area overlaps the fishery where there have been low, medium and high levels of fishing intensity during 2010 to 2023. See Appendix B12 MAP-REG-EPM-106. • The Operational Area overlaps a high proportion of the fishing area that is likely, due to its location (See Appendix B12 MAP-REG-EPM-106), to be fished from the Portland, thus it is unlikely that fishers would relocate to the other main fishing area closer to King Island. • The squid fishery vessels use lights to attract the squid to the vessel where they are caught using barbless lures on monofilament fishing lines which are jigged up and down in the water by machines (AFMA 2025d). Interactions and relocations with these more static vessels can be managed by communications prior to the start of the survey, and daily lookahead information provided during the survey. • Seismic acquisition will be undertaken in a north-west to south-east direction with acquisition along a line taking a ~6 hours for the shorter lines and ~10 hours for the longer lines. Thus, the squid vessel would be able to utilise this area during that time. • As detailed in Stakeholder Record 4249, the timing of peak catches for the fishery has centred around February/March in the Western Victoria fishery hence avoiding undertaking the survey during this period has been implemented and the Activity Limitation, no petroleum activity will occur between 1 January and 15 September, has been introduced. The survey will occur in the September, October, November, and December window, avoiding the peak February/March period.	Moderate
Victorian		
Rock Lobster Fishery	Impacts have been assessed as moderate based on: • During 2011 to 2022 the maximum number of vessels that fished in a year within the Operational Area was nine and ranged from 1 to 9. The highest number of vessels (9, 7, 5) are in grids that are overlapped by a small proportion of the Operational Area (See Appendix B12 MAP-REG-EPM-111). • During 2011 to 2022 the maximum days fished in a year within the Operational Area was 212 days and ranged from 2 to 212 days. The highest days fished (112, 212, 174) are in grids that are overlapped by a small proportion of the Operational Area (See Appendix B12 MAP-REG-EPM-111). • Rock Lobsters are caught with baited pots that are generally set and hauled once each day (VFA 2023). Thus, to minimise interactions and relocations communications prior to the start of the survey, and daily lookahead information will be provided during the survey. • Seismic acquisition will be undertaken in a south-east to north-west direction with acquisition along a line taking a ~6 hours for the shorter lines and ~10 hours for the longer lines. As pots are generally set and hauled once each day relocation maybe required from an area for a period of days. As the majority of the	Moderate

Fishery	Predicted Level of Impact	
	Operational Area has only up to four fishers there is more potential to be able to relocate to an alternative viable area.	

9.1.2 Offshore Energy

ConocoPhillips Australia, Beach Energy and Cooper Energy hold petroleum titles that overlap with the Operational Area. Interference could occur if these companies are undertaking exploration, development, or P&A activities during the Regia MSS. To ensure impacts to ConocoPhillips Australia, Beach, Cooper and CGG are minimised, planning between the companies is ongoing and a Petroleum Simultaneous Operations (SIMOPS) Plan will be developed in the event activities are planned to occur at the same time in the same area.

9.1.3 Commercial Shipping

For vessels that are transiting through the Operational Area, such as shipping, they may be required to move around the seismic vessel when the streamers are deployed. This could result in a detour of 10 km and take approximately 16 minutes for a vessel travelling at 20 knots (38 km/hr). However, avoidance of slow-moving vessels or obstacles are normal practice for shipping vessels and impacts can be avoided by Notification to Mariners that alert ships to slow moving vessels or obstacles such as the survey vessel.

9.1.4 Marine Tourism and Recreational Fishing

Recreation and tourism could be affected by restricted access to an area where recreational fishing or fishing tours occur. Most vessel recreational fishing and fishing tours are day tours with no overnight stays. If a recreational fisher or fishing tour operator plans to fish within the Operational Area an area may need to be avoided for a short period of time (hours) while acquisition occurs in the area. From relevant person consultation undertaken during preparation of the EP, a low level of fishing tour operators (one to date) has been identified to occur within Operational Area. Impacts to recreational and fishing tour operators can be minimised via notifications and lookaheads as part of the On-Water Communications Protocol and the Communications Management System.

9.1.5 UXOs

The Operational Area overlaps with UXO sites 1052 King Island and SDG110 Sea Dumping – Bass Strait (Figure E1-1), however, as there are no planned events in which there is physical interaction between survey equipment and the seabed, impacts are not predicted.

9.1.6 Cultural Assessment

Vessels undertaking the petroleum activity may be observable from shore, however, the distance of the Operational Area from the nearest mainland shore is >17 km at the closest point, meaning that the vessels will not be conspicuous and would only be present for relatively short durations (<90 days). The Operational Area is 5.5 km from Deen Maar at the closest point. The distance of the Active Source Area from the nearest mainland shore is >20.7 km at the closest point and the distance of the Active Source Area from Deen Maar is >17 km (adhering to activity limitation: no discharge of sound source within 17 km of Deen Maar). Consultation and literature review indicated the importance of connection to coastal and marine areas for indigenous culture. The physical presence of vessels and associated potential for displacement of marine users has the potential to impact cultural features and heritage values through the following ways:

- Cultural obligations to care for Country: Environmental impacts may be assumed to impact rights and obligations to care for Sea Country. This distance of the activity offshore means that no Traditional Owners will be excluded from Sea Country.
- Knowledge of Country/customary law and transfer of knowledge: Indirect impacts to communities practicing these skills will inherently occur when threats to Sea Country values are felt. Despite this, there is no threat or impediment from the proposed activity on the

transmission of these skills and knowledge. This is particularly true when there are no predicted effects to species at populations levels, to ecosystem integrity, or biodiversity preservation (as demonstrated in Appendices E2-E9, F3 and F4).

- Connection to Country: Where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge this may damage connection to Country (McDonald and Phillips, 2021). No impacts of this type are anticipated.
- Access to Country: Impacts to access to Country can only occur in areas that were traditionally accessed by First Nations peoples. No access issues are anticipated due to the distance offshore.

9.2 Predicted Levels of Impacts

The predicted level of effect to the functions, interests, or activities of other marine users from the physical presence of the survey vessel and towed equipment and the support vessels is assessed as moderate as there may be displacement, however impacts are temporary and, in most cases, avoidable based on:

- Communications prior to the start of the survey, and daily lookahead information provided during the survey. CGG will work proactively and collaboratively with other marine users so that both parties can plan activities in a manner that minimises potential displacement of each party.
- When the seismic vessel has equipment deployed it will typically move along pre-determined survey lines in the sail line plan in a racetrack pattern at a constant speed of ~ 3-6 knots (~ 5.5 to 11 km/hr). Updates to the sail line plan will be communicated to other marine users so they can proactively avoid the Survey Acquisition Area.
- No marine tourism or diving has been identified to occur within the Operational Area.
- Shipping deviations are predicted to be minor and have a negligible impact on travel times or fuel use. Deviations are normal practice, and impacts can be avoided by providing for Notices to Mariners that alert ships to slow moving vessels or obstacles such as the survey vessel.
- Impacts to Indigenous culture and values are not predicted from the presence of the vessels and equipment.
- A low level of fishing charter operators (one to date) has been identified to occur within Operational Area.
- Commercial fishing intensity within the Operational Area ranges from unknown, due to confidential data where there are less than five fishers, too high for the Victorian Rock Lobster Fishery, Southern and Eastern Scalefish and Shark Fishery Shark Gillnet Sub-sector, Commonwealth Trawl and Southern Squid Jig Fishery. Impacts to fishers is predicted to range from low to moderate based on the proportion of key fishing grounds that could be affected, fishing method and the fisheries' capacities to tolerate the predicted level of relocation to alternative viable areas.
- CGG will implement an adjustment protocol in the event displacement cannot be avoided and there is a financial loss to the marine user.

The uncertainty level in the assessment of impacts associated with of the physical presence of the survey vessel to the functions, interests and activities of other marine users is low given:

- Throughout the seismic survey, at least one support vessel will be in constant attendance to support on-water communication with other marine users.
- Notices to Mariners and lookaheads will alert fishers to slow moving vessels or obstacles such as the survey vessel.
- No planned activities in which there is physical interaction between survey equipment and the seabed.
- A Petroleum SIMOPs Plan will be developed in the event other titleholder's activities are planned to occur at the same time in the same area.

- Extensive relevant person consultation was undertaken during the preparation of the EP to identify other marine users that may be present within the Operational Area.
- Consultation did not identify impact pathways to marine tourism, divers, or physical indigenous culture values.
- For Commonwealth fisheries contemporary historical data up to the 2023/2024 season (2010 – 2023) has been used to inform the impact assessment. This dataset shows consistency in the areas fished. This has been supported by a review of AFMA fishery publications such as Fishery Status Report 2024, AFMA website and stakeholder consultation to identify any potential changes in fishing areas during the period of the Regia MSS (2024 – 2028).
- For Victorian fisheries contemporary historical data from 2011 to 2022 has been used to inform the impact assessment. This dataset shows consistency in the areas fished. This has been supported by a review of Victorian Fisheries Authority website and publications, and stakeholder consultation to identify any potential changes in fishing areas during the period of the Regia MSS (2024 – 2028).
- CGG will communicate with marine users prior to and during the survey to ensure other marine users can undertake their activities in a manner that avoids any interactions or can engage with CGG so that both parties can plan activities in a manner that minimises potential displacement to each party.

The predicted level of impact based on the effect (moderate) and uncertainty (low) is assessed as medium.

9.3 Industry Standard Mitigation Measures

9.3.1 Otway Adjustment Protocol

An adjustment protocol for unavoidable interference between commercial marine users and petroleum titleholders is an industry standard measure. ConocoPhillips, TGS, and CGG were founding members of a collaborative initiative called the Otway Marine Industries Coexistence Cooperative (OMICC). This initiative was in response to requests from commercial fishers, fishing industry associations, other stakeholders, and regulators for greater simplicity in making claims for compensation and to reduce consultation fatigue across the sector. OMICC has developed the Otway Adjustment Protocol (OAP), which originated from the National Energy Resources Australia (NERA) Commercial Fishing Industry Adjustment Protocol (NERA, 2021). The Otway Adjustment Protocol has been amended following feedback from fishers and fishing associations who TGS, CGG and ConocoPhillips have consulted with. It should be noted that following cessation of the planning of their proposed project TGS withdrew from OMICC.

9.4 Measures Adopted to Manage Environmental Impacts

The following measures have been adopted to ensure that the impacts associated with the physical presence of the survey and support vessels on other marine users' functions, interests, and activity will be of an acceptable level. These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
CGG Marine Assurance System	System	The CGG Marine Assurance System ensure compliance of contract vessels with legislative requirements including the Navigation Act, MARPOL, COLREGS and Marine Orders.
CGG Technical Operations Manager	Person	Reasonable, evidence-based claims are promptly assessed and paid as per the Otway Adjustment Protocol.
Quality Control and Reporting Representative	Person	Ensures that the contracted vessels follow the contract and deliver the survey as per the permitted activity by using the sail line plan.

Measure	Measure Type	Details and Justification
Support Vessel	Item of Equipment	Throughout the seismic survey, at least one support vessel will be in constant attendance to support on-water communication with other marine users.
Consultation Management System	System	CGG will implement a Consultation Management System which includes pre and during survey communications to ensure other marine users know when, where and how the Regia MSS will be undertaken. This will help them to undertake their activities in a manner that avoids any interactions with the survey. Alternatively, they can engage with CGG so that both parties can plan activities in a manner that minimises potential displacement to each party.
On-Water Communications Plan	Resource	Documents how and when there will be communications with other marine users to minimise interruption with their operations and equipment.
Communicate with other marine users	Responsibility	Vessel captains have legislated responsibilities to communicate with other marine users and follow the On-Water Communications Plan.
Streamer Tail Buoys	Item of Equipment	This item of equipment is used to mark ends of the streamers so that they can be detected by other vessels.
Sail Line Plan	Resource	Ensures that the survey vessel will remain within the scope and boundaries of the EP and reflects the activity limitations.
Adjustment Protocol	Procedure	An adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area. This will extend to fishing cooperatives who can provide an evidence of commercial losses because of the survey.
Fisheries Liaison Officer (FLO)	Person	This is a dedicated competent person available in a local port able to be responsive to any commercial fishers immediate concerns, provide a focal point for queries, and support compensation claims.
Petroleum SIMOPS Plan	Resource	Ensures coordination of activities with other titleholders in the region to minimise interference.
Sea Country Protection Plan	Resource	The SCPP is a mechanism that facilitates the identification and management of new information, relevant to the activity, through collaboration of First Nations people who decide to be part of the program.

10 Demonstration Impacts Will Be of an Acceptable Level

10.1 Principles of ESD, Biological and Ecological Categories

Temporary, Reversible, and Small Scale

The physical presence of survey and support vessels during the Regia MSS is predicted to result in temporary and reversible interference with the functions, interests, or activities of other marine users. The activity will occur over a defined period (up to 90 days) and within a clearly delineated Operational Area, with movement generally restricted to deeper waters and away from high-use zones where practicable. Displacement of other users, including commercial fishers and shipping, is predicted to be short-term and manageable via the measures adopted including the Adjustment Protocol. The assessment found no evidence of long-lasting environmental damage, with impacts characterised as localised and of low intensity.

Based on Sufficient Information

The impact assessment was informed by up-to-date fishery data (Commonwealth data 2010–2023, Victorian data 2011-2022), peer-reviewed sources, consultation input, and relevant persons feedback. Relevant fishery status reports and GIS-based analysis of fishing effort patterns were used to determine the overlap and sensitivity of marine user activities. The application of spatial and temporal constraints to the activity was shaped by known use patterns and seasonal pressures. The analysis confirmed that no irreversible impacts are predicted, and the precautionary principle was not triggered due to low uncertainty in predicted outcomes.

Activity not inconsistent with EPBC Act

No part of the activity's environmental management is inconsistent with relevant EPBC Act provisions or associated plans as it relates to physical presence of the survey.

10.2 Economic Category

The activity has been designed to minimise interference with the rights and functions of other marine users. Communication protocols and a Fisheries Liaison Officer ensure advance notice and real-time coordination with affected parties. Where impacts do occur, the adjustment protocol provides a structured and transparent mechanism to address them. This protocol has been successfully applied in previous activities, offering affected persons a fair and timely pathway to raise and resolve concerns, including loss of equipment, relocation costs, and/or reduction in catch per unit of effort. By documenting impacts, applying evidence-based assessments, and ensuring resolution outcomes are communicated and implemented, the adjustment protocol ensures that no affected person is left worse off because of the activity.

10.3 Cultural and Social Categories

While the vessels may be visible from culturally significant coastal sites such as Deen Maar, the distance offshore and short duration of activity (90 days) limit the potential for interference. Consultation identified connections between marine ecosystems and cultural identity, including species such as Southern Right Whales (Koontapool). As there are no impacts predicted to species at the population level or to physical cultural sites, cultural obligations and connection to Country will not be disrupted. The activity respects cultural protocols by avoiding sound discharge near Deen Maar and adhering to relevant consultation findings. Therefore, culturally significant species, Native Title rights and interests, places, and practices can continue without disruption; and people and communities maintain ongoing access to the natural environment, recreational activities, and heritage values without long-term or irreversible effects.

10.4 Consistency with Company Processes

The impact assessment followed the methodology outlined in Appendix B3 and used up-to-date fishery data, peer-reviewed sources, consultation input, and relevant persons feedback to assess spatial displacement, access restriction, and potential loss of function. The predicted level of effect to other marine users was assessed as moderate, with a low level of uncertainty, resulting in a medium predicted impact level. The activity integrates all mitigation measures recommended through

regulatory guidance and good industry practice, and the consequence ratings remain within CGG's established environmental limits.

This impact assessment has demonstrated that the effect of the physical presence of the survey vessels and towed equipment to marine users has a:

- Predicted level of effect of moderate (3).
- An uncertainty level of low (2).
- Predicted level of impact of medium (6).

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E1-3 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E1-2)	Environmental Performance Outcome	Rationale
The physical presence of vessels does not cause changes in fishing catch patterns that result in measurable effects to the biomass or recruitment of target species.	**The activity is scheduled and located to avoid exclusion of commercial fishing from known, high-effort fishing areas for more than 90 consecutive days, with no resulting adverse effects on fish stock status.**	This EPO ensures that the activity does not significantly disrupt commercial fishing operations or contribute to changes in stock status. A 90-day threshold provides a measurable and conservative duration to manage potential displacement, based on typical seasonal fishing patterns and operational windows. Replacing “core harvest areas” with “known, high-effort fishing areas” allows the titleholder to reference publicly available data (e.g. logbooks, AFMA catch records, or consultation feedback) to identify areas of concentrated fishing activity. This approach reflects a precautionary, evidence-based method for managing spatial conflict with other marine users while supporting sustainable fishery access and ecosystem health.
The activity is carried out in a manner that does not interfere with activities of another person to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the titleholder.	**As a result of the activity limitations and the adoption of the Otway Adjustment Protocol, no commercial marine user will be worse off because of the activity.**	This EPO is supported by consultation with marine users, assessment of spatial overlap with active areas of use, application of minimum safety zones, and appropriate notification of the activity. It ensures that any exclusion or restriction is temporary, limited in extent, and necessary to support the safe execution of the titleholder’s rights.
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	No marine tourism or diving has been identified to occur within the Operational Area. A low level of fishing charter operators (one to date) has been identified to occur within Operational Area. Transiting vessels may be required to divert short distances but will be able to plan their journey based on NOTMAs, etc. to minimise disruptions. Impacts to other companies undertaking exploration or development activities during the Regia MSS will be mitigated via a SIMOPs Plan.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.		
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		This distance of the activity offshore means that no Traditional Owners will be excluded from Sea Country.

Defined Acceptable Level (From Table E1-2)	Environmental Performance Outcome	Rationale
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the impact and risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

The predicted level of impact is medium and below pre-defined acceptable levels. The mitigation and management measures in place provide sufficient confidence around the predicted effect levels.

There may be effects to intangible cultural features because of the physical presence of the activity. It is recommended that these are assessed further in the next stage of the assessment process.

Annex 1

Input from Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. The table below shows how this feedback has been incorporated into the environmental assessments.

Matter	Matter ID	Changes made arising from public comment
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and implement the following Activity limitationthe sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, G1 and G2).

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E1-4. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E1-4 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4001	Regia team not providing information on tonnes, species or revenue from potentially displaced trawl catch and claim this was titleholder indicating unwillingness to work to reduce the impact. Stakeholder stressed ABARES maps inaccuracies.	CGG obtained and provided the information from another reputable consultancy using ABARES data obtained via AFMA, which SETFIA use, this data is described in Appendix E1, section 4.1. Following feedback from SETFIA this was investigated, with AFMA confirming the reliability of the ABARES data (Feedback ID 1237), stating it uses logbook and other AFMA collected data. They did note that industry associations have previously been critical of the economic aspects of the ABARES data, however this data is based on in field surveying of fishing industry operators. However, the information being requested had no utility in managing impacts on commercial fishers. The stakeholder suggested the relevancy being for CGG to know how much they may need to pay via a compensation plan (Event ID 3382). This was deemed to have no utility for minimising impacts as the reports obtained by CGG allowed for consultation with commercial fishers to identify potential high impact areas and manage these. The data would not improve or add to the minimisation of interactions with SETFIA's members, all concessions possible have already been made, as documented in Appendix A2, section 4. The adoption of the compensation protocol is confirmed. An exclusion of acquisition in water deeper than 200 m was confirmed by local fishers to be workable and removed their concerns.	4786
4005	States a detailed data project could provide precise figures on tonnage and revenue, facilitating a more productive discussion.	CGG obtained and provided the information from another reputable consultancy using ABARES data obtained via AFMA, which SETFIA use, this data is described in Appendix E1, section 4.1. Following feedback from SETFIA this was investigated, with	4934

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		AFMA confirming the reliability of the ABARES data (Feedback ID 1237), stating it uses logbook and other AFMA collected data. They did note that industry associations have previously been critical of the economic aspects of the ABARES data, however this data is based on in field surveying of fishing industry operators. However, the information being requested had no utility in managing impacts on commercial fishers. The stakeholder suggested the relevancy being for CGG to know how much they may need to pay via a compensation plan (Event ID 3382). This was deemed to have no utility for minimising impacts as the reports obtained by CGG allowed for consultation with commercial fishers to identify potential high impact areas and manage these. The data would not improve or add to the minimisation of interactions with SETFIA's members, all concessions possible have already been made, as documented in Appendix A2, section 4. The adoption of the compensation protocol is confirmed. An exclusion of acquisition in water deeper than 200 m was confirmed by local fishers to be workable and removed their concerns.	
4019	Any negative impact on the marine environment would also have the potential to negatively impact my employment prospects in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1459
4334	This statement opposes seismic blasting in areas designated as Sacred Birthing Grounds for Southern Right Whales, underlining the cultural and environmental significance of these grounds. It also expresses solidarity with the Gunditjmara Traditional Owners, acknowledging the cultural heritage and environmental stewardship of this region by Indigenous communities. The feedback emphasises the perceived risks to both marine life and Indigenous heritage in the area.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country (Event ID 2101).	2101
4303	The stakeholder stated that they were concerned about both tangible and intangible cultural heritage, as	Indicated that we will be performing non-invasive work in a site survey and could work with the TO's to help	1891

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	well as submerged underwater archaeology.	identify culturally significant sites (Event ID 1891).	
4332	This statement calls for a respectful approach, urging stakeholders to engage deeply with Indigenous knowledge and perspectives, including the views of Elders and Traditional Owners. It emphasises empathy and a meaningful understanding of the environmental and cultural impact of activities on marine life.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country.	2101
4280	The stakeholder expresses strong opposition to the exploration for gas near Deen Maar (Lady Julia Percy Island), emphasising its significance to the local Indigenous community, comparable to the cultural importance of Uluru. They highlight its unique status as Australia's only offshore volcano and assert that such an exploration would be inappropriate in a site of sacred significance, arguing against the project's alignment with respecting Indigenous heritage and environmental integrity.	We are aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how we protect and preserve the values of this site (Event ID 2108).	2108
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an "exclusion zone" will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	2108
4216	Stated that they feel a sense of reparability to listen to the Gunditjmara people and what they wish for their sea country and ancient song lines.	Titleholder responded to the individual confirming consultation was currently being attempted with First Nations Custodians of Country and to engage with them on the activity. Titleholder requested that the individual encourage any potentially relevant people they may know to contact the consultation team and advised that consultation is an important aspect of the marine seismic survey planning process, community input and feedback will be considered in the planning and execution of the survey.	842

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4052	Concern about the impact of the testing on yacht racing off the coastline of Port Fairy.	Titleholder responded to individual advising that the activity will occur approximately 25km offshore (at the closest point) and that the survey is being refined through the consultation process and the distance might change.	3092
4059	Concern about the potential impact on the Abalone industry and the need for compensation if marine species are killed off.	Titleholder acknowledged this concern and noted that potential impacts to commercial fisheries from physical presence is assessed in E1 of the EP, and potential impacts to marine invertebrates from underwater sound is assessed in E4 of the EP. Advised that control measures to reduce impacts to commercial fishers as a result of loss of catch are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	2089
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4072	Concerned of impacts to commercial fishing business	Engaged with stakeholder to understand their concern and undertook thorough assessment, including reviewing paper submitted by stakeholder and providing stakeholder references as requested.	4446
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to	1244

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		reduce any impacts to as low as practicable.	
4074	Concerns about implications for the population of Rock Lobsters in the area going forward.	This claim has been thoroughly assessed in E1 and E5, and F3 for southern rock lobsters. The known effects to individual lobsters are not predicted to have any measurable effect on population levels or dynamics.	2773
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers because of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4551
4083	Concerns about why more seismic needed and what time of the year was the survey going to be done to minimise impacts to fishing for sharks, lobsters, squid	Titleholder acknowledged this concern and each of the species within this claim has been subject to extensive assessment in E1, E3, E4 and F3 with various measure adopted to limit the sound exposure to the lowest level possible to meet geophysical objectives and to protect marine fauna (see G1).	740
4084	Concerns for reduced landed catch during the survey due to displacement. Have historical data going back many years to show if changes.	The titleholder has acknowledged this concern and note that displacement is assessed in the EP E1 and F3 as a potential impact of the physical presence of the activity. Control measures to reduce impacts to commercial fishers as a result of displacement are outline in EP. The Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area. While onshore fish processing is not covered by NERA protocol a claim will	4108

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		be considered based on appropriate historical evidence.	
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	2766
4109	Fishers discussed the historical impact of seismic surveys on the fishing industry, specifically noting that the “3 mile” area, which previously supported two vessels’ catches, has become unfishable since seismic activities.	Regia MSS committed to providing a map of historic seismic activity (2D and 3D) across the proposed area. As well as Map of Regia MSS Acquisition Area, Draft Regia Compensation Protocol, Map of all seismic surveys for past 20-25 years in the region, Fishery Report with analysis of all catch rates, draft impact assessment for fishing (Event ID 1892).	1892
4114	I have serious concerns regarding effects to local industry - tourism and fishing in particular.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E1. Measures to minimise adverse impacts on functions, interests and activities on other marine users including commercial and recreational fishers and marine tourism, are outlined in the EP.	2117
4124, 4125 & 4305	Interference with Orange Roughy Research Program: request for no data acquisition, or turns, over the sample collection areas, with buffer between the acquisition and sample areas.	As shown in map MAP-REG-EPM-050_B (Appendix B12), the activity was reduced to ensure there is no overlap of sampling areas with the active source area, including turns. There are no specific studies focused on seismic effects on Orange Roughy, however, inferences can be drawn	1649, 2002 & 3350

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		from research on other species. In particular, multiple studies have investigated the impact of seismic surveys on the spawning behaviour of cod, given this is a period in the life cycle when individuals gather in large numbers (Mcqueen et al 2022, Mcqueen et al 2023). Both studies found cod were not significantly disrupted from their spawning behaviour after exposure treatments representative of a full seismic survey at distances ranging from 5-40km. These distances closely align with the proximity between the Regia MSS acquisition area and the Orange Roughy Study central sampling area, 5.27 km at its nearest point (see Appendix B12, map MAP-REG-EPM-050_B). Based on this, we do not anticipate any significant level of disturbance to Orange Roughy in the sampling area. A small portion of the central sampling area overlaps with the operational area; however, this will not have a greater impact than any other vessel transiting the area. Therefore, there is no break to the time series of the data, due to lack of overlap with the active source area. An activity limitation of No sound source discharges within the Orange Roughy research program areas, is in place.	
4337	Interference with Orange Roughy Research Program: request the exclusion starts a month earlier from April 2024	As shown in map MAP-REG-EPM-050_B (Appendix B12), the activity was reduced to ensure there is no overlap of sampling areas with the active source area, including turns. A small portion of the central sampling area overlaps with the operational area; however, this will not have a greater impact than any other vessel transiting the area. Therefore, there is no break to the time series of the data, due to lack of overlap with the active source area. An activity limitation of No sound source discharges within the Orange Roughy research program areas, is in place. As the Regia MSS is not prohibiting the ability of the research program to catch the fish required for the study to continue uninterrupted, negating the need for exclusionary months.	2003
4153	Presents a historical account of their catch rates over 24 years, indicating that seismic surveys in the past led to a significant decrease in their catch from 10-15 tons per trip to just 5-6 tons per trip for over two years. They now report a catch rate of 10-14 tons	Titleholder acknowledged this concern and noted that potential impacts to molluscs the Regia MSS is assessed in E1, E4 and F3 of the EP. Advised that control measures to reduce impacts to commercial fishers as a result of loss of catch are outlined	5190

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	per 7 days, suggesting lingering concerns about how current seismic activities may similarly affect their fishing operations.	in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	
4165	Risk of losing craypots due to being cut off by vessels during transit.	Titleholder acknowledged this concern and noted that displacement is assessed in the EP Chapter on physical presence (7.4.1.4 and E1) as a potential impact of the physical presence of the activity. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include mitigation measure: Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4516
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment as a whole.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also made reference to documents relevant to this claim within the environment plan (Event ID 4092).	4091
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2118
4188	Stakeholder expressed concern having other displaced fisherman	Titleholder acknowledged this concern and noted that displacement is assessed in the EP	4516

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	moving into the area they work in has resulted in reduced catch rates.	Chapter on physical presence (7.4.1.4 and E1) as a potential impact of the physical presence of the activity. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include the Adjustment Protocol which stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	
4204	Stakeholder provided feedback post Regia team attendance at AGM regarding OMICC, the report and fishing data. Specifically disputing the claim that the 2019 SETFIA report did not provide an accurate estimation of effects. The feedback asserts that the report is, in fact, highly accurate, detailing the average catch tonnage from fishing operations in the survey area over the past 20 years and using current pricing data. The data was compiled by Fishwell Consulting. It is suggested that CGG may have misunderstood the implications of displacement, believing that all catch would require compensation, while the report indicates that only a portion (20-25%) of catch was affected, emphasising the relevance of these findings for projects in the Otway region.	CGG has already responded to many of these claims in prior correspondence. Avoidance measures and mitigation measures have been adopted to manage interference with commercial fishers. CGG does not misunderstand the importance of historical data, but it is not relevant to the future activities of commercial fishers or have any relevance to the management of interactions.	5231
4213	Stakeholder wanted to enjoy recreational activities without the disruption and destruction caused by the proposed activities.	Titleholder responded advising that displacement of recreational marine users is an assessed impact of the activity that is temporary and recoverable. The activity occurs no closer than 25km to the coastline at its closet point (south of Port Fairy) and lasts for no longer than 90 days.	820
4214	Stakeholder was mainly worried about being displaced from their fishing areas due to the activity.	Titleholder acknowledged this concern and noted that displacement is assessed in the EP Chapter on physical presence (7.4.1.4 and E1) as a potential impact of the physical presence of the activity. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include the Adjustment Protocol which stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the	4516

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		fishery associations that represent the commercial fishers that fish within the Operational Area.	
4219	Survey timing - trawling occurs all year round so shifting timing isn't a protective measure for the economics of the survey.	In addition to the avoidance of the aggregated peak fishing effort in the summer (January, February, and March), the acquisition area has been reduced following consultation to the 200m depth contour, with acquisition in no shallower than 50m water depth. A comprehensive adjustment protocol to pay for evidence-based claims of unavoidable interference with commercial fishers is also in place, along with communications protocols to minimise interference.	4788
4221	The Association expresses concern regarding the potential impacts of the survey, emphasising that the lack of accurate data makes it impossible to determine what those impacts might be. Additionally, members voiced apprehension about CGG's ongoing criticism of the independent consultancy Fishwell, which produced the 2019 report and related BACI study. They view this criticism as a potential tactic to undermine Fishwell's credibility, suggesting that such actions reflect poorly on CGG.	CGG has responded to these claims previously. The accuracy of the historical data has no influence on how the future interactions between commercial fishers and the Regia MSS will be managed. The economic impact to individual fishers will be determined by claims being made through the adjustment protocol and reasonable evidence-based claims will be paid. Further, CGG did not criticise the Fishwell report. CGG did assert that SETFIA/SSIA using the data as an indicator of impact measurement is not appropriate.	5231
4223	The comment states that harming the environment, which is essential for social, cultural, and economic well-being, would be irresponsible. They advocate against the introduction of new gas projects, emphasising the need to prioritise environmental protection.	The titleholder responded indicating Oil and gas activities have occurred in this region for 25 years. The titleholder indicates the industries strong environmental performance. The titleholder ensures impacts will be short-term by maintaining by applying the highest environmental standards for seismic surveying in Australia.	2098
4229	The feedback asserts that CGG's estimation is inaccurate for two main reasons. First, it assumes that fishing activity is uniformly distributed across the fishery, which contradicts the realities of commercial fishing. Second, participants in the meeting expressed concerns about the use of average prices, indicating that it fails to reflect the current value of fish. The feedback points out that it was unclear whether the price data used was from the past 10 or 20 years, suggesting that the average price per kilogram cited by CGG is likely only half of the actual market value. Additionally, it is argued that the average prices may have been	CGG has responded to these claims previously and has outlined the approach to compensation in the OMICC protocol. There have been plenty of opportunities for the relevant person to raise new issues. Further refinements can be made for individual fishers through the evidence-based process which is specific to individuals. The claims made by this person about matters that relate to the whole fishery are irrelevant to compensating displaced fishers.	5231

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	derived from data across the entire fishery rather than being specific to the fish species caught in the Otway Basin and landed fresh in Portland.		
4233, 4234	The feedback provided raises a concern from both SETFIA and SSIA that the titleholder should fulfill its claimed regulatory obligation, and that they remain of the belief, to take reasonable measures to mitigate impacts on stakeholders. They suggest conducting a 20-year data review of catch records across all fisheries, especially their own, to better understand the volume and economic value of catch areas that overlap with the planned activity. By analysing this data, the stakeholders believe that collaborative solutions could be identified to reduce the impact on fisheries with potentially minimal loss to the company's acquisition area.	CGG obtained and provided the information from another reputable consultancy using ABARES data obtained via AFMA, which SETFIA use, this data is described in Appendix E1, section 4.1. Following feedback from SETFIA this was investigated, with AFMA confirming the reliability of the ABARES data (Feedback ID 1237), stating it uses logbook and other AFMA collected data. They did note that industry associations have previously been critical of the economic aspects of the ABARES data, however this data is based on in field surveying of fishing industry operators. However, the information being requested had no utility in managing impacts on commercial fishers. The stakeholder suggested the relevancy being for CGG to know how much they may need to pay via a compensation plan (Event ID 3382). This was deemed to have no utility for minimising impacts as the reports obtained by CGG allowed for consultation with commercial fishers to identify potential high impact areas and manage these. The data would not improve or add to the minimisation of interactions with SETFIA's members, all concessions possible have already been made, as documented in Appendix A2, section 4. The adoption of the compensation protocol is confirmed. An exclusion of acquisition in water deeper than 200 m was confirmed by local fishers to be workable and removed their concerns.	5194
4235	The feedback questions if a strong environmental record includes the severe impacts of seismic activity on fishing industries, like the scallop industry near King Island, which has suffered losses reportedly without compensation.	Seismic survey effects on molluscs, including scallops are well understood and not mortal in our circumstance. There are many environmental pressures that cause fluctuations in fish populations, not just sound. We have a track record of successful co-existence with the fishing industry and of paying reasonable evidence-based claims for compensation - which we will do for the Regia survey.	2083
4239	The feedback raises concerns about the impact of seismic activities on the	It would be unacceptable to have mortal effects on any marine species	2093

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	Abalone industry, suggesting that the industry may be negatively affected by the proposed exploration and seismic testing. This indicates a broader concern for the sustainability of marine life and the economic implications for local fisheries.	from our or any marine seismic survey. We do not predict mortal effects to molluscs (including scallops, abalone, oysters, clams, mussels, limpets, squids, octopus and cuttlefish etc.). Our full assessment of predict impacts on molluscs will be made publicly available as soon as it's completed.	
4242	The fisher expressed concerns due to his smaller vessel, which he launches from the Port Campbell jetty. Unlike larger vessels, his boat's size limits his ability to access deeper or more distant waters.	Understand the constraints on RP and the nature of RP's operations. As a result, confirmed that CGG would consider an exclusion zone around RP's preferred fishing blocks.	2026
4249	The largest jig fishery for squid in Bass Strait operates in the depths and area proposed for the project, raising concerns about the impact on squid reproduction.	As stated in the Commercial Fishers Information Sheet, the Southern squid jig fishery has been identified as present in the area and as such has been assessed in the Impact Assessment and in our Acceptable Levels of Impact and Risk document. From this research and assessment, the following mitigation effectiveness was concluded: While the probability of adverse consequences for squid populations from seismic is extremely low it is appropriate to reduce any probability to as low as possible. The timing of peak catches has centred around February/March in the Western Victoria fishery hence avoiding seismic during this period is advisable. Two windows have been identified for the survey to occur, being April – June and September – December, avoiding the February-March period.	3917
4253	The possible effects to marine life and ecosystems is my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are	2256

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4285	The stakeholder noted their concern as a resident of Port Fairy: noise (land and sea), impact on marine life, potential impacts on the	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	environment and the future potential if gas is found.	impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	
4295	The stakeholder recounted a previous experience where seismic surveys harmed the fishery for two years. They possess catch history data that highlights the decline in fish populations before and after the survey activities took place.	Titleholder acknowledged this concern and noted that potential impacts to commercial fisheries from physical presence is assessed in E1 of the EP. The titleholder advised that control measures to reduce impacts to commercial fishers because of loss of catch are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	5190
4308	The stakeholder was concerned about the environmental impact on Port Fairy residents who have fishing businesses and recreationally fish in the area.	Impacts from physical presence on both commercial and recreational fishing are assessed in the Environmental Plan (EP) and can be found in E1. Measures to minimise adverse impacts on functions, interests and activities on other marine users, including commercial and recreational fishers in the region are outlined in the EP.	2273
4311	The stakeholder, who owns and operates two commercial fishing trawlers based in Portland, Victoria, expressed concern about the potential effects of seismic activities on the southeast trawl operations.	Titleholder acknowledged this concern and noted that potential impacts to commercial fisheries from physical presence is assessed in E1 of the EP. Advised that control measures to reduce impacts to commercial fishers as a result of loss of catch are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that	5190

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		represent the commercial fishers that fish within the Operational Area.	
4336	Threat to coastal aesthetics of Port Fairy and potential impact on property value and tourism income.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will be operating at >25km from the coast and will not impact any aesthetics.	1263
4342	Attendees stated that the fishery has seen significant improvement, marking its best condition in about six years, since the last seismic activity in the region. This feedback highlights concerns regarding the potential negative impacts of upcoming seismic activities on the current health of the fishery.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E1 and F3. Measures to minimise adverse impacts on functions, interests and activities on fisheries are outlined in the EP.	1529
4343	Questions possibility of compensation for the abalone industry if their stocks are depleted as a result of seismic testing, drawing a parallel to the scallop industry near King Island that was adversely affected. It highlights concerns regarding accountability and the financial implications for local fisheries in the event of ecological harm.	The titleholder acknowledged this concern and noted that potential impacts to the abalone industry. It would be unacceptable to have mortal effects on any marine species from our or any marine seismic survey. We do not predict mortal effects to molluscs (including scallops, abalone, oysters, clams, mussels, limpets, squids, octopus and cuttlefish etc.). Our full assessment of predict impacts on molluscs can be found in E1 Section 8, E4 Section 8 and F3 Section 4.	2093
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383
4537	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of	424

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880
4433	Seismic impacts can linger longer than the few hours suggested, the insistence on peer-reviewed work to prove this is opportunistic and suits OMICC's agenda.	Event 6724 - OMICC announces that the latest version of the OMICC Otway Adjustment Protocol has been published, along with a video briefing for fishers, which can be accessed through a provided link. In the briefing, OMICC confirms that, following the relevant persons feedback, a "claim period" and a "lodgment period" have been incorporated into the definitions of the protocol. The claim period is set to 30 days after the end of any activity, while the lodgement period extends up to 6 months after the end date of any activity. OMICC further informs the relevant person that the OMICC Founders reviewed the request for claims up to 6 months after an activity. However, the decision was made to adopt a 30-day claim period, as this duration resulted in a positive compensation outcome for fishers affected by the Gippsland survey in 2019.	6749
4434	It is critical that fishers are compensated if their catches are negatively impacted by MSS.	A compensation protocol has been adopted.	6749
4436	The relevant person stated that it was evident what had impacted rock lobsters in the early 2000s.	Event ID 6595 - Titleholder responded to relevant person outlining approach to assessment of fisheries and SRL, including assessment of mitigations in place.	6594
4449	Concerned about unexploded ordinance in the area.	Event ID 6875 - The Regia team responded in-meeting and explained they had worked with the Department of Defence and that anything the fishers may be finding	6875

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		could be the result of munitions dumped post- World War 2.	
4452	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	7136
4453	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	EVT070
4487	Claims that CGG's proposed activities are inconsistent with the Recovery Plans made under the EPBC Act, the Southern Right Whale Recovery Plan and the Blue Whale Recovery Plan. GMTOAC states that these activities pose known physical and behavioural risks to the Eastern Population of Southern Right Whales and to Pygmy Blue Whales. These risks include impacts from anthropogenic underwater noise, particularly seismic noise, vessel strikes, climate-driven changes in prey availability, and the cumulative effects of these pressures, all of which have the potential to injure or kill individuals and affect populations. GMTOAC notes that under the EPBC Act Program and NOPSEMA's decision-making guidelines, an Environment Plan cannot be accepted if it is inconsistent with a recovery plan. It emphasises that both Recovery Plans contain "Very High" importance actions requiring that Blue Whales and Southern Right Whales must be able to continue using their Biologically Important Areas (BIAs) without auditory impairment, injury, or displacement. The plans also call for preventing disruption and displacement of Karntubul (Southern Right Whales) from BIAs due to anthropogenic noise such as seismic surveys.	CGG maintains that its approach aligns with statutory obligations and industry best practice. It asserts that all regulatory requirements under Regulation 34 have been met, and that its environmental performance outcomes and control measures are grounded in the best available science and tailored to the ecological and cultural sensitivities revealed through consultation. The Regia MSS Environment Plan (EP) was designed to ensure impacts and risks are reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. Regarding whale protection, CGG highlights that the EP includes specific mitigation measures for culturally and ecologically significant marine fauna, including species noted in relevant Recovery Plans. Early correspondence in February 2023 identified Southern Right Whales and Pygmy Blue Whales as key sensitivities, and the EP commits to spatial and temporal avoidance measures, sound-source shutdowns, and exclusion zones to protect them. These measures explicitly consider cultural significance, such as timing restrictions to avoid the Karntubul (Southern Right Whale) birthing period. The whales, Karntubul and Wuuloc, are identified in the EP as sensitive receptors with dedicated protective measures. CGG confirms that these cultural and ecological sensitivities were incorporated into the environmental	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		assessment. The EP acknowledges the sacred cultural status of Koontapool (Southern Right Whale) and Wuuloc (Pygmy Blue Whale) for the Gunditjmara people and includes them in impact and cumulative risk assessments. Appendix F3 references the Nyamat Mirring Plan 2023–2033 and recognises Gunditjmara spiritual connections, including to Karntubul. CGG substantively addresses the relevant issues, including underwater noise, vessel interactions, and cumulative effects. The EP sets out noise-management frameworks, timing restrictions, and cumulative impact analyses consistent with the concerns raised.	
4490	CGG has failed to adequately assess the impacts of its proposed activity on the Budj Bim World Heritage Cultural Landscape. GMTOAC further states that CGG did not sufficiently evaluate impacts on Kooyang, a culturally significant species whose lifecycle and migration underpin the world heritage values of the Budj Bim Cultural Landscape and extend well beyond its physical boundaries.	Culturally significant features, including the Budj Bim landscape, were included in both impact and cumulative risk assessments using a methodology that blends scientific evidence with cultural narratives. Regarding Kooyang (Eel), CGG maintains that this culturally important species, whose lifecycle is central to the world heritage values of Budj Bim, was addressed within the EP's impact and cumulative assessments. These assessments include both Kooyang's cultural significance and ecological role. CGG reiterates that its EP is consistent with statutory obligations, based on best-available science, and tailored to the cultural and ecological sensitivities identified. CGG maintains that the Budj Bim Cultural Landscape and Kooyang have been incorporated into the EP and that this inclusion meets regulatory standards for demonstrating ALARP and acceptable levels of impact.	EVT352

Objections and Claims Raised from Consultation 38

1 Introduction

Underwater Sound was identified through the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) as an environmental aspect needing further assessment. Hence this document presents a detailed examination of **Underwater Sound**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental receptor we are collectively calling **Plankton.**

This assessment is built on the information contained in the following four core studies, which should be read in the order they are listed:

1. PEIRA
2. Seismic Sound Studies Report (Appendix B8)
3. Sound Emissions Initial Modelling Report (Appendix B7)

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was initially published in draft form and uploaded to the Document Library of the Regia MSS Consultation Hub on 11 September 2023 as a stand-alone document, rather than as part of the much more substantial total EP document. This was done to maximise the ability of interested members of the public to read, interpret and respond within the mandated 30-day public comment period.

As such, public and Relevant persons were invited to comment on the document with an explicit request for feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

The primary sound source will be impulsive underwater acoustic emissions coming from the seismic source releasing compressed air (seismic pulse) and creating a sound wave directed downwards towards the seabed.

Secondary sound sources will include continuous underwater acoustic emissions generated by the survey and support vessels and helicopters. Sounds from vessels are generated by thrusters, engines, and propellers. Underwater acoustic emissions from helicopters are generated via the engine and rotors. Underwater acoustic emissions from Ultra-Short BaseLine positioning are generated within the streamer spread.

An overview of underwater sound and studies relevant to seismic is in Appendix B8.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days

Extent: Active Source Area + 740 m based on the furthest distance to modelled sound effect criteria. [Updated in response to Matter: F17]

The seismic source will only be active in the Active Source Area.

Continuous Sound

Duration: 90 days

Extent: Operational Area

The survey and support vessels and helicopters will be active in the Operational Area for the duration of the survey undertaking support activities and acquisition.

3 Cause-Effect Pathway

The PEIRA identified a cause-effect pathway for underwater sound for the following environmental components and their social, cultural, and economic features:

- Plankton.
- People and communities.

Potential environmental impacts to plankton identified from the PEIRA are:

- Change in fauna behaviour.
- Change in physical condition.

There is no scientific information on the potential for underwater sound impacts on phytoplankton and no cause-effect pathway has been established. Thus, the impact assessment focuses on impacts to zooplankton from seismic sound emissions.

In addition, there is no scientific information on the potential for continuous underwater sound impacts to plankton and no cause-effect pathway has been established. Thus, the impact assessment focuses on impacts from impulsive (seismic) underwater sound to zooplankton.

From relevant person consultation, commercial fishers have raised concerns in relation to impacts to commercial fish and invertebrate spawning and recruitment. The assessment of impacts to commercial fish and invertebrate spawning and recruitment is covered by species in the underwater sound Impact assessment sections for invertebrates and fish.

From relevant person consultation, concerns have been raised in relation to impacts to zooplankton, particularly the copepod *Nyctiphanes australis*, generally called krill, which is an important component of the upwelling and productivity systems within the Survey Operational Area. These concerns are assessed in this section.

4 Description of the Existing Environment that may be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8. Plankton is a collective term for marine organisms that are unable to swim against a current. This group is diverse and includes phytoplankton (plants) and zooplankton (animals).

Plankton is a key component in oceanic food chains and supports nearly all marine life and is the dominant biomass of marine ecosystems (CSIRO 2015). The carrying capacity of marine ecosystems (the biomass of fish resources) and recruitment of individual stocks is strongly related to plankton abundance, timing, and composition.

Plankton communities are highly diverse, with members from almost all phyla. Phytoplankton are the [plant] base of this community, capturing energy through photosynthesis while drifting with the ocean currents. They are grazed by zooplankton which are comprised of meroplankton which spend only the early part of their lives in the plankton (e.g. larval stages of jellyfish, molluscs, invertebrates, and fish) and holoplankton, such as copepods, chaetognaths and salps, which spend their entire life as zooplankton (White 2018).

The small sizes, short lifespans and high abundances of zooplankton enables fast rates of production and turnover of populations. It is advantageous to grow and multiply quickly to maximise access to phytoplankton resources when they become available (White 2018). Zooplankton are the key trophic link converting primary production into a food source for fish, such as sardines, which in turn are consumed by top predators such as tuna, shark and dolphins.

Watson and Chaloupka (1982) reported a high diversity of zooplankton in eastern and central Bass Strait, with over 170 species recorded while Kimmerer and McKinnon (1984) reported only 80 species in their surveys of western and central Bass Strait.

CSIRO's Australian Ocean Data Network which is a primary resource for marine science data does not contain any data collection points within the Active Source Area. The closest data points, located south of Wilson's Promontory, show that zooplankton samples taken at these sites from 2011-2020 contained copepods, appendicularians, chaetognaths, decapods, thaliaceans, cladocerans, amphipods, cirripedes and mysids with copepods the most abundant group in the samples. Surveys of the Eastern Great Australian Bight also highlighted the dominance of copepods in the zooplankton community (Van Ruth & Ward 2009).

4.1 Regional Oceanography

The two dominant features of the ocean along the southern Australian margin are a warm mixed-surface layer that is underlain by cooler Antarctic Intermediate Water (AAIW). The mixed surface layer flows in a generally east-southeast direction and is known as the Leeuwin Current off west Australia, the Coastal Current off South Australia and Victoria, and the Zeehan Current off west Tasmania. An underlying counter current of AAIW flows in a generally north-westward direction at a depth of about 400-600 m, extending to depths ranging from 500-1500 m (Wood and Terray 2005, Kampf 2024). This is known as the Flinders Current off western Tasmania, western Victoria and South Australia, and the Leeuwin Undercurrent off west Australia (Middleton and Cirano 2002). This is a perennial subsurface slope current and feeds into shallower shelf circulations during summer as wind from the southeast forces the mixed surface layer offshore and triggers a compensatory upwelling of AAIW from greater depths (Kampf 2024, Levings 2025). This currents role in the regional upwelling system includes the transportation of nutrient-rich, sub-Antarctic slope water westward along the continental slope (Kampf 2024). This upwelling, particularly along the Otway Shelf, influences water temperature and nutrient availability, linking to events like the Bonney Upwelling off South Australia.

Analysis of temperature, salinity, and nitrate data for western Victoria described by Levings (2025) showed distinct stratification of the water column over the shelf in the summer. The constant nature of salinity values ranging from 80 m – 200 m, <14.0°C, and the accompanying nitrate values, indicated the water was reheated Antarctic Intermediate Water (AAIW). Hence summer water at temperatures of <14.0°C was upwelled AAIW and measurement of temperature alone was sufficiently robust to investigate for linkages between the Bonney Upwelling off South Australia and the shelf waters of western Victoria.

Langmuir Circulation is a type of wind-driven surface current that occurs on a smaller, localised scale in regions exposed to high-speed winds traversing unidirectionally. Under the strong winds water flows in a series of "Langmuir cells", each of which can be several meters in depth and width. Adjacent cells rotate in opposite directions. Therefore, the overall direction of these cell systems within the Langmuir Circulation process is the same as the wind direction, the rotation of these cells is typically perpendicular to the wind direction. Regions of divergence and convergence between cells also result in upwelling and downwelling formations (Figure E2 - 1). The velocity within Langmuir cells may be in the order of 30cm/s-1 (G Cresswell, described by Levings 2025). This process creates rotating water patterns that transport nutrients and debris, affecting local ecosystems, and further contributing to the oceanographic complexity on a regional scale.

Australia's southern shelves are subject to a seasonal upwelling system known as the Great Australian Coastal Upwelling System (GSACUS) which occurs seasonally during November to April. This system is comprised of three distinct upwelling centres; one of which is the Bonney Upwelling which extends spatially from Cape Nelson to Cape Jaffa (Kampf 2024). Upwelling refers to physical processes that lift or entrain subsurface water into the eutrophic zone, where it can trigger autotrophic phytoplankton production if nutrient limitation is overcome (Shute et al. 2022). Upwelling in this region is catalysed by seasonal prevailing south-westerly coastal winds. Both the South Australian Current (south-eastward flowing) and north-eastward coastal currents also contribute to the surface circulation of water in the region during the austral summer months (Kampf 2024).

Wood and Terray (2005) present findings from a study conducted approximately 40 nautical miles off the coast of Portland, Victoria where data on wave and current dynamics was gathered in this region of the Otway Basin during the austral winter of 2004 (April to October). Findings from this study included the observed typical wave conditions in the Otway Basin as being long-period, open-ocean swell, with an average wave height of 3.7 meters. The dominant wave directions were identified as coming from the southwest, propagating north-eastward.

Currents at the study site were observed to flow parallel with the slope, either eastward or westward, with easterly flows being the most common. Currents were described as rarely being in the cross-slope, or north-south direction. Currents near the surface were observed as being stronger than those measured in deeper layers. Peak current speeds were recorded as being 2.8 knots near the surface. Current speeds were however observed as being less than 1 knot more than 90% of the time. At 50 meters, peak measured speeds were less than 2 knots while peak speeds were 1.4 knots at 200 meters. In all cases, the strongest currents reportedly flowed eastward. Deeper currents flowed westward typically, especially below 500 meters. Near-bottom currents were affected by local bathymetric relief, but generally flowed downslope (i.e., southward) (Wood and Terray 2005).

Results from Phase I (late autumn, early winter) suggested that currents at the study site could be defined as a two-layer system: the top layer (Coastal Current) flowed eastward while the bottom layer (the Flinders Current) flowed toward the west. The depth interface between these two major current systems appeared to be about 100-200 meters in April, deepening to about 500 meters by late June. Correlations between the upper layer and deeper layers improved during Phase II (winter) of the study when the water column was observed to move in a more uniform manner, with currents near the surface moving in the same direction (generally) as those in deeper layers. It was unclear whether these changes were due to seasonal influences (Wood and Terray 2005).

Deeper currents were most commonly westward, and much weaker typically than those eastward flows nearer the surface. Despite these 'normal' conditions, the study described instances during the six-month study, especially those observed during Phase II (July to October) when the entire water column appeared to flow in the same direction, contradicting the general assumption of two distinct layers. These instances (i.e., when entire water column flowed eastward) was observed as occurring every 30 days on average. Significant variability was also observed with deeper currents, below the eastward-flowing upper layer (the Flinders Current). These deeper layers which were typically observed to flow weakly westward, occasionally reversed to flow to the east (Wood and Terray 2005).

The metocean oceanography of the Otway shelf exhibits complex, seasonal patterns of stratification and mixing, interannual variation, with contributions from diverse locations. Variability of metocean conditions over the Otway Shelf is the subject of ongoing research, to refine understanding of this variability, ecosystem impacts, and climate influences on the region's oceanography.

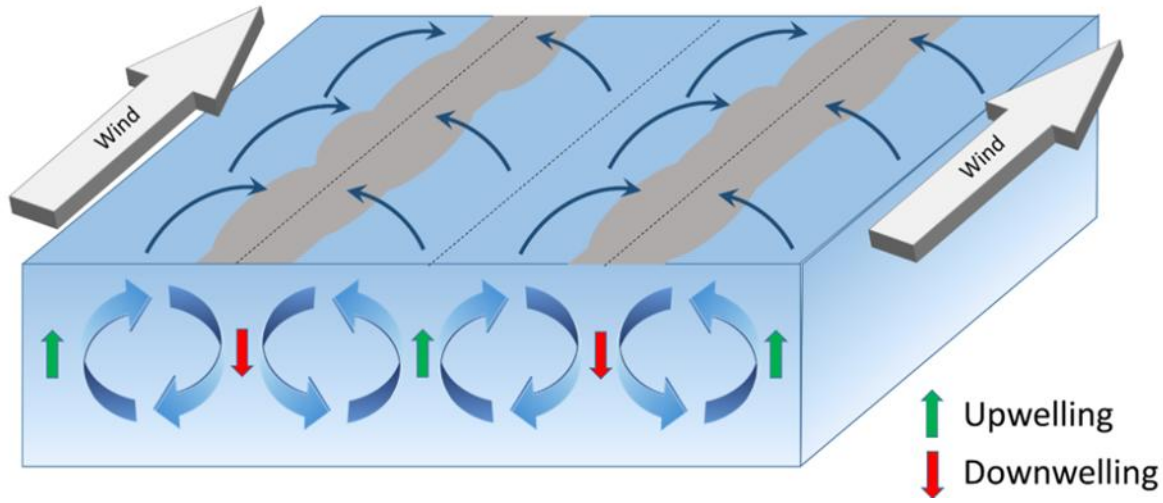

Figure E2 - 1 - Schematic of Langmuir Circulation (Webb 2023).

4.2 Krill - *Nyctiphanes australis*

N. australis is a common endemic coastal species of krill in southern Australian waters and plays an important role in the ecological significance of upwelling events in the area (e.g. the Bonney Coast Upwelling). *N. australis* is one of the most important dietary items for Pygmy Blue Whales, Jack Mackerel, Short-tailed Shearwater, Fairy Prion, Australian Salmon, Skipjack Tuna and Tiger Flathead among other abundant fish and seabirds (Nicol and Endo 1997).

The latitudinal range of *N. australis* in Australian waters extends from 31°S–44°S latitude to 132°E–156°E longitude, reaching their highest abundances in shallow waters of the continental shelf, predominantly during night-time vertical migrations (Hosie 1982). This vertical migration pattern is more evident during summer than winter (July to September), when *N. australis* becomes relatively scarce in the upper water column, even during the night. In southeastern Tasmania, highest abundances are found in summer between the surface and 40 m during the night and 30–100 m during the day; however, it is not rare to observe large numbers swimming ("swarming") at the surface during daytime (Lagos 2021, Gill 2002).

N. australis has one of the highest production-to-biomass ratios, including moulting and egg production, among all krill genera, about 10 times higher than values found for the Antarctic krill species, *Euphausia superba* (Lagos 2021). Production of *N. australis* ranges from 78.3–84.8 mg m^{-3} y^{-1}

(Ritz & Hosie 1982). It also has the fastest growth rate of the *Nyctiphanes spp.* at 40 d (Haywood & Burns 2003 in Lagos 2021).

As detailed in Butler et al. (2002) *N. australis* live ~ 1 year, reach sexual maturity at 3-4 months, with a maximum length of 20 mm and weight of 40 mg and are known to be omnivorous. The species broods its eggs until they hatch rather than spawning them directly into the water column. There is continuous maturation of ova, with an individual female capable of releasing a total of 1100 eggs in a lifetime, which are deposited as a series of batches into a pair of external ovisacs, every 30 days (Hosie 1982).

There is a main peak of spawning from early spring to late autumn, but reproduction continues through all months with as many as three generations produced each year. Continuous reproduction through the year coupled with a high growth rate means that *N. australis* has very high productivity (UTAS 2003). Gill and Morris (2003) noted that surface swarms of *N. australis* were sighted in all months that aerial surveys have been conducted except September, when no surveys were conducted. Sighting covered shelf waters from near King Island to waters 50 km west of Robe, SA.

Krill cannot swim horizontally, which implies that coastal currents are the only means by which krill can appear in the Bonney upwelling region during the seasonal upwelling plumes. These transport route of krill along Australia's southern shelves are currently unknown. Particle tracking conducted in a study by Kampf (2024) suggests that krill swarms are advected northwestward along the narrow continental shelf by the coastal upwelling current and winds, that extend the entire coastline to Cape Otway.

Kampf (2024) suggests that the upwelling current may be too weak in some upwelling seasons to transport krill all the way downstream past Cape Jaffa into the upwelling plume, so it is therefore likely that the largest number of krill swarms remain present in coastal waters upstream from Cape Nelson. This may explain frequent sightings of blue whales in this region. Kampf also notes that the continental shelf becomes narrower from Cape Otway to Cape Nelson, and that this feature supports the funnelling of krill swarms into a narrow, confined stream making it relatively easy for whales to obtain food.

Upwelling-favourable winds in the region have been measured as having a speed of 5-6 m/s (Nieblas et al. 2009). The continental shelf along the Bonney Coast is ~60–100 m in depth. The upper continental slope is relatively steep (up to 1o slope). With a speed of the upwelling jet of ~0.4 m/s (Kampf 2024), it has been determined by Kampf (2025) that it takes 8–10 days for a water parcel to travel along the entire Bonney Coast upwelling region. A key finding from the Kampf (2025) study identified Long Bay as potentially important upwelling shadow, with high zooplankton abundance and a potential region of larvae retention. This pivotal finding offers valuable new insight into the Bonney Coast, identifying a specific region that may serve as a critical zone of heightened productivity for zooplankton in the region.

4.3 Upwelling and Productivity

Upwelling refers to physical processes that lift or entrain subsurface water into the eutrophic zone, where it can trigger autotrophic phytoplankton production if nutrient limitation is overcome (Shute et al. 2022). Phytoplankton are the food source underpinning the trophic structure and flow of energy through marine food webs as they are consumed respectively by zooplankton and these in turn are consumed by larger and larger predators (CoA 2015a).

Each year during summer, a number of well-described coastal upwelling centres develop along Australia's southern coastline off the Bonney coast (Lewis, 1981, Schahinger 1987), the southern tip of the Eyre Peninsula (Kämpf et al. 2004), and the west coast Tasmanian shelf (Kämpf 2015). Upwelling also occurs along the Otway Shelf between Portland and King Island (where the Regia MSS will be undertaken). However, upwelling along the Otway Shelf is primarily sub-surface, with only a narrow

band of surface upwelling inshore during strong upwelling events (Levings and Gill 2010). These sub-areas of upwelling are recognised as components of a unified upwelling system extending from the eastern Great Australian Bight to western Bass Strait/west coast Tasmania and are referred to as the Great Southern Australian Upwelling System (GSACUS) (Kämpf 2004, 2015).

The GSACUS is active during autumn and summer, driving simultaneous upwelling along the Bonney and Otway Coasts (Levings and Gill 2010). Cool upwelled water from depths of 200-400 m is nutrient rich, enhances subsequent upwelling events and leads to phytoplankton growth in the region (Rogers et al. 2013).

4.4 Bonney Coast Upwelling Key Ecological Feature

The Bonney Coast Upwelling (BCU) occurs between Cape Jaffa, South Australia and Portland, Victoria (DCCEEW 2023). It is a productivity hotspot, with high densities of zooplankton including the coastal krill (*N. australis)* which is an important food source for fish, birds and whales.

The BCU is driven by the frequent south-easterly winds which are the result of southern migration of the subtropical ridge (Nieblas et al. 2009, Schahinger 1987), during the austral summer. The upwelling occurs via Ekman dynamics, where the ocean surface experiences a steady wind stress resulting in a net transport of water at right angles to the left of the wind direction which brings cold, nutrient rich water to the sea surface.

The Bonney Coast Upwelling has been shown to follow a clear temporal pattern. When the upwelling season starts during late spring and early summer (November and December), the influence of the BCU was found to be often restricted to the coast. During the mid-summer and early autumn (January to March) when the upwelling is the strongest, the upwelling influence often extends to the shelf break before retreating in April (Huang and Wang 2019).

Gill et al (2011) states that the Bonney Coast Upwelling generally starts in the eastern part of the Great Australian Bight and spreads eastwards to the Otway Basin. At the height of the upwelling during February and March, its area of influence often exceeds 12,000 km^2, while its sea surface temperature anomaly often exceeds 1°C, and its chlorophyll-a concentrations are often >1.5 times adjacent areas (Huang and Wang 2019).

The BCU is one of only two identified seasonal feeding areas for blue whales in Australian coastal waters and is one of 12 known blue whale feeding aggregation areas globally. Sightings of Sei whales and Fin whales in the upwelling indicate this is potentially an important feeding ground for these species also (Gill et al. 2015, Morrice et al. 2004).

The BCU is regionally important as it supports the lucrative local fishing and tourism industry off the Otway towns such as Portland, which annually holds an Upwelling Festival in late October/early November to celebrate the abundance of the Bonney Upwelling, and to begin the summer fishing season (Glenelg Shire 2023).

The Bonney Coast Upwelling is defined as a Key Ecological Feature as it is an area of enhanced pelagic productivity and has high aggregations of marine life (DCCEEW 2023). In addition to whales, many endangered and listed species frequent the area, possibly also relying on the abundance of krill that provide a food source to many seabirds and fish. The high productivity of the Bonney Coast Upwelling is also capitalised on by other higher predator species such as little penguins and Australian fur seals feeding on baitfish (DCCEEW 2023).

The Regia Operational Area overlaps the eastern end of Bonney Coast Upwelling Key Ecological Feature by 1.21 % (Appendix B12 MAP-REG-EPM-003). The Regia Active Source Area does not overlap this KEF. [Paragraph updated in response to Matter E01].

4.5 Marine Flora

In Australia, shallow (<30 m) temperate reefs are defined largely by the distribution of *Ecklonia radiata* kelp forests, which span more than 8000 km of coastline from the subtropical waters of northern New South Wales down the east coast of mainland Australia, around Tasmania, along Australia's southern coastline and north as far as Kalbarri in Western Australia (Bennet et al 2015). Most of Australia's kelp-dominated temperate reefs lie within the 'coastal zone' under state jurisdiction (3 nautical miles or 5.5 km from shore) (Bennett et al 2015). On the south and west coasts of Australia, E. radiata forests typically occur in mosaics of mixed species with large canopy-forming fucoids (e.g. *Cystophora* spp., *Scytothalia dorycarpa*), covering most of the rocky reefs.

Timing of reproduction is variable across its distribution range with seasonal peaks in Western Australia and more continuous reproduction of sori and zoospores in Tasmania. Water temperature is the key driver of reproductive timing but is also influenced by other variables such as wave action. Once *E. radiata* zoospores are released, they have the ability to swim for at least 24 h (although they often do so for only 1–2 h), until they settle onto the substratum and germinate into male or female gametophytes. *Ecklonia radiata* can disperse via three modes; zoospores, sperm and detached fertile drift material. Population genetic studies on *E. radiata* using neutral microsatellite markers (Dolman & Coleman 2009, reported in Wernberg et al 2019) have identified that genetic structure around the Australian continent is weak, suggesting widespread gene flow that is mediated by the strength and direction of prevailing ocean boundary currents. Such strong connectivity should imbue considerable resilience on this species; however, climate change is operating at such a large scale that warming temperatures are negatively affecting kelp across its entire range.

Due to the depths associated with the Survey Acquisition Area, with no discharge of the sound source at full power to occur in water depths less than 50 m, impacts on larger plants and nearshore planktonic phases arising from the activities associated with the Regia MSS are not anticipated. There is no scientific information on the potential for noise-induced effect in macroalgae and no functional cause-effect relationship has been established. Therefore, impacts from acoustic disturbance on macroalgae/ marine flora, or associated cultural values has not been considered further.

It is understood there is potential for kelp in shallower, more coastal areas to be impacted in the highly unlikely event of a marine oil spill, and a detailed description of kelp, its cultural and seaweed industry value, and risks to kelp associated with a spill are detailed in EP Appendix D4 (Accidental Release of Fuel).

[Section added in response to Matters: E09, E10 and FN06].

4.6 People and Communities

4.6.1 Social and Economic Features

During consultation, as presented in Annex 2, objections and claims were raised regarding how impacts of the Regia MSS on plankton and the Bonney Upwelling could affect the reputation, health and function of the local ecosystem. These receptors are assessed below in Section 9.

4.6.2 Cultural features

The Bonney upwelling, where cold, nutrient-rich waters rise to the surface, is a key element in this ecosystem, boosting phytoplankton populations that sustain many species culturally important to the Gunditjmara (GMTOAC, 2023)

Kelp forests, home to giant and bull kelps, are identified as culturally significant to the Wadawurrung People as habitats and food sources for species with cultural values, including rock lobster and abalone and their ability to be used to create water carriers (WTOAC, 2020)

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for species of plankton that may be affected (see Appendix B3). No measures were identified from this process.

6 Defining Acceptable Levels of Impact

To define acceptable levels of impact to plankton, zooplankton, and krill sound exposure guidelines for eggs and larvae have been used by CGG from the American National Standards Institute (ANSI) accredited report of Sound Exposure Guidelines for Fishes and Sea Turtles (Popper et al. 2014).

The sound exposure guidelines from Popper et al. (2014) are based on references and studies on potential impacts of noise emissions on fish eggs and larvae prior to 2014. Results presented in Day et al. (2016b) for embryonic lobsters and Fields et al. (2019) for copepods align with those presented in Popper et al. (2014), which is that mortality and sub-lethal injury are limited to within tens of metres of seismic sources. Additionally, the Popper et al. (2014) sound exposure guidelines are extrapolated from simulated pile driving signals which have a more rapid rise time and greater potential for trauma than pulses from a seismic source.

For eggs and larvae, the sound exposure guidelines provide sound exposure metrics for:

- Mortality and potential mortal injury: Popper et al. (2014) suggests that injury to larvae resulting from seismic impulses may occur for sound exposures above 207 dB PK or above 210 dB SEL_{cum}. However, Popper et al. (2014) suggest that recoverable injury and TTS is likely within tens of metres of a seismic source, which is generally less than the distance associated with their proposed mortal injury threshold, hence there is some discrepancy. The threshold proposed for mortal injury is derived from pile driving impacts to fish and is likely to be conservative. The body of literature indicates that mortality and sub-lethal injury are limited to within tens of metres of seismic sources.

Within these sound exposure guidelines, there was insufficient data to make a quantitative guideline for:

- **Recoverable injury:** There are few studies to base criteria on, however, Popper et al. (2014) provides acoustic criteria extrapolated from simulated pile driving signals which have a more rapid rise time and greater potential for trauma than pulses from a seismic source. Popper et al. (2014) does not recommend a timeframe for cumulative sound exposure levels and thus 24 hrs has been used as is current industry practice.
- **Temporary threshold shift (TTS) in hearing:** There are currently no acoustic criteria for plankton, fish and invertebrate eggs or larvae, however, a scale of relative risk is provided
- **Behaviour / Masking:** There are currently no acoustic criteria for plankton, fish and invertebrate eggs or larvae, however, a scale of relative risk is provided in Popper et al. (2014). The scale assumes that a behavioural response is possible.
- For these impacts, a subjective approach of 'relative risk' (low, moderate, and high) is used to assess risk at three distances from the seismic source (near - tens of metres, intermediate - hundreds of metres, and far - thousands of metres)

Natural mortality rates within the plankton are variable but usually high, across all taxa (e.g. Garrido et al 2015). Estimates can range all the way from very little to as high as >99% (see review by Vaughn et al. 2010). Despite this level of mortality adult populations survive and thrive under natural conditions, indicating that such high mortality levels in the plankton are not an impediment to population persistence. Any potential mortality to planktonic communities from seismic needs to be assessed against this background mortality.

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E2-1 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment. [1]

Table E2-1 - General and Assessment Specific Defined Acceptable Levels

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Sound exposure to plankton communities does not compromise ecological integrity of the pelagic food web. Plankton communities should not be exposed to sound exposure levels of >210dB $SEL_{cum24hr}$ over a spatial or temporal scale likely to result in significant disruption to population dynamics.	Plankton communities are a critical component of marine ecosystems, forming the base of the food web and driving nutrient cycling. Although some individual plankton proximate to the sound source may experience lethal effects, acoustic impacts must not alter community structure or productivity. Maintaining ecosystem integrity ensures broader ecological functions are protected. Scientific literature (Popper et al 2014) and modelling (Appendix B7) conservatively indicate that levels above 210 dB $SEL_{cum\ 24hr}$ cause mortality or sublethal effects in plankton. This threshold represents the onset of ecologically meaningful harm and is a scientifically robust benchmark for assessing acceptability. The threshold can be modelled to understand the distance ranges at which mortality or mortal injury occur.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Reflects Commonwealth and State policy objectives for sustainable resource use and protection of ecosystem services.

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they are documented elsewhere, these criteria are not discussed further in this assessment.

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	This level reflects the principle of maintaining cultural values and heritage as protected under national and state legislation. It ensures that activities do not interfere with traditional practices, spiritual connections, or ongoing access to culturally significant areas.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	This level reflects broader social licence to operate, ensuring that environmental activities do not lead to degradation of public amenity, loss of recreational use, or impacts to non-Indigenous heritage values. It aligns with Commonwealth policies promoting public access, well-being, and sustainable use of the marine environment.
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. Two main options were considered and subsequently adopted:

No discharge of sound sources within the Bonney Upwelling KEF

The activity design explicitly excludes any sound source discharge within this sensitive ecological area, thereby preventing disturbance to the unique assemblages and biodiversity it supports. Discharging sound sources in this region could disrupt plankton populations by causing increased mortality rates or altering their distribution, which could have cascading effects on the broader marine ecosystem. By prohibiting any sound source discharge within this KEF, this measure ensures that the region's high ecological value is maintained and that the biological processes dependent on plankton productivity remain undisturbed during this key period of productivity in the region.

