4500	GMTOAC claims that the Regia MSS may contribute to cetacean strandings, particularly for vulnerable species such as Pygmy Blue Whales and Southern Right Whales. They note that the EP contains only minimal discussion of this issue and appears to dismiss the risk on the	Strandings were assessed in the EP using the best available evidence, which shows only a very low risk of seismic surveys causing cetacean strandings. CGG states that GMTOAC's reliance on a single, outdated reference (Castellote & Llorens 2016) misinterprets the current science, noting that CGG's	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	basis that no conclusive evidence links seismic surveys to strandings. GMTOAC finds this reasoning inadequate, especially given that seismic surveys can occur outside the summer period typically referenced in studies and that CGG itself originally planned to survey in September 2025. CGG cites recent assessments and NOPSEMA's 2019 Senate Inquiry submission, which found no demonstrated causal links between seismic activity and strandings. However, GMTOAC points out that NOPSEMA acknowledges military sonar, another intense anthropogenic sound source, has been linked to mass strandings, and experts caution that seismic surveys often involve additional high-power acoustic equipment that significantly expands the acoustic footprint. International research by Castellote and Llorens indicates that existing mitigation guidelines do not account for behavioural reactions that may lead to strandings, and that such risks cannot be identified without dedicated monitoring during and after surveys. GMTOAC notes that the Regia MSS EP includes no such monitoring plans. Because the possibility of a seismic link to strandings cannot be ruled out, GMTOAC argues that the precautionary principle must apply and that scientific uncertainty should not be used to justify exposing Karntubul and other cetaceans to potentially unacceptable harm.	approach is in fact consistent with the review's main conclusion that seismic operations can alter cetacean behaviour—hence CGG's adoption of updated management and mitigation protocols. CGG emphasises that GMTOAC overlooked more recent literature, including Foord et al. (2019), which documents Victorian stranding patterns and shows no baleen whale strandings in the Otway region, with regular strandings involving only dolphins. CGG maintains that its management program for pygmy blue whales and southern right whales is informed by the latest scientific guidance (e.g., Southall et al. 2021, 2023; Popper et al. 2024; Accomando et al. 2025) and asserts that it has applied a precautionary approach supported by current evidence.	
4505	GMTOAC claims that the April 2025 EP removed the earlier restriction preventing seismic surveying in waters shallower than 50 metres and replaced it with a fixed 17 km buffer around Deen Maar. Given uncertainty in bathymetry data, GMTOAC questions how CGG will reliably ensure it avoids shallow waters outside this buffer. GMTOAC further questions whether either the 17 km buffer or the former 50 m depth limit would protect Koorn Moorn during foraging, as CGG itself notes that adult females feed widely between Portland and Cape Otway out to the 200 m contour. They also highlight NOPSEMA's earlier concerns that the EP did not adequately assess behavioural impacts on the Deen Maar seal colony, including effects on foraging and prey availability. GMTOAC therefore remains	Appendix B12 shows that the Regia MSS uses a 17 km buffer, which is the minimum distance between the active source area and Deen Maar where water depths are ≥50 m, ensuring no seismic work occurs in waters shallower than 50 m. Following NOPSEMA advice, Appendix E7 was updated to assess impacts on foraging Australian Fur Seals at Deen Maar and their prey.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	concerned that the revised control measures do not provide sufficient protection for this culturally important species or for cultural values associated with Deen Maar.		
4512	GMTOAC claims significant concerns about CGG's definition of "acceptable levels" of impact on Blue Whales and Southern Right Whales. CGG maintains that impacts are acceptable so long as each offshore operator conducts activities in a manner consistent with relevant Conservation and Recovery Plans, ensuring whales can continue using the area without injury or displacement. However, NOPSEMA has already criticised this approach, noting that measures designed for individual projects cannot simply be assumed to prevent cumulative impacts from overlapping noise fields without a clearer understanding of combined exposure regimes. Despite this critique, CGG appears to have carried this same rationale forward from its November 2024 EP into the April 2025 version, without addressing the deficiencies identified by NOPSEMA. GMTOAC argues that this is inadequate, especially in light of current environmental pressures affecting Nyamat Mirring.	CGG notes that GMTOAC appears to have referenced an outdated version of the Environment Plan. In the current EP, acceptable impact levels for Blue Whales and Southern Right Whales are defined using each species' Recovery Plan, and these levels are assessed through rigorous, literature-supported impact assessments in Appendices E7 and F3. In response to NOPSEMA's advice, the cumulative impact assessment was updated to include the sound sources and timing of all future and reasonably foreseeable activities. This added detail ensures that any potential cumulative impacts from additive sound exposure are assessed with appropriate contextual information.	EVT352
4513	GMTOAC claims that any cumulative impact assessment must incorporate the ongoing Karenia mikimotoi harmful algal bloom, as required under the Regulations for describing the affected environment and assessing all direct and indirect risks. They point out that harmful algal blooms have been linked to increased calf mortality in Southern Right Whales elsewhere, raising concerns that species already under stress may be unable to withstand additional impacts from CGG's proposed seismic survey.	CGG clarifies that the South Australian algal bloom is caused by Karenia cristata, not K. mikimotoi as stated by GMTOAC. Although the exact cause is not confirmed, the most likely drivers are Murray River flooding with agricultural runoff, upwelling of nutrient-rich deep water, and a marine heatwave. The bloom has been largely confined to the gulfs and northern Kangaroo Island and is now significantly reduced. While harmful algal blooms are known to cause marine mammal deaths, the species responsible in past cases differ from those present in South Australia, and there is little evidence linking K. cristata to whale mortality. The event is being closely monitored, and the Regia MSS EP will be updated if necessary.	EVT352

Annex 4

Summary of Blue Whale Monitoring Data for Otway Regions

Several whale surveys have been undertaken in the Otway Regionwith a focus on blue whales. A summary of the publicly available studies is provided in this section.

Aerial Surveys (2001-02 to 2006-07)

Gill et al. (2011) undertook 69 seasonal aerial surveys for blue whales between Cape Jaffa and Cape Otway over six seasons (2001-02 to 2006-07). This study found that the general pattern of seasonal movement of blue whales is from west to east, with whales foraging in between the Great Australian Bight and Cape Nelson in November and spreading further east in December. Whales are typically widely distributed throughout Otway shelf waters from January through to April (Gill et al. 2011) (Figure E7-4 and Figure E7-5).

Blue whale encounter rates in the central and eastern study (Cape Nelson to Cape Otway) area by month is shown in Figure E7-3 with sighting and effort data presented geographically in Figure E7-4 and Figure E7-5. Data is pooled for all seasons, for central and eastern areas, overlaid on gridded aerial survey effort (10 km x 10 km squares), represented as minutes flown per grid square (key, upper right). Thick solid lines represent 50% and 95% probability contours for blue whale distribution from density kernel analysis. Dashed lines are central and eastern boundaries (Gill et al. 2011).

There had been fewer than 50 sightings of blue whales in Bass Strait up to the year 1999, but since that time feeding blue whales have been more regularly observed in the Discovery Bay area and more generally along the Bonney coast from Robe to Cape Otway. Gill et al. (2011) found that across the eastern zone (Cape Nelson to Cape Otway), there were no blue whale sightings in November (2001-2007) despite significant effort (Figure E7-2).

Based on the pooled aerial survey data (2001-2007), encounter rates increased from 1.6 whales per 1,000 km in December, to 9.8 whales per 1,000 km in February, decreased slightly to 8.8 whales per 1,000 km in March, then declined sharply to a single sighting for May (0.4 whales per 1,000 km) (Gill et al. 2011). A mean blue whale group size of 1.3±0.6 was observed per sighting with cow-calf pairs observed in 2.5% of the sightings. Gill et al. (2011) also identified that 80% of blue whale sightings are encountered in water depths between 50 and 150 m; 93% of sightings occurred in water depths <200 m and 10% of sightings occurred within 5 km of the 200 m isobath in the eastern and central zones.

The data from Gill et al. (2011) shows:

- Blue whales are typically widely distributed throughout central and eastern areas shelf waters from January through to April.
- Blue whale numbers are significantly lower in November, December and January in the eastern area compared to the central area.
- No blue whales were sighted in the eastern area during November for any season despite significant effort. Pooled monthly encounter rates increased from 1.6 whales 1,000 km–1 in December, 5 whales 1,000 km–1 in January, peaked at 9.8 whales 1,000 km–1 in February, dropped slightly to 8.8 whales 1,000 km–1 in March, then declined sharply to a single sighting for May (0.4 whales 1,000 km–1).
- Encounter rates in central and eastern zones peaked in February, coinciding with peak upwelling intensity and primary productivity.

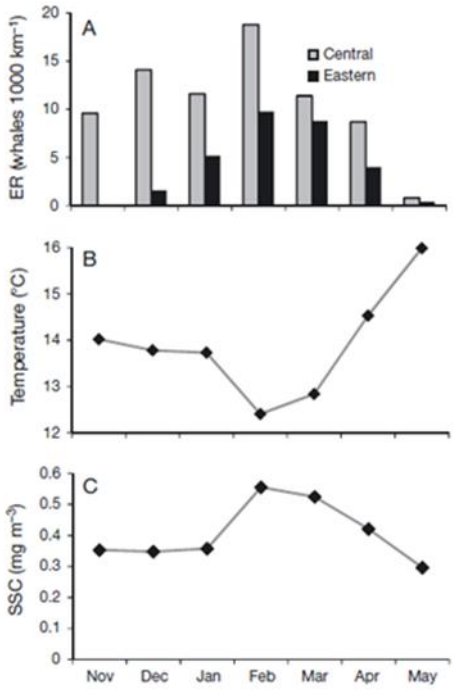

Figure E7-3 - Blue Whale Encounter Rates in the Central and Eastern Study (Cape Nelson to Cape Otway) Area by Month (Gill et al. 2011).

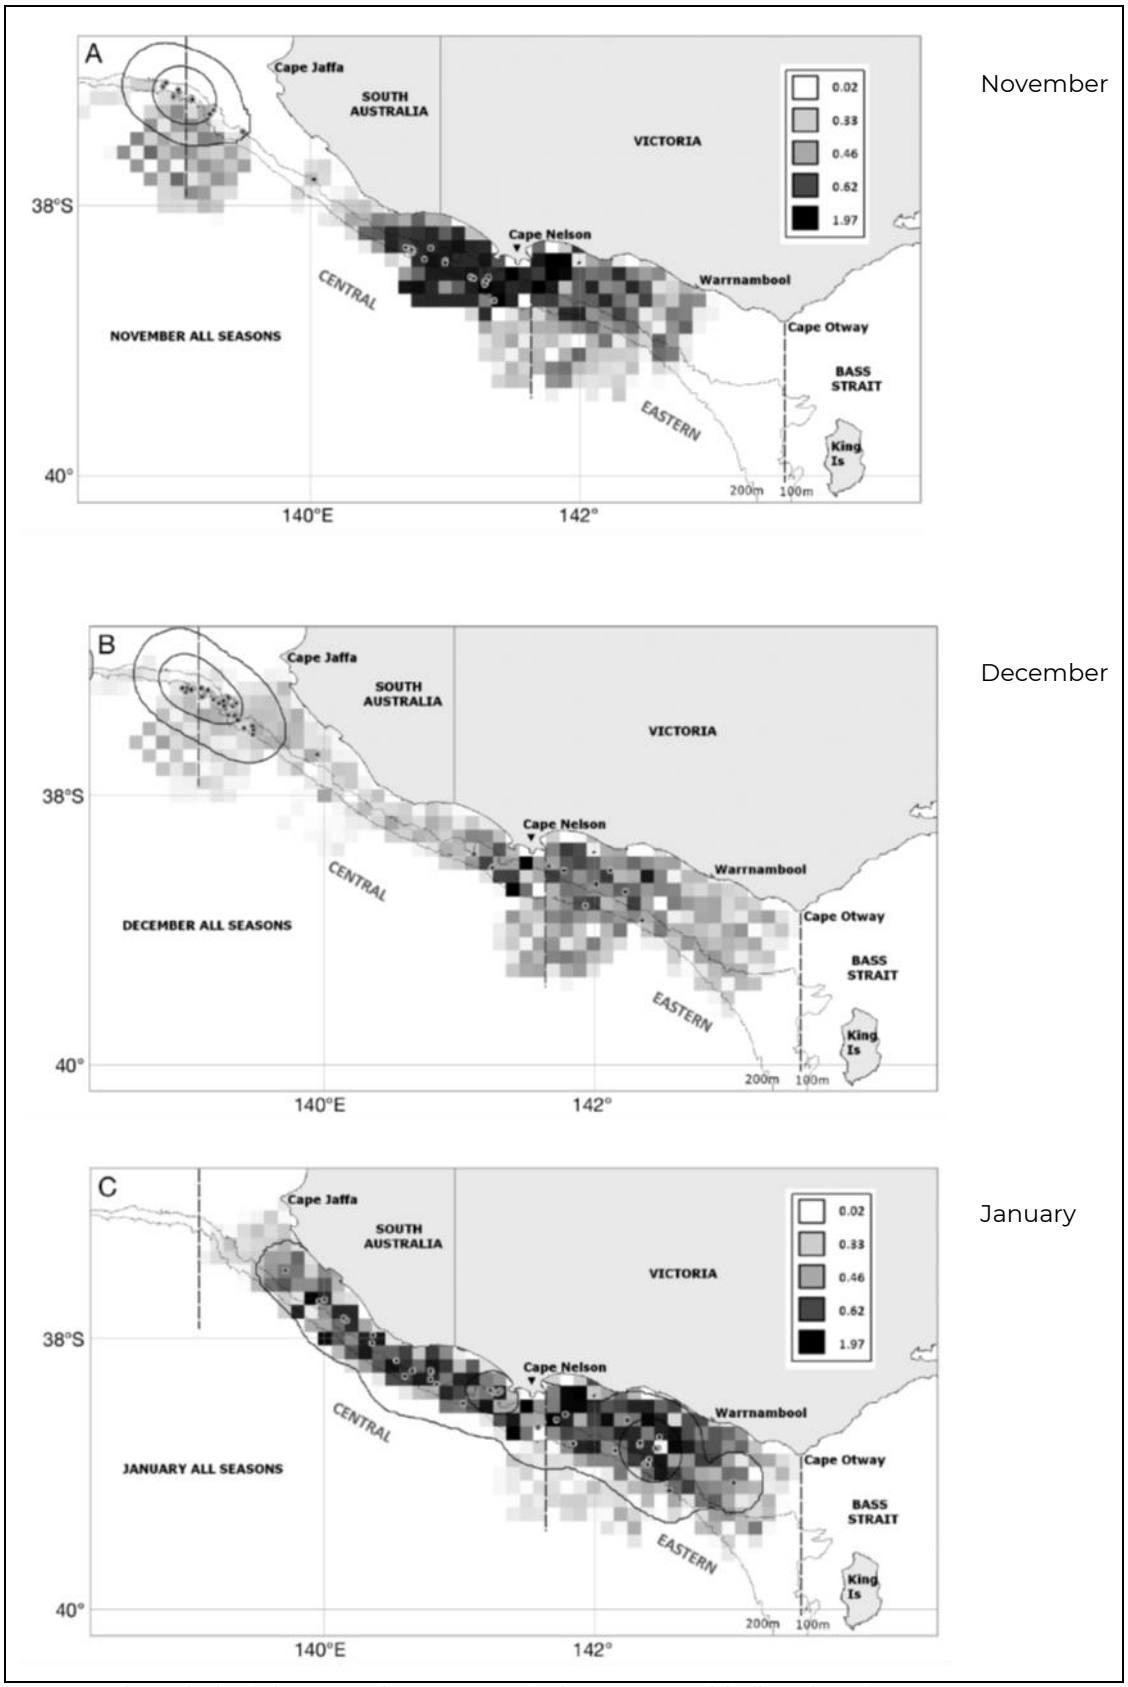

Figure E7-4 - Blue Whale Sightings in the Otway Basin (Nov, Dec, Jan) (Gill et al. 2011).

Note: Dots represent blue whale sightings while squares are aerial survey effort (10 km x 10 km squares) represented as minutes flown per grid square (key, upper right corner of the November and January figures).

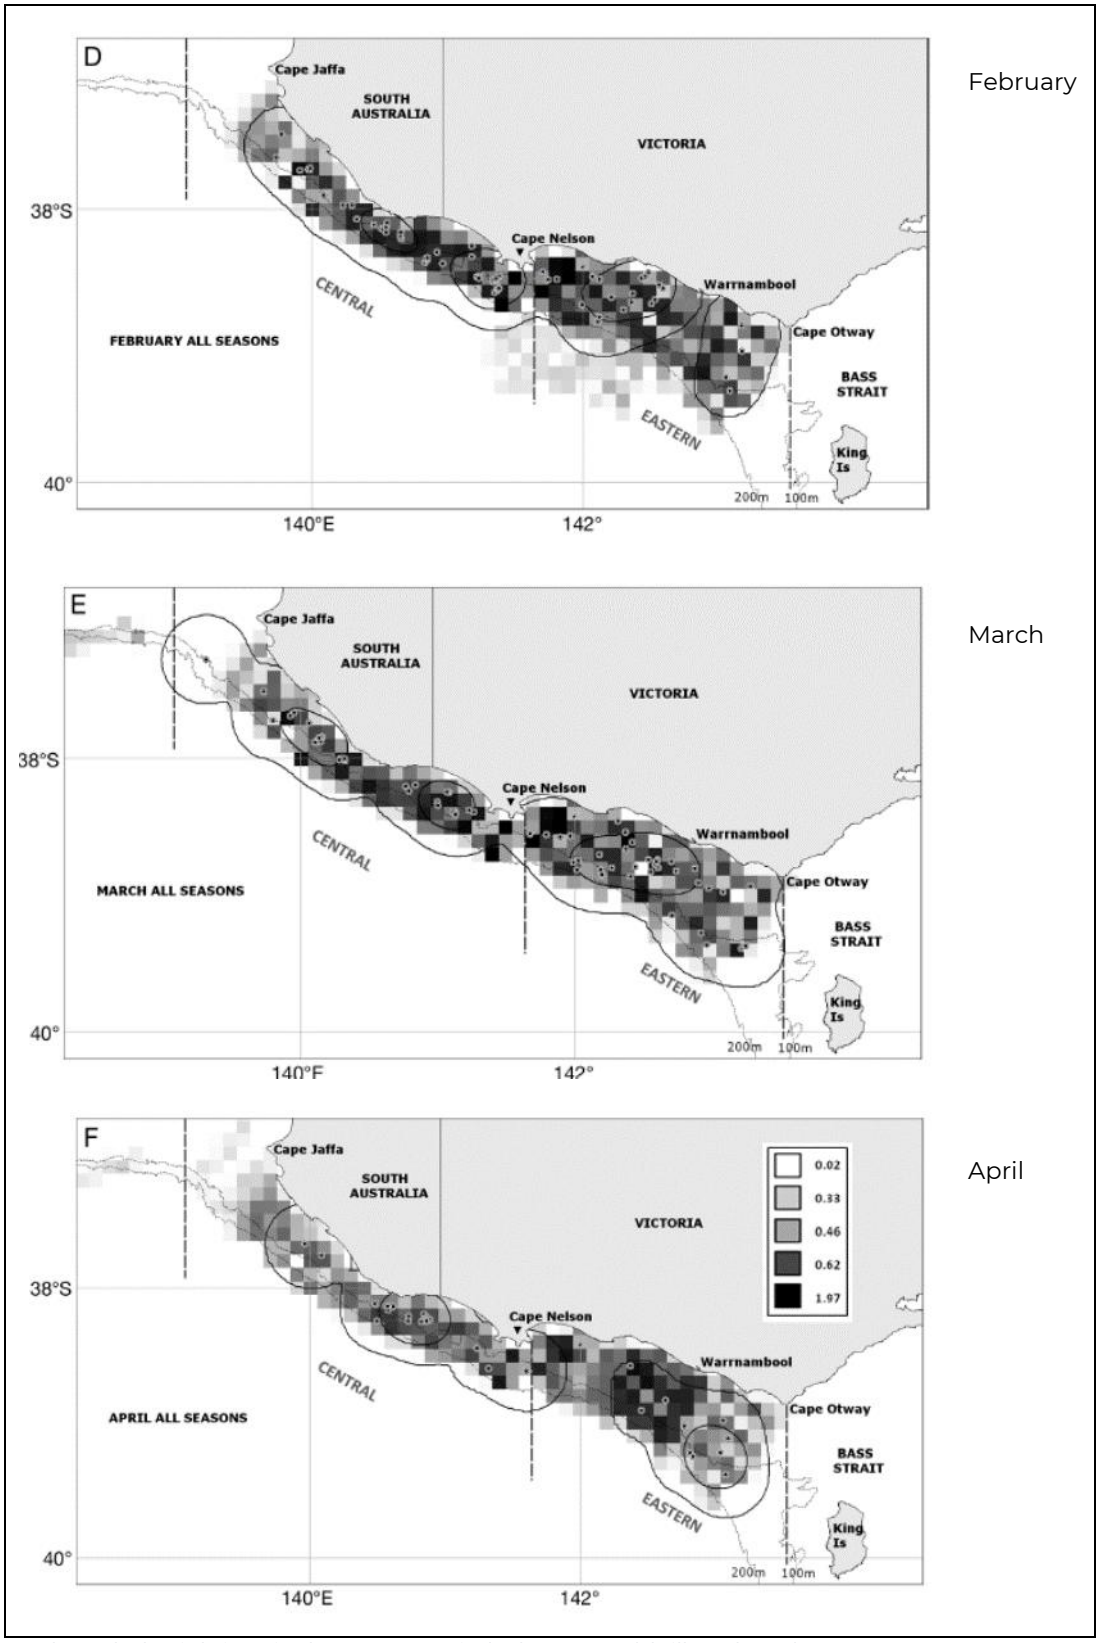

Figure E7-5 - Blue Whale Sightings in the Otway Basin (Feb, Mar, Apr) (Gill et al. 2011).

Note: Dots represent blue whale sightings while squares are aerial survey effort (10 km x 10 km squares) represented as minutes flown per grid square (key, upper right corner of the April figure).

Tagging Study (2015-2016)

Möller et al. 2020 analysis data from the tags of 13 pygmy blue whales that were tagged in the Bonney upwelling region in January 2015 with tags transmitting up to March 2016. In summary:

- Whale movements in the Great Southern Australian Coastal Upwelling System (GSACUS) ranged mostly from eastern South Australia, over the continental shelf south of Kangaroo Island, to between mainland Australia and Tasmania), with a few whales performing some movements to the continental slope and the deep-sea (Figure E7-6).
- In the GSACUS, most tagged whales remained over the continental shelf, utilising this region from at least January to July. This was the area of highest occupancy by the whales, with one whale returning to the Bonney Upwelling in January the year after and remaining there for at least three months. This timing coincides with the upwelling season, which generally occurs from November to March each year.
- A low probability of area restricted search (ARS) behaviour (i.e., high probability of transiting behaviour) was mainly observed between April and June, and then between November and December, suggesting that the pygmy blue whales were mainly migrating during those times.
- Seascape correlates of ARS behaviour for these whales suggested the importance of sea surface temperature, sea surface height anomaly, wind speed and chlorophyll a concentration as proxies of upwelling productivity and presence of krill patches.

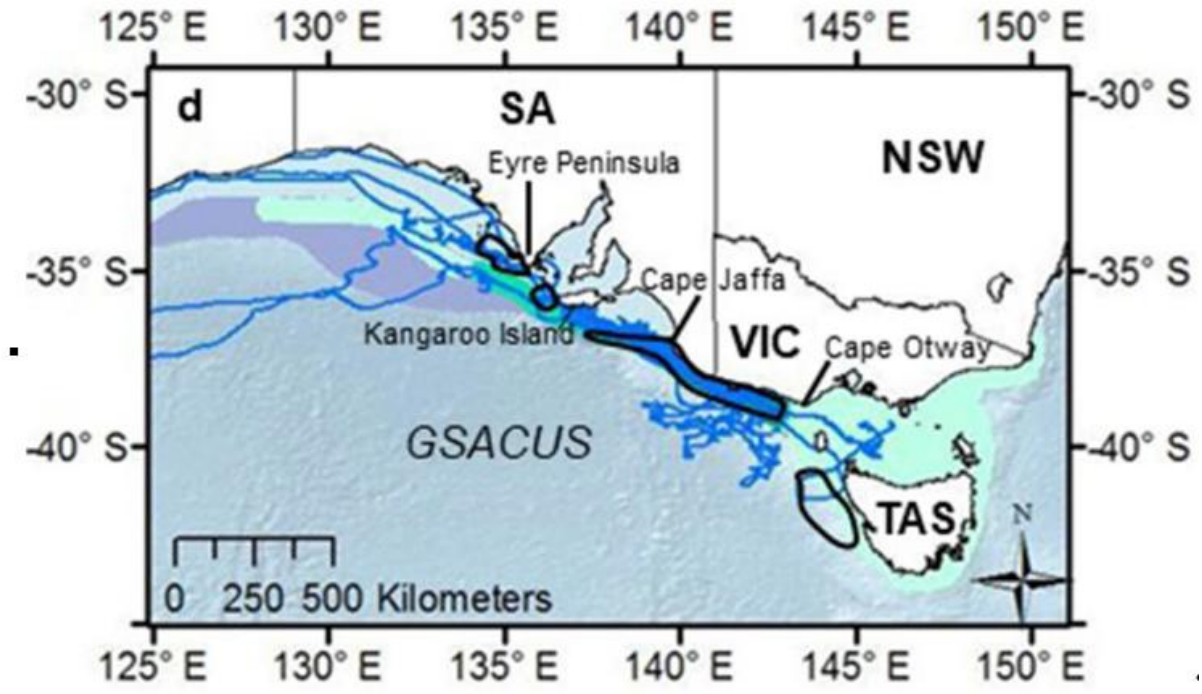

Figure E7-6 - Tracks of 13 Pygmy Blue Whales in the GSACUS (Möller et al. 2020).

Passive Acoustic Recorders (2009-2017)

Between 2009 and 2017 the Integrated Marine Observing System (IMOS) recorded underwater sound south of Portland, Victoria. McCauley et al. (2018) analysed the data from to look at blue whale presence, distribution, and population parameters.

McCauley et al. (2018) analysed data from passive acoustic recorders that were located around Australia to look at blue whale presence, distribution, and population parameters. The primary sites comprised central Bass Strait, western Tasmania, the southeast Australian coast, and the Great Australian Bight area. Each study area had multiple receivers and may have had several sites sampled within the area. Temporal sampling focussed on the southern Australian site southwest of Portland, Victoria. Data was used from 2004 to 2016. The study concluded:

- Antarctic blue whale calls were received via deep sound channel propagation south of Portland and the maximum chorus levels occurred from late February to late June with yearly increases in chorus levels. McCauley et al. (2018) suggests that acoustic detection of Antarctic blue whales indicate they predominantly occur along the entire southern coastline.
- Pygmy blue whales have three migratory stages around Australia; the "southbound migration stage" were predominantly between October to December (sometimes into January) whales travel from Indonesian waters down to the WA coast, the "southern Australian stage" where between January and June whales spread across the southern Australian waters, and the "northbound migration stage" where whales travel back up to Indonesia between April and August.
- The "southern stage" involves animals searching for feeding sites, feeding, and then marking their way north towards June.
- Along the southern Australian coastline pygmy blue whales are most frequently detected towards the east along the Bonney coast over late February to early June, utilising secondary productivity produced by a seasonal upwelling event.
- Within a season it is difficult to predict whale numbers and their specific locations, but when correlated across seasons the strength and persistence of this upwelling event as given by time integrated water temperature south of Portland, significantly correlates with time integrated number of individual whales calling from the same site.
- The Bonney coast upwelling is a strong predicator of pygmy blue whale presence at Portland where whale presence in the area is linked to prey availability.
- Sea noise data was available from the Portland site from 2009 to early 2017 detailed:
    - In 2009 and 2011 pygmy blue whales arrived in November or December whereas in the other years, calls were not detected until January or February (Figure E7-7). There was substantial variation in presence within a season, with some whales remaining in the Portland detection area until mid-June each year.
    - There was considerable variability in whale persistence and presence within a season (Figure E7-7) with no consistent trend other than a peak in presence somewhere over February to June.
- It is difficult to predict numbers within a season but when correlated across seasons the strength and persistence of the Bonney coast upwelling, given by time integrated water temperature, significantly correlates with time integrated number of individual whales calling from the same site. The upwelling index explains 83% of the variability in blue whale calling presence across seasons when using seasonal whale counts (not corrected for population growth). When a growth rate of 4.3% is applied a correlation of 90% of the variance in seasonal occurrence is predicted by the upwelling index.
- The number of pygmy blue whale calling in Portland could be expected in increase yearly with whale population growth.

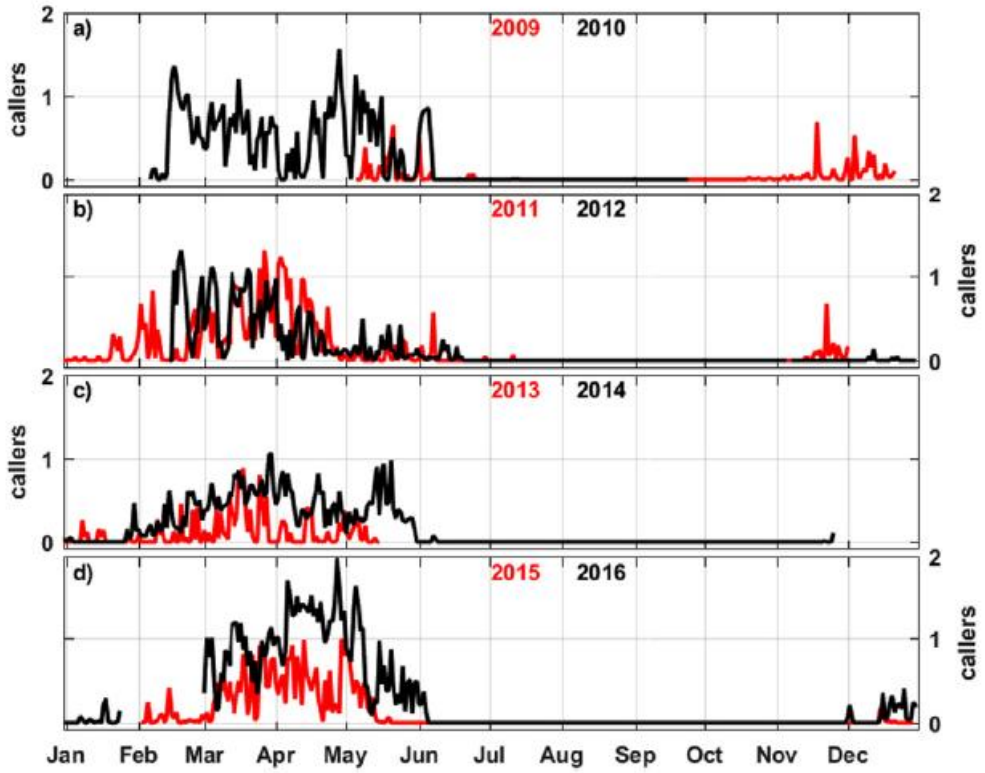

Figure E7-7 - Mean Number of Individual Pygmy Blue Whales Calling (McCauley et al. 2018).

Beach Energy Surveys 2021

Beach Energy commenced its Otway drilling program in February 2021 and engaged the Blue Whale Study to undertaken aerial surveys from February to May 2021 to identify blue whale and krill surface swarms within the Otway Development Area and outside of this area (Beach Energy 2022). A preliminary data summary provided to Beach detailed:

- Nine aerial surveys were undertaken from 25 February to 21 May 2021.
- There were 34 blue whale sightings consisting of 43 individuals.
- The highest number of blue whale sightings was on 7 April with 19 blue whales sighted.
- The first blue whale was sighted 25 February and final blue whale sighted 7 April.
- Blue whales and krill surface swarms were distributed throughout the area surveyed.

1 Introduction

This document presents analysis of an environmental aspect, underwater sound, between the Regia Marine Seismic Survey (Regia MSS) and the existing environment that may be affected by that aspect. This environmental aspect was identified by the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) for further assessment.

This analysis is based on information provided in the preceding studies:

1. Sound Emissions Initial Modelling Report (Appendix B7)
2. Sound Emissions Secondary Modelling JASCO and SLR Reports (Appendix B7b and B7d)
3. Seismic Sound Studies Report (Appendix B8)
4.

1.1 Purpose and Scope

The purpose of this document is to assess all acceptable sources of information to provide clear outcomes around levels-of-impact, and any associated mitigation and management measures that may be needed.

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document was first published in draft form to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (EP) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality

of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Underwater Sound

2.1 How the Aspect Occurs

Impulsive underwater acoustic emissions will result from the seismic source releasing compressed air (seismic pulse) that creates a sound wave that is directed downwards into the seabed.

2.2 Extent and Duration of the Aspect

Impulsive Sound

Duration: 60 days

Extent: Active Source Area and area of sound propagation within which the human health safety criterion will be exceeded as detailed in the impact assessment sections.

Seismic acquisition where the seismic source will be active will occur for up to 60 days within the Active Source area.

3 Cause-Effect Pathway

The PEIRA (Appendix B4) identified a cause-effect pathway for underwater sound for the following environmental components:

- Divers, surfers, and swimmers.

Potential environmental impacts to divers, surfers, and swimmers identified from the PEIRA are:

- Change in physical condition.

4 Description of the Existing Environment that may be Affected by the Activity

For a description of the baseline soundscape in the region relevant to the Regia MSS, refer to Section 1.1 of Appendix B8.

Via stakeholder consultation it was identified that diving, surfing, and swimming occurs along the coastal area adjacent to the Operational Area daily throughout all seasons. Access to Country, including coastal areas, is also a highly valued and key aspect of cultural maintenance for Indigenous peoples. Divers, swimmers, and surfers may be affected at the following popular diving sites are:

- Deen Maar (Lady Julia Percy Reserve)
- Port Campbell Harbour
- Port Fairy – South Beach, Pea Soup Beach, The Passage and Battery Point
- Merri Marine Sanctuary
- Portland Harbour
- Warrnambool Harbour

Popular beaches are:

- Bay of Islands
- Bowkers Beach
- Childers Cove
- Clifton Beach
- Gibsons steps/Gibson Beach
- Massacre Bay
- Newfield Beach
- Rivernook Beach

The JASCO modelling report included 13 representative coastal locations as well as Deen Maar where received sound levels were calculated. These locations were spatially spread out along the coastline adjacent to the Survey Acquisition Area providing considerable coverage for prediction of human health threshold exceedances.

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, that apply to underwater sound and divers, surfers, and swimmers (see Appendix B2). Measures that must be adopted are as follows:

- Diving Medical Advisory Committee (DMAC 2020) requires that efforts are made to implement a SIMOPS plan in consultation with divers with an appropriate risk assessment undertaken.

6 Defining Acceptable Levels of Impact

Scuba divers, surfers and swimmers exposed to high levels of underwater sound can suffer from dizziness, hearing damage or other injuries to other sensitive (mainly air-filled) organs, depending on the frequency and intensity of the sound.

Underwater, the human ear is about 20 dB less sensitive than it is in air at low frequencies (20 Hz), increasing to 40 dB at mid-frequencies (less than 1 kHz), and increasing to 70–80 dB less sensitive at higher frequencies (Parvin 1998).

Information on studies in relation to seismic acoustic emission impacts and diving is provided Seismic Sound Studies Report (Appendix B8).

Seismic activity results in the transmission of acoustic waves through the water which divers or swimmers experience as vibration or a noise analogous to a piling hammer. Multiple reflections of this acoustic wave from the sea surface, seabed and other structures may result in this sounding like a low frequency rumble (DMAC 2020).

A safety criterion for recreational divers and swimmers of 145 dB re 1 µPa is conservatively used to assess potential adverse effects. This does not imply that this level is associated with the onset of injury, which has not been established due to ethical research protocols. Parvin (2005) reported vibration in forearms and thighs at the much higher level of 180 dB re 1 µPa but no physical injury.

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that assessment specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E8-1 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding assessment specific defined acceptable levels established for this assessment. This sets the foundation for relevant and targeted demonstration later in this assessment. [1]

Table E8-1 - Defined acceptable levels of impact from underwater sound effects to fish

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	Sound exposure to coastal users is below the per-pulse safety criterion relating to amenity value of 145 dB re 1 µPa.	This level is based on internationally recognised guidance for human exposure to underwater noise, particularly in relation to comfort and

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they a documented elsewhere, these criteria are not discussed further in this assessment.

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		amenity values for recreational divers and coastal users. An SPL human health assessment (Parvin 2005) supports this threshold. Exceeding this threshold may result in aversion or perceived nuisance, undermining social licence.
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	Reflects Commonwealth and State policy objectives for sustainable resource use and protection of ecosystem services.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	This level reflects the principle of maintaining cultural values and heritage as protected under national and state legislation. It ensures that activities do not interfere with traditional practices, spiritual connections, or ongoing access to culturally significant areas.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	This level reflects broader social licence to operate, ensuring that environmental activities do not lead to degradation of public amenity, loss of recreational use, or impacts to non-Indigenous heritage values. It aligns with Commonwealth policies promoting public access, well-being, and sustainable use of the marine environment.
	The views of public have been considered in the impact and risk assessment.		

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Specific)	Rationale
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic sound on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity, several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In the context of underwater sound, elimination involves removing the source of underwater sound or preventing its generation in the first place. Two main options were considered:

No seismic acquisition within 17 km of Deen Maar / Lady Percy Julia Island

This option has been considered by CGG to eliminate the risk of exposing divers to sound pressure levels that may exceed safe thresholds in shallower waters where sound energy is more likely to reflect and concentrate, thereby increasing potential exposure and associated risks. By eliminating operations in shallower depths, the activity design ensures that risk to diving personnel is avoided in the most sensitive depth zones.

Excise areas of the acquisition area that have been identified to cause exceedances of safe diving thresholds

This approach eliminates potentially high-risk areas within the acquisition area. It ensures that seismic activities do not occur in locations where modelling or empirical data indicate the potential for unsafe sound exposure levels to divers. The limitation was accepted by CGG to prioritise diver safety and reduce the need for more complex mitigation measures during operations. By eliminating high-risk segments of this area, the project reduces the likelihood of adverse impacts while maintaining operational objectives.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. No substitution-based limitations were required in this case, as the elimination measures applied were sufficient (when applied with other measure types) to reduce the identified impact to an acceptable level.

9 Predicted Levels of Impact

To arrive at the predicted levels of impact of underwater sound on divers at this stage in the process requires the reader to have assimilated all prior relevant information that has been assessed on birds. The EP documentation is coded alphabetically to guide the reader through what is a natural process of temporal accumulation and review of evidence. The following documentation forms the evidence lineage for predictions on birds as described here.

- Sound Modelling Reports - JASCO Applied Sciences (JASCO) and SLR performed a numerical modelling study of underwater sound levels associated with the planned Regia Marine Seismic Survey (MSS) to assist in understanding the potential acoustic impacts on key regional receptors including birds, marine mammals, fish, turtles, benthic invertebrates, plankton and recreational divers and swimmers. Acoustic thresholds derived from this document are used to guide assessments of impacts.
- B8 – Seismic Studies Report – This report provides a detailed assessment of the scientific literature related to sound (and specifically seismic) effects on birds and other fauna including divers and swimmers. This literature is the key evidence base from which impact levels are derived.

9.1 Change in physical condition

9.1.1 JASCO Modelling

Based on the second acoustic modelling report (Appendix B7b) there is the potential for received sound levels at coastal areas where diving, surfing, and swimming occurs to exceed the human health safety criterion. As this would not be acceptable, CGG will adapt the Regia MSS so that received level at coastal areas is below the safety criterion for recreational divers and swimmers. The area in which the sound source would operate at full capacity (Survey Acquisition Area) has therefore been further constrained to the area from where the human health safety criterion would not be exceeded at any coastal location assessed. This involves avoiding acquisition using the sound source at full power in the area in red in Figure E8-1.

The second iteration of acoustic modelling undertaken deliberately introduced an assessment of sound exposure at 14 relevant sites across the coastline adjacent to the Survey Acquisition Area. Guidance issued by the Diving Medical Advisory Committee (DMAC 2020) suggests that adverse effects to divers may be experienced at distances of up to 27 km from the seismic source, which is within the range of the modelling distance for the Regia MSS. Five of the coastal locations assessed were within 27 km.

A per-pulse safety criterion of 145 dB re 1 µPa was applied which the modelling indicated could be exceeded at:

- Killarney Beach (150.6 dB re 1 µPa)
- Port Fairy Lighthouse (154.6 dB re 1 µPa)
- Deen Maar / Lady Julia Percy Island (154.8 dB re 1 µPa)
- Merri Sanctuary (151.8 dB re 1 µPa)
- Middle Island (151.8 dB re 1 µPa)

The two closest coastal sites to the Active Source Area (Port Fairy Lighthouse & Deen Maar) at 20.7 and 16.6 km distance, respectively. Figure E8-1 illustrates the sound source location where the safety criterion would be exceeded at any of the coastal sites assessed. Received sound levels at the three

other coastal sites within 27 km of the sound source (Deen Maar, Middle Island and Merri Sanctuary) were below the safety criterion.

The activity design parameters have continued to evolve throughout the preparation of the Regia MSS EP. As such, the northern most lines of the survey area have been removed such that modelled sound impulse sites 1, 2, and 3 are no longer the drivers of the exceedance levels shown above. Analysis of the remaining relevant sound impulse sites (4 – 15) shows that all dive sites now have exposures below 140 dB re 1 µPa, except for waters around Deen Maar / Lady Julia Percy Island (Site 15).

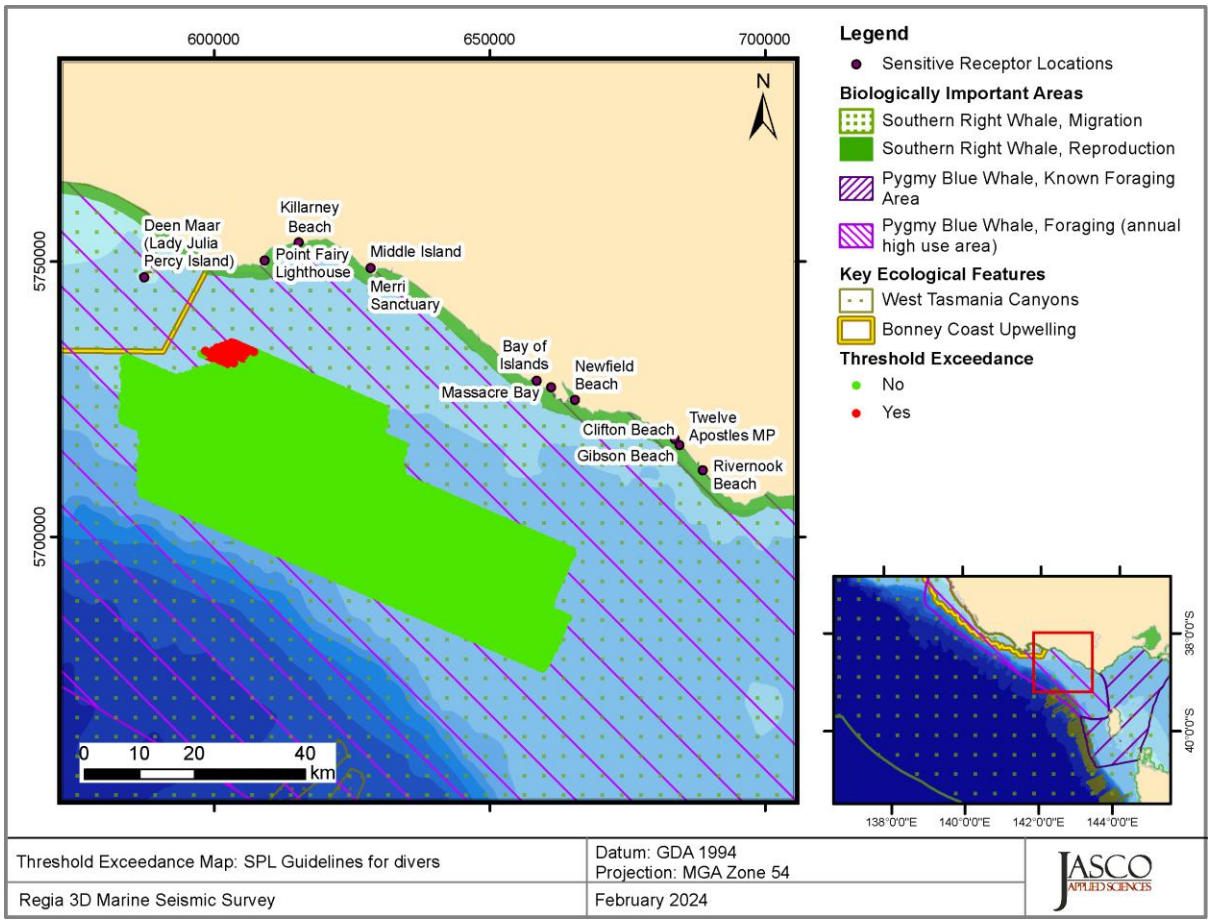

Figure E8-1 - Assessment of safety criterion exceedance at any coastal sites from within the proposed active source area. Area within the proposed active source area from where exceedance of the safety criterion may occur is indicated in red.

9.1.2 SLR Modelling

SLR was commissioned by CGG to conduct an underwater acoustic study using a lower sound source (see Appendix B7c). While SLR did not model received levels at specific receiver locations, this study modelled 3 sites from the JASCO report, sites 15, 10 and 7 (see Figure E8-2 below). A per-pulse safety criterion of 145 dB re 1 μ Pa was applied to each site. The maximum distance at which this threshold was exceeded was at 42.35km from the sound source.