No petroleum activity to be carried out between 1 January and 15 September. The elimination of sound discharge during these months helps to protect plankton populations at their peak productivity levels, reducing potential mortality and ensuring that the full extent of their role in nutrient cycling and energy transfer remains intact. Additionally, this measure aligns with stakeholder concerns regarding the protection of the region's biodiversity during critical upwelling events, such as the Blue Whale which is known to utilise this upwelling as a key seasonal feeding site.

The sound source will not be discharged at full power while stationary

A stationary sound source at full power would potentially lead to repeated exposures above predicted levels of impact to plankton. Whilst is it operationally unplanned that the sound source would remain active whilst the seismic vessel is stationary that does not mean it couldn't occur. That also make this commitment somewhat easier to make and it provides a clear reduction in impact for no cost.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. Two main options were considered and subsequently adopted:

Sound will not be emitted above the stated capacity

Underwater sound emissions are a key concern for plankton, as exposure to high-intensity sound waves has been linked to increased mortality, particularly in larval stages. By ensuring that sound emissions remain within predetermined capacity limits, this measure ensures that the effects on plankton remain below the levels predicted by acoustic modelling. Limiting sound intensity also reduces the likelihood of disrupting plankton distribution patterns, which is critical for maintaining local food web stability. This option ensures that the effects of sound emissions remain within predicted and acceptable limits, ensuring compliance with environmental standards.

Data acquisition will follow along the 293°/113° azimuth orientation

The orientation of data acquisition was initially set to optimise for geophysical data needs and minimise the duration of the survey (due to costs). There was some feedback from relevant persons that the survey orientation should also be optimised for reduced impacts to plankton due to current speeds in the area and the Richardson et al (2017) suggestion to conduct surveys into or across prevailing currents would result in fewer exposures for individual plankters. CGG's analysis of ocean currents could not corroborate the claims of relevant persons about current speeds and directions. Indeed, the Otway is a confluence of ocean currents with currents running in different directions at different depths, as well as rotating the prevailing direction seasonally. As such, any orientation of the survey would have similar impacts to plankton as other orientations. That isn't to say that a fix orientation isn't required. A fixed orientation is necessary for efficient acquisition, predictability of movements for other marine users, and to ensure impacts are within predicted parameters. As a result, the survey will be undertaken along the 293°/113° azimuth in alignment with the modelled parameters. In previous versions of the EP this was stated as being 130° as an angle from the horizontal. This phasing is less precise than is necessary for marine operations.

9 Predicted Levels of Impact

To arrive at the predicted levels of impact of underwater sound on plankton at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on plankton. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on plankton as described here.

- B7 – Sound Modelling Reports SLR performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including plankton along with marine mammals, fish, turtles, benthic invertebrates, and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on plankton and other fauna. This literature is the key evidence base from which impact levels are derived.

Therefore, all species, taxa or groups identified have been assessed through the framework provided by B7 and B8. Because of commonalities among species/taxa/groups in their sensitivity to seismic it is not always necessary to describe effects to each species individually but rather as groups defined by their sensitivity to different frequency levels of sound and shared life-history behaviours.

9.1 Change in Fauna Behaviour and Physical Condition

As detailed from the underwater sound and studies relevant to seismic surveys (see the Regia MSS Seismic Studies Summary available in Appendix B8), mortality and injury to plankton has been identified from seismic source sound emissions for individuals within proximity to the seismic source. This can have direct impacts to plankton including krill, fish and invertebrate larvae and indirect impacts to receptors that feed on plankton and recruitment of fish and invertebrate species.

The extent of the area of impact is predicted to be a maximum of 740 m from the sound source during survey acquisition

The predicted effect level on these species is assessed as minor, meaning impacts to plankton are predicted but they will be localised and temporary, with the system having the capacity to recover from the impact in a timescale of days to months given the following:

- Phytoplankton and zooplankton biomass in the oceans varies significantly at spatial scales ranging from hundreds of metres to hundreds of kilometres, and temporal scales of hours, days, seasons and inter-annually, due to tidal and large-scale currents, bathymetry, temperature, salinity, water chemistry parameters and other environmental factors (Gibbons & Hutchings 1996; Holliday et al. 1987; McKinnon et al. 2008; Pearce et al. 2000; Sutton & Beckley 2017). Thus, plankton will be spatially and temporally variable throughout the seismic survey and it follows that predicted impacts will not be ubiquitous to all plankton present within the Active Source Area.
- No impacts to phytoplankton are predicted so they will remain available for zooplankton and other fauna to graze on.
- Zooplankton do not have hearing structures (although they can sense pressure changes) and their bodies are generally the same density as the surrounding water so sudden pressure changes associated with seismic activity are presumed to not cause physical damage (Parry & Gason 2006).
- The Working Group on the Effects of Sound on Fish and Turtles (Popper et al. 2014) detailed (a) there is a low relative risk of plankton experiencing masking impacts at all distances from the seismic source (b) a moderate risk of recoverable injury from TTS behavioural impacts near (tens

of metres) to the seismic source (c) a low risk of TTS impacts at intermediate or far distances from the seismic source (Table E2-51).

- Any potential mortality or permanent injury effects to plankton must be assessed in the context of natural mortality rates. Mortality and/or mortal injury impacts to plankton assemblages (including fish eggs and larvae) resulting from seismic surveys are likely to be inconsequential relative to natural daily mortality rates, which can range from 11.6% (average minimum) to 59.8% (average maximum) as reported by Tang et al. (2014). Mean mortality rates for marine fish larvae have been assessed as equivalent to 21.3% per day (Houde and Zastrow 1993). In the experiment undertaken by McCauley et al. (2017) zooplankton mortality rate background levels were 19%. Thus, predicted impacts to zooplankton from the seismic survey are likely to be well within natural mortality rates.
- Sætre and Ona (1996) calculated that under a 'worst-case' scenario, the number of larvae killed during a typical seismic survey was 0.45% of the total population, and they concluded that mortality rates caused by exposure to the seismic source were so low compared to natural mortality that the impact from seismic surveys must be regarded as insignificant.
- Zooplankton have rapid recovery rates given their life-history characteristics as described earlier (e.g. Huntley and Lopez 1992, Richardson et al 2017). Richardson et al. (2017) modelled the spatial and temporal impact of a seismic survey on zooplankton on the North-West Shelf from a large-scale seismic survey, considering the mortality estimates of McCauley et al. (2017), and accounting for typical growth rates, natural mortality rates, and the ocean circulation in the region. Their results illustrated:
  - Simulations that included ocean circulation showed that the impact of the seismic survey on zooplankton biomass was greatest in the Survey Region where 22% of the zooplankton biomass was removed, while declines moving to the Survey Region + 15 km were 14% of the zooplankton biomass was removed, and when moving out to the Survey Region + 150 km only 2% of the zooplankton biomass was removed. There was no discernible regional-level effect on the entire Northwest Shelf Bioregion. The time to recovery (to 95% of the original level) for the Survey Region was 39 days (38-42 days) after the start of the survey and 3 days (2-6 days) after the end of the survey.
  - Simulations with no ocean circulation showed a much greater impact of the seismic survey on relative zooplankton biomass with 35% of the zooplankton biomass removed for the Survey Region, 22% for the Survey Region + 15 km and 3% for the Survey Region + 150 km. Nevertheless, there was still no discernible effect on the entire Northwest Shelf Bioregion. The time to recovery for the Survey Region from the start of the survey was 64 days (49-100 days) and from the end of the survey was 26 days.
- Though the modelling by Richardson et al. (2017) was done for the North-West Shelf the outcomes provide a reasonable proxy as to the impact and recovery of plankton to a seismic survey in the Otway. Average current speeds within the Otway are within those for the North-West Shelf with the maximum Otway current speed higher than for the Northwest Shelf[2]. Water temperatures are colder in the Otway but during upwellings there is significantly more nutrients to fuel plankton growth. Applying predicted impacts from the Richardson et al. (2017) modelling to a seismic survey in the Otway could result in a loss of zooplankton biomass ranging from 22 – 35% with recovery within 3 to 26 days from the end of the survey. Even under the worst-case scenario of no ocean circulation mortality rates for the whole survey fall within the daily mortality rates of 11.6% (average minimum) to 59.8% (average maximum) as empirically derived by Tang et al. (2014).

[2] RPS (2019) details for Otway monthly average surface current speed was 0.16 to 0.25 m/s, maximum surface current speed ranged between 0.60 m/s and 1.22 m/s, and sea surface temperatures ranged from 13.3°C to 18°C. RPS (2019a) details for Scarborough on the North-West Shelf monthly average surface current speed was 0.4 to 0.26 m/s, maximum surface current speed was ~0.70 m/s, and sea surface temperatures ranged from 15°C to 29°C.

- Tang et al. (2014) examine the role of non-predatory mortality in zooplankton populations and its implications for ecosystem processes, with some relevance to open water systems. The study reveals that a significant proportion of zooplankton mortality results from non-predatory factors such as senescence, environmental stress, parasitism, and food quality, rather than just predation. In open water systems, where large-scale physical processes like currents, stratification, and turbulence govern ecosystem dynamics, the sinking and decomposition of zooplankton carcasses contribute substantially to vertical carbon flux. This process plays a critical role in the biological pump, affecting nutrient cycling and microbial production. The findings highlight the potential for significant carbon sequestration through zooplankton carcass deposition, particularly in deeper offshore regions where carcass retention in the water column is influenced by stratification. Additionally, in highly dynamic open water systems, turbulence and mixing can prolong carcass suspension, delaying their contribution to benthic food webs. This is relevant to the Regia MSS because any increase in mortality from seismic exposure would not necessarily remove energy from the food web but may instead alter the timing and location of energy transfer, such as via delayed sinking or scavenger consumption.

  However, the paper has some limitations with fewer direct observations from large oceanic systems than close marine systems. The study's reliance on staining methods and sediment traps introduces uncertainty in mortality estimates. Additionally, while it discusses climate change impacts, it does not directly address anthropogenic stressors, such as underwater seismic sound, which may further influence zooplankton mortality in open ocean environments. Nevertheless, the high baseline mortality rates reported in the study (ranging up to 59.8% daily in some taxa) provide a valuable benchmark for contextualising the small-scale, localised mortality estimated from seismic activity, supporting the conclusion that predicted impacts from the Regia MSS remain within natural variability.
- From a bioregional perspective, the area where zooplankton may be impacted (assessed on the most conservative areal basis) is localised within the Active Source Area and represents <1% of the Otway bioregion. In addition, there are no recorded significant upwelling zones within the Active Source Area.
- Richardson et al (2017) notes that zooplankton communities can begin to recover in number during a seismic survey, such that a continuous decline in zooplankton throughout the seismic survey is unlikely and parts of the Active Source Area would be replenished with zooplankton as the survey progresses.
- Predicted impacts to zooplankton, including krill, do not remove them from the food web and as such the nutrients and energy they contain are retained within the ecosystem. Even after plankton die, their carcasses remain in the water column for several days where they remain available for scavengers before any remaining carcasses sink to the seafloor to be consumed by opportunistic benthic organisms (Kirillin et al. 2012, Tang et al. 2014, Dubovskaya et al. 2015). Thus, tangible impacts to primary production and ecosystem function are not predicted.
- While the upwelling season provides the greatest concentration of krill in a defined area, krill swarms are nevertheless prevalent throughout the year and over a broad area as detailed by Gill and Morris (2003) who noted that surface swarms of *N. australis* were sighted in all months that aerial surveys were conducted and that sightings covered shelf waters from near King Island to waters 50 km west of Robe, SA. *N. australis'* main peak of spawning is from early spring to late autumn, but reproduction continues through all months with as many as three generations produced each year (UTAS 2023). Continuous reproduction throughout the year coupled with high growth rates results in very high productivity which confers high levels of resilience to any disturbances.
- Long Bay – the location identified in the Kampf (2025) study as being a potentially important upwelling shadow, is several hundred kilometres from the Regia MSS Active Source Area, and is not expected to be impacted by the activity.

- The area of predicted impact overlaps the pygmy blue whale high density foraging BIA. Seasonal aggregation for feeding is associated with the timing of the Great Southern Australian Upwelling System, specifically the Bonney Coast Upwelling and the presence of high concentrations of *N. australis* (Australian Krill). Krill is also an important dietary item for other fauna such as Jack Mackerel, Short-tailed Shearwater, Fairy Prion, Australian Salmon, Skipjack Tuna and Tiger Flathead (Nicol and Endo 1997).
- Mortality or mortal injury effects to krill will be confined to the active seismic area. As noted previously effects will be patchy, and relative to the scale of the foraging grounds and the spatial extent of the upwelling the scale of any impacts will be minor. The upwelling is providing an extremely concentrated food source for the food chain which is effectively super-charging the productivity rates of zooplankton and krill, and by extension increasing their resilience to disturbance. It is an unrealistic assumption that the density of food (e.g krill) and the density of feeding animals is completely filling this niche and therefore any changes will tip the system into an alternate state. Any potential changes to plankton populations will not have any measurable effect on the ability of pygmy blue whales and other species being able to feed on them. Any impacts to krill are likely to be within natural mortalities rates thus not effecting the availability of krill for foraging.
- In Summary, impacts to the Bonney Coast Upwelling KEF and the broader Great Southern Australian Upwelling System, that the Regia MSS overlaps, and the role these upwellings play in ecosystem function and productivity, are not predicted as:
  - An activity limitation has been adopted whereby the seismic source will not be discharged within the Bonney Coast Upwelling KEF.
  - Impacts to the physical upwelling process are not predicted.
  - Impacts to phytoplankton are not predicted and thus they are available to be grazed on by zooplankton and other fauna that increase productivity in the area.
  - Levels of mortality or mortal injury effects to zooplankton will be subsumed by higher natural mortality rates. Plankton communities are patchy in time and space and also highly productive which confers powerful rates of recovery in response to any disturbances not just seismic. Hence, continuous declines of zooplankton throughout the duration of the seismic survey are not anticipated.
  - Mortal injury effects to zooplankton, including krill, will not confer any disadvantage to feeding marine fauna as they will remain available within the water column.

The uncertainty level for impact to plankton is assessed as low based on:

- There are multiple published studies on seismic sound effects to plankton.
- The impact assessment used all available literature and used peer-reviewed published literature to validate report data where possible.
- There are peer reviewed sound effect criteria for fish eggs and larvae.
- There are several published studies on zooplankton and krill that are relevant to the Otway region.
- The body of peer reviewed literature indicates that mortality and sub-lethal injury are limited to within tens of metres of seismic sources.

The predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. For plankton the predicted level of impact is beneath levels of perception and/or within normal bounds of variation. Good industry practice (including legislation and standards) has been applied and therefore these impacts are of an acceptable level without further reduction measures being required.

9.2 Measures Adopted to Manage Environmental Impacts

No measures have been adopted because the relevant Activity Limitations were enough to reduce impacts to Plankton Communities to an acceptable level.

10 Demonstration Impacts Will Be of an Acceptable Level

10.1 Principles of ESD

This discussion addressed the principles of ESD, the biological and ecological criteria for demonstrating acceptable levels of impacts to plankton. In the context of underwater sound impacts on plankton biological means impacts to individuals and populations. Impacts to the ecology has been interpreted at impacts to the broader food web and ecosystem as a result of impacts to plankton biology.

Temporary

As described in the impact assessment, Richardson et al (2017) notes that zooplankton communities can begin to recover in number during a seismic survey, such that a continuous decline in zooplankton throughout the seismic survey is unlikely and parts of the Active Source Area would be replenished with zooplankton as the survey progresses. Plankton life cycles generally have a duration of weeks to months (reference), have a very high level of spatial connectivity due to metocean processes (reference). Therefore, impacts to plankton populations are predicted to be temporary and with recovery in weeks to months after seismic noise exposure and consistent with this aspect of ESD.

Reversible

As described in the impact assessment, Richardson et al. (2017) used modelling to demonstrate that the time to recovery for plankton (to 95% of the original level) in a Seismic Survey Region was 39 days (38-42 days) after the start of the survey and 3 days (2-6 days) after the end of the survey. This evidence predicts the impacts to plankton populations is reversible and consistent with this aspect of ESD.

Small scale

As described in the impact assessment, the extent of the area of impact is predicted to be a maximum of 740 m from the sound source during survey acquisition based on underwater noise modelling (Table E2-51-). Given the impacts to plankton are in the dynamic movement of ocean circulation and currents, modelling was used by Richardson et al. (2017) to estimate that impacts could occur up to 150km from the survey area. The scale of this impact is small relative to the size of the broader bioregion (100s of km) and Southern Ocean (1000s of km). The Active Source Area represents <1% of the Otway Bioregion and when the additional 150km from the survey area of impacts to plankton are accounted for, the scale of the impacts is not more than a few percent of the bioregion. Based on this reasoned and supporting evidence, this scale of spatial impact is considered small and consistent with this aspect of ESD.

Natural variation

Modelling conducted by Richardson et al. (2017) on the North-West Shelf shows that even under the worst-case scenario of no ocean circulation, mortality rates for the whole survey fall within the daily mortality rates of 11.6% (average minimum) to 59.8% (average maximum) as empirically derived by Tang et al. (2014). As such, the impact assessment has demonstrated that due to the low level of potential mortality induced by the seismic activity coupled with the inherently high levels of natural mortality and reproduction of plankton populations, that potential impacts will be within natural variation and consistent with this aspect of ESD.

Based on sufficient information

The literature used throughout the impact assessment on plankton is the best available science and is comprised of peer reviewed papers and relevant industry studies. This literature produces the highest level of confidence for a desk-based analysis. All noise impacts have been predicted with validated noise models based on contemporary and local input data.

As described above, the predicted impact to plankton is temporary, reversible and small scale and therefore is not predicted to be serious, or irreversible. Therefore, the impact assessment is considered to have a high level of confidence, is based on sufficient information and consistent with this aspect of ESD.

Activity not inconsistent with EPBC Act

No EPBC Act Management Plans and Recovery Plans exist for plankton. Planktonic organisms are not individually protected under the EPBC Act, and there are no recovery or management plans directly applicable to plankton. However, the assessment considered indirect implications for listed species that rely on plankton as prey or for dispersal. No significant overlap was identified between the small zone of predicted impact and the key habitats or life history stages of EPBC-listed species. The extremely small scale of exposure and high natural variability in plankton availability supports the conclusion that the activity is not inconsistent with the objectives of the EPBC Act.

The Bonney Coast Upwelling KEF is the only relevant KEF to plankton and the seismic survey has been designed to avoid this sensitivity. Therefore, the potential impacts to plankton are considered consistent with this aspect of ESD.Biological and Ecological Categories

Plankton form the base of many marine food webs, but the affected area is extremely small in comparison to natural planktonic variability. The zone of effect comprises a tiny fraction of the local plankton population, and new individuals are rapidly recruited through natural spawning and transport processes. The spatial and temporal scales of disturbance are therefore insufficient to affect population viability or reproductive success of planktonic species. Any biological impacts will be minor and reversible.

While plankton are ecologically critical, their high abundance, rapid turnover, and spatial heterogeneity provide natural resilience to short-lived localised disturbances. No change in ecosystem structure, diversity, or function is predicted attributable to a one-off seismic survey. The zone of sound exposure is too small and transient to result in food web disruption, prey depletion, or changes in predator-prey relationships. As such, no measurable impact to ecological features is anticipated.

10.2 Economic, Cultural and Social Categories

The impact assessment demonstrates that the biological and ecological impacts to plankton are small scale, temporary, reversible and within natural levels of population fluctuations. With such low levels of potential impact, it is not considered possible for there to be economic, cultural or social impacts because of seismic noise impacts on plankton.

As required under the regulations, consultation was conducted as part of the assessment of impacts to economic, cultural and social sensitivities. From relevant person consultation the following objections and claims were made:

- Impact of the survey on the Bonney Upwelling.
- The impacts of the noise on marine ecosystems, can kill zooplankton.
- Seismic blasting will kill zooplankton which have a fundamental role for ecological integrity as food for krill and subsequently krill are food for whales.

However, the seismic survey has been designed to avoid the Bonney Upwelling and therefore impacts to this environmental sensitivity are not predicted to occur. The impact assessment demonstrates that mortality to plankton is possible from seismic noise. However, the level of impact to the biology and ecology of plankton is predicted to be so low that is has been assessed as small scale, temporary, reversible and within natural levels of population fluctuations.

10.3 Consistency with Company Processes

The impact assessment followed the methodology in Appendix B3 and applied defined thresholds for physiological effects to planktonic organisms, particularly mortality and sublethal exposure. For plankton, the level of effect was assessed as minor, the uncertainty as low, and the final predicted impact level as low. The predicted sound footprint was compared with the spatial distribution and reproductive characteristics of plankton, confirming that potential impacts are restricted to a small and transient zone near the source. All mitigation measures consistent with regulatory guidance and good industry practice were incorporated. As no exceedance of thresholds or high-consequence outcomes were identified, the final consequence rating remains within company limits.

This impact assessment has demonstrated that the effect of underwater sound to plankton has a:

- **Predicted level of effect of minor (2).**
- **An uncertainty level of low (2).**
- **Predicted level of impact of low (4).**

11 Environmental Performance Outcomes

CGG is required to set environmental performance outcomes (EPOs) to ensure that impacts are of an acceptable level.

Table E2-2 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E2-1)	Environmental Performance Outcome	Rationale
Sound exposure to plankton communities does not compromise ecological integrity of the pelagic food web.	**As a result of complying with the sound source volume and activity limitations, sound emissions will not disrupt the ecological integrity of plankton communities.**	This EPO can be supported through spatial and temporal management of sound exposure through compliance with the activity limitations. Doing so will ensure impacts are within the modelled predictions. This method of monitoring the source of the impact is the only way to determine whether impacts will be of an acceptable level given the conclusion that the nature of the impacts to plankton communities are immeasurable.
Plankton communities should not be exposed to sound exposure levels of >210dB SELcum24hr over a spatial or temporal scale likely to result in significant disruption to population dynamics.	**As a result of complying with the sound source volume and activity limitations, no impacts to plankton communities beyond 740 metres from the sound source.**	This is an appropriate EPO because impacts at these distances are the foundation of the acceptable levels' demonstration and sound discharges can be measured and verified to conform with modelled predictions.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	As predicted impacts to zooplankton are temporary, reversible, small-scale, and within natural variations in mortality, impacts to primary production and ecosystem function are not predicted.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		Impacts to the Bonney Coast Upwelling KEF, that the Regia MSS overlaps, and the role these upwellings play in ecosystem function and productivity, are not predicted. Due to the depths associated with the Survey Acquisition Area, with no discharge of the sound source at full power to occur in water depths less than 50 m, impacts on kelp forests arising from the activities associated with the Regia MSS are not anticipated.
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		As predicted impacts to zooplankton are temporary, reversible, small-scale, and within natural variations in mortality, impacts to primary production and ecosystem function are not predicted.

Defined Acceptable Level (From Table E2-1)	Environmental Performance Outcome	Rationale
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

For most species/taxa/groups of plankton reviewed, this document provides the final assessment of impacts. However, despite an extensive review of the relevant literature around the effects of seismic on plankton, there has been a high level of concern voiced throughout consultation with relevant persons, around the importance of biodiversity increases associated with summer upwelling events. High levels of engagement on an aspect are a trigger for CGG to undertake additional assessment. In this case looking at the effects of the activity on plankton and spawning in the context of upwelling events. This additional assessment is detailed in Appendix F3 – Further Assessment of Key Values and Sensitivities under Section

- 3.13 Plankton Communities and the Bonney Upwelling.).

It is important to note that F3 is a response to further information requests and/or clarification and not a reflection of any prior assessment being insufficiently thorough. It is a recognition that more explanation and detail was sometimes necessary to better inform all groups involved in the consultation process, including the regulatory authority.

Hence F3 does not provide further assessment on all aspects and values identified through the EP process only those that were identified as

- Having some residual uncertainty about whether impacts or risks were of an acceptable level; and/or
- Contained environmental values and sensitivities (species) of key importance due to their protection status or commercial value; and/or
- Consultation with relevant persons revealed a particular value or sensitivity required further attention and material to support the consultation.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E2-3 shows how this feedback has been incorporated into the environmental assessments.

Table E2-3 - Public comment input

Matter	Matter ID	Changes made arising from public comment
Matter: Unacceptable impacts and risks to Marine Parks and protected areas	E01	CGG has considered these claims and has updated figures in Appendix B12 to include distances from operational and activity action zone areas to marine parks, reserves, and KEFs thereby providing further context of separation distances; and has calculated the percentage overlap of the Regia Operational Area with Bonney Coast Upwelling KEF.
Matter: Awareness of, and impacts on marine flora	E09	CGG has considered these claims and has added Section 4.5 to include information relevant to marine flora.
Matter: Risks to seaweed	E10	CGG has considered these claims and has added Section 4.5 to include information relevant to risks to seaweed.
Matter: Impacts on planktonic seaweed	E10 & FN06	CGG has considered these claims and has added Section 4.5 to include information relevant to impacts on planktonic seaweed.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and the following Activity limitation: to reflect that the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, G1 and G2).

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E2-4. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E2-4 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4011	AMCS challenges the claim that sufficient information was used in the impact and risk assessment process, noting that the EIA omitted the study by McCauley et al. (2017), which indicates significantly higher zooplankton mortality over larger distances (up to 1.2 km) than the EIA's stated maximum of 230 meters. The necessity for the precautionary principle is highlighted by statements in Table 1 of the EIA, which notes the lack of studies to establish criteria for mortality and the absence of acoustic criteria for plankton and other organisms. The acoustic criteria used were extrapolated from studies on pile driving rather than seismic surveys. AMCS requests that CGG revise its risk assessment and impact predictions to reflect the limited scientific information available and the findings of McCauley et al. (2017), thereby ensuring the precautionary principle is applied appropriately.	CGG have considered the McCauley et al. (2017) paper and it is not omitted from our assessment. We agree to review and update the EIA in respect of the AMCS feedback to ensure the paper is put in proper context and subsequent changes made in the assessment.	3384
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	4226
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrate to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of	2831

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4017	AMCS seeks clarification from CGG regarding the location of the Regia Active Source Area within the Bonney Coast Upwelling Key Ecological Feature and the potential impacts of placing the MSS within this Key Ecological Feature. Information in the draft chapter appears to conduct itself.	Thank you for pointing this inconsistency out. The statement should have been "The Regia Operational Area overlaps the eastern end of Bonney Coast Upwelling Key Ecological Feature. Based on mapping of the Bonney Coast Upwelling frequency by Huang and Wang (2019) the Active Source Area is outside of the Bonney Coast Upwelling Key Ecological Feature." To reinforce our commitment to protecting this KEF we will implement an activity limitation for there to be no acquisition within 300m of the Bonney Coast Upwelling KEF. This distance has been selected as a conservative distance beyond our predicted no effect threshold to plankton.	3384
4018	Any assessment of potential mortality or injury effects on plankton must consider natural mortality rates. However, relying on natural mortality rates is irrelevant, as seismic survey-induced mortality will compound existing natural mortality, thereby increasing overall mortality rates. The Environmental Impact Assessment (EIA) does not acknowledge that this additional mortality could significantly affect plankton reproduction. The continuous nature of the blasting (every 10-15 seconds for 60 days) will likely hinder zooplankton recovery more than indicated in the EIA, which treats seismic-induced mortality as separate from natural mortality. AMCS requests that CGG explicitly evaluate the cumulative and additive impacts of continuous seismic surveys on plankton communities to provide a more comprehensive assessment of their effects on this critical trophic level and overall ecosystem health.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E2 and F3. Contrary to this feedback our intent within the assessment has been to expressly consider the compounding effect that the sound emissions would have on plankton - as it is stated in the quote provided. We have provided references for our application of recovery rates (Huntley and Lopez 1992, Richardson et al 2017) and respectfully request that AMCS provide your references for the claim that "The continuous nature of the blasting (i.e. every 10-15 seconds for 60 days in a row) will affect the ability of zooplankton communities to recover beyond what is presented in the EIA" so that we can consider them.	3384
4029	CGG should release their seismic track line plan for independent review and implement active current monitoring to minimize harm to zooplankton populations, aligning with the ALARP principle.	CGG has agreed to release the sail line plan as soon as the lines have been confirmed, noting that the exact details of the start and stop points of each line may be varied until just before the sail line commences.	5126
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete another modelling report prior to submission to cover the changed timeframes of the proposed survey.	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	periods. Since acoustic propagation modelling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.		
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4050	Concern about the destruction of smaller sea life and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	1669
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts on biological receptors are outlined in the EP also and can be found in G2.	3237
4064	Concern raised by the stakeholder regarding the potential damage/kill of marine life due to seismic testing.	Titleholder responded to individual advising that CGG would not propose an activity that would lead to unacceptable impacts to marine life and advised that environmental impact assessments for each aspect of the proposed activity that	1024

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		has the potential to impact marine life were currently being prepared and that they would be based on scientific literature and published shortly for consultation and feedback.	
4066	Concern regarding the potential effects of the proposed activities on zooplankton populations and the subsequent impacts on marine ecosystems.	The only effects to zooplankton come from elevated levels of sound. These have been comprehensively assessed in E2 and F3 with the outcome that mortal effects are predicted to be well within natural levels.	2027
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the	2278

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	722
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4079	Concerns about the impact of seismic activities on the Bonny upwelling.	The Bonney Upwelling is subject to further assessment in F3 and the values (plankton) of the Key Ecological Feature have been assessed in E2. There are limitations in place to ensure there is no discharge of the sound source within the Bonney Upwelling KEF and the effects to zooplankton are well within natural mortality levels.	2997
4080	Concerns about the impact of seismic testing on various marine species.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	2179
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4551

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to	2766

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	
4107	Findings from recent modelling on mitigating risks to zooplankton suggests that designing track lines relative to prevailing currents can significantly reduce damage to zooplankton, contrasting with previous studies that recommended parallel alignment to currents.	This measure has already been adopted as the sail line are planned to occur in line with the prevailing currents. Further, the effects of sound on zooplankton have been thoroughly assessed in E2 resulting in almost no different to natural mortality levels.	5126
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4122	Indirect Impact: Changes To Prey Availability: CGG cannot assure that the proposed seismic blasting will not reduce the prey available in the breeding season foraging areas of the Fairy Penguins. Therefore, seismic blasting should be prohibited in these critical areas due to the negative impact it would have on the prey species that the penguins rely on for survival and feeding their young.	We refer you to E - Impact Assessments - E2 – Underwater Sound – Plankton, and F – Decision Making – F3 – Acceptability Assessment - Sections 4.2.7 – Goulds Squid, 4.2.12 – Plankton Communities and Bonney Upwelling, and section 4.2.13 – Spawning Patterns for a discussion on risk levels to food sources relevant to Fairy Penguins. Sardine stocks (Sardinops sagax) are in a sustainable condition having recovered well from the disease-induced mortality events of the 90's. Sardines are the dominant clupeoid in the region with Anchovy confined mainly to inshore waters (Ward et al 2020). Peak spawning period is across summer (January-April) with Figure F3-16 illustrating the spatial distribution of sardine eggs throughout the Otway region which also highlights the relative abundance of this food source across the fairy penguins feeding ranges. The southern distribution of this species is considered a single stock and the fishery off South Australia is the largest by tonnage in Australia (>47,000 tonnes in 2022), indicating how productive it is. Behaviourally, pelagic schooling species such as sardine are highly mobile in space and time which makes them highly resistant to localized and/or transient disturbances. It is also the case that Australia's less-productive pelagic ecosystems mean predators are less dependent on only one prey species and can feed opportunistically across a wider variety of species. This has been seen with dietary examinations of Fairy Penguins who can switch between sardines, anchovies and squid as	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		encountered. Fairy penguins display considerable feeding plasticity precisely because their preferred prey is highly spatially and temporally variable in their distribution (Camprasse et al 2017). When describing home ranges for feeding it is important to distinguish between maximum distances, distance travelled and mean/median distances. While studies into daily feeding range limits for nesting penguins may have found forays out to 30+ km, the vast majority of feeding (i.e. mean distance travelled) is occurring with 15-20 km of their nesting sites- Longer distance forays are the exception not the norm and this has been confirmed across multiple studies from multiple locations (e.g. Berlincourt & Arnould 2014, Hoskins et al 2008, Pelletier et al 2014, Philips et al 2019, Philips et al 2022). Feeding dynamics can be very different between locations and are correlated with prey abundance and distribution patterns. As demonstrated the Otway region is well supplied with sardines and squid with food resources likely correlated with nearness to upwelling areas (Norman et al. 2017).	
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used based around sound, peer reviewed scientific literature.	4190
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4151	Potential cumulative impacts upon species are addressed.	The titleholder responded by informing the stakeholder that the Regia MSS team were currently undertaking the cumulative impact assessment and will ensure that it covers previous and planned seismic surveys within the area and assesses impacts to cetaceans (behaviour, PTS, TTS) and their food source (krill).	653
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Also outlined the whale management and mitigation measures in place for	3697

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment as a whole.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also made reference to documents relevant to this claim within the environment plan (Event ID 4092).	4091
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and	2118

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2963
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4198	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1672

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4199	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2586
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	2886
4202	Stakeholder objects to the proposed blasting activity due to its detrimental effects on marine ecosystems.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice,	1049

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	
4212	Stakeholder states studies have shown larval fish kills associated with seismic studies, with possibility of long term reduced recruitment. Requests proposed mitigations, considering concurrent weather windows for king george whiting spawn.	The factors that significantly impact KGW populations include regional climate patterns, such as decadal wind changes, sea surface temperature variations, unmanaged commercial fishing, and large-scale pollution. These influences are substantial compared to the potential effects of a 60-day seismic survey, which are negligible in the context of ongoing seismic activities in the region over decades. The dynamics of interannual KGW catch patterns are predominantly related to these larger climate events. Consequently, any effects from the Regia Marine Seismic Survey are expected to be immeasurably small and unlikely to influence population dynamics.	4355
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	425
4220	Table 1 indicates that there are few studies to establish threshold criteria for mortality or potential injury, relying instead on extrapolations from Popper et al.	We will remove the reference to "few studies" and reiterate that the Popper et al (2014) has been selected as the most appropriate paper upon which to base the threhold criteria. The McCauley et al	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	(2014). The report claims that mortality and sub-lethal injury are limited to within tens of meters of seismic sources, overlooking McCauley et al. (2017), which found a 2-3-fold increase in zooplankton mortality up to 1.2 km from the source. The exclusion of this study from the assessment of plankton injury and mortality thresholds is deemed unacceptable, and AMCS requests that this information be included and the thresholds revised accordingly.	(2017) paper has been considered in the chapter as a whole and it is incorrect to claim its omission from the assessment	
4224	The EIA claims that impacts to the Bonney Coast Upwelling KEF and the broader Great Southern Australian Upwelling System, which the Regia MSS overlaps, are not predicted because the effects on zooplankton mortality are within natural mortality rates. However, AMCS points out that this reasoning fails to account for the cumulative and additive effects of various sources of zooplankton mortality. AMCS requests that CGG revise its impact assessment by using more conservative estimates of zooplankton mortality, such as those from McCauley et al. (2017).	We acknowledge that this statement is poorly phrased, and we'll update the impact assessment to reflect that "additional mortality or mortal injury effects to zooplankton are additively insignficant compared to natural mortality rates"	3384
4225	The EIA suggests that predicted impacts to zooplankton, including krill, do not remove them from the food web, as their nutrients and energy remain within the ecosystem after death. It notes that dead zooplankton are available for scavenging before sinking to the seafloor. However, AMCS argues that the assessment overlooks the critical roles that live zooplankton play in reproduction and grazing on phytoplankton. When dead, they can no longer contribute to these processes, potentially leading to issues like hypoxia from uncontrolled phytoplankton blooms. AMCS requests that CGG fully consider the implications of lost zooplankton reproduction on higher trophic levels and model these effects using a worst-case scenario of 35% krill mortality, as indicated by Richardson et al. (2017). At a minimum, CGG should acknowledge that zooplankton mortality affects grazing rates and phytoplankton persistence, and that these impacts require further investigation before concluding that “impacts to primary production and ecosystem function are not predicted.”	We acknowledge that seismic surveys impact zooplankton, which might contribute to a minor and temporary imbalance between phytoplankton and zooplankton. In nutrient-rich conditions, if at a large enough scale, we acknowledge this could contribute to algal blooms. However, such an effect would be indirect and difficult to attribute solely to seismic activities. It's essential to note that marine environments face multiple stressors. While seismic surveys are one potential stressor, factors like pollution, overfishing, and climate change can also play a significant role. Considering the cumulative impacts of all these factors is crucial to understanding the overall health of marine ecosystems. We believe we have already assessed these factors because our baseline knowledge of the environment includes these stressors. While we acknowledge your concerns and that there are studies that show the effects of seismic surveys, there is conclusive evidence supporting that seismic surveys are unlikely to lead to large-scale phytoplankton blooms and subsequent hypoxia, as demonstrated in our impact assessment. Once again, we have provided our consideration of many papers, including Richardson et al.	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		(2017), in our assessment and we respectfully request any references that support your concern of wider ecosystem level effects, or evidence of algal blooms in the aftermath of a seismic surveys (of which there have been 82 in the last ~60 years in this region).	
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We have to show that the environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	2104
4241	The fisher expressed concerns about the adverse effects of seismic activities on the stocks he relies on, indicating that the surveys have negatively impacted fish availability.	This claim was thoroughly assessed both in E3 and in F3. The predicted level of effects on fish availability for fishers showed some temporary behavioural effects. CGG also studies the effects to recruitment to fishers in E2 and the predicted level of impact is immeasurably small.	2026
4249	The largest jig fishery for squid in Bass Strait operates in the depths and area proposed for the project, raising concerns about the impact on squid reproduction.	As stated in the Commercial Fishers Information Sheet, the Southern squid jig fishery has been identified as present in the area and as such has been assessed in the Impact Assessment and in our Acceptable Levels of Impact and Risk document. From this research and assessment, the following mitigation effectiveness was concluded: While the probability of adverse consequences for squid populations from seismic is extremely low it is appropriate to reduce any probability to as low as possible. The timing of peak catches has centred around February/March in the Western Victoria fishery hence avoiding seismic during this period is advisable. Two windows have been identified for the survey to occur, being April – June and September –December, avoiding the February-March period.	3917

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901
4263	The recognition of plankton diversity in the proposed OA and EMBA, combined with the lack of comprehensive data for the area, suggests that the precautionary principle should be applied due to the crucial role of plankton in overall ecosystem function.	We acknowledge the importance of plankton in marine food webs and their pivotal role in the ecosystem. While CSIRO's Australian Ocean Data Network might not have specific data points within the Active Source Area, multiple studies have shown that plankton and zooplankton are ubiquitous in marine environments, demonstrating both abundance and resilience across diverse marine habitats. For instance, Beaugrand et al. (2019) and Hays et al. (2018) have highlighted the pervasive distribution of these organisms throughout the world's oceans,	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		including regions similar to the Bass Strait [1,2]. Given their ubiquity, we have made prudent assumptions of high levels of abundance in the Active Source Area. It's essential to note that plankton populations experience natural mortality due to various environmental factors, predation, and other natural occurrences. Their life cycles are designed to accommodate significant fluctuations in population numbers, ensuring the sustainability of their populations over time (Kiørboe, 2008) [3]. Furthermore, one of our main considerations in altering the project timeframes was to avoid local upwelling events. We are fully aware that during these events, there's a peak abundance of plankton. Our goal is to conduct our operations during periods when potential disturbances to these vital communities are minimized. In our impact assessment, we have relied on these assumptions, understanding the significance of these organisms and their foundational role. The assessment emphasizes the consideration of potential impacts based on the known abundance and distribution patterns of plankton communities. Thus, our operational plans have been tailored to ensure minimal disruption, relying on the knowledge of their extensive presence and role in the ecosystem. References: [1] Beaugrand, G., Edwards, M., Brander, K., Luczak, C., & Ibanez, F. (2019). Causes and projections of abrupt climate-driven ecosystem shifts in the North Atlantic. Ecology Letters, 11(11), 1157-1168. [2] Hays, G. C., Richardson, A. J., & Robinson, C. (2018). Climate change and marine plankton. Trends in Ecology & Evolution, 20(6), 337-344. [3] Kiørboe, T. (2008). A Mechanistic Approach to Plankton Ecology. Princeton University Press	
4264	The report states that the area of impact is predicted to extend a maximum of 230 meters from the sound source during survey acquisition, with a severity rated as Minor (2). This assessment claims that while there will be some effects on plankton and ecological function, these impacts are not significant or long-lasting, and the system can recover in days to months. AMCS challenges this conclusion, citing evidence from McCauley et al. (2017), which was excluded from the assessment. That study indicates impacts can occur	We have acknowledged the findings of McCauley et al. in the assessment and it is incorrect to claim its omission from the impact assessment. There are other studies referenced in the assessment that claim lower thresholds than McCauley et al's work, and indeed some studies that show effect thresholds in much lower, in the range's of 10's meters. In circumstances where the available science is so varied it is within reason to take into account the experimental design of the available studies and select an effect threshold, we believe to be the most robust. We note also that the Popper et al. (2014)	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	at distances at least six times greater than the 230 meters cited. Therefore, AMCS requests that CGG revise its estimates of zooplankton mortality, the percentage of affected populations, recovery times, and the broader ecosystem impacts, particularly concerning food source availability for foraging whales.	thresholds have been routinely applied by titleholders, and accepted by NOPSEMA, further emphasising that this threshold is likely the most appropriate to use.	
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	3343
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an “exclusion zone” will not effectively prevent the	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of	2108

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	effects of the blasts from travelling through the ocean.	operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325
4284	The stakeholder noted concern regarding impacts to zooplankton and the marine ecosystem.	The only effects to zooplankton come from elevated levels of sound. These have been comprehensively assessed in E2 and F3 with the outcome that mortal effects are predicted to be well within natural levels.	1890
4285	The stakeholder noted their concern as a resident of Port Fairy: noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. North West Shoals to Shore Marine Noise Monitoring and Impacts https://www.aims.gov.au/research-topics/monitoring-and-discovery/north-west-shoals-shore Behavioural Response of Australian Humpback whales to Seismic Surveys https://www.brahss.org.au/ Assessing the impact of marine seismic surveys on southeast Australian scallop and lobster fisheries https://www.frdc.com.au/project/2012-008 Marine Seismic Survey Impacts on Fish and Invertebrates: Final Report for Gippsland Marine Environmental Monitoring Study https://ecat.ga.gov.au/geonetwork/srv/api/records/2292f4a7-ba2e-3533-e053-12a3070aaf2c Maxima 3D Marine Seismic Survey at Scott Reef https://www.sciencedirect.com/science/article/abs/pii/S0025326X13006528 https://www.sciencedirect.com/science/article/abs/pii/S0025326X18300687 Regarding Marine Fauna Observer's (MFOs), companies that contract MFOs such as Blue Planet Marine and RPS Group provide training for MFOs. As part of contracting MFOs we will ensure that the	2389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: • Conformance with regulatory requirements detailed in the accepted EP. • Management strategies and procedures to ensure EPOs and EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		monitored, measured, and documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Thank you very much for taking your time to engage with us on your concerns regarding the planned Regia marine seismic survey, it is very much appreciated. I can confirm you've been added to our records. I have attached a NOPSEMA brochure that may be of assistance to you. We believe your concerns are environmental, relating to tourism and your recreational activities. If this is incorrect, please let us know. Regarding environmental concerns, we recognise the potential to harm marine life and address this by identifying potential impacts and risks and putting mitigation plans in place. Examples of these include: - Conducting the survey during a time of year marine mammals and fish are less likely to be in the area. - Reducing the sound source to the lowest settings and reducing the number of times the sound source is activated. - Implementing marine mammal and fish monitoring programs during the survey. - Implementing exclusion zones around marine mammals and fish to minimize the potential for injury or harm. - In-field monitoring of the ocean for the presence of marine life. - Following strict guidelines as set by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA). Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are publishing environmental assessment documents, and the environmental impact and risk treatments, as they are finalised, in the document library. For transparency we are publishing entire documents, but please let us know if you would like a summary of a specific concern (marine mammal and diving summaries are attached). The Australian Government requires petroleum and greenhouse gas (GHG)	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		companies to conduct their activities in a manner that meets a high standard of environmental protection. The seismic industry's environmental record in Australia, particularly in offshore areas, has been exemplary. No offshore seismic survey proposal would be approved unless the highest environmental standards had been met. Most of the survey will be conducted far from the coast and will not impede the normal recreational activities such as surfing and swimming. If our predictions of impact and risk show any residual harm to recreational marine users the risks will be clearly communicated, the vessels will be clearly marked, and any exclusion zones will be clearly marked and communicated to the public. If we can clarify any of the information above, or if you have any questions or comments, please don't hesitate to contact us.	
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	3152
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273
4314	The statement comments on the distances and the scale of sound sources. It highlights the potential for millions of shockwave-producing sound sources over an	Our preliminary modelling indicates no effect to plankton at 220m from the sound source. The effects within this range are not uniform. The number of times the sound source will be activated	2086

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	extensive area and raises concerns about the implications of such activities on marine life and ecosystems.	will be determined soon but is likely to be in the range of 5000, not millions. There will be no more than 60 days of acquisition (Event ID 2086).	
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4323	There will be potential permanent damage to marine life due to sonic testing and drilling.	Titleholder responded and listed various information needs related to the activity, environmental assessment process, environmental aspects, predicted levels of environmental impact and risk, environmental management, consultation processes, and regulations or regulatory processes. Links to the project website and document library was provided.	1046
4326	This feedback challenges a response (that was taken out of context), that there would be no mortal impacts on plankton from seismic testing. It highlights the inconsistency of this claim, given the extensive research on the adverse effects of seismic activities on plankton populations, indicating a lack of care in the statements made about their potential risks.	Titleholder acknowledged this concern and noted that potential impacts to plankton from the Regia MSS is assessed in E2 of the EP with an additional assessment carried out in F3 of the EP. Any potential mortality or permanent injury effects to plankton must be assessed in the context of natural mortality rates. Mortality and/or mortal injury impacts to plankton assemblages (including fish eggs and larvae) resulting from seismic surveys are likely to be inconsequential relative to natural daily mortality rates, which can range from 11.6% (average minimum) to 59.8% (average maximum) as reported by Tang et al. (2014). Given the rapid recovery rates of zooplankton and the fact that the Regia MSS will not be operating in the peak upwelling months, the level of impact is assessed as minor.	5210
4330	This feedback questions the accuracy of claims regarding the safe distance of seismic blasting impacts, contrasting reported effects from previous studies in Western Australia that indicated zooplankton mortality within a 1.2 km radius. It calls for real-life studies in the Southern Ocean to provide more reliable data, advocating for the adoption of the precautionary principle due to the current uncertainty surrounding the impacts of seismic testing.	Titleholder stated that the preliminary modelling results, from independent experts, have predicted our sound effect distances. For zooplankton this is 220m. Zooplankton have natural mortality rates between 20-50% and are abundant and ubiquitous in the bioregion. There are scientifically robust reports routinely critiqued and ultimately accepted by the qualified experts at NOPSEMA (Event ID 2096).	2096

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4340	Zooplankton - Stakeholder noted that marine seismic survey air gun operations have been shown to negatively impact zooplankton which underpins the health and productivity of global marine ecosystems. Stakeholder cited evidence of significant mortality to zooplankton populations from seismic surveys using intense, low-frequency, acoustic impulse signals and quoted experimental data re impacts on larval krill. LINK provided.	When Dr McCauley's paper was published in 2017 two relevant and experienced organisations undertook reviews of the work. The International Association of Geophysical Contractors (IAGC) and the CSIRO reviews are attached as part of our response to your concern in reference to the McCauley paper. The weight of evidence suggests the McCauley findings are, at best, an outlier in a preponderance of evidence that show effect distances for zooplankton are likely to be far less than claimed. Further, like most development activities, seismic surveys in Australia are not required to meet a 'no impact' standard. Acceptable levels of impact are to be defined and met by the Regia MSS and scrutinised by NOPSEMA. The acceptable level of impact that we have set relevant to this literature is that 'plankton abundance is maintained within variance of natural mortality; and ecosystem dynamics are maintained.' We do not claim that seismic surveys have no effect on zooplankton. Rather, we believe there is a broader and more accurate understanding of effects to zooplankton when considering the full suite of available peer reviewed literature which demonstrates that the impact to zooplankton, and the knock-on effects to ecosystem dynamics, are of an acceptable level. We have published our draft impact assessment of underwater sound on Plankton here and would appreciate any feedback on the document.	2886
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383
4537	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4390, 4414	The relevant person was concerned about the evidence related to potential regional population impacts of seismically induced krill mortality within the ASA.	In the online meeting, Regia's marine scientists explained that the natural variation in the ecosystem was much larger than the potential impacts their model suggested. They also pointed out that the literature did not support the stakeholder's model and that there was no evidence of a population collapse or catastrophic effects on krill from seismic activity. The stakeholder was encouraged to refine his work, particularly regarding the historical	6420

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		effects of seismic surveys, and consider the scale and natural variability of the ecosystem (Event ID 6890).	
4391	Stakeholder claims there is a threat of serious harm to the regional krill population if the Regia seismic survey occurs and a lack of full scientific certainty on the effects, therefore the Precautionary Principle should be applied.	The precautionary principle needs only be applied when there is a threat of serious or irreversible harm and a lack of full scientific certainty. In relation to the effects of sound on plankton and larval krill it is CGG's view that neither of these preconditions are met. Nevertheless, we have adopted precautionary measures as evidenced by: 1. >39% reduction in acquisition area. 2. Avoidance of the key summer months despite this time providing the best conditions for survey. 3. The 60-day limitation on acquisition. (Event ID 5304) The NOPSEMA quote they have used to support their case has been misinterpreted by the stakeholder, that encourages a precautionary approach rather than describes principle: s391(2): The precautionary principle is that lack of full scientific certainty should not be used as a reason for postponing a measure to prevent degradation of the environment where there are threats of serious or irreversible environmental damage. (Event ID 6517) The Regia EP provides scientific estimates on the natural variations in plankton (including krill) communities globally and regionally, as well as mortality levels in these communities.Based on the long history of seismic surveys in the region, there is no evidence of significant harm to plankton populations, suggesting that serious harm is unlikely. These findings help define what constitutes "serious harm." The stakeholder lacks valid data to support their claim of large-scale harm to regional krill populations. (Event ID 6815)	6432
4392	Claims there will be impact to Bonney Upwelling via krill larvae originating from within the MSS zone.	The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. (Event ID 6815)	6432
4393, 4409, 4411, 4413	As krill is a critical food source for whales, no seismic should be done between the months of November to April.	The claim that krill is a critical food source for whales is well-established, as whales migrate to upwelling areas to support sufficient densities of their preferred food source. However, the stakeholder provides no scientifically	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		supported cause-and-effect pathways or evidence to justify the prohibition of seismic surveys from November to April. The Regia EP offers scientific evidence showing the fluctuating abundance of krill and its connection to whale feeding patterns. While upwelling events can occur at various times and locations, there is a clear understanding of what constitutes major upwelling events and when they occur – as has been identified clearly in the EP. Whales feed throughout the upwelling season, primarily when krill density is highest, and continue their migrations each year despite significant fluctuations in krill abundance between years. (Event ID 6815)	
4394, 4412	Stakeholder claims their modelling indicates that by actively monitoring currents across the Active Source Area (ASA) and defining appropriate operational limits (no active source if mean currents across ASA (stratified) are > 0.5m/s), CGG can reduce mortality of larval Nyctiphanes australis by up to 80%, as stronger currents increase the volume of water exposed to lethal doses of seismic. This would, in turn, minimize the impacts on the blue whale feeding zone and the broader Bonney Upwelling ecosystem.	The stakeholder's model does not consider the following points: Plankton and larval krill abundance and density are not uniformly distributed in the water column either vertically or horizontally. The meso-scale biological and physical characteristics that are the more appropriate scale for investigating flow-on effects on whale populations or other relevant taxa (i.e. at the population level and not the effect to individuals). The vast differences in abundance of plankton (~krill) month-by-month and year-by-year and the significance of CGG's decisions: To avoid the peak upwelling times, where there is traditionally the highest abundance of plankton and larval krill (January, February and March). To limit the survey duration to 60 days of total acquisition. Any of the 30+ peer-reviewed scientific papers beyond the McCauley and Richardson papers about the Bonney Upwelling and the effects of impulsive sound on plankton and krill. The ecological context and purpose of zooplankton and larval krill: In primary productivity in the region regardless of the state of their physical condition, evidenced by the high levels of natural mortality. As a primary food source for Blue Whale. The ± 50% interannual variation in area extent of upwelling (~population abundance of krill) which is driven mostly by climate influences and within which whale populations continue to recover. In austral summer 2008/09 the upwelling season was constrained to the single month of February – we cannot find any scientific literature that describes this season as catastrophic for the visiting whale population. In addition, assumptions are made	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		about krill behavior, distribution, and density, as well as how the model accounts for patchiness and current speeds. The model's treatment of water and krill as uniformly distributed contradicts scientific understanding of their distribution in space and time. The Regia EP provides evidence of the natural variability in marine systems and highlights the resilience of zooplankton communities, including krill, due to high birth, growth, and mortality rates. These communities exhibit high turnover and production-to-biomass ratios, making them resilient to disturbances. Citing the work of Hosie (1982), the EP emphasizes that Nyctiphanes species have higher turnover rates than Euphausid krill, and that similar mortality rates (88-90%) can be expected in both. The assumptions about krill mortality in the EP are based on well-established scientific literature. (Event 6815)	
4395	The project is adjacent to Warrnambool's Logans Beach Whale Nursery for Southern Right Whales and upstream of the Bonney Upwelling Key Ecological Feature, which could be affected.	The titleholder acknowledges this and has spent two years preparing a comprehensive Environmental Plan (EP). This process included ongoing consultations with communities and individuals, summarizing the EP into webinars, information sheets, and holding in-person meetings. The team recognizes the Otway region's marine environment as both spectacular and dynamic and believes environmental assessments must be thorough and detailed to respect its importance. Impacts are assessed in the Environmental Plan (EP) and can be found in Appendix E7 and F3. Measures to minimise adverse impacts to whales and ensures the Regia MSS does not prevent SRW and BW utilising their BIAs include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in Appendix E7 Section 9 and G1. The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. (Event ID 6815)	
4396	Stakeholder objects to Regia's dismissal of the importance of current strength in mitigating impact on krill and Bonney Upwelling biomass as both currents and krill distribution vary with depth, making monitoring at multiple depths beneficial. In the ASA, where water depth is typically less than 200m, larval krill are likely exposed to lethal seismic doses, as noted by McCauley et al. (2017). This region serves as a transport corridor for larval N. australis heading toward the Bonney Upwelling, with a westward current from November to April likely transporting larval krill into nutrient-rich upwelling zones.	The suggestion to monitor all depths lacks a clear rationale or explanation. The assumption that all krill within a specific volume of water will be killed by seismic activity is not supported by evidence. Given the lack of observed effects from past seismic surveys in the region, the model's conclusions are unsupported. If krill and currents are not uniform throughout the water column, the model's assumption of uniform distribution is flawed. The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. The model, which originally aimed to show massive krill mortality, takes a simplistic approach based on basic physical principles, such as the effect of current speeds, but ignores the complexity and scale of regional ecosystem dynamics. The model lacks validation and fails to account for key factors in the region's ecology. (Event ID 6815)	6432
4397	Stakeholder objects to the idea that meso-scale biological and physical characteristics are more appropriate for assessing impacts on whale populations or other taxa at the population level, not individual effects, claiming that individual krill disturbances can scale up to affect whale foraging success and overall population dynamics, quoting Williams 2016, Lagos 2022, Guilpin et al 2020, Santora 2011, and Kampf 2024.	Williams (2016) has been used superficially by the stakeholder. A more thorough reading reveals that the paper pertains to Humpback Whales, which show minimal response to food source reductions below 50%. The paper is useful for demonstrating the variability of ecosystems, which is discussed in detail in the Regia EP. Lagos (2022) is cited by the stakeholder to support a general statement about stress, but the thesis actually focuses on ocean warming and UV radiation impacts on krill—large-scale factors, which the Regia EP identifies as primary drivers of population changes. A small-scale disturbance like the MSS does not align with these larger impacts, which the stakeholder dismisses despite citing related studies. The stakeholder also references Guilpin et al. (2020) (not included in the bibliography). This study models how changes in krill density affect blue whale	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		foraging success, but it highlights that climate change and fishing, not seismic surveys, drive population changes. This supports the Regia EP's focus on large-scale impacts. The stakeholder's citation of Santora (2011) on California upwelling misrepresents the information. The Bonney Upwelling area is well-defined, and the stakeholder is encouraged to consult the DCCEEW website for clarification. Kampf (2024) is used by the stakeholder to suggest upwelling outside the Bonney area, a known fact. The Regia EP addresses how Blue Whale interactions with the MSS will be managed. Kampf's work builds on existing knowledge of upwelling mechanisms, and the stakeholder is encouraged to consider it as a model for understanding ocean dynamics. (Event ID 6815)	
4398	Objects to CGG's actions to avoid peak upwelling (misinterpreted as January–March) and limit survey duration to 60 days, stating that krill populations do not recover linearly after intense disturbances and the life cycle of N. australis is not necessarily aligned with the phytoplankton blooms of the Bonney Upwelling.	The stakeholder cites a study by Rau (2019) to argue that even small disruptions can affect the Southern Ocean food chain. This citation is a clear example of selective use of literature. Rau (2019) is based on aquarium experiments in a freshwater lake in Berlin, and the stakeholder is invited to clarify the relevance of Lake Muggelsee to the Southern Ocean. It appears the stakeholder did not properly review the paper. The peak upwelling season for the Bonney region is well-established through various studies, as noted in the Regia EP. Upwelling is defined by sea surface temperatures (SSTs) and chlorophyll-a (Chl_a) levels, not by wind patterns, as confirmed by the cited Barlow et al. (2021). The stakeholder's assertion that krill exist before upwelling occurs is self-evident. The stakeholder's reference to the Gill (2011) study is also inappropriate, as it does not discuss the lack of synchronization with Bonney upwelling. Furthermore, the stakeholder argues that krill are not closely linked to phytoplankton blooms in the region, contrary to established scientific knowledge. Krill rely on phytoplankton as a primary food source, and upwelling conditions concentrate this food, boosting krill reproduction and survival, which is critical for baleen whales such as Blue Whales.The stakeholder also suggests that whales are not synchronized with upwelling events, despite clear evidence that whales feed in areas where localized upwelling occurs. The Bonney Upwelling is the main upwelling center, but other regions also experience upwelling,	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		albeit less intense, as documented in the Regia EP. Recent work by Kampf (2024, 2025) has provided insights into the mechanisms behind these upwelling events. (Event ID 6815)	
4399	Stakeholder claims that with the potential impact on krill mortality and EPBC protected Blue Whales, the proponent excluding current modelling is not consistent with ALARP framework.	The criticism raised by the stakeholder is unfounded and reveals a misunderstanding of ALARP principles. ALARP involves assessing control measures by balancing environmental benefits with the costs of implementation. The stakeholder's arguments are flawed as they incorrectly suggest mitigation measures should be evaluated independently, only to contradict this by stating that ALARP is about layering controls to reduce risk and they assume their model is a reliable predictor of impacts, yet the model lacks credibility, and there is no justification for assuming mitigation measures will provide any environmental benefit. Timeframe limitations are not control measures but are self-imposed to comply with legislation and support coherent assessments. (Event ID 6815)	6432
4400	The stakeholder claims that CGG's statement fails to consider cumulative effects of seismic blasting, which can push krill populations beyond their ability to recover and disrupt population dynamics. have ecosystem level impacts, disrupting the balance of an evolved system that ensures population stability.	The key point about natural mortality rates is that plankton populations can naturally endure high mortality rates, sometimes exceeding 90%, and still thrive despite large-scale environmental changes like temperature and wind variations. This is well-documented in the Regia EP. There is no evidence to suggest that a single, spatially and temporally limited seismic survey could cause ecosystem changes at the implied scale. The Regia EP explains that planktonic communities can withstand high natural mortality rates and changes in key environmental factors. The comparison of seismic impacts to other natural events, like predation is irrelevant, as predation is a natural process. While climate change and fishing are the most significant drivers of change in marine ecosystems, seismic activity does not pose a comparable threat. The claims about seismic activity's impact on breeding krill lack any relevant scientific support, along with statements about the ripple effects of localized krill reduction. (Event ID 6815)	6432
4401	Objects to CGG's claim that impacts won't be "measurable", arguing that the absence of immediate measurable effects doesn't mean there isn't significant harm.	The case for acceptability does not rely on calculated mortality and recovery levels. Instead, the case is based on the immense size and dynamic nature of the ecosystem. The effects of the seismic survey are considered negligible because they are completely overshadowed by natural variations and dynamics, making any measurable	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		calculation impossible. This argument is further supported by the fact that the survey avoids peak upwelling times, which are when krill populations are expected to be most productive. Additionally, when considering cumulative impacts, any extra mortality caused by the survey is expected to be quickly absorbed by the natural variations and dynamics of the ecosystem, likely within days of the survey's completion. (Event ID 6514)	
4402	Stakeholder claims that equating seismic mortality with natural mortality overlooks the fact that natural mortality is an inherent part of an evolved system that maintains population stability. In contrast, human-induced mortality disrupts this balance by targeting individuals indiscriminately, including those crucial for reproduction and survival.	The Regia EP does not equate seismic mortality with natural mortality. Instead, it defines the scales of natural mortality in plankton populations to provide context for seismic effects. It is clearly stated that the two are not equivalent in any way. The stakeholder seems to misunderstand marine population dynamics, espousing a view of the natural world that was debunked in the 1970s, namely the idea of a stable or climax community where any disturbance disrupts balance. As demonstrated by Connell (1978), high diversity in ecosystems like tropical rainforests and coral reefs is only maintained in a non-equilibrium state. Wu and Loucks (1995) further emphasized that the classical equilibrium view fails because equilibrium conditions are rare in nature, and stability should consider heterogeneity and scale multiplicity. Stability, in ecological terms, is better measured by the ability of a population to continue reproducing through time, ensuring its persistence. For plankton communities like krill, this stability is defined by life-history traits such as rapid population turnover rates, enabling them to withstand extreme fluctuations in numbers and persist over time. Large variations in krill biomass are a fundamental characteristic of stable populations. (Event ID 6815)	6432
4403	Claim of ecosystem impact, as any Krill killed by seismic will become unavailable to predators.	Food chain dynamics in the open ocean are primarily supported by detritus, which serves as the foundation for energy transfer up the food chain. This detritus is mainly composed of dead plankton, with krill carcasses being a significant component, including those potentially killed by seismic activity. Such organic material is consumed by bacteria and other organisms, contributing to the marine food web. However, as demonstrated scientifically, the act of krill falling as marine snow does not cause a large-scale impact. In fact, some models suggest that this process can trigger a positive feedback loop, resulting in a surge in	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		phytoplankton and zooplankton productivity (Skartsaeterhagen et al., 2024). (Event ID 6815)	
4404, 4408 4410	Stakeholder claims that disruptions to krill populations can directly affect Blue Whale feeding, as these whales depend on dense krill aggregations for their energy requirements. Reduced prey densities may impact whale migration and breeding success.	Krill are naturally subject to mortality rates as high as 90%, and their food source fluctuates spatially and temporally, shrinking by up to 50% between and within years. The size, duration, and location of krill swarms also vary. Whales continuously feed across this dynamic space and return annually. The Regia EP argues that there is no evidence suggesting a spatially and temporally constrained MSS would cause a disturbance greater than what already naturally occurs. The stakeholder demonstrates a lack of understanding of how stability is measured in marine environments. The energy whales derive from krill fluctuates month to month and year to year due to natural dynamics in the food chain. The scale of disruption to whale feeding energy when upwelling shrinks by 30% or 50% is far greater than any MSS disturbance. The stakeholder's general statements regarding the MSS's impact lack scientific support. (Event ID 6815)	6432
4405	objects to the assertion that ± 50% interannual variation in upwelling extent, mostly climate-driven, has not constrained whale population recovery.	Whales have evolved to handle significant fluctuations in their food source, with some years yielding more biomass and others less. The Regia EP provides references to support this argument. Upon closer examination of Wiedenmann et al. (2011), which the stakeholder cites, it becomes clear that while whales can adapt to decreases in krill abundance in a particular area, the net effect on their population vital rates is negligible. Wiedenmann et al. (2011) also suggest that blue whales may adjust their foraging behaviors in response to changes in local environmental conditions, mitigating the impacts of declines in krill abundance. They note that blue whales exploit different feeding areas based on large-scale prey abundance and can concentrate in productive areas when prey is scarce, such as during El Nino years (Benson et al. 2002, Bailey et al. 2010). Furthermore, Wiedenmann et al. (2011) propose that blue whales are better equipped to cope with environmental changes than species with more restricted foraging areas, thanks to their adaptive foraging behaviors and ability to travel long distances in a foraging season. (Event ID 6815)	6432
4406	The sender claims that the absence of a defined acceptable threshold	The case for acceptability does not rely on calculated mortality and recovery levels. Instead, the case is based on the	6507

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	for krill mortality in the Regia EP is a core issue.	immense size and dynamic nature of the ecosystem. The effects of the seismic survey are considered negligible because they are completely overshadowed by natural variations and dynamics, making any measurable calculation impossible. This argument is further supported by the fact that the survey avoids peak upwelling times, which are when krill populations are expected to be most productive. Additionally, when considering cumulative impacts, any extra mortality caused by the survey is expected to be quickly absorbed by the natural variations and dynamics of the ecosystem, likely within days of the survey's completion. (Event ID 6514)	
4415	The percentage figure in Appendix E2, Section 4.1 has errors.	The Tang et al. (2014) paper was referenced to discuss non-predatory mortality in zooplankton samples from various marine environments. The stakeholder claimed that this rendered the estimated numbers used in the comparison irrelevant. However, Tang et al. provides a range estimate for non-predatory zooplankton mortality (11.6% to 59.8%) in these samples, which is relevant to the impact assessment. While CGG agree that directly extrapolating these mortality ranges to the entire Otway marine region might be overly simplistic and therefore doesn't carry significant weight in our overall argument, it is still a reasonable and relevant consideration. These ranges can be compared with the potential additional mortality resulting from factors such as predation, other anthropogenic sources, and the proposed survey. (Event ID 6518)	6890
4418	The relevant person raised concern about impacts to plankton and interpretation of the UTAS research in this area within the Regia EP.	Event ID 6321 - The Regia team responded that during consultation, concerns around plankton and the Bonney Upwelling were highlighted by multiple individuals and groups. They explained that they undertook a thorough impact assessment, which can be found in Appendix E2 of the Environment Plan (EP). Following publication of E2, the Regia team continued to receive feedback and as such now have Appendix F3 that provides further assessment of this key sensitivity on Page 48, and updated the appendices analysis with the latest literature, including the ZoopSeis research project funded by the Norwegian Research Council. Despite our assessment outcomes not resulting in the need for the precautionary principle to be applied, the Regia team had adopted measures	6329

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		to assuage the concerns of stakeholders. These are as follows: 1. >39% reduction in acquisition area. 2. Avoidance of the peak upwelling times (January/February/March), where there is traditionally the highest abundance of plankton and larval krill 3. To limit the survey duration to 60 days of total acquisition. Taking these measures into account, along with considering the ecological context and purpose of zooplankton and larval krill (being In primary productivity in the region regardless of the state of their physical condition, evidenced by the high levels of natural mortality, and as a primary food source for Blue Whale), has allowed the Regia team to demonstrate that they have reduced the impact on plankton and larval krill from the Regia MSS to ALARP.	
4419	Concern about the potential impacts of seismic surveys on the planktonic phyllosoma stage of Southern Rock Lobster.	Event ID 6820 - The Regia team responded that the information already provided on Southern Rock Lobster shows the scales of connectivity and dispersal that are intrinsic to the stock of Southern Rock Lobster. They show how any impacts to individual rock lobster larvae within the intended area of seismic will be immeasurably small relative to the mortality that is operating across the regional distribution of this species. Such a well-connected, genetically homogenous stock is, by definition, highly resilient to localised disturbances. Evidence of impacts to individual larval lobsters is not evidence of impacts to the stock of southern rock lobsters. This conclusion is based on published papers presented in the previous document and an understanding of life-history dynamics in marine invertebrates.	6411
4440	Concerned about the impacts of seismic activities on zooplankton.	Event ID 6876 - The Regia team responded in-meeting and provided an outline of the natural dynamic of zooplankton. Explained there may be short term destabilisation but it does not been the impact is additive. Directed fisher to a model study about zooplankton.	6876
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4491	Claims about the SRW and BW BIAs. States proposed activity will cause unacceptable impacts to all Karntubul species, including temporary & permanent hearing loss, displacement from BIAs, vessel strike, prey depletion during peak feeding/migration period, calving interruption, and impact to ecosystems and cultural landscapes as a result of the cumulative impact of these.	CGG has identified all Biologically Important Areas (BIAs) relevant to blue whales (BWs) and southern right whales (SRWs) and incorporated seasonal BIA use into the survey design through substantial temporal and spatial restrictions detailed in the EP. Predicted underwater-sound impacts on these Karntubul species, along with mitigation measures presented in Appendices E7 and F3, demonstrate impacts will remain acceptable and will avoid auditory impairment or displacement from BIAs or Habitats Critical to Survival (HCTS). CGG further notes that vessel-strike risk is already extremely low during seismic surveys and that additional controls in Appendix D2 ensure this risk is prevented and acceptable. It concludes that no changes to ecosystem structure, diversity, or function are expected from the one-off survey, with sound exposure too limited in extent and duration to affect prey, food webs, or predator–prey relationships. A cumulative impact assessment found residual cumulative effects to be low, reduced to ALARP, and acceptable, with no impacts predicted for regional marine parks. CGG also asserts consistency with the National Recovery Plan for Southern Right Whales and the Blue Whale Conservation Management Plan, stating that their objectives and recommended measures have been incorporated. Finally, CGG maintains that all marine mammal species likely to occur in the region have been adequately assessed using up-to-date EPBC Protected Matters data, and that mitigation measures ensure impacts to all listed species will remain acceptable and not inconsistent with EPBC Act protection provisions.	EVT352
4492	Claims that the eastern population of the Southern Right Whale, estimated at only 200–300 individuals, is at particularly high risk because its migration and reproduction Biologically Important Areas (BIAs) overlap directly with CGG's Operational Area and sound propagation footprint. According to the Southern Right Whale Recovery Plan, these whales use the affected region for reproduction between May and September and for migration between April and October. The Recovery Plan also notes that Southern Right Whales do not feed in coastal waters but are expected to feed, and possibly	The Recovery Plan explains that BIAs can be designated for key behaviours such as reproduction, foraging, migration, and resting. While Southern Right Whale BIAs in the Plan cover reproduction and migration, the Plan notes that foraging occurs across a much broader offshore latitudinal range (30°S–65°S) and is not linked to these BIAs. Because the Regia MSS is not located in Antarctic waters, it will not affect cetaceans that forage there. CGG states the survey will avoid peak SRW abundance in the mapped BIA and apply mitigation measures to ensure no SRWs are harmed, injured, or interfered with.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	conceive, within the Australian Whale Sanctuary—an area entirely overlapped by the proposed Regia MSS activity. As a result, the seismic survey could occur within, or affect, conceiving, calving, and feeding grounds for this critically endangered sub-population. The species is particularly vulnerable to human impacts due to its low reproductive rate, long lifespan, and strong site fidelity to key habitats. The submission therefore emphasises the relevance of underwater noise, habitat degradation, and vessel-strike risks in the context of the proposed seismic activities.		
4496	GMTOAC objects to CGG removing a previous control measure limiting seismic discharge in the Pygmy Blue Whale foraging BIA during periods of low whale presence, replacing it with a vague condition requiring CGG to determine whether whale presence is "compatible" with proceeding. GMTOAC argues this new measure lacks detail on how whale presence or "unacceptable disturbance" will be assessed, and that it fails to reference Recovery Plans which define unacceptable impacts. GMTOAC warns that the proposed survey timing (April–June 2026) coincides with peak Pygmy Blue Whale foraging season and Southern Right Whale migration and calving periods, meaning the seismic survey is likely to occur when both species are using their BIAs. Preventing whales from accessing these areas, or exposing them to injury while they remain, would constitute unacceptable impacts inconsistent with Recovery Plan objectives.	CGG has further reduced the likelihood of interactions with marine mammals by excluding the April–June period and commencing the survey only after 15 September. Because blue whales typically do not arrive from Western Australia until November, CGG argues that most of the survey will occur when blue whales are absent from the area. It adds that sighting data show very few blue whales in November and December, with peak abundance occurring later, from January to March during the Bonney Upwelling.	EVT352
4502	GMTOAC objects to the seismic survey's potential impacts on krill populations, including larval krill, which form a foundational part of the marine food web in Nyamat Mirring and are a critical food source for culturally significant species such as Pygmy Blue Whales and Southern Right Whales. They state that CGG's EP downplays potential impacts by comparing them to natural fluctuations in krill abundance, a framing GMTOAC considers inappropriate because it subsumes an anthropogenic disturbance within natural variability rather	CGG undertook an extensive review of the scientific literature to understand regional upwelling systems and their dynamics, assessing more than 65 publications to support the confidence of its analysis. Detailed assessments of upwelling and krill are provided in Appendices E2 and F3 of the EP. CGG does not agree with the suggestion that the assessment is trivial and remains confident in the robustness of its findings. CGG also remains open to receiving questions or new relevant information. Additionally, CGG notes that references to Panama upwelling processes are not applicable to the Regia MSS assessment and maintains	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	than assessing it cumulatively. GMTOAC emphasises that Nyamat Mirring and the broader oceanic system are already under significant stress from climate change and other human impacts. They point to the catastrophic Karenia mikimotoi algal bloom in South Australia as an example of how cumulative pressures can destabilise marine ecosystems. GMTOAC also references the recent failure of the Panama Upwelling, the first such event recorded in over 40 years, as further evidence that natural oceanographic processes are increasingly vulnerable to cumulative stressors. They argue that these examples undermine CGG's assumptions about the robustness of the system and highlight the need for a more precautionary, cumulative-impact-focused assessment.	confidence in the supporting literature base.