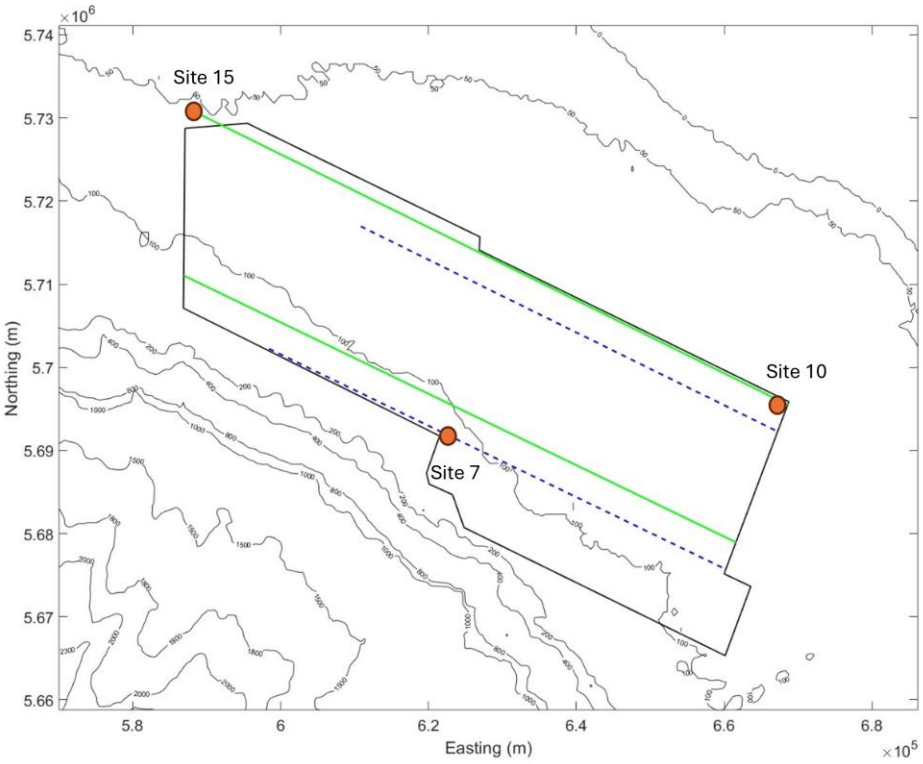

Figure E8-2: A map showing the modelled sites in the SLR underwater sound study.

The uncertainty level for impact to divers is assessed as low based on:

- The conservative human health safety criterion used to identify where potential adverse effects may be experienced (of 145 dB re 1 µPa).
- There were concerns raised throughout consultation with relevant person regarding sound levels at recreational dive sites close to the Operational Area (Event ID 2028).
- Following these concerns, CGG commissioned JASCO to undertake underwater sound modelling report that deliberately assessed received sound levels at 13 representative locations across the coastline adjacent to the proposed Active Source Area as well as Deen Maar.
- CGG also commissioned SLR to conduct underwater sound modelling and found the 145 dB re 1 μ Pa will be exceeded at 42.35km from the sound source.
- The Active Source Area has been further constrained to areas where the human health safety criterion is not exceeded anywhere on the adjacent coastline or at Deen Maar.

The predicted level of impact based on the effect (negligible) and uncertainty (low) levels is assessed as low. The predicted levels of impact are beneath levels of perception and/or within normal bounds of variation. Good industry practice (including legislation and standards) has been applied and therefore these impacts are of an acceptable level without further reduction measures being required.

9.2 Measures Adopted to Manage Environmental Impacts

The following measures have been adopted to ensure that the impacts associated with elevated levels of underwater sound from the survey and support vessels on divers, surfers, and swimmers will be of an acceptable level.

These measures have been taken through to the ALARP assessment in the next stage of the CGG assessment process. This assessment can be found in Appendix F2.

Measure	Measure Type	Details and Justification
Diving SIMOPs Plan	Resource	Best endeavours will be used to ensure this plan is developed with local divers and commercial divers that is consistent with DMAC guidelines.
Consultation Management System	System	Local newspapers will be used to notify the public of the SIMOPS Plan and the timing of the activity.
Sail Line Plan	Resource	This plan is used by all staff and vessels to align on the operational parameters, schedule, and conduct of the survey within the activity limitation required by this EP.

10 Demonstration Impacts will be of an Acceptable Level

10.1 Principles of ESD

Temporary, Reversible, and Small Scale

As described in the impact assessment, the Regia Marine Seismic Survey will generate impulsive underwater sound from an airgun array with a total volume of 2,630 in³, active over 60 days in a 90-day period. SLR modelling shows that the predicted distances at which regulatory thresholds for harm to divers may be exceeded are extremely small: Parvin (2005) and NATO (2006), 184 dB re 1µPa (rms) exposure limit which can cause physiological damage to divers is exceeded only within 520 m of the source, and the more conservative 170 dB re 1µPa (rms) limit for divers which is the tolerance limit is exceeded only within 2.72 km. Swimmers and surfers are not expected to be exposed to these levels given these distances are based on modelled site that are in water depths of more than 50m. . These distances are highly localised compared to the total survey area and survey vessel speed (4–6 knots), meaning any potentially affected area moves continuously and is of short duration. There are no planned survey operations in nearshore waters where these activities commonly occur. Therefore, any potential environmental harm from underwater sound exposure to people is predicted to be of low intensity, short duration, reversible, and confined to a very limited spatial scale. The predicted levels of impact are beneath levels of perception and/or within normal bounds of variation. There is however the potential for received sound levels at coastal areas where diving, surfing, and swimming occurs, but they should not exceed the safe diving criterion.

Based on sufficient information

The impact assessment used peer-reviewed literature, national standards (AS/NZS 2299.1:2015), international health guidance, and site-specific acoustic modelling to define thresholds for safe exposure. Sound propagation modelling was conducted using JASCO's and SLR's established methodology and considered average seasonal propagation conditions. Thresholds from the Australian Standard for occupational diving and conservative limits for recreational and public exposure were applied. There is no evidence of serious or irreversible harm at or beyond the modelled distances, and swimmer and diver hearing injury thresholds (e.g. 230 dB SEL) are not predicted to be exceeded at any distance. The assessment concluded that sufficient information was available to characterise impacts, and uncertainty was low. The precautionary principle was not triggered.

Activity not inconsistent with EPBC Act

Underwater sound exposure to humans is not regulated under the EPBC Act, which focuses on environmental and species conservation. However, the assessment reviewed and followed applicable occupational health standards and international marine planning guidance. The EPBC Act was also considered in relation to sensitive cultural values or protected areas that could coincide with recreational water use, and none were identified within the survey area. No recovery or management plans applicable under the EPBC Act address human use of the marine environment in relation to sound exposure. Accordingly, the activity is not inconsistent with the Act or any associated instruments.

10.2 Biological and Ecological Categories

Not applicable to this impact pathway, no marine fauna or biotic components are assessed in this section. The focus of this assessment is on potential harm to humans engaging in in-water activities. There are no pathways by which diver or swimmer exposure would generate damage to ecological features or ecosystem functioning.

10.3 Economic, Cultural and Social Categories

During consultation, relevant persons including recreational divers, coastal tourism operators, community groups, and marine safety agencies raised concerns about potential impacts on in-water

activities and public safety. Several requested exclusion zones or formal warnings in advance of survey operations. In response, CGG committed to implementing a public notification plan that includes regular updates to the Consultation Hub, coordination with marine safety advisories, and targeted outreach to recreational diving clubs and tourism operators. These measures ensure that water users can make informed decisions and avoid the limited zones where sound levels might exceed recreational or occupational exposure thresholds. The modelling demonstrated that no survey operations would occur near popular dive sites, beaches, or surf breaks. Indigenous harvesting of coastal resources such as torbos, pipis, abalone, limpets, mussels, elephant snails, crayfish/lobster, oysters, cockles, and crabs was identified as culturally significant, along with Native Title non-exclusive rights including access to and use of the land and waters, and the taking of resources from the land and water (Appendix F3 Section 3.16.1). As the activity is located 20km offshore, no disruption to access, use, or harvesting is anticipated, with diving, surfing and swimming not expected to be impeded. The consultation process confirmed that affected persons will not be materially worse off and that all relevant claims were appropriately addressed and incorporated into the final EP.

10.4 Consistency with Company Processes

The impact assessment followed the process set out in Appendix B3, using defined consequence criteria and uncertainty ratings. These ratings reflect the short duration, small spatial extent, and avoidance of exposure above regulatory thresholds. All adopted mitigation measures align with good practice and are within the titleholder's control. The final consequence rating remains within company limits.

This impact assessment has demonstrated that the effect of underwater sound to divers, surfers and swimmers has a:

- **Predicted level of effect of negligible.**
- **An uncertainty of low.**
- **Predicted level of impact of low.**

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E8-2 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E8-1)	Environmental Performance Outcome	Rationale
Sound exposure to coastal users is below the per-pulse safety criterion relating to amenity value of 145 dB re 1 µPa.	**Received sound levels at coastal areas accessible by coastal users will not exceed the human health safety criterion relating to amenity value.**	This EPO can be supported through acoustic modelling calibrated against real-world measurements and by verifying compliance with predicted exposure contours for coastal areas and dive sites. The predicted levels of impact are beneath levels of perception and/or within normal bounds of variation. There is however the potential for received sound levels at coastal areas where diving, surfing, and swimming occurs, but they should not exceed the safe diving criterion.
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	Predicted impacts to fish are low intensity damage at the population level and within currently accepted levels of impact to these species as applied by the commercial fishing industry. The Otway Adjustment Protocol will be implemented to ensure that affected fishers will not be worse off because of the activity.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		The Budj Bim eel traps are protected under the World Heritage Area listing, the eels themselves are not. No impacts to the World Heritage Area are predicted. The predicted impacts to eels are low intensity at a population level and within current accepted levels of impact as applied to the commercial fishing industry. The Yarra Pygmy Perch occurs in lakes, ponds, and slow flowing rivers (Saddlier and Hammer 2010). Because of their freshwater affiliation no impact from underwater sound from offshore seismic is predicted.
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		Predicted impacts to fish are low intensity damage at the population level and within currently accepted levels of impact to these species as applied by the commercial fishing industry.

Defined Acceptable Level (From Table E8-1)	Environmental Performance Outcome	Rationale
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

The impact assessment has adopted a conservative approach to estimation of the predicted level of impact. Good industry practice (including legislation and standards) has been applied and impacts are therefore considered to be of an acceptable level without further recommendations being required.

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E8-3 shows how this feedback has been incorporated into the environmental assessments.

Table E8-3 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Impacts on dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and Activity limitation, to reflect that the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, and G1).

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E8-4. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E8-4 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4003	Risks to the wellbeing of the human population	The risks to divers, surfers, and swimmers have been thoroughly assessed in E8 and a SIMOPS plan will be developed to ensure the amenity value of the diving/swimming/surfing experience is unaffected.	5114
4226	The email expresses concern about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4007	A concern was raised regarding the potential exceedances of safe diving thresholds, highlighting the risks associated with seismic activities on divers.	The risks to divers, surfers, and swimmers have been thoroughly assessed in E8 and a SIMOPS plan will be developed to ensure the amenity value of the diving/swimming/surfing experience is unaffected.	2028

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4020	Any threat to the ocean, poses a threat to my health.	The effects on the amenity value of the diving, swimming, surfing experience have been assessed in E8 and limitations put in place to ensure the thresholds for human health are not exceeded.	2857
4022	Attendees voiced concerns about how seismic activities could impact the sustainability and fish-ability of the immediate and nearby areas.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1529
4030	CGG's email on September 14 indicated that the project's timing has changed to two separate 3-month windows: April-June and September-November. AMCS is concerned that the December sound speed profile may not accurately reflect the physical conditions during these new survey periods. Since acoustic propagation modelling is critical for subsequent analyses and for setting thresholds for mitigation measures required for NOPSEMA approval, AMCS requests an explanation of how the December sound speed profile differs from those in April-June and September-November.	We acknowledge this concern and agree that acoustic propagation modelling is the foundation of subsequent analysis. We will complete another modelling report prior to submission to cover the changed timeframes of the proposed survey.	3384
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4037	Commenter expresses concern that seismic surveys will severely damage the local area and pose significant risks to divers during testing.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. Activity Limitation plans are also in place to remove/ reduce any impacts to as low as practicable. There will be no significant impacts on divers from the Regia MSS.	1432
4049	Concern about the blasts going off while swimming and the harmful sound waves reaching the shores of Port Fairy.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. CGG has assessed impacts to divers and swimmers in E8. The MSS will be operating at >25km from the coast and beyond depths greater than 50m hence significant impacts are not expected. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation.	879

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	potential for further exploration by other companies, particularly regarding the sale of seismic data.	Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	722
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels	917

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		of harm that would endanger the population stability of any taxa.	
4082	Concerns about the noise and effects of seismic surveying on swimming, snorkelling, and observing marine life.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	1263
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4091	DMAC guidelines had been followed, meaning that the threshold used was one of aesthetic value of the experience rather than a physiological effect.	The titleholder acknowledged this claim and provided the project website which contains relevant information.	2282
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4100	Expresses concern that while the proposed exclusion zone for seismic testing is set at depths less than 40 meters, this may not be sufficient to protect abalone divers. Comment that a safer distance of 10.3 kilometres away from the 30-meter	The 40m exclusion was put in place for abalone and other shallow water molluscs/invertebrates, rather than only for commercial divers. Abalone belong to the phylum Mollusca and are considered a benthic invertebrate in the sound modelling study. The 10.3km buffer is the	1846

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	contour should be maintained to ensure that abalone are not exposed to damaging sound levels, similar to the protections applied around Deen Maar.	behavioural response distance for marine mammals. The appropriate distance for abalone is 52m at 40m water depth (Event ID 1846).	
4115	I live in Warrnambool and enjoy the marine life it offers - whale watching, swimming and snorkelling. All of which would be affected by this drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will be operating at >25km from the coast and beyond depths greater than 50m hence significant impacts are not expected. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1459
4117	Impact on enjoyment and overall experience at the beach.	Stakeholder interests were noted and used to inform the analysis and assessment of impacts arising from the Regia MSS. Multiple measures were taken to manage any potential impacts to users enjoyment	1263
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS	537

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	
4150	Outlined concern about any exceedances of safe diving thresholds.	Titleholder acknowledged this concern and noted that potential impacts to divers from the Regia MSS is assessed in E8 of the EP. To ensure divers are not exposed to noise levels above the human threshold for safety, CGG will implement the following measures: No seismic acquisition will be undertaken in water depths shallower than 50 m, Excise areas of the acquisition area that have been identified to cause exceedances of safe diving thresholds, Diving SIMOPs Plan, Consultation System and a sail line plan (see G1).	2282
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4155	Raised concerns about sound levels from the survey and associated effects on marine mammals and other species.	Acknowledged concerns and outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Also outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Also outlined the effects on zooplankton and the case for acceptability of these	3697
4157	Reference to CGG's acoustic modelling report and the predicted sound waves reaching 140-160db at Port Fairy.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will be operating at >25km from the coast and beyond depths greater than 50m hence significant impacts are not expected. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts	2830

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		on the marine environment are outlined in the EP in G1.	
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4179	Seismic sounds have far-reaching effects on the marine environment, causing damage and suffering to species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3237
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2963
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the	1653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares	1662

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		those to the previously defined acceptable levels and is presented in the Environment Plan	
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined	1670

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptable levels and is presented in the Environment Plan	
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	2886
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4213	Stakeholder wanted to enjoy recreational activities without the disruption and destruction caused by the proposed activities.	Titleholder responded advising that displacement of recreational marine users is an assessed impact of the activity that is temporary and recoverable. The activity occurs no closer than 25km to the coastline at its closet point (south of Port Fairy) and lasts for no longer than 90 days.	820
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-	425

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	
4226	The email expresses concerns about the adverse effects of blasting the Southern Ocean and its creatures, particularly mentioning the geologically sensitive Bonney upwelling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2940
4230	The feedback asserts that seismic testing is harmful to oceans and marine life, highlighting detrimental effects on the ecosystem.	We acknowledge that the Regia MSS will have some short-term, localised and recoverable effects on some parts of the environment. We will try demonstrating to our independent regulator that these impacts are of an acceptable level and not as detrimental as you claim. We welcome any evidence you can share so that we can consider it fully prior to our submission.	2080
4232	The feedback expresses frustration over repeated seismic blasts in the same area, emphasising the significant environmental impacts associated with these activities. It calls for accountability from NOPSEMA to prevent future occurrences, highlighting the ongoing threat to the environment.	The Regia MSS is targeting areas that have not been surveyed before though we acknowledge there may be some overlap with previous surveys. We must show that the environmental impacts are short-term, localised, or recoverable and that they are controllable with appropriate measures in place.	2104
4257	The primary concern raised was regarding the safety of divers and effective management of simultaneous operations (SIMOPS).	Identified two measures that need further analysis to confirm exactly what to do next. The first was to remodel the sound propagation into shallower waters noting that CGG has made a commitment to offset from popular dive beaches already (Event ID 3367). The second measure was to develop a SIMOPS plan. Asked if abalone divers were likely to dive at night, which was confirmed as unlikely (Event ID 3367). Stated that CGG would do more work to understand the areas that it wanted to access, and the offset distances that would be required, to determine whether CGG needed to commit to certain lines being acquired at night-time only.	3367
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is	1901

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	
4268	The stakeholder argues that it is impossible to ensure zero risk from seismic activities, emphasising that only zero risk is acceptable. This position reflects a strong concern regarding the potential negative impacts of seismic exploration on the marine environment.	The legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an "exclusion zone" will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	2108
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4273	The stakeholder claimed that their leisure interests and activities would be affected by the issue as wildlife and coastal creatures will be scarce in the area affecting swimming, diving, whale watching and fishing.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E1. Measures to minimise adverse impacts on functions, interests and activities on swimming, diving, whale watching and fishing are outlined in the EP.	2060
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna,	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation.	1325

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	indicating a general concern for environmental conservation.	Mitigation plans are in place to reduce any impacts to as low as practicable.	
4285	The stakeholder noted the following concerns as a resident of Port Fairy: Noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	1747
4287	The stakeholder objected to the activities due to sound levels/acoustic trauma experienced by sea creatures	The scientific literature supports that marine fauna may potentially be displaced due to a seismic survey but that these impacts are typically short term with no impact to ecosystem function. Large scale studies undertaken in Australia that you may be interested in are: Australian Institute of Marine Science. North West Shoals to Shore Marine Noise Monitoring and Impacts https://www.aims.gov.au/research-topics/monitoring-and-discovery/north-west-shoals-shore Behavioural Response of Australian Humpback whales to Seismic Surveys https://www.brahss.org.au/ Assessing the impact of marine seismic surveys on southeast Australian scallop and lobster fisheries https://www.frdc.com.au/project/2012-008 Marine Seismic Survey Impacts on Fish and Invertebrates: Final Report for Gippsland Marine Environmental Monitoring Study https://ecat.ga.gov.au/geonetwork/srv/api/records/2292f4a7-ba2e-3533-e053-12a3070aaf2c Maxima 3D Marine Seismic Survey at Scott Reef https://www.sciencedirect.com/science/article/abs/pii/S0025326X13006528 https://www.sciencedirect.com/science/a	2389

		rticle/abs/pii/S0025326X18300687 Regarding Marine Fauna Observer's (MFOs), companies that contract MFOs such as Blue Planet Marine and RPS Group provide training for MFOs. As part of contracting MFOs we will ensure that the persons provided meet the requirement of the Australian Government EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales, that requires MFOs to be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, details the competency requirements for MFOs and ongoing awareness (page 23 and 24). The Regia MSS Implementation Strategy is available on the Regia MSS Website Document Library see https://klarite.mysocialpinpoint.com.au/regiamss/document-library As detailed in the Regia MSS Implementation Strategy, which will form part of the environment plan to be submitted to NOPSEMA, CGG will only use appropriately experienced MFOs as determined by a review of their CVs (page 23). The Regia MSS Implementation Strategy also details how CGG will monitor the performance of the control measures during the activity (page 25). For example: Audits and Inspections Post acceptance of the EP, conformance will be monitored on an at least quarterly basis by the Client Site Representative, or delegate, via audits and inspections, as well as through the commitments under the Management of Risk, Management of Change, and Management of Knowledge parts of this Implementation Strategy. During the activity, conformance will be monitored on an at least fortnightly basis by the Client Site Representative, or delegate, via audits and inspections during the activity. Conformance auditing or inspection while the EP is in-force will be based on the Conformance Register and will target the following: · Conformance with regulatory requirements detailed in the accepted	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		EP. • Management strategies and procedures to ensure EPOs and EPSs are being implemented, monitored, measured, and evaluated. • Emissions and discharges are being monitored, measured, and documented As stated in the previous email, matters of national energy policy are not within the purview of CGG or the Regia MSS. We will however register claims related to the ongoing need for gas and provide those to NOPSEMA. Please find attached a brochure from NOPSEMA that describes this and may be of use to you.	
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4289	The Stakeholder outlined concern about any exceedances of safe diving thresholds.	The Regia team discussed the sound modelling that has been completed to date and that the DMAC guidelines had been followed meaning that the threshold used was one of aesthetic value of the experience rather than a physiological effect. (Event ID 2282)	2282
4300	The stakeholder stated that sound impacts to human health were unacceptable.	The titleholder acknowledged the feedback, noting that potential impacts of underwater sound to surfers, divers and swimmers is assessed in the Environmental Plan (EP) and can be found in E8. Measures to minimise adverse impacts on functions, interests and activities on humans are outlined in the EP.	1890
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined	1747

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		acceptable levels and is presented in the Environment Plan	
4304	The stakeholder stated that they were concerned about the correlation between the risk of shark attacks and sound caused as a result of a seismic activity.	CGG has completed an assessment of the impacts to divers from elevated levels of sound. Whilst preparing this document a literature review was complete to explore the claim that sharks may be more aggressive or predatory as a result of exposure to elevated levels of sound. No relevant literature was found.	1890
4310	The stakeholder was concerned about the sensitivity of different divers to sound exposure.	This has been thoroughly assessed in E8 and a SIMOPS Plan will be developed with local divers to ensure that the amenity value of the diving experience is maintained.	2282
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4329	This feedback highlights the uncertainty regarding the long-term impacts of seismic blasting on abalone populations, particularly emphasising that the effects may not be immediately observable and could depend on the juvenile stages at the time of blasting.	We have recently installed an exclusion zone down to the 40m bathymetry contour primarily as a result of discussions with abalone fishers who dive down to 30m. This will help protect early life-cycle stages of abalone. Further, seismic surveys have occurred in this region for many years and the two industries (fishing and petroleum) have successfully coexisted over time (Event ID 2095).	2095
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4355	Request for seismic blasting not to occur within 20km of specific beaches.	Titleholder acknowledged this concern and commissioned specialist underwater sound modelling to assess impacts to divers and swimmers (see E8). This was done to ensure sound exposure to coastal users is below the per-pulse safety criterion relating to amenity value of 145 dB re 1 µPa. CGG advised that control measures to reduce impacts to divers and swimmers as a result of the survey are outlined in the EP and include a sail line plan, a SIMOPS plan, an activity limitation where no acquisition will occur in in water depths shallower than 50 m, and the Regia MSS will avoid any areas	2831

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		where there are exceedances of safe diving thresholds.	
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880

1 Introduction

This document presents an assessment of an environmental aspect between the Regia Marine Seismic Survey (**Regia MSS**) and the existing environment that may be affected by that aspect. This environmental aspect was identified by the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) for further assessment.

1.1 Purpose and Scope

This assessment is the second stage of the environmental assessment. Its purpose is to rank the impact according to the criteria set out in the Environmental Assessment Process found in Appendix B3. The purpose of this stage of the assessment is to demonstrate that the impact can be managed to an acceptable level through the adoption of mitigation measures and the setting of an appropriate environmental performance outcome.

The measures adopted because of consultation and because of the assessment will be carried through to the ALARP assessment which occurs in stage three of the overall assessment process. Recommendations will be made if there is any further assessment required in the third stage of the assessment.

1.2 Consultation in Preparation of the EP

This document presents analysis of an environmental aspect between the Regia Marine Seismic Survey (Regia MSS) and the existing environment that may be affected by that aspect. This environmental aspect was identified by the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) for further assessment.

This document was first published in draft form to the Document Library of the Regia MSS Consultation Hub on 11 September 2023. This was done to acknowledge that the final full Environment Plan (EP) can be a large document that is difficult for readers to digest in the 30-day public comment period. As such, the public and relevant persons were invited to comment on the document with an explicit request for readers to provide feedback on:

- The accuracy of the described environment that may be affected.
- Any omissions of environmental values and sensitivities relevant to the environmental aspect.
- Any errors or omissions of scientific/peer reviewed literature that should be considered.
- Any errors or omissions of relevant legislation or documents of standing that should be considered.
- Any further mitigation or management measures that should be considered.

1.3 Modifications Arising from Further Assessment

To ensure this environmental assessment remains contemporary, accurate, and reflects feedback from the regulator and relevant persons, this document will be updated from time-to-time. In particular, the CGG environmental assessment process requires consideration of whether further assessment was needed to verify, or dive deeper into a topic, to further improve the predictive quality of the assessment. When this has occurred, reference to such changes will be communicated in the Recommendation section and identified at relevant points in the assessment.

2 Aspect – Light Emissions

2.1 How the Aspect Occurs

Navigational and safety lighting on the seismic and support vessels emit light when operating at night.

2.2 Extent and Duration of the Aspect

Duration: 90 days

Vessel navigational and safety lighting will be required at night for the duration of the activity.

Extent: Operational Area +20 km

The National Light Pollution Guidelines for Wildlife (CoA 2023) detail that where there is important habitat for listed species that are known to be affected by artificial light within 20 km of a project, species specific impacts should be considered through an Environmental Impact Assessment.

The 20 km extent provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings demonstrated to occur at 15-18 km and fledgling seabirds grounded in response to artificial light 15 km away (CoA 2023). Seabird grounding, as described in Rodriguez et al. (2014), relates to impacts of onshore fixed light sources such as streetlights and buildings and the effect this can have on young fledgling birds making their first flight from their nests to the open ocean. Subsequently, 20 km is adopted as the extent of light emissions for the impact assessment.

For zooplankton, fish and invertebrates, the Guidelines detail that for vessel lights zooplankton and their vertebrate predators to descend away from the surface; these effects occurred at depths of up to 200 m, and up to 200 m horizontally from the light source. Experiments using light traps also detailed that some fish and zooplankton species are attracted to light sources (Meekan et al. 2001), with traps drawing catches from up to 90 m (Milicich et al. 1992). Thus, for zooplankton, invertebrates, and fish the extent of impact is within 200 m of the light source.

3 Cause-Effect Pathway

The Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4) identified a cause-effect pathway for light for the following environmental components and their social, cultural, and economic features:

- Plankton.
- Invertebrates.
- Fish.
- Birds.
- Marine reptiles.
- People and communities.
- Marine mammals.
- Coastal communities.

The PEIRA (Appendix B4) identified that the environmental impact of light to the following environment components was ranked as having a negligible level of effect and are not assessed further:

- Marine mammals.
- Coastal communities.

4 Description of the Existing Environment that may be Affected by the Activity

As detailed in the Section 2.2, the Operational Area plus 20 km has been adopted as the extent of light emissions for the impact assessment to light sensitive species such as marine turtles, seabirds, and migratory shorebirds, thus a Protected Matters Search to identify these species was undertaken for the Operational Area plus 20 km with the report available in Appendix B5.

As detailed in the Section 2.2, the Operational Area plus 200 m has been adopted as the extent of light emissions for the impact assessment to light sensitive species such as zooplankton, invertebrates, fish, thus a Protected Matters Search to identify these species was undertaken for the Operational Area with the report available in Appendix B5.

Annex 3 details those species that may be affected by light from the PMST report and identifies any biologically important areas and conservation advice or management plans.

4.1 Zooplankton

The PMST Report (Appendix B5) identified that the area potentially affected by light emissions out to 20 km overlaps the Bonney Coast Upwelling Key Ecological Feature (Appendix B12 MAP-REG-EPM-003) which is a seasonal upwelling that brings cold nutrient rich water to the sea surface and supports regionally high productivity. Krill and potentially other zooplankton productivity are a key feature of the upwelling providing a food source for several threatened species, including the blue whale, migrate into the area to forage (CoA 2015a).

Zooplankton is likely to be present throughout the Operational Area as in all marine environments.

4.2 Invertebrates

Studies by the Museum of Victoria found that invertebrate diversity was high in southern Australian waters although the distribution of species was patchy, with little evidence of any distinct biogeographic regions (Wilson and Poore 1987). This is supported by studies in the eastern part of the Operational Area undertaken by Beach Energy (2022) and Cooper Energy (2017) that found:

- In water depths from 20 – 70 m much of the seabed to ~ 60 m water depth was sand or fine gravel. No epifauna were observed and the biological component was likely to be primarily in-faunal or pelagic. Beyond 60 m water depth, this broad flat area has a sparse cover of filter-feeding epifauna dominated by sponges and also probably hydrozoans, bryozoans, and algae.
- In water depths from 70 to 104 m, samples percent cover of epifauna ranged from 0 to 80% but on average the percent cover was typically no more than 37%. Of the individual epibenthic organisms, Gastropoda sp. 2 (a cone shell) and crionids (featherstars) were the most abundant.

The Operational Area overlaps the Southern Squid Jig Fishery and Southern and Eastern Scalefish and Shark Fishery Commonwealth Trawl Sector where there has been low, medium and high levels of fishing intensity during 2010 to 2023. Details on these fisheries is provided in Appendix E1: Physical Presence. The Southern Squid Jig Fishery targets a single species, Gould's squid, using either hand operated or mechanically powered jigs. Squid jigging typically occurs midwater at depths between 50 and 100 m at night using large lights that illuminate the waters around a boat. Southern and Eastern Scalefish and Shark Fishery Commonwealth Trawl Sector can retain Gould' squid.

4.3 Fish

The PMST Report identified multiple fish species or species habitat within the area potentially affected by light emissions out to 200 m. Annex 3 provides a summary of the PMST Report. None of these fish species were identified to be undertaking biologically important behaviours or have BIAs or habitat critical to the survival of the fish species within the area potentially affected by light

emissions. Three threatened fish species were identified from the PMST Report and are discussed below.

Southern Bluefin Tuna (*Thunnus maccoyii*) has been removed from the February 2025 PMST Reports for all areas searched, as it is no longer listed as a threatened species under the EPBC Act (DCCEEW 2024k). This species is retained for assessment based on a precautionary approach remains appropriate to assess this species that was only recently delisted, the species known relevance to regional fisheries, and to accurately reflect the passage of time over which this EP has been constructed.

The Australian Grayling is a small to medium-sized, slender, silvery fish with soft-rayed fins lacking any spines. It is endemic to south-eastern Australia, including Victoria, Tasmania and New South Wales, and is a migratory species that inhabits estuarine waters and coastal seas as larvae/juveniles, and freshwater rivers and streams as adults (Backhouse et al. 2008).

The Blue Warehou is a medium-sized, deep-bodied fish, reaching a maximum total length of 90 cm and a maximum weight of 7 kg (TSSC 2015). Globally, the Blue Warehou is confined to Australian and New Zealand waters predominantly in coastal shelf, upper continental slope and seamount waters offshore from New South Wales, Tasmania, Victoria and South Australia (TSSC 2015). Blue Warehou is a target species for the Tasmania Scalefish Fishery.

The Orange Roughy is a demersal fish targeted by the Southern and Eastern Scalefish and Shark Fishery. They are widely distributed throughout the world and forms dense spawning and feeding aggregations on or near topographic features such as seamounts, canyons and plateaus (DCCEEW 2023). No spawning or feeding aggregation areas have been identified in the area that may be affected by light emissions.

Southern Bluefin Tuna can grow to 225 cm in length and 200 kg in weight (TSSC 2010). They are a highly migratory species that occurs globally in waters between 30°S and 50°S forming on single global population (TSSC 2010). In Australian waters, they range from northern Western Australia, around the southern region of the continent, to northern New South Wales (TSSC 2010). Southern Bluefin Tuna are a target species for the Southern Bluefin Tuna Fishery.

Most of the listed marine ray-finned fish species identified in the PMST report for the area affected by light emissions are syngnathids, which includes seahorses and their relatives (sea dragon, pipehorse and pipefish). Most of these species are associated with seagrass meadows, macroalgal seabed habitats, rocky reefs and sponge gardens located in shallow, inshore waters (e.g., protected coastal bays, harbours and jetties) less than 50 m deep (Fishes of Australia, 2015). They are sometimes recorded in deeper offshore waters, where they depend on the protection of sponges and rafts of floating seaweed such as sargassum.

4.4 Birds

The PMST Report identified multiple bird species or species habitat within the area potentially affected by light emissions. Annex 3 provides a summary of the PMST Report. Several of these bird species were identified to be undertaking biologically important behaviours and/or have BIAs that the area potentially affected by light emissions overlaps. Table E9-1 provides a summary of this information. No habitat critical to the survival of the bird species were identified within the area potentially affected by light emissions overlaps.

PMST searches were run again prior to resubmission (Rev 2) to ensure any changes to species or listings were identified to control for passage of time. Conservation Advice has also been updated for several species and subsequent changes have been made to Appendix B2 and Annex 3 relevant to the assessment of light emissions include:

- Changes to EPBC Act status of several species
    - Red Knot is listed as Vulnerable (previously Endangered)
    - Sharp-tailed Sandpiper is listed as Vulnerable (previously not listed as threatened)
    - Sooty Shearwater is listed as Vulnerable (previously not listed as threatened)
    - Western Alaskan Bar-tailed Godwit is listed as Endangered (previously Vulnerable)
    - Common Greenshank is listed as Endangered (previously not listed as threatened)

    - Ruddy Turnstone is listed as Vulnerable (previously not listed as threatened)
    - Latham's Snipe is listed as Vulnerable (previously not listed as threatened)
    - Blue-winged Parrot is listed as Vulnerable (previously not listed as threatened)
- Updates to conservation advice for several species
    - Conservation Advice for *Calidris canutus* (Red Knot) (DCCEEW 2024)
    - Conservation Advice for *Calidris acuminata* (Sharp-tailed Sandpiper) (DCCEEW 2024a)
    - Conservation Advice for *Ardenna grisea* (Sooty Shearwater) (DCCEEW 2023i)
    - Conservation Advice for *Limosa lapponica baueri* (Bar-tailed Godwit western Alaskan) (DCCEEW 2024b)
    - Conservation Advice for *Tringa nebularia* (Common Greenshank) (DCCEEW 2024e)
    - Conservation Advice for *Arenaria interpres* (Ruddy Turnstone) (DCCEEW 2024c)
    - Conservation Advice for *Gallinago hardwickii* (Latham's Snipe) (DCCEEW 2024d)
    - Conservation Advice for *Neophema chrysostoma* (Blue-winged Parrot) (DCCEEW 2023l)
    - Conservation Advice for *Calidris ferruginea* (Curlew Sandpiper) (DCCEEW 2023m)
    - Conservation Advice for *Numenius madagascariensis* (Far Eastern Curlew) (DCCEEW 2023n)
    - Conservation Advice for *Charadrius leschenaultii* (Greater Sand Plover) (DCCEEW 2023o)

All changes listed above remain relevant after the PMST searches were rerun prior to resubmission of Rev 3, with two additional changes also noted:

- Breeding BIA added for Short-tailed Shearwater within the area potentially affected by light emissions.
- Breeding BIA removed for Wedge-tailed shearwater from the area potentially affected by light emissions.

These changes have been incorporated throughout the EP and the impact assessment has been revised accordingly [Section added in response to Matters: I16 and I17].

4.4.1 Albatrosses and Petrels

Twelve albatross and two petrel species are identified as having foraging, feeding or related behaviour and/or BIAs within the area potentially affected by light emissions (Table E9-1). These BIAs cover either most or all the South-east Marine Region (CoA 2015a). It is likely these species will forage in the EMBA. In addition, the common diving-petrel breeds on Lady Julia Percy Island which is within the area potentially affected by light emissions.

Albatrosses and petrels are among the most oceanic of all seabirds and seldom come to land unless breeding (CoA 2021). Albatross and petrel species exhibit a broad range of diets and foraging behaviours, and hence at-sea distributions are diverse. Combined with their ability to cover vast oceanic distances, all waters within Australian jurisdiction can be considered foraging habitat, however the most critical foraging habitat is those waters south of 25° where many species spend much of their foraging time (CoA 2021).

Albatrosses have a widespread distribution throughout the southern hemisphere. They feed mainly on cephalopods, fish and crustaceans, using surface feeding or plunge diving to seize their prey (ACAP 2020). Albatrosses are colonial, usually nesting on isolated islands and foraging across oceans in the winter months with most observations along the edge of the continental shelf (CoA 2021).

Petrels are oceanic and have a widespread distribution throughout the southern hemisphere. They are colonial and breed on sub-Antarctic and Antarctic islands in a circumpolar band generally between 40°S and 60°S. Petrel species feed on small fish, cephalopods (octopus, squid and cuttlefish) and crustaceans along the edge of the continental shelf and open waters (CoA 2021).

Table E9-1 - Bird Species Biologically Important Behaviours and/or BIAs within the Area Potentially Affected by Light Emissions.

Receptor	Biologically Important Behaviour
Albatross	
Antipodean Albatross	Foraging, feeding or related behaviour likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-059)
Black-browed Albatross	Foraging, feeding or related behaviour likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-060)
Buller's Albatross	Foraging, feeding or related behaviour likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-071)
Campbell Albatross	Foraging, feeding or related behaviour likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-061)
Indian yellow-nosed Albatross	Species or species habitat likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-063)
Northern Buller's Albatross	Foraging, feeding or related behaviour likely to occur within area
Northern Royal Albatross	Foraging, feeding or related behaviour likely to occur within area
Salvin's Albatross	Foraging, feeding or related behaviour likely to occur within area
Shy Albatross	Foraging, feeding or related behaviour likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-066)
Southern Royal Albatross	Foraging, feeding or related behaviour likely to occur within area
Wandering Albatross	Foraging, feeding or related behaviour likely to occur within area
	Foraging BIA (Appendix B12 MAP-REG-EPM-072)
White-capped Albatross	Foraging, feeding or related behaviour likely to occur within area
Petrels	
Common Diving Petrel	Breeding known to occur within area
	Foraging, Breeding BIA (Appendix B12 MAP-REG-EPM-062)
Northern Giant Petrel	Foraging, feeding or related behaviour likely to occur within area
Other	
Australasian Gannet	Foraging, Aggregation BIA (Appendix B12 MAP-REG-EPM-073)
Black-faced Cormorant	Breeding known to occur within area
Cape Gannet	Breeding known to occur within area
Double-banded Plover	Roosting known to occur within area
Greater Crested Tern	Breeding known to occur within area
Grey-tailed Tattler	Roosting known to occur within area
Lesser Sand Plover	Roosting known to occur within area
Little Curlew	Roosting likely to occur within area
Little Penguin	Breeding known to occur within area
Marsh Sandpiper	Roosting known to occur within area
Orange-bellied Parrot	Migrating likely (Appendix B12 MAP-REG-EPM-058)
Pacific Golden Plover	Roosting known to occur within area
Pied Stilt	Roosting known to occur within area
Pin-tailed Snipe	Roosting likely to occur within area
Red-capped Plover	Roosting known to occur within area
Red-necked Avocet	Roosting known to occur within area
Red-necked Stint	Roosting known to occur within area

Receptor	Biologically Important Behaviour
Ruddy Turnstone	Roosting known to occur within area
Sanderling	Roosting known to occur within area
Satin Flycatcher	Breeding known to occur within area
Sharp-tailed Sandpiper	Roosting known to occur within area
Silver Gull	Breeding known to occur within area
Short-tailed Shearwater	Breeding known to occur within area
	Foraging, Breeding BIA (Appendix B12 MAP-REG-EPM-065)
Swinhoe's Snipe	Roosting likely to occur within area
Wedge-tailed Shearwater	Foraging BIA (Appendix B12 MAP-REG-EPM-067)
Whimbrel	Roosting known to occur within area
White-bellied Sea-eagle	Breeding known to occur within area
White-fronted Tern	Foraging, feeding or related behaviour likely to occur within area
Wood Sandpiper	Roosting known to occur within area

4.4.2 Shearwaters

The Short-tailed Shearwater was identified as breeding known to occur (Lady Julia Percy Island) and a foraging and breeding BIA to be present within the area potentially affected by light emissions (Table E9-1). The Short-tailed Shearwater migrates to the Northern hemisphere for the austral winter and generally only present in Australian waters from September to May. They are common in the South-east Marine Region and largely found on numerous islands off Victoria and Tasmania during breeding (Baker and Hamilton 2013, Skira et al. 1996). During breeding they conducts a bimodal feeding strategy, alternating short foraging trips to local waters with long foraging trips (up to 17 days) to the Polar Frontal Zone. Short trips allow greater chick provisioning at the sacrifice of body condition, which is then recovered in richer subantarctic waters. Diet includes fish particularly myctophids, crustaceans and squid (Weimerskirch and Cherel 1998).

The Wedge-tailed Shearwater was identified as having a foraging BIA within the area potentially affected by light emissions (Table E9-1). The foraging BIA is associated with Muttonbird Island, however, a review of the DCCEEW Species Profile and Threats Database (SPRAT), Atlas of Living Australia and South-east Marine Region Profile did not provide any information on the Victorian Muttonbird Island Wedge-tailed Shearwater colony. The DCCEEW SPRAT profile does not show any locations for the Wedge-tailed Shearwater in Victoria, and Beaver (2018) details Montague Island in NSW was the southernmost known colony, however, in 2017 breeding individuals of Wedge-tail Shearwaters were discovered a couple of hundred kilometres further south on Gabo Island Lighthouse Reserve, Victoria near the NSW border.

Movement patterns of the Wedge-tailed Shearwater are poorly known but populations at the northern and southern extremities of the known range are migratory, departing nests in early April to early May and spending the nonbreeding season in the tropics (DCCEEW 2023a). In Australia, Wedge-tailed Shearwaters have been observed feeding along the junction between inshore and offshore water masses. There is no detailed analysis of the diet of Australian adult Wedge-tailed Shearwater's, however tropical residing Wedge-tailed Shearwater birds are known to mostly consume fish, some cephalopods, insects, jellyfish and prawns (DCCEEW 2023a). Food is taken by contact-dipping, dipping, surface-seizing and, rarely, deep-plunging up to 2 m deep (DCCEEW 2023a).

4.4.3 Australasian Gannet

The Australasian Gannet was identified as having foraging and aggregation BIAs within the area potentially affected by light emissions (Table E9-1). The BIA is a 40 km buffer around Portland where the Australasian Gannet breeds between July and March.

The Australasian Gannet generally feeds over the continental shelf or inshore waters. Their diet is comprised mainly of pelagic fish, but also squid and garfish. Prey is caught mainly by plunge-diving, but it is also seen regularly attending trawlers (CoA 2015a).

4.4.4 Orange-bellied Parrot

The Orange-bellied Parrot was identified as migrating likely within the area potentially affected by light emissions (Table E9-51). The Orange-bellied Parrot breeds in Tasmania during summer, migrates north across Bass Strait in autumn and spends winters on the mainland. The migration route includes the west coast of Tasmania and King Island (Appendix B12 MAP-REG-EPM-058).

Birds depart the mainland for Tasmania from September to November (Green 1969). The southward migration is rapid (Stephenson 1991), so there are few migration records. The northward migration across western Bass Strait is more prolonged (Higgins & Davies 1996). The parrot's breeding habitat is restricted to south-west Tasmania, where breeding occurs from November to mid-January mainly within 30 km of the coast. The species forage on the ground or in low vegetation (Loyn et al. 1986). During winter, on mainland Australia, Orange-bellied Parrots are found mostly within 3 km of the coast. In Victoria, they mostly occur in sheltered coastal habitats, such as bays, lagoons and estuaries. The orange bellied parrot may overfly the coastal waters of the area potentially affected by light emissions, however, parrots do not alight or forage out at sea.

4.4.5 Little Penguin

The Little Penguin was identified as breeding known to occur within the area potentially affected by light emissions (Table E9-1). However, no breeding biologically important areas (BIAs) were identified with the area potentially affected by light emissions and the nearest breeding BIA is at King Island and is ~ 30 km from the area potentially affected by light emissions.

During consultation breeding colonies were also identified on Lady Julia Percy Island / Deen Maar, and Middle Island [Event ID 2023]. It is understood that even though these colonies do not represent breeding or foraging BIAs, they are of significant value to local communities. Breeding typically occurs from September to February. [Paragraph added in response to Matter: B02]

The Little Penguin is the smallest penguin species and is endemic to Australia and New Zealand. In Australia, the species occurs from Western Australia (Carnac Island) to New South Wales (Broughton Island) and Tasmania. The distribution is not continuous, with sections of the southern coast of Australia without occurrence of breeding colonies (CoA 2020a).

The Little Penguin breeds during the austral autumn to summer months, however, the breeding season can vary between individuals, locations and years. They are the only truly nocturnal penguin species on land and during this period, adults always arrive after dusk and leave before dawn (CoA 2020a). Following nesting the adults go out to sea to feed prior to the moulting season which occurs between December and February. During this period the feathers are not waterproof, and the birds need to stay on land. At these times they are particularly vulnerable to land predators and interference. Moulting is followed by another feeding period prior to commencing breeding again. [Paragraph added in response to Matter: B02].

This species is a generalist feeder, with large variability in diet amongst colonies and even between years at the same colony. They feed mainly on clupeids, such as anchovy *Engraulis austalis* and sardines *Sardinops sagax*, when feeding chicks, but they may also feed on krill *Nyctiphanes australis* and several species of cephalopods at all stages of breeding (CoA 2020a).

4.4.6 Shorebirds

Twenty-four shorebirds were identified as breeding or roosting within the area potentially affected by light emissions (Table E9-1). These species are commonly found on coastal shores including beaches and rocky shores and either feed at low tide on worms, crustaceans and molluscs or fish species or feed on aquatic biota. Many of the wader species are migratory travelling from the Northern Hemisphere in non-breeding months. Most inhabit intertidal mudflats, rocky islets, sand beaches, mangroves, rocky coastline and coral reefs. Roosting occurs in similar habitats and species

are found feeding on fish, crustaceans, aquatic insects, as well as plants and seeds (Higgins & Davies 1996).

4.5 Turtles

The PMST Report identified three turtle species within the area potentially affected by light emissions, green, leatherback and loggerhead turtle. Annex 3 provides a summary of the PMST Report. No BIAs or habitat critical to the survival of the species were identified.