1 Introduction

Underwater Sound was identified through the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) as an Aspect needing further assessment. Hence this document presents a detailed examination of Underwater **Sound**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental Receptor we are collectively calling **Fish.**

This assessment is built on the information contained in the following four core studies, which should be read in the order they are listed:

1. PEIRA
2. Seismic Sound Studies Report (Appendix B8)
3. Sound Emissions Modelling Reports (Appendix B7)

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was initially published in draft form and uploaded to the Document Library of the Regia MSS Consultation Hub on 11 September 2023 as a stand-alone document, rather than as part of the much more substantial total EP document. This was done to maximise the ability of interested members of the public to read, interpret and respond within the mandated 30-day public comment period.

As such, public and Relevant persons were invited to comment on the document with an explicit request for feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

The primary sound source will be impulsive underwater acoustic emissions coming from the seismic source releasing compressed air (seismic pulse) and creating a sound wave directed downwards towards the seabed.

Secondary sound sources will include continuous underwater acoustic emissions generated by the survey and support vessels and helicopters. Sounds from vessels are generated by thrusters, engines, and propellers. Underwater acoustic emissions from helicopters are generated via the engine and rotors. Underwater acoustic emissions from Ultra-Short BaseLine positioning beacons are generated within the streamer spread.

An overview of underwater sound and studies relevant to seismic is in Appendix B8.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days

Extent: Active Source Area + 86 m – 10.95 km based on the furthest distance to modelled sound effect criteria. [Updated in response to Matter: F17]

Active seismic acquisition will occur for up to 60 days within the Active Source area.

Continuous Sound

Duration: 90 days

Extent: Operational Area +1.6 km based on the assessment of vessel sound.

The survey and support vessels will be active in the Operational Area for the duration of the survey undertaking support activities and acquisition.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for impulsive (seismic) underwater sound for the following environmental receptors and their social, cultural, and economic features:

- Fish (including eels and sharks).
- People and communities.

In addition, indirect impacts were identified to the following, via relevant person consultation:

- Commercial fisheries and fishing tour operators

Potential environmental impacts to fish identified from the PEIRA are:

- Change in fauna behaviour.
- Change in hearing capacity.
- Change in physical condition.

Species are grouped according to their sound modelling characteristics which are influenced by the presence or absence of a swim bladder, as defined by Popper et al. (2014) Most bony fishes have a swim bladder which is used for buoyancy control but may also be used for hearing, sound production, and/or respiration. Species with a swim bladder have a greater potential to suffer from physiological trauma than those without. Fish species that lack a gas-filled cavity, such as elasmobranchs (sharks, skates, and rays) some tuna species and other pelagic and deep-sea species, are not as vulnerable to trauma from extreme sound pressure changes as fish with a gas-filled space (Popper et al 2014).

In 2006, the Working Group on the Effects of Sound on Fish and Turtles was formed to continue developing noise exposure criteria for fish and turtles, work begun by a panel convened by NOAA two years earlier. The resulting guidelines included specific thresholds for different levels of effects and for different groups of species (Popper et al. 2014). These guidelines defined quantitative thresholds for three types of immediate effects: ·

- Mortality, including injury leading to death.
- Recoverable injury, including injuries unlikely to result in mortality, such as hair cell damage and minor haematoma.
- TTS

PTS was not identified by Popper et al (2014), thus there is no cause-effect pathway for PTS effects to fish.

4 Description of the Existing Environment That May be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8.

To identify fish species (including sharks and rays) that are covered by the Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act) and that may be present within the area affected by underwater sound, a PMST search was undertaken. The PMST search area was defined as the Active Source Area plus an 8 km buffer. This buffer distance was based on the furthest distance to modelled sound effect criteria for fish of 8.35 km at the time of searching. The PMST Report is available in Appendix B5. Annex 3 provides details on these protected fish species and relevant conservation advice or management plans.

.PMST searches were run multiple times prior to resubmission to ensure any changes to species or listings were identified to control for passage of time. Yarra Pygmy Perch and Eastern Dwarf Galaxia have been removed from the 2025 PMST search for the underwater sound EMBA that may impact fish. Conservation Advice has also been updated for several species and subsequent changes have been made to Annex 3.

Changes relevant to the assessment of underwater sound and fish are:

- Southern Bluefin Tuna (*Thunnus maccoyii*) has been removed from the February 2025 PMST reports for all areas searched, as it is no longer listed as a threatened species under the EPBC Act (DCCEEW 2024k). This species has been retained for assessment based on a precautionary approach remains appropriate to assess this species that was only recently delisted, the species known relevance to regional fisheries, and to accurately reflect the passage of time over which this EP has been constructed.
- Grey Nurse Shark (*Carcharias taurus*) has been added to list as species or species habitat may occur within area.

[Section added in response to Matters: I16 and I17].

In addition to the fish species identified from the PMST searches, all commercial species of relevance as identified from a review of Appendix B6: Commercial Fisheries Analysis Report (Appendix B6) are described here.

Stakeholder consultation concerns were raised about the potential impact of seismic sound on eels, hence they are also included.

4.1 Protected Species with Swim Bladder

4.1.1 Australian Grayling (*Prototroctes maraena*)

The Australian Grayling is a small to medium-sized, slender, silvery fish with soft-rayed fins lacking any spines. It is endemic to south-eastern Australia, including Victoria, Tasmania, and New South Wales, and is a migratory species that inhabits estuarine waters and coastal seas as larvae/juveniles, and freshwater rivers and streams as adults (Backhouse et al. 2008) i.e. amphidromous. Australian Grayling generally migrate downstream to the lower freshwater reaches of rivers to spawn, usually over a two-week period, typically from late-summer to mid-winter (TSSC 2021). Fecundity of this species varies between 25,000 and 68,000 eggs, with an average of 47,000 eggs (TSSC 2021). Eggs hatch between 10 and 20 days after being laid. Larvae emerge at 6.5 mm in length, are buoyant, and while they are free swimming, they are typically swept downstream into marine habitats by river flow (TSSC 2021). A lack of genetic diversity between Australian Grayling collected from coastal rivers in Victoria suggested that a single population occurs in Victoria, as larvae are most likely dispersed during the marine stage of their life cycle (TSSC 2021). This result indicates that the marine larval and juvenile phase facilitates extensive gene flow among coastal rivers. Such a dispersal strategy would enable recolonization of rivers that experience localized extinction provided that connectivity between freshwater habitats and the sea is sufficient to permit migration and that enough source populations remain intact to support viability of the wider population. Similarly to the freshwater eels (Anguiulla sp.) the key threats to Australian Grayling come from pollution, loss and fragmentation of

their riverine habitat. The key riverine habitats for this species are all located to the east of the Regia MSS, along the south-east axis of Victoria and extending up into NSW (Figure E3-1).

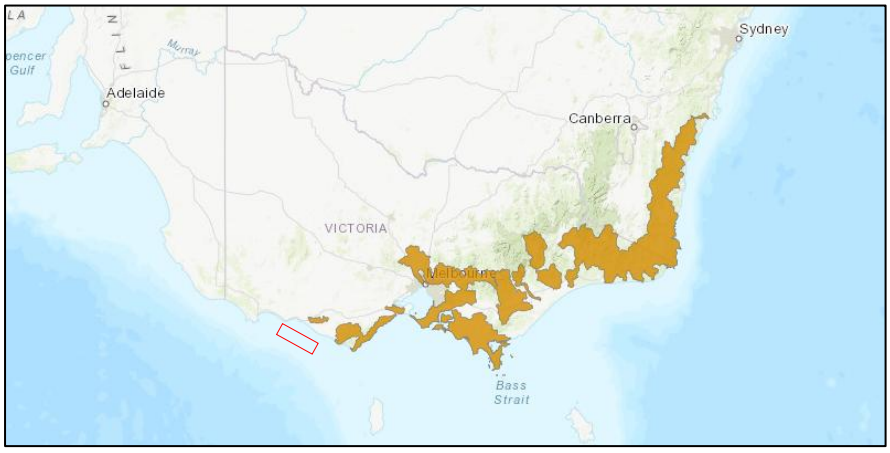

Figure E3-1 - Geographic range of the Australian Grayling (from Lintermans et al 2019 IUCN Red List Assessment). Red box is approximate location of proposed Regia MSS

4.1.2 Blue Warehou (*Seriolella brama*)

The Blue Warehou is a medium-sized, deep-bodied fish, reaching a maximum total length of 90 cm and a maximum weight of 7 kg (TSSC 2015). Globally, the Blue Warehou is confined to Australian and New Zealand waters predominantly in coastal shelf, upper continental slope, and seamount waters offshore from New South Wales, Tasmania, Victoria and South Australia (TSSC 2015). It is nevertheless a highly mobile species that is genetically well-connected over its range. [Paragraph updated in response to Matter: F03]

Blue Warehou is a bentho-pelagic species that inhabits continental shelf and slope waters. Adults can be found at depths from 50 - 300 m. Blue Warehou is a schooling fish and usually aggregates close to the seabed. Juveniles can sometimes be found schooling close to the surface in estuaries, often in association with jellyfish (AFMA 2023).

Spawning occurs during winter and early spring. Larval sampling has found that the major spawning locations are along the west coast of Tasmania (Figure E3-2 from Bruce et al 2001).

On average female's spawn around three times per season, producing 430,000 – 1,350,000 eggs per spawning event depending on their body size (AFMA 2023). [Paragraph updated in response to Matter: F03]

While Blue Warehou is a target species for the Southern and Eastern Scalefish and Shark Fishery and Tasmania Scalefish Fishery, catch levels are extremely small at ~4T and 1T per fishery respectively. AFMA (2023) states that the stock are depleted and actively avoided by fishers.

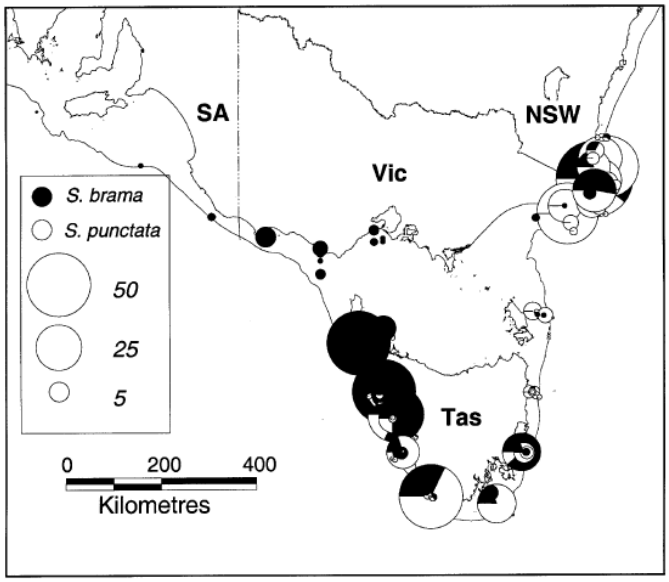

Figure E3-2 Distribution of S. brama larvae and S. punctata larvae in southern Australia (all sizes combined). Scale, number of larvae per 1000m³ (from Bruce et al 2001).

4.1.3 Orange Roughy (*Hoplostethus atlanticus*)

Orange Roughy are a deepwater species that inhabits waters over steep continental slopes and ocean ridges. They are usually found dispersed over rough bottoms and steeps at depths of 700 - 1400 m (AFMA 2023a). Orange Roughy form dense spawning aggregations in winter, with non-spawning aggregations occurring sporadically in summer and autumn. Aggregations usually occur from 5 - 10 m above the seabed, with some extending over 50 m in height from the sea floor. Aggregations are usually associated with submerged hills or pinnacles. Excluding substantial migrations to spawning grounds, Orange Roughy are a relatively sedentary species (AFMA 2023a).

Orange Roughy reach reproductive maturity at 27-32 years of age. Spawning aggregations form between mid-July and late August. Adult males appear to spawn over a 1–2-week period, with females spawning for up to 1 week. Females produce 10,000 -,90,000 eggs in a single spawning event each season. The eggs float to the surface after fertilisation before sinking again to hatch close to the sea floor. Hatching is thought to occur 10-20 days after fertilisation. It is likely that females do not spawn every year (AFMA 2023a).

The Orange Roughy is a demersal fish targeted by the Southern and Eastern Scalefish and Shark Fishery. They are widely distributed throughout the world and form dense spawning and feeding aggregations on or near topographic features such as seamounts, canyons, and plateaus (DCCEEW 2023b). No spawning or feeding aggregation areas have been identified in the Operational Area, with their major spawning locations located on the east coast of Tasmania (Knucky & Smith 1997). [Paragraph updated in response to Matter: F03]

4.1.4 Southern Bluefin Tuna (*Thunnus maccoyii*)

Southern Bluefin Tuna can grow to 225 cm in length and 200 kg in weight (TSSC 2010). They are a highly migratory species that occurs globally in waters between 30°S and 50°S. In Australian waters, they range from northern Western Australia, around the southern region of the continent, to northern New South Wales (TSSC 2010). Southern Bluefin Tuna forms a single, widely distributed population in the southern, temperate oceans, but with a single known spawning ground in the Indian Ocean, between Java and northern Western Australia (TSSC 2010). Southern Bluefin Tuna are known to be among the fastest ocean swimmers in the world and can travel in speed bursts of up to 70 km/hr while feeding (TSSC 2010).

Southern Bluefin Tuna are a target species for the Southern Bluefin Tuna Fishery and in Australian waters, they are found mainly in the Great Australian Bight (AFMA 2023b) where they are most caught

during the summer months (December to April). They are also caught off the New South Wales coastline during winter (AFMA 2023b).

Southern Bluefin Tuna is not commercially caught in the Operational Area. It is sometimes caught recreationally off Victoria.

4.1.5 Syngnathids

Most of the listed marine ray-finned fish species identified in the PMST report are syngnathids, which includes seahorses and their relatives (sea dragon, pipehorse and pipefish). However, of the 26 species listed in the report all of them are assessed as "Species or species habitat may occur within area", which reflects the almost complete lack of evidence to support their presence. Nevertheless the majority of these species are associated with seagrass meadows, macroalgal seabed habitats, rocky reefs and sponge gardens which are all located in shallow, inshore waters such as protected coastal bays, harbours and jetties less than 50 m deep (Fishes of Australia, 2015). They can also be found in deeper offshore waters, where they are 'rafting' around floating seaweed such as sargassum, seen as a method of dispersal between locations.

The most common habitats they associate with in temperate waters are dominated by seagrass and algae (Foster & Vincent 2004) while also being regularly associated with anthropogenic features, such as aquaculture pens, moorings, swimming (shark) nets and jetty pylons (Clynick, 2008;;Harasti et al., 2010) to the extent that these features are likely important habitats for some, or even many, species.

Identified threats to Syngnathids include physical habitat modifications, decreased water quality and bycatch from commercial fishing.

There is a dearth of literature on effects of underwater noise on Syngnathids however Vincent et al (2011) noted a study by Anderson (2009) that found seahorses exposed to loud aquarium noises for a month displayed multiple stress responses but without any measured changes in reproduction or feeding. They also highlighted the work of Simpson et al (2008) that found Syngnathids showed a positive response to high frequency noise.

Given the lack of compelling evidence for significant populations of seahorses along the Otway Coast region and their prevalence for seagrass and algae dominated habitats, which are mostly confined to sheltered bays and estuaries in shallow water, there is no further assessment conducted on this group.

4.1.6 Eels (*Anguilla spp.*)

The Short-finned Eel (*Anguilla australis australis*) and the Long-finned Eel (*A. reinhardtii*) both occur naturally within Victoria and are the target species of the Victorian Eel Fishery. The eels have differing but overlapping distributions east and south of the Great Dividing Range in estuarine and freshwater catchments (VFA 2023) (Figure E3).

The Short-finned Eel is widespread across the southern parts of the Victoria and occurs occasionally in northern streams draining into the Murray River, while the Long-finned Eel is found within southeast parts of Victoria only (VFA 2023). Both species spend the majority of their life cycle in fresh water or estuaries before travelling to the ocean to spawn once before dying (VFA 2023). The Operational Area or area potentially impacted by underwater sound does not overlap habitat associated with the Long-finned Eel and hence is not discussed further.

Both species migrate to the ocean once matured; male Short-finned Eels generally mature at 8-12 years of age, whilst females mature at 10-20 years. Migration occurs during late summer to autumn (VFA 2023a). Spawning is thought to occur in the vicinity of the Coral Sea, although no precise spawning location for either species has been identified. Eggs are thought to be pelagic and hatch after about two days. Larvae are transported southwards along the east coast of Australia where they metamorphose into glass eels and swim into coastal bays and estuaries (VFA 2023). Most Short-finned glass eels migrate in the winter and spring, although glass eels may continue to arrive anytime throughout the year (VFA 2017).

The distributions of Short-finned Eels are extensive from subtropical Queensland to western Victoria, Tasmania, and New Zealand (VFA 2023).

Koster et al (2021) tracked the Short-finned Eel spawning migration for the first time in Australia. Sixteen eels were collected and tagged from the Hopkins and Fitzroy River estuaries as they migrated from the river mouths outwards to the Southern Ocean over a sandbar in 2019. They were then released at either Warrnambool Harbour, Hopkins mouth beach or Killarney beach. Of the 16 tags twelve returned data. The results showed that the Short-finned Eels exhibit diel vertical migration, where they travel in the top layers of water during the night and travel further down in the water column during the day (Koster et al. 2021). Of the small number of eels that made the entire journey to the spawning location their last movements were recorded in the Coral Sea. Many of the eels (about 30%) migrations were cut short due to predation, suspected by sharks, tuna, or other marine mammals.

It has been noted by Van Wichelen, et al (2022) that glass eels feeding during their migration is highly restricted, therefore when discussing impacts to glass eels, this has been considered.

Short-finned Eel is listed as 'near threatened' on the IUCN red list, with barriers to riverine movement and freshwater habitat loss being key threats. Additionally changes in ocean currents, primary production, and thermal regimes may also affect eel migration, spawning success, and recruitment (Koster et al. 2021). The long-finned eel is listed as 'least concern' by the IUCN. Short-finned Eel is not listed under the EPBC Act and is fished by the Victorian Eel Fishery.

Victorian Eel Fishery

Both the Long-finned and Short-finned Eel are the target species for the Victorian eel fishery. The first commercial catches of eel were recorded in 1914, and up until 1950 eel was primarily fished for bait. Export of frozen Short-finned eel to Europe began in the 1960s (VFA 2023a). Eel are harvested in Victorian coastal river basins south of the Great Dividing Range using fyke nets, with a maximum of 18 licences allowed in Victoria. Certain waterways are closed to fishing to allow for eels to escape and spawn (VFA 2023a). Short-finned Eels are the most abundant and the most keenly targeted eel species in Victoria, productivity from the fishery is highly susceptible to short and long term and seasonal environmental variations, particularly drought (VFA 2017).

The eel fishery comprises both a wild catch sector and a culture (stock enhanced) sector. The culture sector has developed strategies for growth consistent with the species life cycle by translocating juvenile eels from other parts of Victoria into lakes and impoundments (culture waters) in western inland Victoria where they continue to grow (VFA 2017). Fishing for glass eels has been of limited success due to the highly variable abundance in Victoria. Most of Victoria's eel catch is taken by commercial fishers and is comprised of adult eels during different stages of their migration.

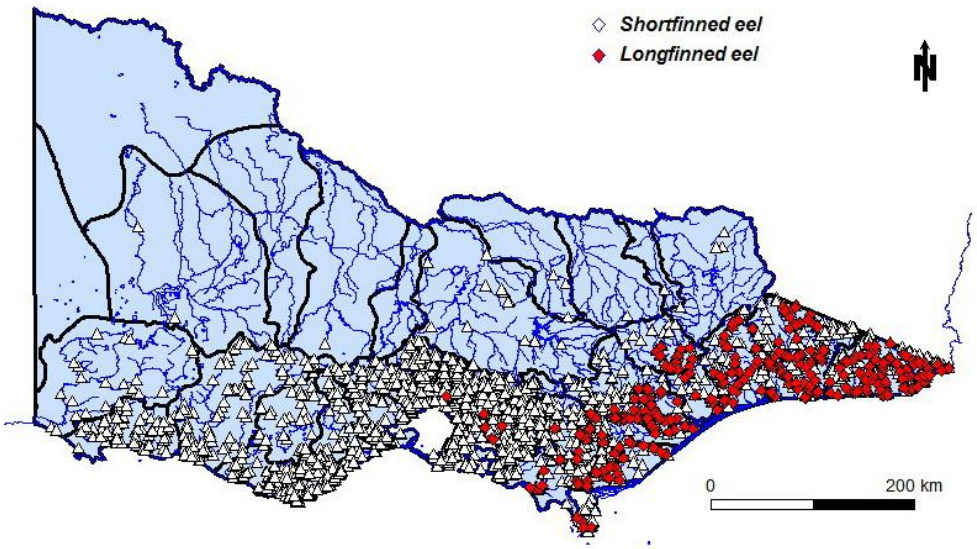

Figure E3-3: Distribution of Long-finned and Short-finned Eels in Victoria (VFA 2017)

4.2 Protected Species without Swim Bladder

4.2.1 Grey Nurse Shark (*Carcharias taurus*)

The east coast population status for the Grey Nurse Shark is critically endangered under the EPBC Act. In addition, this species is also protected in the coastal waters of Victoria under the Fisheries Act 1995. The recovery plan for this species highlights that all but one of the nineteen key aggregation sites for this species are listed as 'habitat critical for the survival of the species'. Of most relevance here is that none of these key aggregation sites are in waters off the Victoria coast (CoA 2014).

The Grey Nurse Shark is reported to have two distinct populations in Australia: a west coast population and an east coast population. This shark species is found mostly in inshore regions in cool temperate to sub-tropical waters (Compagno, 1984; Last & Stevens, 2009). The east coast population covers a range of approximately 2,700 km and extends from the Capricornia coast (central Queensland) to Narooma in southern New South Wales. Sightings data from the New South Wales Department of Primary Industries (NSW DPI) includes sightings as far south as the NSW/Victoria border (CoA 2014). Grey Nurse Sharks tend to live in shallow inshore waters with their preferred habitats being sandy-bottomed gutters or rocky caves and close to inshore rocky reefs or islands (DCCEEW 2021).

The Grey Nurse Shark is slow growing and long-lived with late onset sexual maturity and low fecundity. Lifespans of this species have been known to reach at least 40 years for females and 34 years for males (Passerotti et al. 2014, Harry 2018). The longest records for wild *C. taurus* in mark and recapture studies are 22 years (male) off the south coast of Western Australia and 26 years (female) off the coast of South Africa (Jakobs & Braccini 2019, Hoschke et al. 2023). The east coast population is currently estimated to be around 2,000 individuals with recovery of this population considered slow (DCCEEW 2023a).

As highlighted in this species' recovery plan, the principal threats to this population and contributors to the lack of Grey Nurse Shark recovery in Australia are mortality resulting from incidental (accidental and/or illegal) capture by commercial and recreational fishers and from shark control activities. Other potential threats to the species mentioned in the recovery plan include impacts from ecotourism, collection for public aquaria, pollution and disease and ecosystem effects as a result of habitat modification and climate change. Exploration activities, including seismic, have not being identified as key threats to this species (CoA 2014).

4.2.2 Little Gulper Shark (*Centrophorus uyato*)

The Little Gulper Shark is listed as Conservation Dependent. Gulper Sharks are targeted by the Southern and Eastern Scalefish and Shark Fishery but are mostly taken as bycatch in the trawl fishery. They are endemic to Australia, occupying demersal habitats on the upper slope of the southern continental shelf, between 180 m to 900 m (Williams et al. 2012). There are likely to be three distinct stocks of Gulper Shark:

- An eastern stock along the east coast of Australia down to eastern Tasmania.
- A central stock from western Tasmania through the Great Australian Bight.
- A western stock from the western Great Australian Bight, southwestern Australia.

Gulper Sharks have life history characteristics that make them vulnerable to overfishing, which is the biggest driver of declines in this species. These include slow growth, late age-at-maturity, low fecundity, and low natural mortality (TSSC 2013a). Young are born live, and reproduction is continuous and non-seasonal (TSSC 2013a). Estimated foraging range for Gulper sharks is up to 50 nm based on acoustic telemetry data (Williams et al. 2012). They undertake day-night migrations across their depth range from relatively deep day time residence depths (1000 m) to shallower nighttime feeding depths (to 200 m) (Williams et al. 2012). [Section updated in response to response to Matter: F03]

4.2.3 School Shark (*Galeorhinus galeus*)

School Shark are a temperate demersal species found on the continental shelf and slope. They can be found to depths of 550 m and often move up into the water column at night. School shark segregate into schools according to size and sex (AFMA 2023). Size generally increases from inshore to offshore. Pups and juveniles aggregate in shallower 'nursery' waters during the spring and

summer. School Shark undertake long migrations of up to 1400 km along the southern coast of Australia, which are thought to be associated with homing to natal mating and pupping grounds (Last and Stevens 1994). However, while extensive migrations within regions have been recorded, studies of different global populations indicate that each region hosts a genetically distinct population. Within regions, it is suspected that there may be localised subpopulations (TSSC 2009a).

School Shark are a target species for the Southern and Eastern Scalefish and Shark Fishery but are also taken as bycatch in the trawl fishery.

School Shark is listed as Conservation Dependent. It appears to have undergone a significant reduction in numbers as a result of commercial fishing in southeastern Australian waters (TSSC 2009a). School Sharks move extensively throughout the waters of southern Australia. School Shark is primarily a deep water demersal (bottom-dwelling) species, although individuals have been recorded undertaking daily vertical migrations, remaining at depths of around 500 m during the day and moving up to around 100 m at night (McLoughlin, 2007). Females and juveniles utilise inshore coastal areas around Victoria, Tasmania, and parts of South Australia for nursery areas (Pogonoski et al., 2002). Birth occurs in early summer after a gestation period of 12 months. Pups are born in shallow bays and estuaries (AFMA 2024).

4.2.4 White Shark (*Carcharodon carcharias*)

The White Shark is listed as Vulnerable. White Sharks are long-lived, living for 30 years or more (Bruce 2008), and are found throughout temperate and sub-tropical regions in the northern and southern hemispheres (Last & Stephens 2009). The species is also commonly found in inshore waters in the vicinity of islands, and often near seal colonies (Malcolm et al. 2001). The White Shark foraging BIA within the area that may be impacted by underwater sound above the behavioural threshold for sharks, is centred on Lady Julia Percy Island which is a known seal breeding colony (Appendix B12 MAP-REG-EPM-077).

4.3 Commercial Fish Species with Swim Bladder

The following commercial fish species were identified from the Commercial Fisheries Analysis Report available in Appendix B6.

4.3.1 Australian Salmon (*Arripis truttaceus* – Western Australian Salmon, *Arripis trutta* – Eastern Australian Salmon)

The following is from;

https://www.fish.gov.au/report/351-Western-Australian-Salmon-2023

https://www.fish.gov.au/report/350-Eastern-Australian-Salmon-2023

The Western Australian Salmon biological stock is distributed from Kalbarri in Western Australia southwards to South Australia, Victoria and the west coast of Tasmania. The species spawns in Western Australia and eggs and larvae are dispersed by the Leeuwin Current. The fish then grow and mature in eastern waters before moving back towards their spawning areas in the west.

This cross-jurisdictional biological stock has components in Western Australia, South Australia and Victoria. The status presented here for the entire biological stock has been established using evidence from all jurisdictions. However, the breeding component of this stock resides exclusively in Western Australia, with only immature/nonbreeding fish occurring in South Australia and Victoria [Cappo et al. 2000].

In Victoria, Western Australian Salmon are subject to very low exploitation by recreational and commercial fisheries. The species is not a common target in the major Victorian bay and inlet fisheries; for example, “Salmon” were listed as the primary target species by only 0.38% of recreational fishers interviewed in creel surveys in Port Phillip Bay [Bell et al. 2023]. Western Australian Salmon are targeted in small-scale recreational fisheries elsewhere (e.g., in estuaries and along the coast), however these catches are likely small within the context of the species' wide-ranging behaviour and ability to use a diverse range of habitats [Bell et al. 2023].

The above evidence indicates that the biomass of this stock is unlikely to be depleted, recruitment is unlikely to be impaired, and the current level of fishing mortality in each jurisdiction is unlikely to cause the stock to become recruitment impaired.

In Victoria, the Eastern Australian Salmon stock is targeted by the commercial purse seine ocean fishery, mostly off eastern Victoria, with small catches also taken from Corner Inlet and the Ocean Fishery. This cross-jurisdictional biological stock has components in New South Wales, Victoria and Tasmania. The entire Eastern Australia biological stock is classified as a sustainable stock.

Australian Salmon is a target of the Victorian Multispecies Ocean Fisheries.

4.3.2 Australian Sardine (*Sardinops sagax*)

The following is from AFMA 2023d ((https://www.afma.gov.au/species/australian-sardine)).

Australian Sardine is found primarily in temperate waters throughout the eastern Pacific Ocean. They are a coastal species that can usually be found from inshore waters to the edge of the continental shelf, down to depths of about 200 m. Australian Sardine is often found in large schools. Feeding is thought to mainly occur during the day.

Australian Sardines are a key food source in marine food chains throughout their range, being targeted by marine mammals, birds and pelagic fish species such as tuna. They are the dominant clupeoid in the region occurring throughout coastal and shelf waters in contrast to the Australian Anchovy which is mostly confined to inshore waters (Ward et al 2020).

There are four recognised sub-populations centered on Southwestern Australia, Eastern Australia, Southeastern Australia and Southern Australia. The major fishing grounds are in South Australia. Stocks are considered sustainable. Spawning occurs during spring-summer in the southern part of its range, and in summer-autumn in the northern part (Figure E3 - 4). It was previously thought that Australian Sardine only spawn once or twice in a season, but research on similar species suggests that they may spawn multiple times. Females produce 10,000 – 45,000 eggs per spawning event depending on their body size.

A recent study has discovered a hitherto unestimated large Australian Sardine resource off South Eastern Australia (Ward et al 2023). The new estimates suggest that catches could be increased by an order of magnitude without endangering the sustainability of the stock.

Australian Sardine is a target species for the Small Pelagic Fishery and the Southern and Eastern Scalefish and Shark Fishery. [Section updated in response to Matter: F03]

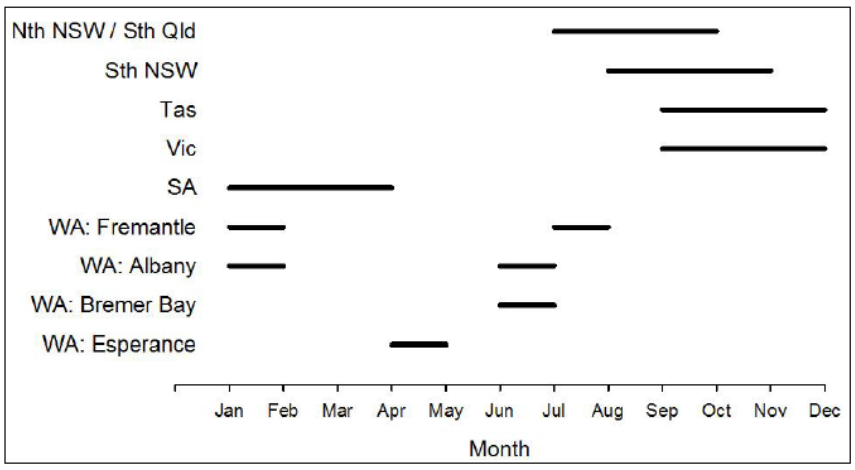

Figure E3 - 4 Periods of peak spawning of Australian sardine throughout its Australian distribution (from Izzo et al 2012).

4.3.3 Bigeye Tuna (*Thunnus obesus*)

The following is from AFMA 2023e.

Bigeye Tuna is a highly migratory species, swimming continuously over large distances. They are found commonly in eastern Australian waters, but they are also found in the waters of other countries within the Pacific and Indian Oceans.

In Australia, Bigeye Tuna is caught anywhere along both the east and west coasts and is a targeted species by fishers in both the Eastern Tuna and Billfish Fishery and the Western Tuna and Billfish Fishery.

Bigeye Tuna is a tropical tuna species and prefers warmer oceanic waters and is not likely to be present in the Otway area of the Operational Area.

4.3.4 Blue Grenadier (*Macruronus novaezelandiae*)

The following is from AFMA 2023f.

Blue Grenadier is a deepwater species that occurs on the continental slope. They can be found at depths of 200 - 700 m. Juveniles often occur in shallower bays and inlets. Blue Grenadier aggregate near the seabed during the day and move up into the water column at night. Spawning occurs in winter and early spring. The main spawning ground for blue grenadier is on the west coast of Tasmania. Females release about 1 million eggs in a single spawning event.

Blue Grenadier is a target species for the Southern and Eastern Scalefish and Shark Fishery. Catch rates in Australia are highest off the west coast of Tasmania on the shelf slope during winter where the species aggregates to spawn, and this region has been confirmed as a major spawning ground for the species (Gunn et al. 1989, and Bulman et al. 1999). [Paragraph updated in response to Matter: F03].

4.3.5 Blue Mackerel (*Scomber australasicus*)

The following is from AFMA 2023g.

Blue Mackerel are a schooling pelagic species that occurs in tropical and temperate waters of the Pacific Ocean. They can be found to depths of 200 m over the continental shelf, although juveniles inhabit inshore waters and shallower waters. Blue Mackerel tend to school by size, as well as with other fish such as jack mackerels. Feeding is thought to occur during the day.

Blue Mackerel reach reproductive maturity at about 3 years of age. Spawning occurs in spring and summer in outer continental shelf waters off northern New South Wales and southern Queensland.

Fishing for Blue Mackerel in the Small Pelagic Fishery has historically been focused off southeast NSW, eastern Tasmania, and South Australia. These areas are outside of the Operational Area.

4.3.6 Blue-eye Trevalla (*Hyperoglyphe antarctica*)

The following is from AFMA 2023h.

The Blue-eye Trevallas are stout-bodied fish with a blunt snout and small scales. The Blue-eye Trevallas are benthic species that are associated with rocky ground on continental slopes often found in continental shelf and upper slope waters at depths from 100 - 600 m and on seamounts and undersea features. They generally remain close to the seabed during the day and move up into the water column at night. Spawning occurs in summer and autumn. Mature fish are thought to move into shallower waters and aggregate over specific areas for spawning. Most spawning activity occurs in waters from central New South Wales to north-eastern Tasmania (AFMA 2024). [Reference added in response to Matter: F03]

Blue-eye Trevallas are a target species for the Southern and Eastern Scalefish and Shark Fishery.

4.3.7 Broadbill Swordfish (*Xiphias gladius*)

The following is from AFMA 2023i.

Broadbill Swordfish is an oceanic species and is caught worldwide throughout tropical, temperate, and occasionally cold waters. They are commonly found in eastern Australian waters, but they are also found in the waters of other countries within the Pacific and Indian Oceans.

In Australia, Broadbill Swordfish are caught anywhere along both the east and west coasts, and it is a targeted species by fishers in both the Eastern Tuna and Billfish Fishery and the Western Tuna and Billfish Fishery.

Broadbill Swordfish are not commercially caught in the Operational Area.

4.3.8 Eastern School Whiting (*Sillago flindersi*)

The following is from AFMA 2023j.

Eastern School Whiting is a benthic species found from shallow tidal flats down to depths of 180 m on the continental shelf. They are usually associated with sandy substrates. Juveniles tend to be found in shallower waters than adults.

Spawning is regionally variable and occurs from October to March in the eastern Bass Strait, late summer in Tasmania, and during winter in northern New South Wales. Females spawn twice each year in deeper waters. Females produce 30 000-110 000 eggs per spawning season depending on their body size.

Eastern School Whiting is a target species for the Southern and Eastern Scalefish and Shark Fishery.

4.3.9 Jack Mackerel (*Trachurus declivus* and *T. murphyi*)

The following is from AFMA 2023m.

Jack Mackerel are a pelagic schooling species found around the southeast and southern coasts of Australia over the continental shelf and outer shelf margin. They are commonly found at depths of 20 - 300 m. Jack Mackerel school by size. Juveniles tend to be found in shallower waters than adults. Feeding is thought to occur both during the day and at night.

Spawning occurs during late spring to early summer. Spawning begins off the southeast coast of Australia and moves progressively southwards over the summer.

Fishing for Jack Mackerel in the Small Pelagic Fishery has historically focused on the area of waters off Southeast NSW, Eastern Tasmania and South Australia.

4.3.10 King George Whiting (*Sillaginodes punctatus*)

King George Whiting are found within the bays, estuaries, and coastal waters of Victoria. They are a popular target of recreational fishers with most fish taken within the semi-sheltered waters of Port Phillip Bay (PPB), Corner Inlet-Nooramunga (CI) and Western Port (WP), where commercial fishers are also located. Population dynamics are strongly influenced by climatic factors determining numbers of larvae transported to bay and estuarine nurseries from coastal spawning areas in spring [Jenkins and May 1994, Hamer and Jenkins 1996, Jenkins et al. 2000, Jenkins 2005]. As most King George Whiting leave the bays and inlets permanently by four years of age (prior to adulthood) [Hamer et al. 2004], these fisheries are based on just a few age classes at any one time, making catches highly variable over relatively short time scales. Over the past 60 years catches have shown peaks and troughs at about 10 to 12-year intervals. These cycles are thought to be related to variation in westerly winds driving larval transport and survival (Jenkins 2005). Because fishing effort is concentrated in bays and inlets, adults in coastal waters are likely subject to low fishing mortality.

King George Whiting has a complex life history, exhibiting ontogenetic shifts in habitat at different life history stages (Fowler and Jones, 2008). Spawning occurs during late autumn and early winter at offshore reefs, shoals, and mounds in relatively deep water (30 – 100 m) in exposed locations (Fowler, 2000, Fowler et al., 1999, Steer et al., 2018). The larvae of King George Whiting can be advected across hundreds of kilometers over a prolonged pre-settlement period (3 – 5 months), dispersing larvae from the offshore spawning grounds to the shallow water nursery areas in protected shallow bays (Fowler et al., 2000b, Rogers, 2019). Juvenile fish develop and grow in the vicinity of these nursery areas until 3 - 4 years of age (Fowler et al., 2000a) when they move to their offshore spawning grounds to repeat the cycle (Fowler et al., 2000a, Fowler et al., 1999).

This species is a target species of the Marine Scalefish Fishery in South Australia as well as the Bays and Inlet Fisheries of Victoria.

Given the high level of significant interest from relevant persons further analysis and assessment of this species can be found in Appendix F3 - Further Assessment of Key Environmental Values and Sensitivities. Details of relevant references will also be found there.

4.3.11 Pink Ling (*Genypterus blacodes*)

The following is from AFMA 2023n.

Pink Ling are a demersal species that inhabits the continental shelf and slope. They can be found at depths of 20 - 1000 m. Juveniles tend to occur in shallower waters than adults. Pink Ling occur over a variety of substrates, from rock ground to soft sand and mud in which they burrow. Aside with some movement associated with spawning, pink ling are thought to be relatively sedentary.

Spawning occurs over an extended period during late winter and spring. Pink Ling are thought to be serial spawners, with egg batches being released in a floating gelatinous mass in each spawning event. Females produce about 333,000 eggs per spawning event depending on body size.

Spawning aggregations have been reported by commercial fishers off Strahan, Tasmania, Lakes Entrance Victoria, and Gabo Island NSW (Bruce et al 2002). [Sentence added in response to Matter: F03]

Pink Ling is a target species for the Southern and Eastern Scalefish and Shark Fishery.

4.3.12 Redbait (*Emmelichthys nitidus*)

The following description is from Ward et al (2019) except for paragraph 2 which is from AFMA website.

Redbait is widely distributed throughout the southern hemisphere, with the species reported from Tristan da Cunha in the southern Atlantic, the south-western coast of South Africa, St Paul and Amsterdam Islands, mid-oceanic ridges and seamounts through the Indian Ocean, Australia, New Zealand, submarine ridges in the south-eastern Pacific, and the southern coast of Chile (Markina and Boldyrev 1980, Meléndez and Céspedes 1986, Parin et al. 1997). Within Australian waters, the range of Redbait extends from mid New South Wales to south-west Western Australia, including Tasmania (Gomon et al. 2008).

They can be found at depths of 20 - 500 m and form schools by size and by depth. Juveniles tend to occur near the surface while adults are found in deeper water closure to the sea floor. Adults move up into the water column at night. They feed on large planktonic crustaceans, cephalopods and small fish and are themselves food for seals, seabirds and tunas (AFMA 2023o)

Redbait is an asynchronous batch spawner with indeterminate fecundity. Annual trends in Gonadosomatic Index (GSI) and macroscopic gonad stages indicated that Redbait from eastern Tasmania spawn between September and November, with a peak in activity during September and October (Ewing and Lyle 2009). A similar pattern was evident for south-western Tasmania, although the peak occurred one month later during October and November (Ewing and Lyle 2009). Spawning occurs along a 2.5 nautical mile (nm) corridor either side of the continental shelf break when mid-water temperatures are between 12 and 15.2°C (Neira et al. 2008). Redbait populations are spatially extensive and relatively abundant across southern Australia occurring continuously at the shelf break between southern NSW and south-western Western Australia (Ward et al 2019).

Redbait eggs are positively buoyant and hatch about 2–4 days after fertilisation depending on temperature (Neira et al. 2008). Newly hatched yolk sac larvae range from 1.9 – 3.3 mm TL. Little is known about the early life history of Redbait post-hatching, although the distribution of eggs and larvae off eastern Australia have been described by Neira et al. (2008).

The spawning habitat of Redbait was described from egg, larval and environmental data collected over shelf waters between north-eastern Bass Strait and lower south-western Tasmania in 2005 and 2006 (Neira et al. 2008).

Redbait is a target species of the Commonwealth Small Pelagic Fishery (Western sub-zone) however it is a minor component of the fishery with no catches reported for 2020-21 and 2021-22 for the CSPF and no state catches either (Status of Australian Fish Stocks – Redbait 2023).

4.3.13 Ribaldo (*Mora moro*)

The following is from AFMA 2023p.

Ribaldo are a temperate deepwater species that occurs on the continental shelf. They can be found near the seafloor at depths of 450 - 2,500m and it appears to be most common at depths of 500 – 1000 m. Ribaldo are associated with sea mounts and rough seabeds. Juveniles may be pelagic.

Spawning occurs in winter and early spring. Ribaldo are not thought to form large spawning aggregations.

Ribaldo is a target species for the Southern and Eastern Scalefish and Shark Fishery.

4.3.14 Striped Marlin (*Kajikia audax*)

The following is from AFMA 2023r.

Striped Marlin is an oceanic species caught worldwide throughout tropical, temperate, and occasionally cold waters. They are found commonly in eastern Australian waters, but they are also found in the waters of other countries within the Pacific and Indian Oceans.

In Australia, Striped Marlin are caught anywhere along both the east and west coasts and is a targeted species by fishers in both the Eastern Tuna and Billfish Fishery and the Western Tuna and Billfish Fishery.

Though Striped Marlin is not commercially caught in the Operational Area it is sometimes caught recreationally off Victoria.

4.3.15 Snapper (*Chrysophrys auratus*)

The following is from;

https://www.fish.gov.au/report/365-Snapper-2023

Snapper is widely distributed in Australia and managed as twelve stocks. Six are sustainable, one is recovering, four are depleted and one is undefined. The Western Victoria stock is currently defined as 'sustainable'.

Snapper has a wide distribution in Australia, ranging from waters off the north coast of Western Australia, around the south of the continent, and up to northern Queensland around Hinchinbrook Island [Kailola et al. 1993]. Within this broad distribution, the biological stock structure is complex and there are considerable differences in the spatial scales over which populations are divisible into separate stocks.

Snapper to the west of Wilsons Promontory, including the important fisheries of Port Phillip Bay and Western Port, constitute the Western Victorian biological stock. This stock extends westward from Wilsons Promontory to near the mouth of the Murray River in south-eastern South Australia [Sanders 1974; Donnellan and McGlennon 1996; Hamer et al. 2011; Fowler et al. 2017].

The Western Victorian stock extends westward into south-eastern South Australia, and depends on recruitment into, and subsequent emigration from, Port Phillip Bay in Victoria. Port Phillip Bay, the main spawning and nursery area for the stock [Hamer et al. 2011]. Although this stock extends throughout the coastal waters of central/western Victoria and south-east South Australia, the main indicator data are derived from the major bay fisheries in Victoria: Port Phillip Bay and Western Port.

Snapper is a target of the Victorian Multispecies Ocean Fisheries.

Given the high level of significant interest from relevant persons further analysis and assessment of this species can be found in Appendix F3 - Further Assessment of Key Environmental Values and Sensitivities

4.3.16 Southern Garfish (*Hyporhamphus melanochir*)

The following is from Earl et al (2024) Stock Assessment Report to PIRSA Fisheries and Aquaculture.

Southern Garfish are productive fast-growing members of the Hemiramphidae family and endemic to southern Australia. They form large schools in shallow, inshore marine waters and are particularly abundant in South Australia's northern Gulfs.

They are a multiple batch spawning species that has a protracted spawning period of 6 months from October to March, with only a small proportion of the population in spawning condition at any one time. Population studies have shown that adult garfish are mostly associated with a particular area for much of their lives indicating that the state-wide population consists of numerous discrete populations.

Southern Garfish are caught within the Marine Scalefish Fishery which operates within South Australia. The area of most relevance to the REGIA MSS is the South-Eastern fishing zone which extends from Kangaroo Island to the SA-Victorian border. The SE fishing zone has been the least productive zone for the southern garfish fishery since 1983/84 with total annual catches usually < 2 tonnes. This stock is classified as sustainable.

4.3.17 Tiger Flathead (*Platycephalus richardsoni*)

The following is from AFMA 2023s.

Tiger Flathead are a demersal species that is found at depths of 10 - 400 m. Juveniles inhabit shallow waters of the continental shelf and move into the deeper outer shelf zone as they reach maturity. They are not an active species and normally rest in areas of mud and sand on the seabed during the day and move into the water column at night to feed. There is evidence that mature fish migrate to shallower waters prior to the spawning period. Spawning occurs over an extended period from spring to autumn, with some variation on the timing of spawning depending on location. Females produce 1.5-2.5 million eggs per spawning season.

Tiger Flathead is a target species for the Southern and Eastern Scalefish and Shark Fishery. The southern Australian population is considered sustainable under current fishing effort. [Section updated in response to Matter: F03]

4.3.18 Yellowfin Tuna (*Thunnus albacares*)

The following is from AFMA 2023t.

Yellowfin Tuna is a highly migratory species, swimming continuously over large distances. They are usually found in eastern and western Australian waters but are also found in the waters of other countries within the Pacific and Indian Oceans.

Spawning occurs throughout the year in tropical waters and seasonally in subtropical waters. The peak spawning period in the southern hemisphere occurs in summer. In tropical waters females spawn almost daily. Spawning occurs almost entirely at night. Females can produce over 0.2-8 million eggs per spawning event depending on their body size.

In Australia, Yellowfin Tuna are caught along both the east and west coasts and is a targeted species by fishers in both the Eastern Tuna and Billfish Fishery and the Western Tuna and Billfish Fishery.

Though Yellowfin Tuna is not commercially caught in the Regia MSS area it is sometimes caught recreationally off Victoria.

4.3.19 Wrasse (multiple species)

The following is from VFA 2023.

The Victorian Wrasse (Ocean) Fishery targets Bluethroat Wrasse and Purple Wrasse, also called Saddled Wrasse (*Notolabrus fucicola*). Small catches of Rosy Wrasse, Senator Wrasse and Southern Maori Wrasse are also caught.

Wrasse inhabit depths up to 160 m where individuals tend to remain close to a home reef and are territorial. They are relatively long lived and have a relatively long larval period (Bluethroat Wrasse: 44

to 66 days; Purple Wrasse: 40 to 87 days) leading to potentially wide dispersal that can repopulate depleted areas. The two species are thought to interbreed to produce hybrids.

4.4 Commercial Fish Species without Swim Bladder

4.4.1 Albacore Tuna (*Thunnus alalunga*)

The following is from AFMA 2023c.

Albacore Tuna is a highly migratory species, swimming continuously over large distances. They are found commonly in eastern Australian waters, but they are also found in the waters of other countries within the Pacific and Indian Oceans. In Australia, Albacore Tuna are caught anywhere along the east coast and is a targeted species by fishers in the Eastern Tuna and Billfish Fishery.

Though Albacore tuna is not commercially caught in the Operational Area it is sometimes caught recreationally off Victoria.

4.4.2 Elephant Fish (*Callorhinchus mili, Harriotta haeckeli* and *H. raleighana)*

The following is from AFMA 2023k.

Elephant Fish are the common name for Ghost Shark (*Callorhinchus mili) and S*pookfish *(Harriotta haeckeli and H. raleighana)*

Ghost Sharks are often found in shallow bays and large estuaries, but also to depths of 200 m on the continental shelf. Juveniles inhabit shallow coastal waters for about three years and gradually move into deeper water as they mature. Ghost Sharks appear to school by gender.

Spookfish are a deepwater species that occurs on the continental slope. They can be found in depths of 380 – 2,600 m. *H haeckeli* are generally found in deeper water than *H. raleighana*. Little is known about the habitat of spookfish. Adults and juveniles probably occupy different habitats.

Ghost Sharks are oviparous (lay eggs) and it is presumed that spookfish do as well.

Elephant Fish have a broad distribution across much of southern Australia, but actual biological stock structure is unknown. The species is caught in relatively low quantities in NSW, Victoria and Tasmania. In Victoria, Elephant Fish were historically landed in low to moderate quantities by commercial bay and inlet fisheries, particularly in Western Port Bay (WPB). Females move inshore to lay pairs of leathery egg cases on sandy or muddy bottoms (AFMA 2024). [Paragraph added in response to Matter: F03]

Elephant Fish is a target species for the Southern and Eastern Scalefish and Shark Fishery although it is reported as incidental catch.

4.4.3 Gummy Shark (*Mustelus antarcticus*)

The following is from AFMA 2023l.

Gummy Sharks are a demersal species that inhabits the continental shelf from the near shore region to depths of 80 - 350 m. They remain either on or near the seabed. Newborn and juvenile Gummy Sharks aggregate in many areas across southern Australia, while young and adult gummy sharks are more widely distributed. Gummy Shark are considered a single genetic stock across their entire range from Bunbury, WA to Jervis Bay, NSW, with 3 sub-stocks centred on Bass Strait, Tasmania and Southern Australia. Gummy Sharks are oviparous (lay eggs).

Gummy Sharks are a target species for the Southern and Eastern Scalefish and Shark Fishery where catches have remained stable for many years. [Section in response to Matter: F03]

4.4.4 Saw Sharks (*Pristiophorus cirratus - Common, P. nudipinnis - Southern, P. peroniensis-Eastern)*

The following is from AFMA 2023q.

Sawsharks are a common demersal species that inhabits the continental shelf and upper slope. They can be found in depths to 300 metres. Sawsharks are sometimes found in large schools or feeding

aggregations. Some species segregate according to age, with adults being found in deeper water than juveniles.

- *Common*: in depths of 40 – 310 m
- *Southern*: in depths of 40 – 165 m
- *Eastern*: in depths of 100 – 630 m

Sawsharks are relatively small sharks growing up to 1.5 m in length and 4.3 kg depending on species. Females grow slightly larger than males. Common sawsharks are generally slightly larger than southern sawsharks. Lifespans are up to 9 years for southern sawsharks and 15 years for common sawsharks.

Sawsharks reach reproductive maturity at about 2 years of age. They are aplacental viviporous (bear live young). Young are born during winter in shallow coastal areas after a 12-month gestation period. Common and southern sawsharks produce about 5 - 20 pups per litter and probably breed only every second year. The rostral teeth emerge before birth but lie flat against the snout of the foetus until after birth.

Sawsharks are a target species of the Southern and Eastern Scalefish and Shark Fishery (SESSF) - Shark Gillnet and Hook Sector.

4.5 People and Communities

4.5.1 Social and Economic Features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local economy and environment. Species that may be affected, including commercial and recreationally fished species, are described above in sections 4.1 to 4.4.

4.5.2 Cultural Features

Eels were, and continue to be, an important resource for certain First Nation communities. Their use for communal gatherings and for barter and trade was extensive in pre-colonial times. Today, eel remains a popular food for community events (VFA 2017). Short-finned Eels in particular hold a cultural significance to First Nations people (Appendix F3, Sections 3.7, 3.15 and 3.16). For example, the Gunditjmara people of south-western Victoria built and used sophisticated aquaculture systems throughout the Budj Bim Cultural Landscape to exploit eel migrations at least 7,000 years ago. These systems are outside of the area that may be affected by underwater sound.

Perch are also identified as being culturally significant to the Eastern Maar People as a resource and in traditional, social and economic practices (EMAC, 2015). Blackfish are also harvested by both Eastern Maar and Gunditjmara peoples (Appendix F3, Section 3.16). The PMST report did not find Blackfish as occurring in the area affected by underwater sound, and since Perch is associated with freshwater no impact from underwater sound from offshore seismic is predicted, so these species are not discussed further.

5 Relevant Legislative and Other Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for all fish species that may be affected (see Annex 3). No specific requirements related to the effect of sound on fish were identified through this process.

6 Defining Acceptable Levels of Impact

Although hearing ranges and sensitivities vary substantially between species (Ladich and Fay 2013), all fish species tested to date can detect sound and vibration to some degree (Dale et al. 2015). Fishes have developed two sensory mechanisms for detecting, localising, and interpreting underwater sounds and vibrations: the inner ear, which is tuned to sound pressure detection, and the lateral line system, which allows a fish to detect vibration and water flow. Inter-specific variations in hearing range and sensitivity result from the different adaptations in these systems for perceiving sound pressure and particle motion information (Popper and Fay 2011).

Because the presence or absence of a swim bladder has a role in hearing, Popper et al. (2014) classified fishes into three categories for assessment of sound effects.

1. Fishes without a swim bladder that can sink and settle on the substrate when inactive. e.g., mackerel, Scomberomorus spp., some species of tuna, Thunnus sp. and sharks (Casper et al. 2012, Popper et al. 2014, Carroll et al. 2017).
2. Fishes with swim bladders whose hearing does not directly involve the swim bladder or other gas volumes. e.g. snappers, emperors, groupers and rock cods (Lutjanids and Lethrinids such as *Pristipomoides* spp., *Lethrinus* spp., *Lutjanus* spp., and family Serranidae), and some species of tuna (*Thunnus* sp.) (Tavolga and Wodinsky 1963, Higgs et al. 2006, Braun and Grande 2008, Engineering-Environmental Management Inc. 2008, United States Department of the Navy 2008, Caiger et al. 2012, Bertrand and Josse 2000, Song et al. 2006).
3. Fishes whose hearing does directly involve a swim bladder or other gas volume. e.g., family Clupeidae (herrings, sardines, pilchards and shads) and some Haemulidae (grunters and sweetlips) (Nedwell et al. 2004, Braun and Grande 2008, Popper et al. 2014). Eels are included in this group (Jerko et al 1989).

The most relevant metric for perceiving underwater sound for most fish species is particle motion (Popper and Hawkins 2019, Popper et al. 2019) but, except for a few species (Popper and Fay 2011, Popper et al. 2014), there is an almost complete lack of relevant data on particle motion sensitivity in fishes (Popper and Hawkins 2019).

Most fish species detect sounds from below 50 Hz up to 500-1500 Hz. A smaller number of species can detect sounds to over 3 kHz, and a very few can detect sounds to well over 100 kHz. Whether a particular anthropogenic sound affects hearing is contingent on the hearing frequency range of the species and whether the sound level is above a calculated minimum threshold. For this impact assessment, it is assumed that all fishes can detect signals below 500 Hz and therefore can 'hear' the seismic source.

Sound exposure guidelines for fish have been established by the American National Standards Institute (ANSI) accredited report of Sound Exposure Guidelines for Fishes and Sea Turtles (Popper et al. 2014). The sound exposure guidelines from Popper et al. (2014) are based on the presence or absence of a swim bladder and ancillary structures which determines the level of susceptibility of fishes to injurious effects from exposure to intense sound. Accordingly, different exposure guidelines were developed for fishes without a swim bladder, fishes with a swim bladder not involved in perception of acoustic signals and fishes that use their swim bladders for hearing.

No studies to date have demonstrated direct mortality of adult fish in response to seismic emissions, even at proximity (within 1–7 m; DFO 2004, Boeger et al. 2006, Popper et al. 2014, Carroll et al. 2017). Nevertheless, exposure guidelines from Popper et al. (2014) were still modelled as part of the impact assessment process. Outcomes were less than or equal to recoverable Injuries hence they are not tabulated here but can be referred to in the modelling report if interested.

Based on the above discussion, Table E3-1 justifies and defines the acceptable levels of impact from underwater sound on fish. Further information on studies in relation to seismic acoustic emission impacts to fishes is provided in the Regia MSS Seismic Studies Summary available in Appendix B8.

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that aspect specific statements

would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E3-1 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding aspect specific defined acceptable levels established for this assessment. Defining the acceptable levels is the starting point for the required demonstration that environmental impacts and risks of the activity will be of an acceptable level. The defined acceptable levels found in this section are subsequently carried through the prediction of impacts in this document, to the demonstration found in Section 10. [1]

Table E3-1 - Defined acceptable levels of impact from underwater sound effects to fish

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Fish and aquaculture stocks continue to be assessed as having the same stock status they held prior to commencement of the activity.	This acceptable level draws on established fisheries management frameworks which monitor stock status to ensure sustainable harvest and ecological balance. Retaining stock status through and beyond the activity period reflects that no material or sustained impact has occurred. People and communities rely on commercial fishing and commercial catch such that protecting the stock levels / biomass available for fishing is an appropriate level of impact to set.
	The impact and risk assessment process is based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they are documented elsewhere, these criteria are not discussed further in this assessment.

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.	No fish should be exposed to sound at or exceeding threshold levels for TTS set at 186 dB SEL24hr.	In fish with no swim bladder, TTS is a temporary reduction in hearing sensitivity caused by exposure to intense sound. After termination of the sound source normal hearing ability returns over a time that is variable, depending on the intensity and duration of sound exposure (Popper et al. 2014). Sound exposure guidelines proposed in Popper et al. (2014) use a cumulative sound exposure level of 24 hrs (SELcum24hrs) for TTS. Recoverable Injury: 216 dB SELcum24hr. TTS: 186 dB SELcum24hrs. In fish with a swim bladder not involved in hearing, pressure-related injuries may occur, but recovery is possible. TTS for this group is also set at 186 dB SELcum24hr, and recoverable injury at 203 dB SELcum24hr.
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.	As above for Principles of ESD.	
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Reflects Commonwealth and State policy objectives for sustainable resource use and protection of ecosystem services.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	This level reflects the principle of maintaining cultural values and heritage as protected under national and state legislation. It ensures that activities do not interfere with traditional practices, spiritual connections, or ongoing access to culturally significant areas.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	This level reflects broader social licence to operate, ensuring that environmental activities do not lead to degradation of public amenity, loss of recreational use, or impacts to non-Indigenous heritage values. It aligns with Commonwealth policies promoting public access, well-being, and sustainable use of the marine environment.

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. Five main options were considered and subsequently adopted:

No discharge of the sound source within the West Tasmania Canyons KEF

This measure eliminates potential noise impacts in a KEF characterised by complex bathymetry and high productivity, which may be important for spawning, feeding, or migration of fish. It has been applied by CGG to protect the ecological integrity and fish biodiversity associated with this KEF, which is recognised for its national environmental significance.

No MSS acquisition beyond 200 m depth contour

Deepwater habitats may support unique and less-studied fish assemblages that could be sensitive to noise and extending the survey beyond this boundary may increase environmental uncertainty and operational risk. The limitation was applied to confine the activity within a well-characterised depth zone and reduce exposure of deepwater species to anthropogenic sound.

No seismic acquisition within 17 km of Deen Maar / Lady Percy Julia Island

This limitation reduced the overlap with most fishing effort in the region and is protective for mobile or short ranging fish species that are more likely to be present in water depth < 50 m. The shallow depths are also where most lobster will settle when ready to do so. This measure was adopted to avoid disturbance to coastal and nearshore invertebrate communities and to prevent elevated acoustic energy in shallow, sensitive environments. This was confirmed during consultation with commercial fishers who agreed that the data was correct and most fishing activities occurred in shallower waters close to ports (Event ID 4107, Feedback ID 1277).

This island is known for its ecological significance, including nearby fish habitats and potentially sensitive species that rely on the surrounding waters. The buffer zone was applied to provide spatial protection for species utilising this ecologically and culturally important area, thereby reducing potential impacts. For derivation of the 17 km buffer refer to Table 6 in the EP document under the constraint “Protection for marine fauna associated with Deen Maar/Lady Julia Percy Island”.

No sound source discharges within the Orange Roughy research program areas.

During consultation (Event IDs 2002, 3350, 1649, 2003, Feedback IDs 4125, 4305, 4124, 4337) claims were raised by a fishing association to avoid interference with an Orange Roughy Research Program by ensuring there was no data acquisition, or turns, over the sample collection areas, with a buffer between the acquisition and sample areas, with preferred non-acquisition months to be April to October. As shown in map MAP-REG-EPM-050_B (Appendix B12), the activity was reduced to ensure there is no overlap of sampling areas with the active source area, including turns. A small portion of the central sampling area overlaps with the operational area; however, this will not have a greater impact than any other vessel transiting the area. Therefore, there is no break to the time series of the data, due to lack of overlap with the active source area. In addition, the Regia MSS is not prohibiting the ability of the research program to catch the fish required for the study to continue uninterrupted, negating the need for exclusionary months. CGG has since committed to an additional activity limitation to include no petroleum activity being carried out between 1 January and 15 September.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. One option was considered and subsequently adopted:

Sound will not be emitted above the stated capacity

By selecting a sound source and operational settings that remain within a defined maximum acoustic output, the activity substitutes more harmful, higher energy alternatives for lower-intensity ones. This measure was adopted to ensure predicted effects on fish remain within modelled thresholds, avoiding excessive acoustic exposure that could disrupt behaviour or physiology.

9 Predicted Levels of Impact

To determine the predicted levels of impact of underwater sound on fish at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on fish. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on fish as described here.

- B5 – PMST Reports – The Protected Matter Search Tool was used to search for environmental values and sensitivities potentially located within the proposed Regia MSS planning area, with eight specific searches undertaken of which one was for Fish within the region defined by the Regia MSS Active Source Area with an included buffer area out to 8km.
- Commercial Fisheries Review – In August 2023 all commercial fisheries and their targeted species, associated with the Commonwealth and/or the states of Victoria were identified and mapped to indicate fishing effort relative to the proposed Regia MSS (Appendix B6: Commercial Fisheries Analysis Report. In March 2025, a further review was undertaken of the commercial fisheries to include the 2023 Commonwealth fishery data and the updated Operational Area. The outcomes of this latest review are detailed in Appendix E1 – Impact Assessment Physical Presence.
- B7 – Sound Modelling Reports - SLR performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including marine mammals, fish, turtles, benthic invertebrates, plankton and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on fish and other fauna. This literature is the key evidence base from which impact levels are derived and provides a template for how effects to fish can be assessed by following the recommendations of Popper et al (2014).

All species identified through B5 and the Commercial Fisheries Reviews (B6 and E1) have been assessed through the framework provided by B7 and B8. Because of commonalities among species in their sensitivity to seismic it is not necessary to describe effects to each species individually but rather as groups defined by swim bladder presence/absence.

9.1 Change in Fauna Behaviour, Hearing Capacity, and Physical Condition

As detailed from the underwater sound and studies relevant to seismic surveys (see Regia MSS Seismic Studies Summary available in Appendix B8), mortality and injury to fish are not predicted based on the received sound levels to these species.

Fishes were grouped and modelled according to the role of a swim bladder in their potential responses to seismic. However, in discussing predicted levels of impact here we group by type of impact. This is because modelled effects are very similar across the 3 groups.

9.1.1 Mortality and Potential Mortal Injury and Recoverable Injury

Maximum modelled distance to sound effect criteria for mortality/potential mortal injury and recoverable injury was 86 m – 2 km. The predicted effect level on these species is assessed as minor given the following:

- Mortality of fish (both immediate and delayed) is not predicted based on no scientifically documented cases of mortality in free-swimming fish exposed to seismic source emissions under experimental or field conditions (DFO 2004; Boeger et al. 2006; Popper et al. 2014; Popper et al. 2016; Carroll et al. 2017; Popper and Hawkins 2019).
- Injury impacts may occur if the seismic array commences at full power adjacent to fish. However, the implementation of the Fauna Management System requires the seismic source to be slowly ramped up to full power over 30 minutes. This would allow demersal and pelagic species to move away from the source before it is at full power. However, once

the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04].

- Site-attached fish species are species that have a very high degree of site fidelity to the extent that they are unlikely or unable to flee an approaching seismic source and are likely to remain and/or seek refuge within habitat structures. Impacts to site-attached fish were studied by Woodside at Scott Reef during the Maxima 3D MSS activities (Miller and Cripps 2013) and no lethal or sub-lethal effects on fish were experienced nor any significant decreases in the diversity and abundance of fish after the seismic survey, compared with the long-term temporal trend before the survey.
- Commercially targeted fishes within the area of impact that are generally considered site attached include a range of commercially targeted species such as Blue-eye Trevalla, Eastern School Whiting, flathead, Gummy Shark, Orange Roughy, Pink Ling, Ribaldo and Sawsharks. Examination and testing of seismic effects on commercial catches of fish, (including flathead and shark species), in the Gippsland Basin region found little evidence of changes induced by seismic surveys for 12 species (Bruce et al. 2018).
- National Recovery Plans and Conservation List Advice for EPBC Act list and migratory for species do not identify underwater sound as a threat to the recovery of fish species.

The uncertainty level for impacts to fish causing mortality and potential mortal injury and recoverable injury from seismic sound is assessed as low based on:

- Sound effect criteria used in the impact assessment have been published in peer reviewed scientific journals.
- There is a significant body of published studies that demonstrate no cases of mortality in free-swimming fish exposed to seismic source emissions under experimental or field conditions.

Thus, the predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. These validated impacts are of an acceptable level without further reduction measures being required.

9.1.2 Temporary Threshold Shift

As detailed in Table E3-1 maximum modelled distance to sound effect criteria for temporary threshold shift (TTS) is 10.95 km.

The predicted effect level to these species is assessed as minor because while impacts are predicted to have some effect on fish, they are not considered significant enough to affect the population given the following:

- The Popper et al. (2005) study that informed the Popper et al. (2014) TTS sound exposure guideline, was done using a static source (airgun array) and static receptors (fish in cages at 13-17 m from the array) and is therefore not representative of a marine seismic survey which is a moving source, and animals are not constrained in their movements. On this basis, the Popper et al (2005) study represents a worst-case scenario as the source is fixed and not moving (i.e. fish received five pulses of identical intensity over five minutes) and nor are the fish.
- Since the Popper et al. (2014) TTS sound exposure guidelines were developed Professor Popper has provided feedback on the appropriateness of using a 24-hour period to assess the potential for TTS and other effects associated with SEL_{cum} (Popper 2018). The review considered the potential impacts of cumulative seismic noise from the proposed Santos Bethany 3D seismic survey on fish, including TTS effects, and length of time for recovery and the applicability of a SEL24h metric. Though this information was based on another survey it is applicable to the Regia MSS as the premise for the modelling was a racetrack survey design that bought the vessel back to a similar starting point within 24 hours, thus receiving the closest shots within a 24-hour period. The review noted:
    - It is highly unlikely that there would be physical damage to fishes because of the survey unless the animals are very close to the source (perhaps within a few meters).

  - If TTS does take place, the duration of exposure to the most intense sounds that could result in TTS will be over just a few hours. Thus, accumulation of energy over longer periods than a few hours is probably not appropriate.
  - If TTS takes place, its level is likely to be sufficiently low that it will not be possible to easily differentiate it from normal variations in hearing sensitivity. Even if fishes do show some TTS, recovery will start as soon as the most intense sounds end, and recovery is likely to even occur, to a limited degree, between seismic pulses. Based on very limited data, recovery within 24 hours (or less) is very likely.
  - Little is known about the behavioural implications of TTS in fishes in the wild. However, since the TTS is likely very transitory, the uncertainty of it having a significant impact on fish fitness and survival is very low.