The PMST Report identifies leatherback and loggerhead turtles breeding likely to occur within the area potentially affected by light emissions. However, this is not supported by other information sources:

- South-east Marine Region Profile (DSEWPaC 2012): The region is an important feeding area for the leatherback turtle which is a pelagic feeder that is regularly found in the high latitudes of all oceans. No major nesting has been recorded in Australia, but the species is regularly seen and known to forage in the waters of the South-east Marine Region. Loggerhead turtle species or species habitat known to occur with South-east Marine Region.
- Recovery Plan for Marine Turtles in Australia (DoEE 2017): Does not identify breeding grounds for leatherback or loggerhead turtles in Victoria or waters off Victoria.
- Species Profile and Threats Database: Details that loggerhead turtles show fidelity to both their feeding and breeding areas but does not identify any breeding area in Victoria or waters off Victoria.
- Species Profile and Threats Database: Details that leatherback turtles are regularly found in waters offshore from Victoria with feeding recorded in the coastal waters of all Australian States, however no breeding or nesting sites are detailed in Victoria.

Green turtles' nest, forage and migrate across tropical northern Australia. Green turtles spend their first 5-10 years drifting on ocean currents. Green turtles are predominantly found in Australian waters off the Northern Territory, Queensland, and Western Australian coastlines, with limited numbers in NSW, Victoria and South Australia (DoEE 2017).

Small numbers of leatherback turtles' nest on the Cobourg Peninsula (NT) and there are unconfirmed accounts of leatherback turtles nesting in Western Australia. Leatherback turtles are more commonly found foraging in Australian waters along the east coast and in Bass Strait. The southern waters of Australia are one of five identified foraging sites (where area restricted behaviour occurs) for Leatherback turtles (DoEE 2017).

There are two genetically distinct stocks of loggerhead turtles nesting in Australia, one in Queensland (known as the south-west Pacific stock) and one in Western Australia. Loggerhead turtles forage in all coastal states and the Northern Territory, but are uncommon in South Australia, Victoria and Tasmania (DoEE 2017)

4.6 People and Communities

4.6.1 Social and Economic Features

During consultation, as presented in Annex 2, objections and claims were raised regarding concerns of impacts on the ecosystem, including commercially fished squid and coastal birds, which may impact tourism and local enjoyment of the area. These species are described in Sections 4.2 and 4.4, respectively.

As detailed in Section 3, the PEIRA (Appendix B4) identified that the environmental impact of light to coastal communities was ranked as having a negligible level of effect and is not assessed further.

4.6.2 Cultural Features

Several invertebrate species including torbos, pipis, abalone, limpets, mussels, elephant snails, crayfish/lobster, crabs and squid are identified as culturally significant to the Gunditjmara People as both a resource and in harvesting as a cultural practice (GMTOAC, 2023). Barnabeel (oyster), murrabal

(mussel), bam bam (crayfish), abalone and pipi are also culturally important resources to the Wadawurrung People (WTOAC, 2020). Invertebrate species are an important traditional, social and economic resource for the Eastern Maar People. Abalone, cockles and crayfish are collected as tucker along the coast (EMAC, 2015) (Appendix F3, Section 3.16.1).

Short-tailed shearwaters (mutton birds) are identified as being culturally significant to the Gunditjmara People and are used in harvesting practice (GMTOAC, 2023). Shearwaters are also identified as culturally significant species to the Eastern Maar people, along with gannets and Little Penguins (Appendix F3, Section 3.16.1).

Two Native Title determinations were identified as being within the area potentially affected by light emissions, Eastern Maar and Gunditjmara (Appendix B12 MAP-REG-EPM-092), including the currently under consultation Nyamat Mirring (GMTOAC, 2023). The respective Native Title determinations encompass cultural obligations and responsibilities which arise from Country and law and ensure that customs and beliefs are upheld (GMTOAC, 2023). They also recognise Traditional Owner rights to land, waters and other resources – rights to access, use and manage these resources for economic as well as cultural benefits (EMAC, 2015). For the Gunditjmara people, Native Title also includes culturally significant sites such as the 'Convincing Ground' (Appendix F3, Section 3.16.1).

Point Nepean, and the Mornington Peninsula, was identified as an area of high cultural importance (Appendix F3, section 3.16). However, the area is not with the area potentially affected by light emissions.

Access to Country is described as highly valued and a key aspect of cultural maintenance (Woods, 2020) and Country represents a deep, intrinsic connection to the land, a source of identity, nurturing individuals and communities through shared knowledge, stories, values, and traditions passed down through generations. For those who live away, the bond remains strong, with frequent returns to reconnect with both the land and the community, reinforcing their role in caring for and preserving Country (EMAC, 2015).

5 Relevant Legislative Requirements

CGG has considered all the relevant legislative requirements, conservation management and recovery plans for all species that may be affected (see Appendix B2). Measures that will be adopted to demonstrate how these requirements will be meet are as follows:

- Marine Assurance System ensure compliance of contracted vessels with the Navigation Act and relevant marine orders related to the management of light.
- It is standard practice for CGG to conduct OVID-Style inspections which will ensure that all vessels have and implement a Vessel Lighting Management Plan.

These measures will ensure that light emissions will be reduced to a level where wildlife will not be disrupted within, nor displaced from, important habitat; and will be able to undertake critical behaviours such as foraging, reproduction and dispersal. Recovery objectives of all relevant conservation advice have been considered in Appendix B2 and impacts to recovery are not predicted to any bird species.

6 Defining Acceptable Levels of Impact

CGG defined acceptable levels of impact and risk as part of its decision-making processes and published them as part of its consultation efforts, inviting relevant persons to comment on their appropriateness. During the preparation of the EP, it became clear that aspect specific statements would be necessary to create a stronger link between the defined acceptable level and the predictions of impacts and risks.

As such, Table E9-2 shows the general acceptable level statements which cover the whole of the activity (which are consistent across all environmental impacts and risks), and the corresponding aspect specific defined acceptable levels established for this assessment. The defined acceptable levels found in this section are subsequently carried through the prediction of impacts in this document, to the demonstration found in Section 10.[1]

Table E9-2 - Defined acceptable levels of impact from artificial light

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.	**Birds** Artificial light will be managed so wildlife is not disrupted within, nor displaced from important habitat, and is able to undertake critical behaviours such as foraging, reproduction and dispersal. **Turtles** Turtles continue to utilise the area without disruption to critical life-cycle behaviours. **Fish, Invertebrates, and Zooplankton** Artificial light exposure to fish, invertebrates, and zooplankton will not exceed those produced by other marine users during nighttime operations in the region and will not cause impacts at a population level.	Artificial light is known to disorient seabirds and other wildlife, altering their flight patterns, increasing collision risk, and disrupting critical behaviours such as nocturnal foraging or resting. Light pollution is identified as a high-risk threat in the Recovery Plan for Marine Turtles in Australia (DoEE 2017). This acceptable level aligns with Commonwealth marine wildlife protection guidelines and supports ecosystem integrity. It is consistent with the aims of the National Light Pollution Guidelines for Wildlife (CoA 2023) for the management of artificial light and aligns with the Recovery Plan for Marine Turtles in Australia (DoEE 2017).
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.		
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.		
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.		

[1] Note: The acceptable levels related to demonstrating ALARP and the adoption of specific measures to ensure the effectiveness of control measures can be found in Appendix F2 and B3 respectively. As they are criteria integral to the acceptance of the Environment Plan, and they a documented elsewhere, these criteria are not discussed further in this assessment.

Category	Defined Acceptable Levels (General)	Defined Acceptable Levels (Aspect Specific)	Rationale
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.		
Economic	Affected persons will not be worse off because of the activity.	Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	For species and sensitivities with social, cultural and/or economic values, if the potential ecological impact or risk is deemed acceptable, it is likely that the corresponding impact on social, cultural and/or economic values will also be considered acceptable, as the physical presence and health of these species are key for maintaining their social, economic and cultural roles. Therefore, predicted levels of impact for social, cultural and economic values for species will be assessed on a receptor level.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.	Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.	
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons. The views of public have been considered in the impact and risk assessment.	People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.	
Company	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	As per the general levels.	CGG is a company familiar with managing the effects of seismic surveys, including light, on the marine environment, and its global operational history supports the reliability of its internal assessment process. The use of CGG's impact and risk matrix, when consistently applied, has not resulted in unacceptable environmental outcomes, which indicates the process produces conservative and realistic assessment outcomes.

7 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

8 Minimisation of Impacts Through Activity Design

As part of planning and design of the activity several activity limitations were considered in accordance with the hierarchy of controls and through the consultation process (see Annex 2). These limitations were evaluated to determine whether the source of impact could be eliminated or substituted through changes in the timing, technology, or design of the activity. As described in Appendix F3, section 3.16.2, due to the interconnection between the tangible and intangible cultural values, all activity limitations are relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas.

8.1 Elimination

Elimination involves removing the source of an impact or risk entirely through changes to the activity design. In some cases, this may reduce one impact while introducing others, requiring careful consideration of environmental trade-offs. One main option was considered:

Elimination of Light Emissions from the Regia MSS

Eliminating light emissions from the Regia MSS would require removing all non-essential lighting, including navigational lights. While this could reduce exposure for light-sensitive fauna, doing so would increase the risk of vessel collisions, compromise crew safety, and breach international maritime safety obligations. These outcomes carry significantly higher environmental and operational risks, such as marine fuel spills or emergency response failures, which outweigh the potential benefit of reduced light emissions.

In this case, the trade-off clearly supports retaining navigational lighting, with impact reduction instead achieved through vessel lighting management practices that minimise unnecessary illumination. As a result of this analysis, there are no viable elimination options available for managing light emissions. The impact pathway remains and requires further consideration through substitution.

8.2 Substitution

Where elimination is not viable, substitution involves altering the timing, location, or sequencing of the activity to reduce the likelihood or consequence of the impact. Two main options were considered:

Seasonal Avoidance of Light-Sensitive Species

One option considered was avoiding survey operations during periods when light sensitive species are most likely to be present in the region. While this could reduce light exposure for certain individuals, implementing this option would have required the survey to be delayed or staged in multiple non-continuous phases. This would have significantly extended the total duration of the activity, increasing vessel presence and compounding impacts such as underwater noise, fuel use, and light emissions. In addition, the broad distribution and mobile nature of light-sensitive species in the area meant that any marginal benefit gained from this timing change would have been uncertain and limited. The trade-off between potential benefit and the increase in duration and cumulative environmental impact was not justified, and this option was rejected.

Daylight-Only Operations

A second substitution option considered was restricting operations to daylight hours only, thereby removing artificial light emissions at night. While this would effectively remove the light-related impact pathway for nocturnally active light sensitive species, it would also double the number of operational days required to complete the survey. This extended duration would result in increased impacts to a range of other environmental values, all of which are affected by the presence and duration of the survey. Again, the environmental trade-off of protecting one group of species at the expense of broader and potentially more sensitive receptors was not considered acceptable, and this option was also rejected.

These considerations demonstrate that reasonable substitution options were explored during the planning and environmental assessment process. However, none were adopted, as each would have introduced greater environmental impacts overall or resulted in unacceptable trade-offs. The residual light emissions associated with the activity are therefore not avoidable through substitution, and their impacts are addressed through assessment and management.

9 Predicted Levels of Impact

Ambient light is defined as the light that is already present within an environment. Any additional emission of light will result in a change in the ambient light. Natural ambient light sources offshore are dominated by solar and lunar luminescence but can also include bioluminescence emission from some marine organisms and incandescence emissions from electromagnetic radiation expressed as lighting.

The primary sources of artificial lighting in the offshore marine environment during the Regia MSS will result from the deck and navigational lights onboard the survey vessels. Deck areas need to be always lit for personnel safety, with deck lighting typically consisting of bright white lights focused on working areas. Spot lighting may be required for in-sea inspection, deployment, and retrieval of survey equipment. Navigational lights are typically elevated on the vessel, outwards facing, and of lesser intensity than deck lighting.

The impacts of the changes in ambient light from the vessel are discussed below.

9.1 Change in Fauna Behaviour

For the light impact assessment, the process outlined in the National Light Pollution Guidelines for Wildlife (CoA 2020) is used. The aim of the guidelines is that artificial light will be managed so wildlife is:

1. Not disrupted within, nor displaced from, important habitat.
2. Able to undertake critical behaviours such as foraging, reproduction and dispersal.

The Wildlife Conservation Plan for Seabirds (CoA 2020a) details that all species of seabird are vulnerable to impacts from lighting. The National Light Pollution Guidelines for Wildlife (CoA 2023) details those seabirds active at night while migrating, foraging or returning to colonies are most at risk. Fledglings are more affected by artificial lighting than adults due to the synchronised mass exodus of fledglings from their nesting sites. They can be affected by lights up to 15 km away.

The National Light Pollution Guidelines for Wildlife (CoA 2023) details that there is evidence that night-time lighting of migratory shorebird foraging areas may benefit the birds by allowing greater visual foraging opportunities. However, where nocturnal roosts are artificially illuminated, shorebirds may be displaced, potentially reducing their local abundance if the energetic cost to travel between suitable nocturnal roosts and foraging sites is too great. Artificial lighting could also act as an ecological trap by drawing migratory shorebirds to foraging areas with increased predation risk.

The National Light Pollution Guidelines for Wildlife (CoA 2023) details that artificial light can interfere with daily and seasonal light cues for zooplankton, invertebrates and fish resulting in changes in behaviour.

The Recovery Plan for Marine Turtles (DoEE 2017) details that artificial light poses a threat to marine turtles because it disrupts critical behaviours as they use light as an orientation cue. Artificial light can inhibit nesting by females (Salmon 2003) and can disrupt hatchling orientation and sea finding behaviour (Philibosian 1976; Witherington and Bjorndal 1991).

9.1.1 Birds

Twelve albatross and two petrel species are identified as having foraging, feeding or related behaviour and/or BIAs within the area potentially affected by light emissions (Table E9-1). These BIAs cover either most or all the South-east Marine Region (CoA 2015a). It is likely these species will forage in the EMBA. In addition, the common diving-petrel breeds on Lady Julia Percy Island which is within the area potentially affected by light emissions.

The National Recovery Plan for Albatrosses and Petrels (CoA 2022) identifies that seabirds are at risk of disorientation at night from artificial light sources and that seabird interactions have been reported across the marine infrastructure sectors including vessels. The paper cited (Black 2005) detailed that the species involved in the incidents were consistently small burrow nesting petrels with events

occurring in conditions of reduced visibility and in the vicinity of major burrowing petrel breeding sites. The use of ice-lights or other deck lighting was a key factor in all three incidents recorded.

No breeding sites for albatrosses or petrels are present within the area potentially affected by light emissions.

Albatrosses forage most actively during daylight and are less active at night because their ability to see and capture prey from the air is reduced (Phalan et al. 2007). Petrels seem more likely to forage during both that day and night (Brooke (2004) cited on Animal Diversity Web (2020), DCCEEW 2023a).

Though the National Recovery Plan for Albatrosses and Petrels (CoA 2022) identifies marine lighting as a threat to albatrosses and petrels it does not provide a risk category as the number of species affected in or outside Australian jurisdiction as nil.

Two shearwater species were identified within the area potentially affected by light emissions. The Wedge-tailed Shearwater was not identified in the PMST Report for the area potentially affected by light emissions (Appendix B5) though a foraging BIA was. The foraging BIA is a buffer around Muttonbird Island, Victoria but there is not data to support that this species breeds on the Victorian Mutton Island but there is data to support that they breed on Muttonbird Island in NSW. This species is listed as marine and migratory and does not have a recovery plan or conservation advice. Light has not been identified as a threat to this species in the SPRAT profile (DCCEEW 2023a) or the Wildlife Conservation Plan for Seabirds (CoA 2020a).

The Short-tailed Shearwater breeds on Lady Julia Percy Island which is within the area potentially affected by light emissions. This species is listed as marine and migratory and does not have a recovery plan or conservation advice. The Wildlife Conservation Plan for Seabirds (CoA 2020a) details that light pollution represents a potential threat to this species in parts of its range. A number much higher than anticipated, of (predominantly juvenile) shearwaters were found dead or injured as a result of being attracted to lights and grounded over a 15-year period of patrols on Phillip Island, Victoria (1999-2013).

During consultation breeding colonies of Little Penguin were also identified on Lady Julia Percy Island / Deen Maar, and Middle Island [Event ID 2023]. Breeding typically occurs from September to February. Studies suggest that penguins were habituated to artificial lights and were unaffected by low level (15 lux) increase in artificial illumination (Rodriguez et al. 2016). [Paragraph added in response to Matter: B02]

The Orange-bellied Parrot migration route overlaps the area potentially affected by light emissions. The Orange-bellied Parrot is classed as critically endangered and there are about 50 remaining in the wild (DELWP 2016a). Survey activities may overlap the period when Orange-bellied Parrot migrates between Tasmania and Victoria between late February to early April (Australian Museum 2020). The Orange-bellied Parrot Recovery Plan identifies illuminated structures and illuminated boats as a potential barrier to migration and movement (DELWP 2016).

Of the other bird species identified from the PMST Report (Appendix B5) that may occur within the area potentially affected by light emissions, the following had conservation advice that identified that disturbance can result from night lighting or that light pollution has indirect impacts on habitat critical to survival; Bar-tailed Godwit (western Alaskan) (DCCEEW 2024b), Common Greenshank (DCCEEW 2024e), Curlew Sandpiper (DCCEEW 2023m), Far Eastern Curlew (DCCEEW 2023n),Greater Sand Plover (DCCEEW 2023o) Latham's Snipe (DCCEEW 2024d), Lesser Sand Plover (TSSC 2016), Ruddy Turnstone (DCCEEW 2024c) and Sharp-tailed Sandpiper (DCCEEW 2024a). These species are migratory wetland species.

The predicted effect level to birds from light emissions is assessed as minor (some affect but not considered significant or long lasting, no overall threat to populations) based on:

- The presence of birds within the area potentially affected by light emissions is expected to be representative of their wide distribution in southern Australian waters during the survey period.
- The increase in light level intersecting the coastline at Warrnambool, Middle Island and Lady Julia Percy Island would be comparable to that associated with light emissions from typical

marine traffic and short-duration, minor changes in ambient light in these locations is unlikely to cause behavioural changes or result in injury/mortality to the Little Penguin. [Paragraph added in response to Matter: B02]

- As the area potentially affected by light emissions overlaps a number of foraging and breeding BIAs, the migratory route for the critically endangered, Orange-bellied Parrot and areas where birds are likely or known to be foraging, breeding or roosting all vessels will have a Vessel Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.
- As all survey vessels will have a Vessel Lighting Management Plan such that effects to birds from light emissions are predicted to be temporary and not result in significant or lasting effects.

The uncertainty level for impact to birds from light emissions is assessed as low based on:

- Peer review literature and studies have been used to inform the impact assessment.
- A conservative 20 km area has been used for assessment of impacts for birds as recommended by the National Light Pollution Guidelines for Wildlife (CoA 2023) which details that the 20 km is a precautionary limit based on observed effects of sky glow on marine turtle hatchlings demonstrated to occur at 15-18 km and fledgling seabirds grounded in response to artificial light 15 km away.
- The 20 km area has been used for assessment of impacts for birds does not consider that survey vessels will have a Vessel Lighting Management Plan to minimise external light emissions, thus the area of potential impact will be significantly less than 20 km.
- The impact assessment has been undertaken as per the National Light Pollution Guidelines for Wildlife (CoA 2023).
- Mitigation and management measures recommended by the National Light Pollution Guidelines for Wildlife (CoA 2023) relevant to vessels have been assessed and all survey vessels will have a Vessel Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.

The predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. For birds the predicted levels of impact are clearly below the pre-defined acceptable levels of impact and the mitigation and management measures in place provide sufficient confidence in the predicted effect levels.

9.1.2 Fish, Invertebrates and Zooplankton

Normal working lights on marine research vessels—and, by implication, lights from other sources including fishing boats, cargo vessels, recreational watercraft, jetties and oil and gas platforms—have been shown to cause zooplankton and their vertebrate predators to descend away from the surface; these effects occurred at depths of up to 200 m, and up to 200 m horizontally from the light source (Berge et al. 2020 in DCCEEW 2022). Since most zooplankton need to ascend to forage on phytoplankton near the water's surface, light pollution may lead to an overall reduction in zooplankton, with cascading effects on their predators, and so on up the food chain (DCCEEW 2022).

Phototactic behaviour (the attraction to artificial light) has been observed both in fish and squids with some species known to have a positive phototaxis by moving towards and aggregating in the illuminated zone of artificial lights (Ibrahim and Hajisamae 1999). Hence fishing with artificial lights (surface light) is one of the most advanced and successful methods to increase the catch rate of squid and pelagic fish (Nguyen and Winger 2019).

Experiments using light traps have found that some fish and zooplankton species are attracted to light sources (Meekan et al., 2001), with traps drawing catches from up to 90 m (Milicich et al., 1992). Lindquist et al (2005) concluded from a study of larval fish populations around an oil and gas platform in the Gulf of Mexico that an enhanced abundance of clupeids (herring and sardines) and engraulids (anchovies), both of which are highly photopositive, was caused by the platforms' light fields. The concentration of organisms attracted to light results in an increase in food source for predatory species and marine predators are known to aggregate at the edges of artificial light halos. Hernandez

& Shaw (2002), in a similar light trap study, noted that juvenile tunas (Scombridae) and jacks (Carangidae), which are highly predatory, may have been preying upon concentrations of zooplankton attracted to the light field of the platforms. This could potentially lead to increased predation rates compared to unlit areas.

The predicted effect level to fish, invertebrates and zooplankton from light emissions is assessed as minor (some affect but not considered significant or long lasting, no overall threat to populations) based on:

- There are no biologically important areas or habitat critical to the survival of fish or invertebrate species within or adjacent to the area potentially affected by light emissions.
- For threatened or listed fish species identified in the PMST Report, none of the recovery plans, conservation advice or conservation listings identify light emissions as a threat.
- No fish spawning or aggregation areas were identified within the area potentially affected by light emissions.
- The presence of fish and invertebrates within the area potentially affected by light emissions is expected to be representative of their wide distribution in southern Australian waters during the survey period.
- The area potentially affected by light emissions relevant to zooplankton, invertebrates, and fish (200 m) overlaps a small portion of the Bonney Coast Upwelling Key Ecological Feature which during November to April results in increased productivity, consisting of krill and other zooplankton, within the area. Thus, all vessels will have a Vessel Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines. This will ensure that krill and other zooplankton associated with the Bonney Coast Upwelling Key Ecological Feature are not affected by light emissions associated with the survey vessels.
- Several threatened species including the blue whale migrate into the Operational Area and area that may be affect by light, to forage. As the Regia MSS will occur during the November to April season, when foraging typically occurs, all vessels will have a Vessel Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines. This will ensure that krill and other zooplankton are not affected by light emissions associated with the survey vessels.
- As all survey vessels will have a Vessel Lighting Management Plan to minimise external light emissions, light emissions will be significantly less and not aimed into the water as per squid fishing vessels, thus attraction of squid to the moving survey vessels is unlikely.
- Effects to fish, invertebrates and zooplankton that may be present in the area potentially affected by light emissions are predicted to be temporary and not result in lasting effects.

The uncertainty level for impact to fish, invertebrates and zooplankton from light emissions is assessed as low based on:

- Peer review literature and studies have been used to inform the impact assessment.
- The impact assessment has been undertaken as per the National Light Pollution Guidelines for Wildlife (CoA 2023).
- Mitigation and management measures recommended by the National Light Pollution Guidelines for Wildlife (CoA 2023) relevant to vessels have been assessed and all survey vessels will have a Vessel Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.

The predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. For fish the predicted levels of impact are clearly below the pre-defined acceptable levels of impact and the mitigation and management measures in place provide sufficient confidence in the predicted effect levels.

9.1.3 Turtles

Light pollution is identified as a high-risk threat in the Recovery Plan for Marine Turtles in Australia (DoEE 2017) with the action of: *Artificial light within or adjacent to habitat critical to the survival of marine turtles will be managed such that marine turtles are not displaced from these habitats.*

No habitat critical to the survival of marine turtles or biologically important areas have been identified within or adjacent to the area potentially affected by light emissions, from the Recovery Plan for Marine Turtles in Australia (DoEE 2017) or PMST Report (Appendix B5).

The PMST Report (Appendix B5) identifies leatherback and loggerhead turtles breeding likely to occur within the area potentially affected by light emissions. However, as detailed in the Section 4.5 this is not supported by other information sources. Thus, it is likely that the three marine turtle species identified in the PMST Report (green, leatherback and loggerhead) may be present within the area potentially affected by light emissions and may undertake critical behaviours such as foraging, but it is unlikely that they are undertaking breeding.

As there are no habitat critical to the survival of marine turtles within or adjacent to the area potentially affected by light emissions, thus displacement of turtles by artificial light from these areas is not predicted.

Marine turtles use light as an orientation cue, and therefore artificial light has the potential to inhibit nesting by adult females and disrupt the orientation and sea-finding behaviour of hatchlings (CoA 2023; DoEE 2017). The general guidance is that turtles require naturally illuminated beaches for successful nesting and sea-finding behaviour (DoEE 2017a; Limpus et al. 2015; Robertson et al. 2016).

Artificial lighting may adversely affect hatchling sea-finding behaviour in two ways: disorientation – where hatchlings crawl on circuitous paths; or misorientation – where they move in the wrong direction, possibly attracted to artificial lights (CoA 2023). Hatchlings have been observed to respond to artificial light up to 18 km away during sea finding (CoA 2023).

No nesting beaches are present within the area potentially affected by light emissions so disruption to turtle nesting, hatchling orientation, sea-finding and dispersal behaviour is not predicted.

The predicted effect level to marine turtles from light emissions is minor (some affect but not considered significant or long lasting, no overall threat to populations) based on:

- There is no habitat critical to the survival of marine turtles within or adjacent to the area potentially affected by light emissions, thus displacement of turtles by artificial light from these areas is not predicted.
- No nesting beaches are present within the area potentially affected by light emissions so disruption to turtle nesting, hatchling orientation, sea-finding and dispersal behaviour is not predicted.
- The Recovery Plan for Marine Turtles in Australia (DoEE 2017) identifies light pollution as a threat to nesting turtles and hatchlings. Light emissions have not been identified as a threat to turtles away from nesting beaches (i.e. there is no inhibition of orientation cues noted in open waters). There are no nesting beaches within the area potentially affected by light emissions.
- The area potentially affected by light emissions does not represent key foraging, breeding, migration, or aggregation areas for marine turtles; and marine turtle presence is expected to be representative of their wide distribution in southern Australian waters during the survey period.
- Changes to biologically important behaviours (such as nesting, hatchling orientation, sea-finding and dispersal behaviour) for marine turtles is not predicted.
- Effects to turtles that may be present in the area potentially affected by light emissions are predicted to be minor or insignificant and are unlikely to result in lasting effects.

The uncertainty level for impact to turtles from light emissions is assessed as low based on:

- There are long-term tagging studies of sea turtles in Australia, and there are no nesting habitats are BIAs identified within or adjacent to the area that may be affected by may be affected by light emissions.
- The Recovery Plan for Marine Turtles in Australia (DoEE 2017) identifies light pollution as a threat to nesting turtles and hatchlings. Light emissions have not been identified as a threat to turtles away from nesting beaches (i.e. there is no inhibition of orientation cues noted in open waters). There are no nesting beaches within the area potentially affected by light emissions.
- Peer review literature and studies have been used to inform the impact assessment.
- The impact assessment has been undertaken as per the National Light Pollution Guidelines for Wildlife (CoA 2023).
- Mitigation and management measures recommended by the National Light Pollution Guidelines for Wildlife (CoA 2023) relevant to vessels have been assessed and all contracted vessels will have a Vessel Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.

The predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. For turtles the predicted levels of impact are clearly below the pre-defined acceptable levels of impact and the mitigation and management measures in place provide sufficient confidence in the predicted effect levels.

9.2 People and Communities

9.2.1 Cultural Features

The presence of lighting associated with the activity has potential to impact cultural features and heritage values through the following ways:

- Cultural obligations to care for Country: Environmental impacts may be assumed to impact rights and obligations to care for Sea Country.
- Knowledge of Country/customary law and transfer of knowledge: Indirect impacts to communities practicing these skills will inherently occur when threats to Sea Country values are felt.
- Connection to Country: Where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge this may damage connection to Country (McDonald and Phillips, 2021).
- Access to Country: Impacts to access to Country can occur in areas that were traditionally accessed by First Nations peoples.

Deen Maar and two Native Title determinations were identified as being within the area potentially affected by light emissions, Eastern Maar and Gunditjmara (Appendix B12 MAP-REG-EPM-092), including the currently under consultation Nyamat Mirring (GMTOAC, 2023).

Consultation and literature review indicated the importance of connection to coastal and marine areas for indigenous culture.

The predicted effect level to cultural features from light emissions is minor (some affect but not considered significant or long lasting) based on:

- Commercial shipping companies and commercial fishing vessels transit adjacent to and within the Operational Area and the Southeast Marine Region is one of the busiest shipping regions in Australia and Bass Strait is one of Australia's busiest shipping routes. Vessel lighting may be seen at night from Deen Maar and Native Title areas, however, they would not be distinguishable from any other vessel that may be in the area. Survey vessels will become less distinguishable as they move further away from the coast as the survey is undertaken. Over the 90 day survey the vessels will spend the majority of the time undertaking acquisition within the Active Source Area which is at its closest point >20.7 km from the mainland and >17 km from Deen Maar (adhering to activity limitation: no discharge of sound source within 17km of Deen Maar), at these distances it is unlikely that the vessels would be noticeable at night.

- Light emissions will not exclude Traditional Owners from Country including Sea Country.
- Light emissions will not obstruct access to resources or locations that have been or may continue to be used for traditional practices such as harvesting, hunting, gathering, or camping.
- There is no threat or impediment from the activity on the transmission of knowledge of Country/customary law and transfer of knowledge by light emissions. This is particularly true when there are no predicted effects to light sensitive species of cultural significance at populations levels, to ecosystem integrity, or biodiversity preservation.

The uncertainty level for impact to cultural features from light emissions is assessed as low based on:

- No cause-effect pathway has been identified for light emissions affecting access to Country, including Sea Country, knowledge of Country/customary law and transfer of knowledge or connection to Country.
- Peer review literature and studies have been used to inform the impact assessment, and the impact assessment has been undertaken as per the National Light Pollution Guidelines for Wildlife (CoA 2023) for light sensitive species of cultural significance.
- Mitigation and management measures recommended by the National Light Pollution Guidelines for Wildlife (CoA 2023) relevant to vessels have been assessed and all contracted vessels will have a Vessel Lighting Management Plan to minimise external light emissions.

The predicted level of impact based on the effect (minor) and uncertainty (low) is assessed as low. For cultural features the predicted levels of impact are clearly below the pre-defined acceptable levels of impact and the mitigation and management measures in place provide sufficient confidence in the predicted effect levels.

9.3 Measures Adopted to Manage Environmental Impacts

Measures adopted to ensure environmental impacts will be of an acceptable level and ALARP.

Measure	Measure Type	Details and Justification
Vessel Lighting Management Plan	Resource	Contracted vessels are required to have a Vessel Lighting Management Plan to minimise light emissions while meeting vessel navigational light requirements. The Lighting Management Plan will also cover the process for handling of birds, releasing of birds and reporting to DCCEEW in the case of protected species.
Light Minimisation	Responsibility	Vessel crew to be aware of their requirement to minimise non-essential light emissions.
Minimise non-essential lighting	Practice	For all survey vessels, the following will be implemented where it does not contravene vessel lighting requirement for safe navigation: – Non-essential lights switched off when not in use. – Window blinds closed at night. – Shield lights and contain light spill on the deck unless required for safe operations. – Use of suitable light types recommended in the National Light Pollution Guidelines.
CGG Marine Assurance System	System	The CGG Marine Assurance System ensure compliance of contract vessels with legislative requirements including the Navigation Act, MARPOL, COLREGS and Marine Orders.
Survey Environment Advisor	Person	This person is the primary environmental authority on the vessel and has a role related to environmental management and performance on the vessel, along with specific responsibilities for the management of fauna interactions.
Sail Line Plan	Resource	Ensures that the survey vessel will remain within the scope and boundaries of the EP and reflects the activity limitations.
OVID-Style Inspection	Practice	The pre-survey inspections of all contracted vessels will confirm that the light management plan is in place and that the crews are aware of their responsibilities to minimise non-essential lighting.
Activity Specific Induction	Practice	All vessel crew will undertake an activity specific induction, which will include information about the requirements for management of light.

10 Demonstration Impacts will be of an Acceptable Level

10.1 Principles of ESD

Temporary, Reversible, Small Scale and Natural Variation

As discussed in the impact assessment, the activity is expected to result in short-term and reversible impacts from artificial light, primarily associated with vessel navigation and safety lighting during night operations. These impacts are limited to the duration of the activity, which is less than 90 days, and are geographically confined to the Operational Area plus a precautionary 20 km buffer for birds and turtles, and 200 m for fish, zooplankton, and invertebrates. The predicted changes in fauna behaviour are minor in effect, with no long-term or population-level consequences anticipated. Peer-reviewed literature, field studies, and adherence to national guidelines support the conclusion that the activity will not cause lasting changes to the environment.

Based on sufficient information

The assessment was informed by a range of peer-reviewed scientific literature, national guidelines (e.g. the National Light Pollution Guidelines for Wildlife), field data from previous studies in the region, and expert input. The quality and sufficiency of this information enabled robust conclusions about the potential impacts. Where uncertainty existed, precautionary buffer distances were applied (e.g. 20 km for birds and turtles), and conservative assumptions were used in the absence of local data. No serious or irreversible impacts were predicted, and the precautionary principle was not triggered.

Activity not inconsistent with EPBC Act

The environmental management measures adopted for the activity are not inconsistent with the EPBC Act, including relevant Management and Recovery Plans. Species considered include listed marine turtles, seabirds, and migratory shorebirds. The Recovery Plan for Marine Turtles (DoEE 2017), Wildlife Conservation Plan for Seabirds (CoA 2020a), Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015) and species recovery plans were reviewed, with vessel lighting measures aligned to their recommendations. All contracted vessels will implement Vessel Lighting Management Plans to avoid disruption to critical behaviours such as foraging, reproduction and dispersal. No habitat critical to the survival of listed species is present within the area potentially affected by light emissions.

10.2 Biological and Ecological Categories

Biological features assessed are fish, zooplankton, invertebrates, birds, and turtles that are identified as light sensitive in the National Light Pollution Guidelines for Wildlife (CoA 2023). Impacts are predicted to be minor and reversible, confined to localised areas near the vessels (within 200 m for aquatic species, and up to 20 km for avian and turtle species). There are no population-level consequences predicted, and no critical habitats or aggregation areas overlap the affected area. Phototactic behaviour in squid and fish may cause localised effects, but these are common in the region due to existing fishing activity. The implementation of light management measures ensures impacts remain low in intensity and scale.

The activity is predicted to cause only minor and temporary changes in the behaviour of individual species without affecting ecosystem structure or function. The Bonney Coast Upwelling, a Key Ecological Feature, slightly overlaps with the area affected by light emissions, but no disruption to ecological processes is predicted. Vessel lighting is not expected to significantly alter food webs, and all emissions will be minimised through a structured lighting management approach. No impacts are predicted at an ecosystem level.

10.3 Economic, Cultural and Social Categories

The cultural heritage review, desktop research and consultation with relevant persons confirmed that light emissions from the activity are not expected to result in material disadvantage. The activity occurs more than 17 km offshore and is of short duration. No disruption to fishing grounds,

recreational use, or tourism was identified because of artificial light. Measures such as minimising non-essential lighting help avoid interference with amenity values or access to key resources.

Cultural values assessed included the significance of invertebrates, seabirds, and connection to Country for Traditional Owners. No direct disturbance to cultural sites or practices will occur. The presence of lighting from vessels may be visible from Native Title areas, as per any other vessels in the area, but will not disrupt cultural access or obligations. The short duration and offshore distance of the activity, coupled with mitigation measures, ensure that cultural connections and practices can continue without interruption.

Consultation identified concerns related to impacts on birds, squid, and ecosystem integrity. These were considered in the assessment, and several design and management measures were adopted in response. These include requiring all vessels to implement Vessel Lighting Management Plans and undertaking pre-survey inspections to ensure compliance. As these values are closely tied to the physical presence and health of the species, the corresponding social, cultural and economic impacts are likewise considered acceptable. The measures directly address objections by reducing impacts to culturally significant species, commercial species, and biodiversity values.

10.4 Consistency with Company Processes

The impact assessment followed the methodology in Appendix B3 and applied the impact assessment process as per the National Light Pollution Guidelines for Wildlife (CoA 2023) and was informed through consultation input and relevant persons feedback. The predicted level of effect to light sensitive fauna and people and communities was assessed as minor, with a low level of uncertainty, resulting in a low predicted impact level. The predicted spatial extent of light emissions was compared against known distributions, behavioural sensitivities, and key ecological features. This confirmed that potential impacts are localised and temporary, confined to the vicinity of the light source. All mitigation measures consistent with regulatory guidance and good industry practice were incorporated. As no threshold exceedances or high-consequence outcomes were identified, the final consequence ratings remain within company-defined limits.

The impact assessment has demonstrated that the effect of light emissions to light sensitive fauna (birds, fish, invertebrates, zooplankton, and turtles) and people and communities, has a:

- Predicted level of effect of minor (2).
- An uncertainty level of low (2).
- Predicted level of impact of low (4).

11 Environmental Performance Outcomes

Environmental Performance Outcomes (EPOs) are measurable and activity-specific outcomes that describe the environmental performance the titleholder must achieve to ensure impacts and risks are managed to acceptable levels. EPOs are critical to the structure of an Environment Plan because they form the clear link between the defined acceptable level of impact and the predicted level of environmental consequence. Each EPO must be measurable, achievable, and within the control of the titleholder to implement, providing a transparent and enforceable statement against which performance can be assessed.

Table E9-3 - Environmental Performance Outcomes and Justifications

Defined Acceptable Level (From Table E9-2)	Environmental Performance Outcome	Rationale
Artificial light will be managed so wildlife is not disrupted within, nor displaced from, important habitat, and is able to undertake critical behaviours such as foraging, reproduction and dispersal.	**Biologically important behaviours within a BIA or outside a BIA can continue while the activity is being undertaken.**	These EPOs are supported through adherence to the Vessel Light Management Plan, which includes documented procedures for minimising light intensity and optimising directional control. Evidence of performance may include lighting audits, crew training records, absence of wildlife disturbance incidents and verification that lighting is consistent with safe navigational standards while minimising ecological risk.
Artificial light exposure to fish, invertebrates, and zooplankton will not exceed those produced by other marine users during nighttime operations in the region and will not cause impacts at a population level.	**Light emissions will be reduced to minimum levels for safe operations and navigation in accordance with the Vessel Management Plan**	
Turtles continue to utilise the area without disruption to critical life-cycle behaviours.	**Light emissions are managed to avoid displacing turtles or disrupting nesting, foraging, or migratory behaviours within or near biologically important areas.**	
Industries, livelihoods, and ecosystem services remain viable, with no sustained financial or operational consequences resulting from changes in species behaviour, abundance, or access to resources.	**Social, cultural, and economic features are protected, sustaining their value for people and communities.**	Predicted impacts to economic receptors (e.g. squid) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation, thus commercial squid fishers will not be worse off because of the activity.
Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability.		Predicted impacts to biological receptors (fish, invertebrates, birds, turtles) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation. Vessel lighting associated with petroleum activity may be visible from Native Title areas, but due to distance and duration, it is not predicted to impact associated cultural values.

Defined Acceptable Level (From Table E9-2)	Environmental Performance Outcome	Rationale
People and communities can continue engaging with the natural environment, recreational activities, and heritage values without experiencing long-term or irreversible disruption.		Predicted impacts to biological receptors (fish, invertebrates, birds, turtles) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation.
Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.	**The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.**	This EPO enables ongoing assessment of effectiveness through internal reviews and operational audits. It provides a clear link between the risk assessment process and implementation strategy, supporting regulatory compliance and continuous improvement without requiring environmental outcome monitoring.

12 Recommendations

The predicted level of impact is low for all light sensitive fauna and people and communities, and below pre-defined acceptable levels. Good industry practice (including legislation and standards) has been applied; therefore, impacts are of an acceptable level to all species. The orange-bellied parrots migratory path has a small overlap with the Operational Area and due to the conservation status of this species it should be assessed for cumulative impact pathways with light from other reasonably foreseeable projects or activities. This can be found in Appendix F1.

13 Document Control

Date	Revision	Update
6 June 2023	A	Draft prepared for initial comment
20 August 2023	B	Update based on comments and relevant person feedback

Annex 1

Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. Table E9-4 shows how this feedback has been incorporated into the environmental assessments.

Table E9-4 - Public comment input.

Matter	Matter ID	Changes made arising from public comment
Matter: Acknowledgement of breeding colonies	B02	CGG has included additional detail in EP Appendix E9 to assess impacts to breeding colonies at Middle Island and Deen Maar and other coastal locations in response to these claims.
Matter: Geographic range and all species need to be defined and considered	I16	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has considered these claims and has rerun the PMST reports to ensure that all information on the likely/known presence of relevant species within the area, as well as information on their protection status, Biologically Important Areas (BIAs) and behaviours is up to date. The updated PMST reports are provided in full in EP Appendix B5.

Annex 2

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table E9-5. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table E9-5 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4357	The stakeholder raised an objection to seismic surveys as they negatively affect the fishing industry, local economy and environment.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	424
4050	Concern about the destruction of smaller sealife and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and	1669

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		relevant mitigation measures are outlined in the EP.	
4051	Concern about the detrimental impacts on marine animals.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1452
4063	Concern for various birds and little penguins and the effects of sound and light.	Impacts from underwater sound and artificial light on birds, including little penguins, are assessed in the Environmental Plan (EP) and can be found in E5 and E9. Further assessment of little penguins was also undertaken by CGG to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level. Measures to minimise adverse impacts on birds in the region are also outlined in the EP.	1783
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4068	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4073	Concerns about impacts both reputational and physical to the region if the activity is allowed.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population	1244

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	722
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4081	Concerns about the impact on whale habitat, endangered marine life, and commercial fisheries	Titleholder acknowledged this concern and noted that potential impacts to whales and relevant endangered marine species is assessed in the EP Chapters on underwater sound and light (E2-E7, and E9). Any interactions with seismic are mitigated and managed through spatial boundaries and a comprehensive fauna management plan. Advised that control measures to reduce impacts to commercial fishers as a result of displacement are outlined in the EP and include Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the	4551

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		commercial fishers that fish within the Operational Area.	
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4093	Doubted the effectiveness of mitigation measures and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artificial light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to	2766

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures are outlined in the EP.	
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4123	Insufficient information about potential damage from seismic testing.	The titleholder is confident that sufficient relevant and available information has been used to inform this this EP and to complete a comprehensive assessment of relevant aspects of the activity. Information used based around sound, peer reviewed scientific literature.	4190
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808
4131	Light pollution concerns related to the activity.	Title holder has undertaken a thorough analysis and assessment of all relevant literature related to light impacts on the environment. Impacts are assessed as low and there are multiple measures in place to minimise impacts.	1247
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2274
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in	1389

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		place to reduce any impacts to as low as practicable.	
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	3343
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2963
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation	1653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels.	1662

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4198	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1672
4199	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2586
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk	2886

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments is covered below in response to concern 6.	
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049
4217	Strong objection to the proposal for 3D seismic blast in the Otway Basin due to harm to oceans and unacceptable environmental impact or risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1656
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	425

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4253	The possible effects to marine life and ecosystems are my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would	Acceptable levels of impact are established based on relevant up-to-	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	impact every marine creature and sea bird.	date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publicly responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of	1325

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4285	The stakeholder noted the following concerns as a resident of Port Fairy: Noise (land and sea), impact on marine life, potential impacts on the environment and the future potential if gas is found.	We are also concerned about the welfare of marine fauna. We have undertaken an impact assessment process that includes whale, seals, pelagic and shorebirds. As part of this assessment, we must show that impacts to these species will be of an acceptable level. We have determined that it is acceptable to have temporary behavioural changes, such as moving away from the survey vessel, and no injury or long-term impacts. Our Preliminary Environmental Impact and Risk Assessment document has been published on the project website and is available here. We are also publishing environmental impact, risk and mitigation documents as they are completed, in the document library. We are publishing the entire documents in order to remain transparent, but I have also attached a summary document.	1747
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	3152
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4315	The statement suggests that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4319	There are concerns regarding the potential impacts of seismic surveys on penguins, diving birds, and other marine fauna. Stakeholders are particularly worried about how the noise and disturbance from these surveys could affect the breeding and foraging behaviours of these species.	This effects of sound on birds were initially assessed in E4 and further assessments for penguins can be found in F3. Birds can also be affected by artificial light, which has been assessed in E9. The conclusion is that the measures adopted to protect foraging birds will mean that impacts are of an acceptable level.	2006
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4004	Seismic blasting in our ocean so close to our beautiful home is deeply concerning given the toll will inevitably take on sea life and further unknown impacts.	The titleholder acknowledged the feedback, noting that impacts and risks to sea life are assessed in the Environmental Plan (EP) and can be found in Appendices E1 to E9 and F3. Measures to minimise adverse impacts to sea life are outlined in the EP in G1.	2757
4057	Concern about the long-lasting impacts of the proposed activity on marine life and coastlines, highlighting ecological and cultural repercussions.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation nor interfere with cultural practices or values. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1022
4061	Concern about the welfare of whales, seals, and birds due to the activity.	The titleholder acknowledged concerns outlined in email regarding welfare of whales, seals and birds due to the activity.	4061
4417	The relevant person was concerned that about the proposed seismic activity effecting the behaviours of certain species.	Event ID 6880 - The Regia team responded in-meeting that the first half of the EP is associated with assessment work undertaken prior to commencing the activity. First and foremost, because there are so many different species, they explained that they had grouped species together from a physiological perspective. Secondly, the Regia team explained that their focus is on the mega-fauna and species which have protection under the EPBC act.	6880

1 Introduction

The National Offshore Petroleum Safety and Environmental Management Authority (**NOPSEMA**) defines cumulative environmental impacts in the context of offshore petroleum activities, as successive, additive, or synergistic impacts of collectively significant activities or projects with material impacts on the environment that have the potential to accumulate over temporal and spatial scales (NOPSEMA Environment Plan Decision Making Guideline, N-04750-GL1721).

The focus of this Cumulative Impact Assessment (**CIA**) is to further build on these assessments by considering the impacts of the proposed activity on key environmental values and sensitivities in conjunction with the impacts from other reasonably foreseeable future projects.

The types of activities and projects typically considered in CIA are large in scale and are of relevance in terms of potentially contributing to or compounding material impacts in the operational area of the Regia MSS.

2 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 1.

3 Methodology

Cumulative impacts were inherently considered in Stage 2 of the environmental assessments by virtue of considering the existing environment as a dynamic place inclusive of other natural and anthropogenic pressures. Specifically, the effects of past projects and activities, and currently operating projects, are captured when describing the existing condition of environmental values and sensitivities, inclusive of any pressure or threats affecting that value or sensitivity.

This baseline condition and understanding of the capacity of the receiving environment and receptors to accommodate changes, considering existing pressures and threats, informs the environmental impact assessments conducted in the Preliminary Environmental Impact and Risk Assessment (**PEIRA**) (Appendix B4) and more extensively in Appendices E1 – E9.

However, during consultation in preparation of the Environment Plan (EP), explicit consideration of future activities in the context of cumulative impacts was requested.

There are many ways of considering cumulative impacts and the following guidelines have been used as the basis of this assessment:

- United Kingdom National Infrastructure Planning Advice Note Seventeen: Cumulative effect assessment relevant to nationally significant infrastructure programs (UK Gov 2019)
- New South Wales Cumulative Impact Assessment (CIA) Guidelines for State Significant Projects (NSW 2022).

Both guidelines are intended to apply to large-scale national and state significant projects, respectively which have a greater potential for long term cumulative impacts than the Regia MSS. The guidelines are rigorous and have merit for application to the shorter-term, smaller scale, Regia MSS.

3.1 Scoping the Assessment

Scoping considerations identified for CIAs include:

- Successive, additive, or synergistic material impacts.
- Effects on key environmental matters within the relevant spatial extent.
- The pathways for impacts to accumulate over the relevant temporal extent.

Material impacts are impacts of the project and other reasonably foreseeable future projects and activities that may not align with the defined acceptable levels, for example, threats of wide-scale, serious or irreversible damage due to cumulative impacts.

Successive impacts are those that occur one after the other.

Additive impacts are those where the combined impact is the sum of the separate impacts.

Synergistic impacts are those where the combined impact is greater than the sum of the separate impacts.

Key environmental matters are features of the environment (ecological, socio-economic, and cultural values and sensitivities) that are valued because of their rarity or importance, including the critical role they play in supporting systems which are essential for the environment, people and / or the economy (NSW 2022), for example, commercial fisheries and threatened species undertaking biologically important behaviours.

The relevant **spatial extent** depends on the key matter. For example, for ecological impacts the spatial extent may be based on the range and distribution of a listed threatened species when undertaking biologically important behaviour. The NSW guideline recommends that while the study area chosen for each matter must be broad enough to capture all relevant cumulative impacts, it should not be unnecessarily large or include areas where the cumulative impacts are likely to be negligible relative to the baseline condition of the relevant matter.

Temporal extent is dependent on the key matter and the scale and nature of potential impacts on the matter (NSW 2022). For example, for commercial fishers the temporal extent may be based on a part of a season or several seasons depending on how long the impact may occur. For this CIA the

temporal extent selected has been aligned to reasonably foreseeable timeframes associated with the project and other reasonably foreseeable projects and activities within the Otway Basin.

3.2 Identifying Reasonably Foreseeable Future Projects and Activities

Table F1-1 shows the projects and activities that are reasonably foreseeable within the spatial and temporal extent of the assessment. The activities for which CGG were able to obtain shapefiles are shown in Appendix B12 MAP-REG-EPM-169_A, along with the Regia Operational Area and Acquisition Area.

Table F1-1 - Reasonably foreseeable ongoing and future projects and activities in the offshore Otway region.

Titleholder	Activity Type	Sound Sources and Exposures for Each Activity	Status	Window (Activity)
Beach Energy	Production - Thylacine	Geophysical surveys (10 days once a year though more likely to be between two and five years) Platform resupply via helicopter (2 days every 3 months ~6 hrs per day) Standby vessel at platform when working over water (Twice per year ~ 6 hrs per day) Geographe and Thylacine subsea infrastructure and wells (Choke valve operation, ~1- 2 hours if required) Maintenance and Repair (Subsea tree choke replacement, ~1- 2 hours if required) IMR campaigns	Ongoing	Ongoing
Beach Energy	Production - Geographe		Ongoing	Ongoing
(Previously Cooper Energy) Amplitude Energy	Production – CHN	Geophysical surveys (MBES, Sidescan sonar, or Sub bottom profiler, 4 – 6 hrs per structure and 1 – 2 days for pipelines, totalling circa 2 – 4 weeks at sea for an entire inspection program) Platform resupply Helicopter Operations (1-2 times per week during IMP activities) Inspections (4 – 6 hrs per structure and 1 – 2 days for pipelines, totalling circa 2 – 4 weeks at sea for an	Ongoing	Ongoing

Titleholder	Activity Type	Sound Sources and Exposures for Each Activity	Status	Window (Activity)
		entire inspection program)		
ConocoPhillips Australia	Otway Drilling	Geophysical surveys (maximum of 9 surveys with each survey taking one week) and Vertical Seismic Profiling (VSP) (three 250 cubic inch air gun configuration, 12 hours per well for a maximum of 2 wells), with up to 130 shots) Anchor prelay and collection 24-46 days Mooring the MODU (connection and disconnection) (15 days) Drilling with vessel on standby (180-540 days) Drilling with vessel on standby and resupply (30 days)	Ongoing	2024-2028 (Typically, 30-40 days per well, max 6 wells)
(Previously Cooper Energy) Amplitude Energy	Production Drilling and tie-in	Geophysical survey: ~ 7 days (No VSP) Well construction activities- logging Pre-lay moorings: ~ 7 – 14 days Well drilling and suspension or P&A: ~ 60 days Well Integrity Monitoring: ~ 2 days per inspection	Proposed	2024-2026 1 January 2025 and be completed no later than 1 January 2030. Each drilling campaign is expected to take up to 60 days excluding environmental and operational delays.
Woodside Energy	Minerva Decommissioning	Generation of underwater noise from project vessel, ROV, subsea cutting and infrastructure deburial activities (45 to 60 days), noise from helicopter operations, and underwater noise from acoustic survey equipment within operational area.	Proposed	2024-2025 three to five months,)
Beach Energy	Drilling and tie-in	Drilling: 300 days for the full drilling and P&A activities Resupply: 3 hours per day	Accepted	2024-2027 Drilling: 30 - 40 days per well. Plug and abandonment: 15 – 20 days per well.

Titleholder	Activity Type	Sound Sources and Exposures for Each Activity	Status	Window (Activity)
		Helicopter Operations: 11 seconds on take-off and landing at the drill rig up to 7 times per week. Wellhead Cutting: ~1 - 2 hours though may take up to 6 hours for more complex wells		
CGG	Seismic Survey (Regia MSS)	2630 cubic inches over 60 days	Proposed	2023-2028 (60 days)
Beach Energy	Seismic Survey (Calico MSS)	Between 250 and 750 cubic inches	Proposed	2025 (Between February and May)

This defines the boundaries of the assessment by including projects and activities that have a realistic likelihood of occurring and could contribute to cumulative impacts.

To identify these projects and activities a search was conducted of the NOPSEMA and DEECA (Vic) Environment Plan website to identify any relevant projects and activities. In addition, titleholders within the Otway Basin have been meeting regularly to discuss environmental management in the region, including processes for improved CIA. This has provided a more accurate representation of projects and activities and the potential for cumulative impacts, ensuring these are appropriately assessed and managed.

The NOPSEMA, DECCA (Vic), and DCCEW Environmental Plan websites were checked again on the 10/03/2025 and there are no new proposed activities scheduled in the Otway region. It should be noted the Beach Energy Seismic Survey was due to commence in February 2025, CGG understand this did not happen and its current start date is unknown. Projects and activities that are not reasonably foreseeable or speculative have been excluded from the assessment scope to maintain practicality and relevance in decision-making processes. These included an offshore wind declared area that is unlikely to be developed within 24 months of the end of operation of the Regia MSS EP.

Further, there was another seismic survey proposed in the region that was withdrawn from NOPSEMA's assessment process in September 2024. CGG understands that this activity will not progress. This activity has been removed from this assessment.

Information on projects and activities is typically accessible once consultation commences and relevant technical supporting information is submitted for public comment or assessment. Information relevant to this CIA has been discussed at the ongoing Otway Basin Petroleum Titleholder meetings. Where project/activity-specific data is not yet available, data from similar projects has been used as a proxy prior to technical information being made available. Given the similarity of impacts, there is a high level of certainty in the prediction of cumulative impacts in most cases.

Assumptions around specific timings for projects or activities have been made as there is some level of flexibility in schedules and timing of approvals. Consequently, a conservative approach has been adopted whereby credible worst-case scenarios (e.g. concurrent activities with overlapping environments that may be affected (EMBAs)) are assessed.

3.2.1 Temporal Overlap

For proposed activities that are reasonably foreseeable, and following consultation between the titleholders in this region, there is:

- A high likelihood of consecutive drilling (exploration, appraisal, or plug and abandonment (P&A)) activities given the titleholders are all planning on using the same rig.

- A very low likelihood that there will be concurrent drilling activities.
- Some likelihood that there will be concurrent seismic survey and drilling activities.
- A very low likelihood that there will be concurrent seismic operations.
- A slightly higher likelihood that seismic surveys may be consecutive.

3.2.2 Spatial Overlap

Annex 2 shows a matrix of the ongoing and reasonably foreseeable activities in the region. This analysis was completed considering the spatial extent of impacts from the projects and activities rather than just an overlap of activity locations. This analysis revealed that there is:

- An extremely remote likelihood of direct spatial overlap of seismic survey areas.
- An extremely remote likelihood of direct spatial overlap of drilling/P&A areas.
- A possible overlap of a drilling activity over petroleum title VIC/P79.
- A possible likelihood of overlap of light EMBAs associated with drilling/P&A at a single location.
- An extremely remote likelihood of overlap of sound EMBAs associated with concurrent drilling/P&A at a single location.

3.2.3 Identified Aspects and Extents

During the environmental assessment process, components of the environment and aspects of the ongoing and reasonably foreseeable projects and activities were identified where there was the potential for successive, additive, or synergistic impacts to reasonably accumulate over temporal and spatial scales, when considered in the context of ongoing and reasonably foreseeable future projects or activities. There were some terminology differences between titleholders. These have been assessed and are not material to this CIA.

The CIA Scoping Tool (Annex 3) details the assessment undertaken of the components of the environment and aspects of the reasonably foreseeable projects and activities to identify where a potential cumulative cause-effect pathways may occur and, if it may occur, was likely to have a material impact. Where a potential cumulative cause-effect pathway and material impact was identified further assessment was undertaken.

The components of the environment and aspects identified during the CIA scoping process requiring further assessment include:

- Light – impacts on light-sensitive bird species.
- Underwater sound – impacts on noise-sensitive species.
- Birds – nocturnal behaviours of species such as the common diving petrel which has a breeding biologically important area (BIA)on Lady Julia Percy Island, and the orange-bellied parrot which may overfly the light EMBAs on migration.
- Marine Mammals – biologically important behaviours of species such as the blue whale and southern right whale within relevant BIAs that overlap underwater sound EMBAs.
- Commercial Fisheries – displacement from within relevant fishery management zones.

It was also identified that the conservation values and sensitivities of the Zeehan Marine Park and the First Nations cultural heritage values associated with the above environmental components could be affected by cumulative impacts.

4 Assessment Process for Cumulative Impacts

For those components of the environment and aspects where a potential cumulative cause-effect pathway and material impact was identified, a CIA process was applied in general alignment with the activity-specific methodologies of titleholders, in accordance with NOPSEMA guidelines and the cumulative impact assessment guidelines previously referenced.

The CIA process applied to each aspect and component of the environment is provided below which includes a discussion that identifies other reasonably foreseeable ongoing future projects where the environmental aspect has both a temporal and spatial overlap. Then each identified area of potential cumulative impact is assessed by looking at the:

- Conservation (or other) values or sensitivity.
- Management Plans or legislation that applies to the value or sensitivity.
- Threatening processes to the value or sensitivity.
- Relevant spatial and temporal extent of cumulative impact.
- Recovery (or other) actions that apply.
- Baseline environment condition.
- Defined acceptable level of impact.
- Predictive certainty of the assessment.

Once the assessment of cumulative impacts had been completed and the titleholders with ongoing and future activities in the Otway Basin have discussed the outcome and agreed to adopt control measures (individually and collectively) for effects to commercial fishers, light sensitive birds, low frequency hearing whales, and cultural heritage values of First Nations peoples.

5 Cumulative Impact Assessments

5.1 Interference with Commercial Fishers

Cumulative impacts could occur from the occurrence of one seismic survey occurring concurrently with a drilling activity, and/or consecutive drilling activities with operational exclusion boundaries overlapping fishery management zones.

Commercial fishers with fishing activity in the Regia MSS operational area may be displaced within their Fishery Management Zones in the offshore Otway Basin. This may lead to multiple applications for compensation to be lodged with a range of titleholders and a reduction in the area available to be fished.

The Regia MSS operational area overlaps with:

- Commonwealth fisheries:
    - Bass Strait Central Zone Scallop Fishery (0.29% overlap with this fishery)
    - Eastern Tuna and Billfish Fishery (0.22% overlap with the fishery)
    - Southern and Eastern Scalefish and Shark Fishery SSKK (1.28% overlap with the fishery)
    - Southern and Eastern Scalefish and Shark Fishery SSKN (1.12% overlap with the fishery)
    - Southern and Eastern Scalefish and Shark Fishery SCTR (1.15% overlap with the fishery)
    - Southern and Eastern Scalefish and Shark Fishery SCDS (2.32% overlap with the fishery)
    - Southern and Eastern Scalefish and Shark Fishery SSCK (0.95% overlap with the fishery)
    - Southern Squid Jig Fishery SSJF (1.99% overlap with the fishery)
    - Southern and Eastern Scalefish and Shark Fishery SCSQ (1.31% overlap with the fishery)
    - Small Pelagic Fishery (0.12% overlap with the fishery)
    - Western Tuna and Billfish Fishery (0.04% overlap with the fishery)
- Victorian fisheries:
    - Wrasse (Ocean) Fishery (Victorian) (1.33% overlap with the fishery)
    - Giant Crab (39.85% overlap with the fishery)
    - Rock Lobster (14.81% overlap with the fishery)
    - Octopus (3.69% overlap with the fishery)
    - Ocean General (5.62% overlap with the fishery).

Cumulative impacts could occur from the occurrence of two successive seismic surveys, one seismic survey occurring concurrently with drilling/P&A activities and/or consecutive drilling/P&A activities with operational exclusions zones overlapping fishery management areas, in addition to existing pressures.

Table F1-2 - Assessment of cumulative impacts for interference with commercial fishers.

Conservation (or other) value	Socio-economic value to local communities and the national economy. Some operational areas overlap moderate or high fishing intensity areas.
Management Plans	Southern and Eastern Scalefish and Shark Fishery (SESSF) Species Summaries (AFMA 2023). Western Victorian rock lobster zone RLAG annual assessment,
Threatening Processes	Nil, other than unintentional fishing pressure on school shark.
Relevant Spatial and Temporal Extent	Fishery management zones focusing on fisheries with evidence of activity in the operational areas.
Recovery (or other) Action	Compensation for evidence-based claims for loss of gear, reduced catch or increased costs due to displacement.
Baseline Environment Condition	Some fisheries overlap with the existing shipping channel and areas with existing oil and gas activity. The fisheries with historical activities in the operational areas have sustainable stock status. However, school sharks are listed as Conservation Dependent (fishing pressure) in the SESSF – Shark Gillnet Sector. The fisheries are "Quota" managed and harvesting is limited to a set amount of "Total Allowable Catch" (TAC) annually.
Acceptable Level	That commercial fishers are not worse off because of petroleum activities in the offshore Otway Basin.
Comparison of Predicted Level of Impact with Defined Acceptable Levels	Predicted impacts are temporary and in most cases avoidable. A compensation process will be implemented in the event that interference with commercial fishers cannot be avoided, and claimants provide supporting evidence.
Predictability/ Certainty of Assessment	Given the intensity of fishing in the area, and the overlap of fishery management zones with the proposed activities of multiple titleholders, the assessment of cumulative impacts is made with a high level of predictability and certainty.

5.2 Effects of Elevated Levels of Artificial Light to Albatross, Petrels and Shearwaters

There is a potential cumulative impact for birds with foraging BIAs, and it is identified that there is a potential for overlap when considering a single seismic survey and a single drilling operation, as well as with sequential drilling activities. However, when examining the breeding BIAs for the short-tailed shearwater, predictions indicate no significant overlap from multiple projects. The only exception is for drilling within the T/49P area, where the activity impact assessment has forecasted no behavioural impacts or injury/mortality to the species. Consequently, no cumulative impact pathway has been identified.

For the wedge-tailed shearwater breeding BIA, the overlap is anticipated only with flaring from exploration drilling and light from other consecutive drilling activities. Concurrent activities do not contribute to this overlap. With respect to the Common diving-petrel, a species particularly sensitive to coastal light impacts, disturbances to adult nest attendance are a concern when these birds are returning to or leaving their nesting colony. The Regia MSS and ConocoPhillips Australia Otway Drilling Program in the north of VIC/P79 are scheduled in such a way that they do not coincide, thereby minimising potential impacts. These operations are also planned to be more than 18 months apart in this area, and no cumulative impact pathway has been identified for them.

In evaluating the potential for cumulative impacts, it is important to consider the limited spatial extent of effects in comparison to the available area for foraging. Most species conduct foraging activities during daylight hours. The National Recovery Plan for Albatrosses and Petrels has classified interactions with marine infrastructure, including those associated with artificial light, as posing no risk priority, and affecting no species within the Australian jurisdiction.

Specifically for the breeding BIA of the wedge-tailed shearwater, overlap is only by flaring from ConocoPhillips Australia's Otway Exploration Drilling activity, which is restricted to 120 hours per well. Since this species is not listed as threatened and since periodic changes in ambient light within the area affected are unlikely to induce behavioural changes or result in injury/mortality, the effect is low.

Overall, the cumulative impact of light emissions from petroleum activities in the Otway area is assessed to be low, especially when compared to the light emissions from existing shipping and fishing operations. It is also noted that most of these vessels do not follow a Light Management Plan.

Table F1-3 - Assessment of cumulative impacts for elevated levels of artificial light to Albatross, Petrels and Shearwaters.

Conservation (or other) value	Antipodean, southern royal, wandering, northern royal, Sooty, Buller's, shy, grey-headed, Campbell, black-browed, Salvin's, Indian yellow-nosed, and white-capped albatrosses; southern and northern giant, common diving and white-faced storm-petrels; short-tailed and wedge-tailed shearwaters. Endangered, Vulnerable, not listed, some with foraging BIAs, common diving petrel (nocturnal), short-tailed shearwater and wedge-tailed shearwater with breeding BIAs within EMBAs. Short-tailed shearwater also identified cultural value.
Management Plans	National Recovery Plan for Albatrosses and Petrels (DCCEEW 2022e). Wildlife Conservation Plan for Seabirds (DCCEEW 2020). National Light Pollution Guidelines for Wildlife (CoA 2023).
Threatening Processes	Light emissions are identified as a threat in the National Recovery Plan for Albatrosses and Petrels but marine infrastructure interactions, including those associated with artificial light, are classified as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. The National Recovery Plan for Albatrosses and Petrels also states that light associated with coastal developments at or adjacent to breeding sites represents a moderate threat to short-tailed shearwater. Light pollution, including from gas flaring, is listed as a threat to seabirds in the Wildlife Conservation Plan for Seabirds, with potential for consequences affecting individuals but not whole populations.

Relevant Spatial and Temporal Extent	Foraging BIAs for Antipodean, black-browed, Buller's, Campbell, Indian yellow-nosed, shy and wandering albatross, white-faced storm petrel, short-tailed shearwater and common diving-petrel within operational light and flaring EMBAs. Only common diving-petrel identified as foraging at night. Breeding BIAs for short-tailed shearwater and wedge-tailed shearwater within flaring EMBA. Breeding BIA for common diving petrel within operational light and flaring EMBAs.
Recovery (or other) Action	National Recovery Plan for Albatrosses and Petrels: no relevant actions. Wildlife Conservation Plan for Seabirds: Mitigate against impacts of light pollution around breeding colonies. National Light Pollution Guidelines for Wildlife recommend: Always using Best Practice Lighting Design to reduce light pollution and minimise the effect on wildlife. Undertaking an Environmental Impact Assessment for effects of artificial light on listed species for which artificial light has been demonstrated to affect behaviour, survivorship or reproduction.
First Nations Cultural Heritage	Short-tailed shearwaters (mutton birds) are identified as being culturally significant to the Gunditjmara People and are used in harvesting practice (GMTOAC, 2023). It is considered that the potential for cumulative impacts to short-tailed shearwater) may prevent First Nations people's obligations to maintain spiritual connections and care for culturally significant species. Where a potential impact to culturally important species has been identified and assessed as acceptable from an ecological impact point of view – the corresponding impact to cultural heritage is likely to be the same. Impacts to culturally important species of birds, including shearwaters have been assessed acceptable from an ecological perspective, as detailed in EP Appendix E9. Cumulative impacts from drilling and P&A activities resulting in elevated light levels to birds species that are identified as cultural values are at a very small scale, which is not predicted to be material to contribute to cumulative impacts. Cumulative impacts to culturally significant bird species arising from seismic surveys is not expected as the only other seismic survey scheduled to occur in close proximity to the Regia MSS has not received approval yet and it's status is unknown.
Baseline Environment Condition	Existing lighting in the area includes fishing vessels, shipping traffic, existing offshore oil and gas platform and coastal developments. The shipping channel for vessels coming from Melbourne to Tasmania is one of the busiest shipping routes in offshore Australia.
Acceptable Level	Cumulative light does not impact breeding colonies of short-tailed shearwaters, wedge-tailed shearwaters or the common diving petrel, or populations of other species that forage in the area.
Comparison of Predicted Level of Impact with Defined Acceptable Levels	Cumulative light impacts to breeding colonies of short-tailed shearwaters, wedge-tailed shearwaters or the common diving petrel, or populations of other species that forage in the area are not predicted based on the rig and vessels will have a Light Management Plan to reduce light emission to as low as reasonably practicable for safe navigation and work and that flaring will be for short durations.
Predictability/ Certainty of Assessment	The overlap of light affected areas with foraging and breeding BIAs is predicted to be limited to only two concurrent activities at a time (e.g. seismic survey and drilling/P&A at one location – Lady Julia Percy Island) and then only consecutively from individual drilling activities. This assessment of cumulative impacts is made with a high level of predictability and certainty.

5.3 Effects of Elevated Levels of Artificial Light to Orange-bellied Parrot

The only interaction between the Otway projects is with light affected areas, rather than any illuminated structures or vessels. Spatially, there's a potential one-season overlap of the Regia MSS and a single drilling operation within light affected areas along the likely migration path. This overlap is temporal as well, with consecutive drilling operations potentially creating light affected areas over this migration route for several years.

The seismic-related cumulative impact of light emissions on the migration path would be brief, occurring only at night when work is carried out on the eastern side, in conjunction with a single drilling operation. The seismic program is confined to a maximum of 90 days, with active acquisition for 60 of those days.

Over the years, a single drilling rig may emit light that intermittently overlaps with various portions of the migration route. However, there has been no evidence of the orange-bellied parrot offshore during Beach Energy's 18-month drilling campaign in the region, nor in the last decade of Beach Otway Operations. Despite continuous petroleum activities in the Otway Basin, the parrot populations are on the rise.

Overall, the cumulative impact of light emissions from petroleum activities in the Otway area is assessed to be very low, especially when compared to the light emissions from existing shipping and fishing operations along the migration route. It is also noted that most of these vessels do not follow a Light Management Plan.

Table F1-4 - Assessment of cumulative impacts for elevated levels of artificial light to Orange-bellied Parrot.

Conservation (or other) value	Listed as Critically Endangered and Marine under the EPBC Act and noted as a species of cultural significance.
Management Plans	National Recovery Plan for the Orange-bellied Parrot (DoE 2016)
Threatening Processes	Illuminated boats and structures within the migration route as a barrier to migration (weak evidence for impact, moderate risk rating) when overflying the light affected areas.
Relevant Spatial and Temporal Extent	Probable Migration Route September-November (Southward); February-mid-March (northwards). The light affected areas of the reasonably foreseeable activities do not overlap with the Migration Route.
Recovery (or other) Action	Assess the risk of barriers, being illuminated structures or boats, on the probable migration route. Manage threat if the risk rating warrants action. National Light Pollution Guidelines for Wildlife recommends: Always using Best Practice Lighting Design to reduce light pollution and minimise the effect on wildlife. Undertaking an Environmental Impact Assessment for effects of artificial light on listed species for which artificial light has been demonstrated to affect behaviour, survivorship or reproduction.
Baseline Environment Condition	The orange-bellied parrot probable migration route is within the shipping channel for vessels coming from Melbourne to Tasmania - one of the busiest shipping routes in offshore Australia.
Acceptable Level	Light from cumulative sources does not affect migration of the orange-bellied parrot at a population level.
Comparison of Predicted Level of Impact with Defined Acceptable Levels	Cumulative light impacts are not predicted to affect the migration of the orange-bellied parrot at a population level based on the rig and vessels will have a Light Management Plan to reduce light emission to as low as reasonably practicable for safe navigation and work and that flaring will be for short durations.

Predictability/ Certainty of Assessment	There is no published information available on the sensitivity of the orange-bellied parrot to light, and only anecdotal evidence exists regarding the impact of barriers to migration (DELWP 2016). This introduces some uncertainty into the assessment of cumulative impacts.

5.4 Effects of Elevated Levels of Sound to Blue Whales

With the current uncertainty on the timing of some other projects and the distance of underwater sound affected areas, there is the potential for cumulative impact if the following occur within the migration BIA during the biologically relevant periods (nominally November to May):

- Overlap between one drilling activity for one season.
- Consecutive drilling/P&A activities over several seasons.
- Consecutive seismic surveys in one season or over several seasons.

Without appropriate detection and actions in place there is the potential that blue whales could be exposed to underwater sound from two sources (seismic and drilling) within the foraging BIA that could result in them expending more energy to move away from the sound source to forage or restrict the area of foraging. This could also occur for consecutive years whilst drilling activities are undertaken within the Otway Basin.

Cumulative impacts resulting in an increase in the likelihood of PTS and TTS for foraging blue whales are not predicted due to the distances to the PTS and TTS noise criteria for activities.

Table F1-5 - Assessment of cumulative impacts for elevated levels of sound on Blue Whales.

Conservation (or other) value	Listed as Endangered under the EPBC Act.
Management Plans	Conservation Management Plan for the Blue Whale (DoE 2015c) Guidance on key terms within the Blue Whale Conservation Management Plan (DAWE 2021a)
Threatening Processes	Conservation Management Plan for the Blue Whale identifies anthropogenic noise interference as a threat.
Relevant Spatial and Temporal Extent	Underwater sound affected areas overlap Foraging and Annual High Use Foraging BIAs. Blue whales are typically present within the BIAs between November to June, peaking in February and March.
Recovery (or other) Action	Conservation Management Plan for the Blue Whale states that anthropogenic noise in BIAs must be managed so that blue whales can continue to utilise the area without injury and [are] not displaced from a foraging area. DAWE (2021a) details that underwater anthropogenic noise should not: Stop or prevent any blue whale from foraging Cause any blue whale to move on when foraging, or Stop or prevent any blue whale from entering a foraging area

First Nations Cultural Heritage	Although there is the potential for foraging blue whales to be present in the sound EMBA, the proposed activity is not inconsistent with the Conservation Management Plan for the blue whale, which recognises the cultural values of cetaceans for the people of the South Pacific. EP Appendix E7 stated underwater sound emissions will be managed in a manner to not impact on the recovery of the blue whales and will ensure impacts are of an acceptable level. Cumulative impacts from drilling and P&A activities resulting in elevated sound levels to blue whales are at a very small scale, which is not predicted to be material to contribute to cumulative impacts. Cumulative impacts to blue whales arising from seismic surveys is not expected as the only other seismic survey scheduled to occur in close proximity to the Regia MSS has not received approval yet and it's status is unknown
Baseline Environment Condition	The BIAs overlap existing shipping channel, area of high commercial fishing effort, and existing oil and gas activity.
Acceptable Level	Each activity will be carried out in a manner that will not be inconsistent with the Conservation Management Plan for the Blue Whale such that blue whales can continue to utilise the area without injury and [are] not displaced from a foraging area.
Comparison of Predicted Level of Impact with Defined Acceptable Levels	Cumulative impact to Blue Whale's are not predicted as each titleholder will be required to undertake their activity in a manner that will not be inconsistent with the Conservation Management Plan for the Blue Whale such that blue whales can continue to utilise the area without injury and [are] not displaced from a foraging area.
Predictability/ Certainty of Assessment	There is a high level of predictability and certainty in the limited potential for cumulative impacts, given the requirements in place for each activity to prevent impacts.

5.5 Effects of Elevated Levels of Sound to Southern Right Whales

Cumulative impacts from current and reasonably foreseeable activities to the SRW migration and reproductive BIA are not predicted as the sound affected areas do not simultaneously overlap with these areas.

With the current uncertainty on the timing of some other projects and the distance of underwater sound affected areas, there is the potential for cumulative impact if the following occur within the migration BIA during the biologically relevant periods (nominally April and October):

- Overlap between one drilling activity for one season.
- Consecutive drilling/P&A activities over several seasons.

Without appropriate detection and actions in place there is the potential that SRWs could be exposed to underwater sound from two sources (seismic and drilling) within the migration BIA that could result in them expending more energy to move away from the sound source when migrating to and from coastal breeding areas. This could also occur for consecutive years whilst drilling activities are undertaken within the Otway Basin.

Cumulative impacts resulting in an increase in the likelihood of PTS and TTS for a migrating SRW is not predicted due to the small distances to the PTS and TTS noise criteria for drilling activities.

Table F1-6 - Assessment of cumulative impacts for elevated levels of sound on Southern Right Whales.

Conservation (or other) value	Listed as Endangered under the EPBC Act and noted as a species of cultural significance in the National Recovery Plan for the Southern Right Whale (DCCEEW 2024).
Management Plans	Conservation Management Plan for Southern Right Whale (DSEWPaC 2012b) National Recovery Plan for the Southern Right Whale (DCCEEW 2024)
Threatening Processes	Conservation Management Plan for the Southern Right Whale and National Recovery Plan for the Southern Right Whale identify noise interference as a threat.
Relevant Spatial and Temporal Extent	Overlap of underwater sound affected areas with migration and reproductive BIAs. Southern right whales are typically within the migration BIA from April to October.
Recovery (or other) Action	National Recovery Plan for the Southern Right Whale: " Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment"," and "Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that the risk of behavioural disturbance is minimised".
First Nations Cultural Heritage	Although there is the potential for migrating southern right whales to be present in the sound EMBA, the proposed activity is not inconsistent with the with the Recovery Plan for southern right whales which recognises the cultural significance of this species as totemic ancestors to some groups, the importance of coastal bays, known resting/feeding sites for mothers and calves and the importance of the arrival of southern right whales to communities and people following a songline or ancient memory code, and will not affect the ability of locals to gather on Gunditjmara Sea Country to welcome koontapool back to her traditional birthing waters. EP Appendix E7 stated underwater sound emissions will be managed in a manner to not impact on the recovery of southern right whales and will ensure impacts are of an acceptable level. Cumulative impacts from drilling and P&A activities resulting in elevated sound levels to southern right whales are at a very small scale, which is not predicted to be material to contribute to cumulative impacts. Cumulative impacts to southern right whales arising from seismic surveys is not expected as the only other seismic survey scheduled to occur in close proximity to the Regia MSS has not received approval yet and it's status is unknown
Baseline Environment Condition	The BIAs overlap existing shipping channel, area of high commercial fishing effort, and existing oil and gas activity.
Acceptable Level	The activity will be carried out in a manner that will not be inconsistent with the National Recovery Plan for the Southern Right Whale (DCCEEW 2024) such that Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment, and ensure the risk of behavourial impacts are minimised.
Comparison of Predicted Level of Impact with Defined Acceptable Levels	Cumulative impact to Southern Right Whales are not predicted as each titleholder will be required to undertake their activity in a manner in a manner that will not be inconsistent with the National Recovery Plan for the Southern Right Whale (DCCEEW 2024) such that Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment and and ensure the risk of behavourial impacts are minimised. .

Predictability/ Certainty of Assessment	There is a high level of predictability and certainty in the limited potential for cumulative impacts, given the requirements in place for each activity to prevent impacts.

Notes:
1. Legal definition of 'Should' means expected course of action or policy to be followed unless inappropriate for a particular circumstance. No habitat critical to the survival of SRWs have been identified.

5.6 Effects of Elevated Levels of Sound to Fin, Sei Whales, and Pygmy Right Whales.

While there are no BIAs for Fin, Sei and Pygmy Right Whales within Australian waters, Fin, Sei, and Pygmy Right Whales are considered likely to be foraging in the area that may be affected by underwater sound at a similar time as Blue Whales, i.e. predominately between January and April. While the Regia MSS will not take place during this period, with the current uncertainty on the timing of some other projects and the distance of underwater sound affected areas, there is the potential for cumulative impact if the following occur during the biologically relevant periods (nominally November to May):

- Overlap between one drilling activity for one season.
- Consecutive drilling/P&A activities over several seasons.
- Consecutive seismic surveys in one season or over several seasons.

Without appropriate detection and actions in place there is the potential that fin, sei, and pygmy right whales could be exposed to underwater sound from two sources (seismic and drilling) within the foraging BIA that could result in them expending more energy to move away from the sound source to forage or restrict the area of foraging. This could also occur for consecutive years whilst drilling activities are undertaken within the Otway Basin.

Cumulative impacts resulting in an increase in the likelihood of PTS and TTS for foraging fin, sei, and pygmy right whales are not predicted due to the distances to the PTS and TTS noise criteria for activities.

Table F1-7: - Assessment of cumulative impacts for elevated levels of sound on Fin, Sei, and Pygmy Right Whales.

Conservation (or other) value	Fin and Sei Whales are listed as Vulnerable under the EPBC Act, the Pygmy right whale (PRW) not listed as threatened under the EPBC Act.
Management Plans	Conservation Advice Balaenoptera physalus (fin whale) (TSSC 2015a). Conservation Advice Balaenoptera borealis (sei whale) (TSSC 2015b). There are no management plans or conservation advice for the PRW.
Threatening Processes	Conservation advice *Balaenoptera physalus* (fin whale) identifies anthropogenic noise and acoustic disturbance as a minor threat. Conservation *advice Balaenoptera borealis* (sei whale) identifies anthropogenic noise and acoustic disturbance as a minor threat. There are no threats identified for the PRW.
Relevant Spatial and Temporal Extent	There are no BIAs or habitat critical to the survival of the fin whale and sei whale were identified within the underwater sound EMBAs. Presence within EMBAs for fin and sei whales is listed as known to occur within the area and may be undertaking foraging or feeding-related behaviour, PRW is listed as likely to occur within the EMBA and may be undertaking foraging or feeding-related behaviour
Recovery (or other) Action	The Conservation Advices for Balaenoptera physalus (fin whale) and for Balaenoptera borealis (sei whale) identify anthropogenic noise and acoustic disturbance as a minor threat. There are no management plans, conervation advice, or recovery plans listed for PRW.
Baseline Environment Condition	The areas of use by fin, sei and pygnmy right whales overlap existing shipping channel, area of high commercial fishing effort, and existing oil and gas activity.

Acceptable Level	Fin, Sei and Pygmy Right Whales can continue to the area, with the risk of injury and disturbance minimised.
Comparison of Predicted Level of Impact with Defined Acceptable Levels	Cumulative impact to Fin, Sei and Pygmy Right Whales are not predicted as each titleholder will be required to undertake their activity in a manner in which the risk of injury and disturbance minimised.
Predictability/ Certainty of Assessment	There is a high level of predictability and certainty in the limited potential for cumulative impacts, given the requirements in place for each activity to prevent impacts.

5.7 Industry Standard Control Measures

The following sections outline the standard measures which any titleholder relying on this CIA would adopt, with environmental performance suitable for their activities and management systems specified in their Environment Plan. Titleholders may choose to collaborate with one another on any of the measures noting the likely need to specify environmental performance on their own terms.

5.7.1 On-Water Communication Protocol

All titleholders in the region will likely apply the industry standard of adopting communication protocol (or similar) to manage interactions with commercial fishing activities.

5.7.2 Petroleum SIMOPS Plan

Titleholders with ongoing or planned activities in the Otway region are in regular consultation with each other and are working collaboratively to manage potential cumulative impacts. Details about this plan can be found in Appendix B3.

5.7.3 Compensation/Adjustment Protocol

Each titleholder will adopt a compensation/adjustment protocol to manage cumulative impacts to commercial fishers. Titleholders may collaborate to reduce the burden on affected fishers and standardise the processes for making evidence-based claims.

5.7.4 Light Management Plan

Titleholders predicting elevated levels of artificial light overlapping or adjacent to bird foraging or breeding BIAs, or the orange-bellied parrot migration routes are required to have a light management plan that meets the requirements of the National Light Pollution Guidelines. It is likely that all titleholders will have some form of assurance processes associated with the contracting of rigs and vessels to ensure this control measure in adopted and project rigs and vessels comply with all maritime laws.

5.7.5 Fauna Management Plans

It is expected that each titleholder will carry out observations, report incidents, and share opportunities for improvement with other petroleum titleholders in the Otway Basin regarding underwater sound management and whale interactions. Titleholders in the region are all individually responsible for ensuring the acceptable level of impact for Blue Whales and Southern Right Whales is not exceeded and titleholders have agreed to collaborate with the aim of minimising the potential for cumulative impacts associated with underwater sound, should activity timings overlap biologically important periods for Blue Whales and or Southern Right Whales.

5.8 Identification of Additional Control Measures

Additional measures have been considered because of this CIA to support titleholders in the Otway region to demonstrate cumulative impacts have been reduced to as low as reasonably practical (**ALARP**) and meet acceptable levels for cumulative impacts.

Additional measures may include a review and strengthening of existing measures, investigating the feasibility of additional mitigation measures or adaptive management processes, refining the activity description to reduce impact, and working with the proponents of other relevant reasonably foreseeable future projects to develop holistic mitigation strategies that consistently improve outcomes.

6 Outcome of CIA

The potential for cumulative impacts is considered low, with lower-order effects, given:

- The contracting of a single rig to conduct drilling related activities in the region which has eliminated the potential for concurrent cumulative impacts associated with multiple rig and support vessel operations.
- The physical overlap of a drilling activity within a seismic acquisition area has not been predicted and would make one, or the other activity unworkable.

6.1 CIA Outcome on Conservation Values and Sensitivities

Based on the outcome of the CIA, it is considered that cumulative impacts associated with the each of the projects and activities in this CIA both individual and collectively will not affect the representativeness of the South-east Commonwealth Marine Reserves Network, nor the conservation values of the Zeehan Marine Park associated with seabirds, the white shark and marine mammals, or sea-floor features.

6.2 Cumulative Impacts Reduced to ALARP

The residual cumulative impacts are considered to be of lower order because the cause effect pathways to impact have been identified and can be reduced with the adoption of industry standard control measures specified in Section 5.7, plus the additional measures in Section 5.8.

6.3 Cumulative Impacts Reduced to Acceptable Levels

Following completion of the CIA process, the residual cumulative impacts are of lower order because good practice controls are defined and will be implemented and each of the activities will be managed in accordance with relevant company, Commonwealth, international, and Industry standards, guidelines, and requirements.

Annex 1

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table F1-8. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table F1-8 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4151	Potential cumulative impacts upon species are addressed.	The titleholder responded by informing the stakeholder that the Regia MSS team were currently undertaking the cumulative impact assessment and will ensure that it covers previous and planned seismic surveys within the area and assesses impacts to cetaceans (behaviour, PTS, TTS) and their food source (krill).	653
4152	Potential harm to marine species like dolphins and whales due to disorientation caused by intense noise.	The Regia EP has conducted a thorough assessment of the literature which is both aspect-focused and also receptor- focused for those taxa of increased public concerns. Marine mammals, Blue Whale and Southern Right Whale in particular, have been subject to increased levels of assessment which have been used to decide outcomes.	1263
4173	Seismic blasting has adverse effects on the marine environment, with critical gaps in understanding the effects on individual species and the marine environment as a whole.	The titleholder responded with an explanation of the information sources used to inform the Regia MSS impact and risk assessments, and explained how these information sources and resulting measures are specific to the potential impact. The titleholder also referred to documents relevant to this claim within the environment plan (Event ID 4092).	4091
4489	Claims that CGG cannot determine what constitutes an “acceptable” level of impact or risk to Gunditjmara cultural values in Nyamat Mirring. States the April 2025 Environment Plan contains flawed cumulative impact assessments due to this lack of consultation.	CGG rejects GMTOAC’s claim that inadequate consultation prevents CGG from determining “acceptable” levels of cultural impact, asserting that it fully met its consultation obligations. CGG argues that the legal test is whether the Environment Plan demonstrates impacts and risks are reduced to ALARP and to an acceptable level. It maintains that GMTOAC’s critiques conflate subjective opinion with the regulatory standard under Regulation 34	EVT352

	GMTOAC identifies several shortcomings: CGG's interpretation of potential impacts to Gunditjmara and other First Nations cultural heritage is too narrow; CGG wrongly assumes that acceptable ecological impacts equate to acceptable cultural impacts; and CGG's cumulative impact assessment for Karntubul (Southern Right Whale), previously criticised by NOPSEMA in its February OMR, remains unchanged.	and emphasises that the law does not grant stakeholders a veto over design decisions. In response to the assertion that its interpretation of cultural heritage is too narrow, CGG maintains that GMTOAC has already articulated its cultural values clearly and extensively through published materials and received during consultation. These values, encompassing ceremony, obligations, kinship systems, spiritual relationships, and ecological connections are thoroughly integrated across the EP. The EP references the Nyamat Mirring Plan 2023–2033, incorporates cultural values and sensitivities into Appendix F3, and identifies culturally significant species and places as sensitive receptors with tailored management measures, for example, timing restrictions to avoid birthing seasons. CGG states that it has incorporated analysis of cumulative effects on Sea Country, including those arising from the survey in combination with other activities. It confirms that Karntubul is included in cumulative risk assessments with corresponding mitigation commitments.	
4491	Claims about the SRW and BW BIAs. States proposed activity will cause unacceptable impacts to all Karntubul species, including temporary & permanent hearing loss, displacement from BIAs, vessel strike, prey depletion during peak feeding/migration period, calving interruption, and impact to ecosystems and cultural landscapes as a result of the cumulative impact of these.	CGG has identified all Biologically Important Areas (BIAs) relevant to blue whales (BWs) and southern right whales (SRWs) and incorporated seasonal BIA use into the survey design through substantial temporal and spatial restrictions detailed in the EP. Predicted underwater-sound impacts on these Karntubul species, along with mitigation measures presented in Appendices E7 and F3, demonstrate impacts will remain acceptable and will avoid auditory impairment or displacement from BIAs or Habitats Critical to Survival (HCTS). CGG further notes that vessel-strike risk is already extremely low during seismic surveys and that additional controls in Appendix D2 ensure this risk is prevented and acceptable. It concludes that no changes to ecosystem structure, diversity, or function are expected from the one-off survey, with sound exposure too limited in extent and duration to affect prey, food webs, or predator–prey relationships. A cumulative impact assessment found residual cumulative effects to be low, reduced to ALARP, and acceptable, with no impacts predicted for regional marine parks. CGG also asserts consistency with the National Recovery Plan for Southern Right Whales and the Blue Whale Conservation Management Plan, stating that their objectives and recommended measures have been incorporated. Finally, CGG maintains that all marine mammal species likely to occur in the region have been adequately assessed using up-to-date EPBC Protected Matters data, and that mitigation measures ensure impacts to all listed species	EVT352

		will remain acceptable and not inconsistent with EPBC Act protection provisions.	
4492	Claims that the eastern population of the Southern Right Whale, estimated at only 200–300 individuals, is at particularly high risk because its migration and reproduction Biologically Important Areas (BIAs) overlap directly with CGG's Operational Area and sound propagation footprint. According to the Southern Right Whale Recovery Plan, these whales use the affected region for reproduction between May and September and for migration between April and October. The Recovery Plan also notes that Southern Right Whales do not feed in coastal waters but are expected to feed, and possibly conceive, within the Australian Whale Sanctuary—an area entirely overlapped by the proposed Regia MSS activity. As a result, the seismic survey could occur within, or affect, conceiving, calving, and feeding grounds for this critically endangered sub-population. The species is particularly vulnerable to human impacts due to its low reproductive rate, long lifespan, and strong site fidelity to key habitats. The submission therefore emphasises the relevance of underwater noise, habitat degradation, and vessel-strike risks in the context of the proposed seismic activities.	The Recovery Plan explains that BIAs can be designated for key behaviours such as reproduction, foraging, migration, and resting. While Southern Right Whale BIAs in the Plan cover reproduction and migration, the Plan notes that foraging occurs across a much broader offshore latitudinal range (30°S–65°S) and is not linked to these BIAs. Because the Regia MSS is not located in Antarctic waters, it will not affect cetaceans that forage there. CGG states the survey will avoid peak SRW abundance in the mapped BIA and apply mitigation measures to ensure no SRWs are harmed, injured, or interfered with.	EVT352
4496	GMTOAC objects to CGG removing a previous control measure limiting seismic discharge in the Pygmy Blue Whale foraging BIA during periods of low whale presence, replacing it with a vague condition requiring CGG to determine whether whale presence is "compatible" with proceeding. GMTOAC argues this new measure lacks detail on how whale presence or "unacceptable disturbance" will be	CGG has further reduced the likelihood of interactions with marine mammals by excluding the April–June period and commencing the survey only after 15 September. Because blue whales typically do not arrive from Western Australia until November, CGG argues that most of the survey will occur when blue whales are absent from the area. It adds that sighting data show very few blue whales in November and December, with peak abundance occurring later, from January to March during the Bonney Upwelling.	EVT352

	assessed, and that it fails to reference Recovery Plans which define unacceptable impacts. GMTOAC warns that the proposed survey timing (April–June 2026) coincides with peak Pygmy Blue Whale foraging season and Southern Right Whale migration and calving periods, meaning the seismic survey is likely to occur when both species are using their BIAs. Preventing whales from accessing these areas, or exposing them to injury while they remain, would constitute unacceptable impacts inconsistent with Recovery Plan objectives.