- As detailed above, Popper et al. (2005) reports that fish showing a TTS recovered to normal hearing levels within 18-24 hours, thus any hearing loss and subsequent decrease in fitness would be temporary with recovery taking place in a relatively short timeframe after the seismic source has moved away from the exposed fish. Based on this, the potential for impacts to individuals' fitness and survival is limited and impacts to fish community structures are not predicted.

The uncertainty level for impact to fish causing TTS from seismic sound is assessed as medium based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed scientific journals.
- Published studies show TTS impacts to fish are short lived (up to hours), however there are limited published studies on the effects of seismic sound on fish specifically in the Otway region.
- An absence of long-term monitoring data of the effects of seismic on fish in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) is assessed as medium. For fish the predicted level of impact is clearly below the predefined acceptable levels of impact as detailed in Section 10.

9.1.3 Change in Behaviour

There are currently no quantitative exposure guidelines or criteria for behaviour or masking for fish for impulsive sounds. The Working Group on the Effects of Sound on Fish and Turtles (Popper et al. 2014) found that there was insufficient data available and instead applied a subjective approach using 'relative risk' to assess risk at three distances from the source. These are:

- Behavioural response: high at near (within tens of metres) and intermediate (hundreds of metres) distances from the seismic source and moderate at distances far (thousands of metres) from the source.
- Masking: low at near (within tens of metres) and intermediate (hundreds of metres) distances from the seismic source and moderate at distances far (thousands of metres) from the source.

Thus, the extent of the area of impact is predicted to be within thousands of metres of the seismic source. In the most recent acoustic modelling study (Appendix B7), a 150 dB threshold for behavioural disturbance for fish was applied. It is acknowledged in the report that the derivation and origin of the informal 150 dB threshold is not as well-defined as other thresholds. However, recent publications do not refute that behavioural disturbance for fish can occur around this level (Hawkins et al. 2014). The maximum predicted behavioural disturbance impacts for fish was predicted to be 13.81 km from the sound source. The predicted effect level to these species is assessed as minor because while the impacts are predicted to have some effect on fish, the effects are not considered significant or at a level high enough to affect the population given the following:

- Meekan et al. (2021) undertook a large-scale experiment that quantified the impacts of exposure of an assemblage of tropical demersal emperors, snappers and groupers targeted by commercial fisheries to a commercial-scale seismic source on the Northwest Shelf off Western Australia. They did not identify any short-term (days) or long-term (months) effects of exposure on the composition, abundance, size structure, behaviour, or movement of fishes at any exposure sites.
- Shark species are highly vagrant and naturally cover large distances. As such, short-term exposures from the transient seismic source are expected to result in localised behavioural responses and movements of sharks. Research by Bruce et al. (2018), which tagged two commercially targeted shark species (Broadnose Shark and School Shark) and monitored their movements in response to a seismic survey in Australian waters noted that both control sharks and exposed sharks moved freely in and out of the study area which did not indicate any changes in behaviour or distribution because of seismic sound exposure.
- No BIAs, critical habitats, or key aggregation sites have been identified within or adjacent to the area potentially affected by underwater sound for the critically endangered Grey Nurse Shark.
- The White Shark foraging BIA within the area that may be impacted by underwater sound above the behavioural threshold for sharks, is centred on Lady Julia Percy Island / Deen Maar which is a known seal breeding colony. The sound source will not be discharged within 17 km of Lady Percy Julia Island / Deen Maar which will significantly reduce the potential impacts of underwater sound on White Shark behaviour near the foraging BIA. [Point added in response to Matter F08 and F17]
- Fishes' awareness of the sound and any resultant behavioural responses may be limited to a few hours as the seismic source passes by, while significant behavioural responses (startle or avoidance) are more likely to be limited to a shorter period (less than an hour) when the seismic source is closest. As the seismic source will be transient (i.e., continuously moving) during seismic data acquisition, demersal fishes will only be exposed to significant sound levels for a relatively short period of time as the seismic survey vessel passes nearby before sailing away again.
- Impacts to site-attached fish were studied by Woodside at Scott Reef during the Maxima 3DMSS activities (Miller and Cripps 2013) and they determined that there was a lack of significant impacts to fish species considered sensitive because of their site-fidelity requirements (i.e., being restricted to reef habitat and unable move far when the seismic sound approaches) based on the following:
    - Behavioural responses were observed at close range with general movement from the water column to the seabed, however normal feeding behaviour returned within 20 minutes of the survey vessel passing and when the vessel was beyond 1.5 km.
    - No significant decreases in the diversity and abundance of fish after the seismic survey were detected compared with the long-term temporal trend before the survey.
- Any behavioural impacts are likely to be short-lived and fish would return to normal behaviours once the vessel has moved away based on research by Miller and Cripps (2013) and Wardle et al. (2001). Behavioural impacts to pelagic fish species are possible but would be temporary, localised, and unlikely to impact at a population level.
- Limited data on biochemical stress indicators in fishes exposed to seismic sound indicate there may not be any discernible change (e.g., McCauley et al. 2000, 2003). However, if fishes were to experience stress because of sound exposure, levels may return to normal within 72 hours (Santulli et al. 1999).

- Sardines are a key food source in the Otway region hence evidence of significant changes in behaviour of this species and other clupeids in response to a seismic MSS could have flow-on effects to their predators. However, research does not support significant changes in the behaviour of clupeids in the presence of MSS. A key reference that is cited to support seismic effects on penguins (Pichegru et al 2017) found there were no significant changes in distribution and/or abundance of small pelagic fish in the region compared to a few months

prior to or after the seismic operations (Pichegru et al 2017). An even more targeted study that exposed herring schools to a full-scale 3D seismic survey off Northern Norway found no changes in the behaviour of herring schools from a transmitting seismic vessel as it approached from a distance of 27 km to as close as 2 km (Pena et al 2013). The schooling behaviour of sardines is complex and varies within and among locations, days, months and years at both spatial and temporal scales (Ward et al 2011). This variability is clearly intrinsic to their behaviour and would influence feeding strategies and adaptability of those species that target them as a food source.

The uncertainty level for impact to fish causing a change in behaviour from seismic sound is assessed as medium based on:

- Published studies show behavioural impacts to fish are short lived with fish returning to normal behaviour once the vessel has moved away (in some cases within 20 minutes). While there are limited published studies on the effects of seismic sound on fish behaviour specifically in the Otway region there is no reason to expect different behaviour of similar species from different locations.
- An absence of long-term monitoring data of the effects of seismic on fish in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) is assessed as medium. For fish the predicted level of impact is clearly below the defined acceptable levels of impact as detailed in Section 10.

9.1.4 Change in Commercial Catch

As detailed in the review of Commercial Fisheries (see Appendix B6 and subsequently updated in E1) the Operational Area overlaps with some fisheries to varying degrees.

Commonwealth Fisheries

Non-significant Overlap

- Bass Strait Central Zone Scallop (BSCZSF), Eastern Tuna and Billfish (ETBF), Small Pelagic (SPF) and Western Tuna and Billfish Fisheries (WTBF) all have allowable fishing areas located within some part of the Operational Area but with little or no active fishing in these areas for at least 10 years between 2010-2023. This is also the case for the Southern and Eastern Scalefish Fishery (SESSF) – Shark Hook sub-sector. Hence these fisheries are not assessed for impacts (refer to cited figures in B6 and E1 as needed).

Significant Overlap

- The SESSF- Commonwealth Trawl – Danish Seine sub-sector has seen declining fishing effort since 2019 however because it involves less than 5 fishers, confidentiality does not allow for assessment of fishing intensity.
- The SESSF – Shark Net sub-sector has significant fishing effort across the operational area including the acquisition area (MAP-REG-EPM-102_B). However, in the context of the entire fishery, it constitutes a tiny proportion of the fishing effort which is concentrated through Bass Strait and off South Australia (MAP-REG-EPM-130_B). The species targeted are elephant fish, gummy shark, saw sharks and school sharks.
- The SESSF – Trawl sub-sector has significant fishing effort in the southwest of the operational area (MAP-REG-EPM-103_B). However, in the context of the entire fishery, it constitutes a tiny proportion of the fishing effort which extends from northern NSW to Kangaroo Island South Australia (MAP-REG-EPM-131_B). The species targeted are blue-eye trevalla, blue grenadier, eastern school whiting, orange roughy, pink ling, ribald and tiger flathead. Danish Seine sub-sector
- The SESSF – Scalefish Hook sub-sector has a low level of fishing effort restricted to an area towards the SE corner of the operational area (MAP-REG-EPM-105_B). In the context of the entire fishery, it constitutes a tiny proportion of the fishing effort which is centred along the east coast of Tasmania and off the coast of Robe, South Australia (MAP-REG-EPM-133_B). However, because it involves less than 5 fishers, confidentiality does not allow for assessment

of fishing intensity. Species caught in this fishery have some overlap with the Trawl sub-sector, which is assessed.

-

Victorian Fisheries

Non-significant Overlap

- The Bays and Inlets and Eel fisheries do not overlap with the operational area of the Regia MSS hence no impacts are expected. Nevertheless, further assessment has been done for Eels in response to feedback (see section 13).
- The Wrasse (Ocean) Fishery has minor overlap with the operational area in the northwest corner.

Significant Overlap

- While the multispecies Ocean Fishery has significant overlap with the operational area in terms of presence, less than 2% of >3000 days fished between 2011-2022 were within the operational area highlighting the relative lack of fishing that goes on inside this area (MAP-REG-EPM-113_B). The species targeted are gummy shark, school shark, Australian salmon and snapper.

In August 2023 a review of commercial fisheries was undertaken to identify Commonwealth and State (Victorian, Tasmanian, and South Australian) fisheries that fish or potentially fish within the Activity Planning Area and is available in Appendix B6: Commercial Fisheries Analysis Report. In March 2025, a further review was undertaken of the commercial fisheries to include the 2023 Commonwealth fishery data and the updated Operational Area. The outcomes of this latest review are detailed in Appendix E1 – Impact Assessment Physical Presence. Table E1-1. In summary

The following fisheries that target fish species were assessed as having or potentially having a high level of activity within the Operational Area:

- Commonwealth Southern and Eastern Scalefish and Shark Fishery
  - Commonwealth Trawl Sector.
  - Shark Gillnet Sub-sector.
  - Scalefish Hook Sector.

Impacts to commercial catch rates could occur through a number of pathways. The physical presence of seismic vessels could hinder the ability of fishers to access a fishing ground, and this type of disturbance is addressed in Appendix E1 – Impact Assessment Physical Presence.

The other pathway has two components – firstly, the impacts of seismic on individuals of a species or group i.e. the specific vulnerability to seismic according to their biological makeup and secondly, the impacts of seismic on the most vulnerable aspects of their life-history. This second component specifically refers to aggregation behaviours such as spawning which creates conditions where individuals are concentrated in relatively small areas such that if impacts from seismic are possible, they have the potential to be disproportionately harmful to a population. Because of the importance of commercial fishing and concerns raised by relevant persons further assessment has been undertaken for spawning behaviours of key fisheries species in Appendix F3 – Further Assessment of Key Values and Sensitivities under Section 3.14. This rationale is further explained in the Recommendations section of this document.

The effects of seismic on individuals has been assessed in B8 (Seismic Studies Summary) where the scientific literature has been interpreted and summarised to describe the consensus on seismic effects across species. Here is where the rationale for grouping species by the role of a swim bladder is clarified.

There have also been multiple studies looking at behavioural effects of commercial fish species in response to seismic sound to determine whether this has translated into reduced catches for commercial fishers.

Results across studies focussing on fisheries within Victorian waters have not been able to find clear, consistent, negative effects on commercial catch rates that can be attributed to seismic sound.

- A study by CSIRO and Geoscience Australia (Thomson et al. 2014) examined fisheries catches and catch rates for potential effects from 183 seismic surveys undertaken in the Gippsland Basin (Bass Strait). Fisheries catch and effort data was obtained from commercial logbooks for the following species: commercial scallops, school whiting, tiger flathead, eastern gemfish, silver warehou, jackass morwong, blue eye trevalla, arrow (Gould's) squid, school shark, and gummy shark. No clear or consistent relationships between seismic surveys and subsequent fisheries catch rates could be found and if effects occurred, they could not be distinguished from inter-annual changes in stock size or availability to fishing gear resulting from other dynamics.
- Catch studies undertaken as part of a marine seismic survey in the Gippsland Basin found no clear evidence of adverse effects on scallops, fish or commercial catch rates (Przeslawski et al. 2016a; Bruce et al. 2018). Species covered here included John dory (*Zeus faber*), tiger flathead (*Neoplatycephalus richardsoni*), red gurnard (*Chelidonichthys kumu*), morwong (*Nemadactylus macropterus*), goatfish (*Upeneichthys* spp), sawshark (*Pristiophorus* spp), elephantfish (*Callorhinchus milii*), gummy shark (*Mustelus antarcticus*); Gould's squid (Nototodarus gouldi), Boarfish (Pentacerotidae); sawshark; swell shark (*Cephaloscyllium* spp); elephantfish; angel shark (*Squatina* spp); broadnose shark (*Notorynchus cepedianus*); school shark (*Galeorhinus galeus*) and snapper (*Pagrus auratus*).
- An investigation into the effect of a 2015 seismic survey in the Gippsland Basin on deepwater flathead catches did conclude that the significant drop in catch per unit effort was very likely influenced by the seismic survey (Haddon 2017). However, Haddon (2017) went on to add that the seismic survey did not appear to have had a lasting impact on deepwater flathead catch per unit effort, which returned to typical values in the first month following the seismic survey.
- Preliminary results from a FRDC funded BACI study to investigate the effects of a 3D marine seismic survey in eastern Bass Strait on Danish Seine catch rates (Knuckey 2020) indicated a negative impact of seismic acquisition on whiting catch rates up to ~100 days following the survey and on flathead rates up to ~200 days. Unfortunately, this study has not been peer-reviewed and nor has a final report ever been issued, despite the project finishing in 2021. Given outstanding questions remain around study design and implementation and a lack of serious review, we do not consider these results robust to interpretation, so they have not been a consideration for this assessment.

The predicted effect level to commercial fisheries catches from the Regia MSS is assessed as minor based on the lack of clear negative outcomes from multiple targeted studies.

The uncertainty level in the assessment of impacts to commercial fish catches from seismic sound is assessed as medium based on:

- There have been multiple studies supporting lack of significant changes to commercial fish catches from seismic surveys with, at worst, possible short term but recoverable effects.
- There is no evidence for mortality of fish (both immediate and delayed) exposed to seismic source emissions either under experimental or field conditions.

The predicted level of impact based on the effect (minor) and uncertainty (medium) is assessed as medium.

9.2 Measures Adopted to Manage Environmental Impacts

The following measures have been adopted to ensure that the impacts associated with underwater sound from the survey and support vessels on fish will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Table E3-2 Measures adopted to manage environmental impacts

Measure	Measure Type	Details and Justification
Ramp up of sound source to full power over 30 minutes.	Practice	Mobile marine fauna (including demersal and pelagic fish, octopus, squid, diving birds, penguins, and turtles) are expected to move away from the source before it is at full power, providing them a level of protection. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04, I05, E08].
CGG Technical Operations Manager	Person	Reasonable, evidence-based claims are promptly assessed and paid as per the Otway Adjustment Protocol.
Quality Control and Reporting Representative	Person	Ensures that the contracted vessels follow the contract and deliver the survey as per the permitted activity by using the sail line plan.
Fisheries Liaison Officer (FLO)	Person	This person will conduct specific consultation with commercial fishers and support the processing of compensation claims.
Adjustment Protocol	Procedure	An adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area. This will extend to fishing cooperatives who can provide an evidence of commercial losses because of the survey.
Sail Line Plan	Resource	Ensures that the survey vessel will remain within the scope and boundaries of the EP and reflects the activity limitations.

10 Demonstration Impacts will be of an Acceptable Level

10.1 Principles of ESD

Temporary, Reversible, Small Scale and Natural variation

As described in the impact assessment, the Regia Marine Seismic Survey will generate impulsive underwater sound from a 2,820 in^3 airgun array over 60 days constrained within a 90-day period. Modelling predicts that sound exposure levels capable of causing for mortality/potential mortal injury and recoverable injury was reached between 86 m –2 km The distance to temporary threshold shift (TTS) is limited to 10.95 km Behavioural disturbance may occur up to 13.81 km from the sound source. As discussed in the impact assessment, Miller and Cripps (2013) found no significant impacts on site-attached fish species, with only short-term behavioural changes observed that resolved within 20 minutes and no long-term changes in fish diversity or abundance compared to pre-survey trends. Santulli et al. (1999) noted if fishes were to experience stress because of sound exposure, levels may return to normal within 72 hours, indicating any impacts will be temporary and reversible.

There has been no scientifically documented cases of mortality in free-swimming fish exposed to seismic source emissions under experimental or field conditions (DFO 2004; Boeger et al. 2006; Popper et al. 2014; Popper et al. 2016; Carroll et al. 2017; Popper and Hawkins 2019). Effects are most likely to be short-term behavioural responses, such as avoidance or startle, particularly in hearing-specialist fish.

Any physiological effects are expected to be minor and reversible, with no measurable impact on individual fitness or population viability. No critical spawning aggregations, fish nursery areas, or habitats of significance occur within area where thresholds are exceeded. Fish have high reproductive capacity and dispersal ability, and many species migrate through broad areas of habitat. The predicted sound footprint is narrow and transient, moving continuously with the vessel, resulting in limited and localised exposure. Overall, the potential environmental damage is temporary, reversible, and of low intensity.

Based on sufficient information

The assessment applied internationally recognised exposure thresholds for impulsive sound, including criteria recommended by Popper et al. (2014), to account for hearing sensitivity across fish groups. Site-specific acoustic modelling, literature on fish responses to seismic surveys, and expert judgment were used to define impact distances. While some uncertainty remains regarding variability in individual sensitivity and behavioural consequences, the assessment applied conservative thresholds and considered both physiological and behavioural endpoints. No potential for serious or irreversible harm was identified, and the precautionary principle was not triggered.

Activity not inconsistent with EPBC Act

The assessment considered all species listed under the EPBC Act and associated recovery or conservation plans. No protected fish species were found to have critical habitats within the Active Source Area. Activity design explicitly avoided areas like the West Tasmania Canyons Key Ecological Feature and Lady Julia Percy Island. No inconsistencies with management objectives or recovery plans were identified.

10.2 Biological and Ecological Categories

The modelled sound exposure areas are limited in scale, and most fish species are expected to respond to approaching vessels and sound sources by moving away. No mass mortality, spawning disruption, or physical injury is predicted (DFO 2004; Boeger et al. 2006; Popper et al. 2014; Popper et al. 2016; Carroll et al. 2017; Popper and Hawkins 2019, Miller and Cripps 2013). Populations are expected to remain dynamically stable within their natural ranges of variability without intervention. The assessment concluded that biological effects will be minor and unlikely to result in any population-level consequences.

Fish play important ecological roles as predators and prey, but the minor, localised and transient nature of the predicted impacts means that there will be no measurable effect on community structure or ecosystem processes. The sound footprint will not persist in any one area, and the short-

term displacement of individuals will not alter energy flows or trophic interactions. Ecosystem function and biodiversity will remain intact.

10.3 Economic, Cultural and Social Categories

Eels were identified through the cultural heritage review, consultation and desktop research as species with social, cultural and/or economic significance that may be impacted by underwater sound. The ecological impact of underwater sound on eel species has been assessed (see Appendix F3) and determined to be low intensity at a population level and within current accepted levels of impact as applied to the commercial fishing industry.

Several fish species were identified as valued to commercial and recreational fishing and, during consultation, a fishing tour operator. Assessed impacts to each fish species were all sub-lethal and mostly behavioural. There is no evidence of reduced fecundity nor developmental effects in any fish species, therefore long-term effects over multiple fishing seasons are not predicted.

As these values are closely tied to the physical presence and health of the species, the corresponding social, cultural and economic impacts are likewise considered acceptable. Ongoing assessment is conducted at the receptor level and via the corresponding measurement criteria and adopted mitigation measures. Therefore, industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational impacts; culturally significant species, places, and practices continue without disruption; and people and communities maintain ongoing access to the natural environment, recreational activities, and heritage values without long-term or irreversible effects.

10.4 Consistency with Company Processes

The impact assessment followed the methodology in Appendix B3 and applied peer-reviewed sources and defined thresholds where available, for physiological and behavioural effects based on fish hearing group classifications. The activity integrates all mitigation measures recommended through regulatory guidance and good industry practice, and the consequence ratings remain within CGG's established environmental limits. The conclusion of the assessment of seismic sound to fish is summarised below.

Table E3-3 Impact Assessment Effect Levels

Potential Impact	Predicted Level of Effect	Uncertainty	Predicted Level of Impact
Mortality and Potential Mortal Injury and Recoverable Injury	Minor	Low	Low
Temporary Threshold Shift	Minor	Medium	Medium
Change in Behaviour	Minor	Medium	Medium
Change in Commercial Catch	Minor	Medium	Medium

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E3-4 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E3-1)	Environmental Performance Outcome	Rationale
Fish and aquaculture stocks continue to be assessed as having the same stock status they held prior to commencement of the activity.	**No change in the assessed stock status of commercial and aquaculture species during and following the activity.**	The EPO can be supported through review of public fisheries stock reports and alignment with acoustic discharge levels remaining below modelled sound volume. No change in stock status indicates no unacceptable impact occurred.
No fish should be exposed to sound at or exceeding threshold levels for greater than 24 hrs for a TTS set at 186 dB SEL24hr.	**Fish will not be exposed to cumulative sound levels exceeding 186 dB SEL $_{cum24hr}$ for more than 24 hrs.**	This EPO is enforceable and verifiable through modelling of acoustic exposure fields and operational logs. It reflects a scientifically established threshold for temporary, recoverable effects and avoids threshold exceedance for both fish hearing sensitivity and pressure injury risk.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	Predicted impacts to fish are low intensity damage at the population level and within currently accepted levels of impact to these species as applied by the commercial fishing industry. The Otway Adjustment Protocol will be implemented to ensure that affected fishers will not be worse off because of the activity.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		The Budj Bim eel traps are protected under the World Heritage Area listing, the eels themselves are not. No impacts to the World Heritage Area are predicted. The predicted impacts to eels are low intensity at a population level and within current accepted levels of impact as applied to the commercial fishing industry. The Yarra Pygmy Perch occurs in lakes, ponds, and slow flowing rivers (Saddlier and Hammer 2010). Because of their freshwater affiliation no impact from underwater sound from offshore seismic is predicted.
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		Predicted impacts to fish are low intensity damage at the population level and within currently accepted levels of impact to these species as applied by the commercial fishing industry.

Defined Acceptable Level (From Table E3-1)	Environmental Performance Outcome	Rationale
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the impact and risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

For most species/taxa/groups of fish reviewed, this document provides the final assessment of impacts. However, despite an extensive review of the relevant literature on the effects of seismic on fish, there has been a high level of concern voiced throughout consultation with relevant persons, in relation to the importance of certain commercially targeted species and/or species of high cultural value. High levels of engagement on an aspect are a trigger for CGG to undertake additional assessment. In this case looking at the effects of the activity on the following species and/or behaviours. This additional assessment is detailed in Appendix F3 – Further Assessment of Key Values and Sensitivities under the following Sections

- 3.7 – Glass Eels
- 3.11 – Pink Snapper
- 3.12 – King George Whiting
- 3.14 – Spawning Patterns

It is important to note that the assessments detailed in Appendix F3 are as a response to further information requests and/or clarification and not a reflection of any prior assessment being insufficiently thorough. It is a recognition that more explanation and detail was sometimes necessary to better inform all groups involved in the consultation process, including the regulatory authority.

Hence, Appendix F3 does not provide further assessment on all aspects and values identified through the EP process only those that were identified as:

- Having some residual uncertainty about whether impacts or risks were of an acceptable level; and/or
- Contained environmental values and sensitivities (species) of key importance due to their protection status or commercial value; and/or
- Consultation with relevant persons revealed a particular value or sensitivity required further attention and material to support the consultation.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E3-5 shows how this feedback has been incorporated into the environmental assessments.

Table E3-5 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Impact Assessments (Appendices E, and F where relevant) to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Additional information to support impact assessment for fish	F03	CGG has reassessed and referenced literature in Section 4, which clarifies that there is no evidence of significant spawning aggregations occurring within the proposed Regia MSS area for the following species: Blue Warehou, Orange Roughy, Gulper Shark, School Shark, Australian Sardine, Blue Grenadies, Blue-eye Trevalla, Elephant Fish, Gummy Shark, Pink Ling, and Tiger Flathead.
Matter: Impacts of underwater sound on elasmobranchs	F07	CGG has considered these claims and is satisfied that the concerns raised were adequately addressed but has include reference to activity limitation where the sound source will not be discharged within 17km of Deen Maar and it's mitigating effect against potential impacts to sharks and rays in EP Appendix E3.
Matter: Impacts of underwater sound on white sharks	F08	CGG has considered these claims and is satisfied that the concerns raised were adequately addressed but has include additional information on the White Shark BIA and activity limitation here the sound source will not be discharged within 17km of Deen Maar, and it's mitigating effect against potential impacts to White Sharks, in EP Appendix E3.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and the following Activity limitation: the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion human health safety criterion for recreational divers, surfers and swimmers along the coastline CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, G1 and G2). feedback
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E3-6. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E3-6 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey periods. Since acoustic propagation modelling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete another modelling report prior to submission to cover the changed timeframes of the proposed survey.	3384
4035	Comment about the impact of human activities on wildlife habitats and calls for a halt to such destruction for profit. It emphasises the negative consequences of competing interests in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2109
4036	Comment claims that seismic activity is known to cause significant harm to marine life, arguing that the proposed project will lead to further degradation of the coastal environment and should be abandoned as a result.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2098
4038	Commenter highlights that fish populations have been adversely affected by seismic testing over the past few years, leading to a decline in their numbers. This decline could also impact other marine species and have negative effects on whale populations.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. A fauna management plan is in place to manage whale interactions.	1432
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa	2940

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	mentioning the geologically sensitive Bonney upwelling.	within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4035	Comment about the impact of human activities on wildlife habitats and calls for a halt to such destruction for profit. It emphasises the negative consequences of competing interests in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2109
4036	Comment claims that seismic activity is known to cause significant harm to marine life, arguing that the proposed project will lead to further degradation of the coastal environment and should be abandoned as a result.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2098
4038	Commenter highlights that fish populations have been adversely affected by seismic testing over the past few years, leading to a decline in their numbers. This decline could also impact other marine species and have negative effects on whale populations.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. A fauna management plan is in place to manage whale interactions.	1432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4050	Concern about the destruction of smaller sea life and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	1669
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts on biological receptors are outlined in the EP also and can be found in G2.	3237
4064	Concern raised by the stakeholder regarding the potential damage/kill of marine life due to seismic testing.	Titleholder responded to individual advising that CGG would not propose an activity that would lead to unacceptable impacts to marine life and advised that environmental impact assessments for each aspect of the proposed activity that has the potential to impact marine life were currently being prepared and that they would be based on scientific literature and published shortly for consultation and feedback.	1024
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation.	879

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	by other companies, particularly regarding the sale of seismic data.	Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biological importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation	722

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4080	Concerns about the impact of seismic testing on various marine species.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	2179
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4551
4083	Concerns about why more seismic needed and what time of the year was the survey going to be done to minimise impacts to fishing for sharks, lobsters, squid	Titleholder acknowledged this concern and each of the species within this claim has been subject to extensive assessment in E1, E3, E4 and F3 with various measure adopted to limit the sound exposure to the lowest level possible to meet geophysical objectives and to protect marine fauna (see G1).	740
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological	2766

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		receptors in the region and relevant mitigation measures are outlined in the EP.	
4102	Expresses opposition due to proximity to local fishing industries. Emphasises concern about potential risks this testing poses.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Adjustment protocol in place for fishers to seek compensation if impacted by MSS.	428
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used based around sound, peer reviewed scientific literature.	4190
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		reduce any impacts to as low as practicable.	
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4153	Presents a historical account of their catch rates over 24 years, indicating that seismic surveys in the past led to a significant decrease in their catch from 10-15 tons per trip to just 5-6 tons per trip for over two years. They now report a catch rate of 10-14 tons per 7 days, suggesting lingering concerns about how current seismic activities may similarly affect their fishing operations.	Titleholder acknowledged this concern and noted that potential impacts to molluscs the Regia MSS is assessed in E1, E4 and F3 of the EP. Advised that control measures to reduce impacts to commercial fishers as a result of loss of catch are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	5190
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan	2088

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		(EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Also outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	3697
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also referred to documents relevant to this claim within the environment plan (Event ID 4092).	4091
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2118
4181	Seismic testing has also been found to have sub-lethal impacts on fisheries species	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1893
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and	1665

		compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4198	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1672
4199	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information	2586

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	2886
4202	Stakeholder objects to the proposed blasting activity due to its detrimental effects on marine ecosystems.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously	1049

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		defined acceptable levels and is presented in the Environment Plan.	
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	425
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We have to show that the	2104

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	
4241	The fisher expressed concerns about the adverse effects of seismic activities on the stocks he relies on, indicating that the surveys have negatively impacted fish availability.	This claim was thoroughly assessed both in E3 and in F3. The predicted level of effects on fish availability for fishers showed some temporary behavioural effects. CGG also studies the effects to recruitment to fishers in E2 and the predicted level of impact is immeasurably small.	2026
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	3343
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an “exclusion zone” will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware	2108

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325
4285	The stakeholder noted their concern as a resident of Port Fairy: noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. North West Shoals to Shore Marine Noise Monitoring and Impacts https://www.aims.gov.au/research-topics/monitoring-and-discovery/north-west-shoals-shore Behavioural Response of Australian Humpback whales to Seismic Surveys https://www.brahss.org.au/ Assessing the impact of marine seismic surveys on southeast Australian scallop and lobster fisheries https://www.frdc.com.au/project/2012-008 Marine Seismic Survey Impacts on Fish and Invertebrates: Final Report for Gippsland Marine Environmental Monitoring Study https://ecat.ga.gov.au/geonetwork/srv/api/records/2292f4a7-ba2e-3533-e053-12a3070aaf2c Maxima 3D Marine Seismic Survey at Scott Reef https://www.sciencedirect.com/science/article/abs/pii/S0025326X13006528 https://www.sciencedirect.com/science/article/abs/pii/S0025326X18300687 Regarding Marine Fauna Observer's (MFOs), companies that contract MFOs such as Blue Planet Marine and RPS Group provide training for	2389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		MFOs. As part of contracting MFOs we will ensure that the persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: • Conformance with regulatory requirements detailed in the accepted EP. • Management strategies and procedures to ensure EPOs and	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being monitored, measured, and documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4305	The stakeholder was concerned about interference with the Orange Roughy Research Program.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact any research being done on Orange Roughy. While this species is found throughout southern Australia, no spawning or feeding aggregations have been identified in the Operational area.	3350
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country,	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the	3152

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	the marine and coastal environment, the local economy, Traditional Owners, and local communities.	Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4323	There will be potential permanent damage to marine life due to sonic testing and drilling.	Titleholder responded and listed various information needs related to the activity, environmental assessment process, environmental aspects, predicted levels of environmental impact and risk, environmental management, consultation processes, and regulations or regulatory processes. Links to the project website and document library was provided.	1046
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		waters and offered to provide individual with impact assessments when they became available.	
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4433	Claims seismic impacts can linger longer than the few hours suggested, the	OMICC announces that the latest version of the OMICC Otway	6749

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	insistence on peer-reviewed work to prove this is opportunistic and suits OMICC's agenda.	Adjustment Protocol has been published, along with a video briefing for fishers, which can be accessed through a provided link. In the briefing, OMICC confirms that, following the relevant persons feedback, a "claim period" and a "lodgement period" have been incorporated into the definitions of the protocol. The claim period is set to 30 days after the end of any activity, while the lodgement period extends up to 6 months after the end date of any activity. OMICC further informs the relevant person that the OMICC Founders reviewed the request for claims up to 6 months after an activity. However, the decision was made to adopt a 30-day claim period, as this duration resulted in a positive compensation outcome for fishers affected by the Gippsland survey in 2019.	
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880
4452	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	7136
4453	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	EVT070
4469	Objects to the negative effects of seismic testing on the short-finned eel.	CGG undertook scientific assessment for underwater sound impacts on Fish (Appendix E3 and F3), including short-finned eels. Short-finned Eels possess a swim bladder and were grouped with	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		other fish having swim bladders for acoustic impact analysis, following the guidance of Popper et al. (2014). For fish in general, and eels in particular, the key impact mechanisms considered were potential for hearing damage or physiological injury from intense sound close to the source, and behavioural disturbance (e.g. startle responses or avoidance movement) at various distances. The EP concluded that no fish, including eels, would be close enough to the seismic source to suffer mortality or physical injury, with measures in place such as soft-starts the free-swimming fish are able to move away from the sound source, and that they anticipate no direct fatalities or lasting injuries to adult eels in the water. The titleholder acknowledges that fish may exhibit behavioural reactions to seismic noise and they assumed a conservative scenario where fish might show avoidance responses at substantial distances. In the worst case, an eel migrating through the area might detect the seismic pulses at distance and alter its course or depth to avoid the highest sound levels. The EP considered such avoidance to be a temporary and localised effect and that any diversion would likely be on the scale of hundreds of meters to a few kilometres at most. Given that migrating eels travel thousands of kilometres to reach spawning grounds, a short detour or a brief pause is not expected to jeopardize their overall journey. The EP's finding was that behavioural changes would be temporary and would not have long-term impacts on individuals or the population. (Responded to in EVT346)	
4470	Objects to the insufficient consideration of the physical presence and migration interference caused by seismic activities in eel migratory pathways.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. The titleholder acknowledged that the Regia MSS Operational Area is offshore in the Otway Basin (south-west of Vic), which is adjacent to, with some limited overlap, to the potential migration corridor for these eels heading toward the western Tasman Sea. Appendix E3 identified "Eels (Anguilla spp.)" as a receptor in the environment that could be affected by underwater sound (section 4.1.6), precisely because	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Short-finned Eels are present in coastal catchments adjacent to the survey area and undertake marine migrations. (Responded to in EVT346)	
4471	Objects to the insufficient consideration of daily vertical migrations of the short-finned eel.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. CGG recognises that Short-finned Eels spend most of their life in freshwater/estuarine environments and undertake a once-in-a-lifetime spawning migration to the ocean. Specifically, the EP notes that mature adults (typically 8–20 years old, depending on sex) depart their rivers in late summer to autumn to migrate to oceanic spawning grounds. The EP also describes the return journey of the progeny: eggs hatch into larvae that drift southward on currents, metamorphose into “glass eels” and eventually enter coastal estuaries (with peak recruitment in winter–spring), which is consistent with established literature and references cited by the stakeholder (e.g. Gooley et al. 2002 , Jacoby et al. 2015). Appendix E3 incorporated the latest research on eel migration behaviour, notably Koster et al. (2021). The EP explicitly references Koster et al. and confirms the phenomenon of diel (daily) vertical migration in migrating eels: tagged eels from the Hopkins and Fitzroy Rivers exhibited a pattern of surfacing at night and diving deeper during the day while at sea. CGG acknowledges that this is a crucial behavioural detail that the EP does acknowledge. (Responded to in EVT346)	EVT178
4472	Objects to the insufficient consideration in Regia MSS Environment Plan's of the cultural value of the short-finned eel in South-West Victoria and South Australia beyond Budj Bim.	The Regia MSS EP was prepared and assessed under an objective based regulatory regime, which requires the titleholder to consider a broad definition of the environment which may be affected, including cultural heritage. The EP recognises the intangible cultural or spiritual connections to Sea Country and undertook research and assessment, including consultation with Traditional Owner groups, within the relevant Sea Country. While no significant impact is predicted, they remain committed to respectful ongoing engagement with Indigenous stakeholders regarding any spiritual or cultural concerns. Cultural heritage to the	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		eels is stated in Appendix E3 section 4.6.1, Appendix F3 section 3.7 and 3.16. Titleholder also explained that the EP contains a dedicated assessment of the Budj Bim Cultural Landscape (World Heritage Site) and its connection to Short-finned Eels and directed the stakeholder to Appendix F3 (Section 3.15). They stated that the conclusion of that assessment was that no threat or damage to Budj Bim's heritage values is expected from the proposed activity and that the cultural practices and eel stocks that underpin Budj Bim's value will not be materially affected. They stated that the EP goes further to acknowledge that beyond formally listed World Heritage values, there may be intangible cultural or spiritual connections to Sea Country that are difficult to quantify and that the Titleholder has regognised these and consulted Traditional Owner groups to better understand them.	
4478	Objects to the inadequate consideration of the habitat and lifecycle of the short-finned eel as their habitat includes all the areas essential to its lifecycle.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. The titleholder acknowledged that the Regia MSS Operational Area is offshore in the Otway Basin (south-west of Vic), which is adjacent to, with some limited overlap, to the potential migration corridor for these eels heading toward the western Tasman Sea. Appendix E3 identified "Eels (Anguilla spp.)" as a receptor in the environment that could be affected by underwater sound (section 4.1.6), precisely because Short-finned Eels are present in coastal catchments adjacent to the survey area and undertake marine migrations. The EP outlines the broad geographic distribution of Anguilla australi, extending from Queensland through Victoria, Tasmania, South Australia, and New Zealand, to demonstrate that eels from various regions may pass through or near the survey area. Accordingly, the EP did not overlook the potential for eels originating from rivers west of the survey area (such as the Glenelg River, Coorong, and Murray River) to travel along the continental slope. Instead, it treated the Short-finned Eel as a wide-ranging species and assessed it on that basis. The EP did not list each river individually because it considered the species at a regional	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		population level. The evidence and conclusions therefore apply to all Short-finned Eels in the area, irrespective of origin, as their marine behaviour and sensitivities are expected to be consistent across populations. The EP also includes detailed description of lifecycles, referencing the latest science, including the migrations in these lifecycles. (Responded to in EVT346)	
4474	Claims that seismic sounds can cause sublethal and lethal impacts on short-finned eels, such as disorientation, reduced energy budgets, stress or mortality.	Scientific assessment was completed for underwater sound impacts on Fish (Appendix E3) and how short-finned eels were accounted for in that assessment. As Short-finned Eels possess a swim bladder they were grouped with other fish having swim bladders for acoustic impact analysis, following the guidance of Popper et al. (2014). For fish in general, and eels in particular, the key impact mechanisms considered were potential for hearing damage or physiological injury from intense sound close to the source, and behavioural disturbance (e.g. startle responses or avoidance movement) at various distances. The assessment concluded that no fish, including eels, would be close enough to the seismic source to suffer mortality or physical injury, with measures in place such as soft-starts the free-swimming fish are able to move away from the sound source, and that they anticipate no direct fatalities or lasting injuries to adult eels in the water. The titleholder also acknowledged that fish may exhibit behavioural reactions to seismic noise and that they assumed a conservative scenario where fish might show avoidance responses at substantial distances. In the worst case, an eel migrating through the area might detect the seismic pulses at distance and alter its course or depth to avoid the highest sound levels. The EP considered such avoidance to be a temporary and localized effect and that any diversion would likely be on the scale of hundreds of meters to a few kilometres at most. Given that migrating eels travel thousands of kilometres to reach spawning grounds, a short detour or a brief pause is not expected to jeopardize their overall journey. The EP's finding was that behavioural changes would be temporary and would not have long-term impacts	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		on individuals or the population. (Responded to in EVT346)	
4475	Objects to the inconsistent consideration of short-finned glass eels arriving during April to October as they have been recorded to arrive throughout the year.	The EP describes the Short-finned Eel migration from Victoria largely occurring during late summer through autumn consistent with prevailing scientific theory. (Responded to in EVT346)	EVT178
4476	Objects to the lack of consideration of glass eel feeding, or the potential of having to 'swim out of the way' of seismic testing on energy budgets.	The Environment Plan (EP) fully considered potential effects of seismic activity on Short-finned Eels, particularly in relation to their ability to detect, avoid, and respond to underwater sound while migrating. The assessment followed internationally recognised scientific frameworks (e.g., Popper et al. 2014) and incorporated conservative sound-modelling to determine thresholds for injury and behavioural disturbance. The assessment concluded that no eels would be close enough to the seismic source to suffer injury or mortality, as eels are free-swimming and capable of moving away from noise. A soft-start procedure will also allow animals to detect and avoid the source gradually. Behavioural responses such as temporary avoidance or course adjustment were acknowledged and assessed as the most likely effect. Any such diversion would be localised and short-term, on the scale of hundreds of metres to a few kilometres, and would not meaningfully affect the eels' long-distance migration or energy reserves, given their natural capacity for endurance. The EP therefore determined that behavioural changes would be temporary, reversible, and of low intensity, with no population-level consequences. Supporting evidence from global studies shows no recorded cases of eel mortality or population decline linked to seismic surveys, including in the Otway Basin, where over 80 surveys have occurred in the past six decades. The assessment concludes that Short-finned Eels may move away from the survey area when exposed to sound, but will resume migration without harm or delay, and that predicted impacts are minor, transient, and not significant at individual or population scales. (Responded to in EVT346) Appendix E3 section 4.1.6 has been updated to include: It has been noted by Van Wichelen, et al (2022) that glass eels feeding during their migration is highly restricted, therefore when	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		discussing impacts to glass eels, this has been considered.	
4477	Objection about the lack of adequate recognition and consideration of non-lethal, cumulative, and long-term impact of seismic noise on short finned eel.	Short-finned Eels possess a swim bladder and were grouped with other fish having swim bladders for acoustic impact analysis, following the guidance of Popper et al. (2014). For fish in general, and eels in particular, the key impact mechanisms considered were potential for hearing damage or physiological injury from intense sound close to the source, and behavioural disturbance (e.g. startle responses or avoidance movement) at various distances. The assessment concluded that no fish, including eels, would be close enough to the seismic source to suffer mortality or physical injury, with measures in place such as soft-starts the free-swimming fish are able to move away from the sound source, and that they anticipate no direct fatalities or lasting injuries to adult eels in the water. The titleholder also acknowledged that fish may exhibit behavioural reactions to seismic noise and that they assumed a conservative scenario where fish might show avoidance responses at substantial distances. In the worst case, an eel migrating through the area might detect the seismic pulses at distance and alter its course or depth to avoid the highest sound levels. The EP considered such avoidance to be a temporary and localized effect and that any diversion would likely be on the scale of hundreds of meters to a few kilometres at most. Given that migrating eels travel thousands of kilometres to reach spawning grounds, a short detour or a brief pause is not expected to jeopardize their overall journey. The EP's finding was that behavioural changes would be temporary and would not have long-term impacts on individuals or the population. The Titleholder noted that the EP acknowledges the existing pressures on the Short-finned Eel population and was developed to demonstrate that the proposed seismic survey would not materially increase the cumulative impact on the species. The cumulative impact assessment concluded that, even when accounting for other regional activities, the incremental effect of the survey on overall conservation values would be neutral to	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		negligible. (Responded to in EVT346)	
4478	Objection to CGG's statements of 'no predicted mortality' on short finned eels is not supported.	This conclusion is supported by conservative modelling, peer-reviewed scientific research, and a precautionary evaluation of worst-case scenarios. No new scientific information was identified in the submission that had not already been considered in the Environment Plan. References such as Koster et al. (2021) were already incorporated into the EP, which includes the IUCN listing of near threatened. CGG notes that while Jacoby et al. (2015) raised conservation concerns for the species, the EP's findings are consistent with ensuring that the proposed activities do not exacerbate those concerns. (Responded to in EVT346)	EVT178
4479	Objection to CGG's statements about proposed mitigation measures in relation to the short finned eel.	The Environment Plan (EP) adopts an evidence-based, risk-weighted, and precautionary approach, consistent with both the letter and spirit of the precautionary principle in Australian law. The EP concludes that the impacts and risks to Short-finned Eels have been reduced to As Low As Reasonably Practicable (ALARP) and remain acceptable, meeting the requirements for EP acceptance under Regulation 34. While recognising that NOPSEMA's independent review will make the final determination on the EP's adequacy, CGG's view is that the document meets the regulatory acceptance tests, including demonstrating no unacceptable impacts on World Heritage values and consistency with the principles of Ecologically Sustainable Development (ESD). (Responded to in EVT346)	EVT178
4480	Objection to CGG's frequency range of 0-200Hz on migrating eels, stating the EP minimises how seismic testing may affect the eels.	Short-finned Eels possess a swim bladder, though it is not primarily used for hearing, and were therefore grouped with other fish possessing swim bladders for the purpose of acoustic impact assessment. The Environment Plan (EP) applied the internationally recognised framework of Popper et al. (2014) to establish scientifically validated thresholds for potential injury and behavioural disturbance. The assessment considered possible hearing damage, physiological effects from intense sound near the source, and behavioural responses, such as avoidance or startle reactions, at varying distances. As no specific audiograms exist for Short-	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		finned Eels, the EP adopted a conservative approach, assuming they would respond similarly to other fish with comparable anatomy. (Responded to in EVT346)	
4481	Claims that content provided in the Regia Environment Plan is inconsistent, incomplete, misleading and has multiple errors in logic and critical thinking and does not accurately represent the evidence about the life cycle of the short-finned eel.	The version of the EP referenced by the stakeholder (June 2024) had been substantively updated with multiple iterations during NOPSEMA's assessment and following public comment which addresses all scientific and policy related claims. Titleholder also explained that the Regia MSS EP was prepared and assessed under an objective based regulatory regime, which requires the titleholder to consider a broad definition of the environment, including cultural heritage and social values, not just the immediate onshore operational area.	EVT178
4482	Claims the inadequacy of the Regia MSS Environment Plan in applying the precautionary principle and using transparent, comprehensive evidence for impact assessment.	The claim that the process lacked transparency is not supported by record as the project ran an unusually open process where the EP and appendices were published on the Consultation Hub, and the public were provided with updates at every revision. The EP's approach is fully consistent with Australian regulatory requirements for EP's which demand evidence-based assessment and precaution in the face of uncertainty and that the Regia MSS EP applied conservative assumptions and safety margins wherever scientific uncertainty existed. CGG are confident that the EP's evidence-based, risk-weighted approach – supplemented by precautionary, worst-case scenarios – meets both the letter and spirit of the precautionary principle in Australian law. The EP applies precaution through conservative assumptions, rigorous modelling, and layered safeguards, while also ensuring that conclusions remain scientifically defensible and evidence based. CGG have taken precautionary measures without abandoning accuracy or overstating unverified threats.	EVT178
4483	Claims insufficient monitoring and need for application of conservation recommendations and the IUCN's ongoing monitoring advice.	The EP applies the precautionary principle and ESD, using a conservative risk assessment that predicts negligible impact and is consistent with avoiding any deterioration in the species' conservation status. The EP acknowledges the conservation concerns highlighted in scientific literature, noting that the Short-finned Eel is classified as Near	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Threatened on the IUCN Red List. However, this classification is attributed primarily to freshwater habitat issues, not marine threats. The EP did not propose species-specific monitoring for eels because the predicted impacts were deemed so low (minor, transient disturbances with no lasting harm to individuals or the population), however would be open to assisting researchers.	
4484	Claims that the Regia MSS assessment on mortality of eels shows a critical thinking error, confirmation bias, logical fallacy and exaggerated language.	CGG maintains that the EP contains no fundamental logical flaws and expresses confidence that NOPSEMA, as the independent regulator, would identify any such issues in fulfilling its statutory role. The EP applies a structured weight-of-evidence approach, drawing on multiple lines of scientific information rather than selectively minimising impacts; where uncertainty was identified, the EP adopts precautionary assumptions. CGG states that the EP meets all regulatory requirements by describing the activity and environment, identifying all credible impacts and risks, and demonstrating that they are reduced to ALARP and acceptable levels. Regarding eel mortality, CGG notes that the EP explicitly predicts no mortality or injury based on modelled sound levels. Acoustic modelling shows the distance at which injury could occur is limited (60–230 m), and because eels are mobile, combined with the soft-start procedure, the likelihood of harm is extremely low. In response to concerns about confirmation bias or minimising language, CGG explains that terms such as “low risk” and “no measurable impact” are technical descriptors supported by evidence, not value judgments. They state that contextual information—such as the species’ resilience and broader existing pressures—is provided to ensure accuracy rather than diminish concerns. CGG also acknowledges minor typographical errors in species names but clarifies that these do not affect the scientific assessment.	EVT178
4485	Claims the activity will exacerbate existing pressures on freshwater eel.	The EP directly acknowledges the conservation concerns identified in the scientific literature and states that its impact conclusions are designed to ensure the proposed	EVT200

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		activity does not exacerbate those threats. It contextualises the Short-finned Eel's resilience by noting that the species faces far greater long-term pressures, such as overfishing, river barriers, drought, and climate-driven changes to ocean currents, and that its Near Threatened status on the IUCN Red List is primarily due to freshwater habitat issues rather than marine impacts. Within this broader context, the EP concludes that the Regia MSS survey will not materially add to the cumulative pressures on the eel population. The cumulative impact assessment predicts the survey's incremental effect to be neutral to negligible, and that any impacts will be minor and temporary, with no risk of jeopardising migration success or the species' viability.	
4486	Claims that the overall ecological health of systems is impacted by stressors affecting the short finned eel.	The EP recognises the ecological significance of the Short-finned Eel within the wider system. It notes that the species plays an important dual role in aquatic food webs, as both predator and prey, and is an ecologically connected component of marine and freshwater ecosystems. The EP describes the species' resilience, highlighting that Short-finned Eels are broadly distributed, migratory, and have persisted through natural environmental fluctuations over millennia. The EP assesses whether any predicted impacts could translate into population-level or ecosystem-level consequences. It concludes that Short-finned Eels are expected to experience only minor and temporary behavioural disturbance from the seismic survey, with no lasting harm to individuals or the population. Because abundance and function are predicted to remain intact, the species' ecological roles are not expected to change. Consistent with defined acceptable impact criteria, the assessment finds that effects will be temporary, reversible, small-scale, and low intensity at the population level. On this basis, the EP concludes there will be no ripple effects on predators, prey, or ecosystem processes. The document further supports this conclusion by noting that more than 80 seismic surveys have taken place in the Otway Basin over six decades, with no recorded decline in Short-	EVT200

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		finned Eel populations attributable to seismic activity.	
4490	CGG has failed to adequately assess the impacts of its proposed activity on the Budj Bim World Heritage Cultural Landscape. GMTOAC further states that CGG did not sufficiently evaluate impacts on Kooyang, a culturally significant species whose lifecycle and migration underpin the world heritage values of the Budj Bim Cultural Landscape and extend well beyond its physical boundaries.	Culturally significant features, including the Budj Bim landscape, were included in both impact and cumulative risk assessments using a methodology that blends scientific evidence with cultural narratives. Regarding Kooyang (Eel), CGG maintains that this culturally important species, whose lifecycle is central to the world heritage values of Budj Bim, was addressed within the EP's impact and cumulative assessments. These assessments include both Kooyang's cultural significance and ecological role. CGG reiterates that its EP is consistent with statutory obligations, based on best-available science, and tailored to the cultural and ecological sensitivities identified. CGG maintains that the Budj Bim Cultural Landscape and Kooyang have been incorporated into the EP and that this inclusion meets regulatory standards for demonstrating ALARP and acceptable levels of impact.	EVT352
4491	Claims about the SRW and BW BIAs. States proposed activity will cause unacceptable impacts to all Karntubul species, including temporary & permanent hearing loss, displacement from BIAs, vessel strike, prey depletion during peak feeding/migration period, calving interruption, and impact to ecosystems and cultural landscapes as a result of the cumulative impact of these.	CGG has identified all Biologically Important Areas (BIAs) relevant to blue whales (BWs) and southern right whales (SRWs) and incorporated seasonal BIA use into the survey design through substantial temporal and spatial restrictions detailed in the EP. Predicted underwater-sound impacts on these Karntubul species, along with mitigation measures presented in Appendices E7 and F3, demonstrate impacts will remain acceptable and will avoid auditory impairment or displacement from BIAs or Habitats Critical to Survival (HCTS). CGG further notes that vessel-strike risk is already extremely low during seismic surveys and that additional controls in Appendix D2 ensure this risk is prevented and acceptable. It concludes that no changes to ecosystem structure, diversity, or function are expected from the one-off survey, with sound exposure too limited in extent and duration to affect prey, food webs, or predator–prey relationships. A cumulative impact assessment found residual cumulative effects to be low, reduced to ALARP, and acceptable, with no impacts predicted for regional marine parks. CGG also asserts consistency with the National Recovery Plan for Southern	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Right Whales and the Blue Whale Conservation Management Plan, stating that their objectives and recommended measures have been incorporated. Finally, CGG maintains that all marine mammal species likely to occur in the region have been adequately assessed using up-to-date EPBC Protected Matters data, and that mitigation measures ensure impacts to all listed species will remain acceptable and not inconsistent with EPBC Act protection provisions.	
4492	Claims that the eastern population of the Southern Right Whale, estimated at only 200–300 individuals, is at particularly high risk because its migration and reproduction Biologically Important Areas (BIAs) overlap directly with CGG's Operational Area and sound propagation footprint. According to the Southern Right Whale Recovery Plan, these whales use the affected region for reproduction between May and September and for migration between April and October. The Recovery Plan also notes that Southern Right Whales do not feed in coastal waters but are expected to feed, and possibly conceive, within the Australian Whale Sanctuary—an area entirely overlapped by the proposed Regia MSS activity. As a result, the seismic survey could occur within, or affect, conceiving, calving, and feeding grounds for this critically endangered sub-population. The species is particularly vulnerable to human impacts due to its low reproductive rate, long lifespan, and strong site fidelity to key habitats. The submission therefore emphasises the relevance of underwater noise, habitat degradation, and vessel-strike risks in the context of the proposed seismic activities.	The Recovery Plan explains that BIAs can be designated for key behaviours such as reproduction, foraging, migration, and resting. While Southern Right Whale BIAs in the Plan cover reproduction and migration, the Plan notes that foraging occurs across a much broader offshore latitudinal range (30°S–65°S) and is not linked to these BIAs. Because the Regia MSS is not located in Antarctic waters, it will not affect cetaceans that forage there. CGG states the survey will avoid peak SRW abundance in the mapped BIA and apply mitigation measures to ensure no SRWs are harmed, injured, or interfered with.	EVT352
4496	GMTOAC objects to CGG removing a previous control measure limiting seismic discharge in the Pygmy Blue Whale foraging BIA during periods of low whale presence, replacing it with a vague condition requiring CGG to determine whether whale presence is "compatible" with proceeding. GMTOAC argues this new measure lacks detail on how whale presence or "unacceptable disturbance" will be assessed, and that it fails to reference Recovery Plans which define unacceptable impacts. GMTOAC warns that the proposed survey timing (April–June 2026) coincides with peak Pygmy Blue Whale foraging season and Southern Right Whale migration and calving periods, meaning the seismic survey is likely to occur when both species are using their BIAs. Preventing whales from accessing these areas, or exposing	CGG has further reduced the likelihood of interactions with marine mammals by excluding the April–June period and commencing the survey only after 15 September. Because blue whales typically do not arrive from Western Australia until November, CGG argues that most of the survey will occur when blue whales are absent from the area. It adds that sighting data show very few blue whales in November and December, with peak abundance occurring later, from January to March during the Bonney Upwelling.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	them to injury while they remain, would constitute unacceptable impacts inconsistent with Recovery Plan objectives.		
4508	GMTOAC claims inadequate assessment of noise on culturally important Kooyang. GMTOAC notes that CGG's EP groups Kooyang with other fish possessing swim bladders, and acknowledges that fish with swim bladders may be more susceptible to physiological trauma from seismic noise. However, while the EP claims no studies have demonstrated direct mortality of adult fish from seismic emissions, GMTOAC highlights that it has repeatedly requested an independent study on Kooyang specifically, a request CGG has refused. Across multiple appendices, CGG's assessment appears inconsistent. Some sections state that eels fall within the category of fish whose hearing directly involves a swim bladder, while other parts of the EP fail to mention this heightened sensitivity or cross-reference relevant acoustic impact studies. GMTOAC argues these inconsistencies obscure the true risk profile and hinder meaningful evaluation of proposed controls. Finally, GMTOAC challenges CGG's conclusion that risks to adult Kooyang will be "extremely low" and indistinguishable from natural population variation. GMTOAC notes that this claim lacks scientific justification and appears to rely on the eel's behavioural avoidance or instinctual drive to migrate rather than on concrete control measures to prevent harm.	CGG recognises kooyang as a profoundly important Gunditjmara cultural value and not just an ecological species. The Environment Plan explicitly protects kooyang by applying culturally defined acceptability criteria, including ensuring no material reduction in kooyang abundance, recruitment, or sustainable harvesting that could impact Budj Bim practices or World Heritage values. This cultural framing underpins the entire assessment. CGG rejects claims that its underwater-noise assessment is inadequate, noting that it is detailed, conservative, peer-reviewed, and fully compliant with best-practice standards. Kooyang are assessed using the highest-sensitivity category under EPBC Policy 2.1, and predicted noise-effect zones are extremely small. The survey timing has been shifted to September–December, avoiding: peak adult silver-eel migration (Feb–May), most glass-eel recruitment (Oct–Feb), and juveniles that would already be inside river/estuary systems. This means minimal temporal or spatial overlap with key life stages. There is no credible pathway for population-level or culturally significant effects, and global evidence shows no seismic survey has ever been linked to effects on anguillid eel recruitment. Overall, the assessment is precautionary, culturally informed, and reduces risks to ALARP. CGG remains open to incorporating additional Gunditjmara knowledge or scientific evidence, but based on current information, no material impact on kooyang is credible.	EVT352
4509	GMTOAC claims that CGG's approach to assessing impacts on Kooyang is inconsistent with the precautionary principle under the EPBC Act, especially given Kooyang's cultural significance and its central role in the World Heritage–listed Budj Bim Cultural Landscape. GMTOAC states that CGG has repeatedly	CGG affirms the deep cultural importance of kooyang to the Gunditjmara People and agrees that any activity causing a population-level decline in kooyang that recruit into the Budj Bim wetland systems would be unacceptable. However, the claims in paragraphs 118–132 are	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	asserted, without scientific evidence, that juvenile eels will not be near the seismic activity, despite the absence of data tracking their migration from the Coral Sea to Gunditjmara Sea Country. They outline the well-established seasonal migration patterns of adult and juvenile Kooyang and state that these movements directly link the open ocean to the Budj Bim aquaculture systems. UNESCO inscribed Budj Bim as a World Heritage property because of Gunditjmara's long-standing eel aquaculture, which relies on the uninterrupted migration of Kooyang. GMTOAC highlights that published research, co-authored by Gunditjmara Elders and scientists, shows adult eels travel through areas that overlap with CGG's Operational Area and EMBA, meaning migrating Kooyang are likely to encounter the seismic survey if undertaken in April 2026. GMTOAC also raises concerns regarding CGG's framework for assessing impacts on World Heritage values. They argue that CGG wrongly limits its definition of "direct effects" to the physical boundaries of the property, failing to recognize that Kooyang moving through the marine environment outside the site are essential to the World Heritage values themselves. GMTOAC rejects CGG's categorisation of impacts to Kooyang and Gunditjmara cultural practices as merely "indirect," and notes the EP provides no explanation for its claim that such impacts are "immeasurable." Further, GMTOAC states that CGG has only referenced one of the required Budj Bim management plans and has not demonstrated engagement with the others. They contend that CGG has not shown how the proposed activities align with or avoid contravening the management goals, especially those aimed at restoring healthy Kooyang populations. GMTOAC concludes that CGG's failure to properly account for the cultural, ecological, and World Heritage significance of Kooyang is unacceptable to Gunditjmara, whose stewardship of Budj Bim spans millennia and underpinned the site's World Heritage listing.	based on legal and factual misunderstandings. The World Heritage property is strictly limited to the freshwater Budj Bim wetlands on the lava flow and does not include estuarine, coastal, or oceanic waters. Under UNESCO rules, World Heritage protection applies only within the fixed site boundaries and cannot extend to migratory species outside them. No World Heritage site has ever been interpreted the way GMTOAC suggests. CGG clarifies that the OUV attribute "ecology and life-cycle of kooyang" refers specifically to the parts of the life cycle occurring within the engineered aquaculture systems inside the property, not the entire oceanic migration. International precedents—such as the Monarch Butterfly Reserve, the Yellow Sea Migratory Bird Sanctuaries, and the Wadden Sea, show that impacts outside property boundaries are not considered direct impacts on World Heritage values. Scientifically, the EP uses best-practice criteria, with predicted noise effects on kooyang limited to very small distances (<300 m), and the survey timing (Sept–Dec) avoids overlap with major migration and recruitment periods. No tracking data show a kooyang migration corridor through the survey area, and the contribution of one 60-day survey to cumulative pressures is negligible. Appendix F3 confirms alignment with relevant management plans, which only consider impacts inside the property's boundaries. CGG states it remains open to further Gunditjmara knowledge and evidence, and has updated the EP to consider the provided management plans, but concludes that no credible pathway exists for material impact on kooyang abundance within the Budj Bim wetlands or on the property's Outstanding Universal Value. The EP is therefore lawful, scientifically robust, and compliant with Australia's World Heritage and EPBC Act obligations.

1 Introduction

Underwater Sound was identified through the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) as an Aspect needing further assessment. Hence this document presents a detailed examination of Underwater **Sound**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental Receptor we are collectively calling **Invertebrates.**

This assessment is built on the information contained in the following four core studies, which should be read in the order they are listed:

1. PEIRA.
2. Seismic Sound Studies Report (Appendix B8).
3. Sound Emissions Modelling Reports (Appendix B7).

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was initially published in draft form and uploaded to the Document Library of the Regia MSS Consultation Hub on 11 September 2023 as a stand-alone document, rather than as part of the much more substantial total EP document. This was done to maximise the ability of interested members of the public to read, interpret and respond within the mandated 30-day public comment period.

As such, public and Relevant persons were invited to comment on the document with an explicit request for feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality

of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

The primary sound source will be impulsive underwater acoustic emissions coming from the seismic source releasing compressed air (seismic pulse) and creating a sound wave directed downwards towards the seabed.

Secondary sound sources will include continuous underwater acoustic emissions generated by the survey and support vessels and helicopters. Sounds from vessels are generated by thrusters, engines, and propellers. Underwater acoustic emissions from helicopters are generated via the engine and rotors. Underwater acoustic emissions from Ultra-Short BaseLine positioning beacons are generated within the streamer spread.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days

Extent: Active Source Area + 90m – 2.74 km m based on the furthest distance to modelled sound effect criteria. [Updated in response to Matter: F17]

Active seismic acquisition will occur for up to 60 days within the Active Source Area.

Continuous Sound

Duration: 90 days

Extent: Operational Area

The survey and support vessels will be active in the Operational Area for the duration of the survey undertaking support activities and acquisition.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for impulsive (seismic) underwater sound for the following environmental components and their social, cultural, and economic features:

- Invertebrates
- People and communities

In addition, indirect impacts were identified to the following via relevant person consultation:

- Commercial Fishers

Potential environmental impacts to invertebrates identified from the PEIRA are:

- Change in fauna behaviour.
- Change in hearing capacity.
- Change in physical condition.

3.1.1 Exempted Areas

Invertebrates were identified as a value within the West Tasmanian Canyons Key Ecological Feature (KEF) which the initial Activity Planning Area overlapped. Hence, an assessment of impacts to invertebrates within this KEF was included in the initial draft of this document first published to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. However, since then the Active Source Area has been further refined and is now ~20 km from the West Tasmanian Canyons KEF (Appendix B12 MAP-REG-EPM-004). Given that the furthest distance to the modelled sound effect criteria for invertebrates is between –90 m – 2.74 km from the Active Source Area, impacts are not predicted.

Invertebrates were also identified as a value within the Twelve Apostles Marine National Park which was adjacent to the previous Activity Planning Area. Since then, the Operational and Active Source Areas have been refined and now include a 5 km buffer from the Operational Area to the Twelve Apostles Marine National Park (Appendix B12 MAP-REG-EPM-047). The Active Source Area is ~20 km from the seaward boundary of the Twelve Apostles Marine National Park (Appendix B12 MAP-REG-EPM-047). Given that the furthest distance to the modelled sound effect criteria for invertebrates is between 90 m – 2.74 km from the Active Source Area, impacts to invertebrates are not predicted within the park.

There is no scientific information on the potential for continuous underwater sound impacts to invertebrates and no cause-effect pathway has been established. Thus, the impact assessment focuses on impacts from impulsive (seismic) underwater sound to invertebrates.

4 Description of the Existing Environment that may be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8.

Marine invertebrates include:

- Crustaceans such as crabs and rock lobsters.
- Molluscs such as bivalves (abalone, clams, mussels, and scallops), gastropods (sea snails/trochus, sea slugs and nudibranchs) and cephalopods (squid and octopus).
- Hard and soft corals.

Marine invertebrates not only represent the largest proportion of marine biomass, but many species also have important socio-economic values (Sole et al. 2023).

Species are grouped according to their sound modelling characteristics as outlined in Section 5: Acceptable Levels of Impact

4.1 Invertebrates - General

Studies by the Museum of Victoria found that invertebrate diversity was high in southern Australian waters although the distribution of species was patchy, with little evidence of any distinct biogeographic regions (Wilson and Poore 1987). This is supported by studies in the region.

Studies for the Beach Otway Gas Development that is in the eastern part of the Regia Operational Area identified the following:

- A video survey of the seabed at selected sites along proposed offshore pipeline routes for the Otway Gas Development was undertaken during 2003 (Beach Energy 2022) and found:
  - Substrate in water depths between 82 and 66 m was predominantly low-profile limestone with an incomplete sand veneer that supported a low to medium density, sponge dominated filter feeding community. Fish and other motile organisms were uncommon.
  - In shallower depths between 30 and 63m the video surveys showed a rippled, sand or sand/pebble substrate with minor sponge dominated benthic communities. The epibenthic organisms were generally attached to outcropping or sub-outcropping limestone pavements. Only in waters shallower than ~ 20 m, was significant, high-profile reef and associated high density macroalgae dominated epibenthos encountered.
- A drop camera survey at the seabed for the next phase of the Otway Gas Development was undertaken from November 2019 to January 2020 in water depths from 70 to 104 m (Beach Energy 2022) and found:
  - Percent cover of epifauna ranged from 0 to 80% for all samples, averaging no more than 37%. Of the individual epibenthic organisms, Gastropoda sp. 2 (a cone shell) and crinoids (featherstars) were the most abundant.
  - The general impression of the seafloor was of an unmodified marine environment that supports a patchy complex of branching epibiota (i.e., bryozoans, gorgonian cnidarians and sponges) providing microhabitat for a range of macrofauna such as amphipods, isopods, polychaete worms and molluscs.
  - There was a low abundance and diversity of infauna living within the sediment which reflects the coarse nature of the substrate. This type of substrate is highly

mobile making it difficult for filter feeders and soft bodies invertebrates to survive and establish significant populations.

- Epibiota on the seabed in the area surveyed was representative of what is expected at depths around 70-100 m. The infauna was of relatively low abundance and diversity as expected for coarse sand substrates. No species or ecological communities listed as threatened under the *Environmental Protection and Biodiversity Conservation Act* 1999 (the EPBC Act) were observed.

Studies for the proposed pipeline for the Cooper Energy Casino, Henry, Netherby Development (Cooper Energy 2017) located in the eastern part of the Regia Operational Area, found that.

- in water depths from 20 – 60 m much of the seabed was sand or fine gravel. No epifauna were observed in these large tracts of sand and the biological component was likely to be primarily in-faunal or pelagic.
- Beyond 60 m water depth, the seabed was characterised by concreted outcroppings with very low relief and structural complexity separated by gullies of sand or fine gravel. Survey footage indicated that this broad flat area has a sparse cover of filter-feeding epifauna dominated by sponges and probably hydrozoans, bryozoans and algae.

4.2 Invertebrates – Commercial Species

Based on the review of commercial fisheries within the Regia MSS Operational Area (Appendix B6), a number of fisheries have been identified as having catch-effort for invertebrate species within the Operational Area (Table E4-1).

Table E4-1 - Commercial Invertebrate Fisheries with Catch-Effort within the Regia MSS Operational Area.

Jurisdiction	Fishery	Species	Note
Commonwealth	Southern Squid Jig Fishery	Gould's squid (*Nototodarus gouldi*	The Operational Area overlaps the Southern Squid Jig Fishery and Southern and Eastern Scalefish and Shark Fishery Commonwealth Trawl Sector Squid maximum fished area and where there has been fishing intensity during 2010 – 2020.
Victoria	Giant Crab Fishery	*Pseudocarcinus gigas*	The Operational Area overlaps the area actively fished by the Giant Crab Fishery.
Victoria	Octopus Fishery	Pale octopus (*Octopus pallidus*) Maori octopus (*Octopus maorum*) Gloomy octopus (*Octopus tetricus*)	The Operational Area overlaps the area where there has been one vessel with a maximum fishing day of one since the fishery commence in 2020. Currently octopus fishing in the Western Zone, which overlaps the Operational Area is via exploratory, temporary permits.
Victoria	Southern Rock Lobster Fishery	*Jasus edwardsii*	The Operational Area overlaps the area actively fished by the Rock Lobster Fishery.
Victoria	Abalone Fishery	Blacklip *(Haliotis rubra)* *Greenlip (Haliotis laevigata)*	Based on water depths, the Activity Planning Area does not overlap the fishery, while the Environmental Planning Area overlaps the Western and Central zones of the fishery.

4.2.1 Crustaceans

4.2.1.1 Giant Crab

Giant Crab (*Pseudocarcinus gigas)* occurs in southern Australian waters between central New South Wales to southern Western Australia, including Tasmania. Giant crabs inhabit the continental slope at approximately 200 m depth and are most abundant along the narrow band of the shelf edge (VFA 2023b).

The stock of Giant Crabs distributed along the Victorian coast is part of a larger, genetically homogenous population that is endemic to southern Australia and maintained through widespread larval dispersion (VFA 2010). There has been little Giant Crab fishing in the Eastern Zone so the stocks in that zone are considered to be close to their natural state.

Giant Crabs are slow moving carnivores that feed primarily on sedentary benthic species such as starfish and on carrion. Growth of Giant Crabs is relatively slow; females and males taking approximately seven years and four to five years, respectively, to reach the legal minimum length of 150 mm (VFA 2010). The inter-moult period is one of the longest of the crab species and can be up to fifteen years for mature females (VFA 2010).

Female Giant Crabs are highly fecund and their ability to store sperm gives them the ability to fertilise their eggs over several successive breeding seasons. Eggs are released during autumn and incubated by the female until the following spring when they are released in the shallower depths of the shoulder of the continental slope (VFA 2010).

While there is little scientific data on the population, stock status records show the species to be sustainable throughout Western Australia, South Australia and Victoria but depleted in the Tasmania region (FRDC 2020).