1. This overlap is based on a 20 km area of effect from these activities noting that ConocoPhillips Australia have not identified final drilling locations.
2. This overlap is from the activities being proximate to the production facilities.

3. The overlap in sound is taking from a conservative estimate of 50 km between sound sources noting that distance is an inadequate but conservative measure to determine spatial overlap between projects and activities.

Annex 3

CIA Scoping Tool

Environmental Component	Sub-Component	Environmental Aspect (yellow = drilling specific)									CIA Scoping					
		Physical Presence	Seabed Disturbance	Artificial Light - Operational	Artificial Light - Flaring	Atmospheric Emissions	Underwater Sound - Continuous	Underwater Sound - Impulsive	Routine Discharges	Drilling Discharges	Acceptable Levels (Effect) Ecological integrity and biodiversity conservation (Temporary/reversible/recoverable, small scale and/or low intensity) Assessing scale and nature	Potential for Cumulative Impact - Spatial Extent	Potential for Cumulative Impact - Temporal Extent	Predictability and Certainty	Scoping Assessment Outcome	Cumulative Cause-effect Pathway
Physical Environment	Water Quality		✓						✓	✓	Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity discharge location	N - Limited to duration of individual activity	High for individual and cumulative impacts.	No cumulative impact cause-effect pathway identified. Impacts to water quality from activities are predicted to rapidly disperse given the open ocean environment and prevailing currently within 500 m to 2 km of the discharge, thus there is no potential to accumulate over spatial or temporal scales.	None identified
	Sediment Quality		✓							✓	Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity discharge location	N - Limited to months - year after individual activity	High for individual and cumulative impacts.	Cumulative impact cause-effect pathway identified but impacts not material. No impacts to sediment quality are predicted for seismic surveys. Impacts to sediment quality drilling activities are predicted to be localised within 500 m of each well. Though there is the potential for an increase in potential impact as each area is very small (500 m) material impacts are not predicted.	Identified but impacts not material nor added to by the Regia MSS. No further assessment required.
	Air Quality					✓					Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity discharge location	N - Limited to duration of individual activity	High for individual and cumulative impacts.	No cumulative impact cause-effect pathway identified. Impacts to air quality from activities are predicted to be localised, and atmospheric emissions will rapidly disperse to background levels close to the emissions source given the open ocean environment and prevailing wind. Emissions are not predicted to affect the achievement of the National Environmental Protection Measure for Ambient Air Quality (NEPM AQQ) (NEPC 2021) protection goals., with no potential to accumulate over spatial or temporal scales.	None identified
	Climate					✓					Small-scale and low intensity impacts.	N - Global climate	N - Indeterminable	High for individual and cumulative impacts.	Although GHG emissions from activities will add to the global atmospheric levels of GHG emissions, the quantities estimated to be released are insignificant on a global scale.	None identified
	Ambient Light - Operational			✓							Temporary, small-scale, and recoverable impacts.	Y - Bioregion, BIAs, and biologically important behaviours for sensitive species	Y - Consecutive activities, and seismic and single drilling operation may occur concurrently	High for individual and cumulative impacts.	There is potential for cumulative impacts depending on location of activities and sensitive receptors. Although changes in ambient light are restricted to typically 20 km radius of individual activities, activities may occur consecutively over several years within the Otway Basin and seismic and drilling at a single location have the potential to occur concurrently	Identified and further assessment required to determine if impacts are material.
	Ambient Light - Flaring			✓	✓						Temporary, small-scale, and recoverable impacts.	N - Only single drilling operation at any one time	Y - Consecutive activities if others are flaring in similar location	High for individual and cumulative impacts.	There is potential for cumulative impacts depending on location of activities and sensitive receptors. Although flaring light impacts are restricted to typically 50 km radius of individual short-term operations (max. 120 hours per well), flaring may occur consecutively over several years within the Otway Basin.	Identified and further assessment required to determine if impacts are material.

Environmental Component	Sub-Component	Environmental Aspect (yellow = drilling specific)									CIA Scoping					Cumulative Cause-effect Pathway
		Physical Presence	Seabed Disturbance	Artificial Light - Operational	Artificial Light - Flaring	Atmospheric Emissions	Underwater Sound - Continuous	Underwater Sound - Impulsive	Routine Discharges	Drilling Discharges	Acceptable Levels (Effect) Ecological integrity and biodiversity conservation (Temporary/reversible/recoverable, small scale and/or low intensity) Assessing scale and nature	Potential for Cumulative Impact - Spatial Extent	Potential for Cumulative Impact - Temporal Extent	Predictability and Certainty	Scoping Assessment Outcome	
	Ambient Sound						✓	✓			Temporary, small-scale, and recoverable impacts.	Y - Bioregion, BIAs, and biologically important behaviours for sensitive species	Y - Consecutive activities Seismic and single drilling operation may occur concurrently	Moderate for individual and cumulative impacts.	There is potential for cumulative impacts depending on location and timing of activities and sensitive receptors. Although sound impacts are restricted to within typically 10s of kms around individual activities, activities may be occurring consecutively over a period and seismic and drilling (at a single location) have the potential to occur concurrently.	Identified and further assessment required to determine if impacts are material.
Ecological Environment	Benthic Habitats and Communities		✓							✓	Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity area	N - Limited to weeks-months after individual activity	High in individual and cumulative impacts.	No cumulative impact effect pathway identified. The area of impact is relatively small compared to the extent of the distribution of benthic habitats and associated benthic fauna found within the Otway Basin. Widespread changes to the benthic environment or ecosystem functioning or integrity are not predicted. No overlap with threatened ecological communities. Overlap with Zeehan AMP, which has benthic habitat as a value, only occurs one activity.	None identified
	Coastal Habitats and Communities										N/A for planned activities. (No impact to coastal areas from planned drilling operation impacts).					None identified
	Plankton						✓	✓	✓	✓	Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity area	N - Recovery days post activity	Moderate for individual and cumulative impacts.	No cumulative impact effect pathway identified. Discharges to the water column are not predicted to impact water quality at a cumulative scale and therefore will not impact plankton at an ecological integrity level. Continuous noise from drilling and vessel operation is not predicted to impact plankton. The cumulative impact of impulsive sound from consecutive seismic operations has been assessed and controlled in relevant EPs. Impacts from VSP are short term (<20 hours per well and nor predicted to result in impacts at scale to contribute to cumulative impacts.	None identified
	Invertebrates		✓				✓	✓		✓	Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity with exception of multiple seismic operations	N - Limited to weeks-months after individual activity	High for individual and cumulative impacts.	No cumulative impact effect pathway identified. Continuous noise from drilling and vessel operation and VSP is not predicted to impact invertebrates. The cumulative impact of impulsive sound from consecutive seismic operations has been assessed and controlled in relevant EPs.	None identified

Environmental Component	Sub-Component	Environmental Aspect (yellow = drilling specific)									CIA Scoping					Cumulative Cause-effect Pathway
		Physical Presence	Seabed Disturbance	Artificial Light - Operational	Artificial Light - Flaring	Atmospheric Emissions	Underwater Sound - Continuous	Underwater Sound - Impulsive	Routine Discharges	Drilling Discharges	Acceptable Levels (Effect) Ecological integrity and biodiversity conservation (Temporary/reversible/recoverable, small scale and/or low intensity) Assessing scale and nature	Potential for Cumulative Impact - Spatial Extent	Potential for Cumulative Impact - Temporal Extent	Predictability and Certainty	Scoping Assessment Outcome	
	Fish and Sharks						✓	✓			Not inconsistent with EPBC Act Management Plans, and Recovery Plans. Temporary, small-scale, and recoverable impacts.	N - Limited to individual activity with exception of multiple seismic operations	N - Periods of biologically important behaviours for sensitive species	High for individual and cumulative impact sense.	No cumulative impact cause-effect pathway identified. Underwater sound from drilling is predicted to be localised to within 190 m for recoverable injury and TTS for fish and sharks and within 450 m for VSP. The area of impact from concurrent seismic and drilling activities is small compared to the extent of the distribution of fish and shark species. The area of impact from concurrent seismic and drilling activities is small compared to the white shark distribution BIA but is considered moderate for the foraging BIA. However, seismic survey and drilling operations with the potential to affect the foraging BIA in the northern extent of VIC/P79 are mutually exclusive and cannot occur concurrently. Sound impacts are not identified as a threat within the Recovery Plan for the White Shark (Carcharodon carcharias) (DSEWPaC 2013a).	None identified
	Birds			✓	✓		✓	✓			Not inconsistent with EPBC Act Management Plans, and Recovery Plans. Temporary, small-scale, and recoverable impacts.	Y - BIAs for sensitive species (Bioregion)	Y - Periods of biologically important behaviours for sensitive species	High for individual and cumulative impacts.	There is potential for cumulative impacts associated with light depending on location of activities and sensitive receptors, i.e. foraging, migrating, and breeding birds. There is no cumulative effect pathway for underwater sound with the consequence of underwater sound on birds from drilling activities assessed as negligible. Regarding the potential for cumulative impacts to diving birds and little penguins associated with underwater sound from seismic activities, there is only one other seismic survey scheduled to occur in proximity to the Regia MSS. The Beach Energy Calico seismic survey was due to commence in February through to May 2025. CGG understands this project has yet to receive regulatory approval, it is not anticipated this survey will be occurring at the same time as the Regia MSS. Thus, cumulative impacts to diving birds and penguins as a result of one or more seismic surveys occurring in proximity to the Regia MSS operational area are not expected. Although changes in ambient light are restricted to typically 20 km radius of individual activities, activities may be occurring consecutively over several years throughout the region and seismic and drilling at one location have the potential to occur concurrently.	Identified and further assessment required to determine if impacts are material.
	Marine Reptiles			✓	✓		✓	✓			Not inconsistent with EPBC Act Management Plans, and Recovery Plans. Temporary, small-scale, and recoverable impacts.	N - No BIAs or critical habitat	N - No periods of biologically important behaviours for sensitive species	High for individual and cumulative impacts.	No cumulative effect pathway identified. Individuals in the area are expected to be transient, with no BIAs, critical habitat, or biologically important behaviours within the Otway Basin. Lighting doesn't impact in water navigation or behaviours and impacts from noise will be temporary and recoverable.	None Identified

Environmental Component	Sub-Component	Environmental Aspect (yellow = drilling specific)									CIA Scoping					
		Physical Presence	Seabed Disturbance	Artificial Light - Operational	Artificial Light - Flaring	Atmospheric Emissions	Underwater Sound - Continuous	Underwater Sound - Impulsive	Routine Discharges	Drilling Discharges	Acceptable Levels (Effect) Ecological integrity and biodiversity conservation (Temporary/reversible/recoverable, small scale and/or low intensity) Assessing scale and nature	Potential for Cumulative Impact - Spatial Extent	Potential for Cumulative Impact - Temporal Extent	Predictability and Certainty	Scoping Assessment Outcome	Cumulative Cause-effect Pathway
	Marine Mammals						✓	✓			Not inconsistent with EPBC Act Management Plans, and Recovery Plans. Temporary, small-scale, and recoverable impacts.	Y - BIAs for sensitive species (Bioregion)	Y - Periods of biologically important behaviours for sensitive species	Moderate for individual and cumulative impacts.	There is potential for cumulative impacts associated with underwater sound depending on location of activities and sensitive receptors, i.e. endangered species, foraging and migrating BIAs. Although sound impacts are restricted to within typically 10s of kms around individual activities, activities may be occurring consecutively over a period and seismic and drilling at one location have the potential to occur concurrently.	Identified and further assessment required to determine if impacts are material.
	Conservation Values and Sensitivities		✓			✓	✓	✓		✓	Not inconsistent with SE Marine Parks Network Management Plan. Temporary, small-scale, and recoverable impacts.	Y - Zeehan AMP	Y - Periods of biologically important behaviours for conservation values	High for individual and cumulative impacts.	The Zeehan Marine Park is overlapped by three proposed activities. See individual ecological receptors above for assessment of conservation values of the Zeehan Marine Park which include benthic habitats that supports animal communities and invertebrates, seabirds, the white shark and migrating blue whales and humpback whales.	Identified for seabirds and whales and further assessment required to determine if impacts are material.
Socio-economic Environment (Other marine and coastal users)	Coastal Communities and Onshore Tourism Activities	✓		✓	✓						Temporary, small-scale, and low intensity impacts.	N - Not predicted to see multiple activities from single vantage point (King Island, Victorian coast)	Y - May be able to see different activities over time from single vantage point (King Island, Victorian coast)	High for individual and cumulative impacts.	Cumulative effect pathway identified, associated with visibility of different activities over time, but impacts not material. The likelihood of visibility of multiple activities from a single vantage point is considered low given the distances offshore it is not predicted that rig and vessel would be distinguishable from other existing vessel traffic.	Identified but impacts not material. No further assessment required.
	Offshore Petroleum Activities	✓									Temporary, small-scale, and low intensity impacts.	N	N	High for individual and cumulative impacts.	Cumulative effect pathway identified but impacts not material. Other activities are scheduled and/or operate within their own exclusion zones/petroleum titles. Notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoidance of a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal impact.	Identified but impacts not material. No further assessment required.
	Offshore Renewable Energy Activities	✓									Temporary, small-scale, and low intensity impacts.	N	N	High for individual and cumulative impacts.	No cumulative impact effect pathway identified. There are no reasonably foreseeable future projects or activities in the offshore Otway Basin.	None Identified
	Defence Activities	✓	✓								Temporary, small-scale, and low intensity impacts.	Y - Displacement from concurrent and consecutive seismic and drilling areas	Y - Displacement from concurrent and consecutive seismic and drilling areas	High for individual and cumulative impacts.	Cumulative effect pathway identified but impacts not material. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal impact. Impacts to maritime archaeological heritage are not predicted from seismic surveys. Drilling activities required to undertake seabed surveys prior to seabed disturbance. Impacts to UXO are not a planned event and therefore cumulative impacts are not predicted.	Identified but impacts not material. No further assessment required.

Environmental Component	Sub-Component	Environmental Aspect (yellow = drilling specific)									CIA Scoping					
		Physical Presence	Seabed Disturbance	Artificial Light - Operational	Artificial Light - Flaring	Atmospheric Emissions	Underwater Sound - Continuous	Underwater Sound - Impulsive	Routine Discharges	Drilling Discharges	Acceptable Levels (Effect) Ecological integrity and biodiversity conservation (Temporary/reversible/recoverable, small scale and/or low intensity) Assessing scale and nature	Potential for Cumulative Impact - Spatial Extent	Potential for Cumulative Impact - Temporal Extent	Predictability and Certainty	Scoping Assessment Outcome	Cumulative Cause-effect Pathway
	Shipping	✓									Temporary, small-scale, and low intensity impacts.	Y - Displacement from concurrent and consecutive seismic and drilling areas	Y - Displacement from concurrent and consecutive seismic and drilling areas	High for individual and cumulative impacts.	Cumulative effect pathway identified but impacts not material. The area of impact is small compared to the area available for shipping. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal impact.	Identified but impacts not material. No further assessment required.
	Marine Tourism	✓									Temporary, small-scale, and low intensity impacts.	Y - Displacement from concurrent and consecutive seismic and drilling areas	Y - Displacement from concurrent and consecutive seismic and drilling areas	High for individual and cumulative impacts.	Cumulative effect pathway identified but impacts not material. The area of displacement is small compared to area available for tourism. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal impact.	Identified but impacts not material. No further assessment required.
	Recreational Diving and Surfing						✓	✓			N/A for planned activities. No affect to divers and surfers from planned drilling operations are predicted.					None identified
	Recreational Fishing	✓									Temporary, small-scale, and low intensity impacts.	Y - Displacement from concurrent and consecutive seismic and drilling areas on-shelf area	Y - Displacement from concurrent and consecutive seismic and drilling areas	High for individual and cumulative impacts.	Cumulative effect pathway identified but impacts not material. The area of displacement is small compared to area available for recreational fishing. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan activities. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal impact.	Identified but impacts not material. No further assessment required.
	Commercial Fisheries	✓	✓				✓	✓			Affected persons will not be worse off because of the activity.	Y - Displacement from concurrent and consecutive seismic and drilling areas	Y - Displacement from concurrent and consecutive seismic and drilling areas	High for individual and cumulative impacts.	Cumulative effect pathway identified. Displacement of fishers operating in fisheries with spatial extent that may be overlapped by several offshore activities, i.e. displaced by multiple exclusion zones (rig and seismic survey) or different exclusion zone over time. Although displacement impacts are restricted to within typically 2 kms around individual activities, drilling may be occurring consecutively over a period and seismic and drilling at one location have the potential to occur concurrently. Minor behavioural disturbances are predicted to commercial fish species from underwater sound and cumulative impacts are not predicted.	Identified and further assessment required to determine if impacts are material.
Cultural Environment	First Nations Peoples Heritage including but not limited to Sea Country, Song Lines, and totemic species.	✓	✓	✓	✓		✓	✓		✓	Not inconsistent with Indigenous Protected Area Plans. Temporary, small-scale, and recoverable impacts.	Y - Sea Country	Y - Over term of activities	Moderate in individual and cumulative impacts.	Cumulative effect pathway identified. Drilling and other activities may have the potential to cumulatively affect cultural values and sensitivities in the region.	Identified and further assessment required to determine if impacts are material.

Environmental Component	Sub-Component	Environmental Aspect (yellow = drilling specific)									CIA Scoping					
		Physical Presence	Seabed Disturbance	Artificial Light - Operational	Artificial Light - Flaring	Atmospheric Emissions	Underwater Sound - Continuous	Underwater Sound - Impulsive	Routine Discharges	Drilling Discharges	Acceptable Levels (Effect) Ecological integrity and biodiversity conservation (Temporary/reversible/recoverable, small scale and/or low intensity) Assessing scale and nature	Potential for Cumulative Impact - Spatial Extent	Potential for Cumulative Impact - Temporal Extent	Predictability and Certainty	Scoping Assessment Outcome	Cumulative Cause-effect Pathway
	Maritime Archaeological Heritage		✓								No disturbance of maritime cultural heritage.	N - Only single drilling operation at any one time	N - Control Measures in place to detect and prevent interactions	High for individual and cumulative impacts.	No cumulative effect pathway identified. Impacts to maritime archaeological heritage are not predicted from seismic surveys. Drilling activities required to undertake seabed surveys prior to seabed disturbance. Impacts to maritime archaeological heritage are not a planned event and therefore cumulative impacts are not predicted.	None Identified

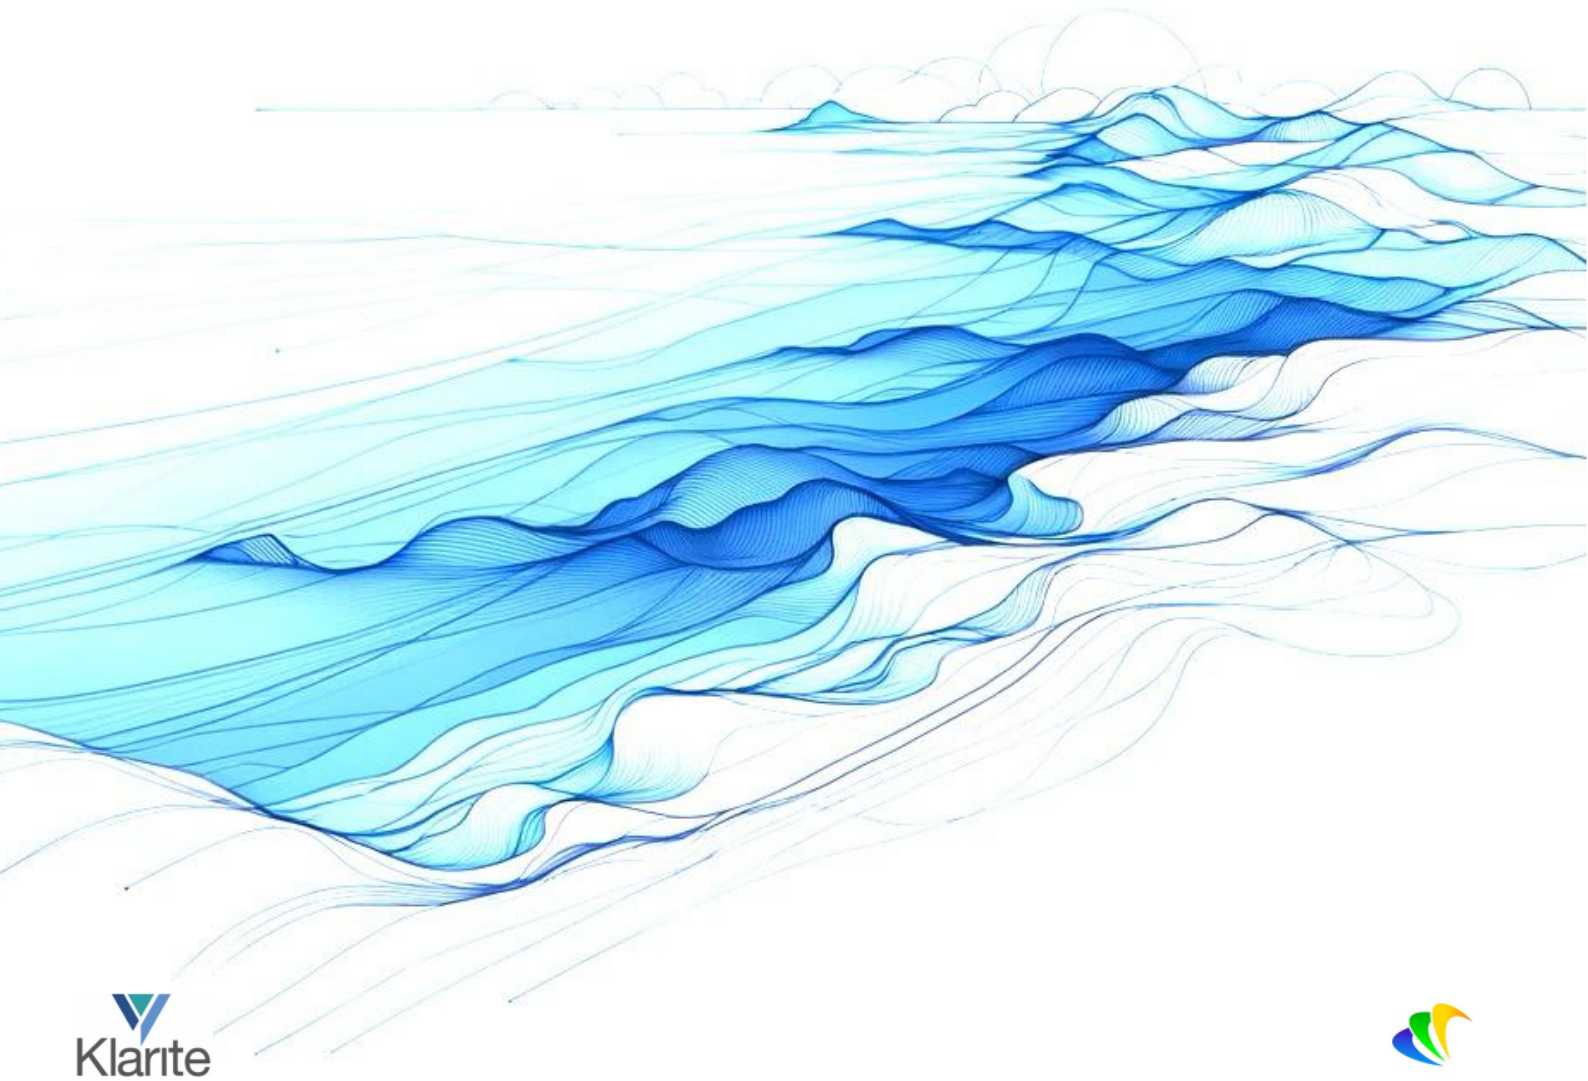
REGIA
Marine Seismic Survey

ALARP Assessment

Appendix F2: REG-EP-031-F2

Rev 5

December 2025



Klarite

Executive Summary

This report presents a comprehensive ALARP (As Low As Reasonably Practicable) assessment across ten environmental impact and risk pathways relevant to the Regia Marine Seismic Survey (Regia MSS). The assessment applies a consistent, step-by-step framework that combines baseline compliance obligations, discretionary control measures, and a semi-quantitative analysis of effectiveness and cost (sacrifice).

For each impact or risk pathway, the process identifies:

- The baseline level of residual impact or risk after legal and operational requirements are applied.
- The cumulative cost, time, or operational effort (sacrifice) required to implement additional control measures.
- The marginal environmental benefit achieved at each step.

Control measures were adopted where they delivered meaningful reductions in impact or risk relative to their cost. Measures were rejected where further reduction would be grossly disproportionate to the sacrifice required. This ensures that effort is concentrated where environmental returns are highest.

A final cross-pathway analysis confirmed that:

- Most total sacrifice was invested in pathways with the highest baseline risk, such as underwater sound, physical presence, and collisions with marine fauna.
- Pathways with already low impact levels, such as atmospheric emissions and planned discharges, showed diminishing returns, supporting early cut-off points in the assessment.
- A comparative metric — impact reduction per unit of sacrifice — demonstrates that CGG's approach delivers proportionate and justifiable environmental outcomes.

Overall, the assessment confirms that impacts and risks have been reduced to a level that is as low as reasonably practicable, in accordance with regulatory expectations and environmental best practice.

1 Introduction

This document presents the **ALARP** (As Low As Reasonably Practicable) assessment undertaken by CGG for the Regia Marine Seismic Survey (**Regia MSS**). The ALARP principle is a core requirement of environmental management under the *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023* ("**the Regulations**"). It requires that environmental impacts and risks associated with the activity are reduced to a level that is ALARP.

The ALARP assessment forms one of the key demonstrations in support of the Environment Plan (**EP**) for the Regia MSS. It complements the environmental impact and risk assessment by evaluating whether further reductions in environmental impacts and risks can be achieved through additional or alternative control measures, and whether any such measures are reasonably practicable to adopt in the context of the activity.

This assessment is supported by:

- The environmental assessments in Appendices D1–D4 and E1–E9, which establish the baseline level of environmental impact and risk after legislative requirements have been applied.
- The risk and impact matrices contained in Annexes 1 and 2 of Appendix B3.
- A stepwise, semi-quantitative evaluation of environmental benefit and associated sacrifice for each control measure considered.

Figures, tables, and supporting materials are provided to clearly communicate the decision-making process and demonstrate compliance with the ALARP requirement of the Regulations.

1.1 Purpose

The purpose of this assessment is to demonstrate that the environmental risks and impacts associated with the Regia MSS have been reduced to a level that is as low as reasonably practicable. It does so by evaluating whether additional or alternative control measures offer environmental benefit that is proportionate to the sacrifice required to implement them. The assessment provides a transparent, stepwise justification for which measures have been adopted and which have not, in accordance with the Regulations.

1.2 Definitions

The following definitions are used throughout this document and their distinctions and nested nature is imperative in being able to reproduce the outcomes of the assessments.

Table F2-1 - Definitions

Term	Definition
Measures	A collective term for anything that eliminates, substitutes, controls, manages, or administers an impact or risk.
Activity limitation	A measure that eliminates or substitutes, constrains, limits, or otherwise restricts the activity such that impacts and risks can be avoided, or lessened to or below acceptable levels.
Control Measure	A system, an item of equipment, a person or a procedure, that is used as a basis for managing environmental impacts and risks of an activity. (OPGGS (Environment) Regulation 5).

Term	Definition
Environmental Performance Standard	A statement of the performance required of a control measure.
Environmental Management System	For an activity, includes the responsibilities, practices, processes and resources used to manage the environmental aspects of the activity.

1.3 ALARP Concept

ALARP is a core element of environmental management in the Regulations. It recognises that while environmental impacts and risks can often be further reduced, not all potential measures are reasonably practicable. ALARP is not a simple cost-benefit exercise — it requires a balanced judgement of the level of risk or impact against the sacrifice involved in implementing further control measures.

The goal of an ALARP assessment is to determine whether additional impact and risk reduction is achievable without incurring sacrifices that are grossly disproportionate to the environmental benefit. To support this, Table F2-1 outlines the key conceptual parameters that influence ALARP assessments.

Table F2-2 - Conceptual parameters in assessing whether ALARP has been reached.

Impact or Risk Reduction Achievable (Intrinsic Effectiveness)	Sacrifice Required for Adoption
Reduced Occurrence: This includes decreasing the occurrence (either likelihood or uncertainty) (E.g., of emissions and discharges).	Financial Cost: The most obvious sacrifice is the direct financial cost of implementing a control measure. This includes the cost of purchasing equipment, technology, or services, as well as any ongoing maintenance and operational costs.
Reduced Severity: This includes decreasing the effect or consequence (E.g., of emissions and discharges).	Time and Effort: Implementing new processes or technologies often requires significant time and effort. This can include the time taken for research and development, training staff, and integrating new systems into existing workflows.
Compliance with Regulations: Meeting or exceeding environmental regulations can improve environmental outcomes and avoid legal penalties.	Operational Disruption: Introducing new control measures can disrupt regular operations. This might mean downtime, reduced productivity, or the need to alter business practices temporarily or permanently.
Long-term Sustainability: Sustainable practices can ensure long-term viability and resilience of the business and the environment.	Resource Allocation: Resources, including human resources, might need to be reallocated. This could mean diverting staff from managing one impact or risk to managing a different or new impact or risk.
Ecosystem Preservation: Protecting natural habitats and biodiversity, which has intrinsic value and can support long-term ecological balance.	Opportunity Cost: Implementing a control measure might mean foregoing other opportunities. For instance, investing heavily in one area of environmental protection might limit a company's ability to invest in other areas.

Measures that offer risk or impact reduction *commensurate with the sacrifice* must be adopted. Further, even measures involving *disproportionate sacrifice* may be required, provided the sacrifice is not *grossly* disproportionate. Only in cases of gross disproportionality can a control measure be justifiably excluded.

This makes it essential that the levels of risk and impact are well understood before the ALARP process begins. These levels were determined through the environmental assessment process outlined in Appendix B3 and applied in the Preliminary Environmental Impact and Risk Assessment, Appendices D1–D4 and E1–E9. Together, they provide the foundation for evaluating which control measures can be considered reasonably practicable.

2 Scope of the ALARP Assessment

The ALARP assessment for the Regia MSS forms a key part of CGG's approach to ensuring that environmental impacts and risks are reduced to a level that is as low as reasonably practicable. The assessment considers each identified risk and impact and evaluates the adoption or rejection of additional, alternative, or improved control measures. The process begins from a realistic baseline, already incorporating all legally required measures and activity constraints.

The scope of the assessment includes:

- Establishing baseline levels of impact/risk and sacrifice using the outcomes of the environmental assessments (Appendices D1–D4 and E1–E9).
- Evaluating discretionary control measures beyond those mandated by legislation or company policy.
- Assessing the environmental benefit of adopting a control measure in terms of additional risk or impact reduction.
- Comparing the benefit to the cumulative sacrifice required to adopt and maintain the control measure (e.g. cost, time, disruption, opportunity cost).
- Determining whether the control measure is reasonably practicable or grossly disproportionate.
- Documenting the rationale for adopting or rejecting each measure.

This structured approach ensures the assessment supports a transparent and traceable demonstration that the environmental risks and impacts of the activity have been reduced to ALARP in accordance with the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023.

2.1 Exclusions from Scope

The ALARP assessment focuses on the decision-making process for adoption/rejection of control measures only. Several other elements of the broader environmental management system are excluded from this assessment, as explained below.

2.1.1 Activity Limitations

Activity limitations are not control measures and are therefore excluded from the ALARP assessment. These limitations form part of the baseline definition and the environmental context in which control measures are assessed. They cannot reasonably be considered in ALARP decisions because:

- Their costs are variable and context-specific, arising from survey design and environmental constraints rather than implementation choices.
- They relate to the activity's scope and objective, not the cost of adopting a control measure.
- They are either complied with or not, lacking a performative or measurable management component.
- They eliminate or substitute risks (at the top of the hierarchy of controls), rather than managing them.

- They are used to set the boundaries of the assessment, forming the baseline against which ALARP can be argued.
- They do not serve as discretionary control measures subject to cost-benefit evaluation.

2.1.2 Environmental Management System

Similarly, supporting measures that are part of the Environmental Management System (found in the Implementation Strategy (Appendix B3)) are part of establishing baselines for the ALARP assessment and excluded from the ALARP assessment. These elements are designed to support the effectiveness of all control measures, not act as control measures themselves. For example, an oil pollution emergency plan or an induction program does not directly protect the environment it is the performance of personnel and the availability of equipment, rather than the plan itself, that delivers environmental protection.

While these measures are essential for ensuring the effectiveness of adopted control measures, they do not form part of the ALARP decision-making process. Rather, they form part of the baseline sacrifice required to manage environmental impacts and risks and are addressed separately in the implementation and performance monitoring framework.

3 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2 - Objections and Claims Raised from Consultation.

4 Establishing ALARP Baselines

The starting point for an ALARP assessment is never assumed to be zero sacrifice or maximum (inherent) impact or risk. This is because:

- Titleholders are legally required to implement certain environmental management measures (e.g. under the EPBC Act or maritime law).
- These measures already incur sacrifice in the form of time, effort, and financial cost.
- They have already contributed to reducing the unmitigated impact or risk associated with the activity.

The ALARP assessment must therefore begin from a realistic and regulated baseline, which includes all legally required measures, and any activity limitations or constraints already committed to that shape how the activity is carried out. It is the combined effect of these measures on residual impact or risk that form the baselines.

4.1 Baseline for Risk and Impact

The baseline level of impact or risk is drawn directly from the outcomes of the environmental assessments (see Appendices D1–D4 and E1–E9), which apply all relevant legislative requirements and activity limitations as the starting point. The ranking values are derived from the risk and impact assessment matrices provided in Annexes 1 and 2 of Appendix B3.

While the nominal values assigned to each impact or risk level originate from these matrices, the subsequent reductions resulting from the adoption of additional control measures are used for relative comparison only. They do not correspond to absolute values in the original matrices but instead support a semi-quantitative and transparent tracking of progress lower toward ALARP.

4.2 Baseline for Sacrifice

The baseline level of sacrifice is defined as the total cost of meeting all relevant legislative requirements and activity limitations for undertaking the activity relevant to each aspect.

This includes:

- The cost of preparing the Environment Plan (EP).
- The cost of complying with environmental management legislation.
- Costs associated with undertaking consultation to gather input into the EP.
- The time value of regulatory engagement and approvals.

This combined sacrifice is expressed in the assessment as a unit value of 1 at the commencement of each individual assessment. All subsequent discretionary control measures are evaluated as proportionate increases above this baseline. Each assessment shows the incremental sacrifice per control measure, or group of control measures, and the cumulative sacrifice as a ratio above the baseline of 1. For example, if the baseline was equal to $100 (ratio = 1) and the cost of the first additional control measure is $50 (ratio = 0.5) then the cumulative total is $150 (ratio 1.5).

4.3 Why This Approach Was Adopted

This method of establishing baselines was selected to ensure that the ALARP assessment does not compare discretionary controls to a hypothetical “do nothing” case, which is inconsistent with regulatory obligations. Further, this approach ensures the marginal benefit of each control measure is evaluated against the actual residual impact/risk reduction it achieves. This reflects accepted good practice that environmental legislation sets the minimum standard, and that each control measure is assumed to be functioning and in place before assessing whether additional reduction is reasonably practicable.

4.4 Consideration of Alternative Approaches

Following feedback during the consultation process, CGG considered several alternative methods for calculating baselines and comparisons. These included:

- Absolute cost comparisons between control measures and total project profit. This approach was not adopted, as it would have required the disclosure of commercially sensitive pricing and contract terms, which is not in CGG’s interests nor a legislative requirement.
- A strict monetary valuation of environmental benefit. This was also rejected, as it fails to consider the effectiveness of control measures and assumes a linear relationship between cost and environmental value, which often does not hold in practice.
- Proportional cost methods, in which additional control measures would be assessed as a percentage of total project costs. This method was considered but ultimately set aside because it risks over-simplifying the ALARP assessment. For example, a low-cost control could be highly effective, while a high-cost control may offer little additional benefit.

CGG's adopted method ensures that the ALARP assessment reflects the context of the project, recognises existing commitments, and applies a balanced, defensible and repeatable framework for assessing the reasonableness of further risk or impact reduction.

5 ALARP Process

The purpose of this process is to assess whether an environmental impact/risk has been reduced to ALARP by progressively evaluating the effectiveness and cost of control measures.

5.1 Assigning Subjective Values

The ALARP process relies on the application of professional judgement and expertise within a structured and calculated method. It is a semi-qualitative process that will vary depending on the participants and the context in which the assessment is made. There follow instructions on how to assign values in this process which aim to reduce subjectivity.

5.1.1 Assigning Intrinsic Effectiveness

A central element of ALARP assessments is determining the degree to which a control measure provides an environmental benefit. This can be otherwise stated as degree to which a control measure reduces environmental impact or risk. For the purposes of this ALARP process, ***intrinsic effectiveness*** is used as a suitable and practical proxy for measuring environmental benefit.

Intrinsic effectiveness refers to the degree to which a control measure, on its own merits, is expected to reduce the impact or risk it is designed to address. In this process, this is expressed as a percentage reduction in the residual impact or risk. A control measure that is 90% intrinsically effective is considered to reduce 90% of the remaining impact/risk for that specific pathway.

This makes intrinsic effectiveness an ideal proxy for environmental benefit because it:

- Quantifies the marginal gain achieved by the control measure.
- Allows comparability across different measures and impact pathways.
- Provides a basis for calculating the residual impact/risk after each step.
- Enables the plotting of environmental return on sacrifice using the ALARP graphs.

Intrinsic effectiveness is not a generic rating but rather a context-specific estimate based on the following attributes:

- Functionality – How well does the measure perform its intended role?
- Availability – Is the measure accessible or deployable when and where needed?
- Reliability – Does it perform consistently in real-world conditions?
- Survivability – Can it maintain its function under expected stressors?
- Independence – Can it operate effectively without relying on other measures?
- Compatibility – Does it integrate well with existing activity design and systems?

The collective baseline measures, and each control measure considered thereafter in the ALARP process, is assigned an intrinsic effectiveness rating based on these characteristics. This rating serves as the quantified expression of its environmental benefit.

5.1.2 Assigning Sacrifice in ALARP Assessments

In the context of this ALARP process, sacrifice is the cumulative burden incurred by adopting the baseline measures and each control measure. Sacrifice is considered in the broadest sense, encompassing not only direct financial costs but also time requirements and broader operational or environmental complications collectively understood as money, time, and trouble.

Sacrifice = Money + Time + Trouble

Each component of sacrifice should be considered and described in qualitative terms in the discussions, as relevant, to underpin the semi-quantitative output required for the assessment.

Money

This refers to any direct or indirect financial outlay associated with the adoption of the measure, including:

- Equipment purchases or hire
- Additional staffing or consultancy costs
- Fuel, maintenance, or other operational expenses
- Cost of training, onboarding, or coordination
- Data processing, integration, or analysis costs

Time

This refers to any extension to the activity duration or any increase in lead time or delay caused by the adoption of a measure. Time-based impacts often carry a compounding effect, as they may extend environmental exposure periods, inflate operational costs, or affect coordination with third parties. Examples include:

- Longer vessel deployment periods
- Delay in acquisition
- Administrative time required to gain approvals or permits
- Increased mobilisation or demobilisation time

Trouble

This refers to all other burdens or trade-offs that may not be directly financial or time-based but still influence the overall cost of adoption. “Trouble” is especially relevant where a control measure increases other environmental impacts or risks, creates practical implementation issues, or introduces uncertainty that itself becomes a risk. This includes:

- Cross-pathway environmental trade-offs (e.g. increased emissions from an additional whale spotter vessel that provides increase protections for whales)
- Operational complexity or safety risks (e.g. deploying gear in tight conditions)
- Regulatory, stakeholder, or reputational risks
- Technical reliability and compatibility issues (e.g. new technologies introducing uncertainty)
- Burden of coordination, logistics, or collaboration

5.2 Step-by-Step Process

1. Identify the environmental impact / risk pathway for consideration.
2. To establish the baseline sacrifice:
    a. Start by identifying (and consider grouping) the:
        i. mandatory mitigation measures already required (by law, regulation, or standards).
        ii. relevant activity limitations.
        iii. management system elements that will contribute to the management of impacts and risks.
    b. Record the results in tabular form using the template at Table F2-3 adding rows for each mitigation measure (or group) that form the baseline. Explain why this measure has been included and what makes it effective. The baseline table should now be completed.
    c. Consider the incremental sacrifice (cost, time, effort) required to comply with all baseline measures in a dollar value where possible and note for later use. This value is not included. Do not record this value in the assessment.
3. Set the baseline impact / risk level using the conclusion of the relevant impact or risk assessment, enter the value in Table F2-4 at both locations with an 'X'.
4. Determine the first measure to be assessed and:
    a. Assign intrinsic effectiveness percentage and enter the value into Table F2-4 at 'Y' and justify this scoring in Table F2-4 (See Section 5.1.1 for instruction).
    b. Consider the incremental sacrifice (cost, time, effort) in a dollar value where possible and using the baseline sacrifice value convert to a ratio for publication. Enter that the ratio value in Table F2-4 at 'Z' and justify this scoring in Table F2-4. Create a running total in the cumulative sacrifice column.
5. Once the estimated intrinsic effectiveness percentage has been assigned calculate the marginal reduction (MR) and residual impact / risk after adoption (Res_{After}) using the formulas:

$$MR = Res_{Previous} \times IE\ (\%)$$

$$Res_{After} = Res_{Previous} - MR$$

Where:

MR = Marginal Reduction (of an impact or risk).

Res (Previous) = Residual impact or risk after the adoption of the previous control measures.

IE = Intrinsic effectiveness of a control measure or group of control measures in the context of the previously considered baseline and additional control measures.

Res (After) = Residual impact or risk after the adoption of the control measure under consideration.

The first measure row should now be completed and the Res $_{After}$ value can be carried down a row to become the Res $_{Previous}$ value for the next control measures to be assessed.

6. Identify the most effective control measure, or group of control measures and in the next row of the table:

    a. Estimate its additional benefit by assigning a percent to its intrinsic effectiveness (IE) in the context of the residual impact / risk of previous control measures (Res $_{Previous}$).

    b. Record the result in Table F2-4 and separately document why the percent of effectiveness has been assigned by discussing the control measures functionality, availability, reliability, survivability, independence, and/or compatibility.

    Note: The next most effective measure doesn't necessarily mean the one with the next highest intrinsic effectiveness. It is preferred that professional judgement is used to attempt to fill gaps in impact / risk management. This may or may not be the control measure attributed with the highest percentage intrinsic effectiveness.

7. Estimate the incremental additional sacrifice (money, time, or trouble) on a monetary basis that it would take to adopt the measure and record the result in the table. Enter the cumulative sacrifice by calculating the running total as the sum of all sacrifices for previously considered and adopted control measures.

8. Keep adding rows to the table, detailing the next most effective control measure, or group of control measures, and assigning its intrinsic effectiveness and incremental sacrifice as done previously. Keep considering additional control measures until the Res $_{Previous}$ is less than a value of 0.5.[1]

9. Plot the data from Table F2-4 (Res Previous and Cumulative Sacrifice) graphically including an order two polynomial trendline. Find the point of inflection on the trendline which is the point at which there are diminishing returns (i.e. there is no amount of sacrifice that is going to reduce the risk or impact further). This is typically the point where the trendline is nearly horizontal. Then, draw in the vertical ALARP threshold line using the point of inflection as the coordinates. Control measures on the left of the ALARP threshold line should be adopted and control measures on or beyond the vertical line can be justifiably rejected.

10. Plot the same data on another graph showing the cumulative sacrifice (line) and reduction achieved (bar) and check that the measure adopted closest to the point of inflection shows that the cumulative sacrifice is clearly grossly disproportionate to the benefits gained. This would be shown by a large and comparatively significant gap between the cumulative sacrifice and the resultant benefit reduction show for the control measure being considered.

[1] This value is justified later.

Table F2-3 - Example Baseline Measures Table

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Measure 1 Title	*Explain why this measure is included, how it managed the impact/risk, and reference its origins.*	*Explain why this measure is effective considering the instructions in Section 5.1.1*
Measure 2 Title		
Measure 3 Title		
Measure 4 Title		

Table F2-4 – Example Step-by-step ALARP Assessment Table

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See previous tables.	-	-	-	'X'	1.0	1.0	See Table F2-2	
2	First measure		'X'	'Y'			'Z'			
3	Second measure									

5.3 Endpoint of the ALARP Assessment

The ALARP assessment reaches its endpoint when it can be demonstrated that any further control measures would require a sacrifice that is grossly disproportionate to the environmental benefit (i.e. risk or impact reduction) that could be achieved. This does not mean that all risk or impact has been eliminated, nor that every conceivable control has been considered. Rather, ALARP requires that all reasonably practicable measures have been identified, assessed in context, and either adopted or justifiably rejected.

Figure F2-1 and Figure F2-2 illustrate this principle. As control measures are progressively adopted, residual risk or impact is reduced and cumulative sacrifice increases. Over time, the environmental benefit gained from each new measure typically diminishes, while the associated sacrifice rises. The point at which this trade-off becomes grossly disproportionate marks the practical and conceptual endpoint of the ALARP process.

5.3.1 Justification for Residual Impact/Risk Threshold of 0.5

A residual impact or risk value of 0.5 has been used as the cut-off point for further assessment in this ALARP process. This value reflects a logical and proportionate threshold based on two key principles:

- A threshold of 0.5 ensures that even relatively low residual values (e.g. 1) must still demonstrate a reduction by at least half before being considered ALARP. For higher residuals, the process requires consideration of multiple control measures to achieve this low level, reinforcing a structured and progressive reduction. This reinforces that greater effort is put towards higher residual levels of impact or risk.
- If the residual level has been reduced to less than 0.5, especially from a higher starting point, this shows a significant and measurable reduction has occurred. Coupling this with the use of a polynomial trendline to identify the point of diminishing returns provides a practical and evidence-based end to the assessment — once the line flattens and residuals are <0.5, enough has been done to reduce the risk or impact to a level that is demonstrably as low as reasonably practicable.

This approach supports transparent decision-making while ensuring the focus remains on material reductions with genuine environmental or safety benefit.

5.3.2 Cost of Further Analysis Endpoint

In accordance with this approach, it is not necessary to assess every potential variation or emerging technology to demonstrate that ALARP has been achieved. Control measures must be assessed relative to the current baseline, which already includes legally mandated and previously adopted measures. The remaining risk or impact must then be weighed against the additional sacrifice required to reduce it further.

A control measure may be considered not reasonably practicable, and therefore rejected for any of the following reasons:

- **Marginal Reduction**: The residual impact or risk is already low, and the additional reduction achievable is minor, offering limited environmental benefit.
- **High Cost**: The measure imposes a high financial or operational burden for only a slight improvement in impact or risk reduction, resulting in diminishing returns.
- **Limited Effectiveness**: The control is unlikely to significantly reduce the relevant risk or impact, and the cost or disruption cannot be justified.

- **Better Alternatives Exist**: More effective or less costly options are available to achieve a similar or greater outcome.
- **Unacceptable Trade-offs**: The measure would interfere with other critical business, safety, or environmental functions in a way that outweighs its benefits.
- **Risk Transfer Without Net Benefit**: The measure shifts the risk or impact without reducing its overall significance, undermining the value of the sacrifice.

These criteria support a structured and transparent conclusion that ALARP has been reached. Justification for the rejection of any control must be documented and linked to the existing risk profile, anticipated effectiveness of the measure, and the scale and nature of the associated sacrifice.

This progressive, contextual method ensures that the ALARP standard is met without turning the assessment into an open-ended or speculative exercise. It aligns with both the regulatory intent of the *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023* and the practical realities of managing environmental impacts and risks in offshore petroleum activities.

5.4 Process Outputs

5.4.1 Tables

Each ALARP assessment includes structured tabular outputs that provide transparency and traceability in the stepwise evaluation of control measures. These tables complement the graphical outputs and discussion points by clearly presenting the rationale, sequence, and comparative value of each control measure assessed. Two key tables are included in each assessment:

1. **Baseline Measures Table**

Table F2-3 is an example table that will be reproduced for each ALARP assessment. This table documents the measures included in the baseline for each specific impact or risk. It identifies the activity limitations, and mandatory measures that are already in place due to regulatory requirements, company standards, or previous design decisions. The purpose of this table is to:

- Establish a clear and consistent starting point for the ALARP assessment.
- Demonstrate that legally required measures and activity limitations have already been applied.
- Show that the residual impact/risk level being assessed is not the unmitigated or inherent level, but rather the level remaining after baseline measures are adopted.

Each entry in the table includes the name of the measure (or group of measures), the reason for its inclusion (e.g. legislative obligation, internal policy), and its intrinsic effectiveness on reducing impact or risk. This ensures clarity in how the baseline was derived and provides a defensible foundation for evaluating additional control measures.

2. Step-by-step ALARP Assessment Table

Table F2-5 is an example table that will be reproduced for each ALARP assessment where each column has the following meanings:

Step	Sequence of control application (starting from baseline)
Short Title	Name of the measure (or group of measures) under consideration
Details of Control Measures	Summary of the measure (or group of measures) under consideration
Res $_{\text{Previous}}$	Impact or risk level before applying this control measure.
Intrinsic Effectiveness (IE):	Estimated % reduction if applied to the baseline.
Marginal Reduction (MR)	Actual reduction achieved from the baseline.
Res $_{\text{After}}$	New impact or risk level after the control measure is applied.
Incremental Sacrifice	Cost or burden added by this control shown as a ratio of cost from the baseline.
Cumulative Sacrifice	Total sacrifice including previous controls shown as a ratio of cost from the baseline
Intrinsic Effectiveness	As described in Section 5.4.3.
Sacrifice Quantum	As described in Section 5.4.3

This table presents the core of the ALARP assessment and captures the progressive evaluation of additional, alternative, or improved control measures. It lists each control measure (or group of control measures) considered and shows:

- The incremental reduction in impact or risk it would achieve relative to the baseline.
- The sacrifice required to implement it, including financial, time, operational, and opportunity costs.

This stepwise format allows the reader to follow the logic of the assessment in a transparent, structured manner. It also enables comparisons across measures and supports the conclusion of whether the final residual level of risk or impact has been reduced to ALARP.

Together, these tables demonstrate that each measure has been considered in context, with due regard to its contribution to impact/risk reduction, its relative sacrifice, and the existing baseline from which it is assessed.

Table F2-5 - Example ALARP Assessment Table (Grey text is instructional and/or should be replaced by the assessor)

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	*4*	1	1	See Baseline Measures Table	*The sacrifice quantum for baseline measures is always 1. Any justification or context that is useful for later comparisons can be included here.*
2	*Next Most Effective Measure*	*Detail of the control measures or group of control measures.*	*4*	*90%*	*3.6*	*0.4*	*0.6*	*1.6*	*Describe and justify the scoring (%) assigned for intrinsic effectiveness highlighting any gaps or uncertainties and following the instructions in Section 5.1.1*	*Describe and justify the scoring for the incremental sacrifice assigned highlighting any assumptions and following the instructions in Section 5.1.2.*
3	*Next Most Effective Measure*	*Detail of the control measures or group of control measures.*	*0.4*	*50%*	*0.2*	*0.2*	*0.2*	*1.8*		
4	*Next Most Effective Measure*	*Detail of the control measures or group of control measures.*	*0.2*	*75%*	*0.15*	*0.05*	*0.8*	*2.6*		

5.4.2 Graphs

Two graphs are used to show the results of each ALARP assessment. They are described below.

1. **Residual Impact/Risk vs Cumulative Sacrifice (Scatter Plot)**

In concept, these graphs are about establishing a rate of return on environmental benefit. This graph shows the progressive adoption of control measures, beyond baseline measures, that reduce impact/risk plotted against the cumulative sacrifice it takes to adopt each subsequent control measure. Once plotted, an order two polynomial line-of-best-fit can be used to show how residual impact/risk decreases as more sacrifice is invested. This helps to identify the point of inflection where additional effort no longer results in proportionate benefit. Once the point of inflection is found, an ALARP threshold can be plotted as a vertical line at that point of inflection. These graphs focus on the efficacy of each control measure as it is confirmed as adopted and helps with the decision such as: *Have you done enough?*

A second-order polynomial trendline is used in preference to linear or exponential trendlines because it best reflects the real-world behaviour of cumulative environmental benefit relative to incremental investment. In the context of ALARP assessments, control measures tend to show non-linear returns: initial actions often yield large reductions in impact or risk with relatively low sacrifice, while later measures offer progressively smaller reductions for greater sacrifice. This creates a natural curve rather than a straight-line relationship.

A linear trendline assumes a constant rate of reduction per unit of sacrifice, which oversimplifies the decision-making process and can misrepresent when grossly disproportionate sacrifice is reached. An exponential trendline, on the other hand, implies a continuously accelerating or decelerating trend, which does not align with the plateau effect typically observed once the most effective measures have been adopted.

The second-order polynomial (a parabolic curve) allows for both the initial steep reduction and the subsequent flattening of the curve, making it ideal for identifying the point of diminishing returns shown by the vertical line originating at the point of inflection of the curve. This is a useful visual cue for determining when ALARP has been achieved. This makes it a more appropriate and defensible choice for evaluating the proportionality of environmental benefit to sacrifice across a range of control measures.

2. **Combined ALARP Chart**

In concept, these graphs are about validating the point of inflection (from the previous scatter plot graph) as a point at which the costs of adopting further measures are grossly disproportionate (not just disproportionate) and providing a visual aid to communicate the stepwise ALARP process. The combined ALARP charts combine a bar chart showing residual impact/risk in discrete steps (i.e. how much each control measure reduces impact/risk) based on its effectiveness and a line chart showing cumulative sacrifice. The visual effect contrasts the size of the benefit each control measure gives (bar height drop) with the amount of sacrifice required to achieve it. These graphs focus on the direct effect of each control measure and highlight the cost-benefit trend. It makes it easy to point out which control measures had the most benefit versus cost and confirms that the point of inflection in the first graph is at a grossly disproportionate level.

5.4.3 Discussions

Each ALARP assessment includes three structured discussion components that accompany the tables and graphs. These discussions are essential to documenting how values were assigned, providing justification for key assumptions, and supporting the interpretation of outputs.

Baseline 'Inclusion Rationale'

A column in Table F2-3 includes a discussion that should explain how the baseline residual impact or risk and baseline sacrifice were established. It provides the context for the first row of the assessment table and ensures transparency in defining the starting point for all subsequent evaluation. The baseline cost established also sets the relevant baseline sacrifice ratio for that assessment.

Intrinsic Effectiveness Discussion

This discussion, detailed in each impact and risk ALARP Assessment table, justifies the percent effectiveness assigned to each control measure (or group of measures) in the context of the residual impact or risk remaining at that point in the assessment. It is linked directly to Step 4b of the process and supports the calculation of marginal reduction and residual values.

For each measure considered, the discussion should address:

- How the measure functions to reduce the impact or risk (i.e. mechanism of effect),
- One or more of its intrinsic characteristics that influence effectiveness, such as:
  - Functionality (how well it performs).
  - Availability (how accessible or deployable it is).
  - Reliability (how consistently it performs).
  - Survivability (its robustness under expected conditions).
  - Independence (whether it operates effectively without relying on other measures).
  - Compatibility (whether it works well with previously adopted measures or the baseline activity design).

This qualitative explanation supports the numerical effectiveness percentage and helps show that values were assigned with technical judgement and context-specific reasoning.

Sacrifice Quantum Discussion

This discussion, detailed in each impact and risk ALARP Assessment table, justifies the estimated additional sacrifice associated with adopting each control measure. It supports the value entered in the process and ultimately feeds into the cumulative sacrifice curve used in graphing and inflection point analysis.

The discussion will:

- Identify the nature of the sacrifice — whether it relates to financial cost, additional time, increased effort, or other opportunity costs (e.g. lost data, reduced survey efficiency).
- Where a dollar estimate is used, explain what is included in the estimate and whether it represents one-off or ongoing costs and be converted to a ratio.
- Discuss any non-monetary trade-offs, such as:
  - Increased exposure to different environmental risks.
  - Reduced safety margins.
  - Disruption to core activity objectives.

This discussion ensures that the sacrifice values are understood not just numerically, but in terms of real-world implications and helps the reader evaluate whether a control measure's cost is reasonably proportionate to the benefit achieved.

Alternative, Additional, or Improved Control Measures Discussion

As part of each ALARP assessment, a structured and systematic process is applied to ensure that all reasonably practicable control measures are identified and evaluated. This includes consideration of additional, alternative, or improved measures before, during, and after the stepwise assessment of control measures. The intent is to ensure that the assessment demonstrates that current control measures adopted are the most effective in the circumstance and that no viable opportunities for further reduction have been overlooked.

Before beginning the stepwise ALARP assessment, a feasibility scan is undertaken to identify the full range of potentially applicable control measures for the impact or risk pathway under consideration. This includes measures that are:

- Additional to those already included in the baseline.
- Alternative to proposed measures that may offer a different approach to risk reduction.
- Improved versions of existing measures that could increase effectiveness or efficiency.

This feasibility search is not limited to measures previously implemented by the titleholder. It also includes emerging technologies, peer-reviewed recommendations, relevant person suggestions, and relevant guidance or regulatory instruments. Importantly, identification at this stage does not imply that the measure must be implemented or fully assessed, but rather that it has been acknowledged and will be considered through the assessment process.

Throughout the step-by-step ALARP assessment, each control measure or group of measures is considered in order of effectiveness. At each step, the opportunity to substitute in additional, alternative, or improved control measures is explicitly evaluated before proceeding to the next step. This may result in refinement of the control measure selection, modification of grouping, or comparative evaluation to determine whether the current selection represents the best practicable approach at that stage. This ongoing consideration ensures that the process is adaptive and incorporates the best available information as the assessment progresses.

After the primary assessment has been completed and the point of diminishing returns has been reached, the final step is to review any remaining additional, alternative, or improved control measures not already addressed. These are evaluated to determine whether their adoption would result in any material benefit to impact or risk reduction, or whether the cost and effort associated with their implementation would be clearly grossly disproportionate.

5.5 Ensuring Integrity in ALARP Assessments

ALARP assessments rely on structured judgment, evidence-based reasoning, and transparency. However, the method is also inherently susceptible to manipulation if not undertaken with discipline and integrity. Two common avenues of manipulation include:

- **Overestimating Intrinsic Effectiveness**: Assigning a control measure a higher-than-warranted effectiveness score can artificially reduce the residual impact/risk early in the process. This can result in fewer subsequent control measures being assessed or adopted and may falsely suggest that risks or impacts have been reduced to ALARP levels.

- **Overestimating Sacrifice**: Similarly, inflating the estimated cost, time, or operational burden (i.e. sacrifice) of adopting a control measure can lead to the premature rejection of otherwise reasonable measures by classifying them as grossly disproportionate.

To avoid these pitfalls, the assessment should be guided by a disciplined and conservative approach:

- **Underestimate Intrinsic Effectiveness Where Justifiable**: Wherever a level of uncertainty exists in the functional performance of a control measure, it is appropriate to conservatively assign a slightly lower effectiveness score. This helps ensure that the assessment does not overstate environmental benefit and that opportunities for further improvement are not prematurely excluded.
- **Strengthen Sacrifice Justifications**: Sacrifice estimates should be clearly documented with transparent assumptions, references to comparable costs or operational experience, and a clear distinction between incremental and baseline effort. Conservative framing should be avoided unless supported by evidence, and vague estimates should not be used to dismiss measures without adequate rationale.

Those completing and reviewing ALARP assessments should be alert to signs of these manipulations. An overly rapid drop in residual impact/risk, repeated rejection of measures based on loosely justified sacrifice, or a pattern of assigning very high effectiveness scores with minimal explanation may indicate that the assessment is not being applied rigorously.

Maintaining a disciplined and transparent approach ensures that ALARP decisions genuinely reflect environmental performance that is ALARP, rather than merely defensible on paper. Annex 3 - Ensuring Integrity in ALARP Assessments provides the guidance that CGG gave its ALARP assessors and ALARP reviewers to ensure the integrity of the process.

6 ALARP Assessment – Impacts

Following the completion of the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4), and the subsequent full impact assessments (Appendices E1-9), this ALARP assessment covers the following impact pathways:

- Change to benthic habitat from anchoring.
- Change to local air quality, climate, or ecosystem dynamics from atmospheric emissions.
- Change to water quality, fauna behaviour, or physical condition from planned discharges.
- Change to the functions, interests, and activities from physical presence.
- Change in fauna behaviour, hearing capacity, or physical condition from underwater sound.
- Change in fauna behaviour from artificial light

The following sections of this document assess each impact pathway in turn.

6.1 Benthic Disturbance

This impact was assessed in the PEIRA. Initially, the following measure was adopted to remove this cause effect pathway: no anchoring permitted within the activity planning area. However, due to the possible deployment of anchored acoustic monitoring buoys as part of the Fauna Management Plan, this pathway re-emerged following updates to regulatory guidelines.

The nature and scale of this impact is so small and necessary for protection of an important species that an abbreviated demonstration is applied in this case.

The possible deployment of up to three anchored acoustic monitoring buoys is expected to result in localised, minor, and reversible disturbance to the seabed, with each anchor and associated gear occupying approximately 2 square metres. This scale and type of interaction is comparable to routine demersal fishing practices (e.g. lobster potting) already occurring in the area and does not involve dragging, excavation, or long-term placement.

Sensitive benthic habitats that would be unable to tolerate this extremely small disturbance are not expected to occur and routinely experience these impacts from fishing activities and vessel anchoring prolific in the areas the buoys are expected to be located.

The only control measure reasonable to adopt is a procedure to select deployment locations such that mapped features of ecological significance are avoided.

Given the very limited footprint, temporary nature of the interaction, the tolerance of the benthic habitat to these small-scale effects, and the benefits gained for marine fauna protection, no further control measures are reasonably practicable to reduce the environmental impact of anchoring. Alternative buoy designs (e.g. free-floating or mid-water) are not viable due to the need for positional stability in offshore conditions and would introduce operational reliability risks without meaningfully reducing environmental impacts. On this basis, the impact of benthic disturbance is ALARP.

6.2 Atmospheric Emissions

6.2.1 Baseline

Table F2-6 specifies the activity limitations, legislative requirements, and components of the implementation strategy elements have been considered in the establishment of a baseline impact level and baseline quantum of sacrifice.

Table F2-6 - Baseline Measures - Atmospheric emissions

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Exclusive Use of Marine Diesel Oil (MDO)	MDO is a low-sulphur fuel (<0.5% sulphur by mass) that complies with MARPOL Annex VI and Australian law. It avoids the need for exhaust gas cleaning systems and provides cleaner combustion than residual fuels.	High. This measure eliminates most sulphur oxide emissions and significantly reduces particulate and other noxious emissions. It is highly functional and reliable.
MDO-specific bunkering, fuel sampling, and quality verification	Ensures that only compliant fuel is used throughout the operation, minimising the risk of non-compliance and environmental breaches.	High. Provides independent verification of compliance and ensures emission reductions are consistently achieved across the duration of the survey.
Maintenance of compliant engines and emission control systems	Required to support the use of MDO and maintain combustion efficiency and emissions performance.	High. Enables consistent emissions reduction through proper engine function and compatibility with low-sulphur fuel.
Emissions recordkeeping and compliance verification	Administrative burden required to demonstrate compliance with MARPOL Annex VI. Forms part of legal obligations and ensures transparency and auditability.	Moderate. While indirect, this measure supports ongoing compliance and enhances the effectiveness of other baseline measures.

The outcome of the impact assessment (conducted in the PEIRA) for atmospheric emissions was that the effect was ranked as negligible (1) and the uncertainty ranked as low (2). Therefore, the residual impact after the application of baseline measures is 3.

The quantum of sacrifice for complying with the baseline has been calculated and includes the following:

- The commitment to use Marine Diesel Oil (MDO) as the sole fuel type throughout the survey, which meets the requirements of Regulation 14 of MARPOL Annex VI and the Protection of the Sea (Prevention of Pollution from Ships) Act 1983. This fuel contains no more than 0.5% sulphur by mass, in accordance with the International Maritime Organization's global sulphur cap and eliminates the need for exhaust gas cleaning systems. While MDO is significantly more expensive than higher-sulphur residual fuels, its exclusive use represents a necessary and unavoidable cost to comply with Australian law and international obligations.
- Additional costs included in the baseline sacrifice include MDO-specific bunkering, fuel sampling and quality verification, and the maintenance of compliant engine systems and emission controls. These measures are mandatory for lawful operation in Australian waters and form part of the base level of sacrifice.
- The administrative burden associated with emissions recordkeeping and compliance verification under MARPOL Annex VI is also included.

These combined costs and efforts form the cumulative baseline sacrifice, which is assigned a unit value of 1.0 in the ALARP assessment. This allows subsequent discretionary control measures to be evaluated proportionally.

6.2.2 Assessment

Table F2-7 shows the step-by-step process followed for the ALARP assessment of atmospheric emissions. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-7.

6.2.3 Consideration of Alternative, Additional or Improved Control Measures

In accordance with the ALARP assessment process, CGG has considered a range of additional, alternative, and improved control measures that might reduce atmospheric emissions beyond those already adopted in the baseline. While these measures were technically feasible in some instances, each was assessed in the context of the small residual impact remaining after implementation of the legally mandated baseline measures. As such, all were found to involve grossly disproportionate sacrifice relative to their marginal environmental benefit and were therefore rejected.

Advanced Emission Reduction Technologies

This option included the potential use of exhaust gas cleaning systems (commonly known as scrubbers), selective catalytic reduction (SCR) systems, and the retrofit of more environmentally advanced engines. These systems are proven in the maritime industry and can reduce emissions effectively when used with heavy fuel oils. However, in the context of this activity—where Marine Diesel Oil (MDO) is already in use and compliant with the 0.5% sulphur limit—the additional emissions reductions offered by such technologies are negligible. Retrofitting costs, downtime, integration risks, and increased operational complexity were assessed, and the measure sacrifice was estimated at 100.0, far exceeding any potential incremental benefit.

Alternative Fuels

The use of alternative fuels such as liquefied natural gas (LNG) or hydrogen was also considered as a substitution for MDO. These fuels can deliver cleaner combustion and reduced atmospheric emissions, especially when replacing residual or bunker fuels. However, the environmental benefits compared to already low-sulphur MDO are marginal in this context. Further, the technical and logistical challenges of adapting a seismic survey vessel to run on LNG or hydrogen—including lack of supply infrastructure, vessel compatibility, and regulatory hurdles—render this option technically unfeasible at present. The measure sacrifice was estimated at 200.0, due to the need for substantial capital investment and operational redesign.

These evaluations support the conclusion that no further practical control measures exist that could meaningfully reduce atmospheric emissions from the Regia MSS without incurring clearly excessive cost, effort, or operational compromise. The residual impact has therefore been reduced to ALARP.

Table F2-7 - Step-by-step ALARP Assessment - Atmospheric Emissions

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	3	1	**1**	The baseline measures collectively provide a comprehensive and enforceable framework for minimising emissions. The use of low-sulphur Marine Diesel Oil (MDO) ensures compliance with MARPOL Annex VI and significantly reduces sulphur oxide and particulate matter emissions. Mandatory bunkering controls, fuel sampling, and maintenance of compliant engine systems ensure these reductions are reliably achieved. Recordkeeping and verification measures add an administrative compliance layer, ensuring transparency and auditability. These baseline measures are highly effective and have little to no dependency on other systems. Their effectiveness is primarily driven by their legal status.	The baseline sacrifice includes the higher cost of MDO relative to residual fuel oils, expenses associated with fuel sampling and quality verification, and the ongoing maintenance of compliant engine systems. These costs are substantial and unavoidable, as they represent legal minimum standards for operation in Australian waters. The administrative burden associated with emissions recordkeeping under MARPOL Annex VI also adds time and resource requirements. These baseline costs are assigned a unit value of 1.0 and reflect a significant proportion of total emissions mitigation expenditure.
2	CGG Marine Assurance System	Company-wise system that ensures all emissions-related compliance processes and vessel audits are completed.	3	90%	2.7	0.3	0.1	**1.1**	This system supports emissions management by ensuring that environmental requirements are embedded within vessel selection, auditing, and operational readiness procedures. It includes pre-survey OVID-style inspections, vessel vetting, crew briefings, and assurance reviews. Its functionality is high because it enhances implementation of already effective control measures. It is	The Marine Assurance System is part of CGG's existing operational framework, meaning much of its structure is already established. While not insignificant, the incremental cost of applying it to this specific emissions context is relatively low. It involves internal auditing and oversight rather than the deployment of new systems or equipment. However, the measure requires experienced personnel and

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
									reliable and compatible with all baseline measures, ensuring that procedural and technical standards are upheld consistently across the operation. However, the marginal benefit is small due to the already low residual impact following baseline compliance.	planning effort. Given the minimal remaining impact to be reduced (Res = 1.0), even this relatively small additional cost is proportionally significant—but it remains reasonable. This justifies its adoption.
3	Energy Efficiency Operating Procedures	Procedures to reduce emissions through fuel-efficient operations (e.g., speed optimisation, load balancing).	0.3	30%	0.09	0.21	1.5	**2.6**	Energy Efficiency Operating Procedures (EEOPs) are rated at 30% effectiveness due to their capacity to reduce emissions further by lowering fuel consumption. They improve operational efficiency during transits, standby, and low-activity phases. Their performance is functional, available, and highly compatible with existing baseline measures.	The cost of implementing EEOPs is minimal however a seismic survey relies on keeping a true heading at a given speed to improve data quality. Therefore, implementing these procedures for the duration of the survey is of high cost and so is given a sacrifice score of 1.5.

6.2.4 Results

Figure F2-1 displays the progressive ALARP assessment for the impact pathway of atmospheric emissions, plotting impact reduction against cumulative sacrifice. Each point on the graph represents a control measure (or group of measures), beginning with baseline compliance and progressing through discretionary enhancements.

The baseline measures achieve most of the impact reduction and are plotted at a cumulative sacrifice of 1.00. These are considered essential for lawful operations and establish the starting point of the assessment.

The next control measure, CGG Marine Assurance System, adds oversight and enforcement capacity, resulting in a modest additional reduction in residual impact. Its low cost and functional compatibility with existing systems place it well before the ALARP threshold, indicating that it is a proportionate and reasonable measure.

A third measure, Energy Efficiency Operating Procedures (EEOPs), adds minimal cost and further reduces emissions by optimising vessel operations (e.g. speed adjustments and load balancing). However, due to the already low residual impact after baseline mitigation measures, and the high relative sacrifice, the environmental benefit of this control measure is beyond the ALARP threshold drawn at the point of diminishing returns and thus has not been adopted.

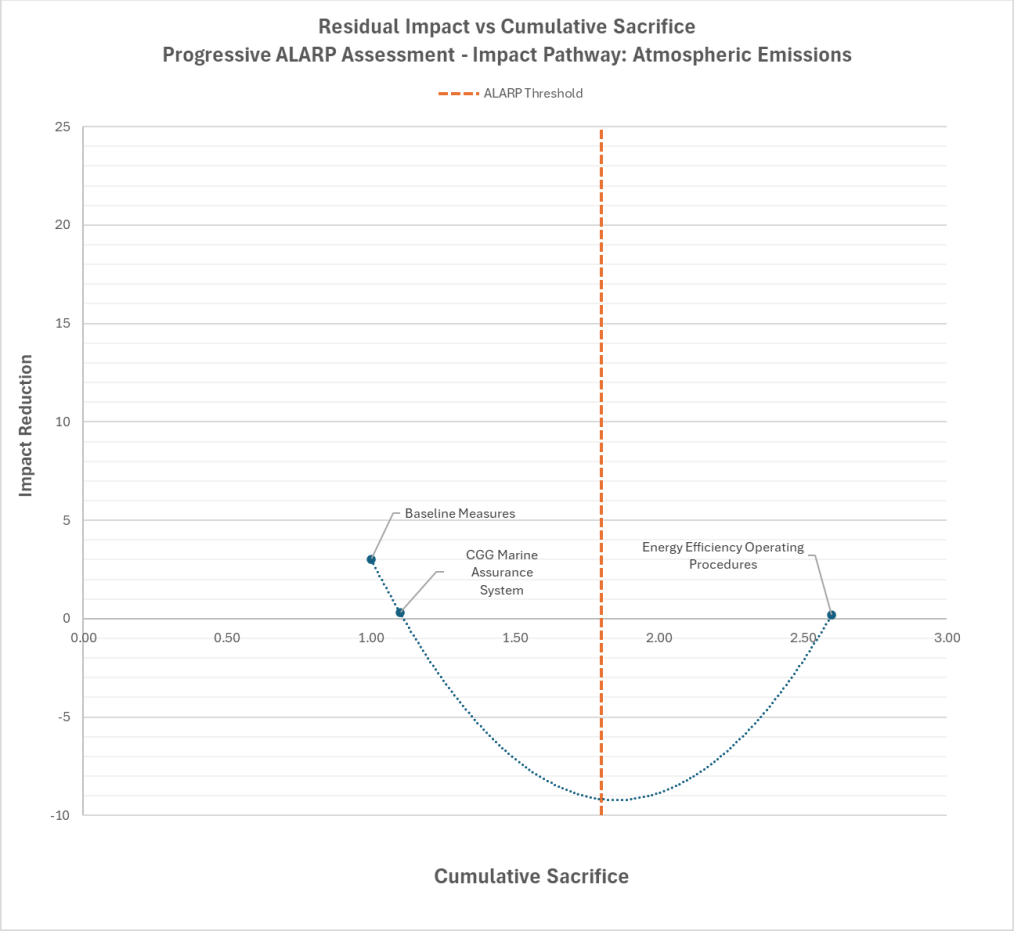

Figure F2-1 - Residual Impact vs Cumulative Sacrifice for Atmospheric Emissions. This chart illustrates the diminishing environmental benefit of additional control measures as cumulative sacrifice increases.

Figure F2-2 presents a combined view of the residual impact reduction (bar) and cumulative sacrifice (line) associated with each control measure or group adopted or considered in the ALARP assessment for atmospheric emissions.

The baseline measures, shown as the first and tallest bar, deliver the greatest reduction in atmospheric emissions, with a residual impact reduction value of 3.0. The CGG Marine Assurance System, reflected as the second bar, contributes a modest additional environmental benefit by ensuring that emissions-related protocols are consistently implemented and audited. The associated sacrifice is small relative to the benefit, resulting in a proportionate and adopted control measure.

The third measure considered aims to reduce emissions further by optimising vessel operation (e.g. speed adjustments and fuel usage efficiency). However, this measure provides only marginal benefit in the context of already low residual emissions and incurs a relatively high cumulative cost. As indicated by the steep rise in the cumulative sacrifice line with little corresponding impact reduction, EEOPs were rejected as grossly disproportionate.

This chart provides visual confirmation that most of the emissions reduction is achieved through baseline compliance, with only one additional discretionary measure adopted, and further options confirmed to show gross disproportion.

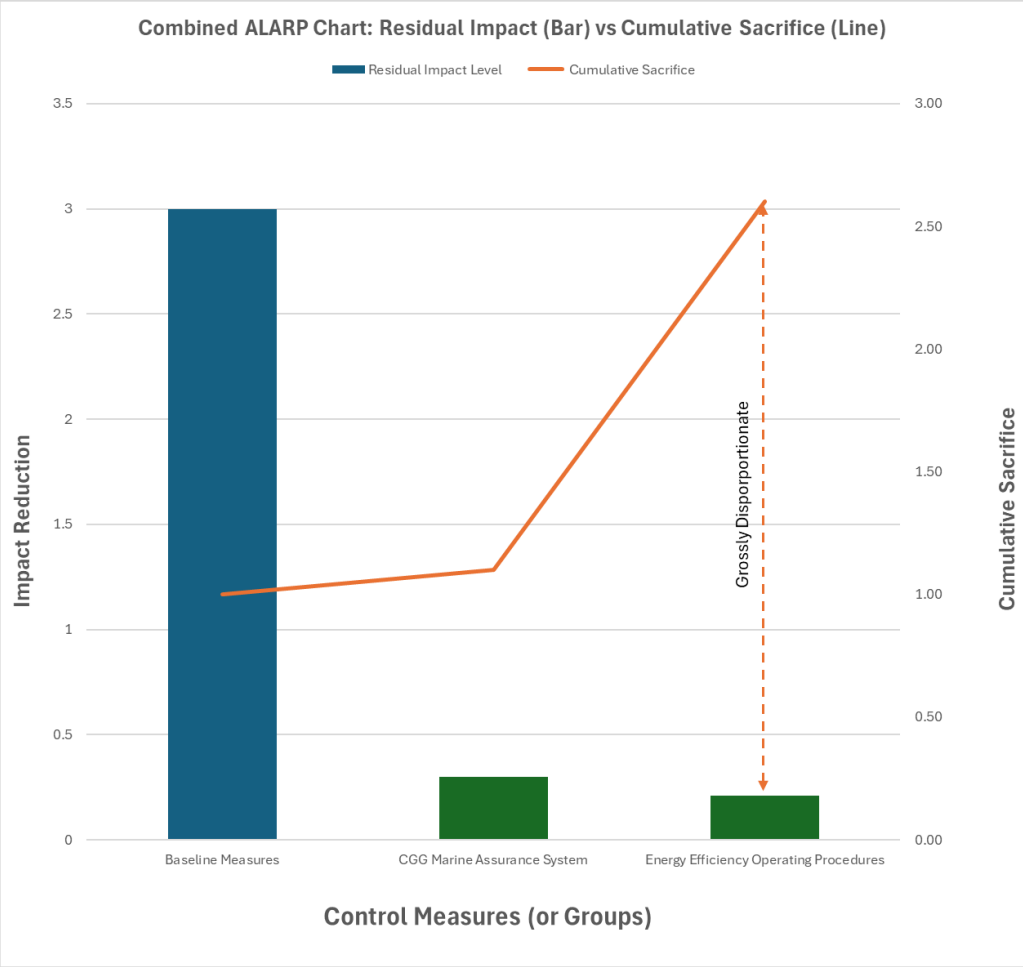

Figure F2-2 - Combined ALARP Chart: Residual Impact (Bar) vs Cumulative Sacrifice (Line) for Atmospheric Emissions. Most impact reduction is achieved through baseline measures.

6.3 Planned Discharges

6.3.1 Baseline

Table F2-8 specifies the activity limitations, legislative requirements, and components of the implementation strategy elements have been considered in the establishment of a baseline impact level and baseline quantum of sacrifice.

Table F2-8 - Baseline Measures – Planned Discharges

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
CGG Marine Assurance System	Ensures compliance with all relevant maritime discharge standards including MARPOL and Marine Orders. Includes vessel vetting, pre-survey inspections, and operational assurance processes.	High. This measure ensures planned discharges such as bilge and wastewater are managed in accordance with international law. It is functional, reliable, and compatible with all vessel operations.

The outcome of the impact assessment (conducted in the PEIRA) for planned discharges was that the effect was ranked as negligible (1) and the uncertainty ranked as low (2). Therefore, the residual impact after application of baseline measures is 2.

The quantum of sacrifice for complying with the baseline has been calculated and includes:

- The implementation of the CGG Marine Assurance System, which includes vessel audits, discharge protocol reviews, and contractor pre-qualification requirements.
- Administrative oversight to ensure discharge equipment and handling procedures meet legal standards.
- Ongoing operational effort to maintain vessel discharge performance in compliance with regulatory expectations.

These measures are embedded into CGG's broader management system and are well established. Accordingly, the cumulative baseline sacrifice is assigned a value of 1.0 to enable proportional comparison with subsequent measures.

6.3.2 Assessment

Table F2-9 shows the step-by-step process followed for the ALARP assessment of planned discharges. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-9.

Table F2-9 - Step-by-step ALARP Assessment – Planned Discharges

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	2	1	**1**	The CGG Marine Assurance System ensures that all discharges are compliant with international maritime discharge standards (e.g. MARPOL). It is functional, reliable, and fully integrated with CGG's existing assurance processes, including vessel audits, inspections, and contractor pre-qualifications.	Assigned a value of 1.0 to reflect the normal cost of prequalification, discharge compliance verification, and vessel inspection protocols. These are routine and embedded company practices and not seen as discretionary expenditure.
2	Enhanced Wastewater Treatment	Advanced filtration or chemical treatment systems to reduce pollutants in discharged water.	2	5%	0.1	1.9	8	**9**	Enhanced wastewater treatment systems offer marginal additional reductions in trace pollutant concentrations but provide negligible environmental benefit due to already low-volume and regulated discharges. The systems are technically feasible but redundant in this context.	These systems are expensive to retrofit, especially for seismic support vessels, and involve increased maintenance costs. With little added environmental benefit, the sacrifice is grossly disproportionate and is assigned a value of 8.0.
3	Zero Discharge Systems	Full containment and post-survey disposal of wastewater and bilge.	1.9	5%	0.095	1.805	8	**17**	Zero discharge systems eliminate planned discharges by capturing and storing all waste fluids for later disposal. However, given the small volumes and low risk, the environmental benefit of this approach is negligible.	These systems are proven in other industries but require costly modifications and space onboard. The operational burden and poor cost-benefit ratio render the measure grossly disproportionate, with a sacrifice rating of 8.0.

6.3.3 Consideration of Alternative, Additional or Improved Control Measures

In accordance with the ALARP assessment process, CGG considered a range of additional, alternative, and improved control measures that might reduce the impact associated with planned discharges beyond those already achieved through the baseline. Given the low level of residual impact, all measures considered were determined to offer negligible benefit or involve grossly disproportionate sacrifice.

Recycling and Reuse

This option explored the potential for onboard water recycling systems to reduce the volume of planned discharges. However, due to the low discharge volumes associated with this activity and the complexities involved in installing and maintaining such systems aboard seismic vessels, the net benefit was found to be negligible. The measure sacrifice was estimated at 0.8. Additionally, human health and hygiene considerations added complexity and risk. The measure was rejected.

These evaluations support the conclusion that the residual impact from planned discharges during the Regia MSS has been reduced to ALARP.

6.3.4 Results

Figure F2-3 illustrates that the residual impact after applying the baseline measures is already low (assigned a value of 3). Two additional control measures were evaluated to determine whether further reductions could be justified. However, these measures provide only marginal environmental benefit while introducing substantial additional cost and complexity.

Despite their technical feasibility, the environmental benefit curve clearly flattens after the baseline, and both additional measures fall well beyond the ALARP threshold indicated on the graph. This shows that the cumulative sacrifice required to adopt these measures is grossly disproportionate to the limited improvement in environmental outcome they would deliver. As such, no further measures are warranted, and the impact of planned discharges is considered reduced to ALARP.

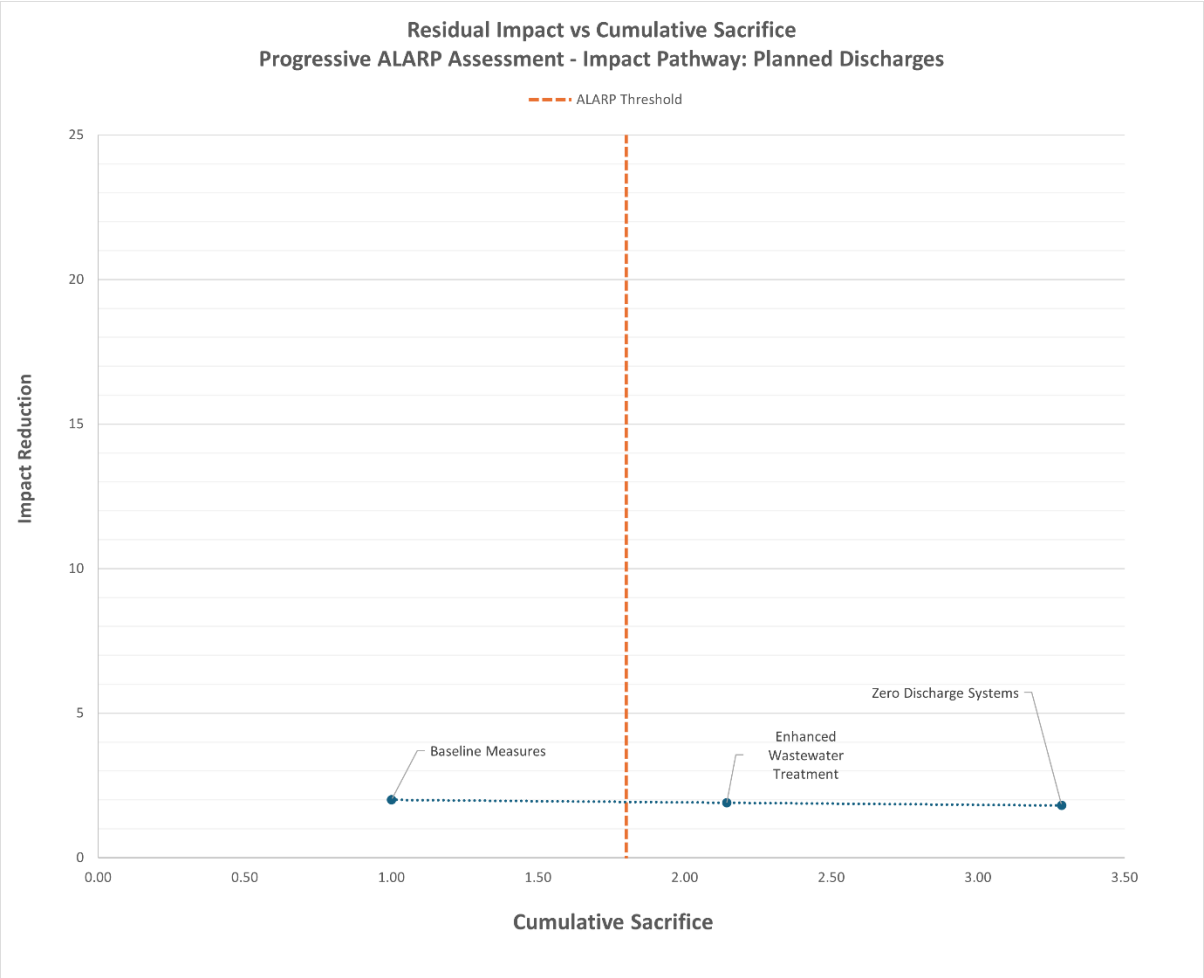

Figure F2-3 -Residual Impact vs Cumulative Sacrifice – Planned Discharges. The graph illustrates the progressive reduction in impact from planned discharges as control measures are considered, plotted against the cumulative sacrifice required to implement each measure.

Figure F2-4 is a combined ALARP chart which presents both the residual impact reduction (bars, left axis) and the cumulative sacrifice (line, right axis) for control measures addressing planned discharges. The baseline measures achieve a substantial reduction in impact with minimal sacrifice. The next two measures offer almost no additional reduction in impact (as they target discharges already reduced to minimal levels) but incur increasingly significant costs. The graph confirms that both control measures clearly exceed the point of gross disproportionality. This graph reinforces that, for this impact pathway, environmental outcomes are best managed through compliance with baseline maritime discharge standards and oversight mechanisms, without the need for more extreme and costly measures.

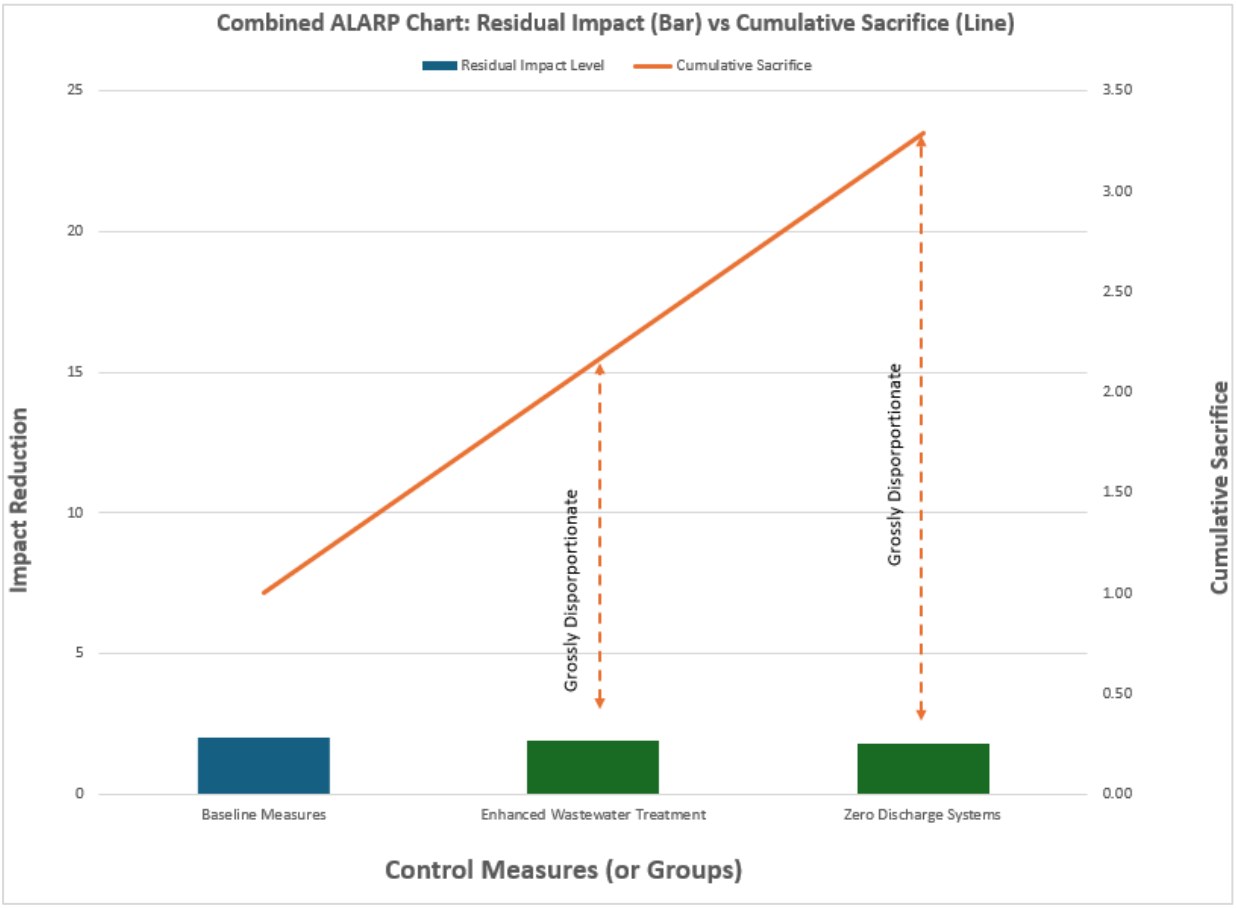

Figure F2-4 - Combined ALARP Chart – Planned Discharges. This chart overlays residual impact levels (bars) with cumulative sacrifice (line) across control measures.

6.4 Physical Presence

6.4.1 Baseline

Table F2-10 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline impact level and baseline quantum of sacrifice.

Table F2-10 - Baseline Measures - Physical Presence

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Activity limitations	The activity limitations derived through consultation have ensured that it is possible for the survey to be undertaken in a manner that minimises interference with other marine users.	These commitments provide certainty to other marine users and keep the impacts of physical presence to a minimum.
CGG Marine Assurance System	This measure includes the CGG Technical Operations Manager and the Quality Control Representative along with all the practices and processes required to safely undertaken the activity. It is considered by CGG as integral to undertaking any activity.	It is in CGG's interests to cooperate with other marine users and CGG's and its contractors are experienced in marine operations.
Support Vessel	The support vessel is another company minimum standard and works to remove obstructions and communicate with other marine users. It'll be partly responsible for implementing the On-Water Communications Plan.	This measure ensures the uncertainty levels associated with this impact are kept at low levels through communications on the water and forward planning with other marine users.
Consultation Management System	The CMS ensures that multiple forms of communication are used to compliment the on-water comms efforts. This measure provides forward operations look ahead notifications to those who requested it.	This measure increases the number of communications channels and provides forward notifications, adding to the effectiveness of the other measures.
Streamer Tail Buoys	This measure ensures that the ends of the submerged towed streamers can be detected.	This measure means that other marine users know which areas to avoid after the survey vessel has passed an area of interest and when it may be safe to return to the area.
Sail Line Plan	This document governs and coordinates the activity on the water and is agreed by CGG and all contracted parties prior to the commencement of the survey.	This document provides alignment between different vessels and contractors and therefore reduces impacts.