Harvesting of the species has been undertaken for decades, though total allowable catch has been decreasing in Victoria significantly since 2011 from 25 tonnes to 10 tonnes by 2020 (VFA 2023b). Aspects of the species' biology (e.g., long-lived, slow-growing) and life-history characteristics make the species vulnerable to overfishing. The Victorian fishery stock status is listed as 'sustainable' while the Tasmania stock status is listed as 'depleted' based on percentage of egg production relative to unfished level.

Both the Victorian and Tasmanian fisheries recognise the importance of the breeding season with closures in effect from 1 June to 15 November for females while they are breeding and in berry. The Victorian fishery also closes between 15 September to 15 November to protect males during moult, while Tasmania remains open all year round for males.

4.2.1.2 Southern Rock Lobster

The Southern Rock Lobster (*Jasus edwardsii*) is found on coastal reefs from the south-west coast of Western Australia to the south coast of New South Wales, including Tasmania and the New Zealand coastline. Southern Rock Lobsters have extensive larval dispersal and can be found to depths of 150 metres, with most of the catch coming from inshore waters less than 100 metres deep (VFA 2017).

As the species is distributed continuously across southern Australia, the population is considered a single biological stock (VFA 2023, Bruce et al. 2007, Ovenden et al. 1992). Bruce (2007) detailed that, with the exception of southwest Western Australia, all regions receive more pueruli from outside their own boundaries than from self-recruitment.

In Victoria, the abundance of Southern Rock Lobster decreases from west to east reflecting a decreasing area of suitable rocky reef habitat (VFA 2017). Most adult Southern Rock Lobster remain within the same region (moving less than 1 km), though some tagged Southern Rock Lobster have moved more than 80 km between inshore and offshore reefs (SRL 2023). In the Otway Bioregion, Southern Rock Lobster habitat occurs as patchy, discontinuous low-profile reef running parallel to the coast.

The life cycle of the Southern Rock Lobster is complex. After mating in April to July (SRL 2023), fertilised eggs (from 100,000 up to 1,000,000 per female) are carried under the tail of the female for approximately 4-6 months before being released, typically between September and November (VFA

2017). Larval release occurs across the southern continental shelf, which is a high-current area, facilitating dispersal.

Once released, Southern Rock Lobster larvae (phyllosoma) live in the plankton and undergo 11 developmental stages over a period of between 12 and 24 months (Hartmann et al. 2013; SRL 2023). This stage is spent far out to sea beyond the continental shelf where ocean currents can carry phyllosoma hundreds or even thousands of kilometres from where they were released by the female lobster.

At the end of this developmental phase, phyllosoma larvae moult and metamorphose into a puerulus larvae (a transparent miniature version of the adult), still living in the water column but not feeding (SRL 2023). Successful metamorphosis from the final stage phyllosoma to puerulus stage occurs offshore but close to the continental shelf (Curtin University 2009). The puerulus swim inshore at night to settle onto reef habitat in depths from 50 m to the intertidal zone (Booth et al. 1991) where they moult into pigmented juvenile lobsters (SRL 2023).

This settlement of puerulus is very important and is monitored using specifically designed collectors placed in many locations around southern Australia. Only a very small number of the eggs released actually reach the stage of settling as puerulus, and very few of these puerulus survive to become adults (SRL 2023). From the millions of larvae annually produced by each adult lobster, only two on average survive to become adult lobsters (SRL 2023a). By measuring the annual settlement of puerulus, fisheries scientists gain an indicator of future stock levels.

Bruce et al. (2007) reported data for state-maintained puerulus collector sites, which indicates that most puerulus settlement in Portland occurs June through September, tapering off in October.

Southern Rock Lobster grow by moulting or shedding their exoskeleton. The frequency of the moulting cycle declines with age from five per year for newly settled juveniles to once per year for mature adults (VFA 2017). Males grow faster and larger than females, reaching 160 mm in carapace length after ten years. Females generally reach 120 mm in the same period. Growth rates also vary spatially, with growth faster in the east than in the west (VFA 2017). It can take between three and ten years for Southern Rock Lobsters to reach commercial fishing size (SRL 2023).

Adult Southern Rock Lobster are carnivorous and feed mostly at night on a variety of bottom dwelling invertebrates such as molluscs, crustaceans, and echinoderms. The main predators of Southern Rock Lobster are octopus, sharks, and reef fish such as wrasse and ling (SRL 2023).

The latest stock status determination for the Southern Rock Lobster across South Australia, Tasmania, Victoria, and Western Australia details that it is sustainable (FRDC 2021). The 2021/22 Victorian Rock Lobster Fishery Stock Assessment Report (VFA 2023) details the that the egg production for the Western Zone, which the Operational Area overlaps, has been relatively consistent at 23-24% in the last seven years, in 2021/22 egg production was lower at 22.0% but still above the 20% limit reference point. Overall, the stock indicators in the Western Zone continue to show improvement.

The Victorian and Tasmanian Southern Rock Lobster Fisheries close between 1 June and 15 November to protect females in berry (with eggs attached) during the spawning period and between 15 September and 15 November to protect males during the moulting period when soft shells increase their vulnerability (VFA 2023a).

4.2.2 Cephalopods

4.2.2.1 Gould's Squid

The following is from AFMA (2023):

Gould's squid (*Nototodarus gouldi*) is a commercially important species that inhabits temperate and subtropical waters of Australia and New Zealand. They can be found in estuaries and pelagic environments to depths of 825 m but are most abundant over the continental shelf at depths of 50-200 m. Larvae and juveniles are often found in shallow coastal waters. Gould's squid aggregate near the seabed during the day and move into the water column at night to feed.

Gould's squid reach reproductive maturity at an age of 6-9 months. They spawn throughout the year, with 2-3 peaks in spawning activity. Females mate before they are fully mature, with sperm bundles ('spermatophores') from the male being stored in buccal pouches around the mouth. It is not known how long spermatophores are retained before fertilisation occurs. Eggs are fertilised as they pass the buccal pouch and are released in a free-floating jelly-like mass. Each egg mass can contain several thousand eggs, although reproduction is highly variable depending on environmental conditions. Hatching occurs 1-2 months after fertilisation. Gould's squid die shortly after spawning.

Gould's squid feed on crustaceans, fish and cephalopods at night and are in turn prey for birds, large fish, sharks, and marine mammals (O'Sullivan and Cullen 1983).

The species is commercially fished using jigging by the Southern Squid Jig Fishery and is incidental catch for the Southern and Eastern Scalefish and Shark Fishery – Commonwealth Trawl Sector. Fishing mortality and biomass are classed as not overfished.

4.2.2.2 Octopus

The Pale Octopus is a benthic species with no pelagic stage in its development. It has a depth range of 7–275 m and is found from the Great Australian Bight around Tasmania to southern New South Wales (Leporati et al. 2008a, 2008b). It has a single reproductive episode where the females stay with their eggs until they hatch, shortly after which they die. Leporati et al. (2008a, 2008b) details that Pale Octopus have a maximum life span of ~18 months and that peak-spawning season is around late summer and early autumn.

The Gloomy Octopus is unlikely to be present in the Operational Area as it is found throughout Subtropical eastern Australia and northern New Zealand (Australian Museum 2023).

Maori Octopus is the largest octopod in Australasia and can exceed an arm span of 3 m and mass of 10 kg (Lalas 2008). They live in the benthic zone in soft-sediment and rubble habitats from depths of 0-549 m and will sometimes forage in nearby hard-reef habitats but are less common at the fringes between reefal and soft sediment habitats (Animalia 2023).

Currently, only exploratory fishing for octopus is occurring in the western zone that overlaps the Operational Area with Pale Octopus classified as an undefined stock (FRDC 2020a).

4.2.3 Molluscs

4.2.3.1 Abalone (Blacklip and Greenlip)

The Abalone Fishery is one of Victoria's most valuable commercial fisheries. Almost all of the catch is exported to international markets, predominately in Asia. Abalone are caught along the majority of the Victorian coastline and the fishery is primarily based on targeting blacklip abalone (*Haliotis rubra*) although Greenlip abalone are also targeted (*Haliotis laevegata*). Blacklip abalone stocks within the contemporary fishing grounds are fully fished while Greenlip abalone stocks have limited abundance in the Western and Central Zones. Historical catch of greenlip in WZ has been small, with 41.6 t reported landed from 1965-2005, including 37.6 t from 1969-1980 and only 850 kg from 1981-2005. In recent years, greenlip catch has remained low (i.e. <2.0t per year) compared to previous years, and 0 t was landed in the fishing period to December 2022 (Peeters et al 2023).

Blacklip Abalone stocks in Victoria are in relatively poor condition having suffered greatly from disease and overfishing. The pelagic larval duration of abalone is short at ~10 days, nevertheless genetics studies have found that abalone stocks along Victorias south coast are well connected, with high levels of gene flow within and between reef patches. Larval supply and recruitment success may therefore not depend predominantly on local reef sources. The marine physical environment of the south coast is highly variable, driven by converging ocean currents, strong environmental gradients, habitat discontinuities and varying degrees of exposure to wave energy (Miller et al 2016).

Regia MSS will be operating at depths greater than 50m. While almost all diver-harvested abalone will come from depths <30m the majority will come from depths <20m, hence there is approximately 15-20km distance between the 20m and 50m depth contours adjacent to where the proposed Regia MSS will approach the coast.

4.3 People and Communities

4.3.1 Social and economic features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local economy and environment, including commercial species and marine life in general. Species that may be affected are described above in sections 4.1 and 4.2.

4.3.2 Cultural features

Several invertebrate species including torbos, pipis, abalone, limpets, mussels, elephant snails, crayfish/lobster, crabs and squid are identified as culturally significant to the Gunditjmara People as both a resource and in harvesting as a cultural practice (GMTOAC, 2023). Barnabeel (oyster), murrabal (mussel), bam bam (crayfish), abalone and pipi are also culturally important resources to the Wadawurrung People (WTOAC, 2020). Invertebrate species are an important traditional, social and economic resource for the Eastern Maar People. Abalone, cockles and crayfish are collected as tucker along the coast (EMAC, 2015). Invertebrate species may also hold totemic values and kinship. (Appendix F3, Section 3.16.1).

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for all invertebrate species that may be affected. No measures were identified from this process.

6 Defining Acceptable Levels of Impact

To define acceptable levels of impacts to invertebrates the species identified have been grouped according to similarity of impact pathways:

- Crustaceans - Southern Rock Lobster and Giant Crab
- Bivalves (Molluscs)
- Cephalopods
- Coral

Invertebrates do not sense sound pressure but rather particle motion, the other major component of sound waves. Particle motion is a more difficult component to measure, and this has meant most available research on seismic impacts to invertebrates characterises received sound levels in terms of the sound pressure only. Sound exposure levels can nevertheless be used as a reasonable proxy of particle motion at distances >250m from the source but at lesser distances there is too much signal saturation (McCauley et al. 2021).

The sound effect criteria adopted for the assessment of sound impacts to invertebrate groups are based on studies identified and cited in the Seismic Sound Studies Report and Sound Modelling Reports (Appendices B7 and B8 respectively). They have been used to define the acceptable levels of impact.

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment.[1]

Table E4-2 - Defined acceptable levels of impact from underwater sound effects to invertebrates

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	**Commercial Fishing** Fish and aquaculture stocks continue to be assessed as the same stock status they held prior to commencement of the activity. **Crustaceans** Exposure of individual invertebrates to sound levels exceeding 202 dB PK-PK may occur but is acceptable provided that the affected species or functional groups have sufficient abundance, distribution, or	**Commercial Fishing** Whilst this level is not related to a specific sound exposure level, this is a suitable proxy for effects on the commercial species under consideration. **Crustaceans** Payne et al (2008) and Day et al (2016a) Crustaceans are the most studied group in terms of the range of metrics investigated, including catch rates and physical, behavioural, and physiological effects (Carroll et al. 2017). Particle motion rather than sound pressure is the likely mechanism of impacts
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they a documented elsewhere, these criteria are not discussed further in this assessment.

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.	reproductive capacity to maintain population viability and ecological function. .**Molluscs** Sound exposure to molluscs must be below PK-PK sound levels of 212 dB re 1 μ Pa a. **Cephalopods** Sound exposure to cephalopods must be below temporary threshold shifts at thresholds in exceedance of 162 dB SEL. **Corals** Sound exposure to corals and sponges are below 226 dB PK.	for invertebrates however this has not been rarely studied so PK-PK sound pressure is used here, based on work by Payne et al. (2008) who identified no effects on righting time in lobster at 202 dB re 1 μ Pa (PK-PK), and Day et al. (2016a) who found effects at 209 dB re 1 μ Pa (PK-PK). **Molluscs** Day et al (2017). A threshold of PK-PK 212 dB for molluscs is based on sub-lethal effects to scallops and oysters exposed at these levels from Day et al (2017). **Cephalopods** Fewtrell and McCauley (2012). A threshold of 162 dB SEL per-pulse for squid is used, based on the "inking and startle" response from Fewtrell and McCauley (2012). This is the most conservative measure available from the literature. **Corals** Heyward et al. (2018). A threshold of 226 dB PK received levels is used, based on no impacts to coral were identified at this level by (Heyward et al. 2018).
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Therefore, ongoing assessment for social, cultural and economic values will be on a receptor level.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	
	The views of public have been considered in the impact and risk assessment.		

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

7.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. Four main options were considered and subsequently adopted:

No vessel movements within 5 km of the Twelve Apostles Marine Park

This activity limitation was adopted through the consultation process with Marine Parks Victoria. It is protective of cultural values of the marine park and Southern Rock Lobsters which are also a key value.

No vessel movements within 700 m of fishing blocks G12, G13, H13, and H14

During consultation concerns were raised by a fisher regarding the use of a smaller vessel which the fisher launches from a pier in Port Cambell. This restricts the fisher to access deeper waters and limits the fisher to fishing blocks G12, G13, H13 and H14 exclusively (see MAP -REG-EPM-037_A in Appendix 12).

To ensure this fisher was not worse off as a result of the activity, CGG implemented an activity limitation where the Regia MSS would not operate within 700m of Southern Rock Lobster Fishing Blocks G12, G13, H13, and H14. This activity limitation is based on the underwater sound modelling results where 700m is the no effect distance for invertebrates including Southern Rock Lobster, which is the target species fishers in these blocks.

No discharge of the sound source within the West Tasmania Canyons KEF

This measure eliminates potential noise impacts in a KEF characterised by complex bathymetry and high productivity, which may be important for key behaviours for invertebrates. It has been applied by CGG to protect the ecological integrity and invertebrate biodiversity associated with this KEF, which is recognised for its national environmental significance.

No seismic acquisition within 17 km of Deen Maar / Lady Percy Julia Island

This limitation reduced the overlap with most fishing effort in the region and is protective for mobile or short ranging fish species that are more likely to be present in water depth < 50 m. The shallow depths are also where most lobster will settle when ready to do so. This measure was adopted to avoid disturbance to coastal and nearshore invertebrate communities and to prevent elevated acoustic energy in shallow, sensitive environments. This was confirmed during consultation with commercial fishers who agreed that the data was correct and most fishing activities occurred in shallower waters close to ports (Event ID 4107, Feedback ID 1277).

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas

8.1 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. One main option was considered and subsequently adopted:

Sound will not be emitted above the stated capacity

By selecting a sound source and operational settings that remain within a defined maximum acoustic output, the activity substitutes more harmful, higher energy alternatives for lower-intensity ones. This measure was adopted to ensure predicted effects on fish remain within modelled thresholds, avoiding excessive acoustic exposure that could disrupt behaviour or physiology.

9 Predicted Levels of Impact

To arrive at the predicted levels of impact of underwater sound on invertebrates at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on invertebrates. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on invertebrates as described here.

- B6 – Commercial Fisheries Review – all commercial fisheries and their targeted species, associated with the Commonwealth and/or the states of Victoria, Tasmania and South Australia were identified and mapped to indicate fishing effort relative to the proposed Regia MSS.
- B7 – Sound Modelling Reports –SLR) performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including benthic invertebrates, marine mammals, fish, turtles, plankton and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on invertebrates and other fauna. This literature is the key evidence base from which impact levels are derived.

Therefore, all species identified through B6 have been assessed through the framework provided by B7 and B8. Because of commonalities among species in their sensitivity to seismic it is not always necessary to describe effects to each species individually but rather as groups defined by their sensitivity to different frequency levels of sound and shared life-history behaviours.

9.1 Change in fauna behaviour, hearing capacity, and physical condition

As detailed from the underwater sound and studies relevant to seismic surveys, provided in the Seismic Sound Studies Report (Appendix B8), mortality and injury to invertebrates are not predicted based on the received sounds levels to these species.

No impacts to corals are predicted as the threshold in the underwater sound modelling was not reached.

9.1.1 Crustacean - Giant Crab

Giant Crab are likely to be present in the deeper waters (>200 m) of the Operational Area which overlaps areas where Giant Crab are caught by the Victorian Giant Crab Fishery. The Operational Area does not overlap the Tasmanian Giant Crab Fishery.

The extent of the area of impact is predicted to be 232m-397m.

The predicted effect level to this species is assessed as minor. While some level of impact is possible any potential effects are not considered significant or at a level to affect the population given the following:

- Available scientific literature has demonstrated no direct mortality of crabs from exposure to seismic sounds (Morris et al. 2017, Christian et al. 2003, Christian et al. 2004, DFO 2004).
- Sub-lethal effects, relating to impairment of reflexes, damage to the statocysts and reduction in numbers of haemocytes are documented in rock lobsters at received levels of 209 dB re 1 µPa (PK-PK) (Day et al. 2016a) and could also occur in Giant Crab. Based on the distances from the seismic source that these levels would be reached it is possible that some individual Giant Crabs will incur a reduction in fitness. However, there is no evidence to support large-scale fitness reductions or consequential changes to population health.
- A range of studies have exposed female crabs bearing eggs to seismic sound, with no reports of acute or chronic mortality in the adult lobsters and no mortality of embryos

(Christian et al. 2003, DFO 2004, Pearson et. al 1994). Day et al. (2016a, 2016b) also reported that exposures equivalent to approximately 205 dB re 1 µPa (PK) did not impact the condition or development of eggs carried by female lobsters, or the size or morphology of the larvae once hatched. Therefore, potential exposure of berried females to the seismic source is unlikely to result in any mortalities to adult females in addition to natural or fishing mortalities and, therefore, no reduction in the adult spawning biomass.

- No change to development rate in exposed fertilised crab eggs/embryos is predicted compared with unexposed eggs/embryos based on Payne et al. 2008, Christian et al 2003, DFO 2004 and Pearson et al. 1994. Therefore, impacts at a population level due to reduced recruitment would be unlikely as impacts to larvae and eggs were not observed.
- At received noise levels of 209 – 212 dB re 1 µPa (PK-PK) impacts to rock lobster embryonic development were not observed, with hatched larvae found to be unaffected in terms of egg development, the number of hatch larvae, larval dry mass and energy content and larval competency (Day et al. 2016a), thus recruitment should be unaffected. Though a different species, these results align with the outcomes of studies into the effects of seismic on fertilised crab eggs/embryos (Payne et al. (2008), Christian et al (2003), DFO (2004) and Pearson et al. (1994)).
- The stock of Giant Crabs distributed along the Victorian coast is part of a larger, genetically homogenous population that is endemic to southern Australia and maintained through widespread larval dispersion (VFA 2010).

The uncertainty level for impact to Giant Crab from seismic sound is assessed as medium based on:

- There are no published sound effect criteria for acoustic impacts from seismic exposure to crustaceans.
- In the absence of a published sound effect criteria for acoustic impacts from seismic exposure to crustaceans no effects on righting time in lobster at 202 dB re 1 µPa (PK-PK) from Payne et al. (2008) was applied in this assessment as a precautionary threshold to determine potential impacts.
- There are limited published studies on the effects of seismic on Giant Crab, none of which are specific to the species in the Otway region.
- An absence of long-term monitoring data of the effects of seismic exposure on Giant Crab in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) is assessed as medium. For Giant Crab the predicted level of impact is clearly below the defined acceptable levels of impact as detailed in Section 10. The mitigation and management measures detailed in Section 9.2 provide sufficient confidence in the predicted effect levels.

9.1.2 Crustacean - Southern Rock Lobster

The Operational Area overlaps where Southern Rock Lobster are likely to be present in waters up to 150 m, and the nearshore waters where the majority of catch for the Victorian Rock Lobster Fishery occurs. The Operational Area does not overlap the Tasmanian Rock Lobster Fishery.

The extent of impact to Southern Rock Lobsters is predicted to be within 232m-397m from the seismic source.The extent of impact to larvae is predicted to be within 740 m from the seismic source (see Appendix E2 Underwater Sound – Plankton) for on how this distance has been determined.

The duration of the predicted physical and physiological impacts to individuals:

- May be permanent in some adults directly below the sound source.
- May be recoverable in puerulus and is permanent in juvenile life-stages.

The duration of the predicted impacts to the SRL population are uncertain due to potential increased vulnerability to predators and increased intermoult period arising from the possible impacts to individuals. However, given fishery recruitment is largely unimpeded by the Regia MSS, the duration of population level impact is expected to be limited to juveniles in the current cohort.

The predicted effect level to this species is assessed as minor as impacts are predicted to have some effect on Southern Rock Lobster, but the effect is not considered significant or at a level to affect the population given the following:

- Scientific literature has demonstrated no direct mortality of lobsters including eggs, puerulus, juvenile, and adults, proximate to a seismic source (Day et al. 2016a, Payne et al. 2008, Day et al. 2021). The Day et al (2016 and 2021) assessments are considered conservative given the water depths in the Operational Area and the protection afforded by typical habitat features such as holes, crevices, or rocky dens within structurally complex reef habitats in nearshore area where most Southern Rock Lobsters would be present. Scientific studies have detected impacts in shallower water depths, and as scientific literature identifies, behavioural and physiological responses in crustaceans are likely to be related to particle motion effects, located close to the operating array, rather than pressure effects (Carroll et al. 2017).
- Southern Rock Lobster population is sustainably fished meaning that the population is not vulnerable to mortal effects to large portions of the adult populations.
- A single seismic survey has a negligible impact on larval supply by comparisons with the size of the larval populations (McCauley et al. 2000) and recruitment into or out of the area is unlikely to be impaired.
- Pueruli are likely to use a range of orientation cues to locate suitable settlement areas (Hinojosa et al. 2016), reducing the potential impact of increased ambient sound on the ability to locate suitable settlement areas.
- The impact assessment has evaluated impacts from underwater sound on Southern Rock Lobster stocks, including at key life stages based on contemporary scientific literature.
- Conservative thresholds have been adopted and given the small spatial overlap with likely Southern Rock Lobster habitat, the potential for impact at the population level is negligible, localised, and recoverable.
- The Southern Rock Lobster population is highly recoverable shown by the overlaps with the Victorian Rock Lobster Fishing Area which have removed their full quota or close to their quota since quotas were introduced, which was a combined Total Allowable Commercial Catch (TACC) of 286 tonnes of the adult population in 2019/20.
- The Southern Rock Lobster population is resilient to mortal effects because the population is a connected, broadly distributed stock across the whole of southern Australia in water depths from 0 m to 400 m.
- The predicted physical and physiological effects to individuals are unlikely to affect the current population, or future populations, because of the high resilience of the species to more severe impacts.
- Despite the uncertainty in the duration of population level effects, the extent of impacts is ecologically insignificant in comparison to any of the analysed areas.
- This assessment is considered highly conservative given that:
  - Puerulus larvae settle onto reef habitat in shallow waters (50 m to the intertidal zone) not present within the operational area; and
  - Juveniles are normally found in isolated holes and crevices, with larger juveniles and sub-adults residing in large aggregations inside rocky dens within structurally complex reef habitats and are not typically exposed at the seafloor.

The uncertainty level for impact to Southern Rock Lobster from seismic sound is assessed as medium based on:

- There are no published sound effect criteria for acoustic impacts from seismic exposure to crustaceans.
- In the absence of a published sound effect criteria for acoustic impacts from seismic exposure to crustaceans no effects on righting time in lobster at 202 dB re 1 µPa (PK-PK) from Payne

et al. (2008) was applied in this assessment as a precautionary threshold to determine potential impacts.
- There are limited published studies on the effects of seismic on Southern Rock Lobster, none of which are specific to the species in the Otway region.
- An absence of long-term monitoring data of the effects of seismic exposure on Southern Rock Lobster in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) is assessed as medium. For Southern Rock Lobster the predicted level of impact is clearly below the defined acceptable levels of impact as detailed in Section 10. The mitigation and management measures detailed in Section 9.2 provide sufficient confidence in the predicted effect levels.

9.1.3 Molluscs

Molluscs may be present within the Operational Area although no commercial fishing for molluscs such as scallops or abalone was identified within the Operational Area. However, based on consultation with Abalone Fishers a separate assessment on abalone has been added to Appendix F3. The predicted levels of impact as reported for Molluscs as a group are nevertheless the same for Abalone specifically.

As detailed in CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment. The maximum modelled distance to sound effect criteria for molluscs is expected within 90m from the sound source at water depths of 67.4m.

The predicted effect level to this species is assessed as negligible as impacts to molluscs are predicted to have little or no effect on the environment or the affected species, populations, or ecosystems based on:

- The Abalone fishery usually operates in less than 50m water depth, therefore, CGG has implemented an operational constraint where the seismic source will not be operated in water depths less than 50 m, thus impacts to abalone and other molluscs in these water depths are not predicted.

The uncertainty level for impact to molluscs from seismic sound is assessed as medium based on:

- There are no published sound effect criteria for acoustic impacts from seismic exposure to molluscs.
- There are several published studies on the effects of seismic on molluscs, none of which are specific to the species in the Otway region.
- An absence of long-term monitoring data of the effects of seismic on molluscs in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (negligible) and uncertainty (medium) is assessed as medium. For molluscs the predicted level of impact is clearly below the defined acceptable levels of impact as detailed in Section 10. The mitigation and management measures detailed in Section 9.2 provide sufficient confidence in the predicted effect levels.

9.1.4 Cephalopods - Octopus and Squid

The extent of the area of impact is predicted to be a maximum of 2.74 km from the sound source during survey acquisition (CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment.) which would result in a startle response.

The predicted effect level to this species is assessed as negligible as impacts to octopus and squid are predicted to have little or no effect on the environment or the affected species, their populations, or the broader ecosystem. The impact will be localised and temporary, and octopus and squid have the capacity to recover from the impact without significant harm based on:

- Verified impacts remain limited to behavioural startle responses and potentially inking (Fewtrell & McCauley (2102)
- Fewtrell and McCauley (2012) detailed that caged squid exposed to an air gun signal displayed a significant decrease in alarm responses in the second exposure to the air gun noise when compared with the first, supporting general habituation to the sound.
- Mortality and harm to adult octopus and/or hatchlings exposed to seismic was not detected during a targeted study by Day et al. (2023) to octopus.
- While individual octopus and squid may be injured if they are in very close proximity to a seismic source at full power, the use of soft starts will moderate this interaction. This is in addition to the lack of mortality found by Day et al. 2023 in caged individuals. [Paragraph updated in response to Matter I05].

The uncertainty level for impact to octopus and squid from seismic sound is assessed as medium based on:

- There are no published sound effect criteria for acoustic impacts from seismic exposure to octopus and squid.
- In the absence of a published sound effect criteria for acoustic impacts from seismic exposure to octopus and squid, the inking and startle response received level of 162 dB re 1 µPa from Fewtrell and McCauley (2012) was used which provides a conservative assessment as the study was undertaken on caged squid which could not move away from the air gun.
- There are no published sound effect criteria for acoustic impacts from seismic exposure to cephalopods.

The predicted level of impact based on the effect (negligible) and uncertainty (medium) is assessed as low thus good industry practice (including legislation and standards) has been applied and therefore these impacts are of an acceptable level without further reduction measures being required.

9.2 Measures Adopted to Manage Environment Impacts

The following measures have been adopted to ensure that the impacts associated with elevated levels of underwater sound from the survey and support vessels on invertebrates will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
Ramp up of sound source to full power over 30 minutes.	Practice	Mobile marine fauna (including demersal and pelagic fish, octopus, squid, diving birds, penguins, and turtles) are expected to move away from the source before it is at full power, providing them a level of protection. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04, I05, E08].

10 Demonstration impacts will be of an acceptable level

10.1 Principles of ESD

Temporary, Reversible, Small Scale and Natural variation

Site-specific modelling predicts that impulsive sound levels capable of eliciting behavioural or physiological changes in marine invertebrates are confined to a limited spatial extent. Impacts to invertebrates will be predominantly behavioural or sub-lethal, including startle responses such as inking in cephalopods. Except for lobsters, these effects are short-lived and reversible and occur in populations that are naturally resilient to both environmental and fishing-related mortalities. For cephalopods, the predicted distance for behavioural startle response extends up to 2.74 km from the source. For molluscs, the effect distance is 90 m, and since the minimum water depth of the Regia MSS is 50 m, no impacts to molluscs are expected.

Predicted distances for recoverable injury to commercially and culturally significant species are 397 m for Southern Rock Lobster, and up to 397 m for Giant Crab depending on water depth. Modelled distances do not intersect any sensitive benthic habitats or invertebrate spawning areas. Importantly, the scientific literature has demonstrated no direct mortality of lobsters or crabs including eggs, puerulus, juvenile, and adults, proximate to a seismic source (Day et al. 2016a, Payne et al. 2008, Day et al. 2021). Therefore, any mortality or physiological stress that may occur is not expected to exceed natural or fishing-related mortality rates. Effects to invertebrates, where they occur, are considered minor, temporary, and immeasurably small at the population level (Payne et al. 2008, Christian et al 2003, DFO 2004 and Pearson et al. 1994). No impacts to corals are predicted, as the seismic sound thresholds for effect are not exceeded at water depths greater than 50 m. Overall, the predicted impact is low intensity, reversible, and spatially limited.

Based on sufficient information

The assessment utilised site-specific acoustic modelling, a review of peer-reviewed literature (including McCauley et al. 2017 and Day et al. 2016), and available guidance on invertebrate sensitivity to impulsive sound. While invertebrate hearing mechanisms differ from vertebrates and data is limited for some taxa, sufficient evidence exists to characterise likely exposure effects. The most sensitive group identified was cephalopods, and the assessment applied conservative thresholds derived from controlled laboratory studies. No evidence of permanent population-level harm was identified. As a result, the precautionary principle was not triggered.

Activity not inconsistent with EPBC Act

Invertebrates are not currently the subject of specific recovery plans under the EPBC Act. Nonetheless, the assessment reviewed relevant conservation advice for listed marine species and benthic environments, confirming no inconsistency between the activity and the objectives of the Act. No listed invertebrate species or key ecological communities occur within the modelled impact area. Mitigation and environmental management measures adopted for the activity, including soft-start procedures and adherence to spatial boundaries, align with best practice and maintain consistency with EPBC principles.

10.2 Biological and Ecological Categories

Marine invertebrates may display behavioural responses to impulsive sound, particularly within tens of metres of the source. However, the rapid dissipation of sound energy, limited duration of exposure, and lack of evidence of mortality or lasting physiological damage support the conclusion that any biological impacts will be minor. Species with low mobility are likely shielded by substrate, and more mobile taxa can avoid or quickly recover from exposure. No population-level effects are predicted.

The spatial and temporal scale of potential disturbance from seismic sound is too limited to disrupt ecological functions. The affected footprint, which has the potential to cause recoverable injury, but not mortality, moves continuously with the vessel and does not intersect with unique or sensitive habitats. Furthermore, the footprint of the survey area is extremely small in the context of a spatially

very large population that has a high level of connectivity (VFA 2010, VFA 2023, Bruce et al. 2007, Ovenden et al. 1992). Therefore, there is no anticipated cascade effect on trophic relationships, and ecosystem diversity and function will remain intact. Recovery is expected without intervention.

10.3 Economic, Cultural and Social Categories

Several invertebrate species including turbos, pipis, abalone, limpets, mussels, elephant snails, oyster, cockles, crayfish/lobster, crabs and squid were identified through the cultural heritage review, consultation and desktop research as species with social, cultural and/or economic significance that may be impacted by underwater sound. Concerns raised via consultation focused on possible sublethal effects, larval sensitivity, and cumulative exposure alongside fishing pressure. Stakeholders requested additional evidence that recoverable injury would not affect catch rates or access to culturally or economically significant species. In response, CGG integrated updated modelling that confirmed the distance to recoverable injury thresholds for southern rock lobster and giant crab are well within the spatial footprint of the survey and do not overlap with fishing grounds or culturally significant areas.

The assessment confirmed that no spawning areas, traditional harvest sites, or sensitive habitats would be affected, and that effects would be limited to temporary behavioural responses or minor, reversible physiological effects. As these values are closely tied to the physical presence and health of the species, the corresponding social, cultural and economic impacts are likewise considered acceptable. CGG also updated the impact characterisation to better reflect input from relevant persons and added further literature to address uncertainty about indirect ecological consequences. These actions demonstrate that the views of affected persons were seriously considered and incorporated into the environmental assessment. Therefore, industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational impacts; culturally significant species, places, and practices continue without disruption; and people and communities maintain ongoing access to the natural environment, recreational activities, and heritage values without long-term or irreversible effects and no person or group is expected to be materially worse off due to the activity.

10.4 Discussion on Consistency with Company Processes

The impact assessment used the ranking system outlined in Appendix B3. For invertebrates, the overall predicted level of effect was assessed as minor, with uncertainty rated as medium due to limited field validation studies. This reflects the application of conservative thresholds and recognition of remaining scientific uncertainty, while confirming that the impact remains within acceptable company limits. All mitigation measures are in place and effective in managing the impact pathway. The conclusion of the assessment of seismic sound to invertebrates is summarised below.

Invertebrates	Predicted Level of Effect	Uncertainty	Predicted Level of Impact
Giant Crab	Minor	Medium	Medium
Molluscs	Negligible	Medium	Medium
Southern Rock Lobster	Minor	Medium	Medium
Octopus and Squid	Negligible	Medium	Low

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E4-3 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E4-2)	Environmental Performance Outcome	Rationale
Fish and aquaculture stocks continue to be assessed as the same stock status they held prior to commencement of the activity.	No change in the assessed stock status of commercial and aquaculture species during and following the activity.	This EPO is supported through alignment with fisheries science reporting and stock assessments, allowing external verification of biomass trends. It provides a clear threshold for biological consequence and supports cumulative impact management.
Exposure of individual invertebrates to sound levels exceeding 202 dB PK-PK may occur, but is acceptable provided that the affected species or functional groups have sufficient abundance, distribution, or reproductive capacity to maintain population viability and ecological function.		
Sound exposure to molluscs must be below PK-PK sound levels of 212 dB re 1 μ Pa a.		
Sound exposure to cephalopods must be below temporary threshold shifts at thresholds in exceedance of 162 dB SEL.		
Sound exposure to corals and sponges are below 226 dB PK.		
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		

Defined Acceptable Level (From Table E4-2)	Environmental Performance Outcome	Rationale
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

For most species/taxa/groups of invertebrates reviewed, this document provides the final assessment of impacts. However, despite an extensive review of the relevant literature around the effects of seismic on invertebrates, there has been a high level of concern voiced throughout consultation with relevant persons, around the importance of commercially targeted species. High levels of engagement on an aspect are a trigger for CGG to undertake additional assessment. In this case looking at the effects of the activity on certain commercial fish species. This additional assessment is detailed in Appendix F3 – Further Assessment of Key Values and Sensitivities under Section

- 3.5 Southern Rock Lobster
- 3.6 Giant Crab
- 3.8 Goulds Squid
- 3.9 Pale Octopus
- 3.10 Blacklip Abalone
- 3.14 Spawning Patterns

It is important to note that F3 is a response to further information requests and/or clarification and not a reflection of any prior assessment being insufficiently thorough. It is a recognition that more explanation and detail was sometimes necessary to better inform all groups involved in the consultation process, including the regulatory authority.

Hence F3 does not provide further assessment on all aspects and values identified through the EP process only those that were identified as

- Having some residual uncertainty about whether impacts or risks were of an acceptable level; and/or
- Contained environmental values and sensitivities (species) of key importance due to their protection status or commercial value; and/or
- Consultation with relevant persons revealed a particular value or sensitivity required further attention and material to support the consultation.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E4-4 shows how this feedback has been incorporated into the environmental assessments.

Table E4-4 - Public comment input

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Impact Assessments (Appendices E, and F where relevant) to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and the following Activity limitation: the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, G1 and G2).

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E4-5. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E4-5 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4022	Attendees voiced concerns about how seismic activities could impact the sustainability and fish-ability of the immediate and nearby areas.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1529
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey periods. Since acoustic propagation modeling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.	another modelling report prior to submission to cover the changed timeframes of the proposed survey.	
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4047	Concern about spawning activity of the Giant Crab, rather than the impact of the fishing overlap given exclusion of surveying at +200m water depths.	Titleholder acknowledged this concern and carried out an additional impact assessment for Giant crab and spawning species has been included in F3. There is expected to be no measurable effect on giant crab populations as a result of the survey.	4076
4050	Concern about the destruction of smaller sea life and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	1669
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts on biological receptors are outlined in the EP also and can be found in G2.	3237
4054	Concern about the impact on marine species, specifically molluscs, due to the seismic survey.	Titleholder acknowledged this concern and noted that a thorough assessment of the potential impacts to marine invertebrates, including molluscs, from underwater sound is assessed in E4 of the EP.	2089
4059	Concern about the potential impact on the Abalone industry and the need for compensation if marine species are killed off.	Titleholder acknowledged this concern and noted that potential impacts to commercial fisheries from physical presence is assessed in E1 of the EP, and potential impacts to marine invertebrates from underwater sound is assessed in E4 of the EP. Advised that control measures to reduce impacts to commercial fishers as a result of loss of catch are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	2089
4062	Concern expressed regarding the timing of juvenile marine species' settlement, which is critical for their survival.	The titleholder noted the settlement is almost exclusively in inshore waters and the 50 m exclusion would protect querulous. Timing wise the likely settlement time is 9-12 months after spawning. As spawning occurs in Sept/Oct/Nov the settlement is likely in July/Augur/Sept.	3228
4064	Concern raised by the stakeholder regarding the potential damage/kill of marine life due to seismic testing.	Titleholder responded to individual advising that CGG would not propose an activity that would lead to unacceptable impacts to marine life and advised that environmental impact assessments for each aspect of the proposed activity that has the potential to impact marine life were currently being prepared and that they would be based on scientific literature and published shortly for consultation and feedback.	1024
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in	879

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	other companies, particularly regarding the sale of seismic data.	place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4074	Concerns about implications for the population of Rock Lobsters in the area going forward.	This claim has been thoroughly assessed in E1 and E5, and F3 for southern rock lobsters. The known effects to individual lobsters are not predicted to have any measurable effect on population levels or dynamics.	2773
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	722
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4080	Concerns about the impact of seismic testing on various marine species.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	2179
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4551
4083	Concerns about why more seismic needed and what time of the year was the survey going to be done to minimise impacts to fishing for sharks, lobsters, squid	Titleholder acknowledged this concern and each of the species within this claim has been subject to extensive assessment in E1, E3, E4 and F3 with various measure adopted to limit the sound exposure to the lowest level possible to meet geophysical objectives and to protect marine fauna (see G1).	740
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and	2766

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		relevant mitigation measures are outlined in the EP.	
4102	Expresses opposition due to proximity to local fishing industries. Emphasises concern about potential risks this testing poses.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Adjustment protocol in place for fishers to seek compensation if impacted by MSS.	428
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used based around sound, peer reviewed scientific literature.	4190
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4132	Lobsters - Stakeholder claimed that seismic air guns damage rock lobster mechanosensory organs and impair righting reflex - impacts of anthropogenic aquatic noise on marine invertebrates being poorly understood. Cited a study of the impact of seismic surveys on the righting reflex and statocyst morphology of the palinurid rock lobster, Jasus edwardsii, using field-based exposure to air gun signals which showed impaired righting and significant damage to the sensory hairs of the statocyst which persisted up to 365 days post-exposure and did not improve following moulting. These results indicate that exposure to air gun signals caused morphological damage to the statocyst of rock lobsters, which can in turn impair complex reflexes. Stakeholder also	Scientific literature has demonstrated no direct mortality of lobsters including eggs, puerulus, juvenile, and adults, proximate to the seismic source (Day et al. 2016a, Payne et al. 2008, Day et al. 2021). The Day et al (2016 and 2021) assessments are considered conservative given the water depths in the Activity Planning Area and the protection afforded by typical habitat features such as holes, crevices, or rocky dens within structurally complex reef habitats in nearshore area where the majority of Southern Rock Lobsters would be present. Scientific studies have detected impacts in shallower water depths, and as scientific literature identifies, behavioural and physiological responses in crustaceans are likely to be related to particle motion effects, located close to the operating array, rather than pressure effects (Carroll et al. 2017). Our full Southern Rock Lobster	2886

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	referenced study stating seismic surveys leave lobsters flat on their backs and unable to avoid predators, because of damaged statocysts, an organ similar to the human inner ear. It left the lobsters with an impaired ability to right themselves when flipped over.... "We didn't detect any sign of recovery, even one year after. LINK provided.	draft impact assessment is available here on page 13 and 14, for your review.	
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low	537

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	them unacceptable in a whale sanctuary area.	as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	
4153	Presents a historical account of their catch rates over 24 years, indicating that seismic surveys in the past led to a significant decrease in their catch from 10-15 tons per trip to just 5-6 tons per trip for over two years. They now report a catch rate of 10-14 tons per 7 days, suggesting lingering concerns about how current seismic activities may similarly affect their fishing operations.	Titleholder acknowledged this concern and noted that potential impacts to molluscs the Regia MSS is assessed in E1, E4 and F3 of the EP. Advised that control measures to reduce impacts to commercial fishers as a result of loss of catch are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	5190
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Also outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	3697
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and	4091

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	the marine environment as a whole.	resulting measures are specific to the potential impact. The titleholder also made reference to documents relevant to this claim within the environment plan (Event ID 4092).	
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2118
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies,	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to	1659

		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4198	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1672

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4199	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2586
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	2886
4202	Stakeholder objects to the proposed blasting activity due to its detrimental effects on marine ecosystems.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are	1049

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	425
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any	2080

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		evidence you can share so that we can consider it fully prior to our submission.	
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We have to show that the environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	2104
4235	The feedback questions if a strong environmental record includes the severe impacts of seismic activity on fishing industries, like the scallop industry near King Island, which has suffered losses reportedly without compensation.	Seismic survey effects on molluscs, including scallops are well understood and not mortal in our circumstance. There are many environmental pressures that cause fluctuations in fish populations, not just sound. We have a track record of successful co-existence with the fishing industry and of paying reasonable evidence-based claims for compensation - which we will do for the Regia survey.	2083
4239	The feedback raises concerns about the impact of seismic activities on the Abalone industry, suggesting that the industry may be negatively affected by the proposed exploration and seismic testing. This indicates a broader concern for the sustainability of marine life and the economic implications for local fisheries.	It would be unacceptable to have mortal effects on any marine species from our or any marine seismic survey. We do not predict mortal effects to molluscs (including scallops, abalone, oysters, clams, mussels, limpets, squids, octopus and cuttlefish etc.). Our full assessment of predict impacts on molluscs will be made publicly available as soon as it's completed.	2093
4246	The fishing industries in Port Fairy and King Island have reported significant impacts without financial compensation.	Through our extensive research we have not found any evidence of causation between seismic survey and mortal effects on molluscs. In fact, the evidence we have found (which we will publish in full) suggests seismic and fishing can happily co-exist. Please provide references, evidence, or testimonials for your claims so that we can take them into consideration in the proper process (Event ID 2084).	2084
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	3343
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an “exclusion zone” will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	2108
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are	2255

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325
4285	The stakeholder noted their concern as a resident of Port Fairy: noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	1747
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. North West Shoals to Shore Marine Noise Monitoring and Impacts https://www.aims.gov.au/research-topics/monitoring-and-discovery/north-west-shoals-shore Behavioural Response of Australian Humpback whales to Seismic Surveys https://www.brahss.org.au/ Assessing the impact of marine seismic surveys on southeast Australian scallop and lobster fisheries https://www.frdc.com.au/project/2012-	2389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		008 Marine Seismic Survey Impacts on Fish and Invertebrates: Final Report for Gippsland Marine Environmental Monitoring Study https://ecat.ga.gov.au/geonetwork/srv/api/records/2292f4a7-ba2e-3533-e053-12a3070aaf2c Maxima 3D Marine Seismic Survey at Scott Reef https://www.sciencedirect.com/science/article/abs/pii/S0025326X13006528 https://www.sciencedirect.com/science/article/abs/pii/S0025326X18300687 Regarding Marine Fauna Observer's (MFOs), companies that contract MFOs such as Blue Planet Marine and RPS Group provide training for MFOs. As part of contracting MFOs we will ensure that the persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: • Conformance with regulatory requirements detailed in the accepted EP. • Management strategies and procedures to ensure EPOs and EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being monitored, measured, and documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4292	The stakeholder raised concern about the sound level from the survey and its effect on marine mammals and other species.	Outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection	3697

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		technology trails, and citizen science program access. Outlined the effects on zooplankton and the case for acceptability of these impacts noting the movement of the survey timing to avoid the upwelling period. (event ID 3697)	
4293	The stakeholder raised concerns about the lack of evidence of the effects of seismic on abalone.	Noted the distances for effects are likely from particle motion, which is very short range from the sound source.	948
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	3152
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273
4313	The statement challenges that seismic blasting will harm shellfish like scallops, citing research by Ryan Day et al. (2017) that demonstrates physiological harm and altered behaviour in scallops due to exposure to seismic air gun signals.	We understand that there are impacts of seismic surveys. The findings of the paper have been used to define the distance at which some effects may occur. Our current understanding is that the effects are initially sub-lethal, that increased mortality was observed post exposure, and that increased mortality was within natural variation. Our draft assessments will be published soon (Event ID 2078).	2078
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual	2076

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	
4319	There are concerns regarding the potential impacts of seismic surveys on penguins, diving birds, and other marine fauna. Stakeholders are particularly worried about how the noise and disturbance from these surveys could affect the breeding and foraging behaviours of these species.	This effects of sound on birds were initially assessed in E4 and further assessments for penguins can be found in F3. Birds can also be affected by artificial light, which has been assessed in E9. The conclusion is that the measures adopted to protect foraging birds will mean that impacts are of an acceptable level.	2006
4322	There is measurable damage done to one species which will be an example of potential damage to others in the vicinity of King Island and surrounds	While the claim was noted the REGIA EP has conducted an extensive assessment of the literature and found no evidence of measurable damage to populations of invertebrates or fish in the vicinity of King Island and surrounds. The seismic acquisition area is also located ~100km from nearest King Island landfall.	2773
4323	There will be potential permanent damage to marine life due to sonic testing and drilling.	Titleholder responded and listed various information needs related to the activity, environmental assessment process, environmental aspects, predicted levels of environmental impact and risk, environmental management, consultation processes, and regulations or regulatory processes. Links to the project website and document library was provided.	1046
4329	This feedback highlights the uncertainty regarding the long-term impacts of seismic blasting on abalone populations, particularly emphasising that the effects may not be immediately observable and could depend on the juvenile stages at the time of blasting.	We have recently installed an exclusion zone down to the 40m bathymetry contour primarily as a result of discussions with abalone fishers who dive down to 30m. This will help protect early life-cycle stages of abalone. Further, seismic surveys have occurred in this region for many years and the two industries (fishing and petroleum) have successfully coexisted over time (Event ID 2095).	2095
4343	Questions possibility of compensation for the abalone industry if their stocks are depleted as a result of seismic testing, drawing a parallel to the scallop industry near King Island that was adversely affected. It highlights concerns regarding accountability and the financial implications for local fisheries in the event of ecological harm.	The titleholder acknowledged this concern and noted that potential impacts to the abalone industry. It would be unacceptable to have mortal effects on any marine species from our or any marine seismic survey. We do not predict mortal effects to molluscs (including scallops, abalone, oysters, clams, mussels, limpets, squids, octopus and cuttlefish etc.). Our full assessment of predict impacts on molluscs can be found in E1 Section 8, E4 Section 8 and F3 Section 4.	2093

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks	2383

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	
4419	Concern about the potential impacts of seismic surveys on the planktonic phyllosoma stage of Southern Rock Lobster.	Event ID 6820 - The Regia team responded that the information already provided on Southern Rock Lobster shows the scales of connectivity and dispersal that are intrinsic to the stock of Southern Rock Lobster. They show how any impacts to individual rock lobster larvae within the intended area of seismic will be immeasurably small relative to the mortality that is operating across the regional distribution of this species. Such a well-connected, genetically homogenous stock is, by definition, highly resilient to localised disturbances. Evidence of impacts to individual larval lobsters is not evidence of impacts to the stock of southern rock lobsters. This conclusion is based on published papers presented in the previous document and an understanding of life-history dynamics in marine invertebrates.	6411
4420	Research indicating potential impacts of seismic activity to “pruning” of egg clutches by female Pale Octopus.	Event ID 6820 - The Regia team responded that the point raised repeats some of the key findings from Day et al 2023. They stated that they had discussed this in the information previously provided, along with the other implications which indicated that there was no evidence for significant long-term damaging effects or impairment. The Regia team said that it was conflating an effect at the individual level with population-level effects.	6411
4421	Reports on the impacts of a commercial seismic survey off the coast of Victoria on the Pale Octopus indicating a sub-lethal neurotoxic effect capable of altering behaviour and locomotor abilities.	Event ID 6820 - The Regia team responded that the point raised repeats some of the key findings from Day et al 2023. They stated that they had discussed this in the information previously provided, along with the other implications which indicated that there was no evidence for significant long-term damaging effects or impairment. The Regia team said that it was conflating an effect at the individual level with population-level effects. The study showed there were effects to individual octopus, however it also showed great variation in the scale of effects and a lack of evidence to support significant harm. Scale of effects is crucial to understanding outcomes. There are many disturbances acting on marine invertebrates and they span a scale from insignificant to very impactful. Climate changes and commercial	6411

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		fishing are at the very impactful level with potentially large changes to populations. Current science indicates that population changes are not going to result from a stand-alone seismic survey, irrespective of whether individual octopi are affected.	
4422	Uncertainty about whether Giant Crab are sensitive to seismic air gun exposure and if so, to what degree. The relevant person was also concerned about the lack of data on safe threshold distances for exposure.	Event ID 6820 - The Regia team responded that Appendix F3, Section 3.6 (provided a link), provides a specific assessment of the sensitivities of Giant Crab stocks and likely impacts from the proposed Regia MSS. This assessment addresses the questions posed here using all the available science. They recommended this section be read or re-read however they provided relevant excerpts to illustrate the assessment that has been done. Multiple studies have looked at seismic effects on crustacean larvae amongst other taxa, and results have been mixed, with any mortality limited to very close proximity to the source. Adult crab species that have been tested have shown very little response to seismic pulses (Appendix E4 and references therein). They stated that there was no evidence to support an expectation of significant and measurable cumulative impacts to P. gigas because of the MSS. Large scale environmental drivers driven by a changing climate, and fishing effort, will continue to be the major influences on the population health of giant crab. The Regia team reiterated that fishing effort is the major anthropogenic driver of changes to crab populations, and it is this driver interacting with a changing climate that will drive population changes in the future.	6411
4433	Seismic impacts can linger longer than the few hours suggested, the insistence on peer-reviewed work to prove this is opportunistic and suits OMICC's agenda.	Event 6724 - OMICC announces that the latest version of the OMICC Otway Adjustment Protocol has been published, along with a video briefing for fishers, which can be accessed through a provided link. In the briefing, OMICC confirms that, following the relevant persons feedback, a "claim period" and a "lodgement period" have been incorporated into the definitions of the protocol. The claim period is set to 30 days after the end of any activity, while the lodgement period extends up to 6 months after the end date of any activity. OMICC further informs the relevant person that the OMICC Founders reviewed the request for claims up to 6	6749

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		months after an activity. However, the decision was made to adopt a 30-day claim period, as this duration resulted in a positive compensation outcome for fishers affected by the Gippsland survey in 2019.	
4436	The relevant person stated that it was evident what had impacted rock lobsters in the early 2000s.	Event ID 6595 - Titleholder responded to relevant person outlining approach to assessment of fisheries and SRL, including assessment of mitigation in place.	6594
4437	Relevant person was concerned about impacts of seismic to rock lobsters.	Event ID 6595 - The titleholder responded that they had undertaken a thorough assessment of potential impacts on SRL, including a further assessment on the effectiveness of the mitigations in place.	6592
4438	Relevant person was concerned about the impacts of seismic surveys on lobster populations.	Event ID 6875 - The Regia team responded in-meeting and explained that there is an impact of the seismic activity on lobster associated with their righting reflex. Discussed that they needed to look at what the resource tolerates. Discussed research boat in Tasmania and directed relevant person to recent research paper "Boom, Shake the Room."	6875
4439	Concerned about impacts to squid, octopus and scallops.	Event ID 6875 - The Regia team responded in-meeting with a discussion about the assessment work undertaken on impacts to squid, octopus and scallops.	6875
4441	Concerned about the impacts of seismic activities on crab populations.	Event ID 6876 - The Regia team responded in-meeting that seismic can cause a physiological reaction in crab - delayed righting. Discussed that they will only go to 200m.	6876
4443	Concerned that the Regia team said there will be zero effect and that every historical seismic activity has had a worse effect.	Event ID 6876 - The Regia team responded in-meeting that they did not say there would be zero effect. Offered to analyse fishing data provided by commercial fishers and reproduce long-term catchability analysis. An analysis is also included in Appendix F3, section 3.5.3	6876
4444	Concerned that there are no studies about the effect of seismic after adult malting.	Event ID 6786 - The Regia team responded in-meeting and discussed UTAS study which looked into effects of seismic during different stages of juvenile development. Explained that the sample size was very small. Study showed that there is a repairing period. Asked relevant person about malting seasons.	6876
4447	Asserted that non-productive catch areas are a result of seismic activity.	Event ID 6876 - The Regia team responded in-meeting that they could re-run their long-term catchability analysis with data provided by commercial fishers. Stated that they	6876

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		could reduce block size and make it granular.	
4448	Concerned that seismic was hurting the industry and catch rates would be higher but for seismic testing.	Event ID 6876 - The Regia team responded in-meeting and went through their box plot analysis. Explained that the data used was landed catch data each month from 2016 - 2023. Also went through CPUE data set and stated that the analysis showed although landed catch was lower, CPUE was still in range in 2020. Explained the Regia team are looking at recruitment of the fishery. Explained that the fishers take 30% of the fishery. Stated there was evidence there was no stock level effect.	6876
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880
4450	Claimed that the Regia team should avoid September activity window due to female crays carrying eggs.	The effects on berried female Southern Rock Lobsters (SRL) and subsequent recruitment are considered minimal due to the species' high fecundity, variable recruitment patterns, and likely larval input from distant sources. These minor effects are outweighed by the benefits of avoiding impacts to more sensitive species, like blue whales, and avoiding surveys during summer when biodiversity peaks. Additionally, because SRL settle continuously from June to September, there is a high degree of certainty that major stock damage from a September start will not occur.	6876

Underwater Acoustic Sensitive Species 63

1 Introduction

Underwater Sound was identified through the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) as an aspect needing further assessment. Hence this document presents a detailed examination of **Underwater Sound**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental receptor we are collectively calling **Birds.**

This assessment is built on the information contained in the following four core studies, which should be read in the order they are listed:

1. PEIRA
2. Seismic Sound Studies Report (Appendix B8)
3. Sound Emissions Modelling Reports (Appendix B7)

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was initially published in draft form and uploaded to the Document Library of the Regia MSS Consultation Hub on 11 September 2023 as a stand-alone document, rather than as part of the much more substantial total EP document. This was done to maximise the ability of interested members of the public to read, interpret and respond within the mandated 30-day public comment period.

As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In

particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality of the assessment. When this has occurred, reference to such changes will be communicated in Section 0 -

Recommendations and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

The primary sound source will be impulsive underwater acoustic emissions coming from the seismic source releasing compressed air (seismic pulse) and creating a sound wave directed downwards towards the seabed.

Secondary sound sources will include continuous underwater acoustic emissions generated by the survey and support vessels and helicopters. Sounds from vessels are generated by thrusters, engines, and propellers. Underwater acoustic emissions from helicopters are generated via the engine and rotors. Underwater acoustic emissions from Ultra-Short BaseLine positioning beacons are generated within the streamer spread.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days

Extent: Active Source Area + 55 m6 to 10.62 km. based on the furthest distance to modelled sound effect criteria. [Updated in response to Matter: F17]

Seismic acquisition where the seismic source will be active will occur for up to 60 days within the Active Source area.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for underwater sound for the following environmental components and their social, cultural, and economic features:

- Diving birds and penguins.
- People and communities

Potential environmental impacts to bird identified from the PEIRA are:

- Change in fauna behaviour.
- Change in hearing capacity.
- Change in physical condition.

These were initially assessed as not requiring further assessment. However, during consultation with relevant persons it was determined that a detail assessment should be completed.

4 Description of the Existing Environment that may be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8.

To identify diving birds and penguins that may be present within the area affected by underwater sound a PMST search was undertaken using the Active Source Area with a 50 km buffer. Note: the furthest distance to a sound effect criteria was updated to Active Source Area +.10.4 to 77 km for the Little Penguin. [Updated in response to Matter: F17]). The PMST report is available in Appendix B5. The updated furthest distances of 5.6 to 10.62 km have been derived from the most recent modelling study (Appendix B7c), and supersede previously defined predicted effect distances for this receptor group.

To ensure all diving bird species with biologically important behaviours were identified, a further review was undertaken of the Department of Climate Change, Energy, the Environment and Water National Conservation Values Atlas (NCVA) (now AMSIS).

A summary of all bird species identified from the PMST report and review of the NCVA/AMSIS is provided in Annex 3 of this document along with any relevant conservation advice or management plans.

The area above the sound effect criteria for diving birds overlaps the following marine protected areas that identified foraging birds as a value:

- Apollo Australian Marine Park for which one of the values are important foraging area for Black-browed and Shy albatross, Australasian Gannet, Short-tailed Shearwater, and Crested Tern.
- Zeehan Australian Marine Park for which one of the values are important foraging areas for Black-browed, Wandering and Shy albatrosses, and Great-winged and Cape Petrels.

PMST searches were run again prior to resubmission to ensure any changes to species or listings were identified to control for passage of time. A Breeding BIA for the Short-tailed Shearwater was added to the area potentially affected by underwater sound. As of 5th March 2025 the Little Tern has been assigned a threatened category (Vulnerable) under the EPBC Act. The Breeding BIA for the Wedge-tailed shearwater has been removed from area potentially impacted by underwater sound [Section added in response to Matters: I16 and I17].

These species are described below.

4.1 Albatrosses and Petrels

Twelve albatross and six petrel species are identified as having foraging, feeding or related behaviour and/or BIAs within the area potentially affected by underwater sound (Annex 3). These BIAs cover either most or all the South-east Marine Region (CoA 2015a). In addition, the Common Diving-petrel breeds on Lady Julia Percy Island which is within the area potentially affected by underwater sound.

Albatrosses and petrels are among the most oceanic of all seabirds and seldom come to land unless breeding (CoA 2022). Albatross and petrel species exhibit a broad range of diets and foraging behaviours, and hence at-sea distributions are diverse. Combined with their ability to cover vast oceanic distances, all waters within Australian jurisdiction can be considered foraging habitat, however the most critical foraging habitat is those waters south of 25° where many species spend much of their foraging time (CoA 2022).

Albatrosses have a widespread distribution throughout the southern hemisphere. They feed mainly on cephalopods, fish and crustaceans, using surface feeding or plunge diving to seize their prey (ACAP 2020). Albatrosses are colonial, usually nesting on isolated islands and foraging across oceans in the winter months with most observations along the edge of the continental shelf (CoA 2022).

Petrels are oceanic and have a widespread distribution throughout the southern hemisphere. They are colonial and breed on sub-Antarctic and Antarctic islands in a circumpolar band generally between 40°S and 60°S. Petrel species feed on small fish, cephalopods (octopus, squid and cuttlefish) and crustaceans along the edge of the continental shelf and open waters (CoA 2022).

4.2 Black-faced Cormorant (*Phalacrocorax fuscescens*)

The Black-faced Cormorant was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 3). This species is found along the coast of Tasmania and Victoria with two independent populations one on the coast of southern Western Australia, the other on the coasts of South Australia (del Hoyo et al. 1992). Breeding usually occurs on rocky islands, but also on stacks, slopes, and sea cliffs in colonies of up to 2,500 individuals (del Hoyo et al. 1992). It feeds in coastal waters, sometimes in sheltered places such as bays and islets and can be found entering rivers along the coast (CoA 2020a) and thus is unlikely to feed within the area potentially affected by underwater sound.

4.3 Crested Tern (*Thalasseus bergii*)

The Greater-crested Tern was identified as breeding known to occur within the area potentially affected by underwater sound. Crested Terns are medium sized, slender terns that are widely distributed. They are commonly found in near-coastal environments and estuaries, but also inhabit lakes and rivers inland (GSA 2023). They dive from heights of five to eight metres when foraging but only penetrate a few centimetres below the surface of the water (GSA 2023). Their diet includes small fish such as Sardines, Australian Anchovies and Leatherjackets (GSA 2023).

4.4 Gannets (*Morus serrator* and *M. capensis*)

The Australasian Gannet was identified as breeding known to occur and both a foraging BIA and an aggregation BIA within the area potentially affected by underwater sound (Annex 3). The BIA is a 40 km buffer around Portland (Point Danger) where the Australasian Gannet breeds between July and March.

The Australasian Gannet generally feeds over the continental shelf or inshore waters. Their diet is comprised mainly of pelagic fish, but also squid and garfish. Prey is caught mainly by plunge-diving, but it is also seen regularly attending trawlers (CoA 2015a).

The Cape Gannet was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 3). There is limited information on where this breeding location but it is likely that it is also at Point Danger (Portland) based on Pizzey (2007) that details that several birds have occasionally been found breeding on offshore Australian islands, together with Australasian Gannets, although the Cape species is never represented by more than a few pairs.

4.5 Little Penguin (*Eudyptula minor*)

The Little Penguin was identified as breeding within the area potentially affected by underwater sound (Annex 3). Initial investigations identified that breeding occurs on Lady Julia Percy (Deen Mar) Island and Middle Island. Consultation then identified an additional six breeding colonies of variable and unreliable size on the mainland between Portland to the West and Apollo Bay to the East: Gibson Steps, Lawrence Rocks, Griffith Island, London Bridge, the Twelve Apostles and Portland Harbour.

The Little Penguin is the smallest penguin species and endemic to Australia and New Zealand. In Australia, the species occurs from Western Australia (Carnac Island) to New South Wales (Broughton Island) and Tasmania. Their distribution is not continuous, with sections of the southern coast of Australia without occurrence of breeding colonies (CoA 2020a).

The Little Penguin breeds during the austral autumn to summer months and is the only truly nocturnal penguin species on land; adults always arrive after dusk and leave before dawn (CoA 2020a). Females typically lay 2 eggs in a season with most egg-laying occurring between September

and November, with chicks fledging some three months later (Dann et al. 2000), although egg-laying has been observed to start as early as July at Middle Island (Overeem and Wallis 2003).

This species is a generalist feeder, with large variability in diet amongst colonies and even between years at the same colony. They feed mainly on clupeids, such as anchovy and sardines, when feeding chicks, but they may also feed on krill and several species of cephalopods at all stages of breeding (CoA 2020a).

Using electronic tags Hoskins et al. (2008) examined the foraging range and diving behaviour of the Little Penguin from three breeding colonies (Rabbit Island, Kanowna Island and Phillip Island) in central northern Bass Strait, during the chick-guard stage. Although there were large overall differences between individuals, the mean maximum foraging range (16.9 to 19.8 km) and mean total distance travelled (41.8 to 48.0 km) were similar between the 3 colonies, despite different bathymetric environments. Individuals from all three colonies selected foraging habitats within a narrow sea surface temperature (SST) range (16.0 to 16.4°C). While there were significant differences in mean dive depths (5.4 to 10.9 m) and mean durations (13.2 to 28.6 s) between the different colonies, the mean diving effort (vertical distance travelled: 936.3 to 964.3 m h–1) was similar. These findings suggest little penguins from the three colonies employ relatively similar foraging efforts yet are flexible in their foraging behaviours.

McCutcheon et al. (2011) used satellite telemetry to determine the at-sea movements and foraging range of 47 Little Penguins from Phillip Island, south-eastern Australia, during the winter non-breeding period. Individuals conducting single-day trips (72% of individuals) typically foraged 8–14 km from the colony, whereas individuals conducting longer trips (28%; 2–49 days) foraged either within Port Phillip Bay or in the coastal waters of western Bass Strait at maximum distances of 62–147 km from the colony. McCutcheon et al. (2011) noted that the results of this study indicate that Little Penguins remain within continental shelf waters no more than several hundred kilometres from the breeding colony during the non-breeding period, suggesting food availability is adequate within this region throughout the year.

4.6 Little Tern (*Sternula albifrons*)

The Little Tern (vulnerable) was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 3). Little Terns forage in shallow waters of estuaries, coastal lagoons, and lakes, frequently over channels next to spits and banks or entrances, and often close to breeding colonies (DCCEEW 2023). They also forage along open coasts, especially around bars off the entrances to rivers and lagoons, less often at sea, and usually within 50 m of shore (DCCEEW 2023). Little Terns are primarily diurnal, and feed by plunging in shallow water of channels and estuaries, or in surf on beaches, typically from 3–10 m above the surface though up to 13 m above water (DCCEEW 2023).

4.7 Shearwaters (*Ardenna tenuirostris* and *A. pacifica*)

The Short-tailed Shearwater was identified as breeding known to occur (Lady Julia Percy Island) and both a breeding BIA and a foraging BIA to be present within the area potentially affected by underwater sound (Annex 3). The Short-tailed Shearwater migrates to the Northern hemisphere for the austral winter and generally only present in Australian waters from September to May. They are common in the South-east Marine Region and largely found on numerous islands off Victoria and Tasmania during breeding (Baker and Hamilton 2013, Skira et al. 1996). During breeding they conduct a bimodal feeding strategy, alternating short foraging trips to local waters with long foraging trips (up to 17 days) to the Polar Frontal Zone. Short trips allow greater chick provisioning at the sacrifice of body condition, which is then recovered in richer subantarctic waters. Diet includes fish particularly mycotphids, crustaceans and squid (Weimerskirch and Cherel 1998). During consultation breeding colonies were also identified on Middle Island and Griffiths Island [Event ID 2023], and they are of significant value to local communities. These are not identified as BIAs, likely due to a lower number of breeding pairs in comparison to other offshore islands. [Paragraph updated in response to Matter: B07 and B08].

The Wedge-tailed Shearwater was identified as having a foraging BIA within the area potentially affected by underwater sound (Annex 3). The foraging BIA is associated with Muttonbird Island, however, a review of the DCCEEW Species Profile and Threats Database (SPRAT), Atlas of Living Australia and South-east Marine Region Profile did not provide any information on the Victorian Muttonbird Island Wedge-tailed Shearwater colony. The DCCEEW SPRAT profile does not show any locations for the Wedge-tailed Shearwater in Victoria, and Beaver (2018) details Montague Island in NSW was the southernmost known colony, however, in 2017 breeding individuals of Wedge-tail Shearwaters were discovered a couple of hundred kilometres further south on Gabo Island Lighthouse Reserve, Victoria near the NSW border.

Movement patterns of the Wedge-tailed Shearwater are poorly known but populations at the northern and southern extremities of the known range are migratory, departing nests in early April to early May and spending the nonbreeding season in the tropics (DCCEEW 2023a). In Australia, Wedge-tailed Shearwaters have been observed feeding along the junction between inshore and offshore water masses. There is no detailed analysis of the diet of Australian adult Wedge-tailed Shearwater's, however tropical residing Wedge-tailed Shearwater birds are known to mostly consume fish, some cephalopods, insects, jellyfish and prawns (DCCEEW 2023a). Food is taken by contact-dipping, dipping, surface-seizing and, rarely, deep-plunging up to 2 m deep (DCCEEW 2023a).

4.8 Silver Gull (*Chroicocephalus novaehollandiae*)

The Silver Gull was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 3). The breeding area is between Port Fairy and Warrnambool (DCEEW 2023b). Sliver Gulls natural diet consists of insects, worms, fish, and crustaceans. They are not known to plunge dive and thus are unlikely to be affected by underwater sound.

4.9 People and Communities

4.9.1 Social and economic features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local economy and environment, including tourism and local enjoyment of the area with recreational activities such as bird watching. Species that may be affected are described above in sections 4.1 to 4.8.

4.9.2 Cultural features

Short-tailed shearwaters (mutton birds), described above (section 4.7) are identified as being culturally significant to the Gunditjmara People and are used in traditional harvesting practice (GMTOAC, 2023). Shearwaters are also identified as culturally significant species to the Eastern Maar people, along with gannets (section 4.4) and Little Penguins (section 4.5) (Appendix F3, Section 3.16.1).

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for all bird species that may be affected (see Appendix B2). No measures were identified from this process.

6 Defining Acceptable Levels of Impact

There are no regulatory thresholds for understanding underwater sound effects on bird species. Thus, for assessing potential sound–induced impact of impulsive seismic source signals on diving birds, the least sensitive marine mammal hearing group, Other Carnivores in Water (OCW), from Southall et al. (2019), is used as a proxy. This hearing group has been selected due to similar hearing sensitivity in the frequency band of underwater hearing for diving birds and otariid pinnipeds, which are included in the group. This provides a conservative approach, as otariids are considered more sensitive to underwater sound at higher frequencies than diving birds. A very recent study has modelled sound thresholds for Little Penguins (*Eudyptyla minor*) from head scans of deceased birds (Wei & Erbe 2024). Their results indicate a potential disturbance threshold at 50-100 dB above the minimum hearing threshold of ~110 dB re.1 µPa at 200Hz (see Fig. 7 in Wei & Erbe 2024) which supports the use of the modelled thresholds used in CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E5-1 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment.

There are also no regulatory thresholds or criteria established to assess potential behavioural responses by diving birds to underwater sound. To allow for assessing the potential for such impacts, an onset criterion for behavioural responses of 120 dB re 1 µPa (SPL) for impulsive sources was used based on information from Sørensen et al. (2020). They exposed gentoo penguins (*Pygoscelis papua*) in a controlled exposure experiment to underwater noise bursts (impulsive signals) and demonstrated that the animals show a graded reaction depending on received sound levels.

Further information on studies in relation to seismic acoustic emission impacts to diving birds is provided in the Seismic Sound Studies Report (Appendix B8).