The outcome of the impact assessment for physical presence was that the effect was ranked as moderate (3) and the uncertainty ranked as low (2). Therefore, the residual impact after the application of baseline measures is six (6).

The quantum of sacrifice for complying with the baseline has been calculated and includes the following:

- While the baseline measures adopted to manage physical presence are demonstrably effective, their present-day cost to CGG is relatively low. The activity limitations (such as exclusion zones, depth constraints, and block restrictions) are the result of design

compromises made through consultation. These limitations do not represent a direct financial outlay, but they restrict survey coverage and reduce the area of interest available to CGG, effectively diminishing potential data yield and commercial flexibility. This trade-off forms part of the embedded sacrifice.

- The other systems and plans included in the baseline—such as the Marine Assurance System, Consultation Management System, Sail Line Plan, and associated on-water procedures—are the product of years of operational experience. While they no longer carry high implementation costs, their effectiveness today reflects historical investment in systems development, staff training, and lessons learned through previous campaigns. In this sense, the cost has already been borne and is embedded in CGG's standard practice, even though the marginal cost of applying them to the Regia MSS is little.

As a result, while these measures significantly reduce residual risk and contribute to the credibility of the baseline, only a small proportion of their historical cost is allocated to the baseline sacrifice in this ALARP assessment. The cumulative baseline sacrifice is therefore assigned a conservative unit value of 1.0, with the understanding that the cost-efficiency of these measures is high due to CGG's prior experience and integration of these processes into standard operations. These combined costs and efforts form the cumulative baseline sacrifice, which is assigned a unit value of one (1) in the ALARP assessment. This allows subsequent discretionary control measures to be evaluated proportionally.

6.4.2 Assessment

Table F2-11 shows the step-by-step process followed for the ALARP assessment of physical presence. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-11.

Table F2-11 - Step-by-step ALARP Assessment – Physical Presence

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness Section 5.4.3 Disc	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	6	1	1	The baseline measures include a combination of activity limitations and procedural systems designed to minimise interference with other marine users. This includes spatial restrictions developed through consultation, CGG's Marine Assurance System, the use of a support vessel, tailored on-water communications protocols, and notification systems via the Consultation Management System. Collectively, these controls are highly effective due to their compatibility, availability, and the way they operate as integrated standard procedures.	The baseline sacrifice reflects the accumulated investment CGG has made in operational systems, consultation processes, and support infrastructure over time. While the marginal cost of their implementation on any single project is relatively low, they represent years of refinement and are treated here as the foundational cost of doing business responsibly.
2	Adjustment Protocol	This procedure ensures monetary adjustment for any unreasonable interference with other marine users.	6	90%	5.4	0.6	2	3	The Adjustment Protocol provides financial assurance to other marine users in the event of unreasonable interference. Its functionality, availability, and compatibility make it highly effective at mitigating conflict and maintaining good faith with stakeholders. By offering a transparent and pre-agreed resolution pathway, it significantly reduces the impact of spatial overlaps and conflict escalation.	This is primarily an administrative measure, requiring upfront development of a protocol and internal commitment to follow through. Its costs are minor relative to the overall activity budget and are more than offset by the value of resolving disputes efficiently without recourse to litigation or lengthy negotiation.
3	Fisheries Liaison Officer (FLO)	This is a dedicated competent person available in a local port able to be responsive to any immediate concerns, provide a focal point for queries, and support	0.6	90%	0.54	0.06	0.05	3.05	The FLO serves as a direct point of contact for fishers and other marine users. Its functionality, availability, and independence make it a highly responsive and effective control measure. The ability to provide real-time support, local presence, and continuity across interactions contributes to strong stakeholder confidence and early resolution of concerns.	The measure has a low financial footprint—generally requiring part-time engagement of a locally based professional—but delivers high returns in maintaining relations and avoiding unnecessary delays. Its incremental sacrifice is minimal and fully justified by its stakeholder-facing role.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness Section 5.4.3 Disc	Sacrifice Quantum
		compensation claims.								
4	Petroleum SIMOPS Plan	Ensures coordination of activities with other titleholders in the region to minimise interference.	0.06	90%	0.054	0.006	0.025	3.10	The SIMOPS plan ensures operational coordination with other offshore petroleum activities, reducing the risk of conflict or safety issues. Its functionality, compatibility, and survivability in complex operating environments make it a trusted tool for managing shared marine spaces. It formalises what might otherwise be ad hoc communications, preventing misalignment or unintentional interference.	This control is primarily procedural, building on existing industry practice. It requires updates to project documentation and alignment with third-party operational schedules. The cost is minor and primarily borne during planning, making it a low-burden but high-value measure.
5	Sea Country Protection Plan	This measure facilitates the identification and management of new information, relevant to the activity, through collaboration of First Nations people who decide to be part of the program.	0.006	50%	0.003	0.003	0.10	3.2	The Sea Country Protection Plan provides a culturally appropriate pathway for Traditional Owner groups to engage with CGG regarding marine access or presence. It reflects availability, independence, and compatibility with other stakeholder management processes. While not a control measure, it meaningfully reduces potential social impact.	This program is modest in cost, generally involving coordination with internal or contracted community engagement professionals. It strengthens CGG's social licence to operate and ensures marine access issues are managed respectfully and constructively.

6.4.3 Consideration of Alternative, Additional or Improved Control Measures

Given the inherent nature of marine seismic surveys, the physical presence of vessels and equipment in the marine environment cannot be eliminated. As such, a comprehensive suite of control measures has already been adopted to minimise the impact of this unavoidable presence on other marine users. These include spatial planning commitments, dedicated consultation systems, real-time communications, and commercial resolution mechanisms. The adopted measures are well-established, operationally proven, and tailored to the survey context, providing high levels of intrinsic effectiveness with relatively low sacrifice. Because physical presence is not a variable that can be managed away — only managed better — there are no reasonable additional, alternative, or improved control measures that could further reduce this impact without introducing significant duplication, operational inefficiency, or grossly disproportionate cost. Consequently, no further control measures have been considered in this assessment.

6.4.4 Results

Figure F2-5 illustrates the stepwise reduction in residual impact from the physical presence of the seismic survey, plotted against the cumulative sacrifice associated with each adopted control measure. The downward-sloping polynomial trendline indicates that successive measures continue to achieve meaningful reductions in impact up to a clear point of diminishing returns. Notably, the *Adjustment Protocol* provides the most significant marginal reduction following the baseline measures, highlighting its critical role in managing and resolving interference with other marine users. This measure alone substantially decreases the residual impact through a transparent and proactive compensation mechanism, enabling early resolution of conflict. The *Fisheries Liaison Officer*, *Petroleum SIMOPS Plan*, and *Sea Country Protection Plan* each provide incremental benefits that fine-tune engagement with different stakeholder groups. All adopted measures fall well within the ALARP threshold, demonstrating that each contributes proportionate benefit in exchange for relatively low sacrifice. The assessment confirms that impacts from physical presence have been reduced to ALARP through targeted, effective, and reasonably practicable controls.

Figure F2-6 presents the residual impact reductions (bar graph) and the associated cumulative sacrifice (line graph) for control measures adopted to manage the impact pathway of physical presence. The baseline measures provide the largest single reduction in impact, with the *Adjustment Protocol* contributing the next most significant improvement through clear, functional mechanisms for resolving interference with other marine users. With baseline measures adopted and the adjustment protocol in place there is almost no residual impact to manage.

Subsequent measures — including the *Petroleum SIMOPS Plan* and *Fisheries Liaison Officer (FLO)* — provide smaller but still meaningful reductions, with relatively low additional sacrifice. Notably, the final two measures — the *Sea Country Protection Plan* and the *FLO* — sit beyond the point of diminishing returns, where cumulative sacrifice begins to exceed proportionate environmental benefit. Although these final measures may be considered grossly disproportionate by standard ALARP thresholds, they have been adopted regardless to reflect commitments made through consultation and to ensure environmental performance outcomes can be easily achieved.

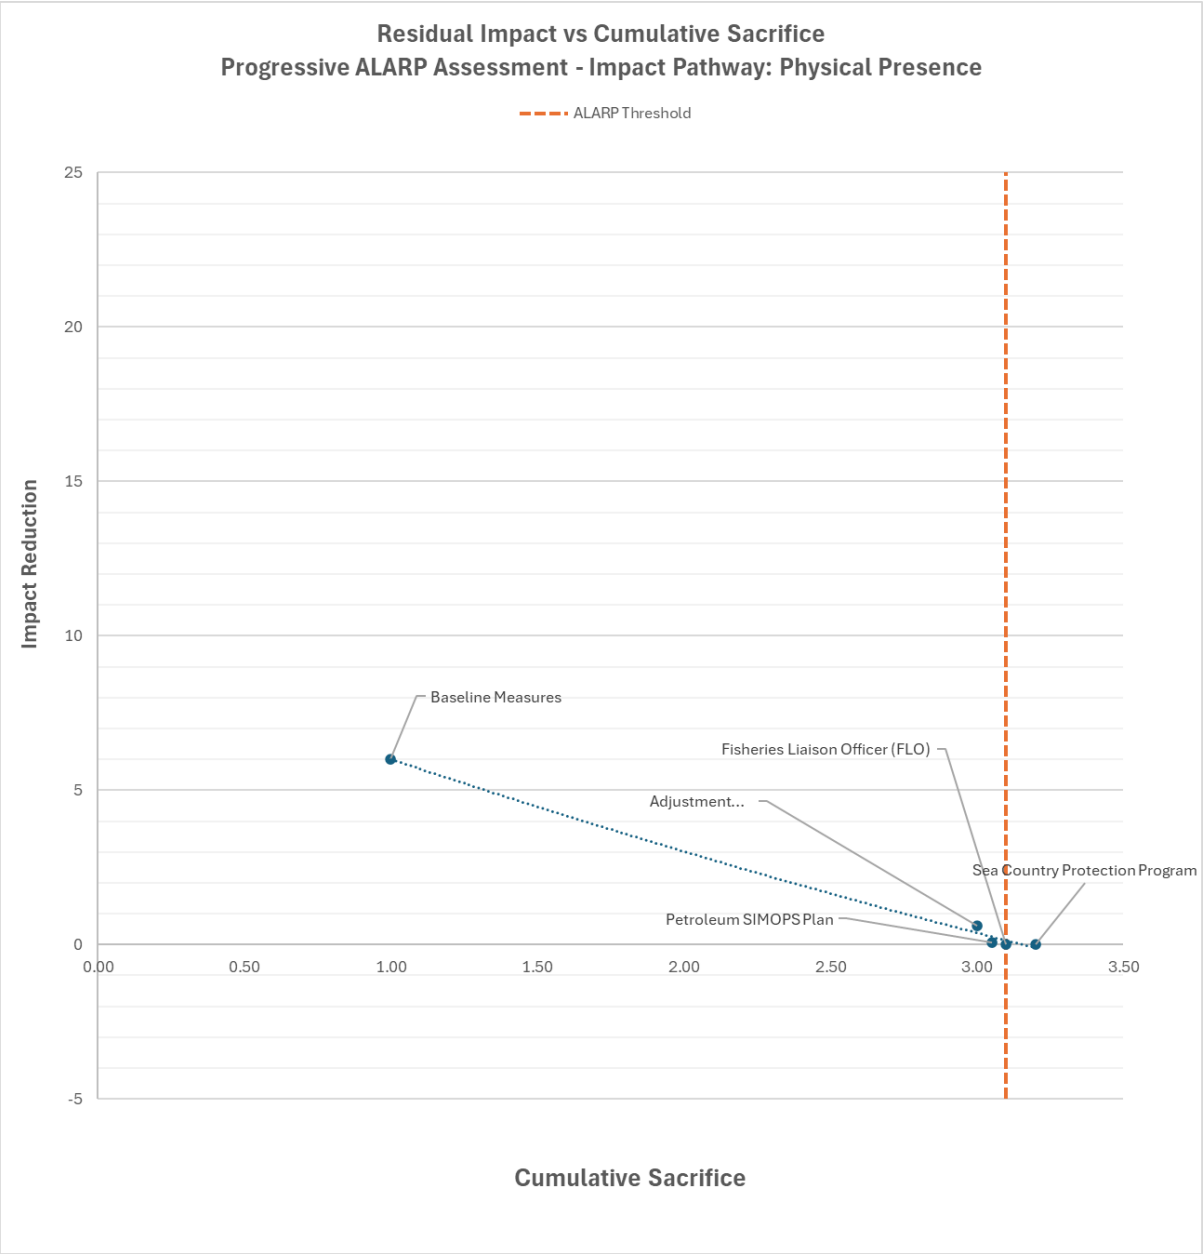

Figure F2-5 - Residual Impact vs Cumulative Sacrifice – Physical Presence: This graph presents the progressive reduction in residual impact from the survey's physical presence against the cumulative sacrifice required to implement each adopted control measure. The curve demonstrates meaningful stepwise reductions, with the Adjustment Protocol providing the largest marginal improvement following baseline commitments. All measures were adopted prior to reaching the ALARP threshold, confirming that the impact has been reduced as low as reasonably practicable.

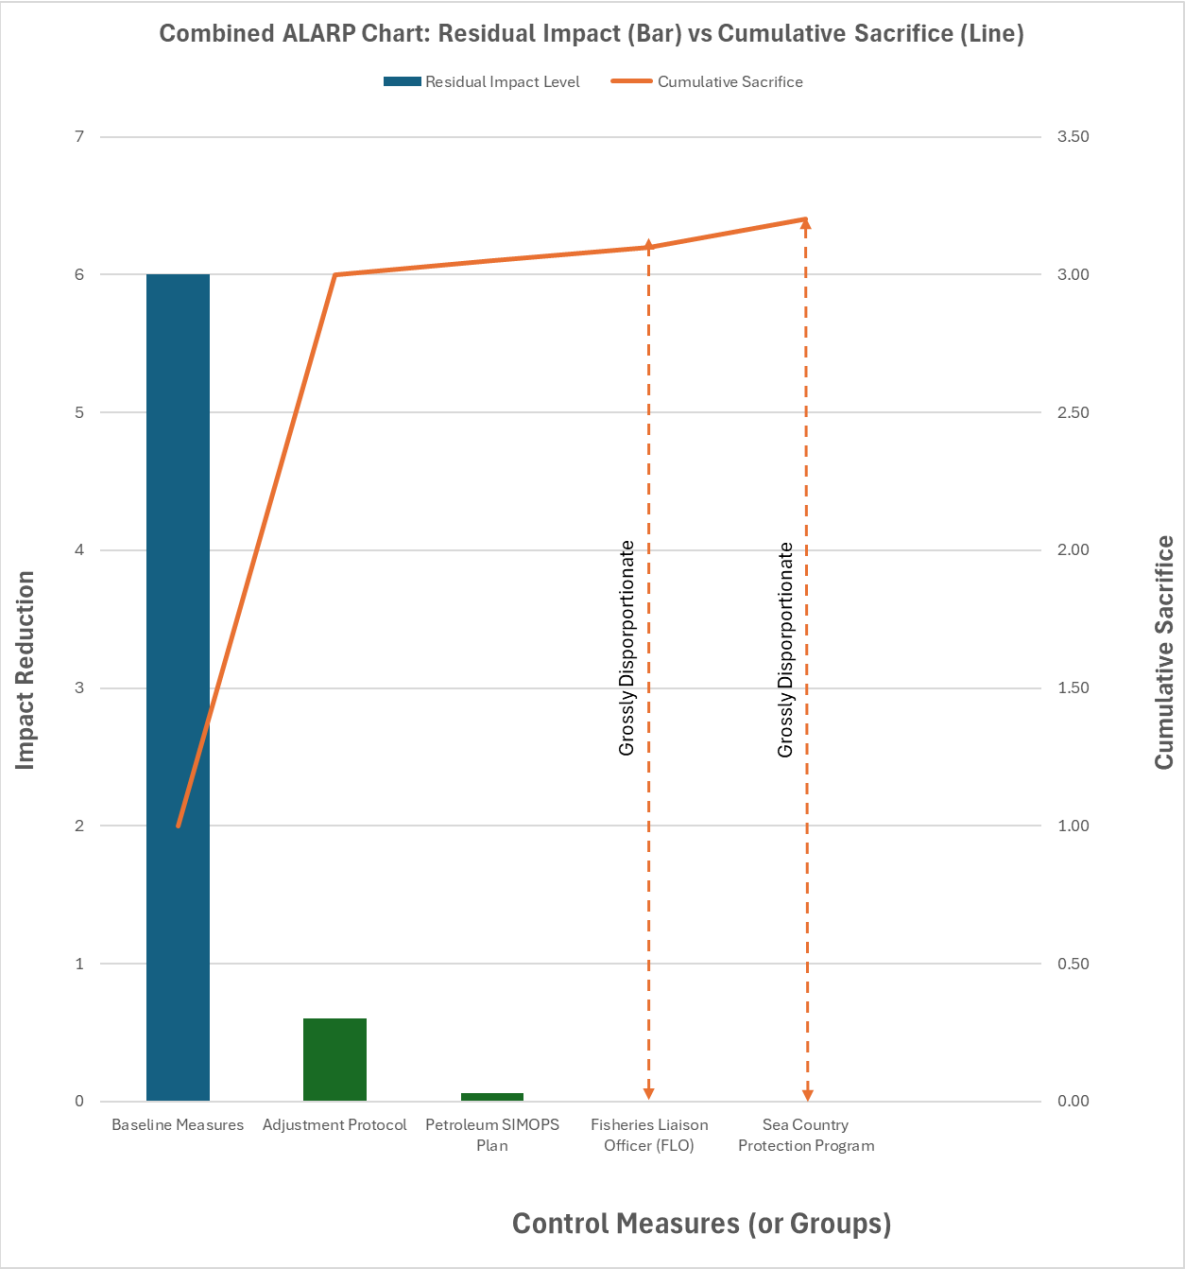

Figure F2-6 -Combined ALARP Chart – Physical Presence: This chart displays the residual impact reductions (bars) and cumulative sacrifice (line) associated with each adopted control measure. It highlights the dominant role of baseline measures and the substantial benefit of the Adjustment Protocol. Despite providing only marginal additional reduction in impact, the final two measures were adopted to support equity, responsiveness, and stakeholder inclusion beyond the point of strict cost-benefit proportionality.

6.5 Underwater Sound

The impact assessment for sound was separated into seven (7) individual impact assessments due to the complexity of the pathway between sound and each receptor category. The outcome of the impact assessments for underwater sound were as follows:

Table F2-12 - Impact Assessment Rankings - Underwater Sound

Receptor	Effect	Uncertainty	Predicted Impact Level
Plankton	Minor (2)	Low (2)	Low (4)
Fish	Minor (2)	Medium (3)	Medium (6)
Invertebrates	Minor (2)	Medium (3)	Medium (6)
Birds	Minor (2)	Medium (3)	Medium (6)
Turtles	Minor (2)	Low (2)	Low (4)
Marine Mammals	Moderate (3)	High (4)	High (12)
Diving, Surfing, & Swimming	Negligible (1)	Low (2)	Low (3)

While each of these receptors has different sensitivities and modes of exposure, a detailed ALARP analysis for each individual receptor group is neither practical nor proportionate – particularly when the control measures adopted for marine mammals provide a conservative and encompassing form of impact reduction for all others.

Marine mammals have been selected as the representative or surrogate receptor group for this assessment because they are both the most acoustically sensitive and the most legislatively protected. The impact pathway for marine mammals was assessed as carrying the highest residual impact ranking (12). As such, control measures required to reduce impacts to marine mammals are more stringent than those that would be warranted for less sensitive receptors. Further supporting this approach, the control measures act at the source-pathway level, reducing the intensity, timing, and proximity of acoustic emissions in a way that inherently reduces exposure for all other receptor groups.

By addressing the highest impact pathway to the most sensitive receptor group and demonstrating that these control measures achieve ALARP for marine mammals, it is reasonable to infer that impacts to all other receptors from underwater sound have also been reduced to ALARP.

6.5.1 Baseline

Table F2-13 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline impact level and baseline quantum of sacrifice.

Table F2-13 - Baseline Measures – Underwater Sound

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Avoided core Blue Whale and SRW seasons through shoulder-period scheduling	Seasonal timing selected to avoid overlap with peak presence of either species while maximising survey efficiency.	Shoulder-season scheduling reduces overlap with both Southern Right Whale and Blue Whale peak periods. This activity design element avoids the need for active mitigation during known high-risk periods. Independent of equipment-based controls and highly compatible with operational efficiency.
EPBC Act Policy Statement 2.1 (Part A) Procedures	Mandatory under national policy; includes pre-start, start-up, and shut-down procedures to minimise acoustic impacts on whales.	Reduces the likelihood of auditory injury and behavioural disturbance through procedural controls. Implements structured pre-start, soft-start, and shutdown procedures that directly interrupt the acoustic exposure pathway during sensitive periods. High functionality and reliability, as procedures are well-defined, tested, and incorporated into national policy. Compatible with vessel operations and implemented independently through Fauna Management Plans.
EPBC Regulations Part 8: Vessel and Operating Procedures	Legal requirement; governs vessel behaviour around cetaceans to minimise disturbance.	Provides physical buffer zones around cetaceans that reduce proximity risk and behavioural disturbance. These requirements are mandatory and standardised, ensuring reliability and compatibility across vessel types. Functional and easily implemented by vessel crew.
Fauna Management Plan (FMP)	Industry standard and operational document that ensures detection, classification, and response protocols are implemented for marine mammals.	Serves as the core implementation document for species detection and mitigation. Ensures standardised response protocols are in place and followed. High functionality and compatibility with marine operations. Reliable framework supporting consistent performance.
Marine Fauna Observers (MFOs)	Highly trained observers ensure continuous real-time monitoring of whale presence to inform adaptive mitigation measures.	Ensures real-time detection and behaviour monitoring. Visual detection range is typically up to 5 km under good conditions but limited at night or in poor weather. MFOs are experienced and trained, offering high reliability and independent verification. Functionality is high during daylight but reduced during dark hours.
Application of DMAC 12 Guidelines – Management of Seismic Survey Interactions with Diving Operations	Adopted to ensure diver safety during seismic operations by avoiding acoustic interference with known commercial or scientific diving activities. This measure reflects international best practice for managing sound-related interactions with divers and aligns with CGG's duty of care obligations.	This measure functions by providing pre-survey notification and real-time coordination with known diving operations in the area. The DMAC 12 guidelines are well-established and widely recognised across the industry, offering high functionality and reliability. They are also independent of other mitigation measures. Because divers are not present in large numbers and most areas of operation are far offshore, the application of this measure provides a highly effective safeguard at relatively low operational cost.

The quantum of sacrifice required to implement the baseline control measures for underwater sound is the most substantial of any impact pathway considered in the ALARP assessment. These measures reflect both legislative obligations and adopted standards that significantly shape the design, duration, and conduct of the survey. The Fauna Management Plan (FMP), which operationalises EPBC Policy Statement 2.1, includes detailed pre-start, soft-start, and shut-down procedures. These procedures require continuous monitoring and, when triggered, lead to temporary cessation of the seismic source, introducing vessel downtime and potential delays to the survey. Each shutdown and start-up cycle can result in the loss of optimal acquisition conditions and increased total survey duration.

The requirement for MFOs demands the deployment of trained personnel and adds direct labour, training, and compliance monitoring costs. Additionally, the shoulder-season scheduling to avoid peak presence of Blue Whales and Southern Right Whales limits the available acquisition window, increasing the risk of weather-related disruption and reducing scheduling flexibility. These constraints translate to higher operational costs due to narrowed survey windows and increased likelihood of weather-induced downtime.

Collectively, these measures form a baseline that carries a significant cumulative sacrifice, not just in financial terms, but in terms of lost efficiency, reduced flexibility, and constrained survey design. However, they also deliver a high degree of effectiveness and reflect CGG's commitment to regulatory compliance and environmental protection. This baseline is assigned a unit value of 1.0 in the ALARP assessment, representing the minimum necessary sacrifice to meet legal and industry standards while setting the platform for evaluating discretionary additional controls.

6.5.2 Assessment

To support the ALARP assessment for underwater sound emissions, a dedicated review of potential mitigation technologies and practices was conducted and documented in Appendix F5 – Marine Mammal Detection Technology Assessment. The purpose of that appendix was to ensure that a wide range of available, emerging, and alternative control measures were identified and considered as part of the overall ALARP assessment.

The inclusion of Appendix F5 in the submission does not imply that all listed technologies or methods require detailed assessment within the ALARP process. Rather, the appendix served as a scoping and input tool, informing the structured, step-by-step ALARP process by ensuring that no obvious or commonly cited mitigation approach was overlooked without consideration.

It is important to clarify that an ALARP assessment does not require exhaustive analysis of every conceivable control measure. Instead, the process is intended to identify and adopt those measures that provide clear, demonstrable reductions in impact – unless the cost, time, or effort required to implement them would be grossly disproportionate to the environmental benefit they offer. Once the assessment shows that diminishing returns have been reached, and that further mitigation options provide no material improvement or involve clearly disproportionate sacrifice, then the ALARP threshold has been satisfied.

Table F2-14 shows the step-by-step process followed for the ALARP assessment of underwater sound. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-14.

Table F2-14 - Step-by-step ALARP Assessment – Underwater Sound

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	12	1.00	1.00	Baseline measures represent the full suite of mandatory controls under law and guidance, including implementation of exclusion zones, shutdown procedures, and seasonal timing restrictions. These controls act directly at the source and through procedural intervention. They are highly functional, independently applied, and broadly compatible across the vessel systems. Their consistent use over multiple surveys and refinement through experience provides high reliability. As such, the baseline effectiveness is considered high.	This baseline includes significant embedded costs such as downtime from shutdown procedures, additional personnel for MFOs and implementation of legislative compliance systems. The cumulative effort to design, coordinate, and deliver baseline measures is taken as a unit value of 1.00, representing substantial but unavoidable cost of compliance.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
2	Towed PAM	Towed PAM equipment and PAM detection monitors	12	50%	6	6	0.19	1.19	Towed PAM enables continuous underwater acoustic monitoring for marine mammal vocalisations, especially in low-visibility conditions or at night. Its effectiveness may be limited by background noise, vocalisation behaviour of species, and operational interpretation. However, the extended range of >10 km from the sound source makes it a valuable addition to the suite of detection lines of evidence. To add to its efficacy, it functions independently from visual observation, is available and widely deployed in the industry, and is compatible with vessel systems. A 50% effectiveness rating reflects its supplementary but imperfect contribution alongside the baseline.	Towed PAM involves acquisition, calibration, and maintenance of acoustic arrays and analysis systems. Monitoring requires a dedicated operator. Compared to baseline systems, it adds a specialised capability with moderate effort and cost, estimated at 0.19 sacrifice units, reflecting modest additional investment relative to operational cost.
3	Night-time Procedures	Additional procedures associated with startups and shutdowns.	6	20%	1.2	4.8	0.13	1.31	Night-time start-up and shutdown procedures add precautionary steps when visibility is reduced, functioning by increasing the likelihood of avoiding interactions with undetected fauna. However, the absence of visual verification limits their reliability. They are procedural, compatible, and independently implemented, justifying a modest 20% effectiveness rating due to the inherent uncertainty they address.	Night-time procedures involve increased procedural checks, potential delays, and crew attention during hours of reduced visibility. Compared to the baseline, this measure has a minor cost impact but reduces operational flexibility. A sacrifice of 0.13 reflects time costs and complexity added to survey scheduling.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
4	Spotter Vessel	Additional vessel in the field with marine fauna observers and associated procedures	4.8	50%	2.4	2.4	0.58	1.90	A dedicated spotter vessel extends detection range spatially and provides redundancy to onboard MFOs. It increases visual coverage and facilitates early detection of whales at greater distances. The measure is highly functional and independent, and its reliability depends on weather and observer performance. MFO's onboard are still only effective during daylight hours and in good visibility. Given its increased surveillance capacity, a 50% effectiveness score is justified.	Operating a second vessel requires significant expense for chartering, crew, and fuel. It introduces logistical complexity and coordination challenges. However, the added coverage and redundancy make this one of the more expensive discretionary measures, assigned a sacrifice of 0.58, which is more than half the baseline cost.
5	Pre-start aerial overflight	Prior to commencing survey, a clearance survey of the starting line and the adjacent SRW BIA	2.4	5%	0.12	2.28	0.01	1.90	One gap in the measures considered so far is the need to understand the broader abundance of marine mammals prior to starting the survey and reliance on behavioural avoidance may occur. A pre-start aerial overflight allows a one-time broad area scan of the start location and SRW BIA. It is independent and functional but only offers a snapshot view, with limited duration of effectiveness. It is compatible with vessel-based procedures but overlaps with visual and acoustic systems. As such, its marginal contribution is rated at 5%.	Aerial overflights require aircraft, crew, and coordination. The pre-start flight is short-duration and planned, so the cost impact is minimal. The one-time cost is low, with a sacrifice unit of 0.01 though this is only justified because of the specific need identified.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
6	Acoustic Detection Units	3 x tethered buoys	2.28	40%	0.912	1.368	0.16	2.06	Acoustic detection buoys provide passive monitoring in fixed locations (e.g., adjacent to BIAs). They will be used specifically for protections for Southern Right Whales. They function independently from other control measures and enhance detection where vessel systems have gaps. Their effectiveness depends on placement, detection range, and interpretation. They are reliable under good conditions and compatible with existing detection processes. Whilst the PAM technology being used is tried and tested, the application of the equipment on a tethered buoy is relatively untested. There are questions about the accuracy of detections in the presence of seismic sound. Overall, a 40% effectiveness score is a fair estimation of the gap filled by this measure.	Deployment and retrieval of three acoustic detection buoys involve equipment leasing, positioning planning, and monitoring by trained personnel. The measure introduces a high cost and resource burden, but compared to baseline costs, a sacrifice of 0.16 reflects that it is a targeted and limited additional layer of protection.
7	Relief PAM/MFO	Additional person to manage fatigue across observers	1.368	5%	0.0684	1.2996	0.04	2.10	The relief PAM/MFO role addresses fatigue and performance sustainability, following consultation with stakeholders. It ensures uninterrupted coverage and supports consistent quality in observations. Though it doesn't extend detection range, it increases reliability. For this reason, it is rated at 5%, reflecting its indirect but important contribution.	The relief observer role adds to crew numbers and logistics, increasing accommodation and scheduling demands. However, it directly responds to consultation feedback and supports implementation quality. The cost is modest (0.04) relative to the entire program and delivers resilience in staffing.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
8	Support personnel	Whale expert panel, Environment Officer, Survey Environment Advisor	1.2996	80%	1.03968	0.25992	0.09	2.20	The whale expert panel, Environment Officer, and Survey Environment Advisor contribute to strategy, compliance, and real-time decision-making. They enhance implementation quality and adaptiveness of measures. These roles operate independently and are compatible with all other systems. Their support significantly boosts effectiveness of procedural measures, justifying an 80% effectiveness rating.	Support personnel are already part of broader environmental and safety programs, so costs are shared across compliance efforts. Still, dedicated environmental roles and expert panels require coordination, meetings, and operational availability. A 0.09 sacrifice unit captures this indirect but meaningful cost.
9	Additional overflights	A weekly overflight	0.25992	5%	0.012996	0.246924	0.08	2.27	Additional weekly overflights provide periodic updates on whale locations and may support a broader view of the departure of SRW and/or the arrival of PBW. They cannot verify previous detections and can only operate when weather conditions allow reducing their availability. Overflights also overlap with PAM and MFO functions. Their effectiveness is constrained by timing and redundancy, justifying a 5% score.	By this point in the ALARP assessment, the cumulative sacrifice has already surpassed the point at which further investments yield only marginal environmental benefit. The accumulated cost of multiple flights, along with the logistical burden of scheduling and weather dependency, outweighs the minimal incremental risk reduction. As such, the cost—although moderate on its own—is considered grossly disproportionate when viewed in the broader context of measures already adopted.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
10	PAM on the spotter vessel	Towed PAM equipment and PAM detection monitors on the spotter vessel	0.246924	50%	0.123462	0.123462	0.19	2.46	Deploying PAM on the spotter vessel extends passive acoustic coverage and improves detection in the survey area. It functions independently and adds resilience to the PAM system. However, it duplicates an existing function already integrated into the towed PAM system. A 50% effectiveness score is used to reflect improved coverage but not novel capability.	Adding PAM to the spotter vessel introduces a parallel monitoring system already available through towed PAM and static acoustic buoys. While it would improve redundancy, the benefit is marginal given the effectiveness of previously adopted measures. The cost—comparable to the original PAM system—adds significantly to the cumulative sacrifice without providing commensurate risk reduction. At this stage of the assessment, where the residual impact is already low, this duplicated capability represents a grossly disproportionate sacrifice.

6.5.3 Consideration of Alternative, Additional or Improved Control Measures

In accordance with good environmental practice and this ALARP process, a range of additional, alternative, and improved control measures were considered beyond those already included during stepwise assessment. Each control measure was evaluated in terms of its potential to further reduce impacts associated with underwater sound emissions, and its corresponding level of sacrifice. The following discussions outline the reasons why specific measures were either rejected, partially adopted, or deemed infeasible. In each case, consideration was given to the measure's functionality, availability, reliability, independence, compatibility with existing systems, and its cost-effectiveness relative to its environmental benefit.

Frequency Reducing Sound Source Technologies

The Bluepulse (©SERCEL) is a purpose-built acoustic source that is available as a 'new' installation or as an upgrade to existing systems. Its key innovation is minimizing high frequency emissions without compromising accurate and dependable results for seismic acquisition, hence reducing environmental noise impacts.

When comparing the source signature to a conventional airgun array the following can be observed:

- Source signatures are similar in the main seismic frequency band (~ 1-100Hz).
- The Bluepulse frequency spectrum is slightly more oscillatory (ringy) in the low frequencies which would be of concern for a high-end broadband seismic image.
- The Bluepulse frequency spectrum is flatter out to 80Hz not reflecting the traditional signature of a conventional source.
- The Bluepulse frequency spectrum is attenuated outside of the main seismic bandwidth (0-200Hz) which is deemed the (environmental) advantage of this method.

Bluepulse generates considerably less energy with each shot compared to a conventional source. Hence peak-to-peak energy for the Bluepulse is half that of a conventional array and the peak-to-bubble ratio is also significantly less. This suggests the Bluepulse is not as efficient, and the seismic pulse not as clean as a conventional source.

These performance characteristics are the major concern when considering the amplitude supported play of the Otway Basin in general, where high resolution, accurate imaging of the seismic amplitude is required, even more so into the deeper plays expected in the Regia area. Processing complexities in the Otway Basin stem from the hard carbonate seabed and shallow lithologies along with shallow Tertiary canyons.

Adequate energy from the seismic source is required to penetrate these shallow layers to image the zone of interest. Particular seismic attributes are needed to accurately characterise the gas prospect including far angle stacks which require more energy for imaging, especially with the longer streamer length needed to image under the shallow zones. Conventional air gun arrays have an evidentiary track record of meeting all the objectives required of seismic acquisition in the Otway Basin, including successful mitigation of environmental impacts.

A typical contractual standard for a conventional seismic source would be:

- A primary amplitude (peak) of ≥ 50.0 bar-m, a peak-to-peak amplitude of ≥ 100.0 bar-m, and a peak-to-bubble ratio of at least 25

Compare this with the Bluepulse;

- A primary amplitude (peak) of ≥ 30.0 bar-m, a peak-to-peak amplitude of ≥ 60.3 bar-m and a peak-to-bubble ratio of at least 12.3.

To utilise the Bluepulse in the Otway with a required degree of confidence it would need to be qualified against a conventional source. Multiple test lines would need to be shot with a full conventional source array and a full Bluepulse array so a direct comparison could be made to determine whether the final seismic image acquired by the Bluepulse contains all necessary information from the zone of interest. Without this qualification the seismic data would be sub-par and would need to be reacquired with all the issues that would ensue. The risk on the geophysical imaging side of utilizing this new technology is too high without more comprehensive testing to better understand the risk-reward outcomes. Environmental problems associated with conventional seismic have been previously addressed through a range of mitigation methods. If the Bluepulse technology is more extensively tested against industry standards and demonstrates equivalent outcomes it will likely become a system of choice going forward.

However, at this point-in-time the Bluepulse remains a new and relatively untested technology whose outcomes need to be more fully documented and tested. If the seismic source is unreliable it will lead to increased downtime, increased infill shooting and generally more time with the vessel in the field and more shots. A known, reliable conventional seismic source will lead to efficient acquisition with the vessel in field for the shortest time possible and the fewest shots. Therefore, Bluepulse technology has been rejected.

Alternative Acquisition Technology (Marine Vibrosis)

The use of marine vibrosis and other emerging alternatives to conventional airgun technology was also evaluated. These systems may emit lower peak sound levels and offer potential environmental benefits; however, they are not yet commercially mature or widely used in offshore seismic operations. More importantly, their long-term environmental impacts – particularly those associated with particle motion – are not well understood. As such, adopting these technologies would require significant further research, environmental assessment, and investment before they could be demonstrated to offer a net reduction in environmental impact. In this context, it is more prudent to manage the known risks of conventional acoustic sources using well-established and effective control measures. The option was therefore rejected as unfeasible/impracticable.

Bubble Curtains and Acoustic Blankets

Bubble curtains and acoustic blankets are widely used to attenuate underwater noise in point-source construction activities such as pile driving. However, their effectiveness depends on stationary deployment and consistent geometry, making them unsuitable for mobile activities such as seismic surveying. The moving nature of the Regia MSS sound source renders these technologies infeasible from both an operational and effectiveness standpoint. This measure was considered technically infeasible and excluded from further consideration prior to Step 2 of this assessment.

PAM via Third-Party Vessels

The option of utilising third-party or non-dedicated vessels to deploy PAM systems was assessed at Step 2 and again at Step 10 of this assessment. While these vessels may extend geographic coverage, their operational independence and the variability of equipment make the reliability and integration of detection data less certain. When compared to CGG's dedicated and well-integrated PAM installations, the marginal improvement was minimal. This measure was rejected based on reduced reliability and elevated uncertainty.

Infra-red Cameras

Infra-red (thermal) cameras were considered as an alternative and/or additional option at Step 2 for extending marine fauna detection into low-visibility and night-time conditions. However, their detection range—particularly for low-frequency cetaceans—is limited compared to PAM, and their performance offshore remains largely unproven. CGG has ongoing discussions with technology developers who acknowledge the technology is not yet commercially viable. Given the availability of more effective and established technologies already adopted in the baseline and in the steps that follow (e.g. PAM and trained MFOs), the marginal benefit of this equipment was not sufficient to justify its cost.

Drone Technology (Offshore)

Offshore drone platforms were reviewed as a possible enhancement to detection and identification capabilities of marine fauna, particularly during daylight hours. However, drones launched from the survey vessel are limited in range and do not offer significant gains beyond what trained MFOs already provide from elevated vantage points. Their added complexity and limited benefit rendered them a poor investment relative to existing detection systems. This measure was considered as an alternative at Step 3 and rejected.

Satellite Imagery for Whale Detection (Partial Adoption)

The use of satellite imagery to support whale detection was considered for inclusion as an additional line of evidence to inform pre-survey planning at Step 6. While satellite-based observation is not suitable for real-time mitigation due to limitations in spatial resolution, revisit frequency, and weather dependency, it may offer value as a pre-survey tool to identify areas of likely whale presence or absence in the weeks leading up to activity commencement and/or commencement of southerly migration out of the reproductive BIA. As such, CGG has chosen to partially adopt this measure by supporting a trial of satellite-based whale detection prior to the survey. The aim of this trial is to assess whether near real-time imagery, when combined with validated detection algorithms, can offer useful intelligence on whale distribution patterns. This information may assist in refining the initial sail line selection and pre-start procedures. The use of this technology will not replace existing mitigation measures but will complement them where feasible and subject to satellite availability and data quality. The limited cost and potential utility of this measure support its inclusion as a low-sacrifice, trial-based enhancement.

Drone Technology (Onshore)

Drone deployment from onshore positions near the Southern Right Whale Reproduction BIA presents an opportunity to supplement visual monitoring through behavioural observation and wider-area coverage.

Unmanned aerial vehicles (UAVs), drones, have rapidly emerged as an effective tool for marine mammal research, complementing traditional visual observation techniques for assessing whale abundance and distribution. UAVs can conduct large-scale aerial image-based surveys at a fraction of the cost of manned aircraft and without many of the associated safety risks (Koski et al., 2009; Hodgson et al., 2017). Their low operating cost also enables flexible survey designs, including simultaneous multi-UAV coverage. Although UAVs remain subject to aviation regulations and earlier models were range-limited, ongoing technological developments continue to expand their operational capacity.

Recent applications demonstrate their utility. Drone-based surveys in New South Wales covered 23 sites spanning 1,000 km and were found to be a cost-effective method for marine megafaunal assessments under suitable conditions (Kelaher et al., 2023). In South Australia, UAVs have been used to examine spatial relationships between SRW mothers and calves, providing insights into maternal behaviour (Nielsen et al., 2019). For small cetaceans, drone surveys have produced more accurate

population and behavioural data than traditional vessel-based approaches, including for Bottlenose Dolphin (*Tursiops truncatus*) (Fettermann et al., 2022).

Available evidence indicates that UAVs cause minimal disturbance to baleen whales, with studies showing very little drone-generated sound penetrates the water (Christiansen et al., 2016; Christiansen et al., 2020), and that any disturbance is likely minor compared to crewed aircraft or nearby vessels (Raoult et al., 2020). Drone-based observation therefore represents a less invasive alternative for monitoring marine mammals.

Operational challenges remain in sub-optimal weather, low light, high winds, and rough seas. A study in Norway evaluating UAV performance across 12 missions found that detection certainty varied between cetacean groups and was influenced by sea state, glare, and luminance, though overall UAVs were effective when environmental variability was considered (Aniceto et al., 2018).

As flight range, stability, and camera resolution improve, UAVs are becoming an increasingly reliable component of marine mammal monitoring programs. Integrated with traditional methods, UAVs can enhance detection reliability, broaden spatial coverage, and improve the overall effectiveness of marine mammal research and conservation.

Drones offer an alternative to traditional fixed-wing aerial surveillance. The following factors have been considered by CGG in the adoption of this control measure:

- **Cost Effectiveness:** Drone operations deliver substantially lower costs compared with fixed-wing aerial surveys. Traditional aerial monitoring requires aircraft charter fees, pilot and observer wages, fuel, and maintenance, all of which are costly and inflexible.
- In contrast, drone operations involve a small two-person crew and rechargeable batteries, with no airfield or refuelling requirements. The same budget that might fund a single weekly aircraft flight can typically support multiple drone sorties per day, resulting in increased observation hours and improved statistical reliability. Lower mobilisation and maintenance costs also make it feasible to extend the monitoring season or add additional sites without exceeding project budgets.
- **Flexibility in Short Weather Windows:** Drone crews can mobilise within minutes when short calm periods arise - conditions typical of southern coastal environments. Unlike fixed-wing aircraft, drones do not require prior aircrew scheduling or flight slot coordination. This rapid-deployment capability allows operators to take advantage of limited weather windows, maintaining continuity of observations that would otherwise be lost to forecast uncertainty.
- **Launch Site Adaptability:** Drones can be deployed from a wide range of accessible coastal vantage points - such as cliffs, beaches, or headlands - eliminating the need for distant take-off locations or transit over water. Launching near target habitats reduces flight time, increases efficiency, and enables adaptive survey coverage in response to dynamic whale distributions.
- **Station-Keeping and Behavioural Documentation:** Unlike aircraft, which must maintain forward motion and often circle targets, drones can hover motionless above sightings. This allows stable, repeatable documentation of individual animals, group interactions, or calf-cow pairs without causing disturbance. The ability to hold position enhances data quality by removing motion blur and maintaining consistent geometry for photo-identification and behavioural recording.
- **Enhanced Visual and Thermal Detection:** Modern multi-sensor payloads, such as the Zenmuse H30T, integrate high-resolution RGB, thermal, and zoom imaging on a single

gimbal. Thermal sensors can detect whale blow plumes or body heat at extended distances and under low-visibility conditions, while optical zoom enables detailed examination of morphology, scarring, and fine-scale behaviour. Combined, these capabilities deliver a level of visual and thermal fidelity that far exceeds that obtainable from crewed aircraft operating at higher altitudes and speeds.

- **Reduced Disturbance and Acoustic Footprint:** Drones operate quietly and at lower altitudes than manned aircraft, producing minimal acoustic disturbance. This allows for recording of surface behaviour, social interaction, and resting activity, improving behavioural accuracy and welfare outcomes for observed animals. All UAV operations will comply with prescribed minimum separation distances, altitude restrictions, and marine fauna disturbance mitigation requirements.
- **Safety and Risk Reduction:** Uncrewed aerial systems remove the inherent risks associated with low-level flight over water. Operations can continue safely under marginal visibility or moderate wind conditions that would ground manned flights. Redundant telemetry links, automated return-to-home (RTH) functions, and built-in safety protocols provide predictable and secure system recovery, supporting Civil Aviation Safety Authority (CASA)-approved Beyond Visual Line of Sight (BVLOS) operations.
- **High Spatial and Temporal Resolution:** Drone surveys enable concentrated effort within key nearshore nursery zones (e.g., 2-5 km offshore), where whale aggregations are most frequent. Their ability to operate repeatedly across consecutive days provides continuous temporal coverage rather than isolated transects, producing finer-scale mapping of distribution, movement, and habitat use relative to environmental conditions.
- **Data Quality and Integration:** All imagery and telemetry are captured digitally with embedded GPS, UTC timestamp, altitude, and camera parameters, ensuring traceability and repeatability. 4K video and still imagery is immediately suitable for GIS integration and spatial analysis. Drones can also operate in conjunction with coastal observers, enabling real-time triangulation and verification of sightings.
- **Environmental and Regulatory Advantages:** Drone operations have a minimal environmental footprint - no aviation fuel use, reduced noise, and low emissions. They comply with CASA BVLOS regulations designed to mitigate risk to crewed aviation in sensitive coastal airspace. Field teams typically consist of only two personnel, reducing both logistical complexity and site disturbance.
- **Rapid Redeployment and Multi-Site Coverage:** Drone systems can be rapidly redeployed between nearby sectors - such as The Craggs, Narrawong Beach, and Cape Nelson - within a single operational day. Mission parameters are pre-programmed , ensuring consistent transect replication and efficient daily re-tasking in response to whale movements or changing weather conditions.