Table E5-1 - Defined acceptable levels of impact from underwater sound effects to birds

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Diving birds including little penguins are not exposed to sound levels that cause permanent auditory injury or mortality at any life stage. Any temporary hearing effects to diving birds including little penguins remain brief, recoverable, and do not impair essential functions such as foraging, navigation, chick provisioning, or juvenile development. Any behavioural responses to diving birds including little penguins are minor, short-lived, and do not reduce survival, reproductive success, access to nesting sites, or overall population viability.	Diving birds rely on intact hearing, precise underwater orientation, and highly efficient foraging to meet demanding daily energy budgets. Because permanent auditory injury could compromise prey detection, navigation, or predator avoidance for any diving species, a no-auditory injury threshold is the only defensible injury criterion. Allowing any degree of irreversible hearing loss would create a direct pathway to reduced survival or breeding performance. A separate TTS threshold is appropriate as temporary auditory fatigue occurs naturally across marine vertebrates and does not lead to population-level effects when it is brief and fully recoverable. The scientific evidence consistently shows that short-duration TTS does not impair essential functions for diving birds, provided it resolves quickly. Limiting TTS to this benign, recoverable range provides meaningful protection without imposing unnecessary or scientifically unsupported constraints.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		A behavioural threshold is also essential because the ecological Risk for diving birds arises not only from injury but from disruptions that increase energetic costs or reduce access to foraging or breeding habitats. By restricting behavioural responses to minor, short-lived events, the threshold prevents sustained displacement or reduced provisioning success—outcomes that could otherwise affect reproductive performance across species. Together, these three thresholds—no Auditory injury, tightly bounded TTS, and only minor, transient behavioural responses—cover all biologically credible pathways through which underwater sound could affect diving birds at the population level. They provide comprehensive, proportionate protection while acknowledging that brief, recoverable sensory or behavioural responses are both natural and tolerable for all diving bird species, including Little Penguins.
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Therefore, predicted levels of impact for social, cultural and economic values for species will be assessed on a receptor level. Native Title will be assessed separately.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	
	The views of public have been considered in the impact and risk assessment.		

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. One main option was considered and subsequently adopted:

No seismic acquisition within 17 km of Deen Maar/Lady Julia Percy Island

This island is known for its ecological significance, including bird habitats and potentially sensitive species that rely on the surrounding waters. The buffer zone was applied to provide spatial protection for species utilising this ecologically and culturally important area, thereby reducing potential impacts. For derivation of the 17km buffer please refer to Table 6 in the EP document.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. No substitution-based limitations were required in this case, as the elimination measures applied were sufficient (when applied with other measure types) to reduce the identified impact to an acceptable level.

9 Predicted Levels of Impact

To arrive at the predicted levels of impact of underwater sound on birds at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on birds. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on birds as described here.

- B5 – PMST Reports – The Protected Matter Search Tool was used to search for environmental values and sensitivities potentially located within the proposed Regia MSS planning area, with eight specific searches undertaken of which one was for Birds within the region defined by the Regia MSS Active Source Area with an included buffer area out to 50 km.
- B7 – Sound Modelling Reports - SLR performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including birds, marine mammals, fish, turtles, benthic invertebrates, plankton and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on birds and other fauna. This literature is the key evidence base from which impact levels are derived.

Therefore, all species identified through B5 have been assessed through the framework provided by B7 and B8. Because of commonalities among species/taxa/groups in their sensitivity to seismic it is not always necessary to describe effects to each species individually but rather as groups defined by their sensitivity to different frequency levels of sound and shared life-history behaviours.

9.1 Change in fauna behaviour, hearing capacity, and physical condition

There is very little known about the effects of intense underwater sound (i.e. seismic surveys) on marine birds. It is generally thought that noise produced from activities associated with seismic surveys may impact those species of birds that spend large quantities of time underwater, either swimming or plunge diving while foraging for food.

The acoustic modelling predicted that the criteria for temporary threshold shift (TTS) was reached for the per pulse criteria out to 68 m, and AUD INJ was reached out to 55 m from the sound source. The criteria for TTS was reached for the SEL 24hr criteria out to 1.02 km. The modelled distance to sound effect criteria for behavioural impacts ranged from 5.66 km to 10.62 km.

The predicted effect level to these species is assessed as minor as impacts are predicted to have some effect on birds, but the effect is not considered significant or at a level to affect the population given the following:

- Mortality and injury impacts are not predicted for birds. Though the TTS SEL 24hr criteria was reached within 1.02 km of the source it would be highly unlikely for a diving bird or penguin to be within that distance of the source for 24 hours. As the seismic source will be slowly ramped up to full power over 30 minutes this further reduces the risk of a diving bird or penguin being close to the seismic source at full power.
- Impacts to diving birds and penguins would be limited to behavioural impacts which could range from startle response to moving away from the seismic survey to forage in other areas.
- Seabirds feed on multiple prey species and have widespread foraging areas. Indirect impacts including displacement of prey species such as fish will be limited to the proximity of the sound source. While displacement of some prey species may result in the displacement of these birds, this impact is localised, temporary and recoverable in any one location after the survey vessel moves past. Given their widespread foraging areas (ACAP 2020) and the small area possibly affected by prey displacement, seabirds are not expected to be impacted by

reduced net foraging opportunities. [Paragraph has been added in response to Matters B09, B12, B13 and B14].

- Pichegru et al. (2017) who investigated the behavioural response of endangered African penguins and found that penguins foraging within 100 km of the active seismic operations showed a change of foraging direction during seismic periods, increasing their distance between their feeding area and the location of the seismic vessel from 77 km, compared to ca 65 km on average in the absence of seismic activity. The avoidance behaviour by penguins observed in this study may be explained by either a direct disturbance from the noise generated by the operation or a change in fish distribution during that period (possibly because of seismic activities). Small-scale acoustic fish surveys assessing distribution and MSS.
- The African penguins quickly reverted to normal foraging behaviour after cessation of seismic activities during this study, which suggest a relatively short-term influence of seismic activity on these birds' behaviour and/or that of their prey.
- Increasing energy expenditure at sea to locate food can negatively affect penguins' reproductive output. However, Little Penguins have been shown to travel large distances during chick-guard stage with mean total distance travelled of 41.8 to 48.0 km (Hoskins et al. 2008) and during non-breeding periods at maximum distances of 62–147 km from the colony. Suggesting that changes in areas and distances is dependent on food source and that a temporary increase in foraging distances associated with a seismic survey is unlikely to have a significant impact on individual penguins or the population.
- Little penguins prey mainly on Clupeiformes, including anchovy, pilchard, and sprat during the chick guard phase (Camprasse et al 2017) but they may also feed on krill and several species of cephalopods at all stages of breeding (CoA 2020a), Impacts to little penguin prey is discussed in EP Appendix E3 (Underwater Sound Fish) and E2 (Underwater Sound Plankton). Population impacts to fish and plankton are not expected. Sardines are a key food source in the Otway region hence evidence of significant changes in behaviour of this species and other clupeids in response to a seismic MSS could have flow-on effects to their predators. However, research does not support significant changes in the behaviour of clupeids in the presence of MSS. A key reference that is cited to support seismic effects on penguins (Pichegru et al 2017) found there were no significant changes in distribution and/or abundance of small pelagic fish in the region compared to a few months prior to or after the seismic operations (Pichegru et al 2017). An even more targeted study that exposed herring schools to a full-scale 3D seismic survey off Northern Norway found no changes in the behaviour of herring schools from a transmitting seismic vessel as it approached from a distance of 27 km to as close as 2 km (Pena et al 2013). The schooling behaviour of sardines is complex and varies within and among locations, days, months and years at both spatial and temporal scales (Ward et al 2011). This variability is clearly intrinsic to their behaviour and would influence feeding strategies and adaptability of those species that target them as a food source.
- If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Therefore, the predicted level of impact on the cultural features of the short-tailed shearwater is assessed as minor, as per the points above.

The uncertainty level for impact to birds from seismic sound is assessed as medium based on:

- There are no sound effect criteria for underwater sound for bird species.
- There are limited published studies on the effects of seismic on diving birds, with only one study relevant to penguins.
- An absence of long-term monitoring data of the effects of seismic on birds in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) is assessed as medium. For birds the predicted level of impact is clearly below the defined acceptable levels of impact as detailed in Section 10. The mitigation and management measures detailed in the Section 9.2 provide sufficient confidence in the predicted effect levels.

9.2 Measures Adopted to Manage Environmental Impacts

The following measures have been adopted to ensure that the impacts associated with elevated levels of underwater sound from the survey and support vessels on birds will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
The seismic source will shut down if flocks of foraging birds are observed within 500 m of the source.	Practice	Full power can commence when the seismic source is > 500 m from flocks of foraging birds. This will ensure no Diving Bird specifically little penguin is exposed to sound which would result in mortal injury.
Ramp up of sound source to full power over 30 minutes.	Practice	Mobile marine fauna (including demersal and pelagic fish, octopus, squid, diving birds, penguins, and turtles) are expected to move away from the source before it is at full power, providing them a level of protection. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04, I05, E08].

10 Demonstration Impacts Will Be of an Acceptable Level

10.1 Principles of ESD, Biological and Ecological Categories

Temporary, Reversible, Small Scale and Natural variation

The Regia Marine Seismic Survey will generate underwater acoustic emissions primarily from seismic pulses and vessel operations, which are expected to result in short-term and reversible behavioural effects on marine birds. For species such as the Little Penguin and Short-tailed Shearwater, behavioural disturbance may occur within 5.66 km to 10.62 km of the source, with temporary threshold shifts (TTS) possible within 1.02 km and PTS possible within 55m.. These effects are limited to short-term foraging displacement or temporary avoidance, which are not anticipated to disrupt critical life stages or affect population viability. Seabirds in the area are wide-ranging and behaviourally flexible, allowing them to adjust their foraging patterns as needed. The survey area does not intersect with core breeding sites, Biologically Important Areas (BIAs), or key marine protected zones. Ecosystem-level effects, such as prey displacement, are considered negligible and localised, with no disruption to biodiversity, species interactions, or ecological processes. Overall, the impact is temporary, reversible, spatially limited, and of low ecological consequence.

Little Penguins

Temporary and Reversible

Potential impacts of sound exposure on little penguins during the Regia MSS are expected to be temporary, reversible, and of small spatial and population scale. Across all life stages, little penguins are known for their behavioural flexibility, which allows them to maintain essential activities even in the presence of short-term disturbances.

As described in the impact assessment, Pichegru et al. (2017) found penguins altered foraging direction within 100km of a seismic source but reverted back to normal behaviour after seismic ceased, foraging adults little penguins may exhibit temporary avoidance or minor changes in foraging effort in response to sound, but these responses are brief and do not affect survival or breeding output. Even older individuals (senescent penguins) are able to sustain essential behaviours such as resting and feeding without experiencing undue energy expenditure or elevated predation.

As described in the impact assessment, Hoskins et al. (2008) noted little penguions have the ability to increase their foraging ranges, therefore during the chick-rearing period (September to December), adult little penguins can continue to provision their young successfully, and juvenile development proceeds without hearing impairment. While temporary behavioural changes may occur, such as altered foraging patterns, these do not affect chick survival or population viability.

As described in the impact assessment, changes in abundance or distrubution to little penguin prey (i.e Clupeiformes, including anchovy, pilchard, and spratand krill) are not expected, as described by Pichegru et al. (2017). Impacts to little penguin prey is discussed in EP Appendix E3 (Underwater Sound Fish) and E2 (Underwater Sound Plankton). Population impacts to fish and plankton are not expected. Knock on effects to little penguins are not expected.

Reproductive behaviours such as courtship and pair bonding occur on land and are therefore not expected to be affected by the Regia MSS. Similarly, egg formation, incubation, and nest attendance take place within terrestrial nesting sites, where penguins remain protected from underwater acoustic exposure. As such, these critical life stages are not predicted to experience disturbance or injury from the activity.

Overall, the available evidence supports the conclusion that any behavioural responses by little penguins to sound generated during the Regia MSS will be short-lived, non-injurious, and will not result in biologically significant impacts to the species.

Natural variation

The activity will be managed to prevent injury to birds including little penguins and so that areas and periods important to biologically important to foraging and reproduction are avoided or prevented.

Therefore, it is not possible for impacts to important foraging locations to be greater than natural variations of these ecological processes. The Regia MSS does not overlap with any little penguins BIAs.

There may be temporary behaviour impacts to little penguins during the chick rearing. Given little penguins have the ability to increase their foraging distances based on prey availability (Hoskins et al. (2008) and prey distribution is not expected to be impacted by the MSS (Pichegru et al. 2017), any foraging displacement as a result of a behavourial disturbance would not result in little penguins increasing their foraging distances outside of their natural abilities.

Based on sufficient information

The assessment drew upon SLR acoustic modelling, species presence data (PMST and NCVA), and peer-reviewed literature including studies on underwater hearing in birds (Wei & Erbe 2024) and behavioural thresholds (Sørensen et al. 2020). While specific data on seismic sound effects on birds is limited, particularly for penguins, appropriate proxies were used to adopt a precautionary approach. Behavioural thresholds were conservatively set, and modelling results indicated that predicted exposure levels remained below thresholds for serious harm. Consequently, while some uncertainty remains, the assessment was based on a sufficient body of evidence and did not necessitate invoking the precautionary principle.

Activity not inconsistent with EPBC Act

CGG reviewed relevant conservation advice, management, and recovery plans for all identified species. There are no regulatory thresholds for underwater sound impacts on birds, but the assessment incorporated acceptable levels of impact based on the best available science. The approach is consistent with EPBC conservation advice for species such as the Little Tern and Short-tailed Shearwater. Mitigation and performance measures address concerns raised through consultation and are aligned with legislative requirements, ensuring consistency with the EPBC Act and associated planning instruments.

10.2 Economic, Cultural and Social Categories

The cultural heritage review, desktop research and consultation with relevant persons, cultural representatives, and the public identified concerns regarding potential impacts to seabird populations, birdwatching activities, tourism, and culturally significant species such as the Little Penguin and Short-tailed Shearwater.

These concerns were addressed by refining species presence data, incorporating literature on behavioural responses and foraging flexibility, and improving the clarity of exposure thresholds. Although some short-term behavioural responses are predicted, no injury, mortality, or disruption to breeding or foraging success is expected. Mitigation measures adopted in response to feedback include the potential reduction of source power if foraging birds are observed within 500 m of the vessel. As these values are closely tied to the physical presence and health of the species, the corresponding social, cultural and economic impacts are likewise considered acceptable.

Public submissions prompted further clarification of species listings, foraging ranges, and criteria used in the risk assessment. These inputs were reviewed, assessed for merit, and integrated where appropriate, demonstrating a transparent and responsive approach to relevant person engagement. Therefore, industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational impacts; culturally significant species, places, and practices continue without disruption; and people and communities maintain ongoing access to the natural environment, recreational activities, and heritage values without long-term or irreversible effects and no person or group is expected to be materially worse off due to the activity.

10.3 Discussion on Consistency with Company Processes

The impact assessment followed the methodology outlined in Appendix B3 and applied defined thresholds for both physiological and behavioural effects. For birds, the effect level was assessed as minor, with an uncertainty rating of medium, resulting in a final predicted impact level of medium. The predicted sound footprint was compared against the distribution and foraging ranges of identified bird species, including the Little Penguin and Short-tailed Shearwater. All mitigation measures required by regulation and good industry practice, such as ramp-up protocols and source

power reduction in proximity to foraging birds, were incorporated. No exceedance of injury thresholds or high consequence outcomes was identified, and the final consequence rating remains within company limits.

This impact assessment has demonstrated that the effect of underwater sound to birds has a:

- **Predicted level of effect of minor (2).**
- **An uncertainty of medium (3).**
- **Predicted level of impact of medium (6).**

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E5-2 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E5-1)	Environmental Performance Outcome	Rationale
Diving birds including little penguins are not exposed to sound levels that cause permanent auditory injury or mortality at any life stage.	**No death or injury to fauna, including listed threatened or migratory species, from the activity.**	This EPO can be demonstrated through pre-activity acoustic modelling, exclusion zone design, and shutdown protocols when birds are observed in zones where threshold exceedance is predicted.
Any temporary hearing effects to diving birds including little penguins remain brief, recoverable, and do not impair essential functions such as foraging, navigation, chick provisioning, or juvenile development.		
Any behavioural responses to diving birds including little penguins are minor, short-lived, and do not reduce survival, reproductive success, access to nesting sites, or overall population viability.		
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	This EPO ensures that the activity is managed in a way that prevents unacceptable impacts to social, cultural, and economic values associated with marine mammals.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		

Defined Acceptable Level (From Table E5-1)	Environmental Performance Outcome	Rationale
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

For most species/taxa/groups of birds reviewed, this document provides the final assessment of impacts. However, despite an extensive review of the relevant literature around the effects of seismic on birds, there has been a high level of concern voiced throughout consultation with relevant persons, around the prevalence of Little Penguin colonies in the region and the potential impact of seismic on their activities. High levels of engagement on an aspect are a trigger for CGG to undertake additional assessment. In this case looking at the effects of the activity on interfering with the ability of Little Penguins to undertake their normal behaviours. This additional assessment is detailed in Appendix F3 – Further Assessment of Key Values and Sensitivities under Section

- 3.4 Little Penguins

It is important to note that F3 is a response to further information requests and/or clarification and not a reflection of any prior assessment being insufficiently thorough. It is a recognition that more explanation and detail was sometimes necessary to better inform all groups involved in the consultation process, including the regulatory authority.

Hence F3 does not provide further assessment on all aspects and values identified through the EP process only those that were identified as

- Having some residual uncertainty about whether impacts or risks were of an acceptable level; and/or
- Contained environmental values and sensitivities (species) of key importance due to their protection status or commercial value; and/or
- Consultation with relevant persons revealed a particular value or sensitivity required further attention and material to support the consultation.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E5-3 shows how this feedback has been incorporated into the environmental assessments.

Table E5-3 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Impact Assessments (Appendices E, and F where relevant) to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Acknowledgement of breeding colonies	B07	EP Appendix E5 has been updated to include specific mention of the Short-tailed Shearwater.
Matter: Underwater sound impacts on shearwaters	B08	Information has been added to EP Appendix E5 regarding the shearwater colony on Griffiths Island, Victoria.
Matter: Impacts on prey species	B09	Information has been added to EP Appendix E5.
Matter: Impacts to diving birds and their prey	B12	Information has been added to EP Appendix E5.
Matter: Consideration of olfactory foraging in seabirds	B13	Information has been added to EP Appendix E5.
Matter: Community level and cumulative impacts	B14	Information has been added to EP Appendix E5.
Matter: Mitigating sound exposure impacts to seabirds	B15	Clarification has been provided in EP Appendix E5 (Impact Assessment – Underwater Sound: Birds) that the acoustic source will be reduced to the low power setting if flocks of foraging birds are observed by the Marine Fauna Observer within 500 m of the source. Full power can commence when the seismic source is > 500 m from any flocks of foraging birds.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and the following Activity limitation: the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion human health safety criterion for recreational divers, surfers and swimmers along the coastline CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F3, G1 and G2).
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection

		status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E5-4. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E5-4 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4023	Behavioural Response Threshold & Seismic Sound Avoidance: If CGG conducts seismic blasting within 82.8 km of any Fairy Penguin colony during the breeding season, the penguins may experience discomfort and hearing interference, leading them to alter their behaviour to avoid the seismic source. This distance combines the maximum foraging range for a single day trip and the modelled distance for behavioural response thresholds.	CGG has included the study by Pichegru et al. (2017) on penguins in the EP and has referred to this study multiple times across multiple documents See specific examples below: B8 Seismic Study Report, Section 7, Birds: E5 Underwater Sound- Birds Section 6 F3 Section 4.4.1, 4.4.3 and 4.4.4.	5117
4226	The email expresses concerns about the adverse effects of blasting the southern ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4024	Birds and the little Penguin Colony having to travel further away for food and shelter during seismic testing times, causing stress and fatigue.	The titleholder acknowledged the feedback, noting that impacts and risks to penguins are assessed in the Environmental Plan (EP) and can be found in E5 and F3. F3 focuses on foraging capabilities in the area and the potential overlap with the Regia MSS. There is an overlap between the foraging range of little penguins at Deen Maar and the Regia MSS. This overlap is ~5.3 hours spread over 3.5 weeks; therefore, we do not believe little penguins will be displaced from foraging areas.	1784
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey periods. Since acoustic propagation modelling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete another modelling report prior to submission to cover the changed timeframes of the proposed survey.	3384
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4050	Concern about the destruction of smaller sea life and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information	1669

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts on biological receptors are outlined in the EP also and can be found in G2.	3237
4055	Concern about the impact on shearwater birds and their breeding ground at Griffith Island.	Titleholder has conducted a thorough assessment of the literature, with potential impacts to birds assessed in the Environmental Plan (EP) (E5). Measures to minimise potential adverse impacts birds are also outlined in the EP (G2).	2908
4056	Concern about the impact on the Penguin colony at Middle Island.	This effects of sound on penguins were initially assessed in E4 and was later subject to further assessment in F3. The conclusion is that the measures adopted to protect foraging penguins will mean that impacts are of an acceptable level (See G 1 for a list of measures adopted).	2908
4061	Concern about the welfare of whales, seals, and birds due to the activity.	The titleholder acknowledged concerns outlined in email regarding welfare of whales, seals and birds due to the activity. Outlined approach to assessment that included demonstrating that impacts to these species will be of an acceptable level and advised that it had been determined that is acceptable to have a temporary behavioural change such as moving away from the survey vessel and that injury or long-term impacts were not acceptable.	835

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4063	Concern for various birds and little penguins and the effects of sound and light.	Impacts from underwater sound and artificial light on birds, including little penguins, are assessed in the Environmental Plan (EP) and can be found in E5 and E9. Further assessment of little penguins was also undertaken by CGG to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level. Measures to minimise adverse impacts on birds in the region are also outlined in the EP.	1783
4064	Concern raised by the stakeholder regarding the potential damage/kill of marine life due to seismic testing.	Titleholder responded to individual advising that CGG would not propose an activity that would lead to unacceptable impacts to marine life and advised that environmental impact assessments for each aspect of the proposed activity that has the potential to impact marine life were currently being prepared and that they would be based on scientific literature and published shortly for consultation and feedback.	1024
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	722
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4080	Concerns about the impact of seismic testing on various marine species.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	2179
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions	4551

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4094	Effects of seismic testing on birds and the little Penguin Colony and their ability to return to chick, leading to a decimation in colony numbers.	The titleholder responded with some information relating to the large distances normally travelled by some seabird species to search for food sources for their chicks (Event ID 2910).	1784

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	2766
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4119	Implications For Hearing Interference: This persistent loud noise from the proposed activity poses stress to the Fairy Penguin colonies in Western Victoria, potentially interfering with their hearing. Such interference may hinder prey detection and foraging success, affect predator detection and avoidance, disrupt environmental assessment while swimming, and impair essential communication between individuals. Penguins rely on vocalizations to communicate with mates and for parents to locate their young. Ongoing stress and hearing interference could harm individuals, populations, and reproductive success within the colonies.	The following statements can be found in Section 5: Sound Effect Criteria of the document titled Impact Assessment for Underwater Sound: Birds (E5): “There are no regulatory thresholds for underwater sound for bird species. Thus, for assessing potential sound–induced impact of impulsive seismic source signals on diving birds, the least sensitive marine mammal hearing group, other carnivores in water (OCW), from Southall et al. (2019), is used as a proxy. This hearing group has been selected due to similar hearing sensitivity in the frequency band of underwater hearing for diving birds and otariid pinnipeds, which are included in the group. This provides a conservative approach, as otariids are considered more sensitive to underwater sound at higher frequencies than diving birds.” “There are also no regulatory thresholds or criteria established to assess	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		potential behavioural responses by diving birds to underwater sound. To allow for assessing the potential for such impacts, an onset criterion for behavioural responses of 120 dB re 1 µPa (SPL) for impulsive sources was used based on information from Sørensen et al. (2020). They exposed gentoo penguins (Pygoscelis papua) in a controlled exposure experiment to underwater noise bursts (impulsive signals) and demonstrated that the animals show a graded reaction depending on received sound levels." These statements relate to the complexity surrounding the assessments of impacts of sound on bird species due to gaps in scientific literature and research available to date. These statements also present how best efforts have been made to understand how birds, including the Little Penguin, may be impacted by the seismic survey, given the limited information currently available. The above-mentioned impact assessment has stated our prediction that impacts from the seismic activity are expected to have some effect on birds, but that this effect is predicted as minor and is not considered significant or at a level to affect any bird population. CGG are therefore in agreement with you that some ecological and biological-related impacts to Little Penguin individuals may occur. CGG does not believe however, that potential impacts to this species would be at a significant or population level if they were to occur. The reasons for this assessment are stated and explained in this above-mentioned document and so CGG encourages you to read this for a fully comprehensive explanation. Some of the explanations that CGG believe relate to your concerns can be found in Section 6: Predicted Levels of Impact where explanations are made as to why mortality and injury are not predicted in relation to survey design and soft-start implementation, why impacts to birds are predicted to be behavioural only, and why this behaviour-related displacement is not expected to impact foraging opportunities. Some references to findings from relevant studies on penguins and seismic activity have also been discussed here to aid in the assessment of predicted levels of impacts on penguins from the seismic survey. To summarise, CGG believe the concerns you have raised on this matter have been addressed both in this response and in the referenced section of the document.	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used based around sound, peer reviewed scientific literature.	4190
4127	Lack of Acknowledgement of the Fairy Penguin Breeding Colonies in Western Victoria in CGG's Environment Plan, as well as No Acknowledgement of their Biologically Important Foraging Areas.	We believe there is some confusion here on what Biologically Important Areas are. Biologically Important Areas are regions where aggregations of individuals of a particular species are known or likely to display important behaviours such as breeding, foraging, nesting or migration. They have been identified from the literature and using expert scientific knowledge about species' distribution, abundance and behaviour (Australian Marine Parks, 2024). Biologically Important Areas were established to guide decision-making under the Environmental Protection and Biodiversity Conservation Act of 1999. These areas have been designated for a specific group of protected species, selected based on their conservation status and the availability of dependable spatial and scientific data. There are two sources we would use to identify Biologically Important Areas, the Protected Matters Search Tool and the National Conservation Values Atlas website. The closest Fairy Penguin BIA is around Christmas Island (off the northeast coast of King Island), and it is a designated foraging BIA. Nonetheless, just because the colonies are not BIA's doesn't mean they don't deserve consideration in our Environmental Plan. Little Penguins are discussed in detail in E56 Section 4.5, here we have acknowledged the breeding colonies on both Middle Island and Lady Julia Percy Island. See excerpt from E5 below: "The Little Penguin was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 3). Within this area, breeding occurs on Lady Julia Percy Island and Middle Island." CGG will amend the Environmental Plan to include references to fairy penguins located at London Bridge, Gibson Steps and Lawrence Rocks.	5117
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise	4808

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		adverse impacts on marine life are outlined in the EP in G1.	
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389
4142	Non-specific Sound Modelling & Hearing Damage: Current sound modelling for Fairy Penguins is based on their hearing sensitivity but relies on comparisons to the least sensitive marine mammal group, "Other Carnivores In Water," which includes much larger species like the Australian Fur Seal. This comparison is questionable, as these seals can weigh up to 360 kg—360 times the size of a Fairy Penguin—and have distinct ear structures that allow them to close their ear openings underwater. Thus, using such morphologically different species to assess safe sound levels for Fairy Penguins raises significant concerns about the appropriateness of the assumptions being made regarding potential impact risks.	The following statement can be found in Section 5: Sound Effect Criteria of the document titled Impact Assessment for Underwater Sound: Birds (E5) of the Regia MSS EP in reference to choosing the least sensitive marine mammal hearing group, Other Carnivores in Water, as a proxy for diving birds in assessing potential sound-induced impact of impulsive seismic source signals on diving birds: “This hearing group has been selected due to similar hearing sensitivity in the frequency band of underwater hearing for diving birds and otariid pinnipeds, which are included in the group. This provides a conservative approach, as otariids are considered more sensitive to underwater sound at higher frequencies than diving birds.” CGG acknowledges that sound modelling information in relation to diving birds was a proxy, due to insufficient information and regulatory thresholds currently available to accurately conduct this modelling using diving bird data. CGG does however believe that a well-justified and conservative approach has been taken to assess the relevant impact. As highlighted in this concern, CGG does not believe that the association of the Little Penguin with the “least sensitive marine mammal hearing group” is a problem as it has been made evident that the use of this proxy is a conservative approach as this group of marine mammals are more sensitive to underwater sound at higher frequencies than diving birds. CGG agrees that otariid pinnipeds are morphologically physiologically distinct	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		from Little Penguins, but as explained above, despite these differences these marine mammals are considered more sensitive to underwater sound at higher frequencies than Little Penguins. This is evidence that morphological and physiological differences does not necessarily dictate sensitivity and susceptibility to underwater noise.	
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and	3697

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Also outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4161	Related to the effects of seismic testing on various birds, in particular the Little Penguin colony at Middle and Griffith Islands.	The titleholder provided information regarding the update of the environment plan to reflect the inclusion of various seabirds, including the Little Penguin, at the location of concern, not previously accounted for in the environment plan. The titleholder responded with some summarised information from the paper the stakeholder provided about foraging penguins and its relevance to the Regia MSS (Event ID 2910).	2908
4162	Related to the effects of seismic testing on various birds, particularly the Little Penguin colony.	The titleholder responded with a provision of a document link to the titleholder's preliminary impact and risk assessment relevant to shorebirds, some information regarding light being a likely cause of effect on nesting seabirds, and the titleholder has explained the process by which they conducted the relevant impact assessment in line with government guidelines (Event ID 1792). The titleholder provided information regarding the update of the environment plan to reflect the acknowledgement of various seabirds, including the Little Penguin, not previously accounted for in the environment plan (Event ID 2910).	1783
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also referred to documents relevant to this claim within the environment plan (Event ID 4092).	4091

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2118
4182	Seismic testing's impact on migratory seabirds and their flight path movements.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any birds within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1247
4186	Stakeholder expressed concern about the destruction and	Petroleum activities do not operate to a no-impact standard. Instead, the Regia	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	depletion of the ocean due to the activity.	MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels.	1659

4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments are covered below in response to concern 6.	2886
4202	Stakeholder objects to the proposed blasting activity due to its detrimental effects on marine ecosystems.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	425
4226	The email expresses concerns about the adverse effects of blasting the southern ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4228	The EP uses inaccurate and misrepresented data and subsequent assumptions regarding	We appreciate the effort you have undertaken to understand the EP however, page 195 of the	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	the assessment of Fairy Penguins and their behaviours.	Environmental Plan which you have referenced is part of the PEIRA (Preliminary Environmental Impact and Risk Assessment). For context, the PEIRA was written in March 2023 and is only the first step when preparing an Environmental Plan. The purpose of the PEIRA is to a priori, identify key environmental sensitivities and provide an initial evaluation of the environmental impacts and risks associated with the Regia MSS. This is a 'first pass' to support the consultation efforts, it is not the full impact assessment. The full assessment reflects all the feedback from consultation and contains extra assessment as identified. The Fairy Penguin exemplifies the importance of public consultation in the Environmental Plan process. The PEIRA was drafted before public consultation began, and since the colonies along the western Victorian coastline were not designated as BIA's, they were not identified in the PEIRA. However, the Middle Island population of Fairy Penguins was identified through public consultation and subsequently discussed in the Impact Assessment (E5 - Underwater Sound - Birds). It is crucial to read the Environmental Plan in its entirety to fully understand the impact assessment and mitigation measures. Little Penguins are discussed in detail in E56 Section 4.5, here we have acknowledged the breeding colonies on both Middle Island and Lady Julia Percy Island. See excerpt from E5 below: "The Little Penguin was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 3). Within this area breeding occurs on Lady Julia Percy Island and Middle Island." CGG will amend this section of the EP to include the other breeding colonies mentioned above. Regarding the information on the Australian Wildlife website, the table you produced is accurate. However, it's important to note that CGG has not misrepresented the science here. Context is crucial: while it is stated that during the non-breeding season, penguins may forage up to 700 km, the majority remain within 20 km. 700 km foraging trips are not undertaken by most animals and represent the extreme range of travel for this species. Therefore, we consider the average foraging distance to be 20 km. We would recommend you read E5 of the Environmental Plan, we have discussed in detail the fairy penguin and	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		information regarding foraging, see excerpt below: "Hoskins et al. (2008) examined the foraging range and diving behaviour of the Little Penguin from three breeding colonies (Rabbit Island, Kanowna Island and Phillip Island) in central northern Bass Strait, during the chick-guard stage using electronic tags. Although there were large overall differences between individuals, the mean maximum foraging range (16.9 to 19.8 km) and mean total distance travelled (41.8 to 48.0 km) were similar between the 3 colonies, despite different bathymetric environments. Individuals from all three colonies selected foraging habitats within a narrow sea surface temperature (SST) range (16.0 to 16.4°C). While there were significant differences in mean dive depths (5.4 to 10.9 m) and mean durations (13.2 to 28.6 s) between the different colonies, the mean diving effort (vertical distance travelled: 936.3 to 964.3 m h–1) was similar. These findings suggest little penguins from the three colonies employ relatively similar foraging efforts yet are flexible in their foraging behaviours. McCutcheon et al. (2011) used satellite telemetry to determine the at-sea movements and foraging range of 47 Little Penguins from Phillip Island, south-eastern Australia, during the winter non-breeding period. Individuals conducting single-day trips (72% of individuals) typically foraged 8–14 km from the colony, whereas individuals conducting longer trips (28%; 2–49 days) foraged either within Port Phillip Bay or in the coastal waters of western Bass Strait at maximum distances of 62–147 km from the colony. McCutcheon et al. (2011) noted that the results of this study indicate that Little Penguins remain within continental shelf waters no more than several hundred kilometres from the breeding colony during the non-breeding period, suggesting food availability is adequate within this region throughout the year." Multiple studies across spatially distant locations all found that average foraging distances for birds during nesting season were within 20km with a few km of variance around this. There is still extended foraging by individual birds on occasion, but this is not the norm. Feeding ranges are ultimately constrained by availability of food and we have reported the health and abundance of sardines and squid in the region adjacent to the Regia MSS. It has also been noted by Norman et al (2017) that the presence of upwelling in the nearby region equates to greater	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		productivity and hence why penguins in this area do not have to travel as far to obtain food. We recognize the (Berlincourt & Arnould, 2015) is more up to date than the references use in E7, and as a result CGG undertook a literature review to ensure the most up to date information is used in the EP.	
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We have to show that the environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	2104
4237	The feedback questions whether the potential impact of seismic blasting on the local food supply, including fish and zooplankton essential to the marine ecosystem, has been considered, expressing concern over the ability of penguins and other marine life to feed if these populations are diminished.	The titleholder is studying the little penguins and will put in place protections for them. The titleholder ensures detail of the impact assessment of the effects of elevated levels of sound will be published shortly. The titleholder ensures they will consider all life-cycle stages of the penguin and the ecosystem effects, including those pressures on the food chain.	2079
4238	The feedback raises concern about the foraging distance penguins travel at night to feed themselves and their young, urging consideration of this range in seismic planning.	We are studying the little penguins and will put in place protections for them. The detail of our impact assessment of the effects of elevated levels of sound will be published shortly. We will consider all life-cycle stages of the penguin and the ecosystem effects, including those pressures on the food chain (Event ID 2079).	2079
4253	The possible effects to marine life and ecosystems is my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact	2117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	3343
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an “exclusion zone” will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	2108
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the	2255

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	more important than existing marine life and structures.	acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325
4285	The stakeholder noted their concern as a resident of Port Fairy: noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	1747
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. As part of contracting MFOs we will ensure that the persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: • Conformance with regulatory requirements detailed in the accepted EP. • Management strategies and procedures to ensure EPOs and EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being monitored, measured, and documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	3152
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273
4315	The statement suggest that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4323	There will be potential permanent damage to marine life due to sonic testing and drilling.	Titleholder responded and listed various information needs related to the activity, environmental assessment process, environmental aspects, predicted levels of environmental impact and risk, environmental management, consultation processes, and regulations or regulatory processes. Links to the project website and document library was provided.	1046
4331	This feedback raises concerns about the negative impact of seismic blasting on local commercial rock lobster and scallop fishing industries.	This claim has been thoroughly assessed in E1, E5, and F3 for southern rock lobsters. There is no commercial scallop industry in the region. The known effects to individual lobsters are not predicted to have any measurable effect on population levels or dynamics.	2097

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4345	The stakeholder asked how we can be sure that seismic blasting will not harm penguins when conducted 60 meters away, expressing concern that this distance might be insufficient for safety.	The titleholder has acknowledged this feedback relating to underwater sound and penguins. The results from the underwater sound modelling (see E5 Section 6) show the TTS criteria was reached within 60 m of the source. This is a 24-hour cumulative result, meaning the penguin would have to remain within 60m of the sound source to experience TTS. It would be highly unlikely for a diving bird or penguin to be within that distance of the source for 24 hours. As the seismic source will be slowly ramped up to full power over 30 minutes this further reduces the risk of a diving bird or penguin being close to the seismic source at full power.	2079
4346	Requested details on the proximity of seismic blasting to Middle Island, with a specific concern for the range penguins travel offshore to forage at night.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions relating to penguins. The MSS will not impact the foraging abilities of fairy penguins within the area of operation, and CGG has acknowledged breeding colonies of Fairy Penguin along the coast of Victoria (EP E7 Section 4 and 8). CGG undertook an additional assessment of Fairy Penguins in EP F3 and outlined the overlap of foraging colonies along the coast with the Regia MSS. The foraging range of the Middle Island colony does not overlap with the Regia MSS. There is a small overlap with one of the breeding colonies and the Regia MSS, the overlap equates to only ~5.3 hours spread over 3.5 weeks. Mitigation plans are in place to reduce any impacts to as low as practicable.	2079
4347	Enquired about whether the potential impacts on the Fairy Penguin colony have been evaluated, specifically regarding how far they travel to forage and the depths to which they dive. Raises concerns about the effects of seismic activity on this important wildlife species.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions relating to penguins. The MSS will not impact the foraging abilities of fairy penguins within the area of operation, and CGG has acknowledged breeding colonies of Fairy Penguin along the coast of Victoria (EP E7 Section 4 and 8). CGG undertook an additional assessment of Fairy Penguins in EP F3 and outlined the overlap of foraging colonies along the coast with the Regia MSS. There is a small overlap with one of the breeding colonies and the Regia MSS, the overlap equates to only ~5.3 hours spread over 3.5 weeks. Mitigation plans are in place to reduce any impacts to as low as practicable.	2077
4348	Asks if the seismic blasting will occur during the breeding season of the Fairy Penguin colony, emphasising that the penguins forage after dusk, making them	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions relating to penguins. 	less visible at night. It highlights the need to consider the timing of the project to avoid disrupting this vulnerable wildlife population.	penguins within the area of operation. The Regia MSS is scheduled to take place outside of the Fairy Penguin breeding season. CGG undertook an additional assessment of Fairy Penguins in EP F3 and outlined the overlap of foraging colonies along the coast with the Regia MSS. There is a small overlap with one of the breeding colonies and the Regia MSS, the overlap equates to only ~5.3 hours spread over 3.5 weeks. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4349	Raises a concern about whether the sound levels from seismic blasting could be harmful or uncomfortable for Fairy Penguins during their foraging activities.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the foraging abilities of fairy penguins within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2077
4352	Asked if low-power zones or shut-down zones could be applied to penguins and seabirds.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of penguins or seabirds within the area of operation (see E5). Although there were no mitigation measures through the impact assessment, to address concerns to penguins as a result of consultation CGG has agreed to implement the following measure: The seismic source will be reduced to the low power setting if flocks of foraging birds are observed within 500 m of the source.	2006
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		with impact assessments when they became available.	
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383
4376	Relevant person expressed concern about the timing of the seismic blasting project, specifically during the breeding season of the Fairy Penguins.	Event ID 6320 - The Regia team responded that window of April/May/June has been identified as one which offers the most minimal impact to the ecosystem and its constituents. Decisions on the preferred time for conducting seismic are made after detailed assessment and consideration across all identified cause-effect pathways, including Little Penguins. The timing of the MSS to the months of April/ May / June avoids the core period of egg laying and chick rearing which is the most effective mitigation tool at our disposal.	6327

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4380	There should be no seismic during the egg laying and chick raising period; local organisations should monitor each colony in the lead up to the breeding season to ensure this.	Event ID 6882 (Doc ID 9096)- Timing has been selected in an effort to avoid the time of year when the ecosystem is most active and the majority of animals are breeding, which is the summer months. It is not appropriate to cease the activity, which occurs at a minimum 20km offshore, for animals laying eggs onshore.	6412
4384	Stakeholder claims that the Fairy Penguins could be more vulnerable to acute effects because their smaller bodies might lack the capacity to buffer the shock waves.	Event ID 6320 - There is no scientific literature to suggest that this, therefore it appears that this claim is a personal opinion. The stakeholder is encouraged to provide further information on why they may believe this.	6412
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880

1 Introduction

Underwater Sound was identified through the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) as an aspect needing further assessment. Hence this document presents a detailed examination of **Underwater Sound**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental receptor we are collectively calling **Turtles.**

This assessment is built on the information contained in the following four core studies, which should be read in the order they are listed:

1. PEIRA.
2. Seismic Sound Studies Report (Appendix B8).
3. Sound Emissions Modelling Report (Appendix B7).

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was initially published in draft form and uploaded to the Document Library of the Regia MSS Consultation Hub on 11 September 2023 as a stand-alone document, rather than as part of the much more substantial total EP document. This was done to maximise the ability of interested members of the public to read, interpret and respond within the mandated 30-day public comment period.

As such, public and Relevant persons were invited to comment on the document with an explicit request for feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality

of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

Impulsive underwater acoustic emissions will result from the seismic source releasing compressed air (seismic pulse) that creates a sound wave that is directed downwards into the seabed.

Continuous underwater acoustic emissions are generated by the survey and support vessels and helicopters. Underwater acoustic emissions from vessels are generated by thrusters, engines, and propellers. Underwater acoustic emissions from helicopters are generated via the engine and rotors. Underwater acoustic emissions from Ultra-Short BaseLine positioning beacons are generated within the streamer spread.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days

Extent: Active Source Area +50 m to 6.25 km based on the furthest distance to modelled sound effect criteria. [Updated in response to Matter: F17]

Seismic acquisition where the seismic source will be active will occur for up to 60 days within the Active Source area.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for underwater sound for the following environmental components

Potential environmental impacts to reptiles identified from the PEIRA are:

- Change in fauna behaviour.
- Change in hearing capacity.
- Change in physical condition.

Following review of the NCVA (now AMSIS):

- No important inter-nesting habitat is within or adjacent to the area that maybe affect by underwater sound.
- No habitat critical to the survival of marine turtles are within or adjacent to the area that may be affected by underwater sound.
- No Biologically Important Areas for turtles are within or adjacent to the area that may be affected by underwater sound.

4 Description of the Existing Environment that may be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8.

4.1 Turtles

To identify turtle species that may be present within the area affected by underwater sound a PMST search was undertaken using the Active Source Area with a 6 km buffer based on the furthest distance to a sound effect criterion is 6.25 km (Table E6-2). The PMST Report is available in Appendix B5. PMST searches were run again prior to resubmission to ensure any changes to species or listings were identified to control for passage of time. There are no changes to protected matters information for species that may be impacted by underwater sound [Section added in response to Matters: I16 and I17].

The PMST Report identified three turtle species within the area potentially affected by underwater sound, Green (may occur), Leatherback (likely to occur) and Loggerhead turtle (likely to occur). No BIAs or habitat critical to the survival of the species were identified. Annex 3 provides details on these turtle species and relevant conservation advice or management plans.

Green Turtles nest, forage and migrate across tropical northern Australia, spending their first 5-10 years drifting on ocean currents. They are predominantly found in Australian waters off the Northern Territory, Queensland, and Western Australian coastlines, with limited numbers in NSW, Victoria, and South Australia (DoEE 2017).

Small numbers of Leatherback Turtles nest on the Cobourg Peninsula (NT) and there are unconfirmed accounts of Leatherback Turtles nesting in Western Australia. As pelagic feeders, they are more commonly found foraging in Australian waters along the east coast and in Bass Strait however they are also regularly found in the high latitudes of all oceans (DSEWPaC 2012). The southern waters of Australia are an important feeding area for the Leatherback Turtle with five identified foraging sites (where area restricted behaviour occurs) (DoEE 2017) but no major nesting sites recorded. This has been confirmed with a recent study which compiled historical leatherback turtle observations, and satellite tracking data from their nesting beaches in West Papua, Indonesia, and down to SE Australia and found Leatherbacks in southeast Australia primarily forage in waters above 14°C, highlighting the waters off southeast Australia as important foraging area for this species (Hays et al. 2023).

There are two genetically distinct stocks of Loggerhead Turtles nesting in Australia, one in Queensland (known as the south-west Pacific stock) and one in Western Australia. Loggerhead Turtles forage in all coastal states and the Northern Territory, but are uncommon in South Australia, Victoria, and Tasmania (DoEE 2017).

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for all turtle species that may be affected (see Appendix B2). Measures that must be adopted are as follows:

- Recovery Plan for Marine Turtles (DoEE 2017) which includes:
  - In accordance with the EPBC Act Policy Statement 2.1 – Interactions between Offshore Seismic Exploration and Whales: Industry Guidelines, all seismic survey vessels operating in Australian waters must undertake a soft start during surveys irrespective of location and time of year of the survey. Although these guidelines are specifically designed for interactions with cetaceans, the soft start provision may also afford protection for marine turtles.

6 Defining Acceptable Levels of Impact

Marine turtles are less sensitive to sound than marine mammals as they do not have an external hearing organ. They can detect sound through bone-conducted vibration in the skull with their shell providing a receiving surface (Lenhardt et al. 1985). Morphological studies of green and loggerhead turtles (Ridgway et al. 1969; Wever 1978; Lenhardt et al. 1985) found that the turtle ear is like other reptile ears but has adaptations for underwater listening.

There is limited information on marine turtle hearing. Most studies looking at the effect of seismic noise on marine turtles have focussed on behavioural responses given that physiological impacts are more difficult to observe in living animals. Exposure criteria developed by Popper et al. (2014) based on results from the Working Group on the Effects of Sound on Fish and Turtles as well as Finneran et al. (2017) has been adopted. These thresholds are within Australia as relevant threshold levels.

Sound exposure guidelines for turtles have been established by the American National Standards Institute (ANSI) accredited report of Sound Exposure Guidelines for Fishes and Sea Turtles (Popper et al. 2014).

Though mortality or potential mortal injury to turtles from seismic sound exposure has not been reported, Popper et al. (2014) provides exposure guidelines of >207 dB re 1 µPa PK or >210 dB re 1 µPa2.s SEL_{cum}. Popper et al. (2014) also defined semi-quantitative exposure criteria for potential hearing impairment (recoverable injury and TTS). Finneran et al. (2017) recently proposed thresholds of 232 dB re 1 µPa (PK) and of 226 dB re 1 µPa (PK) for AUD INJ and TTS effects in turtles respectively. Therefore, the Popper et al. (2014) criteria for mortality/mortal injury may be conservative.

Finneran et al. (2017) identified 175 dB re 1 µPa SPL as the level at which marine turtles are expected to actively avoid seismic exposures. However, the Recovery Plan for Marine Turtles in Australia (DoEE 2017) acknowledges the 166 dB re1 µPa SPL reported by McCauley et al. (2000) as the level that may result in a behavioural response to marine turtles.

Based on the above discussion, Table E6-1 justifies and defines the acceptable levels of impact from underwater sound on marine turtles. Further information on studies in relation to seismic acoustic emission impacts to turtles can be found in the Seismic Sound Studies Report (Appendix B8).

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E6-1 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment.[1]

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they a documented elsewhere, these criteria are not discussed further in this assessment.

Table E6-1 - Defined acceptable levels of impact from underwater sound effects to turtles

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Sound exposure to marine turtles must be below a permanent threshold shift at thresholds in exceedance of 232 dB PK.	The behavioural disturbance threshold of 175 dB SPL is lower than the PK threshold for AUD INJ indicating that a turtle is expected to be deterred by the approaching seismic array prior to thresholds for AUD INJ being reached.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Therefore, predicted levels of impact for social, cultural and economic values for species will be
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	assessed on a receptor level. Native Title will be assessed separately.
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. One main option was considered:

Continuous Line Acquisition

This method involves maintaining discharge of the acoustic source during vessel line turns to reduce the total number of operational days. In effect, the survey could be acquired without run-ins and run outs. While this could shorten survey duration, it results in longer periods of uninterrupted underwater sound exposure and eliminates natural breaks between sail lines. Furthermore, it increases the risk of degraded data quality due to inconsistent line geometry and off-angle acquisition. If data quality does not meet geophysical thresholds, reacquisition may be necessary, leading to an overall increase in survey footprint and environmental impact. This option was ultimately discarded due to both environmental and operational drawbacks.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. One main option was considered and subsequently adopted:

Operate the sound source at low power during line turns and if transiting between sail lines anywhere in the Mitigation Source Area, Active Source Area, and Survey Acquisition Area

The use of lower power settings during non-acquisition phases—such as line turns, testing, or soft starts—was explored to reduce unnecessary sound emissions. A Mitigation Source Area (MSA) was developed in response to consultation feedback, particularly from the Director of National Parks, who highlighted the importance of maintaining mitigation sound emissions during non-acquisition phases.

CGG is also investigating the feasibility of acquiring the survey using a reduced source size. Environmental and technical assessments are underway to validate whether a smaller source can meet geophysical objectives. Subject to these findings, CGG commits to using the lowest practicable source power that achieves geophysical data requirements.

9 Predicted Levels of Impact

To arrive at the predicted levels of impact of underwater sound on turtles at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on turtles. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on plankton as described here.

- B5 – PMST Reports – The Protected Matter Search Tool was used to search for environmental values and sensitivities potentially located within the proposed Regia MSS planning area, with eight specific searches undertaken of which one was for Turtles within the region defined by the Regia MSS Active Source Area with an included buffer area out to 6 km.
- B7 – Sound Modelling Reports - SLR performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including plankton along with turtles, marine mammals, fish, benthic invertebrates, and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on turtles and other fauna. This literature is the key evidence base from which impact levels are derived.

Therefore, all species, taxa or groups identified through B5 have been assessed through the framework provided by B7 and B8. Because of commonalities among species/taxa/groups in their sensitivity to seismic it is not always necessary to describe effects to each species individually but rather as groups defined by their sensitivity to different frequency levels of sound and shared life-history behaviours.

9.1 Change in fauna behaviour, hearing capacity, and physical condition

The predicted maximum distances from the acoustic modelling from the acoustic modelling are detailed in Table E6-2.

Table E6-2 - Modelled Maximum Distances – Marine Turtles.

	AUD INJ		**TTS**		**Behavioural Disturbance**
Modelled Distances	Per pulse	SELcum	Per Pulse	24 hr	Per Pulse
	47 m – 51 m	500 m-1.06 km	59 m-64 m	4.16 -6.25 km	590 m-1.64 km

The predicted effect level to turtle species is assessed as minor as impacts are predicted to have some effect to turtles, but the effect is not considered significant or at a level to affect the population given the following:

- Mortality or mortal injury to turtles is considered highly unlikely based on no documented cases of mortality in turtles exposed to seismic source emissions under experimental or field operating conditions (Popper et al. 2016).
- As detailed above, the per pulse (PK) exposure criteria for AUD INJ and TTS are reached out to 51 and 64 m from the sound source, respectively. The cumulative exposure criteria for AUD INJ is reached out to 1.06 km, TTS is reached out to 6.25 km, and behavioural disturbance may occur out to 1.64 km. It is considered highly unlikely that a turtle would stay within the AUD INJ and TTS effect distances for 24 hours as there are no BIAs or habitat critical to the survival

of the species identified and thus turtles are likely to be transient in the area. [Section updated in response to Matter: F17]

- The Recovery Plan for Marine Turtles (DoEE 2017) identifies acute noise interference from anthropogenic noise sources, such as seismic surveys, as a low-risk threat to the stocks of marine turtles. Thus, population impacts from the seismic survey are not predicted.
- The Regia MSS is consistent with Recovery Plan for Marine Turtles (DoEE 2017) such that:
  - There is no important nesting habitat within or adjacent to the area that maybe affect by underwater sound.
  - Marine turtles will not be displaced from identified habitat critical to the survival from underwater sound.
  - Biologically important behaviours will not be impacted.

The uncertainty level for impact to turtles from seismic sound is assessed as low based on:

- There are long-term tagging studies of sea turtles in Australia, and there are no nesting habitats identified as BIAs within or adjacent to the area that may be affected by underwater sound.
- There has never been a documented mortality or mortal injury to turtles because of seismic source emissions.
- There are several published studies on the sound effect criteria of sea turtles.

The predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. For turtles the predicted levels of impact are beneath levels of perception and/or within normal bounds of variation. Good industry practice (including legislation and standards) has been applied and therefore these impacts are of an acceptable level without further reduction measures being required.

9.2 Measures Adopted to Management Environmental Impacts

The following measures have been adopted to ensure that the impacts associated with elevated levels of underwater sound from the survey and support vessels on turtles will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
Start-up delay procedure (if sighting)	Procedure	The start-up delay procedures will include provision for turtle detections within 500m to delay the commencement of operations or require movement of the vessel before start-up.
Ramp up of sound source to full power over 30 minutes.	Practice	Mobile marine fauna (including demersal and pelagic fish, octopus, squid, diving birds, penguins, and turtles) are expected to move away from the source before it is at full power, providing them a level of protection. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04, I05, E08].
Shutdown procedures	Procedure	The shutdown procedure will include provision for turtle observations to initiate a shutdown of the sound source if there are detections within 500 m of the sound source.

10 Demonstration impacts will be of an acceptable level

10.1 Principles of ESD, Biological and Ecological Categories

Temporary, Reversible, Small Scale and Natural variation

As described in the impact assessment, the Regia Marine Seismic Survey will generate underwater sound primarily through seismic pulses and vessel operations, with modelled acoustic emissions extending up to 6.25 km. The predicted levels of effect to turtles include potential behavioural disturbance up to 1.64km, temporary hearing shifts up to 6.25 km (TTS), and possible exposure above auditory injury (AUD INJ) criteria within 1.06 km. However, turtles are expected to avoid the sound source (O'Hara & Wilcox 1990) prior to reaching AUD INJ thresholds, and there is no identified critical habitat, inter-nesting area, or Biologically Important Area (BIA) in or near the affected zone. The affected environment is therefore not ecologically or biologically sensitive in terms of turtle use. If turtles are present, they are expected to be in low numbers and low densities.

As highly mobile, pelagic animals, turtles are likely to transit through the area without prolonged exposure. Impacts are not expected to disrupt population health, ecosystem function, or biodiversity. Overall, the impact is predicted to be minor, temporary, reversible, and limited in spatial extent.

Based on sufficient information

The assessment utilised acoustic modelling, species presence data (updated PMST searches), and peer-reviewed studies, including exposure thresholds developed by Popper et al. (2014) and Finneran et al. (2017), to evaluate both behavioural and physiological effects. While data on marine turtle hearing remains limited, these studies offer the most widely accepted criteria for evaluating impact. The Recovery Plan for Marine Turtles (DoEE 2017) was also used to assess whether impacts would be serious or irreversible. No evidence of serious harm, irreversible damage, or substantial knowledge gaps requiring application of the precautionary principle was identified. Uncertainty was assessed as low due to the strength of available evidence and absence of critical habitats.

Activity not inconsistent with EPBC Act

The survey design and environmental management measures align with the EPBC Act and its associated Recovery Plans. Three species — Green, Leatherback, and Loggerhead turtles — were identified in the area, but no nesting beaches, BIAs, or critical foraging areas were recorded within the modelled sound footprint. The soft-start (ramp-up) procedures required under EPBC Act Policy Statement 2.1 (designed for whales) are also applied here and considered protective of turtles. The assessment explicitly integrates the objectives of the 2017 Recovery Plan for Marine Turtles, concluding that no inconsistency exists.

10.2 Economic, Cultural and Social Categories

The activity is not expected to result in any material disadvantage to affected persons or cultural groups. Turtles are important in the traditions of many First Nations peoples, but no cultural heritage sites, inter-nesting areas, or foraging habitats of cultural significance occur within the area exposed to underwater sound above behavioural or injury thresholds. Relevant persons raised concerns about the accuracy of modelling and protection of marine fauna. In response, the project team updated the PMST database results, refined the acoustic model to reflect local propagation conditions, and confirmed the absence of critical turtle habitats. These changes, along with soft-start procedures and other standard mitigation measures, were included in the final assessment. The public also provided feedback via the Regia MSS Consultation Hub, with specific concerns about animal welfare, data quality, and transparency. These were addressed through clarification of assumptions and justification of modelling outcomes. Taken together, the views of affected persons, the public, and cultural stakeholders have been appropriately considered and incorporated.

10.3 Discussion on Consistency with Company Processes

The impact assessment followed the methodology in Appendix B3 and applied defined thresholds for physiological and behavioural effects. For turtles, the effect level was assessed as minor, the uncertainty as low, and the final predicted impact level as low. The sound footprint was compared with species distribution, and all mitigation measures required by regulation and good practice were adopted. As no exceedance of thresholds or high consequence outcomes were identified, the final consequence rating is within company limits.

This impact assessment has demonstrated that the effect of underwater sound to turtles has a:

- **Predicted level of effect of minor (2).**
- **An uncertainty of low (2).**
- **Predicted level of impact of low (4).**

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E9-3 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E6-1)	Environmental Performance Outcome	Rationale
Sound exposure to marine turtles must be below a permanent threshold shift at thresholds in exceedance of 232 dB PK.	**No death or injury to fauna, including listed threatened or migratory species, from the activity.**	This EPO can be demonstrated through pre-activity acoustic modelling, exclusion zone design, and shutdown protocols when turtles are observed in zones where threshold exceedance is predicted.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	This EPO ensures that the activity is managed in a way that prevents unacceptable impacts to social, cultural, and economic values associated with marine mammals.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

As demonstrated in this assessment the predicted level of impact level is low, thus, good industry practice (including legislation and standards) has been applied and these impacts are of an acceptable level without further recommendations being required.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E6-4 shows how this feedback has been incorporated into the environmental assessments.

Table E6-4 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Impact Assessments (Appendices E, and F where relevant) to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Effectiveness of mitigation measures	E08	EP Appendices D2 and E5 have been updated to include existing mitigation and management measures that will reduce the likelihood of injury associated with vessel collision and underwater sound including the EPBC Act Policy Statement 2.1 - Interaction between offshore seismic activities and whales (Soft-start Procedure), which provides for marine turtles to move away from the activity before the airguns reach full power.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and the following Activity limitation: the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F3, and G2).
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E6-5. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E6-5 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey periods. Since acoustic propagation modelling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete another modelling report prior to submission to cover the changed timeframes of the proposed survey.	3384
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are	424

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		in place to reduce any impacts to as low as practicable.	
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4050	Concern about the destruction of smaller sea life and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	1669
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts on biological receptors are outlined in the EP also and can be found in G2.	3237
4064	Concern raised by the stakeholder regarding the potential damage/kill of marine life due to seismic testing.	Titleholder responded to individual advising that CGG would not propose an activity that would lead to unacceptable impacts to marine life and advised that environmental impact assessments for each aspect of the proposed activity that has the potential to impact marine life were currently being prepared and that they would be based on scientific literature and published shortly for consultation and feedback.	1024

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate	722

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	Upwelling, rock lobster fishery and other local fishing industries.	mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4080	Concerns about the impact of seismic testing on various marine species.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	2179
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4551
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-	422

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	2766
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used	4190

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		based around sound, peer reviewed scientific literature.	
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a	537

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		comprehensive fauna management plan	
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Also outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	3697
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment as a whole.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also made reference to documents relevant to this claim within the environment plan (Event ID 4092).	4091
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2118
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2963
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-	1653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels.	1662

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4198	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1672
4199	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2586
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review	2886

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	signs of bleeding from their middle ears. - LINK provided.	and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	
4202	Stakeholder objects to the proposed blasting activity due to its detrimental effects on marine ecosystems.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-	425

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We have to show that the environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	2104
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation	2256

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine	3343

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an "exclusion zone" will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	2108
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4285	The stakeholder noted their concern as a resident of Port Fairy: noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	1747
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. North West Shoals to Shore Marine Noise Monitoring and Impacts https://www.aims.gov.au/research-topics/monitoring-and-discovery/north-west-shoals-shore Behavioural Response of Australian Humpback whales to Seismic Surveys https://www.brahss.org.au/ Assessing the impact of marine seismic surveys on southeast Australian scallop and lobster fisheries https://www.frdc.com.au/project/2012-008 Marine Seismic Survey Impacts on Fish and Invertebrates: Final Report for Gippsland Marine Environmental Monitoring Study https://ecat.ga.gov.au/geonetwork/srv/api/records/2292f4a7-ba2e-3533-e053-12a3070aaf2c Maxima 3D Marine Seismic Survey at Scott Reef https://www.sciencedirect.com/science/article/abs/pii/S0025326X13006528 https://www.sciencedirect.com/science/article/abs/pii/S0025326X18300687 Regarding Marine Fauna Observer's (MFOs), companies that contract MFOs such as Blue Planet Marine	2389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		and RPS Group provide training for MFOs. As part of contracting MFOs we will ensure that the persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: • Conformance with regulatory requirements detailed in the accepted EP. • Management strategies and procedures to ensure EPOs and EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being monitored, measured, and	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	3152
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4323	There will be potential permanent damage to marine life due to sonic testing and drilling.	Titleholder responded and listed various information needs related to the activity, environmental assessment process, environmental aspects, predicted levels of environmental impact and risk, environmental management, consultation processes, and regulations or regulatory processes. Links to the project website and document library was provided.	1046
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and	1410

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		measures currently in place. The stakeholder was provided with consultation information and invited to engage.	
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880

Annex 3

Underwater Acoustic Sensitive Species

Common Name	Presence	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area	Management Plan Conservation Advice Listing Advice

1 Introduction

Underwater Sound was identified through the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) as an aspect needing further assessment. Hence this document presents a detailed examination of **Underwater Sound**, as will typically be produced during the proposed Regia Marine Seismic Survey (**Regia MSS**), and its interaction with the environmental receptor we are collectively calling **Marine Mammals.**

This assessment is based on information from the following studies which should be read in the order listed:

1. PEIRA.
2. Sound Emissions Modelling Reports (Appendix B7)
3. Seismic Sound Studies Report (Appendix B8)

1.1 Purpose and Scope

This document contains the second stage of the environmental assessment and ranks the impacts according to the criteria set out in the Environmental Assessment Process found in Appendix B3.

Its purpose is to demonstrate that impacts can be managed to an acceptable level through the adoption of mitigation measures and the setting of appropriate environmental performance outcomes.

The measures adopted will be carried through to the ALARP assessment in stage three of the process.

1.2 Consultation in Preparation of the EP

This document was first published in draft form and uploaded to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the full Environment Plan (EP) is a large document that is difficult for readers to digest within a 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

Up to 22 December 2023, there were no specific comments received on the content of the document.

1.3 Modifications Arising from Further Assessment

To ensure this assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, it will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality of the assessment. When this has

occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

Impulsive underwater acoustic emissions result from the seismic sound source releasing compressed air (seismic pulse) which generates a sound wave directed into the seabed. Underwater impulsive acoustic emissions also occur from Ultra-Short Baseline Positioning Beacons within the streamer spread.

Continuous underwater acoustic emissions are generated by the survey and support vessels through thrusters, engines, and propellers. Helicopters will also generate underwater sound via the engine and rotors.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days (within a 90-day completion window)

Extent: Active Source Area and area of sound propagation with which relevant sound effect criteria for marine mammals are exceeded as detailed in the impact assessment sections.

Seismic acquisition where the sound source will be active will occur for up to 60 days within the Active Source area.

Continuous Sound

Duration: 90 days

Extent: Operational Area

The survey and support vessels will be active in the Operational Area for the duration of the survey undertaking support activities and acquisition. Helicopters will be active within the Operational Area for short periods of time on arrival and departure from the seismic vessel helipad.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for underwater sound for the following environmental components and their social, cultural, and economic features:

- Marine mammals including whales, dolphins, seals, and sea lions.
- People and communities.

Potential environmental impacts to marine mammals identified from the PEIRA include:

- Change in fauna behaviour.
- Change in hearing capacity.
- Change in physical condition.

Change in physical condition relates to the potential for mass strandings. It does not relate to the potential for mortal injury, or mortality in whales because of increased sound exposures. There has not been any recorded mortality of a marine mammal because of an interaction with impulsive sound. Further, as detailed later in this assessment, received sound levels of sufficient magnitude to cause a permanent threshold shift do occur within <400 m of the sound source, and the legislative requirements in Australia require shutdown of the sound source for observations at 500 m. Therefore, there is no cause-effect pathway for marine mammals to suffer mortality or potential mortal injury from sound exposures used for the Regia MSS.

4 Description of the Existing Environment that may be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8.

Marine mammals include whales, dolphins, and pinniped species (fur-seals and sea lions). To identify marine mammals that may be present within the area affected by underwater sound, a PMST search was undertaken using the Active Source Area with a 44 km buffer based on the furthest distance to a sound effect criterion of 43.5 km, as per acoustic modelling results most-relevant at the time of searching. This distance was reduced in the secondary modelling report to 41.96 km because of changes to the sail line layout. Nevertheless, PMST searches were run with a 44 km buffer zone as a precaution. The largest predicted impact distances produced from the most up-to-date acoustic modelling report remain smaller than this buffer, so the associated PMST searches and reports remain relevant and conservative.

PMST searches were run again prior to resubmission in May 2024 and February 2025 to ensure any changes to species or listings were identified to control for passage of time. The February 2025 search report identified that the distribution BIA for the Pygmy Blue Whale has been removed from the search area. There are no other changes to protected matters information for species that may be impacted by underwater sound [Section added in response to Matters: I16 and I17].

Annex 3 in this document provides a summary of the PMST Report and identifies any relevant conservation advice and management plans.

Marine mammal species identified as may be affected by underwater sound have been grouped based on hearing sensitivities as follows.

- Very High Frequency (VHF) Cetaceans – Porpoises, Dwarf and Pygmy Sperm Whales
- High Frequency (HF) Cetaceans – Dolphins, Beaked Whales, Sperm Whales
- Low-frequency (LF) cetaceans – Baleen Whales
- Otariid Pinnipeds – Sea Lion, Fur Seals

Based on their endangered status, Southern Right Whales and Blue Whales are described separately from other low frequency cetaceans.

4.1 Very High Frequency (VHF) Cetaceans

The PMST Report (available in Appendix B5) identified that Pygmy Sperm Whales and Dwarf Sperm Whales as may occur in the area. No very high frequency species were identified that are listed as threatened or have biologically important behaviour.

4.2 High Frequency (HF) Cetaceans

The PMST Report (available in Appendix B5) identified:

- Six dolphin species that are likely to or may occur in the area,
- Eight beaked whale species that may occur in the area, and
- Five toothed whale species that are likely to or may occur in the area.

No high frequency species were identified that are listed as threatened or have biologically important behaviours.

4.3 Low Frequency (LF) Cetaceans

The PMST Report (available in Appendix B5) identified the following low frequency cetaceans:

- Fin and Sei whales are known to occur within the area and may be undertaking foraging or feeding-related behaviour.
- Pygmy Right Whales are likely to occur within the area and may be undertaking foraging or feeding-related behaviour.
- Pygmy Blue Whales occur in the area and a foraging (annual high use area) BIA and known foraging area BIA overlap with the Operational Area and sound propagation area.
- Southern Right Whales occur in the area and a migration BIA overlaps with the Operational Area and sound propagation area.
- Humpback Whales occur in the area.
- Minke Whales may occur in the area.
- Antarctic Minke Whales are likely to occur in the area.

More information is provided below on species undertaking biologically important behaviour, and species that are known to occur in the area affected by underwater sound.

4.3.1 Sei Whale

The Sei Whale (*Balaenoptera borealis*) is listed as vulnerable and migratory under the EPBC Act. Sei Whales are considered a cosmopolitan species, ranging from polar to tropical waters, but tend to be found more offshore than other species of large whales. Sei Whales move between Australian waters and Antarctic feeding areas; subantarctic feeding areas (e.g. Subtropical Front); and tropical and subtropical breeding areas. The proportion of the global population in Australian waters is unknown as there are no estimates for Sei whales in Australian waters.

In Australia, Sei Whales occur within Australian Antarctic Territory waters and Commonwealth waters, and have been infrequently recorded off Tasmania, NSW, Queensland, the Great Australian Bight, Northern Territory and Western Australia (Parker 1978; Bannister et al. 1996; Thiele et al. 2000; Chatto and Warneke 2000; Bannister 2008).

Sightings of Sei Whales within Australian waters includes areas such as the Bonney coast upwelling off South Australia (Miller et al. 2012), where opportunistic feeding has been observed between November and May (Gill et al. 2015).

There are no BIAs for the Sei Whale within Australian waters. However, Sei Whales are considered likely to be foraging in the area that may be affected by underwater sound at a similar time as Blue Whales, i.e. predominately between January and April.

4.3.2 Humpback Whale

The Humpback Whale (*Megaptera novaeangliae*) is listed as migratory under the EPBC Act. It is distributed in all oceans and due to its recovery from whaling has been removed as a threatened species under the EPBC Act (DAWE 2022a).

Humpback Whales are present around the Australian coast in winter and spring. Humpbacks undertake an annual migration between the summer feeding grounds in Antarctica and winter breeding and calving grounds in northern tropical waters. Along the southeast coast of Australia, the northern migration starts in April and May while the southern migration peaks around November and December (DCCEEW 2023).

A discrete population of Humpback Whales has been observed to migrate along the west coast of Tasmania and through Bass Strait, and these animals may pass through the area that may be affected by underwater sound. The exact timing of the migration period varies between years in accordance with variations in water temperature, extent of sea ice, abundance of prey, and location of feeding grounds (DCCEEW 2023). Feeding occurs where there is a high krill density, and during the migration this primarily occurs in Southern Ocean waters south of 55°S (DCCEEW 2023).

Humpback Whales satellite-tagged off Australia's east coast were tracked during three austral summers in 2008/2009, 2009/2010 and 2010/2011 (Andrews-Goff et al. 2018). Of the thirty tagged humpbacks, 21 migrated south along the coastline across into Bass Strait during October. In November the whales then migrated along the east coast (12 whales) and west coast (1 whale) of Tasmania to Antarctic feeding grounds. The state space model used shows both search and transit behaviour revealing new temperate feeding grounds in Bass Strait, the east coast of Tasmania and in the eastern Tasman Sea.

There is no known feeding, resting or calving grounds for Humpback Whales in the area that may be affected by underwater, although feeding may occur opportunistically where sufficient krill density is present (CoA 2015).

4.3.3 Fin Whale

The Fin Whale (*Balaenoptera physalus*) is listed as vulnerable and migratory under the EPBC Act.

The Fin Whale is a cosmopolitan migratory species that occurs from polar to tropical waters but is rarely sighted in inshore waters. Fin Whales show well defined migratory movements between polar, temperate and tropical waters which are essentially north–south with little longitudinal dispersion.

While Australian Antarctic waters are important feeding grounds for Fin Whales, the species also feeds in the Bonney Upwelling during summer/autumn sometimes in the company of Blue and Sei Whales (DCCEEW 2023b). Areas of upwelling and interfaces with mixed and stratified waters may be an important feature of Fin Whale feeding habitat with the species feeding on planktonic crustacea, krill, some fish and cephalopods (DCCEEW 2023b). Fin Whales frequently lunge or skim feed at or near the surface and they are known to dive to 230 m to feed.

There are no BIAs for the Fin Whale within Australian waters. Fin Whales are likely to be foraging in the area that may be affected by underwater sound at similar time as Blue Whales, i.e. predominately between January and April.

4.3.4 Pygmy Right Whale

The Pygmy Right Whale (*Caperea marginata*) is a little-studied baleen whale that is found in temperate and sub-Antarctic waters in oceanic and inshore locations. The species, which has never been hunted commercially, is thought to have a circumpolar distribution in the Southern Hemisphere between about 30°S and 55°S. Distribution appears limited by surface water temperature as they are almost always found in waters with temperatures ranging from 5° to 20°C (Baker 1985) and staying north of the Antarctic Convergence. There are few confirmed sightings of Pygmy Right Whales at sea (Reilly et al. 2008). The largest reported group was sighted (100+) just south-west of Portland in June 2007 (Gill et al. 2008).

Species distribution in Australia is found close to coastal upwellings and further offshore it appears that the Subtropical Convergence may be important for regulating distribution (Bannister et al. 1996). Key locations include south-east Tasmania, Kangaroo Island (SA) and southern Eyre Peninsula (SA) close to upwelling habitats rich in marine life and zooplankton upon which it feeds (Bannister et al. 1996).

There are no BIAs for the Pygmy Right Whale within Australian waters, but they are likely to be foraging in the area that may be affected by underwater sound at similar time as Blue Whales, i.e. predominately between January and April.

4.3.5 Blue Whale

The PMST Report (available in Appendix B5) identified Blue Whale foraging, feeding or related behaviour known to occur within the area.

The Blue Whale (*Balaenoptera musculus*) is listed as an endangered and migratory species under the EPBC Act. There are two subspecies of blue whales that use Australian waters (including Australian Antarctic waters), the Pygmy Blue Whale (*B. m. brevicauda*) and the Antarctic Blue Whale (*B. m. intermedia*). The Otway region is an important migratory and foraging area for Blue Whales, as shown by passive acoustic monitoring and aerial surveys (Gavrilov 2012, McCauley et al. 2018, Gill et al. 2011). Underwater acoustic monitoring programs have detected Antarctic and Pygmy Blue Whale calls in the Otway Region (McCauley et al. 2018).

Annex 4 in this document provides a summary of aerial and acoustic monitoring studies focused on Blue Whales in the Otway area.

The Blue Whale was extremely abundant until the early 20th century when they were hunted to near extinction. Approximately 341,830 Blue Whale takes were recorded by commercial whaling in the Antarctic and sub-Antarctic in the 20th century, of which 12,618 were identified as Pygmy Blue Whales (Branch et al. 2004). Recent research on historical whaling has noted blue whales were caught in the Otway region (Branch et al. 2023). The current global population of Blue Whales is uncertain but is plausibly in the range of 10,000 to 25,000, corresponding to about 3-11% of the 1911 estimated population size (Reilly et al. 2008).

Important foraging grounds for Blue Whales include the Great Australian Bight, South Australia, and off Portland Victoria (Figure E7-1). Research to date has found that Pygmy Blue Whales occupy the western area of the Bonney Upwelling system in the Eastern Great Australian Bight and adjacent to the Kangaroo Island canyons from November and December (DoE 2015c). Pygmy Blue Whales then move south-east to the Bonney Upwelling system off eastern South Australia and Victoria (e.g., between Robe, SA and Cape Otway, Vic). This occurs predominately between January to April (DoE 2015c). Recent research has used blue whale satellite data to predict suitable habitats for foraging and migration pygmy blue whales. The study predicted the shelf break and slope and the shelf off the Bonney coast as key habitats for pygmy blue whales during foraging and migration in southern and western Australia. The study validated suitable foraging habitat occurred on both the slope and on the shelf in this area. This information is generally consistent with existing knowledge on foraging BIAs and peak visitations in the region (Ferreira et al. 2024).

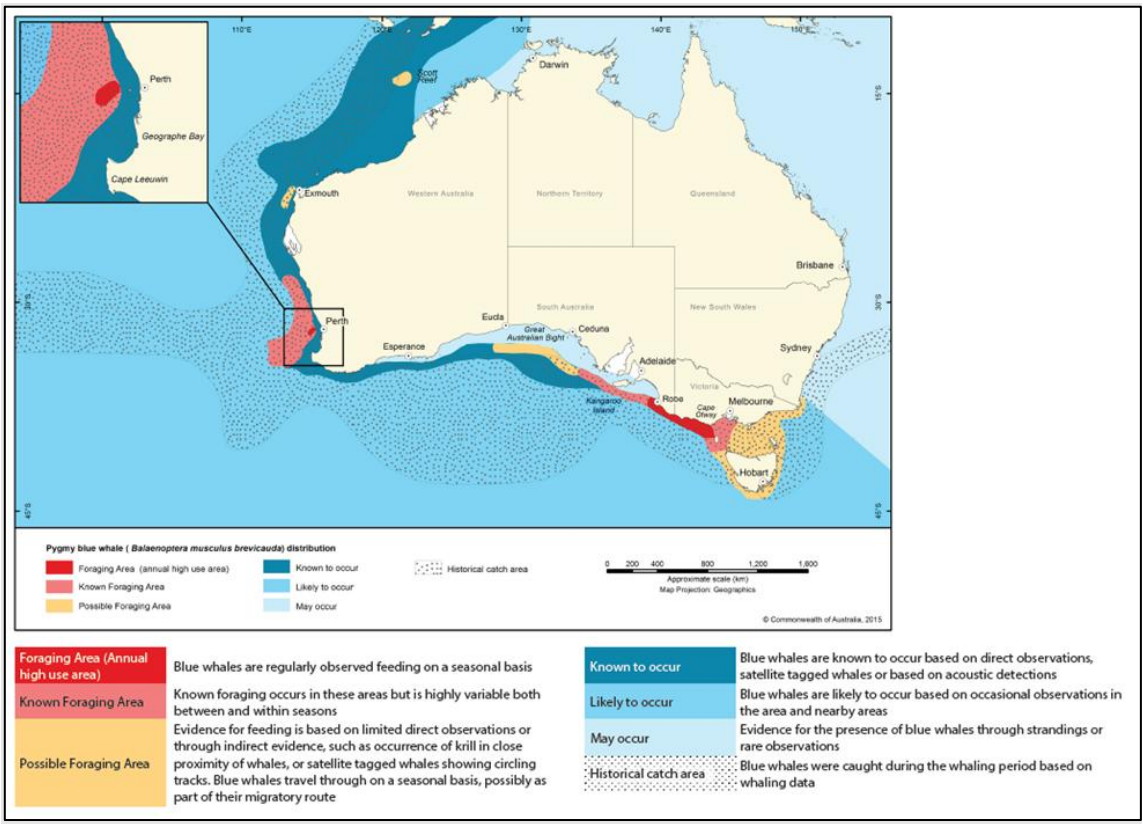

Figure E7-1 - Pygmy Blue Whale Areas around Australia (DoE 2015c).

The time and location of the appearance of Blue Whales in the east generally coincides with the upwelling of cold water in summer and autumn along this coast (the Bonney Upwelling) and the associated aggregations of krill that they feed on (Gill and Morrice 2003). The Bonney Upwelling generally starts in the eastern part of the Great Australian Bight in November or December and spreads eastwards to the Otway Basin around February as southward migration of the subtropical high-pressure cell creates upwelling favourable winds. Sighting data indicates that blue whales are seasonally distributed (Gill et al. 2011; McCauley et al. 2018).

The area that may be affected by underwater sound is within the Pygmy Blue Whale foraging (annual high use) BIA (Appendix B12 MAP-REG-EPM-068). Blue whales predominately occur in this area between January to April (DoE 2015c) though they have been recorded in the Otway area as early as September and as late as July.

4.3.6 Southern Right Whale

The PMST Report (available in Appendix B5) and the National Recovery Plan for the Southern Right Whale (DCCEEW 2024) identified Southern Right Whale breeding behaviours (i.e., mating, calving and nursing) typically occur within reproductive areas (reproduction BIAs which have been classified as habitat critical to the survival of the species) from May to September. Further, a spatially defined migration BIA has been identified with the migration period stated as approximately April to October, The PMST Report identified that Southern Right Whale breeding is known to occur within the area that may be affected by underwater sound, in addition the area where the sound effect criteria for SRW is reached overlaps the migration BIA and reproduction BIA (Appendix B12 MAP-REG-EPM-069).

The Southern Right Whale (*Eubalaena australis*) is listed as endangered and migratory under the EPBC Act. Southern Right Whales were depleted to less than 300 individuals globally due to

commercial whaling in the 19th and 20th centuries (Tormosov et al. 1998). They were protected from whaling in 1935 however, due to illegal whaling in the 1970s and because Southern Right Whales have a slow rate of increase (7% per annum) compared to other marine mammals, their numbers remain low (IWC 2013). Global abundance estimates are 13,000 for the species, across key wintering grounds in South Africa, Argentina, Australia, and New Zealand.

Southern Right Whales are distributed in the Southern Hemisphere with a circumpolar distribution between latitudes of 16°S and at least 65°S. They migrate from southern feeding grounds in sub-Antarctic waters to Australia between May and November to calve, mate and rest (Bannister et al. 1996; DCCEEW 2024). They are distributed across thirteen primary aggregation areas along the southern coast of Australia. In Australian coastal waters, they occur along the southern coastline of the mainland and Tasmania and generally extend as far north as Sydney on the east coast and Perth on the west coast (CoA 2012). There are occasional sightings further north, with the extremities of their range recorded at Hervey Bay and Exmouth (CoA 2012).

The peak period for Southern Right Whale mating is from mid-July through to August (CoA 2012). Pregnant females generally arrive during late May/early June and depart with calves in September to October however the general time of arrivals and departures varies on an inter-annual basis. Sightings of Southern Right Whales have been carried out by the Department of Energy, Environment and Climate Action (DECCA) at Warrnambool since 1985, revealing the majority of females arrive along western Victoria in May (54%) and June (42%). The majority of the last sightings occur in September (50%) and October (38%) (SWIFFT, 2025), although examination of the annual SRW monitoring reports on the SWIFFT website indicates whales were gone by Aug-Sept between 2020-2024. The earliest sighting was recorded at Portland on the 22nd of April (SWIIFT, 2025). Calving females are known to have high site fidelity and a 3 to 4-year calving interval. Other population classes stay for shorter and variable periods undertaking coastal movements and departing the coast earlier than female-calf pairs (CoA 2012). It has been found that females belonging to one subpopulation can relocate to a different calving area in a different region (Watson et al 2021). Counter-clockwise migration has been found to occur with whales from the south-western subpopulation arriving on the Australian coast from summer feeding grounds in sub-Antarctic waters. Movement tends to occur in a circular anti-clockwise direction into south-eastern Australia before traveling west to calving grounds in South Australia and Western Australia (Watson et al. 2021).

The National Recovery Plan for Southern Right Whale (2024) recognises two genetically distinct Australian stocks, the western and eastern populations. The western Australian subpopulation was estimated at 2,242 individuals (Smith et al., 2025). The eastern subpopulation is approximately 268 individuals with an overall increase of 4.7% per annum (Stamation et al., 2020).

The western population occurs in the coastal waters between Cape Leeuwin in Western Australia and Ceduna in South Australia and are particularly concentrated in three main regions of Albany east to Doubtful Island Bay (WA), Israelite Bay (WA) and Head of Bight (SA) (Charlton et al. 2022, Smith et al. 2023). The eastern population occurs to a lesser extent off Victoria, Tasmania, New South Wales and Queensland (Stamation et al. 2020). In Victoria, there is a regular aggregation area in waters off Warrnambool at Logans Beach (see Table E7-2) and increasing numbers of sightings along the Gippsland coast (east from Wilsons Promontory), and relatively regular sightings along the southeast coast of Tasmania (Stamation et al. 2020, Watson et al. 2021).

Photo identification collated between 1980 and 2021 revealed 96 calves were born at Logans Beach (Watson et al. 2021). Other important aggregation areas within the Southern Right Whale Reproductive BIA along Victoria include Portland, and Port Cambell/Peterborough. The mean calving interval for SRWs within the eastern population is estimated to be 3.5 years (Watson et al, 2021).

Recent studies have indicated SRW populations along the southwest coast of Australia are in decline with birth rates decreasing since 2016 (Smith et al. 2025, Grundlehner et al, 2025). Confounding this outcome is the recognition that SRW habitat occupancy has expanded in recent years with density increases at sites such as the Head of the Bight (HOB). It seems SRWs are recolonising historically

important areas such as Fowlers Bay (O'Shannessy et al. 2025). High density years at HOB usually correspond with high density years at Fowlers Bay, suggesting a possible redistribution of SRWs driven by crowding or saturation at the HOB (O'Shannessy et al. 2025) Very recent information from media postings has also suggested that the 2025 calving season at the HOB is one of the largest on record.

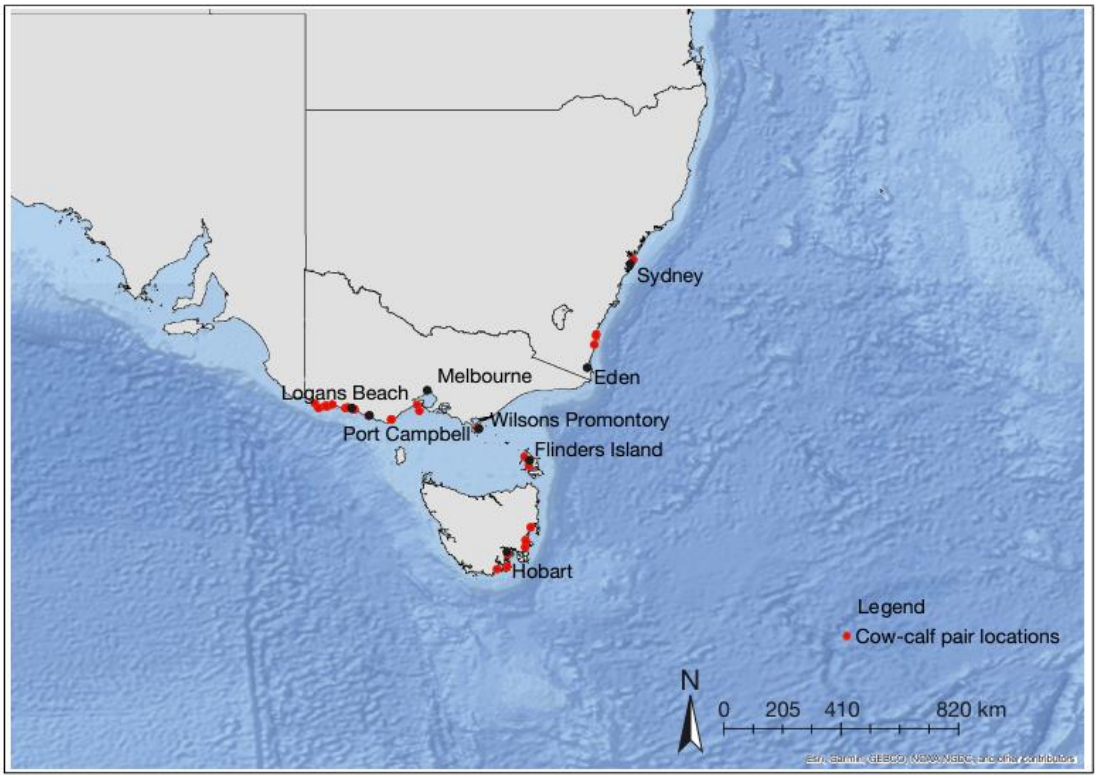

Figure E7-2: Sightings data collated by Stamation et al (2020) showing a higher concentration of Southern Right Whale calf cow pairs at Logans Beach.

4.4 Otariid Pinnipeds

The PMST Report (available in Appendix B5) identified that the Australian Sea Lion may occur in the area, Australian Fur Seal breeding is known to occur in the area, and the Long-nosed Fur Seal may occur in the area. The summer months represent an important period for otariid pinnipeds when lactating females may be alternating between feeding trips at sea and periods ashore to suckle their pups. [Section added in response to Matters M30 and M31].

4.4.1 Australian Sea Lion

The Australian Sea Lion (*Neophoca cinerea*) is listed as endangered under the EPBC Act.

The Australian Sea Lion is the only endemic pinniped, that breeds in Australia (DSEWPaC 2013). All current breeding populations are located between the Abrolhos Islands (Western Australia) and Pages Islands (South Australia). The Australian Sea Lion uses a variety of shoreline types but prefers the more sheltered side of islands and typically avoids rocky exposed coasts (Shaughnessy 1999).

The Australian Sea Lion is a specialised benthic forager, primarily feeding on the sea floor on the continental shelf, most commonly in depths of 20–100 m, with adult males foraging further and into deeper waters. They typically feed on a range of prey including fish, cephalopods (squid, cuttlefish

and octopus), sharks, rays, rock lobster and penguins (DSEWPC 2013). They typically forage up to 60 km from their colony but can travel up to 190 km when over shelf waters (Shaughnessy 1999).

4.4.2 Australian Fur Seal

The Australian Fur Seal (*Arctocephalus pusillus*) breeds on islands of the Bass Strait but ranges throughout waters off the coasts of South Australia, Tasmania, Victoria and NSW. Numbers of this species are believed to be increasing as the population recovers from historic hunting (Hofmeyr et al. 2008). The species is endemic to south-eastern Australian waters.

In Victorian waters they breed on offshore islands, including Lady Julia Percy Island (Deen Maar), Seal Rocks in Westernport Bay, Kanowna and Rag Islands off the coast of Wilson's Promontory and The Skerries off Wingan Inlet in Gippsland. The breeding sites on Lady Julia Percy Island and Seal Rocks are important, with 25% of the population occurring at each of these islands. In Tasmanian water they breed at Reid Rocks. Their preferred breeding habitat is a rocky island with boulder or pebble beaches and gradually sloping rocky ledges.

Haul out sites with occasional pup births are located at Cape Bridgewater, at Moonlight Head, on various small islands off Wilsons Promontory and Marengo Reef near Apollo Bay. Australian Fur Seals are present in the region all year, with breeding taking place during November and December.

Research being undertaken at Lady Julia Percy Island indicates that adult females feed extensively in the waters between Portland and Cape Otway, out to the 200 m bathymetric contour. Seal numbers on the island reach a maximum during the breeding season in late October to late December. By early December, large numbers of lactating females are leaving for short feeding trips at sea and in late December there is an exodus of adult males. Thereafter, lactating females continue to alternate between feeding trips at sea and periods ashore to suckle their pups. Even after pups begin to venture to sea, the island remains a focus, and at any time during the year groups may be seen ashore resting (Robinson et al. 2008, Hume et al. 2004, Arnould & Kirkwood 2007).

Lady Julia Percy Island is within the area that may be affected by underwater sound.

A study on the foraging behaviour of seals from the colony at Lady Julia Percy Island found that lactating Australian Fur Seals tended to search for prey south-east of their colony at 60-200 m depth (Arnould and Kirkwood, 2011). The Regia MSS Operational Area may therefore overlap foraging areas for the Australian Fur Seal. [Paragraph has been added in response to Matter M31].

4.4.3 Long-nosed Fur Seal

The Long-nosed Fur Seal (*Arctocephalus forsteri*) is listed as a marine species under the EPBC Act. There is no approved conservation advice or recovery plans for this species.

Long-nosed fur seals were decimated by fur trade through the 1800's and culling into the late 1900's due to perceived competition for resources with fishers (Shaughnessy, 1999).

The Long-nosed Fur Seal breeds in southern Australia from New South Wales to Western Australia; it also breeds in New Zealand and its subantarctic islands. Most of the Australian population is in South Australia, between Kangaroo Island and the southern tip of Eyre Peninsula (Shaughnessy et al. 2015). Long-nosed Fur Seals have experienced increasing population trends, with 97,200 seals recorded in the state of South Australia (2013–14 census; Shaughnessy et al., 2015) where an estimated 83% of their recorded pup production occurs.

Long-nosed Fur Seals can live up to 25 years old with females reaching maturity between 4 and 8 years of age and weigh between 50-150kg (McKenzie et al. 2007).

Prior to sealing, Long-nosed Fur Seals occupied the Bass Strait. Currently along the coast of Victoria, there are breeding colonies of Long-nosed Fur Seals located at Cape Bridgewater, Deen Maar, Kanowna Island and the Skerries (Kirkwood and Arnould. 2009). Colonies are typically occupied year-

round, with greater activity during breeding seasons. Pups are born from mid-November to January, with most pups born in December (Goldsworthy 2008). Pups begin weaning between the ages of 8 and 11 months (Baylis et al 2005).

Adult males tend to forage at the edge of the continental shelf while females typically use e continental shelf or near-shelf waters in summer and autumn, and pelagic waters associated with the subtropical front much further south during winter, the same region that is favoured by juveniles. During the summer months females and juveniles forage closer to their breeding colonies while females feed their young pups and pups start moulting (Shaughnessy and Goldsworthy, 2020). Tagging studies from lactating females at Cape Gantheaume, Kangaroo Island revealed the strength and duration of the Bonney Upwelling provides important food resources to females that forage ion the continental shelf during the winter months (Baylis et al. 2008).

Long-nosed Fur Seals have a broad diet consisting of mostly bony fish and squid (Boren, 2010). More recent research has revealed Long-nosed Fur Seals in Victoria are predating on seabirds such as shearwaters and little penguins, potentially impacting the recovery of little penguin populations (Hardy et al. 2024).

4.4.4 Southern Elephant Seal

CGG has reviewed relevant literature including Conservation Advice for this species and has noted the Southern Elephant Seal (*Mirounga leonine*) is listed as Vulnerable under the EPBC Act. It is a subantarctic species and, although some individuals have been recorded in coastal habitats, this species was not identified in the PMST search for this area. This species has a nearly circumpolar distribution and visits subantarctic islands to breed and to moult. There are two main populations found in Australian waters and the principal breeding colonies for these populations are located on Heard and Macquarie Islands (Shaughnessy 1999; McMahon et al. 2005). Southern Elephant Seals concentrate on the northern beaches of Macquarie Island, although colonies are scattered around the island (DEH 2003). In the Australian Antarctic Territory, small numbers of pups have been reported from Browning Peninsula and Peterson Island, near Casey station (Murray 1981 cited in Shaughnessy 1999), and there has been a well-frequented haul-out area at Vestfold Hills (Burton 1985). Off the coast of mainland Australia, several pups have been born and many animals recorded on Maatsuyker Island (located at the most southern end, off the south-west coast of Tasmania) (Shaughnessy 1999).

Given the likelihood of encountering this species during the Regia MSS is low, impacts to the species are not predicted and have not been assessed further. [Paragraph added in response to Matter C07].

4.5 People and Communities

4.5.1 Social and economic features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the local economy and environment, with activities including whale watching and tourism. Species that may be affected are described above in sections 4.1 and 4.4

4.5.2 Cultural features

During consultation, the cultural significance of marine mammals, such as the Southern Right Whale, Blue Whale, Killer Whale, seals, sea lions and dolphins, were highlighted, with connections to songlines, totemic value and kinship, and cultural practices (Appendix F3, Section 3.16.1).

The National Recovery Plan for Southern Right whale describes Whale Birthing Dreaming Sites being in coastal bay areas from Port Campbell to Portland, including Warrnambool. These places on Gunditjmara Country are known resting and feeding sites for mothers and calves and are directly related to Gunditjmara Neeyn (midwives), explaining why Gunditjmara is a Matrilineal Nation. (DCCEEW, 2024)

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for marine mammal species that may be affected (see Appendix B2). Measures that must be adopted are as follows:

- EPBC Act Policy Statement 2.1 - Interaction between offshore seismic activities and whales (Part A). This includes a requirement for Marine Fauna Observers and associated procedures for initiating shutdowns at predefined distances.
- Environment Protection and Biodiversity Conservation Regulations 2000 Part 8: Vessel and Operating Procedures:
  - 300 m caution zone for whales.
  - 150 m caution zone for dolphins, turtles and pinnipeds.
  - Helicopters will not fly lower than 1650 ft when within 500 m horizontal distance of a cetacean except when landing or taking off and will not approach a cetacean from head on.
- National Recovery Plan for the Southern Right Whale (*Eubalaena australis*) 2024 (NRPSRW): "Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment" and "Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that the risk of behavioural disturbance is minimised." It is important to also note that the NRPSRW defined an impact as biologically significant effect is one that reflects a change whose direction, magnitude and/or duration is sufficient to have consequences for the fitness of individuals or populations.
- Blue Whale Conservation Management Plan 2015: "Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area."

6 Defining Acceptable Levels of Impact

Marine mammals and especially cetaceans rely on sound for important life functions including individual recognition, socialising, detecting predators and prey, navigation, and reproduction (Weilgart 2007, Erbe et al. 2015, Erbe et al. 2018). Underwater sound can affect marine mammals in various ways including interfering with communication (masking), behavioural changes, a shift in the hearing threshold, physical damage, and stress (Erbe 2012, Rolland et al. 2012).

NMFS finalised technical guidance for assessing the effect of anthropogenic sound on marine mammal hearing (NMFS 2016). The guidance describes injury criteria with new thresholds and frequency weighting functions for different hearing groups described by Finneran and Jenkins (2012) and updated by Accomando et al 2025). The latest revision to this work was published in 2018; with the criteria defined in NMFS (2018). The latest criteria are from Southall et al. (2019) which are applied.

For impulsive sounds, NMFS currently uses step function thresholds of 160 dB re 1 μ Pa SPL (unweighted) to assess and regulate sound-induced behavioural impacts for marine mammals (NOAA 2018, NOAA 2019). The threshold for impulsive sound is derived from the High-Energy Seismic Survey (HESS) panel (HESS 1999) report that, in turn, is based on the responses of migrating mysticete whales to airgun sounds (Malme et al. 1984). The HESS team recognised that behavioural responses to sound may occur at lower levels, but significant responses were only likely to occur above a SPL of 140 dB re 1 μ Pa. Southall et al. (2007) found varying responses for most marine mammals between a SPL of 140 and 180 dB re 1 μ Pa, consistent with the HESS (1999) report, but lack of convergence in the data prevented them from suggesting explicit step functions.

The PTS and TTS thresholds used in the underwater sound modelling (see Appendix B7a and B7b) are from NMFS (2018) and Southall et al. (2019) and were the most current, globally recognised technical guidance for assessing the effects of anthropogenic sound on marine mammal hearing, until October 2024.

In October 2024 the NMFS released the 2024 Update to Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing (Version 3.0) Underwater and In-Air Criteria for Onset of Auditory Injury and Temporary Threshold Shifts (NMFS 2024).

This update provides revised underwater and in-air criteria for the onset of auditory injury and temporary threshold shifts (TTS). The 2024 guidance outlines Level A criteria for auditory injury and Level B criteria for harassment. Notably, the behavioural response thresholds remain unchanged. However, a new approach has been introduced for assessing injury: the thresholds for permanent (PTS) and temporary (TTS) threshold shifts have been updated to reflect the onset of auditory injury for different marine mammal hearing groups, and this is differentiated based on whether the sound source is impulsive or non-impulsive.

Auditory injury, as defined by NMFS, includes but is not limited to PTS and TTS. TTS is described as a temporary, reversible elevation in the hearing threshold at a specific frequency or within a portion of an animal's hearing range, relative to a baseline level. While TTS is acknowledged in the guidance, NMFS does not classify it as a true auditory injury. This position is supported by studies indicating that TTS falls within normal physiological variability and does not cause structural damage. The temporary hearing reduction following exposure to loud noise is attributed primarily to fatigue of cochlear hair cells and supporting structures rather than cell loss, and is fully reversible (Ward, 1997; Southall et al., 2007, 2019, as cited in NMFS 2024).

There were changes to the peak-to-peak thresholds for low frequency cetaceans, and otariid pinnipeds, and changes to the SELcum thresholds for high frequency cetaceans, very high frequency cetaceans and otariid pinnipeds.

It should be noted, where NMFS thresholds were updated, subsequent edits were made to the defined acceptable levels.

It is difficult to determine thresholds for behavioural response in individuals or groups of cetaceans (Southall et al. 2007, 2021). Often the way individuals or groups respond varies (Nowacek et al. 2004; Gomez et al. 2016; Southall et al. 2016, 2021) and is influenced by both biological and environmental factors such as age, sex, and activity at the time etc. The behavioural disturbance threshold criteria applied is the current NOAA (2024) criterion for marine mammals which summarises the most recent scientific literature on the impacts of sound on marine mammal hearing.

This literature was used to inform the thresholds used in the underwater sound modelling report (Appendix B7c). Previous modelling reports (Appendix 7a and 7b used the NMFS 2019 criterion.

To define acceptable levels of impact to marine mammals the species identified have been grouped according to similarity of impact pathways:

- Very-high-frequency (VHF) cetaceans
- High-frequency (HF) cetaceans
- Low-frequency (LF) cetaceans
- Southern Right Whale
- Blue Whale
- Otariid Pinnipeds

Based on the above discussion, Table E7-1 defines and justifies the acceptable levels of impact from underwater sound on marine mammals. Further information on studies in relation to seismic acoustic emission impacts to marine mammals is provided in the Regia MSS Seismic Studies Summary available in Appendix B8.

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that aspect specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E7-1 details the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding aspect specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment.[1]

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they are documented elsewhere, these criteria are not discussed further in this assessment.

Table E7-1 - Defined acceptable levels of impact from underwater sound on marine mammals.

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Marine mammals can continue critical life-cycle stages and are not injured.	Marine mammals rely on undisturbed habitats to complete vital life-cycle stages, including calving, feeding, and migration. Scientific studies and international guidelines (e.g. EPBC Policy 2.1 and Southall et al. 2019) provide injury thresholds. Ensuring no injury or long-term disruption to these life-cycle stages supports ecological sustainability and compliance with protected species legislation.
	The impact and risk assessment process is based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or the application of the precautionary principle is applied in the presence of scientific uncertainty.	Anthropogenic threats are managed consistent with ecologically sustainable development principles to facilitate recovery of all threatened whales.	This level is recognises the broader intent that all actions must align with ecologically sustainable development (ESD) principles to support threatened whale species long-term recovery. ESD ensures a balance between environmental protection and development by applying precaution, intergenerational equity, and adaptive management.
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.	Anthropogenic noise in biologically important areas must be managed such that any blue whale is not displaced from a foraging area.	This level aligns with the objectives of the Blue Whale Conservation Management Plan, which identifies the protection of biologically important foraging areas as critical to the species' survival and recovery. Avoiding displacement from foraging areas due to anthropogenic noise, particularly during peak feeding periods, ensures blue whales can continue to access necessary resources.
		Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that they do not prevent any southern right whale from utilising the area or cause auditory impairment.	This level aligns with the objectives of the National Recovery Plan for the Southern Right Whale (SRW), which requires that actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment.
		Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that they minimise behavioural disturbance.	This level is consistent with the objectives of the National Recovery Plan for the Southern Right Whale (SRW), which requires that actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that the risk of behavioural disturbance is minimised.

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.	Sound exposure levels to low frequency cetaceans must be below PTS per pulse and PTS 24 hr SEL thresholds of 222[2] dB and 183 dB respectively.	These thresholds are based on international scientific consensus (e.g. Southall et al. 2019 and NMFS 2024) for onset of permanent threshold shift (PTS) in very high, high, and low frequencey cetaceans, representing the point at which auditory injury occurs. Ensuring exposure does not exceed these levels is critical for compliance with protected species regulations and prevention of permanent harm.
		Sound exposure levels to high frequency cetaceans must be below PTS per pulse and PTS 24 hr SEL thresholds of 230 dB and 193[2] dB respectively.	
		Sound exposure levels to very high frequencey cetaceans must be below PTS per pulse and PTS 24 hr SEL thresholds of 202 dB and 159[2] dB respectively.	
		Sound exposure levels to otariid pinnipeds must be below PTS per pulse and PTS 24 hr SEL thresholds of 230 dB and 185 dB respectively.	These thresholds are based on international scientific consensus (e.g NMFS 2024) for onset of permanent threshold shift (PTS) in very otariid pinnipeds, representing the point at which auditory injury occurs. Ensuring exposure does not exceed these levels is critical for compliance with protected species regulations and prevention of permanent harm.
		Sound exposure to any blue whale must be below the behavioural effect threshold of 160 dB SPL.	The NOAA NMFS 2024 criteria identifies 160 dB re 1 µPa as a widely accepted threshold for behavioural disturbance in low-frequency cetaceans. While CGG acknowledges uncertainties around its applicability to blue whales, this threshold remains a precautionary reference point for managing impacts from seismic airguns. Expert input from SLR (Appendix B7c) supports its use, though studies compiled by Southall et al. (2021) highlight limited data specific to seismic sources. Southall (2024) also notes the need for more nuanced thresholds and better use of existing data. These uncertainties are further discussed in Section 12 and Appendix F3.

[2] This threshold has been updated based on the NMFS 2024 guidance.

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
(cont.) Biological	(cont.) Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
		Sound exposure levels to blue whales must be below a TTS per pulse and TTS 24 hr SEL thresholds of 216 dB and 168 dB respectively.	This level is based on proposed thresholds from the scientific literature for low-frequency cetaceans, which include blue whales and SRW. The thresholds represents the onset of temporary threshold shift (TTS), a reversible reduction in hearing sensitivity.
		Sound exposure levels to southern right whales must be below a TTS per pulse and TTS 24 hr SEL thresholds of 216 dB and 168 dB respectively.	This level is consistent with the objectives of the National Recovery Plan for the SRW, which requires that Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment. The thresholds represents the onset of temporary threshold shift (TTS), a reversible reduction in hearing sensitivity.
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.	Exposure of marine mammals to impulsive sound will not result in population-level effects.	This acceptable level aligns with the general principle that impacts and risks must be temporary, reversible, and of low intensity, ensuring no long-term or population-level effects to ecological features.
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Reflects Commonwealth and State policy objectives for sustainable resource use and protection of ecosystem services.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	This level reflects the principle of maintaining cultural values and heritage as protected under national and state legislation. It ensures that activities do not interfere with traditional practices, spiritual connections, or ongoing access to culturally significant areas.

Category	Defined Acceptable Level (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	This level reflects broader social licence to operate, ensuring that environmental activities do not lead to degradation of public amenity, loss of recreational use, or impacts to non-Indigenous heritage values. It aligns with Commonwealth policies promoting public access, well-being, and sustainable use of the marine environment.
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. Two alternative technologies – marine vibrosis and BluePulse – were considered in the ALARP assessment and were not adopted. Five main options were considered:

Continuous Line Acquisition

This method involves maintaining discharge of the acoustic source during vessel line turns to reduce the total number of operational days. In effect, the survey could be acquired without run-ins and run outs. While this could shorten survey duration, it results in longer periods of uninterrupted underwater sound exposure and eliminates natural breaks between sail lines. Furthermore, it increases the risk of degraded data quality due to inconsistent line geometry and off-angle acquisition. If data quality does not meet geophysical thresholds, reacquisition may be necessary, leading to an overall increase in survey footprint and environmental impact. This option was ultimately discarded due to both environmental and operational drawbacks.

The remaining activity limitations described below have subsequently been adopted:

No petroleum activity to be carried out between 1 January and 15 September.

Timing of survey is outside summer months of Jan/Feb/Mar which avoids the peak upwelling period. The Bonney Upwelling is driven by spring-summer winds that blow from the south-east. It can vary from year to year but typically starts during November and December, is at its strongest from January to March and retreats in April. Most consultations identified that the upwelling events and the associated increase in biodiversity in the area was a high priority. In April, May and June there are departing Blue Whales and arriving SRW mother/calf pairs. . For SRW, this time of year represents a critical life-cycle stage where pregnant mothers and newborns will arrive and reside in the shallow waters off the coast. Based on analysis of 40 years of sightings data this will reduce temporal overlap with SRW presence to less than 2 weeks (see Appendix F3).

Outside of these months low numbers of Pygmy Blue Whales and other foraging whales such as Fin, Sei and Pygmy Right whales are in the BIA off Otway. Additionally, timing the survey outside of July and August, avoids peak reproduction and migration by SRWs.

Reduced source size to reduce the energy and sound transmission distances.

From the commencement of preparation for the Regia MSS, CGG has committed to using the lowest sound source size possible to meet geophysical objectives. Since new NMFS criteria were published during the EP assessment process and new modelling was required, CGG took the opportunity to undertake additional sound transmission loss modelling and test the environmental benefits of a lower source size (from 2810 to 2630 cubic inches) and new technology (BluePulse). This modelling was undertaken in parallel to geo-acoustic analysis of these sources. The lower source size has been adopted because there were environmental benefits (lower effect distances) and geophysical objectives could be met. However, BluePulse technology was rejected because geophysical

objectives could not be met despite the environmental benefits to some receptors. Further justification for rejecting BluePulse is provided in Appendix F2.

Only commence lines 1-30 after November 1st and then only if SRW are confirmed to have been absent from the reproduction BIA (between and inclusive of Cape Bridgewater to Cape Otway) for 24 hours since last observation

Predictive uncertainty related to behavioural disturbance to SRW led to further assessment in Appendix F3. In turn, to improve certainty that the Regia MSS will not prevent any SRW from utilising the reproduction BIA an activity limitation was designed whereby the most northerly sail lines closest to the reproduction BIA (indicative sail lines 1 to 30) cannot be acquired before 1 November and only after visual detection methods confirm 24 hours absence of SRW from the reproduction BIA between and inclusive of Cape Bridgewater to Cape Otway. This limitation aligns with the data about SRW absence in the reproduction BIA over this area in the previous 6 years (see Appendix F3 – Figure F3.1). The 24-hour absence criterion was selected to reflect the consideration that SRWs may remain in or return to preferred areas over short periods and extensive daily coverage of the SRW detection and management program.

No seismic acquisition within 17 km of Deen Maar / Lady Percy Julia Island

Relevant persons were concerned about behavioural effects on the Australian Fur Seal given the haul out site at Deen Maar. The distance has changed through the preparation of the EP, starting at 10.8 km, growing to 11.8 km (both justified by the behavioural disturbance threshold), and then finally to 17km, due partly to a public comment that sought clarity on the distance the survey would keep from Lady Percy Julia Island / Deen Maar and a commitment from CGG to not conduct surveys within the 50m depth contour. [Distance updated in response to Matters M31, M32, M33 and F17].

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. Six main options were considered:

Daylight-Only Operations – Not Accepted

Limiting operations to daylight hours only, was considered to reduce impacts when traditional observation techniques are not effective. While potentially beneficial for a narrow range of receptors, this would double the duration of the survey, increase fuel use, and elevate overall environmental impact. The marginal benefit to a specific group of species was not considered sufficient to justify the increased impacts to others. This option was therefore rejected on the grounds of disproportionate trade-offs. The remaining activity limitations described below have subsequently been adopted:

Sound will not be emitted above the stated capacity - Accepted

Underwater sound emissions are a key concern for marine mammals, so by ensuring that sound emissions remain within predetermined capacity limits, this measure ensures that the effects on marine mammals remain below the levels predicted by acoustic modelling. Limiting sound intensity also reduces the likelihood of disrupting important biological behaviours. This option ensures that the effects of sound emissions remain within predicted and acceptable limits, ensuring compliance with environmental standards**.**

Operate the sound source at low power during line turns and if transiting between sail lines anywhere in the Mitigation Source Area, Active Source Area, and Survey Acquisition Area - Accepted

The use of lower power settings during non-acquisition phases (such as during line turns, testing, or soft starts) was explored to reduce unnecessary sound emissions. A Mitigation Source Area (MSA) was developed in response to consultation feedback, particularly from the Director of National Parks, who

highlighted the importance of maintaining mitigation sound emissions (low power settings) during non-acquisition phases.

The acquisition lines will be acquired working from the deepest lines first - Accepted

In the spring survey window, southerly lines will be acquired first to minimise overlap with Southern Right Whales as they exit the reproductive BIA, typically by mid-October. Similarly, acquiring the deepest lines first means the survey will be closer to the coast at the time the survey would overlap with the early arrival of Blue Whales. This approach delays activity in the northern survey area, where potential whale presence can continue to be monitored, and has been adopted as a precautionary scheduling measure

9 Predicted Levels of Impact

To arrive at the predicted levels of impact of underwater sound on marine mammals at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on marine mammals. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on marine mammals as described here.

- B5 – PMST Reports – The Protected Matter Search Tool was used to search for environmental values and sensitivities potentially located within the proposed Regia MSS planning area, with eight specific searches undertaken, of which one was for LF Cetaceans within the region defined by the Regia MSS Active Source Area with an included buffer area out to 44 km.
- B7– Sound Modelling Reports SLR performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including marine mammals, fish, turtles, benthic invertebrates, plankton and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on Marine Mammals and other fauna. This literature is the key evidence base from which impact levels are derived.

Therefore, all species identified through B5 have been assessed through the framework provided by B7 and B8. Because of commonalities among species in their sensitivity to seismic it is not always necessary to describe effects to each species individually but rather as groups defined by their sensitivity to different frequency levels of sound.

The type and scale of the effect of seismic sound on cetaceans will depend on several factors. These include the level of exposure, the physical environment, the location of the animal in relation to the sound source, how long the animal is exposed to the sound, the exposure history, how often the sound repeats (repetition period) and the ambient sound level. The context of the exposure plays a critical and complex role in the way an animal might respond (Gomez et al. 2016; NMFS 2016).

In March 2025, CGG commissioned SLR consulting to undertake an assessment using the NMFS 2024 User Spreadsheet Tool (Marine Mammal Acoustic Technical Guidance & Other Acoustic Tools | NOAA Fisheries) to calculate the maximum distances from the seismic source at which the latest noise threshold levels were reached by each marine mammal hearing group. This report was then superseded by a full Sound Transmission Loss Modelling study and accompanied ANIMAT study completed by SLR in November 2025.See Appendix B7c for the full report.

Maximum predicted distances from underwater acoustic modelling and NMFS threshold updates for Marine Mammals are presented in Tables E7-2 to E7-5. It should be noted, to be conservative, whichever modelled distance was the highest from either the secondary modelling or the updated assessments using the 2024 NMFS thresholds was used in the impact assessment.

Table E7-2 - Maximum predicted distances from underwater acoustic modelling and NMFS threshold - VHF Cetaceans

Modelled Maximum Distances – VHF Cetaceans		
Porpoises, dwarf and pygmy sperm whales		
Auditory Injury	Per Pulse (202 dB re 1 μ Pa)	232-397 m
	24 hr SEL (159 dB re 1 μ Pa2·s)	90 m
TTS	Per Pulse (196 dB re 1 μ Pa)	439 m -1.1 km
	24 hr SEL (144 dB re 1 μ Pa2·s)	380-840 m
Behavioural	Per Pulse (160 dB re 1 μ Pa)	3.1-6.9 km

Table E7-3 - Maximum predicted distances from underwater acoustic modelling and NMFS threshold - HF Cetaceans

Modelled Maximum Distances – HF Cetaceans		
Dolphins, beaked whales and sperm whales		
Auditory Injury	Per Pulse (230 dB re 1 μ Pa)	51-55 m
	24 hr SEL (193 1 μ Pa2·s)	80 m
TTS	Per Pulse (224 dB re 1 μ Pa)	63-68 m
	24 hr SEL (178 1 μ Pa2·s)	280-600 m
Behavioural	Per Pulse (160 dB re 1 μ Pa)	3.1-6.9 km

Table E7-4 - Maximum predicted distances from underwater acoustic modelling and NMFS threshold - LF Cetaceans

Modelled Maximum Distances – LF Cetaceans		
Auditory Injury	Per Pulse (222 dB re 1 μ Pa)	67-73 m
	24 hr SEL (183 dB re 1 μ Pa2·s)	6.25-8.53 km
TTS	Per Pulse (216 dB re 1 μ Pa)	80-86 m
	24 hr SEL (168 dB re 1 μ Pa2·s)	23.63-27.92 km
Behavioural	Per Pulse (160 dB re 1 μ Pa)	3.1-6.9 km
Blue Whales (Animat Distances)		
Auditory Injury	Per Pulse (222 dB re 1 μ Pa)	59-71 m
	24 hr SEL (183 dB re 1 μ Pa2·s)	71-127 m
TTS	Per Pulse (216 dB re 1 μ Pa)	71-78 m
	24 hr SEL (168 dB re 1 μ Pa2·s)	2.05-4.32 km
Behavioural	Per Pulse (160 dB re 1 μ Pa)	2.42-4.67 km
Southern Right Whales (Animat Distances)		
Auditory Injury	Per Pulse (222 dB re 1 μ Pa)	43-69 m
	24 hr SEL (183 dB re 1 μ Pa2·s)	59-77 m
TTS	Per Pulse (216 dB re 1 μ Pa)	53-77 m
	24 hr SEL (168 dB re 1 μ Pa2·s)	807 m – 3.76 km
Behavioural	Per Pulse (160 dB re 1 μ Pa)	1.26-4.61 km

Table E7-5 - Maximum predicted distances from underwater acoustic modelling and NMFS threshold - Otariid Pinnipeds

Modelled Maximum Distances – Otariid Pinnipeds		
Sea lion, fur seals		
Auditory Injury	Per Pulse (230 dB re 1 μ Pa2·s)	51-55 m
	24 hr SEL (185 dB re 1 μ Pa)	50-55 m
TTS	Per Pulse (224 dB re 1 μ Pa)	63-68 m
	24 hr SEL (170 dB re 1 μ Pa2·s)	660-1.02 km
Behavioural	Per Pulse (160 dB re 1 μ Pa)	3.1-6.9 km

9.1 Change in fauna behaviour and hearing capacity

9.1.1 Very-high-frequency Cetaceans

From the PMST it was identified that the Dwarf Sperm Whale and Pygmy Sperm Whale which are classed as very-high-frequency cetaceans (VHF) may occur within the area that may be affected by underwater sound.

The predicted effect level to these species is assessed as minor given that impacts are predicted to have some effect to VHF cetaceans, but the effect is not considered significant or at a level that may affect the population given the following:

- AUD INJ and TTS per pulse effect criteria are reached between 232m—397m and 439m-1.1km, respectively, thus the implementation of the EPBC Act Policy Statement 2.1 - Interaction between Offshore Seismic Activities and Whales for soft starts, where prior to acquisition commencing, the sound source power is ramped up over 30 minutes, will ensure no VHF cetaceans are within distances that AUD INJ or TTS could occur. However, once the sound source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I05].
- The AUD INJ 24hr cumulative effect criterion is reached within 90 m and the TTS 24hr cumulative effect criteria is reached within 380m-840m. It is not feasible that a cetacean would be within that distance of the moving vessel for 24 hrs, thus impacts are not predicted.
- Impacts to VHF cetaceans are limited to avoidance behaviour within an area between 3.1 km-6.9 km2from the sound source depending on where in the Operational Area the survey is being undertaken. As VHF cetaceans are not dependent on any specific area within the area affected, impacts may occur to individuals but not at a level to reduce fitness.
- Dwarf Sperm Whales are found in open ocean habitats in temperate to tropical waters around the world with no recorded sightings or strandings off Victoria (DCCEEW 2023a). Pygmy Sperm Whales are also found in ocean habitats in temperate to tropical waters around the world and have been recorded in all states except the NT, though as strandings (DCCEEW 2023q). The PMST identified that Dwarf Sperm Whales and the Pygmy Sperm Whales may occur in the area, however, numbers are predicted to be low and as there are no BIAs these species are likely to be transient in the area affected by sound.
- Auditory masking of high-frequency and very high-frequency cetacean vocalisations is less likely as these species generally vocalise at higher frequencies than those generated by a seismic survey. [Paragraph added in response to Matter M09.]

The uncertainty level for impacts to VHF cetaceans is assessed as medium based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed journals.
- Dwarf Sperm Whale and Pygmy Sperm Whale are not listed as threatened species and there is limited published data on noise studies specific to these species.
- Biologically important areas within Australia are based on published data that routinely acknowledge the small sample sizes in the data.
- An absence of long-term monitoring data of the effects of seismic sound sources on very high frequency cetaceans in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) levels is assessed as medium. For VHF cetaceans the predicted level of impact is clearly below the defined acceptable levels of impact presented in Section 9.3.19.3. The mitigation and management measures presented in Section 9.3 provide sufficient confidence in the predicted effect levels.

9.1.2 High-frequency Cetaceans

From the PMST it was identified that six dolphin and eight beaked whale species, which are classed as high-frequency (HF) cetaceans potentially occur within the area that may be affected by underwater sound.

- The predicted level of impact to these species is assessed as minor given that impacts are predicted to have some effect to HF cetaceans, but the effect is not considered significant or at a level that may affect the population given the following: PTS and TTS per pulse effect criteria are reached between 51-55 m and 63-68 m, respectively, thus the implementation of the EPBC Act Policy Statement 2.1 - Interaction between Offshore Seismic Activities and Whales for soft starts, where prior to acquisition commencing, the sound source power is ramped up over 30 minutes, will ensure no HF cetaceans are within distances that PTS or TTS could occur. The TTS 24hr cumulative effect criteria is reached at up to 280-600m from the sound source, and the AUD INJ 24hr cumulative criteria is reached at up to 80m from the sound source, however, it is not feasible that a cetacean would be within that distance of the moving survey vessel for 24 hrs, thus impacts are not predicted. [Paragraph updated in response to Matter M34].
- Impacts to HF cetaceans are limited to avoidance behaviour within between 3.1-6.9 km from the sound source depending on where in the Operational Area the survey is being undertaken. As HF cetaceans are not dependent on any specific area within the area affected impacts may occur to individuals but not at a level to reduce fitness.
- Auditory masking of high-frequency and very high-frequency cetacean vocalisations is less likely as these species generally vocalise at higher frequencies than those generated by a seismic survey. [Paragraph added in response to Matter M09.]

The uncertainty level for impact to HF cetaceans is assessed as medium based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed journals.
- There is limited published data on noise studies specific to these species.
- Biologically important areas within Australia are based on published data that routinely acknowledge the small sample sizes in the data.
- An absence of long-term monitoring data of the effects of seismic on high frequency cetaceans in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) levels is assessed as medium. For HF cetaceans the predicted level of impact is clearly below the predefined acceptable levels of impact as detailed in Section 9.3.1. The mitigation and management measures detailed in Section 9.3 provide sufficient confidence in the predicted effect levels.

9.1.3 Low-frequency Cetaceans

From the PMST Report it was identified that the following low-frequency (LF) cetaceans[3] potentially occur within the area that may be affected by underwater sound:

[3] Blue Whales and Southern Right Whales are addressed in the following section given they are listed as Endangered under the EPBC Act.

- Long-finned Pilot Whale, Minke Whale, Short-finned Pilot Whale, and Sperm whale may occur.[4]
- Antarctic Minke Whale, False Killer Whale[3], and Killer Whale[3] likely to occur.
- Humpback Whale known to occur.
- Pygmy Right Whale foraging, feeding or related behaviour likely to occur.
- Fin Whale, and Sei Whale foraging, feeding or related behaviour known to occur.

The predicted level of impact to these species is assessed as moderate given that impacts are predicted to potentially have a significant effect on LF cetacean species. The impact may require additional management measures based on:

- AUD INJ and TTS per pulse effect criteria are reached between 67-73m and between 80-86m respectively, thus the implementation of the EPBC Act Policy Statement 2.1 - Interaction between Offshore Seismic Activities and Whales for soft starts, where prior to acquisition commencing the sound source power is ramped up over 30 minutes and while acquisition is being undertaken the sound source will be shut down if a whale (except for Southern Right Whale and Blue Whale, see next section) is within 2 km of the sound source. This will ensure no LF cetaceans are within distances where per pulse PTS or TTS could occur. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I05].
- The AUD INJ 24hr cumulative effect criterion is reached within 6.25-8.53 km, and the TTS 24hr cumulative effect criterion is reached within 23.63-27.92 km for LF cetaceans. This modelling assumes that a whale remains within this distance of the sound source for 24 hrs. This is not considered realistic for species that are transient in the area such as migrating (e.g. Humpback Whales).

For whales undertaking biologically important behaviours:

- The PMST Reports identified foraging known to occur for the Fin and Sei whales. The conservation advice for both these whales (TSSC 2015b, TSSC 2015c) identify anthropogenic noise and acoustic disturbance as a minor consequence rating.
- The PMST Reports also identified Pygmy Right Whale foraging likely to occur. This species does not have a recovery plan or conservation advice.
- There is no information on foraging areas for Fin, Sei, or Pygmy Right Whales off the coast of Victoria, though it is likely foraging occurs in the same areas identified as the foraging BIA for Blue Whales as they are often recorded foraging in the same areas (Gill et al. 2008; Gill et al. 2015; McCauley et al 2018), therefore control measures applied to Blue Whales will ensure no AUD INJ, TTS or behavioural disturbance to foraging Fin, Sei, or Pygmy Right whales.

The uncertainty level for impact to LF cetaceans is assessed as medium based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed journals.
- There is limited published data on noise studies specific to species.
- Biologically important areas within Australia are based on published data that routinely acknowledge the small sample sizes in the data.

[4] In line with Southall et al. (2019) and Finneran et al. (2023), it is understood that these species may be moved into a new functional hearing group as they vocalise at a lower frequency range than the other, mostly delphinid HF species. Consequently, a conservative approach has been taken to assess these species as LF cetaceans to ensure any future increase in protections is afforded in the EP.

- An absence of long-term monitoring data of the effects of seismic on high frequency cetaceans in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (moderate) and uncertainty (medium) levels is assessed as medium. For LF cetaceans the predicted level of impact is clearly below the defined acceptable levels of impact as detailed in Section 9.3.1. The mitigation and management measures detailed in Section 9.3 provide sufficient confidence in the predicted effect levels.

9.1.3.1 Blue Whales

From the PMST Report it was identified that blue whale (**BW**) foraging, feeding or related behaviour is known to occur within the area that may be affected by underwater sound.

Animat modelling was undertaken that considers vessel and BW movements and provides a more realistic prediction of the area that may be affected by underwater sound. The predicted level of impact to BW is assessed as moderate given that impacts without any mitigation could result in temporary hearing impairment, masking and changes in behaviour or habitat use; and that these effects, either in isolation or in combination, can potentially impair population recovery or effect habitat occupancy. Consequently, the impact may require additional management measures based on:

- The predicted maximum distances to the AUD INJ 24hr cumulative effect criterion, TTS 24hr cumulative effect criterion and behavioural effect criterion for Blue Whales is 71-127 m, 2.05-4.32 km and 2.42-4.67 km, respectively. To meet the action from the Conservation Management Plan for the Blue Whale (DoE 2015c) of "Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area", CGG will implement the following activity limitation: The sound source will only be operated in the Pygmy Blue Whale foraging BIA from 16 September and during October, November and December when low numbers of Pygmy Blue Whales and other foraging whales such as Fin, Sei, and Pygmy Right whales are in the BIA within the offshore Otway region. The months of September to December were selected based on acoustic and aerial surveys focused on Blue Whales in the Otway region as detailed in Annex 4. The TTS shut down zone for Blue Whales has been set to 5 km. To mitigate for behavioural effects, the seismic source will shut down within 5km of a blue whale detection. This will ensure the Regia MSS is consistent with the Blue Whale Management Plan, ensuring no blue whale is displaced from a foraging area.
- The sound generated by seismic surveys comprises low frequency pulses in the order of tens of milliseconds, occurring several seconds apart. At great distances from the seismic source, sound levels will be quieter, but transmission of the sound via multiple pathways (water, seabed) and reverberation mean that the pulse duration increases with distance. The sound frequencies that are emitted by seismic acoustic sources are broadband; however, most of the energy is concentrated between 0.1 kHz and 0.25 kHz. Consequently, the lowest frequency cetaceans are particularly affected since they have the most overlap with the frequencies of the seismic survey acoustic sources. As detailed in EP Appendix F3, Blue whale calls last up to 18 s and generally consist of three segments: a 9-s-long, 27-Hz tone, followed by a 1-s downsweep to 19 Hz and another, longer-lasting downsweep to 18 Hz (Širović et al 2004, Rankin et al 2005); and Antarctic blue whale source levels have been estimated to be between 188-191 decibels (Miller et al 2021). Given the short seismic pulse duration relative to the duration of marine mammal vocalisations (several seconds to several minutes or longer), marine mammals are likely to be able to detect calls in between seismic pulses (Wood et al., 2012).

  Further, several studies have documented compensation responses (anti-masking strategies) to anthropogenic underwater noise, including changes in vocalisation strength, frequency, and timing. (Erbe et al., 2016). For example, blue whales increased their calls

(emitted during social encounters and feeding) when a seismic survey was operational in the area (Di Iorio and Clark, 2010). Such adaptations have also been reported for humpback whales (Cerchio et al., 2014; McCauley et al., 1998; 2003b), right whales (Parks et al., 2007, 2011), killer whales (Holt et al., 2008), bowhead whales (Blackwell et al. 2015), and bottlenose dolphins (van Ginkel et al., 2017). It is thought that increased calling enhances the probability that communication signals will be successfully received by conspecifics by reducing the effects of auditory masking.

It is likely that marine mammals in the vicinity of the OA during the Regia MSS, particularly baleen whales, may be subject to some masking effects. The proposed survey timing, i.e. avoiding the peak productivity period for foraging blue whale and other species in the area will reduce the potential for behavioural impacts including interference with communication.

Masking levels are difficult to predict, and no auditory thresholds exist for predicting masking effects on marine mammals (Erbe et al., 2016); however, as outlined above masking responses (e.g. changes in calling rates) have been documented to occur at relatively low exposure levels (i.e. lower than would elicit any behavioural response). Any masking effects will however cease at the completion of the survey and are highly unlikely to have detectable population level effects. [Paragraphs have been added in response to Matter M09.]

The uncertainty level for impact to blue whales is assessed as high based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed journals.
- There is limited published data on noise studies specific to these species.
- The absence of direct hearing data for BW continues to warrant substantial caution in attempting to predict their hearing capabilities and any potential susceptibility of their hearing to nose exposure (South et al. 2019).
- An absence of long-term monitoring data of the effects of seismic sound on BW in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (moderate) and uncertainty (high) levels is assessed as high. For blue whales the predicted level of impact is close to the pre-defined acceptable levels and/or there is enough uncertainty to apply the precautionary principle. Therefore, BW will be assessed further in the third stage of the assessment process (see Appendix F3).

9.1.3.2 Southern Right Whales

From the PMST Report it was identified that southern right whale (SRW) breeding is known to occur within the area that may be affected by underwater sound.

Animat modelling was undertaken that considers vessel and SRW movements, including cows with calves, and provides a more realistic prediction of the area that may be affect by underwater sound. The predicted level of impact to this species is assessed as moderate given that impacts without any mitigation could result in auditory impairment and disturbance; and that impacts from anthropogenic underwater sound is greatest where sound-generating activities occur within or close to the reproduction BIA where whales demonstrate site fidelity, are resident for long periods (e.g., weeks to months) of time, young calves are present, and females are engaged in calving and nursing, either in isolation or in combination. Consequently, the impact may require additional management measures based on:

- The predicted maximum distances to the AUD INJ 24hr cumulative effect criterion, TTS 24hr cumulative effect criterion and behavioural effect criterion for SRW is 59-77 m, 807 m – 3.76 km and 1.26-4.61 km, respectively. The TTS shut down zone for Southern Right Whale has been set to 4 km. To mitigate for behavioural effects, the seismic source will shut down within 5km of a Southern Right Whale.

- CGG acknowledges the literature showing there may be behavioural responses below the NMFS recommended 160 dB SPL threshold, to address this uncertainty CGG will adopt a precautionary shut down measure at the 140 dB threshold for any SRW. CGG will implement a shutdown measure of 13km from the sound source aligning with the modelled ANIMAT distance for SRW calf-cow pairs residing in the Reproduction BIA (see Appendix B7c).
- The activity limitations and control measures that CGG will implement ensure that the survey does not prevent any SRW from utilising the BIA of HCTS, or cause auditory impairment, and that anthropogenic noise is minimised. It should be noted given the behavioural shut down distance of 5 km, CGG can ensure no TTS impacts at 4 km.
- The Conservation Management Plan for the SRW 2011 – 2021 stated that as migratory movements to and from calving grounds remain unknown, whales may be exposed to noise interference from seismic surveys during these movements (CoA 2012). On this basis, there remains the limited potential for TTS 24hr effects in SRWs throughout the Operational Area as they approach or disperse from shelf waters throughout the 'SRW Migration BIA'. However, as outlined above, TTS is only predicted if a SRW were to remain within 4 km of the active source for 24 hours.
- The National Recovery Plan for the Southern Right Whale (DCCEEW 2024) lists anthropogenic underwater noise from seismic surveys as a moderate threat to the eastern population with a high priority for action. The actions associated with a high priority risk include additional mitigation action and an adaptive management plan and the precautionary principle should be applied. CGG will implement a Fauna Management Plan (Appendix G2) which will include adaptive management measures to ensure impacts to SRW is below the acceptable level.

The uncertainty level for impact to southern right whales is assessed as high based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed journals.
- The National Recovery Plan for the SRW (DCCEEW 2024) lists anthropogenic underwater noise from seismic surveys as a moderate threat to the eastern population as moderate and a high priority.
- There is limited published data on noise studies specific to this species.
- The absence of direct hearing data for SRW continues to warrant substantial caution in attempting to predict their hearing capabilities and any potential susceptibility of their hearing to nose exposure (South et al. 2019).
- An absence of long-term monitoring data of the effects of seismic sound on SRW in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.
- Southall et al. (2021) compile various studies, but most focus on impulsive sources like pile driving or sonar, with only four addressing seismic airgun impacts on LF cetaceans, and just one (Malme et al., 1986) offering experimental data on migrating gray whales. Southall (2024) rejects the idea of simple all-or-nothing response thresholds and calls for new approaches and better use of current data to understand and mitigate the effects of human-made noise on marine mammals. In the meantime, the SPL threshold of 160 dB re 1 μ Pa remains widely accepted for assessing behavioral responses to impulsive sound sources, such as seismic air guns.

The predicted level of impact based on the effect (moderate) and uncertainty (high) levels is assessed as high. For SRW the predicted level of impact is close to the pre-defined acceptable levels and/or there is enough uncertainty to undertake further assessment. Therefore, SRW will be assessed further in the third stage of the assessment process (see Appendix F3).

9.1.4 Otariid Pinnipeds

From the PMST Report it was identified that within the area that may be affected by underwater sound the Australian Fur-seal breeds at Lady Julia Percy Island (Deen Maar), and the Australian Sea Lion and the Long-nosed Fur Seal may occur in the area.

The predicted level of impact to these species is assessed as minor given that impacts are predicted to have some effect to seals and sea lions, but the effect is not considered significant or at a level that may affect the population given the following:

- The per pulse effect criteria for AUD INJ and TTs for these species was reached at 51m-55m and 63m-68m respectively, from the sound source.
- The AUD INJ cumulative effect criteria for these species was reached at 50m-55mfrom the sound source and TTs cumulative criteria was reached at 660m-1.02 km from the sound source. It is highly unlikely that a seal or sea lion would stay within 1.02 km of the sound source for up to 24 hr, thus TTS impacts are not predicted.
- Impacts to seals or sea lions are limited to avoidance behaviour within an area between 3.1 km-6.9 km depending on where in the Active Source Area the survey is being undertaken. The Regia MSS Operational Area may overlap foraging areas for the Australian Fur Seal. [Paragraph updated in response to Matter M31]. A 10.3 km buffer from Deen Maar was initially applied to reduce risks and impacts to Australian Fur Seals to an acceptable level. This effect distance for pinnipeds was based on the initial modelling conducted for the activity (see Appendix B7a). The commissioning of subsequent modelling (see Appendix B7b Sound Emissions Secondary Modelling Report) has provided further insights relevant to the management of this species. The secondary modelling was undertaken in response to consultation with commercial divers mainly to address constraining the sound source operation to water depths of no shallower than 50 m. Results from this work show that behavioural sound effect criteria for pinnipeds is now reached at a maximum of 11.8 km from the sound source. As the Active Source Area is a minimum of 17 km from the closest haul out site (Deen Maar), behavioural impacts to pinnipeds at this location are no longer predicted. [Paragraph updated in response to Matters M30, M31, M32, M33 and F17].
- Australian Fur Seal are considered generalist feeders, foraging on a wide range of species including red bait, barracouta, jack mackerel, red cod, leatherjacket as well as Gould's squid (Arnould et al. 2011). A study of Australian Fur Seal diet revealed they prey on 60 to 70 species of fishes and cephalopods (Kirkwood et al. 2008). Impacts to prey species of Australian Fur Seal are predicted to range from negligible for squid to minor for fish species and will be temporary, reversible and of low intensity as detailed in the impact assessment of underwater sound to fish (Appendix E3) and invertebrates (Appendix E4).
- There have been some studies on the variations and changes in Australian Fur Seal diets in Victoria. These studies have found Australian Fur Seal diets are highly variable depending on the availability of prey and oceanic fluctuations, (Kirkwood et al 2008, Arnould et al. 2011). Given Australian Fur Seals exhibit flexible foraging strategies, impacts to prey and the buffer around Deen Marr, impacts to Australian Fur Seal foraging is not expected.

The uncertainty level for impact to pinnipeds is assessed as medium based on:

- The sound effect criteria used in the impact assessment have been published in peer reviewed journals.
- There is limited published data on noise studies specific to these species.
- An absence of long-term monitoring data of the effects of seismic on pinnipeds in the presence of frequent seismic surveys, and other anthropogenic sound generating activities, in the region.

The predicted level of impact based on the effect (minor) and uncertainty (medium) levels is assessed as medium. For pinnipeds the predicted levels of impact are clearly below the pre-defined acceptable levels of impact and the mitigation and management measures in place provide sufficient confidence in the predicted effect levels.

9.2 Change in physical condition

9.2.1 Cetacean Mass Strandings

While there has been considerable conjecture that the displacement of cetaceans from seismic surveys (because of avoidance) could result in stranding events, no solid evidence has yet been forthcoming to support this link. The most recent assessment of whale stranding patterns in Victoria (Foord et al., 2019) makes no reference to seismic surveys and found no seasonal stranding pattern. While Foord et al (2019) didn't specifically investigate the relationship between strandings and seismic surveys, seismic surveys typically occur over the summer months off the south coast of Australia; hence if causal links were present, some evidence of seasonal patterns would be expected. The Foord et al (2019) study nevertheless provides a detailed assessment of cetacean strandings along the Victorian coastline. Dolphins are the only group involved in regular stranding events. Figure 6 in the paper indicates the complete lack of strandings of baleen whales in the Otway region. The design of our management and mitigation program around Pygmy Blue Whales and Southern Right Whales has been guided by the very latest in scientific guidance – for example Southall et al (2023); Southall et al (2021), Popper et al (2024) and Accomando et al (2025). CGG has demonstrably embraced the Precautionary Principal in its deliberations and used current literature for guidance.

Further to this, NOPSEMA (2019) states that "Evidence of mass whale stranding exists from six to seven million years ago, long before anthropogenic sound became a factor, and it is likely that any observable increase in occurrence [of stranding events] is due to greater visibility of previously inaccessible coastline." [Paragraph has been added in response to Matter M11 and M13].

9.3 Measures Adopted to Manage Environmental Impacts

The following measures have been adopted to ensure that the impacts associated with elevated levels of underwater sound from the survey and support vessels on marine mammals will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

After the NMFS guidance assessment, CGG re-assessed the mitigation measures based on the updated distances for marine mammals. No distances in this assessment surpassed the 500m shutdown applied for all marine mammals, therefore no additional mitigation measures were implemented.

Measure	Measure Type	Details and Justification
Survey Environment Advisor	Person	This person is the offshore representative of the titleholder for all on-water decision making related to the management of interactions with marine fauna.
Environmental Officer	Person	This person is the onshore specialist coordinating compliance activities across the entire activity.

Measure	Measure Type	Details and Justification
Marine Fauna Observers	Person(s)	Trained and qualified MFOs with previous survey experience are resident on the seismic vessel at all times during daylight operations. Dedicated, trained and experienced MFOs will also be onboard a dedicated spotter vessel at all times (except for during port calls, bunkering, or crew transfers).
Passive Acoustic Monitoring Operator	Person(s)	PAM operators with previous survey experience are present on the seismic vessel, covering 24-hour operations to detect marine mammals.
Relief PAM/MFO Observer	Person	An MFO who can provide relief, as required, across both visual observation and acoustic detection monitoring tasks. [Sentence added in response to Matters M43, M45 and M49].
Whale Expert Panel	Person(s)	The Expert Panel will have expertise and qualifications in BW, SRW, and marine fauna observations at sea respectively. The Expert Panel will be comprised of: • One expert on Southern Right Whales in Southern Australia • One expert on Blue Whales in Australia • An expert on whale detections/observations. • A CGG operations representative The objective of the panel is to provide technical expertise and advice to CGG on Adaptive Management procedures to minimize impacts to Southern Right Whales and Blue Whales in the Otway Basin The panel will meet at least once prior to the survey to provide input relating to the location of the spotter vessel and design of the flight paths for the aerial surveillance. During the survey the panel will meet at least fornightly to review observation data from MFOs, and PAM and provide advice to CGG on regarding triggers for aerial surveys, and how many aerial surveys are appropiate, reporting and monitoring to minimise impacts to SRW and BW.
Spotter Vessel	Item of Equipment	Vessel will observe for all whales and if not a BW or SRW will communicate the approximate location and bearing of the whale sighting to the SEA on the survey vessel (except for during port calls, bunkering, or crew transfers).

Measure	Measure Type	Details and Justification
Spotter Vessel Procedures	Procedure	These procedures govern the spotter vessel movements in different modes. The detection range for marine fauna monitoring varies depending on the likelihood of encountering Blue Whales (BW) or Southern Right Whales (SRW) during different times of the year. **May to October** – When SRW presence is more likely, the spotter vessel will remain **20 km**[5] to the shoreside from the seismic vessel, therefore adjacent to the SRW reproduction BIA Each procedure should be applied according to the appropriate detection range based on the operational period. Any changes to these ranges will be communicated by the Environment Officer as required. In *Scouting Mode*, it conducts reconnaissance **20 km** ahead of the survey vessel before commencement of the survey and each line turn. In *Sentry Mode*, it maintains a **20 km** distance to the shoreside from the seismic vessel to maximise SRW detection capabilites. **November-December** In *Blue Whale Sentry Mode,* it maintains position **20 km** west of the seismic vessel because blue whale abundance data shows an initial tendency for foraging to occur in South Australian waters and move eastward throughout the summer months. Therefore, it is more likely that the survey will encounter blue whales on its western flank, and if the spotter vessel is in either other mode, it would be positioned on the eastern side of the survey and is less likely to encounter blue whales. In *Scouting Mode*, it conducts reconnaissance **10[6] km** ahead of the survey vessel before commencement of the survey and each line turn.
Pre-survey and aerial surveillance procedures	Procedure	These requirements are derived from adopting and improving on Policy Statement 2.1 and are written into the Fauna Managemnet Plan. Whilst Policy Statement 2.1 requires a 2 km low-power zone and a 500 m shutdown zone, CGG's experience is that moving to low-power during a line is an effective shutdown. As such, a precautionary shutdown zone for all whales can be applied of 2 km.
Pre-Start Up Procedure	Procedure	
Start-up Procedures	Procedure	
Start-up delay procedures (if sighting)	Procedure	
Operating Procedure	Procedure	

[5] The 20 km separation distance is informed by the performance of the PAM systems installed on both the seismic and spotter vessels, each capable of detecting whales at ranges of ~10 km. By positioning the spotter vessel 20 km away from the seismic vessel, CGG maximises combined detection coverage and enhances the likelihood of detecting Southern Right Whales and Blue Whales.

[6]

Measure	Measure Type	Details and Justification
Shutdown procedures	Procedure	Implementation of EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with Cetaceans to reduce the risk of collision with marine fauna during the activity for all vessels at all times. Additionally, start-up delay and shutdown procedures will be implemented to protect dolphins and pinnipeds.
Night-time and low visibility procedures	Procedure	
Helicopter Operation Procedure	Procedure	
Marine fauna detection and observation zone of 40[7]0+ km horizontal radius from the seismic source	Practice	
End-of-Survey Procedure	Procedure	The survey activity limitiation have been set to allow for acquisition into December. There are activity limitiations that mean the survey must stop 90 days after it started and there are ecological triggers that may or may not occur before the 90 days expire, and/or before the end of December. The criteria for early cessation of the survey are outlined in the Fauna Management Plan and will be the performance standards for this control measure.
Integration of marine fauna observations from third parties in the region	Responsibility	Other petroleum titleholders, commercial shipping, and offshore wind project, research institutes and government agencies may have activities on the water that may detect whales. CGG will offer to share its detection data in real-time anticipating that this will be reciprocated, if possible.
Ramp up of sound source to full power over 30 minutes.	Practice	Mobile marine fauna (including demersal and pelagic fish, octopus, squid, diving birds, penguins, and turtles) are expected to move away from the source before it is at full power, providing them a level of protection. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04, I05, E08].
Reduce the sound source to low power if flocks of foraging birds are observed within 500 m of the source.	Practice	This measure has been adopted because of the consultation. It protects foraging little penguins and uses flocks of foraging birds as and indicator of schooling fish that may be targeted by foraging little penguins.

[7] By deploying PAM systems on both the seismic vessel and spotter vessel, each capable of detecting whales out to 10 km, the project achieves 40 km of continuous linear monitoring coverage. When the vessels are positioned approximately 20 km apart along the survey line, each PAM system contributes 20 km of linear detection capability (10 km port and 10 km starboard). Together, these form a seamless 40 km detection corridor, significantly enhancing early-warning potential for whales moving toward the survey area.

Measure	Measure Type	Details and Justification
Acquire Seismic On Paper	Practice	This measure brings together all staff and contractors directly involved in the activity to build connections between participants, familiarise staff with operational requirements, and perform scenario planning for environmental management.
Fauna Management Plan	Resource	This includes the on-water instructions for the various persons involved in protecting marine fauna. It also documents compliance with Policy Statement 2.1.
Sail Line Plan	Resource	Ensures the active source area is located more outside of the distances required by the activity limitations.
Accountability for implementation of the Fauna Management Plan procedure.	Responsibility	CGG Site Representative
Provide sufficient resources to implement the FMP.	Responsibility	CGG Technical Operations Manager
Convene and coordinate the Whale Expert Panel as needed	Responsibility	Environment Officer
Coordinate and document the review of effectiveness and compliance with the FMP.	Responsibility	
A review of the effectiveness and compliance with the FMP will be undertaken within one week of commencement of the Regia MSS and thereafter every four weeks while the Regia MSS is being undertaken.	Responsibility	
Ensure the Regia MSS induction provides an overview of the FMP.	Responsibility	

9.3.1 Additional Fauna Detection Methods

The nature and scale of the impact to marine fauna are also lessened through the adoption of measures that mitigate impacts. The Regia MSS will employ two additional types of fauna detectors Passive Acoustic Monitoring (**PAM**) Operators who are on the vessel. These roles, along with the MFOs, collaborate through the Survey Environment Advisor (**SEA**) to correlate vocalizing marine mammals' identification and localization. The role of these people will support minimising the impact of seismic survey operations on marine mammals, including SRW, BW, and other protected species.

MFOs and PAM operators provide environmental expertise to the vessel crew, implementing various measures outlined in the EPBC Act Policy Statement 2.1, the Australian National Guidelines for Whale and Dolphin Watching 2017, and the FMP.

9.3.2 Fauna Management Plan

The Fauna Management Plan (**FMP**) is designed to safeguard marine fauna, with a primary focus on protection of Southern Right Whales (**SRW**s) and Blue Whales (**BW**), during the Regia MSS. The FMP outlines how various surveillance methods will be used to detect marine mammal presence, assess their classification, monitor behaviour, and ensure the adaptation of the acquisition plan to minimize the impact of sound on these mammals. The FMP is the documentation that implements Policy Statement 2.1.

9.3.3 Acoustic Detection

CGGs whale detection strategy includes the integration of acoustic detection systems, recognising the dynamic nature of whale behaviour. While they may not be visually detected by MFOs unless present on the surface, whales often vocalise allowing for electronic detection. Acoustic detection systems will consist of passive acoustic monitoring (**PAM**) and the use of acoustic detection monitoring.

Acoustic detection methodologies adopted will have 24-hour operation and near real time reporting of whale species and location. The system to be engaged will be able to detect low-frequency whales such as BW and SRW, subject to a successful test deployment prior to the commencement of the survey.

The underwater area is not a constant symphony of whale songs, and the likelihood of vocalisation can vary. Whales are known to communicate using a diverse range of vocalisations, from intricate songs to simpler clicks and whistles, depending on their species and circumstances. Therefore, the effectiveness of our acoustic detection methods can be influenced by factors such as species presence, behaviour, and environmental conditions that may affect vocalization patterns.

This variability underscores the importance of a multifaceted approach to whale detection. While acoustic detection adds a valuable dimension to detection capabilities, it is inherently dependent on whales vocalising. Consequently, the use of multiple detection methods, including visual and aerial observations and acoustic detections systems, enhances overall confidence in detecting whales, both above and below the water surface, regardless of their vocalisation patterns.

9.3.3.1 Marine Fauna Observers

Marine Fauna Observers (MFOs) will be stationed on the survey vessel to undertake observations for marine fauna during daylight hours. MFOs conduct their observations using binoculars and the unaided eye, primarily from the bridge of the vessel (typically the most elevated point on a vessel) or, ideally, from an elevated vantage point. In optimal weather conditions, visual observations are effective up to ~5 km from the survey vessel.

The MFOs will be experienced in whale and other marine fauna observation, distance estimation, data gathering, mitigation procedures and reporting.

9.3.3.2 Passive Acoustic Monitoring

The PAM system can detect cetaceans across all frequency hearing groups including low-frequency hearing group whales such as BW and SRW. Thus, the PAM system, which has a detection distance range of ~10 km from the survey vessel, will be the primary whale detection method at night and during low visibility.

PAM operators will be experienced in identifying whale vocalisation detection, species identification, data gathering, mitigation procedures and reporting.

In addition, officers of the watch on the attending support vessels will be trained to identify whales during daylight hours to support the visual detection of marine mammals. [Sentence added in response to Matters M43, M45 and M49].

9.3.4 Aerial Surveillance

Aerial surveillance is a key component of CGG's multifaceted approach for detecting whales in support of the Regia MSS. Unmanned Aerial Vehicles (UAVs, drones) will be used to detect all whales within the monitoring area, with a particular focus on the movement of Southern Right Whales (SRWs) into and out of the coastal reproduction Biologically Important Area (BIA) and the movement of Pygmy Blue Whales (PBWs) into and out of the Otway region. This capability will help to reduce uncertainty around whale presence and distribution in the broader region, including areas potentially exposed to elevated sound from the Regia MSS. Aerial surveillance outputs will contribute directly to real-time mitigation decision-making and will complement vessel-based observations, Passive Acoustic Monitoring (PAM), and land-based visual monitoring.

UAVs will be deployed from elevated coastal vantage points between Cape Bridgewater and Cape Otway by trained Drone Pilots-in-Command (PICs) working alongside Marine Fauna Observers (MFOs) as Whale Monitoring Teams (WMTs). This approach extends the effective detection range of shore-based observers, increases spatial coverage across nearshore and mid-shelf zones, and enables flexible, weather-responsive monitoring throughout daylight hours. Drone operations will only occur under safe and compliant operating conditions. The combined use of visual observers and UAV-mounted sensors, including high-resolution zoom and thermal imaging, enhances the probability of detecting whales at extended distances and supports the verification of species identity, group composition, and general behaviour.

For PBWs, UAV-based surveillance will also be used as part of the pre-season coastal aerial programme. Early-season flights launched from Cape Nelson Lighthouse, one of the first coastal landforms encountered by PBWs arriving from the west, will survey nearshore to mid-shelf waters up to approximately 40 km offshore, which includes historical migration pathways. These flights are intended to provide an early indication of PBW presence and will inform advice from subject-matter experts on any required scaling of monitoring effort or modifications to mitigation measures during acquisition. All aerial surveillance activities will be undertaken by experienced operators with a proven record of whale-focused UAV operations, ensuring high-quality detection outcomes and alignment with all relevant regulatory requirements.

9.3.5 Adaptive Approach to Monitoring

In addition to described approaches to visual observations, acoustic detections and aerial surveys to ascertain the presence of whales, additional and adaptive approaches may be deployed subject to the advice of the Whale Expert Panel, namely, deployment of additional aerial surveys during the Regia MSS (in addition to a minimum of one (1) aerial survey prior to commencement of the Regia MSS). The Whale Expert Panel will have an advisory role to assist CGG in decision making, help with whale monitoring and provide advice on escalation triggers CGG may need to adapt to ensure impacts to whales are minimised.

Any marine fauna observations from additional aerial surveys or spotter vessel MFOs will contribute to monitoring of pre-acquisition detection criteria and soft start procedures that will affect sound source operations, if not met.

The Whale Expert Panel will be engaged prior to commencement of the Regia MSS and will be informed of any SRW- or BW-related shutdowns within 24 hrs of occurrence during the survey. This will provide the panel with timely opportunity to provide advice and recommendations for ongoing and adaptive management of the activity.

10 Demonstration Impacts will be of an Acceptable Level

10.1 Discussion on Principles of ESD, Biological and Ecological Categories

Temporary and Reversible

Auditory injury (AUD INJ) in cetaceans and Otariids, a permanent damage to hearing, is not predicted to occur because of seismic noise from the Regia seismic activity. It is theoretically possible for AUD INJ to occur both instantaneously and through exposure over 24 hours. However, the impact assessment sets out reasoned and supported rational for why it is not feasible for very high frequency and low frequency cetaceans to remain in close enough proximity to the seismic source for cumulative exposure to practically occur over 24 hours. Where AUD INJ could feasibly occur as demonstrated through animat modelling for BW and SRW, control measures have been adopted to prevent this permanent impact from occurring.

Temporary threshold shift (TTS), changes in cetacean and Otariid behaviour and masking for both these receptors are by definition temporary and reversible when caused by a temporary and moving seismic noise source. TTS temporarily reduces auditory sensitivity, and the best available science indicates this is non-neuropathic (reversible) within approximately 6 to 24 hours (Houser 2021). Behavioural changes are anticipated to return to normal once animals are outside the effect range for altered behaviour (Southall 2021). Similarly, masking will also cease once noise levels return to background levels either as the separation distance between the cetacean/Otariid increases or once the seismic activity ceases. This reasoned and supported evidence demonstrates that potential seismic noise impacts on cetaceans and Otariids will be temporary and reversible and consistent with this aspect of ESD.

Small scale

The spatial scale of potential impacts to cetaceans and Otariids is considered small in the context of their distribution, habitat utilisation and movements within their biologically important areas (BIAs). With the control measures adopted for the seismic survey to manage impacts, cetaceans will be able to utilise their BIAs during the seismic activity. For VHF, HF cetaceans control measures ensure that PTS and TTS will not occur in a BIA, and that if behavioural effects occur, they will only extend up to 7 kms from the survey area. These species of cetaceans can move to other parts of their BIA and continue their biological and ecological activities. For BW the behavioural effects noise threshold will only occupy 0.17% of the foraging BIA and for SRW will only occupy 0.2% of the migration BIA. These extremely low levels of overlap with the BIAs leaves the rest of the BIA available without impact which is deemed inherently acceptable due to such low levels of overlap. There is not expected to be any overlap of seismic noise thresholds with any Otariid BIAs. The evidence presented here demonstrates the spatial extent of noise impacts on cetaceans and Otariids is inherently acceptable due to the extremely small spatial footprint of the noise emissions relative to their biological and ecological functions.

Table E7-6 shows total ensonified area overlaps of behavioural effect area that has been conservatively calculated by using the entire behavioural noise footprint from the entire survey to estimate the proportional overlap (i.e. not just the noise footprint from a single shot).

Table E7-6 - Proportion (%) of overlap between the total ensonified area with noise levels that could influence cetacean behaviour within their BIAs

Species	Migration BIA	Foraging BIA	Reproduction BIA
Blue Whale (BW)	0	0.17	NA
Southern Right Whale (SRW)	0.2	NA	0
Humpback Whale	0	0	NA
Sperm Whale	NA	0	NA

Natural variation

The activity will be managed to prevent injury to cetaceans and Otariids and so that areas and periods important to biologically important foraging and reproduction are avoided or prevented. Therefore, it is not possible for impacts to important foraging locations or reproductive BIAs to be greater than natural variations of these ecological processes.

The only temporary impacts to cetaceans and Otariids that could occur are to their behaviour during general migratory or foraging behaviour. Both these behaviours naturally occur over extremely large spatial areas on a scale of many 1000s of km as demonstrated by their migratory routes and BIAs. Any change to these general migratory and foraging behaviours are only predicted to occur up to 12 km from the seismic source. Therefore, the maximum potential change to their behaviour could only result in changes in movement that are a fraction of 1% of their natural movement patterns. As such, any potential minor impact is considered acceptable with this aspect of ESD.

Based on sufficient information

The assessment drew upon site-specific acoustic modelling, peer-reviewed literature, and regulatory guidance, including EPBC Policy Statement 2.1 and sound exposure thresholds recommended by Southall et al. (2019) and NMFS 2024. Exposure criteria for both impulsive sound (SPL_{peak} and SEL_{cum}) and behavioural disturbance (SPL_{rms}) were applied across marine mammal hearing groups. Where uncertainty existed, such as in the behavioural sensitivity of specific species, conservative assumptions were used. The modelling demonstrated that zones of potential injury are small, species-specific, and highly localised, with no overlap with critical habitats. No serious or irreversible harm was predicted, and the level of scientific uncertainty was considered low due to the maturity of available data and the application of conservative assessment methods. As such, the precautionary principle was not triggered.

Activity not inconsistent with EPBC Act

The assessment reviewed relevant management and recovery plans for marine mammals listed under the EPBC Act, including the Recovery Plan for the Blue Whale and Conservation Advice for species such as the Southern Right Whale and Australian Sea Lion. Whilst the activity overlaps blue whale and southern right whale BIAs, the measure in place to shut down the activity and move away ensure that behavioural effects are avoided and there will be no auditory impairment. At the northern most corner of survey area there is a small overlap with parts of the SRW reproductive BIA (Map - REG-EPM-069). However, the activity will be managed such that no SRW will be exposed to noise levels that could prevent SRW from utilising the reproductive or migration BIA's and is not expected to reduce reproductive success.

Acceptability with the relevant plans of management has been achieved through the adoption of significant and costly additional control measures that are commensurate with the nature and scale of this seismic survey. The control measures adopted to achieve this level of protection for BW and SRW are rarely adopted for other seismic surveys and demonstrates the Titleholder's commitment to a high level of environmental stewardship.

The activity design incorporates all required management measures under the EPBC Act Policy Statement 2.1, including species-specific exclusion zones, pre-start visual observation periods, soft-start procedures, and operational shutdowns where required and will prevent injury to BW and SRW. These measures are consistent with both the objectives of the relevant management instruments and recognised industry standards. As such, environmental management of the activity is not inconsistent with the EPBC Act or its associated plans of management.

10.2 Economic, cultural and social categories

Consultation feedback from relevant persons highlighted concerns regarding the potential for underwater sound to disturb or injure marine mammals, particularly species of cultural or ecological importance such as whales and dolphins. Specific concerns included the adequacy of exclusion zones, the sensitivity of migratory species, and possible effects on species with cultural significance.

In response, CGG incorporated updated species databases, refined exclusion zone boundaries using current modelling, and confirmed alignment with EPBC Policy Statement 2.1 requirements for all marine mammal functional hearing groups. No culturally significant practices or spiritual sites were identified within or near the sound exposure zones, and no affected persons were found to be materially disadvantaged by the activity. While no formal objections were raised, several relevant persons requested stronger justification of threshold distances and clearer presentation of impact characterisation. These inputs were reflected in updates to the impact assessment, which now includes refined species-specific mitigation, expanded justification of assumptions, and clear documentation of all relevant concerns in Annex 2. The process confirmed that cultural values were respected, stakeholder views were incorporated, and appropriate measures were adopted to manage all claims raised.

10.3 Consistency with company processes

The impact assessment followed the methodology outlined in Appendix B3 and applied defined thresholds for physiological and behavioural effects based on regulatory criteria and scientific literature, including SEL_{cum} and SPL_{peak} levels relevant to marine mammals. Mitigation measures consistent with the EPBC Policy Statement 2.1, including pre-start observation periods, and soft-start procedures, were incorporated. No exceedance of regulatory thresholds or high-consequence outcomes was identified, and the final consequence rating remains within company limits. Using the ranking tables from this process the results of assessment are shown in Table E7-7.

Table E7-7 - Environmental Assessment Rankings

Marine Mammal Group	Predicted Level of Effect	Uncertainty	Predicted Level of Impact
Very-high-frequency cetaceans	Minor (2)	Medium (3)	Medium (6)
High-frequency cetaceans	Minor (2)	Medium (3)	Medium (6)
Low-frequency cetaceans	Moderate (3)	Medium (3)	Medium (6)
Blue Whale	Moderate (3)	High (4)	High (12)
Southern Right Whale	Moderate (3)	High (4)	High (12)
Otariid pinnipeds	Minor (2)	Medium (3)	Medium (6)

CGG's own criteria for proceeding with the activity requires that impacts and risks are managed to a 'Medium' ranking. Therefore, further assessment of the species, and relevant behavioural context, will be required. Further mitigation measures will need to be considered to either reduce the predicted level of effect and/or the levels uncertainty in the assessment, as demonstrated in Appendix F3.

11 Environmental Performance Outcomes

CGG is required to set environmental performance outcomes (EPOs) to ensure that impacts are of an acceptable level.

Table E7-8 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E7-1)	Environmental Performance Outcome	Rationale
Marine mammals can continue critical life-cycle stages and are not injured.	**As a result of shutting down or relocating the sound source when whales enter shutdown zones, no physical injury or sustained interference with marine mammal life-cycle behaviours occurs during the activity.**	This EPO is supported through implementation of observation zones, pre-start clearance, shutdown protocols, and verification that sound exposure levels do not exceed recognised injury and disturbance thresholds at relevant distances from the source.
Anthropogenic threats are managed consistent with ecologically sustainable development principles to facilitate recovery of all threatened whales.	**As a result of complying with the activity limitations and environmental performance standards in place to protect threatened whales, environmental impacts and risks associated with the activity are managed in a manner that is demonstrably consistent with ecologically sustainable development principles.**	This EPO allows for holistic assessment of environmental performance beyond individual thresholds. It can be evidenced through documentation of ALARP assessments, adoption of mitigation measures consistent with recovery goals, and clear links between impact assessment outcomes and long-term species conservation objectives.

Defined Acceptable Level (From Table E7-1)	Environmental Performance Outcome	Rationale
Anthropogenic noise in biologically important areas must be managed such that any blue whale is not displaced from a foraging area.	**As a result of shutting down or relocating the sound source when a blue whale is observed within 5 km, blue whales will not be behaviourally disturbed within this range, leading to the protection of important foraging areas and avoidance of displacement.**	The modelled range at which sound exposure reaches 160 dB SEL was 4.67 km, justifying the application of a 5km behavioural exclusion zone. This EPO is measurable, precautionary, and aligned with key blue whale protection strategies. It can be implemented using visual and acoustic monitoring techniques and operational shutdown procedures to prevent displacement from critical foraging habitat. This level aligns with the objectives of the Blue Whale Conservation Management Plan, which identifies the protection of biologically important foraging areas as critical to the species' survival and recovery. It ensures that anthropogenic noise does not displace blue whales from key feeding areas, especially when they are actively foraging. The 5 km distance aligns with the 160 dB behavioural disturbance threshold for low-frequency cetaceans under NOAA NMFS 2024 criteria, and matches the modelled maximum distance at which this threshold is predicted to occur.
Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment.	**As a result of implementing shutdown or relocation procedures when a SRW enters the 13 km ensonified area SRW are not prevented from utilising the area nor subject to auditory impairment.**	This EPO can be met through adherence to modelled thresholds for TTS and AUD INJ, 160 dB SPL and 140 dB SPL behavioural thresholds implementation of visual and acoustic monitoring, and application of precautionary shutdown and exclusion protocols when whales are detected near sensitive areas. It ensures protection of SRW critical habitat functions and compliance with recovery objectives.
Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it minimises behaviour disturbance.	**As a result of the implementation of real-time monitoring and activity limitations, SRW are not exposed to sound levels that cause sustained behavioural disturbance within or adjacent to BIAs or HCTS.**	This EPO can be achieved through the application of conservative behavioural disturbance thresholds (e.g. 160 dB SPL and the precautionary 140 dB SPL), exclusion zones based on modelled sound fields, and operational controls (e.g. shutdowns, delays) when whales are detected near sensitive areas. It ensures behavioural integrity is maintained during critical life-cycle periods.

Defined Acceptable Level (From Table E7-1)	Environmental Performance Outcome	Rationale
Sound exposure to low frequency cetaceans must be below PTS per pulse and PTS 24 hr SEL thresholds of 222[8] dB and 183 dB respectively.	**As a result of shutting down the sound source if:** - **any pinniped or dolphin is observed within 500 metres (except for bow riding dolphins),** - **any whale[9] is detected within 2 km of the sound source, and** - **any low frequency cetacean is detected within 9km of the sound source** **cetaceans will not be exposed to sound levels associated with auditory injury.** **No death or injury to fauna, including listed threatened or migratory species, from the activity.**	This EPO is justified by the fact that all cetacean species hearing groups have been modelled and the largest predicted distance to onset of AUD INJ effects is 397 m. Applying a 500 m shutdown zone ensures all cetaceans are protected from injury in accordance with the defined acceptable level and is operationally enforceable and measurable. It provides a clear, measurable outcome based on accepted injury thresholds. Cetaceans are not exposed to sound levels exceeding 219 dB PK per pulse or 183 dB SEL $_{cum24hr}$. This EPO aligns with acoustic modelling predictions and introduces a conservative time threshold to prevent PTS in low frequency cetaceans. It is operationally clear and verifiable through visual and acoustic observation logs. This EPO is an additional level of protection for low frequency cetaceans related to AUD INJ effects.
Sound exposure to high frequency cetaceans must be below PTS per pulse and PTS 24 hr SEL thresholds of 230 dB and 193[2] dB respectively.		
Sound exposure to very high frequency cetaceans must be below PTS per pulse and PTS 24 hr SEL thresholds of 202 dB and 159[2] dB respectively.		
Sound exposure to otariid pinnipeds must be below PTS per pulse and PTS 24 hr SEL thresholds of 230 dB and 185 dB respectively.		
Sound exposure to blue whales must be below a TTS per pulse and TTS 24 hr SEL thresholds of 216 dB and 168 dB respectively.	**As a result of implementing shutdown or relocation procedures if a blue whale is detected within the 5 km ensonified area, blue whales will not be exposed to physical injury from sound exposure.**	This EPO reflects a measurable acoustic exposure limit based on peer-reviewed scientific criteria and can be verified through comparison of sound source discharges to modelled exposure contours with observed blue whale presence data. Applying this limit ensures consistency with published risk criteria and supports species protection goals under environmental regulations.

[8] This threshold has been updated based on the NMFS 2024 guidance.

[9] As per Policy Statement 2.1 'Whales' includes baleen whales and larger toothed whales, such as, sperm whales, killer whales, false killer whales, pilot whales and beaked whales.

Defined Acceptable Level (From Table E7-1)	Environmental Performance Outcome	Rationale
Sound exposure to southern right whales must be below a TTS per pulse and TTS 24 hr SEL thresholds of 216 dB and 168 dB respectively.	**As a result of implementing shutdown or relocation procedures when a SRW is detected within the 4 km ensonified area, SRW will not be exposed to auditory impairment.**	The 4 km radius is based on the modelled TTS distance (3.76 km) and allows a precautionary spatial buffer. This EPO is supported by real-time visual and acoustic monitoring to detect presence and duration of SRW occupancy.
Exposure of marine mammals to impulsive sound will not result in population-level effects.	**As a result of the implementing the suite of mitigation measures, marine mammals will not experience auditory injury or sustained behavioural disturbance affecting survival, reproduction, or population distribution.**	This EPO is supported through the acoustic modelling, use of scientifically defined injury and behavioural thresholds, implementation of visual and acoustic monitoring, and shutdown protocols. All other EPO's also support the delivery of this EPO. It provides a clear linkage between the suite of mitigation actions, ensuring that exposure remains below levels of ecological significance.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	This EPO ensures that the activity is managed in a way that prevents unacceptable impacts to social, cultural, and economic values associated with marine mammals.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		

12 Recommendations

For most species/taxa/groups of marine mammals reviewed, this document provides the final assessment of impacts. However, despite an extensive review of the relevant literature around the effects of seismic on marine mammals, there has been a high level of concern voiced throughout consultation with relevant persons around the effects of seismic on certain species of marine mammals. High levels of engagement on an aspect are a trigger for CGG to undertake additional assessment. In this case looking at the effects of the activity on the ability of some marine mammal species to undertake their usual activities. This additional assessment is detailed in Appendix F3 – Further Assessment of Key Values and Sensitivities under Sections

- 3.1 – Southern Right Whales
- 3.2 – Blue Whales
- 3.3 – Australian Sea Lion

It is important to note that F3 is a response to further information requests and/or clarification and not a reflection of any prior assessment being insufficiently thorough. It is a recognition that more explanation and detail was sometimes necessary to better inform all groups involved in the consultation process, including the regulatory authority.

Hence F3 does not provide further assessment on all aspects and values identified through the EP process only those that were identified as

- Having some residual uncertainty about whether impacts or risks were of an acceptable level; and/or
- Contained environmental values and sensitivities (species) of key importance due to their protection status or commercial value; and/or
- Consultation with relevant persons revealed a particular value or sensitivity required further attention and material to support the consultation.

Annex 1

Public Comment

The completed EP was published for public comment on the NOPSEMA website on 25 Jan 2024 for a 30-day period, closing 26 February 2024. Table E7-9 shows how this feedback has been incorporated into the environmental assessment.

Table E7-9 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Impact Assessments (Appendices E, and F where relevant) to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Impacts on biologically important behaviours (foraging/ feeding, calving and migrating) and masking	M09	CGG has updated the information provided in EP Appendix E7 (Underwater Sound (Marine Mammals).
Matter: Failure to consult with relevant persons	C07	CGG has considered these claims and the EP Appendix E7 will be updated with the assessment of Southern Elephant Seals.
Matter: Impacts on dolphins	M34	CGG has considered these claims and has updated EP Appendix EP Appendix E7.
Matter: Research on impacts of anthropogenic noise on marine mammals.	M11	Updates have been made to EP Appendix E7 (Impact Assessment – Underwater Sound: Marine Mammals).
Matter: Mass strandings	M13	Updates have been made to EP Appendix E7 (Impact Assessment – Underwater Sound: Marine Mammals).
Matter: Impacts to juvenile seals	M30	Updates have been made to EP Appendix E7 and EP Appendix F1 (Environmental Plan).
Matter: Displacement of Deen Maar and Portland seal colonies	M31	CGG has made updates to EP Appendix E7.
Matter: Operational Buffer around Deen Maar	M32	CGG has made updates to EP Appendix E7.
Matter: Insufficient mitigation measures for seals and sea lions	M33	CGG has made updates to EP Appendix E7.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and the following Activity limitation: the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion

Matter	Matter ID	Changes made arising from public comment
		human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, and G2).
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E7-10. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E7-10 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4002	Risks to the lives of ancient marine mammals	The titleholder acknowledged the feedback, noting that impacts and risks to marine mammals are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to marine mammals are outlined in the EP in E7 and G1.	5114
4035	Comment about the impact of human activities on wildlife habitats and calls for a halt to such destruction for profit. It emphasises the negative consequences of competing interests in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2109
4036	Comment claims that seismic activity is known to cause significant harm to marine life, arguing that the proposed project will lead to further degradation of the coastal environment and should be abandoned as a result.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2098
4038	Commenter highlights that fish populations have been adversely affected by seismic testing over the past few years, leading to a decline in their numbers. This decline could also impact other marine species and have negative effects on whale populations.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. A fauna management plan is in place to manage whale interactions.	1432
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any	4230

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		evidence you can share so that we can consider it fully prior to our submission.	
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4006	A call for a moratorium on seismic surveying in biologically important areas during times when whales are present, emphasizing the need to protect vulnerable species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine mammals are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to marine mammals are outlined in the EP in E7 and G1.	612
4009	Activities are timed to avoid species' peak migration and foraging behaviours.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of	653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		measures is included in E7 Section 8 and G1.	
4010	Activities that may prevent or displace Pygmy Blue Whales or Southern Right Whales' use of BIAs are avoided.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales and ensures The Regia MSS does not prevent SRW and BW utilising their BIAs include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in E7 Section 8 and G1.	653
4012	AMCS critiques the proposed monitoring plan for detecting foraging whales and Southern Right Whales in Biologically Important Areas (BIAs), which relies on two marine fauna observers (MFOs) aboard the survey vessel during daylight hours. They note that this approach may not reliably detect whales that are submerged, in low visibility conditions, or during nighttime operations. Given the potential for seismic surveys to cause temporary and permanent injury to EPBC-listed cetaceans, AMCS requests that CGG provide a comprehensive monitoring plan that ensures reliable detection of whales in all weather conditions and throughout the entire operational schedule, rather than just during daylight or optimal visibility.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in E7 Section 8 and G1.	3384
4013	AMCS highlights discrepancies in the impact thresholds for blue whales as presented in Table 1. The predicted maximum distances for cumulative thresholds—Permanent Threshold Shift (PTS) at 1.4 km, Temporary Threshold Shift (TTS) at 13.2 km, and behavioural effects at 8.09 km—are notably smaller than those for baleen whales (PTS at 4.89 km, TTS at 43.5 km, and behavioural effects at 10.3 km). This is also in stark contrast to	We note that the JASCO modelling report provides some justification for the use of ANIMAT modelling. We will update our impact assessment to comprehensively explain why we have used the effect threshold distances and why we believe these to be more accurate and still apply the precautionary principle. This will also consider information from the updated sound propagation modelling report.	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	previous modelling by JASCO for the Otway's project, which indicated that continuous blasting could affect blue whales up to 156 km away. AMCS requests an explanation for CGG's choice to use shorter distances from animate modelling for setting impact thresholds when more conservative figures are available in the same table and in other assessments by the same company. AMCS highlights the need for more research on baleen whales' responses to seismic surveys, noting current studies show varied individual and species responses. They criticize CGG's reliance on animat modelling, which lacks ground-truthing, for reducing maximum cumulative effects distances. AMCS urges CGG to adopt the precautionary principle by using the maximum TTS distance of 43.5 km for baleen whales. Additionally, they seek justification for the proposed 12 km buffer around southern right whale calving grounds and call for its revision, citing inadequate support for this less conservative threshold.		
4014	AMCS notes that the predicted maximum distances for Southern Right Whales (SRWs) are 1.5 km for PTS, 11.6 km for TTS, and 8.17 km for behavioural effects. To comply with the draft National Recovery Plan, CGG plans to implement a 12 km activity limitation around SRW Biologically Important Areas (BIAs) and Habitat Critical to Survival (HCTS) during their presence. However, AMCS requests that this buffer be increased to 44 km. The EIA indicates that CGG used a 44 km buffer in the Protected Matters Search Tool (PMST) to identify marine mammal species in the area, based on the predicted injury distance of 43.5 km for baleen whales. AMCS points out that the maximum distances for SRWs from animat modelling are significantly smaller than those for baleen whales listed in the same table (4.89 km, 43.5 km, and 10.3 km). They request a clear explanation from CGG on why the shorter animat modelling distances were used for setting impact thresholds when more conservative figures are available in the same table.	We note that the JASCO modelling report provides some justification for the use of ANIMAT modelling. We will update our impact assessment to comprehensively explain why we have used the effect threshold distances and why we believe these to be more accurate and still applying the precautionary principle. This will also consider information from the updated sound propagation modelling report.	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4016	AMCS raises objections regarding the need to update the Environmental Plan (EP) to reference the final endorsed recovery plan for the southern right whale (SRW).	The EP considered and adhered to the draft National Recovery Plan for the Southern Right Whale, produced by Department of Climate Change, Energy, the Environment and Water (DCCEEW). Now the final recovery plan has been released, we are identifying changes and additions and will make the necessary updates to the Regia MSS Environment Plan after the next decision. The Regia MSS EP outlines how CGG have committed to handling new information such as changes to legislation, policies, or scientific literature that becomes available. This is provided in Section 4 of B3 - Implementation Strategy. This section describes the environmental management system we use, including management of change, knowledge, and communications - all of which are relevant to your query. As part of following these processes, we are currently compiling an information sheet for distribution, to both inform of the update to the SRW Conservation Management Plan, how it relates to the Regia MSS EP, and details any updates that have been made.	5040
4028	Cetacean strandings - Stakeholder cited an unusual mortality caused by strandings of adult Humpback whales in Abrolhos Bank, Northeastern coast of Brazil during the 2002 breeding season following 3D seismic surveys. LINK provided.	The titleholder acknowledged the feedback, noting that this claim was assessed in E7, Section 8. Seismic surveys and whale beaching has been an area of research and investigation, and no causal link has been found.	2886
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey periods. Since acoustic propagation modelling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete another modelling report prior to submission to cover the changed timeframes of the proposed survey.	3384
4032	Claim regarding Southern Right Whale calves' hearing sensitivity, stating that no evidence supports the idea that calves have different	The titleholder conducted an extensive scientific literature search and found no evidence suggesting that Southern Right Whale calves have different or	5123

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	sensitivities from adults. CGG invites the sharing of any relevant studies and references several existing studies to support their conclusions.	more sensitive hearing ranges compared to adults.	
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4035	Comment about the impact of human activities on wildlife habitats and calls for a halt to such destruction for profit. It emphasises the negative consequences of competing interests in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2109
4036	Comment claims that seismic activity is known to cause significant harm to marine life, arguing that the proposed project will lead to further degradation of the coastal environment and should be abandoned as a result.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2098
4038	Commenter highlights that fish populations have been adversely affected by seismic testing over the past few years, leading to a decline in their numbers. This decline could also impact other marine species and have negative effects on whale populations.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. A fauna management plan is in place to manage whale interactions.	1432
4040	Comprehensive suite of whale detection measures should be identified.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales and ensures The Regia MSS does not prevent SRW and BW utilising their BIAs include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while	653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in E7 Section 8 and G1.	
4048	Concern about sustained noise impact on cetaceans in the area.	CGG has conducted a thorough impact assessment relating to underwater sound and marine mammals, with mitigation measures and management adopted as a result of both this assessment (which includes relevant marine mammal species) (E7) and a further assessment (which includes two key whale species: Blue Whale and SRW) (F3). A comprehensive fauna management plan was also established as part of this EP development (G2).	1835
4050	Concern about the destruction of smaller sea life and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	1669
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts	3237

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		on biological receptors are outlined in the EP also and can be found in G2.	
4058	Concern about the mass destruction the blasting will cause to local sea animals, particularly mentioning the Southern Right Whales that migrate to Warrnambool every year to give birth.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of Southern Right Whales, within the area of operation. A fauna management plan, along with a suite of measures are also in place to reduce any impacts to as low as practicable.	886
4060	Concern about the vulnerability of seal pups due to seismic testing.	Regia EP has conducted a thorough assessment of the literature and found potential seismic impacts to seals do not pose any threat to the long-term health and sustainability of any populations of these taxa found within the operational area. Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan.	3237
4061	Concern about the welfare of whales, seals, and birds due to the activity.	The titleholder acknowledged concerns outlined in email regarding welfare of whales, seals and birds due to the activity. Outlined approach to assessment that included demonstrating that impacts to these species will be of an acceptable level and advised that it had been determined that is acceptable to have a temporary behavioural change such as moving away from the survey vessel and that injury or long-term impacts were not acceptable.	835
4064	Concern raised by the stakeholder regarding the potential damage/kill of marine life due to seismic testing.	Titleholder responded to individual advising that CGG would not propose an activity that would lead to unacceptable impacts to marine life and advised that environmental impact assessments for each aspect of the proposed activity that has the potential to impact marine life were currently being prepared and that they would be based on scientific literature and published shortly for consultation and feedback.	1024
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling,	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate	722

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	rock lobster fishery and other local fishing industries.	mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4080	Concerns about the impact of seismic testing on various marine species.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	2179
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area.	4551
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	422

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	unjustifiable and express frustration, telling the parties responsible to stop.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	2766
4101	Expresses concern that, while the project has accounted for the presence of Southern Right Whales,	We will have a comprehensive management plan for all whales with a particular focus on blue whales and	2081

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	it may overlook the protection of endangered blue whales, which are in the area from November to May.	southern right whales. SRW are our priority to protect due to our proximity to their critical life stage habitat. This doesn't mean our protection of blue whales is compromised, it means we have to protect them in a different way. We have been gathering data on BW so that we can work around there foraging behaviours.	
4105	Feedback questions who determine acceptable risks for whales, expressing concern over the impact of seismic testing on whale communication and hunting in vital zones. Argument that such risks are only acceptable to gas companies, highlighting frustration with the situation.	The Federal Department of Environment, through the EBPC Act, protect matters of national environmental significance. Whale species have specific levels of protection enacted through legal instruments such as Conversation Management Plans. These plans often contain information about the levels of impact that is unacceptable, and we must adopt them to comply with the law (Event ID 422).	423
4106	Feedback raises concern for the welfare of whales that come to calve in local waters, emphasising the need to consider the impact of proposed activities on these vulnerable marine animals.	We will not survey while SRW mothers and calves are in the area. Oil and gas have successfully co-existed with wildlife in this area for 25 years and we are doing everything we can do protect the wildlife and natural beauty of the area (Event ID 1781).	1781
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used based around sound, peer reviewed scientific literature.	4190
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4135	Mention of being heavily impacted by the whales in the tourism industry.	Title holder has undertaken a thorough analysis and assessment of all relevant literature related to Marine Mammals to inform its decisions. The MSS will not impact the population stability of marine mammals within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389
4140	No mention of ceasing activities when whales are present in the area.	CGG has conducted a thorough impact assessment relating to underwater sound and marine mammals, with mitigation measures and management adopted as a result of both this assessment (which includes relevant marine mammal species) (E7) and a further assessment (which includes two key whale species: Blue Whale and SRW) (F3). A comprehensive fauna management plan was also established as part of this EP development (G2).	1835
4141	No mention of survey in a Biologically Important Area for pygmy blue whales.	The titleholder responded by welcoming the stakeholder's specialist knowledge on blue whales, provided detailed summaries of the current whale measures that had been put in place for the Regia MSS, and informed the stakeholder of other control measures being evaluated with expert opinion from acoustic specialists and whale researchers (Event ID1933).	4036
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in	427

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4152	Potential harm to marine species like dolphins and whales due to disorientation caused by intense noise.	The Regia EP has conducted a thorough assessment of the literature which is both aspect-focused and receptor- focused for those taxa of increased public concerns. Marine mammals, Blue Whale and Southern Right Whale in particular, have been subject to increased levels of assessment which have been used to decide outcomes.	1263
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and	3697

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		different effect level thresholds. Also outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4170	Scientific evidence indicates that seismic blasting using air guns has chronic impacts on whales. These effects include the exclusion of marine mammals from crucial areas during important times, interference with migration, habitat degradation, disruption of vital behaviours, and increased stress levels. Statement that such findings underscore the unacceptable risks associated with seismic testing in marine environments.	The titleholder acknowledged the feedback, noting that impacts to whales are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales are outlined in the EP in E7 and G1.	2073
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment as a whole.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also made a reference to documents relevant to this claim within the environment plan (Event ID 4092).	4091
4174	Seismic blasting in southern right and blue whale migratory and breeding waters.	An additional impact management area for SRW's (which extends 11.3km beyond the proposed reproductive biologically important area), and the change in timing to avoid the expected increase in blue whales associated with the summer upwelling. In addition, we will not be acquiring in water shallower than 50m, increasing the survey's distance from shore and offering additional biodiversity protection.	4808

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4180	Seismic testing and gas exploration/drilling pose undeniable risks to marine fauna, flora, ecosystems, local fishing, and tourism industries.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2118
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are	1659

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares	1663

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		those to the previously defined acceptable levels and is presented in the Environment Plan	
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4198	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk,	1672

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4199	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2586
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	2886
4202	Stakeholder objects to the proposed blasting activity due to its detrimental effects on marine ecosystems.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels.	2255

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4203	Stakeholder outlined impacts to marine animals from seismic testing. It was noted that to communicate with other whales, humpbacks use a complex combination of noises in beautiful melodics and that seismic airguns emit a wide range of frequencies with sounds in the lower frequency ranges which can travel long distances being particularly troublesome sounds with humpback whales known to stop singing when subjected to the sound of a seismic airgun near Scotland. Ending the humpback's haunting song could impact migration, breeding and feeding. (Credit: NOAA's National Ocean Service.) LINK provided.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of dolphins or whales within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	2886
4206	Stakeholder raised concerns about the number of planned overflights stating that 12 was insufficient	CGG has revised its commitment to only 1 aerial surveillance flight as a minimum, there may be up to 10 but the need will be established by the Whale Expert Panel.	3783
4207	Stakeholder stated objection to seismic blasting and gas/oil exploration due to the destructive effects on marine ecosystems, including the southern right whale that is beloved by locals and traditional owners.	Titleholder responded to individual acknowledging concerns and providing information about MSS and the potential to harm marine life if mitigation plans are not in place. Advised that marine mammals, fish, and other marine fauna can be affected by the sound levels they are exposed to from a seismic survey and that the sound generated by the survey can cause hearing loss or injury, as well as disturbance of feeding, breeding, and other essential behaviours. Advised of the requirement and importance to minimise the levels of sound input into the marine environment and manage sound impacts appropriately. Provided overview of measure used to mitigate impacts on marine life and advised that the PEIRA was currently available on consultation website.	836
4210	Stakeholder stated they were concerned at the impact the activity	The Regia MSS will be undertaken in a manner that does not prevent or	870

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	will have on the nearby whale nursery and marine sanctuary. We need to be protecting our oceans and marine life from further disruption and climate change not attempting to extract more gas through seismic blasting.	displace Pygmy Blue Whales or Southern Right Whales' use of BIAs. This will be done by implementing spatial and/or temporal zones and where these cannot be implemented mitigation controls will be implemented. Controls will be evaluated with expert opinion from acoustic specialists and whale researchers to ensure they are effective.	
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined	425

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptable levels and is presented in the Environment Plan.	
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try to demonstrate to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4231	The feedback expresses concern that the project might disrupt blue whale migration, movements, and natural behaviour due to potential interference in their habitat.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for blue whales and an extensive detection area. These measures have been assessed in E7, F3 and G2.	2081
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We have to show that the environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	2104
4236	The feedback questions priorities, suggesting that profit motives may overshadow environmental concerns. It calls for a reconsideration of project locations to avoid populated areas and protect wildlife.	We will not survey while SRW mothers and calves are in the area. Oil and gas have successfully co-existed with wildlife in this area for 25 years and we are doing everything we can do protect the wildlife and natural beauty of the area (Event ID 1781).	1781
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation	2117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901
4262	The random placement of animats representing Southern right whales (SRW) and pygmy blue whales (PBW) is inappropriate, as whale presence in the area is not random. SRWs and PBWs migrate significant distances for calving and feeding in the waters of the OA. Assuming a random distribution in a model meant to reflect complex animal behaviour influenced by environmental factors is flawed. Additionally, the proposed spacing of four animats per square kilometer underestimates the likely higher density of SRWs, particularly in aggregation and calving areas from May to October.	We understand the concern regarding the random placement of animats in the model. The animat modelling creates a foundational understanding of potential whale response to sound emissions once they are in or near the OA. We recognize and agree that the overall migratory and behaviour patterns of the SRWs and PBWs are far from random. The decision to start with a random distribution was in fact a conservative first step to ensure we didn't inadvertently overlook potential areas of concern. Recognizing the specific migratory and behavioural patterns of SRWs and PBWs, is completed in the subsequent impact assessment. Regarding the spacing of animats at 4	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		per sq km, your feedback is valuable. We believe that a 4 per sq km is a significantly conservative density for the model to take given the population levels of these species and their observed behaviours.	
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	3343
4271	The stakeholder asserts that seismic blasts will have a direct negative	Title holder has undertaken a thorough analysis and assessment of all relevant	2108

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	impact on marine life, specifically mentioning that an "exclusion zone" will not effectively prevent the effects of the blasts from travelling through the ocean.	literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4275	The stakeholder did not support the project due to the impact it will have on the significant whale nursery at Logan's Beach.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of whales within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	2250
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined	2255

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptable levels and is presented in the Environment Plan	
4277	The stakeholder expressed concerns regarding the immediate consequences of these explorations, specifically the SRW and for the climate. The stakeholder stated that the activity should not go ahead.	Titleholder responded to individual acknowledging concerns and providing information about MSS and the potential to harm marine life if mitigation plans are not in place. Advised that marine mammals, fish, and other marine fauna can be affected by the sound levels they are exposed to from a seismic survey and that the sound generated by the survey can cause hearing loss or injury, as well as disturbance of feeding, breeding, and other essential behaviours. Advised of the requirement and importance to minimise the levels of sound input into the marine environment and manage sound impacts appropriately. Provided overview of measure used to mitigate impacts on marine life and advised that the PEIRA was currently available on consultation website. CGG acknowledges claims regarding global warming and has reviewed Environment Plan (EP) B4 (Regia MSS Preliminary Environmental Impact and Risk Assessment (PEIRA)), which provided preliminary information on the potential impacts and risks to support consultations with relevant persons and provided the context to the subsequent impact and risk assessments.	836
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325
4279	The stakeholder expresses concern that the proposed seismic blasting will disrupt the travel paths of whales, particularly after efforts have been made to allow their populations to recover. They emphasise the potential harm to these animals from creating explosions in their migratory routes, arguing against any activities that threaten their sustainability.	We are working hard to design our survey so that we limit our impacts to acceptable levels. Our activity is no more than 90 days, so we'll find an appropriate window to operate in. We will not destroy any wildlife habitat as a result of our activity (Event ID 2109).	2109
4282	The stakeholder highlights concern regarding Deen Maar (Lady Julia Percy Island), which is home to the largest fur seal colony in the Southern Hemisphere. They are objecting to the proposed activities,	We are aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how we	2108

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	suggesting that such actions could negatively impact this critical habitat for fur seals, emphasising the ecological significance of the island.	protect and preserve the values of this site (Event ID 2108).	
4285	The stakeholder noted the following concerns as a resident of Port Fairy: Noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	1747
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. North West Shoals to Shore Marine Noise Monitoring and Impacts https://www.aims.gov.au/research-topics/monitoring-and-discovery/north-west-shoals-shore Behavioural Response of Australian Humpback whales to Seismic Surveys https://www.brahss.org.au/ Assessing the impact of marine seismic surveys on southeast Australian scallop and lobster fisheries https://www.frdc.com.au/project/2012-008 Marine Seismic Survey Impacts on Fish and Invertebrates: Final Report for Gippsland Marine Environmental Monitoring Study https://ecat.ga.gov.au/geonetwork/srv/api/records/2292f4a7-ba2e-3533-e053-12a3070aaf2c	2389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Maxima 3D Marine Seismic Survey at Scott Reef https://www.sciencedirect.com/science/article/abs/pii/S0025326X13006528 https://www.sciencedirect.com/science/article/abs/pii/S0025326X18300687 Regarding Marine Fauna Observer's (MFOs), companies that contract MFOs such as Blue Planet Marine and RPS Group provide training for MFOs. As part of contracting MFOs we will ensure that the persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: • Conformance with regulatory requirements detailed in the accepted EP. • Management strategies and procedures to ensure EPOs and EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being monitored, measured, and documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4292	The stakeholder raised concern about the sound level from the survey and its effect on marine mammals and other species.	Outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Outlined the effects on zooplankton and the case for	3697

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptability of these impacts noting the movement of the survey timing to avoid the upwelling period. (event ID 3697)	
4298	The stakeholder stated Australia has adequate gas reserves and was concerned that exploration was to take place in a region that is a whale sanctuary and unspoiled.	We understand community views about the ongoing need for gas in Australia (or lack thereof) as the country navigates the energy transition. The current government policy is that more gas is needed, and petroleum exploration titles continue to authorise the exploration process, including seismic surveys. Matters of national energy policy are not within the purview of CGG or the Regia MSS. We will register claims related to the ongoing need for gas and provide those to NOPSEMA. We also advise that these concerns are better directed to your State or Federal members of parliament and/or the State or Federal Resources Ministers. The Otway Basin has been one of Australia's largest producing gas fields since the 1980's, servicing both domestic and commercial energy needs for the East Coast. It is for this reason that the government has awarded titles for further exploration.	1747
4299	The stakeholder stated that elevated sound levels are an unacceptable impact to marine mammals.	The titleholder acknowledged the feedback, noting that impacts to marine mammals are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to marine mammals are outlined in the EP E7 and G1.	1890
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be	3152

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	environment, the local economy, Traditional Owners, and local communities.	found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4323	There will be potential permanent damage to marine life due to sonic testing and drilling.	Titleholder responded and listed various information needs related to the activity, environmental assessment process, environmental aspects, predicted levels of environmental impact and risk, environmental management, consultation processes, and regulations or regulatory processes. Links to the project website and document library was provided.	1046
4325	This feedback asserts that seismic blasting will significantly disrupt migration routes and birthing grounds for Southern Right Whales, Humpbacks, and Blue Whales.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for whales to ensure there is no injury (TTS) to southern right whales and blue whales. Humpback whales are also protected from a PTS threshold with shutdowns in place should whales enter designated shut down zones. These shut down zones are justified in E7.	2097
4327	This feedback claims the negative impacts of seismic noise on marine ecosystems, including zooplankton mortality, hearing damage, physiological harm to larger marine animals, and disruptions to essential	We acknowledge that there may be mortal effects on zooplankton within a few meters of the sound source. However, given natural mortality rates of 20-50% along with their abundance the population effects to zooplankton are considered negligible (Event ID 2097). There are significant protections	2097

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	behaviours like feeding, breeding, and escape responses.	in place for effects on large marine animals which we will detail in our full impact assessments. The acceptable levels of impacts to whale species are defined in their conservation management plans. It is unacceptable to injure a Blue Whale or displace it from its foraging area. it is unacceptable to injure or disturb a Southern Right Whale. Humpback Whales are recovering and no longer on the endangered list and we are required to protect them along with all other marine life. This project is in the early stages of exploration and the purpose of the survey is to determine if commercially viable deposits of petroleum are even present (Event ID 2097).	
4332	This statement calls for a respectful approach, urging stakeholders to engage deeply with Indigenous knowledge and perspectives, including the views of Elders and Traditional Owners. It emphasises empathy and a meaningful understanding of the environmental and cultural impact of activities on marine life.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country.	2101
4333	This statement expresses strong feedback to the potential impacts of seismic activities on whale communication and hunting abilities, emphasising the unacceptable risks to marine life and local ecosystems for the sake of gas company profits. It reflects concerns about environmental responsibility and the prioritisation of corporate interests over ecological health.	The Federal Department of Environment, through the EBPC Act, protect matters of national environmental significance. Whale species have specific levels of protected enacted through legal instruments such as Conservation Management Plans. These plans often contain information about the levels of impact that is unacceptable, and we must adopt them to comply with the law (Event ID 2099).	2099
4334	This statement opposes seismic blasting in areas designated as Sacred Birthing Grounds for Southern Right Whales, underlining the cultural and environmental significance of these grounds. It also expresses solidarity with the Gunditjmara Traditional Owners, acknowledging the cultural heritage and environmental stewardship of this region by Indigenous communities. The feedback emphasises the perceived risks to both marine life and Indigenous heritage in the area.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country (Event ID 2101).	2101
4335	This statement opposes the disruption of marine habitats,	The titleholder acknowledged this concern and confirmed that CGG will	2101

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	migratory patterns, and cultural songlines due to perceived corporate exploitation. It reflects a strong stance against environmental harm driven by profit, emphasising the cultural and ecological importance of these areas.	not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country (Event ID 2101).	
4338	Concerned that whales in the southwest will no longer return to birth and nurture calves	Titleholder responded to the stakeholder, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1255
4344	Asking for clarification on what measures are in place to ensure the protection of blue whales, specifically in terms of mitigating interference with their natural behaviours and habitat.	The titleholder has acknowledged this feedback relating to mitigation measures for blue whales. CGG has committed to various mitigation measures to reduce impacts to blue whales. These include: -The sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway. -Operate the sound source at low power during line turns and if transiting between survey lines anywhere in the Operational Area. -If the survey occurs in September, October, November or December, the acquisition lines will be acquired working from the deepest lines first. -No discharge of the sound source in January, February, March. - The use of aerial surveys, MFOs, PAM, and fixed PAM technology. The full list of measures is included in E7 Section 8 and G1.	2081
4350	Blue whales are particularly vulnerable to disturbances that may displace them from their food sources, as they do not store significant blubber reserves and rely on daily feeding for energy. A query to another stakeholder in the meeting was raised regarding the alignment of this understanding with observations about underweight blue whales, indicating a need for clarification on how these factors interrelate.	Titleholder acknowledged this concern and noted that impacts to blue whales is assessed in the EP Chapter E7 Section 8.The titleholder advised that control measures to reduce impacts to blue whales as a result of disturbance from the seismic source are outlined in the EP and include several activity limitations including: The sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway and No discharge of the sound	2007

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		source in January, February, March during peak upwelling months. The full list of mitigation measures for blue whales is listed in E7 Section 8 and G1.	
4351	There is a request for information concerning detection technologies utilised for monitoring blue whales.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. CGG has committed to several detection methods including aerial surveys, MFO's, PAM systems, and a fixed buoy detection system. CGG will also establish a whale expert panel to help inform decision making during the survey. This information is included in the EP E7, G1 and G2.	2007
4353	Concerns about the impact of oil and gas exploration on the marine environment, particularly in regard to seismic testing and its harmful impacts on whales.	Titleholder responded that a detailed assessment has been completed of all available relevant scientific literature to inform the management and mitigation of MSS and their interaction with whales. Spatial and temporal zoning in conjunction with mitigation measures will ensure that interactions will minimise disturbances to whales.	612
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4361	Stakeholder shared concern about whales ceasing to visit the Southwest coast to give birth and nurture calves.	The titleholder has undertaken a thorough review of the effects of seismic on whales - see E7 Section 8 and F3 Section 4.1 and 4.2. There is no evidence to suggest whales will cease to visit, give birth and nurture their calves in the southwest as a result of the Regia MSS.	1255
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		with impact assessments when they became available.	
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors were also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383
4373	Objection to seismic blasting occurring in SRW migration routes, which are habitat critical to the survival of the species, and adjacent to the calving and nursing grounds while the whales are in the area.	Event ID 6529 - The stakeholder has misused the definition of Habitat critical to the survival (HCTS) described in the SRW recovery plan. The migration areas are not HCTS and have their own definition in the act. Section 2.10.2 of the SRW National Recovery Plan has a further definition of HCTS which does not include any reference or possible interaction with the definition of the migration area. CGG are of the view that there is no significant impact to SRW habitat	6410

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		critical to the survival of the species as there is no possibility that the proposed Regia MSS (the action) will adversely affect habitat critical to the survival of a species.	
4375	Claims that threats from the survey to SRW and their migration routes and HCTS means that impacts from the Regia survey are not ALARP.	"Event ID 6529 - ALARP (As Low As Reasonably Practicable) is a criterion used to determine whether control measures should be implemented by balancing the environmental benefit with the sacrifice required for their adoption. NOPSEMA guidance and the Regia MSS EP provide details on how to demonstrate that environmental impacts and risks are reduced to ALARP.	6410
4377	Stakeholder claims that the lack of consultation with local experts and scientists could lead to adverse effects on the Fairy Penguin colonies and other species.	The stakeholder claims that ""such threats do not pass the ALARP test,"" but its statements about SRWs and the eastern SRW population, some of which are directly copied from the SRW National Recovery Plan, fail to address control measures, their benefits or costs, or critique the ALARP demonstration presented in the Regia MSS EP. As a result, this claim is unclear in its application of the ALARP concept.	6412
4388	Concerned about the impacts of the seismic survey on Southern Right Whales.	CGG is open to further educating the stakeholder on the ALARP concept, assuming they are trying to provide information that might lead CGG to reconsider the control measures implemented or rejected, which have already demonstrated that environmental impacts and risks of the proposed Regia MSS have been reduced to ALARP."	6878
4389	The relevant person was concerned about the timing of the proposed survey and impacts to the southern right whale.	"Event ID 6882 (Doc ID 9096) - CGG consulted with Parks Victoria (PV) during the planning of the proposed survey, meeting on 11/08/2023. The consultation records are available in the EP (Appendix C2). PV raised concerns about the survey's proximity to the Twelve Apostles Marine Park, leading to a refinement of the survey area. Fairy Penguins were not mentioned in this meeting. CGG also consulted with the Warrnambool Coastcare Landcare Network and their Middle Island Penguin Project. A referenced expert in scientific literature was consulted about penguin foraging ecology and at-sea movements. They advised against relying on outdated population estimates for penguins due to rapid ecosystem changes and predation pressures. CGG has sent the F3	6624

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		assessment from the Regia EP to the Professor for feedback and is awaiting a response. CGG also reached out to DECCA but has not received any information.	
4395	The project is adjacent to Warrnambool's Logans Beach Whale Nursery for Southern Right Whales and upstream of the Bonney Upwelling Key Ecological Feature, which could be affected.	Regarding the other individuals mentioned, they were consulted, with records available on the public website. The Regia MSS EP includes extensive references to studies by blue whale (EP E7 and F3) and Southern Right Whale experts. Additionally, a Professor's work on Fairy Penguins is referenced, along with the Middle Island Penguin Project.	6432
4405	objects to the assertion that ± 50% interannual variation in upwelling extent, mostly climate-driven, has not constrained whale population recovery.	CGG based its impact assessment on peer-reviewed literature, including studies by the scientists mentioned, and disagrees with any suggestion that knowledge was bypassed or cherry-picked. The process has been fully transparent, and CGG has actively sought additional relevant literature. CGG also met with Warrnambool City Council to discuss the Middle Island Penguin Project and is looking to support efforts to gather data on penguin populations.	6432
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880
4451	Stakeholder claims the EP is inconsistent with recovery plans including SRW National Recovery Plan and BW Conservation Management Plan, especially in light of newly published literature regarding the Eastern SRW population.	In event ID 6859 (see feedbacks 2352 & 2353) the titleholder provided the stakeholder with how the EP is consistent: The Regia team responded that as per EP Appendix E7, CGG will ensure there are no behavioural impacts to Blue Whales, as the seismic source will be shut down within 10km of a blue whale. This is based on the underwater sound modelling commissioned by CGG where behavorial impacts to blue whales was predicted to occur within 9.83km of the sound source. The Regia team responded that as per Appendix E7, There are only 3 BIAs associated with whales that are relevant to the Regia MSS, the Southern	7136

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Right Whales Reproductive and Migration BIA, and the Blue Whale Foraging BIA. The sound source will be operated within the Southern Right Whale Reproductive BIA at any time. CGG will ensure the seismic source will only not be operated within the pygmy blue whale foraging BIA if there are low numbers of blue whales present. CGG will use a whale expert panel to help define 'low numbers' CGG will also shut down if a blue whale is detected within 10km of the seismic source. This 10km will ensure there are no behavioural impacts which may displace whales from their foraging BIASs. CGG will shut down the sound source if a blue whale remains resident in the 23 km ensonified area for more than 12 hours, this will ensure blue whales will not experience TTS (temporary auditory injury).	
4487	Claims that CGG's proposed activities are inconsistent with the Recovery Plans made under the EPBC Act, the Southern Right Whale Recovery Plan and the Blue Whale Recovery Plan. GMTOAC states that these activities pose known physical and behavioural risks to the Eastern Population of Southern Right Whales and to Pygmy Blue Whales. These risks include impacts from anthropogenic underwater noise, particularly seismic noise, vessel strikes, climate-driven changes in prey availability, and the cumulative effects of these pressures, all of which have the potential to injure or kill individuals and affect populations. GMTOAC notes that under the EPBC Act Program and NOPSEMA's decision-making guidelines, an Environment Plan cannot be accepted if it is inconsistent with a recovery plan. It emphasises that both Recovery Plans contain "Very High" importance actions requiring that Blue Whales and Southern Right Whales must be able to continue using their Biologically Important Areas (BIAs) without auditory impairment, injury, or displacement. The plans also call for preventing disruption and displacement of Karntubul (Southern Right Whales) from BIAs due to anthropogenic noise such as seismic surveys.	CGG maintains that its approach aligns with statutory obligations and industry best practice. It asserts that all regulatory requirements under Regulation 34 have been met, and that its environmental performance outcomes and control measures are grounded in the best available science and tailored to the ecological and cultural sensitivities revealed through consultation. The Regia MSS Environment Plan (EP) was designed to ensure impacts and risks are reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. Regarding whale protection, CGG highlights that the EP includes specific mitigation measures for culturally and ecologically significant marine fauna, including species noted in relevant Recovery Plans. Early correspondence in February 2023 identified Southern Right Whales and Pygmy Blue Whales as key sensitivities, and the EP commits to spatial and temporal avoidance measures, sound-source shutdowns, and exclusion zones to protect them. These measures explicitly consider cultural significance, such as timing restrictions to avoid the Karntubul (Southern Right Whale) birthing period. The whales, Karntubul and Wuuloc, are identified in the EP as sensitive receptors with dedicated protective measures. CGG confirms that these cultural and ecological sensitivities were incorporated into the environmental assessment. The EP acknowledges the	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		sacred cultural status of Koontapool (Southern Right Whale) and Wuuloc (Pygmy Blue Whale) for the Gunditjmara people and includes them in impact and cumulative risk assessments. Appendix F3 references the Nyamat Mirring Plan 2023–2033 and recognises Gunditjmara spiritual connections, including to Karntubul. CGG substantively addresses the relevant issues, including underwater noise, vessel interactions, and cumulative effects. The EP sets out noise-management frameworks, timing restrictions, and cumulative impact analyses consistent with the concerns raised.	
4491	Claims about the SRW and BW BIAs. States proposed activity will cause unacceptable impacts to all Karntubul species, including temporary & permanent hearing loss, displacement from BIAs, vessel strike, prey depletion during peak feeding/migration period, calving interruption, and impact to ecosystems and cultural landscapes as a result of the cumulative impact of these.	CGG has identified all Biologically Important Areas (BIAs) relevant to blue whales (BWs) and southern right whales (SRWs) and incorporated seasonal BIA use into the survey design through substantial temporal and spatial restrictions detailed in the EP. Predicted underwater-sound impacts on these Karntubul species, along with mitigation measures presented in Appendices E7 and F3, demonstrate impacts will remain acceptable and will avoid auditory impairment or displacement from BIAs or Habitats Critical to Survival (HCTS). CGG further notes that vessel-strike risk is already extremely low during seismic surveys and that additional controls in Appendix D2 ensure this risk is prevented and acceptable. It concludes that no changes to ecosystem structure, diversity, or function are expected from the one-off survey, with sound exposure too limited in extent and duration to affect prey, food webs, or predator–prey relationships. A cumulative impact assessment found residual cumulative effects to be low, reduced to ALARP, and acceptable, with no impacts predicted for regional marine parks. CGG also asserts consistency with the National Recovery Plan for Southern Right Whales and the Blue Whale Conservation Management Plan, stating that their objectives and recommended measures have been incorporated. Finally, CGG maintains that all marine mammal species likely to occur in the region have been adequately assessed using up-to-date EPBC Protected Matters data, and that mitigation measures ensure impacts to all listed species will remain acceptable	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		and not inconsistent with EPBC Act protection provisions.	
4492	Claims that the eastern population of the Southern Right Whale, estimated at only 200–300 individuals, is at particularly high risk because its migration and reproduction Biologically Important Areas (BIAs) overlap directly with CGG's Operational Area and sound propagation footprint. According to the Southern Right Whale Recovery Plan, these whales use the affected region for reproduction between May and September and for migration between April and October. The Recovery Plan also notes that Southern Right Whales do not feed in coastal waters but are expected to feed, and possibly conceive, within the Australian Whale Sanctuary—an area entirely overlapped by the proposed Regia MSS activity. As a result, the seismic survey could occur within, or affect, conceiving, calving, and feeding grounds for this critically endangered sub-population. The species is particularly vulnerable to human impacts due to its low reproductive rate, long lifespan, and strong site fidelity to key habitats. The submission therefore emphasises the relevance of underwater noise, habitat degradation, and vessel-strike risks in the context of the proposed seismic activities.	The Recovery Plan explains that BIAs can be designated for key behaviours such as reproduction, foraging, migration, and resting. While Southern Right Whale BIAs in the Plan cover reproduction and migration, the Plan notes that foraging occurs across a much broader offshore latitudinal range (30°S–65°S) and is not linked to these BIAs. Because the Regia MSS is not located in Antarctic waters, it will not affect cetaceans that forage there. CGG states the survey will avoid peak SRW abundance in the mapped BIA and apply mitigation measures to ensure no SRWs are harmed, injured, or interfered with.	EVT352
4494	The claim highlights guidance from the Blue Whale Recovery Plan, which stresses the need for a precautionary approach when assessing threats at the population level. It notes that blue whales may continue feeding despite disturbance if alternative feeding grounds are limited, meaning that anthropogenic noise may still present significant risk even when behavioural responses are subtle. Drawing on the Recovery Plans, the submission identifies key threats relevant to assessing potential impacts of the Regia MSS activity: underwater anthropogenic noise, climate change, habitat degradation, vessel strikes, prey depletion, and the cumulative effects of these pressures. GMTOAC argues that CGG has not adequately assessed these threats, either individually or cumulatively, given that consultation on these matters remains ongoing. The submission	The EP is consistent with the Blue Whale Conservation Management Plan, which identifies seismic noise as a threat, by implementing measures that ensure blue whales can continue using the area without injury or displacement. This includes using MFOs and PAM, shutting down the seismic source if whales enter behavioural, or TTS-impact ranges, and complying with EPBC vessel-operation requirements such as maintaining a 300-metre caution zone. CGG states it will also avoid peak-abundance periods by commencing the survey after most SRWs have left the BIA and during months when blue whale numbers are low. Drawing on current scientific literature, the recovery plans, and detailed impact assessments, CGG maintains that all risks and impacts have been reduced to acceptable levels. While Appendix E7 initially identifies major impacts for SRWs and BWs due to their threatened status, CGG notes	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	states that, based on CGG's own impact metrics, the proposed seismic activities may result in moderate to major impacts from underwater noise, major risks of vessel strikes, major impacts associated with climate change, and potentially more severe cumulative impacts. It references the Commonwealth's Significant Impact Guidelines, which define significant impact and list criteria for determining when an action may threaten an endangered species' survival or recovery. GMTOAC concludes that moderate to major impacts, especially when cumulative effects are considered, meet the threshold of significant impacts and are therefore unacceptable. Finally, the submission notes that both Recovery Plans and EPBC Act Policy Statement 2.1 emphasise that seismic surveys should avoid biologically important areas during biologically important times and assess 3-4 years of baseline data. GMTOAC argues that this principle is not met in the timing and location of the proposed Regia MSS survey, increasing the potential for displacement from critical habitats essential to whale survival and recovery.	that both species were reassessed in Appendix F3, which added further measures for SRWs; Appendix F3 concludes that residual impacts to both species are reduced to an acceptable level.	
4496	GMTOAC objects to CGG removing a previous control measure limiting seismic discharge in the Pygmy Blue Whale foraging BIA during periods of low whale presence, replacing it with a vague condition requiring CGG to determine whether whale presence is "compatible" with proceeding. GMTOAC argues this new measure lacks detail on how whale presence or "unacceptable disturbance" will be assessed, and that it fails to reference Recovery Plans which define unacceptable impacts. GMTOAC warns that the proposed survey timing (April–June 2026) coincides with peak Pygmy Blue Whale foraging season and Southern Right Whale migration and calving periods, meaning the seismic survey is likely to occur when both species are using their BIAs. Preventing whales from accessing these areas, or exposing them to injury while they remain, would constitute unacceptable impacts inconsistent with Recovery Plan objectives.	CGG has further reduced the likelihood of interactions with marine mammals by excluding the April–June period and commencing the survey only after 15 September. Because blue whales typically do not arrive from Western Australia until November, CGG argues that most of the survey will occur when blue whales are absent from the area. It adds that sighting data show very few blue whales in November and December, with peak abundance occurring later, from January to March during the Bonney Upwelling.	EVT352
4497	GMTOAC objects to 160dB threshold, noting that both Recovery Plans call for precaution, that behavioural impacts occur below 160 dB, and that	CGG's use of a 160 dB behavioural threshold for blue whales is consistent with industry standards, current	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	NOAA and NMFS consider the 160 dB threshold a coarse midpoint, not a universal behavioural threshold. Recent research suggests a more precautionary threshold of around 139–140 dB for low-frequency cetaceans, and GMTOAC notes that some previous seismic proposals adopted stricter thresholds in recognition of species vulnerability.	scientific guidance, and established regulatory practice, noting that this threshold is appropriate for non-reproductive foraging stages when sensitivity to noise is lower. For Southern Right Whales, CGG has adopted an even more precautionary, real-time protection approach by verifying ambient sound levels and implementing immediate shutdowns for any SRW detected within the reproduction BIA, restarting only once whales have clearly departed. This provides a higher level of protection than numerical thresholds used by NOAA or NMFS and aligns with the intent of the National Recovery Plan. CGG also asserts that stakeholder reliance on U.S. "Take Authorization" documents is irrelevant to Australian regulation and that the stakeholder has misrepresented Darias-O'Hara et al. (2025). The study did not recommend a universal 139 dB threshold but instead reported a median expert-elicited response value with large uncertainty, limited applicability, and explicit caveats. CGG maintains that the stakeholder's interpretation selectively uses science out of context and does not reflect the study's stated limitations.	
4498	GMTOAC claims that CGG has not demonstrated these methods' effectiveness in conditions of low visibility or high ambient noise, and that CGG's analogy to motion sensors and security cameras greatly overstates the capability of detection systems. GMTOAC further notes that whale behaviours, such as Pygmy Blue Whales diving in response to vessels, or Southern Right Whale mother–calf pairs communicating quietly, reduce detectability and have not been adequately factored into the assessment.	No single detection method is fully reliable under all conditions, so the survey uses a multi-layered system combining visual observers, passive acoustic monitoring, autonomous detection buoys, vessel-based systems and aerial surveillance. Each method contributes different strengths, such as autonomous buoys providing near-real-time detections regardless of visibility, and visual observers offering species identification and behavioural interpretation, and together they compensate for the limitations of any one tool. This integrated approach maintains effective detection even when environmental conditions or animal behaviour reduce the performance of individual methods, providing a robust and precautionary system for managing uncertainty.	EVT352