Drone-based BVLOS monitoring provides a safer, more flexible, and cost-effective alternative to manned aerial surveys for whale observation. It allows adaptable launch points, stable hover-based behavioural recording, enhanced visual and thermal detection, and efficient utilisation of short weather windows. The approach maintains high spatial and temporal data resolution, minimises environmental impact, and adheres to strict aviation safety and regulatory requirements. All operations remain under the discretion of the pilot-in-command, who retains final authority on flight safety and operational limits.

While this technology is still developing, early consultation and engagement with authorities has indicated that trials could be conducted ahead of the survey period. As such, this option has been

partially adopted as a complementary measure to Step 3, subject to appropriate permits and operational viability.

Unmanned PAM Craft

The deployment of unmanned surface vessels equipped with PAM technology was explored as an alternative platform for acoustic monitoring. While potentially extending coverage, these systems offer similar detection capabilities to static buoys already adopted. It is important context that the need in the case of the Regia MSS is to improve detections of Southern Right Whales within and migrating from their reproductive BIA. This, coupled with their higher cost based and limited improvement in effectiveness led to the conclusion that they did not represent a cost-effective addition. This measure was considered during Step 6 of the ALARP assessment and rejected.

Unmanned PAM Gliders

The deployment of autonomous underwater gliders equipped with PAM systems was investigated as an alternative monitoring platform; however, their operational characteristics do not align with the requirements of the Regia MSS. Gliders provide periodic, rather than continuous, detection and reporting because data are only transmitted when the vehicle surfaces, typically every few hours. This results in delayed or batch reporting cycles. This stands in contrast to the near real-time, continuous telemetry achievable with static tethered buoys, which is essential for the Regia MSS because the primary objective is to monitor received sound levels at fixed, defined locations, not to conduct broad-area whale detection. Static buoys remain at known coordinates, maintain stable hydrophone depth, and provide uninterrupted acoustic measurements and near real-time transmission, making them far more suitable for validating sound source levels during the activity.

Gliders also introduce functional limitations that reduce their utility for this application. Their movement through the water column creates flow noise and wave-wash noise, which can significantly degrade low-frequency signal quality—precisely the band relevant to both Southern Right Whale frequencies and anthropogenic impulsive sound monitoring.

Performance testing of acoustic gliders shows that while glider-based PAM is useful for broad-scale presence/absence assessments, it exhibits substantially higher missed-detection rates for low-frequency baleen whale calls compared to fixed, stationary systems. Baumgartner et al. (2020) report missed-detection rates of 26–62% for right, humpback and fin whales when gliders operate in automated mode, along with data latency inherent to glider design because detections can only be transmitted when the glider surfaces. Their mobility also makes it challenging to maintain consistent monitoring points because the Regia MSS requires fixed-point sound-level verification, a platform that moves tens of kilometres over a deployment cycle cannot fulfil this role with the required precision or repeatability.

Although gliders can extend horizontal spatial coverage, the Regia MSS monitoring strategy already achieves that coverage through a network of strategically placed static PAM buoys. Gliders therefore provide no additional detection benefit relevant to the management measures in this EP. Their higher capital and operational cost mean they do not offer a material improvement in environmental impact reduction. For these reasons, gliders were assessed at Step 6 of the ALARP assessment and rejected on the basis that static buoys provide a more reliable, more direct, and more cost-effective means of meeting the defined monitoring objectives of the Regia MSS.

Citizen Science Observations

Within Step 7, CGG considered incorporating citizen science observations into the Fauna Management Plan was considered as a means of enhancing real-time awareness of Southern Right Whale presence, particularly in the coastal reproduction BIA. While such observations can sometimes

provide useful insights, the data is not validated in real-time reducing reliability and their integration into formal mitigation procedures raises concerns around data quality and verification. Additionally, the existing suite of detection measures already ensures that Southern Right Whales can utilise their BIA's and HCTS and behavioural disturbance is minimised. However, CGG notes that citizen science programs can be effective because observations are occurring all the time and not just for a defined (and likely limited) science program. CGG does not control the program as the data goes to the Arthur Rylah Institute and has confirmed that CGG would be given unvalidated sightings data on request. Therefore, this control measure has been partially adopted as the benefit was sufficient to justify even the relatively low cost of coordination.

Plankton/Larval Krill Dispersion Modelling

This measure was suggested through consultation. It requested further analysis of impacts to planktonic organisms and larval krill through additional dispersion modelling. However, the Regia MSS environmental assessment already includes a detailed evaluation of the Bonney Upwelling and its biological significance. Moreover, current scientific understanding supports those behavioural impacts on larger taxa (e.g. whales) are an appropriate surrogate for impact management across trophic levels. This idea was deemed a supplementary input to the environmental assessment, not a control measure, and was rejected as unnecessary to inform ALARP decisions.

Plankton/Larval Krill Detection and Avoidance

This measure was suggested through consultation. Direct observation or detection of larval krill during the survey was explored but ultimately found to be infeasible. Krill are neither directly observable during operations nor spatially predictable to a sufficient degree to inform real-time mitigation. Given that the survey avoids peak upwelling periods and already incorporates broader area and timing restrictions, this measure was rejected as an unviable additional control.

Additional PAM detection systems of contracted vessels

Passive acoustic monitoring (PAM) has consistently been shown to be a reliable tool for detecting vocalising cetaceans across multiple platforms, environments, and spatial scales. Numerous studies demonstrate that baleen whale calls propagate over substantial distances, allowing detection ranges from several kilometres to tens of kilometres, depending on species, water depth, and ambient noise. For right, humpback and sei whales, moored buoy systems typically achieve instantaneous detection ranges of 9–15 km, with fin whale calls detectable over several tens of kilometres due to their low-frequency, high-source-level signals (Baumgartner et al. 2019). Right whale upcalls have been recorded up to 30 km in shelf basins and, in favourable sub-Arctic conditions, North Pacific right whale calls have propagated to 100 km from the source (Soldevilla et al. 2014). In deep ocean systems, pygmy blue whale calls may be detected at ranges approaching 200 km, depending on frequency band, ambient noise, and propagation conditions (Gavrilov & McCauley 2012). Across calving grounds, feeding areas, and migratory corridors, PAM consistently outperforms visual methods in temporal coverage—often yielding 2–10 times more detection days than aerial or shipboard surveys —and provides continuous monitoring in darkness, poor weather, and remote locations (e.g., Antarctica's PALAOA observatory) (Van Parijs 2009). The capacity for real-time transmission from autonomous buoys further supports mitigation, as demonstrated by reliable near-real-time right whale detections used for vessel-strike risk reduction off the United States east coast (Van Parijs 2009).

While PAM is highly effective for *detecting the presence* of cetaceans, its performance in estimating *distance* and *bearing* depends heavily on the configuration of the monitoring system. Single-hydrophone systems—common in mitigation buoys—detect occurrence but cannot estimate caller range or bearing without additional propagation modelling or opportunistic use of multipath arrivals, and these methods are generally unreliable for operational decision-making (Soldevilla et al. 2014).

Accurate localisation requires hydrophone arrays with precise time synchronisation, as implemented in fixed seabed arrays, bottom-mounted tetrahedral systems (e.g., PALAOA), and towed arrays (Van Parijs 2009). Towed arrays allow bearing estimation and, with vessel motion, full localisation, although performance can be reduced by vessel noise, animal avoidance behaviour, and the left–right ambiguity inherent in linear arrays (Van Parijs 2009). Glider-based systems equipped with onboard detection algorithms (e.g., DMON/LFDCS) can provide reliable near-real-time detections, but localisation remains limited unless multiple gliders or fixed buoys operate as a network (Baumgartner et al. 2020). Overall, PAM localisation accuracy is highest when using multi-sensor arrays and lowest when relying on single sensors.

Across all studies, the reliability of PAM is influenced by ambient noise, calling behaviour, and detector performance. High ambient noise—including wind, rain, vessel noise, fish choruses, and snapping shrimp—can significantly reduce detection ranges, as demonstrated in South Australia's Fowlers Bay where wind-driven noise varied by 30 dB above 100 Hz, thereby constraining baleen whale detectability during poor weather (Ward et al. 2019). Automated detectors must balance false positives and missed detections: conservative right whale detectors deployed on real-time buoys achieved near-zero false detections at the cost of higher missed-call rates (Baumgartner et al. 2019), while automated glider detectors showed species-specific missed-detection rates ranging from 18–67%, depending on call type and analyst review protocol (Baumgartner et al. 2020). PAM performance also depends on the species' vocal behaviour—obligate vocalisers (e.g., sperm whales) are detected reliably, whereas facultative vocalisers may remain silent for extended periods. Despite these limitations, the evidence across all studies shows PAM is a robust, proven, and operationally mature method for detecting cetaceans, particularly when integrated with visual monitoring and deployed using arrays or multi-platform networks.

During Step 10 of the ALARP assessment, CGG evaluated the use of passive acoustic monitoring (PAM) systems on the spotter vessel. At that stage, PAM was rejected on ALARP grounds because the incremental reduction in impact or risk was not proportionate to the additional cost, complexity, and operational burden. However, subsequent further assessment of key environmental values and sensitivities (Appendix F3) identified a critical constraint: the effective detection range of Marine Fauna Observers (MFOs) is typically limited to ~5 km under ideal conditions, substantially less during low visibility, and no visual detections at night. These limitations became highly material when the detection distances to be achieved are >15 km.

To ensure impacts and risks remain at ALARP levels, and to provide extended detection capability during low-visibility conditions where MFO effectiveness is degraded, CGG will adopt PAM technology on the spotter vessel wherever practicable. PAM will operate supplementary to visual monitoring or as a primary trigger for shutdown decisions at night. For detections of Blue Whales during November and December, CGG will require all contracted vessels to undergo a PAM-readiness assessment to confirm whether they can safely and effectively support PAM operations. PAM-ready vessels will be preferentially selected and mobilised where commercially and operationally feasible. Where full PAM deployment is not possible, CGG will implement alternative monitoring arrangements to ensure environmental performance outcomes are met.

Further control measures identified and not assessed

There was further control measures identified in Appendix F5 that were in mind during the ALARP assessment, including:

- Fibre Optic Distributed Acoustic Sensors (DAS)
- Dual Camera Detection Systems (e.g., WhalePOD, SVDS)
- AI-Enhanced Satellite Monitoring (e.g., SpaceWhale)

These measures were identified and considered during the Marine Mammal Detection Technology Assessment as potential supplementary control options. However, they were not assessed in detail within the ALARP process. In each case, the likely effectiveness of the measure was limited by its technical maturity, feasibility, or relevance to real-time seismic survey operations. Furthermore, the primary pathways for impact have already been effectively addressed through an extensive suite of adopted controls, including visual observers, PAM systems, aerial surveys, and scheduling strategies.

Given this strong baseline, any additional environmental benefit from the above-listed measures would be marginal, speculative, or redundant. As such, the cost of conducting detailed analysis for each measure was itself clearly grossly disproportionate to the potential environmental benefit that might be realised. No further action was taken, and this approach is consistent with the principle of focusing detailed ALARP assessments on measures that are either practicable or offer credible additional benefit.

6.5.4 Results

Figure F2-7 presents the progressive ALARP assessment for the impact pathway of underwater sound. Each point on the chart represents a control measure or group of measures applied sequentially, plotted by their associated cumulative sacrifice (x-axis) against the residual impact reduction achieved (y-axis).

The green dotted line is a second-order polynomial trendline fitted to the sequence of adopted measures, representing the declining efficiency of control measures as more are added. The shape of the curve illustrates the concept of diminishing returns, where early measures provide significant benefit per unit of sacrifice, while later measures achieve less additional benefit at increasing cost.

The vertical dashed red line represents the ALARP threshold—the point at which further measures become grossly disproportionate in cost relative to the incremental benefit they offer. Measures falling to the left of this line are adopted, as they provide meaningful impact reduction at reasonable or proportionate cost. Measures to the right of this line (i.e. “Additional overflights” and “PAM on the spotter vessel”) are rejected, as the cost of implementation exceeds what can reasonably be justified given the small additional environmental benefit.

This graph visually supports the decision-making process and demonstrates that ALARP has been achieved, with additional measures considered and transparently excluded based on their cost-benefit profile.

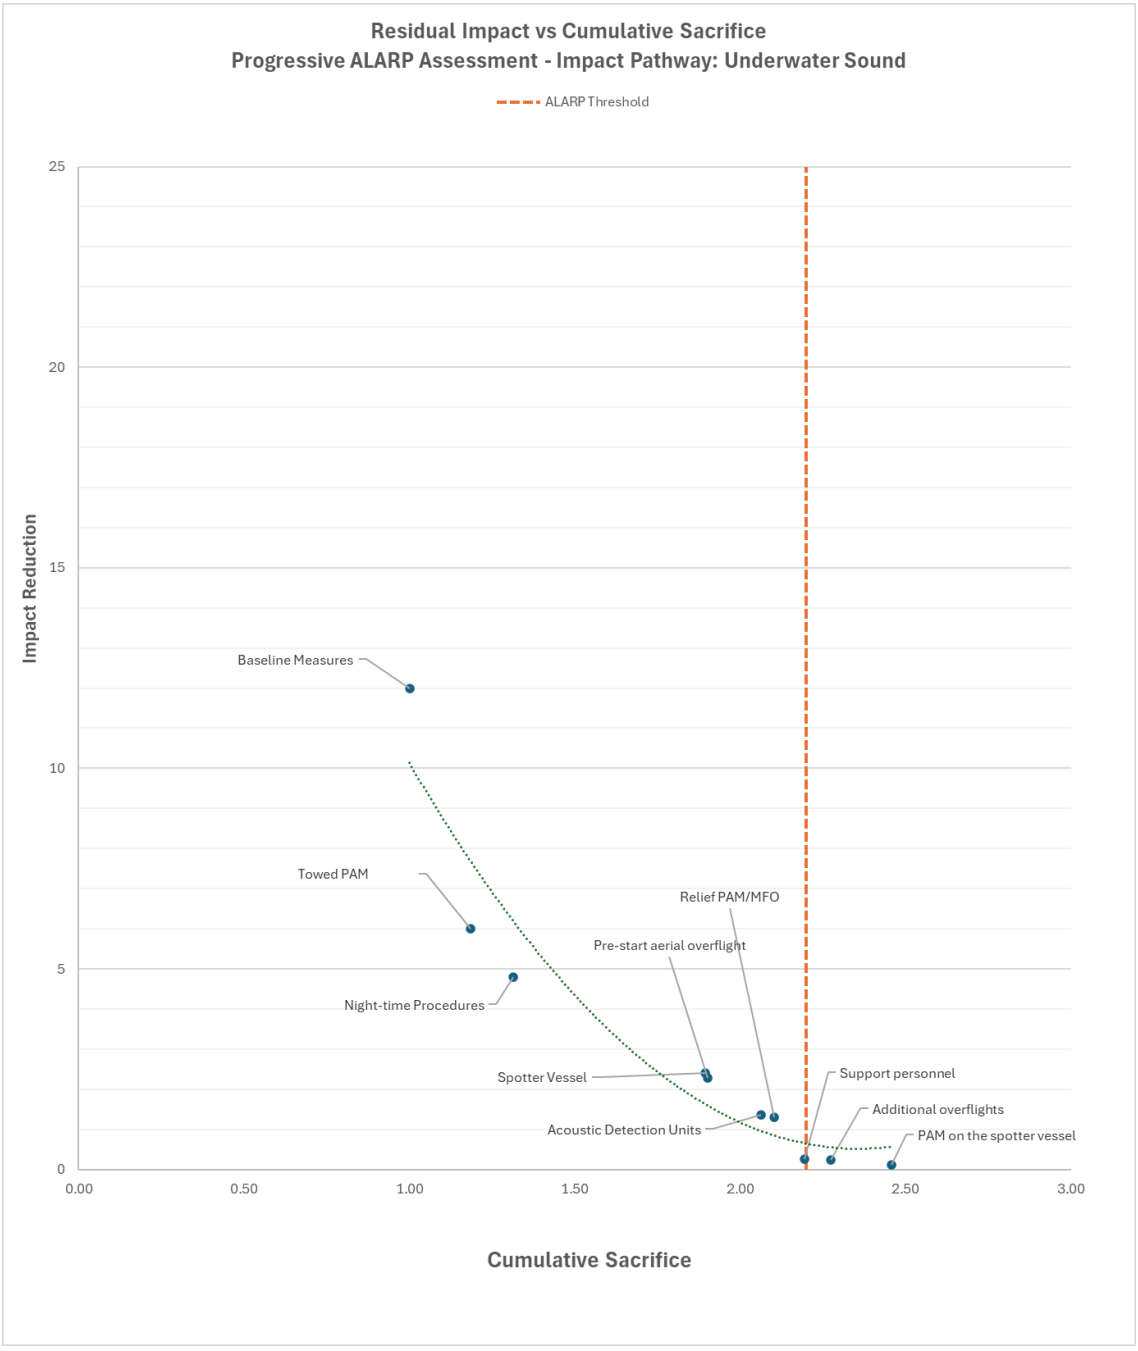

Figure F2-7 - ALARP Assessment Results - Underwater Sound: Residual Impact vs Cumulative Sacrifice for Underwater Sound Control Measures. A progressive ALARP assessment showing the impact reduction achieved by each control measure relative to the cumulative sacrifice required. The second-order polynomial trendline illustrates diminishing returns, and the dashed red line marks the ALARP threshold beyond which further measures are considered grossly disproportionate and therefore rejected.

Figure F2-8 presents a combined bar and line graph to validate the ALARP threshold identified in the residual impact vs cumulative sacrifice analysis. The bars represent the marginal reduction in residual impact or risk delivered by each individual control measure, showing the relative effectiveness of each step in the sequence. The line graph plots the corresponding cumulative sacrifice, illustrating how the total cost or effort increases with the adoption of each additional measure.

This format allows a direct visual comparison between the size of the environmental benefit (bar height) and the cost of achieving it (line slope). Early control measures show large reductions in impact for relatively small investments, while later control measures deliver diminishing benefits for greater cumulative sacrifice. The flattening of the bars combined with the steepening line demonstrates that the rate of return on environmental investment is decreasing.

The turning point, where bars become marginal and the line continues to rise sharply, supports the conclusion that the final adopted measure is at the threshold of gross disproportionality. The two rejected measures clearly fall beyond this threshold, providing confirmation of the ALARP decision made in the preceding graph.

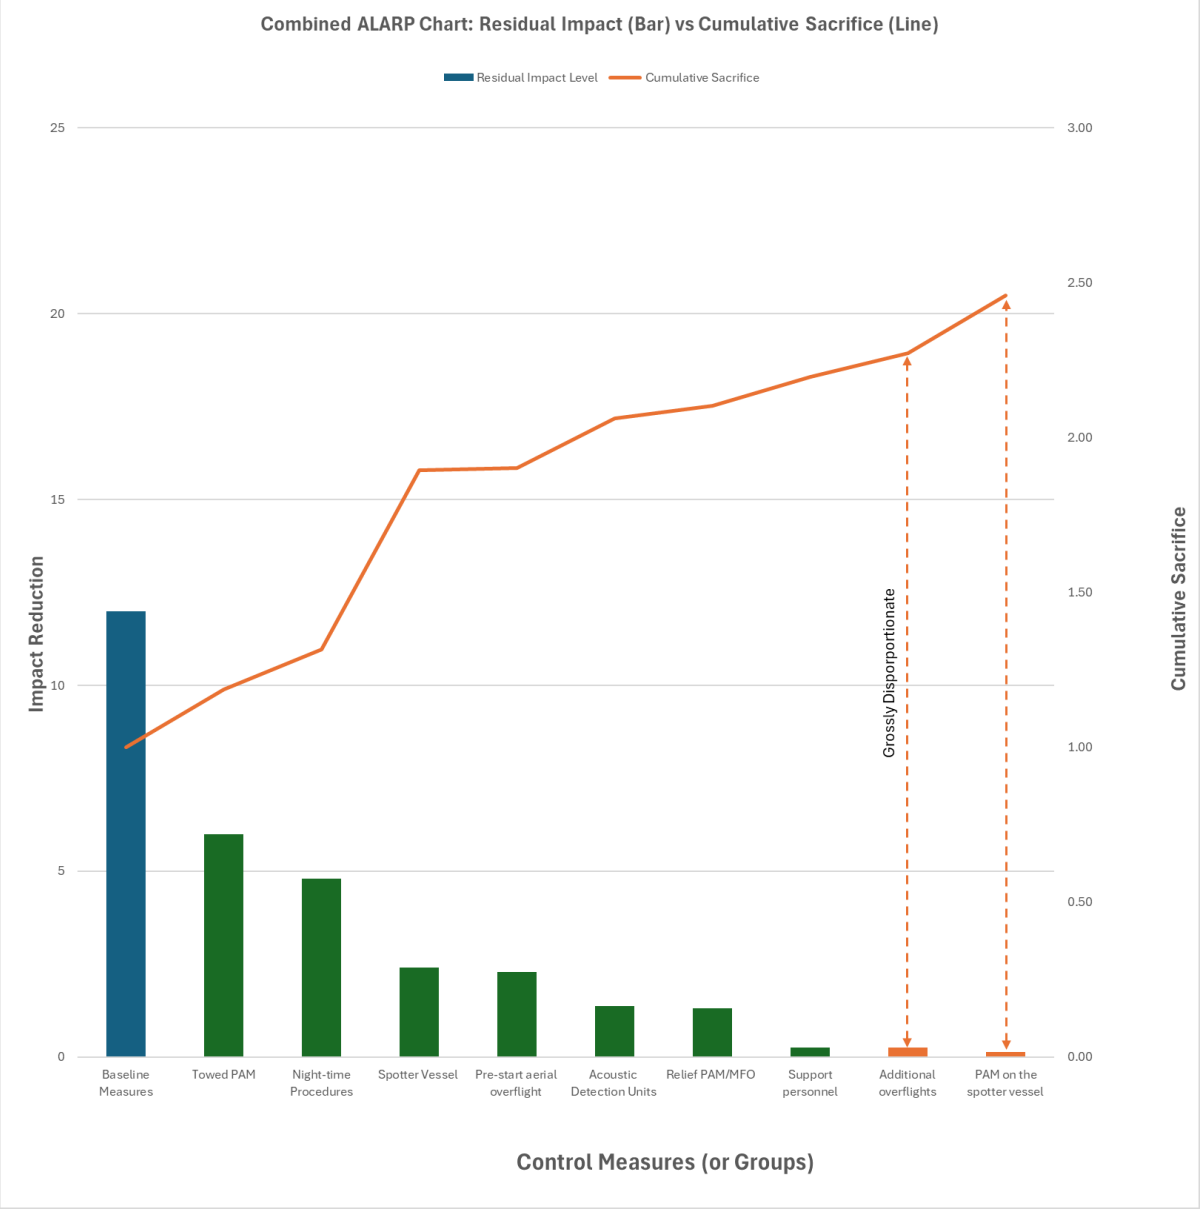

Figure F2-8 - ALARP Assessment - Underwater Sound: Marginal Impact Reduction and Cumulative Sacrifice for Underwater Sound Control Measures. Bars show the impact or risk reduction provided by each control measure; the line indicates cumulative sacrifice. This graph validates the ALARP threshold by illustrating where the marginal benefit becomes negligible relative to the rising cost of additional measures.

6.6 Artificial Light

6.6.1 Baseline

Table F2-15 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline impact level and baseline quantum of sacrifice.

Table F2-15 – Baseline Measures – Artificial Light

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Navigational lighting	Required under maritime safety regulations.	Not reducible due to safety obligation; sets baseline.
Vessel exclusion zone (4nm from coast)	Activity limitation to reduce overlap with recreational users also limits light exposure to the coastline.	Not reducible due to safety obligation; sets baseline.
Lighting Management Plan (LMP)	Company standard to minimise unnecessary light emissions with OVID-Style inspections checking all vessels have a LMP in place.	Minimises attraction/disruption to light-sensitive fauna.

The outcome of the impact assessment for physical presence was that the effect was ranked as minor (2) and the uncertainty ranked as low (2). Therefore, the residual impact after the application of baseline measures is four (4).

The quantum of sacrifice for complying with the baseline has been calculated and includes the following:

- Navigational lighting is required under international maritime safety regulations and is therefore a non-negotiable obligation for safe operation at sea. The commitment to maintain a 4 nm exclusion from the coastline—though primarily an activity limitation designed to reduce overlap with recreational users—has the added benefit of reducing coastal light exposure. However, this constraint limits the survey area and restricts CGG's ability to collect data in potentially high-interest nearshore zones. While not a direct financial cost, this represents a compromise in operational scope.
- The Lighting Management Plan (LMP), required for all vessels, is a company standard developed over time through internal systems and inspections, including OVID-style pre-deployment assessments. As this plan is now a mature part of CGG's operating procedures, its implementation no longer imposes significant operational costs. However, the development of the systems, experience, and refinements required to reach this level of maturity represents a historical investment that has contributed to its current effectiveness.

Overall, the baseline measures reflect a high level of intrinsic effectiveness with relatively low current cost or effort, though they are underpinned by earlier organisational investments and operational trade-offs. These combined costs and efforts form the cumulative baseline sacrifice, which is assigned a unit value of one (1) in the ALARP assessment. This allows subsequent discretionary control measures to be evaluated proportionally.

6.6.2 Assessment

Table F2-16 shows the step-by-step process followed for the ALARP assessment of artificial light. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-16.

6.6.3 Consideration of Alternative, Additional or Improved Control Measures

As part of the ALARP assessment for artificial light, CGG considered additional or improved control measures beyond those already adopted. One such measure was the use of advanced light filters designed to further narrow the spectral output of onboard lighting systems. These filters can reduce visibility to certain marine fauna by removing wavelengths known to trigger behavioural responses. However, when applied on top of existing lighting controls – such as shielded fittings, dimming technologies, and blackout curtains – the additional reduction in light-related impact is minimal. Furthermore, implementing this measure would require retrofitting lighting systems across multiple vessels, introducing substantial procurement, installation, and maintenance costs. These costs include not only hardware but also operational downtime and compatibility assessments. While technically feasible, the sacrifice required (0.125 units) was assessed as grossly disproportionate to the marginal reduction in residual impact, and the measure was therefore rejected.

Other potential improvements, such as the deployment of active light detection sensors or automated brightness adjustment systems, were also considered. While conceptually interesting, these systems introduce complexity into vessel operations and present a risk of malfunction or false responsiveness in the offshore environment. Their benefit would also be marginal considering the existing effectiveness of CGG's Lighting Management Plan and onboard procedures. As such, no further control measures were identified that would provide substantial risk reduction without grossly disproportionate sacrifice.

This assessment confirms that the control measures already adopted represent a point where additional environmental benefit is outweighed by the cost, complexity, or operational risk of implementation, and that the residual impacts from artificial light have been reduced to ALARP.

6.6.4 Results

Figure F2-9 illustrates the outcome of the ALARP assessment for the artificial light impact pathway, showing how progressively adopted control measures reduce residual impact in relation to cumulative sacrifice. Each data point represents a control measure or group of measures that was assessed for its intrinsic effectiveness and corresponding cost, time, or operational effort. The plotted curve uses a second-order polynomial trendline to demonstrate the diminishing returns of environmental benefit as increasing sacrifice is invested.

In this assessment, the baseline measures (including required navigational lighting and exclusion zones) were followed by the adoption of dedicated light minimisation technologies and practices. These early measures provided substantial impact reduction at low to moderate sacrifice. Subsequent measures, such as CGG's Marine Assurance System and the appointment of a Survey Environment Advisor, continued to improve risk management but with increasingly marginal gains relative to their cost. The ALARP threshold, represented by the vertical dashed line, indicates the point at which further sacrifice would be considered grossly disproportionate to the environmental benefit gained. The final measure plotted exceeds this threshold, confirming that ALARP has been demonstrably achieved for this impact pathway.

Table F2-16 - Step-by-step ALARP Assessment – Artificial Light

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	4	1	1	Baseline measures include legally required navigational lighting and a Lighting Management Plan. These measures set a foundational level of impact reduction and are not subject to modification due to their safety-critical nature. Their effectiveness is high in defining the minimum controllable level of light emissions.	Baseline measures involve no additional financial cost to CGG, as they represent legal requirements and company standards already embedded into routine operations. Their historical development involved significant investment, but their marginal cost is low.
2	Light Minimisation Measures	Shielded lighting, dimming technologies, and blackout curtains.	4	90%	3.6	0.4	5	6	The use of shielded lighting, dimming technologies, and blackout curtains directly reduces the intensity and spread of light emissions. These technologies interrupt the pathway between the source and light-sensitive fauna, making them highly effective in minimising impact. A 90% effectiveness rating has been applied to reflect this high performance without overstating precision - this value represents a well-established standard of effectiveness for measures targeting the light pathway directly.	These measures involve moderate upfront investment in technology and vessel outfitting, but they are well-established practices. Their high effectiveness justifies the cost, and the long-term operational burden is minimal.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
3	CGG Marine Assurance System	Ensures compliance with laws and requires an OVID-style inspection prior to the survey to check the light management plan onboard.	0.4	90%	0.36	0.04	4	10	The Marine Assurance System ensures compliance with internal standards and maritime regulations, verified via OVID-style inspections. Its effectiveness lies in ensuring all vessels implement appropriate lighting controls consistently and reliably. The 90% rating is used here to maintain consistency and transparency in evaluating operational systems that consistently deliver high compliance outcomes.	The Marine Assurance System is a company standard. While the inspections involve administrative and operational overheads, these are already incorporated into CGG's workflow and contribute to multiple areas of compliance, keeping incremental cost moderate.
4	Survey Environment Advisor	Ensures the compliance with the sail line plan, the light management plan, inductions for the crews.	0.04	90%	0.036	0.004	12	22	The onboard Survey Environment Advisor ensures the correct implementation of procedures and alignment with the Sail Line Plan. Their role provides operational assurance and continuous improvement, further refining light minimisation performance on the ground. A 90% effectiveness rating is assigned to reflect the Advisor's strong role in implementation assurance.	The Survey Environment Advisor is an added operational resource. While their inclusion adds staffing cost and coordination requirements, the role provides broader assurance benefits beyond lighting and supports overall environmental compliance. The incremental cost is justified by the added certainty in implementation.

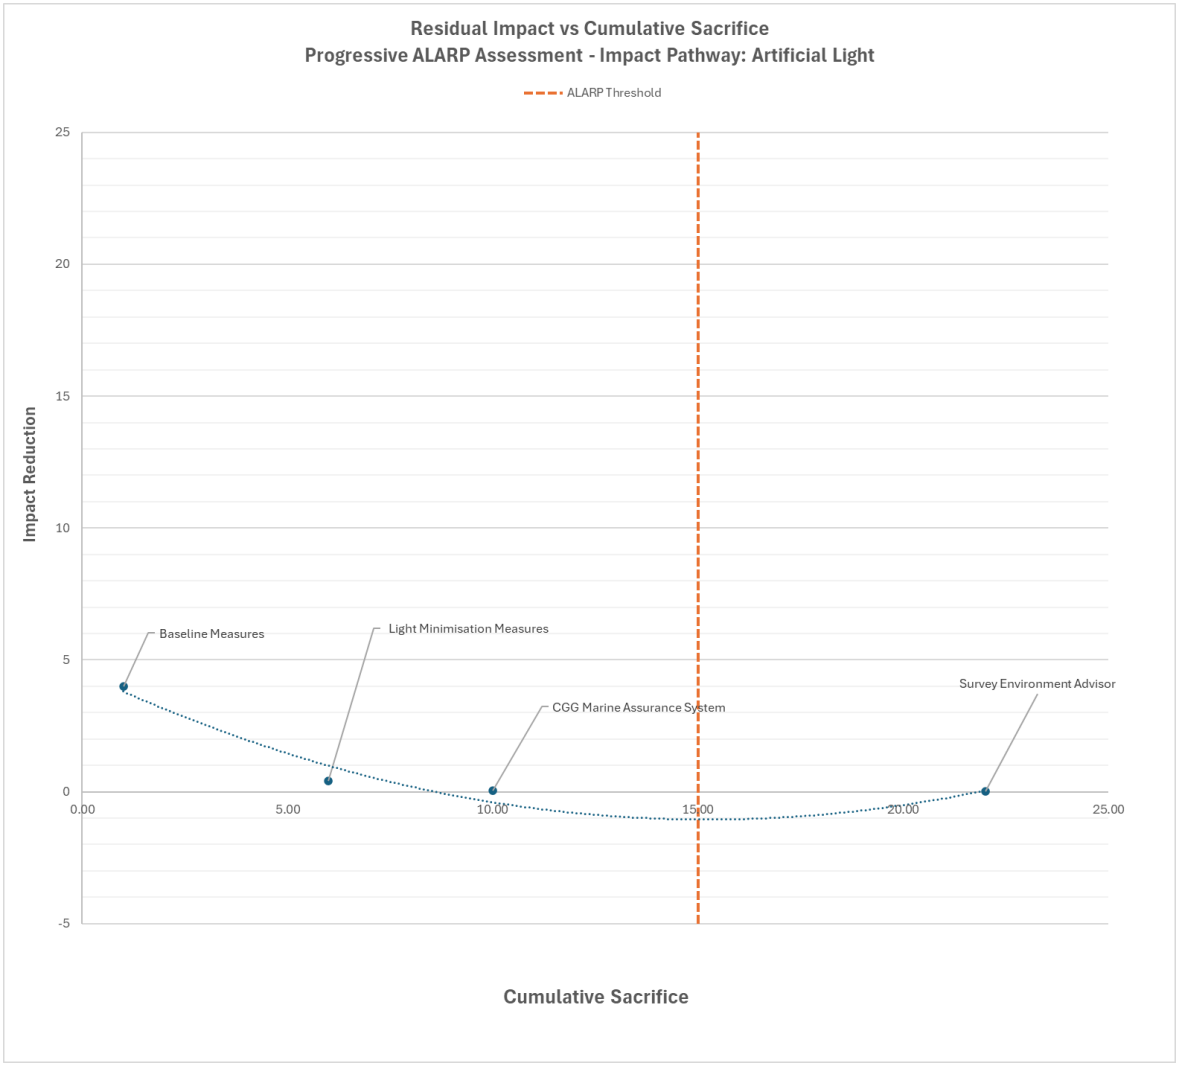

Figure F2-9 - Residual Impact vs Cumulative Sacrifice – Progressive ALARP Assessment for Artificial Light: The graph plots cumulative sacrifice (x-axis) against total impact reduction (y-axis), with a second-order polynomial trendline illustrating diminishing returns. The vertical dashed line represents the ALARP threshold, beyond which additional measures are rejected due to grossly disproportionate cost relative to benefit.

Figure F2-10 provides a combined visual summary of the ALARP assessment for artificial light, comparing the marginal environmental benefit of each control measure (bar graph) against the cumulative sacrifice required to adopt them (line graph). Each bar represents the level of residual impact reduction achieved by an individual or grouped control measure. The orange line tracks the total cost, time, or operational effort (sacrifice) accumulated with each successive measure. The graph illustrates that the greatest impact reduction was achieved through baseline measures, which include legally required lighting and spatial activity limitations. Additional measures, such as light minimisation technologies and procedural controls, yielded further reductions but at progressively higher cost for diminishing return. This contrast between bar height (benefit) and line steepness (cost) makes it visually clear where the balance between benefit and sacrifice begins to diverge — validating the point of inflection identified in the accompanying scatter plot. The chart therefore supports the conclusion that further measures, such as appointment of a dedicated Survey Environment Advisor, are grossly disproportionate and not required to reduce impact to ALARP. However, the Survey Environment Advisor is a measure already in place for other impact and risk mitigation and so remains an adopted control measure.

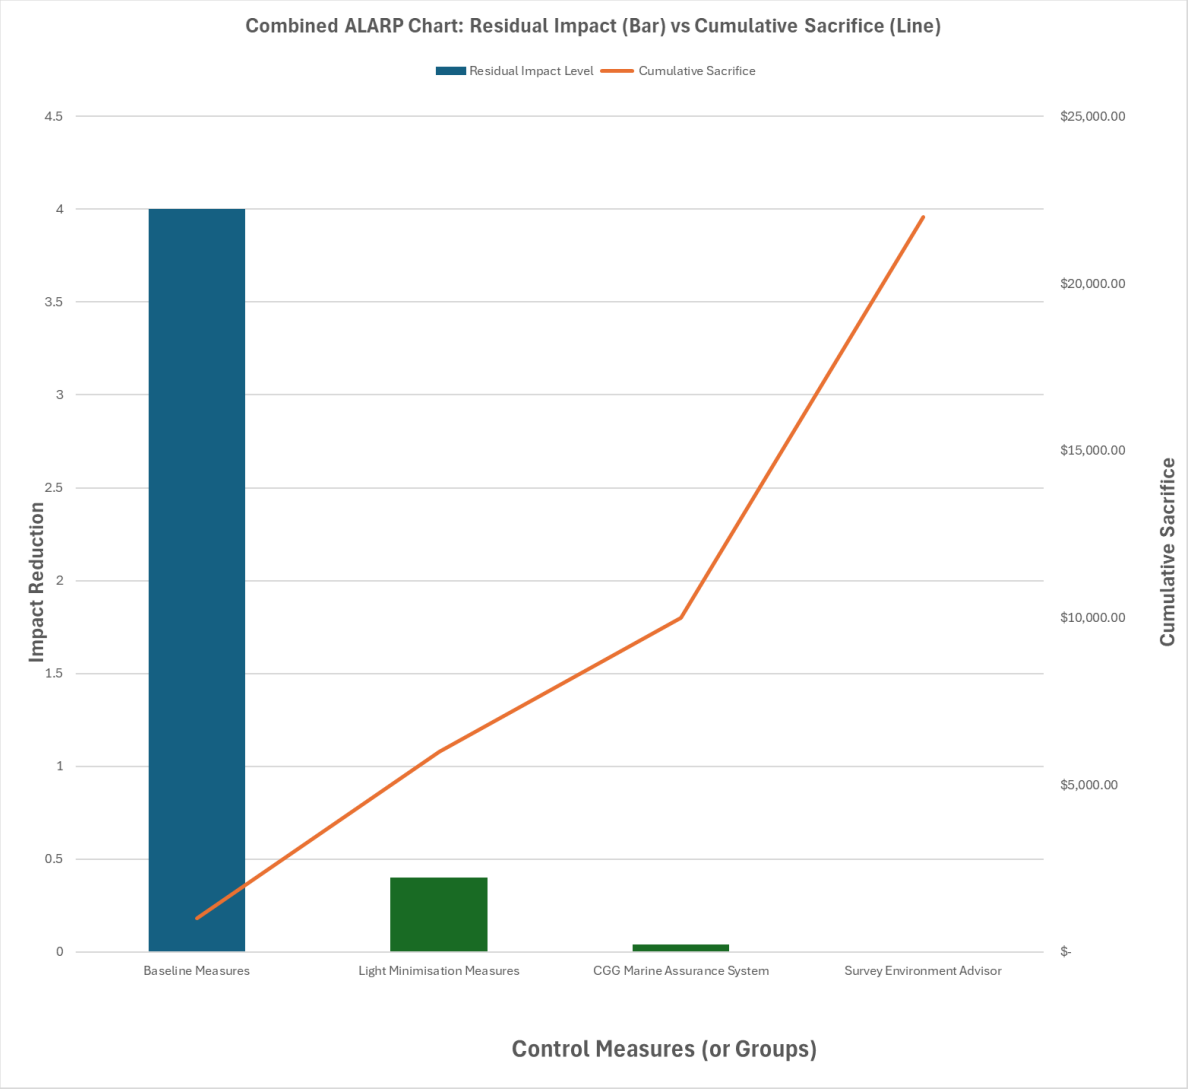

Figure F2-10 - Combined ALARP Chart for Artificial Light – Residual Impact Reduction (Bar) vs Cumulative Sacrifice (Line). The bar chart shows the impact reduction provided by each control measure or group, while the line chart illustrates the rising cumulative cost. This dual-axis visualisation highlights where diminishing returns occur and confirms that further sacrifice yields negligible environmental benefit beyond the ALARP threshold.

7 ALARP Assessment – Risks

Following the completion of the Preliminary Environmental Impact and Risk Assessment (PEIRA) (Appendix B4), and the subsequent full risk assessments (Appendices D1-4), this ALARP assessment covers the following risk pathways:

- Accidental release of materials or waste overboard.
- Collisions with marine fauna.
- Introduction of invasive marine species.
- Accidental release of fuel.

The following sections of this document assess each risk pathway in turn.

7.1 Accidental Release of Materials or Waste Overboard

7.1.1 Baseline

Table F2-17 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline risk level and baseline quantum of sacrifice.

Table F2-17 - Baseline Measures - Accidental release of materials or waste overboard

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Compliance with relevant legislation and MARPOL Annex V	This includes adherence to MARPOL Annex V, which sets strict rules on garbage discharge from vessels, including a complete ban on the discharge of plastics into the sea and specific controls on other types of waste. Vessels must maintain procedures for waste handling, install appropriate storage and disposal systems, and maintain records of all waste disposed. Regular inspections and audits are conducted to verify compliance.	High – Reduces the chance of illegal or accidental discharge and enforces consistent legal standards across operations.
CGG Marine Assurance System	The assurance system covers a range of practical measures to prevent waste from entering the marine environment. These include audits and inspection of contractors Garbage Management Plan, maintenance of a Garbage Record Book to log all disposals and transfers, use of clearly labelled and covered containers for segregated waste storage, and regular crew training.	High – Provides a structured and enforceable approach to prevent waste discharge through standardised procedures and oversight.
Support vessel recovery capacity	In the event of accidental loss of materials overboard, a dedicated support vessel is available to respond. The vessel is equipped with personnel and tools to assist in locating and retrieving floating or drifting materials, where recovery can be conducted safely. Operational procedures include communication protocols, response planning, and post-recovery documentation. Although reactive, this measure ensures that environmental harm can be reduced if an incident occurs.	Moderate – Helps reduce the consequences of accidental loss but does not prevent incidents from occurring.

The baseline sacrifice is set at 1.0 to provide a reference point for comparing other measures. This number does not mean the baseline is cheap or easy to implement. Meeting legal requirements and applying the CGG Marine Assurance System takes effort, resources, and planning.

- Compliance with relevant legislation and MARPOL Annex V requires vessels to maintain waste-handling systems, train crew, keep procedures up to date, and complete regular inspections.
- The CGG Marine Assurance System includes documentation, training, containment practices, and internal audits to ensure waste is handled correctly and in compliance with environmental standards.
- Support vessel recovery capacity involves maintaining readiness, equipment, and procedures to recover released materials safely and effectively if an incident occurs.

The outcome of the risk assessment for accidental release of materials or waste overboard was that the likelihood was ranked as minor (2) and the consequence ranked as unlikely (2). Therefore, the residual risk after the application of baseline measures is medium (4).

7.1.2 Assessment

Table F2-18 shows the step-by-step process followed for the ALARP assessment of release of waste. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-18.

7.1.3 Consideration of Alternative, Additional, or Improved Control Measures

Several potential control measures were considered during the assessment process but not adopted, either because they offered minimal additional benefit or because their cost or complexity was disproportionate to the risk.

Real-time onboard monitoring

Tracking of all potential debris-generating equipment was considered. This would involve installing sensors and GPS tags on disposable items or high-risk components. While this could improve detection of overboard loss events, the effectiveness would be limited unless paired with immediate recovery actions. This option was reviewed in relation to Step 2. It was not adopted due to its high complexity, cost, and the fact that similar functions are already provided by the streamer recovery units, which are more practicable and widely applicable.

Deploying a dedicated marine waste observer

This role would involve real-time observation of deck activities and waste handling practices. While this could offer incremental assurance, it overlaps heavily with existing crew responsibilities. It was considered during discussion of baseline effectiveness (Step 1) and rejected on the grounds that existing controls already provide similar assurance, and the additional role would likely create redundancy without proportionate benefit.

In each case, alternative measures were either already covered in the existing system or provided marginal benefits that did not justify their implementation. The current combination of baseline and additional controls was found to be both effective and proportionate.

Table F2-18 - Step-by-step ALARP Assessment – Accidental Release of Waste

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See previous tables.	-	-	-	4	-	1.0	The baseline is assigned high intrinsic effectiveness because it includes international legal compliance (MARPOL Annex V) and a structured corporate assurance system. These elements ensure all vessel waste is tracked, managed, and minimised, significantly reducing the chance of accidental release.	Assigned a unit value of 1.0 to represent the cumulative effort required to maintain compliance, implement controls, train personnel, and conduct audits. This reflects the total baseline burden rather than implying the measures are low cost or low effort.
2	Streamer Recovery Units	Streamers fitted with recovery units to prevent benthic disturbance and recover lost gear	4	60%	2.4	1.6	0.2	1.2	Streamer recovery units are moderately effective at reducing environmental harm by preventing gear loss and allowing for recovery. They reduce long-term seabed impacts and improve recoverability of materials. While they don't prevent releases, they enable quick response and clean-up.	An incremental sacrifice of 0.2 reflects the costs of installing, maintaining, and monitoring streamer recovery equipment across the spread. These systems add complexity but are manageable within existing marine operations.
3	Support Vessel	Provides capacity to recover released materials where safe and practicable	1.6	50%	0.8	0.8	0.2	1.4	The support vessel offers reactive risk reduction. It cannot prevent incidents but does lower residual impact by recovering waste after accidental release. Its effectiveness is dependent on conditions, crew availability, and time since release, so it is rated at 50%.	The incremental 0.2 rating accounts for operational planning, equipment checks, and readiness protocols. Since the support vessel is already part of operations, the added burden is considered moderate and proportionate.

7.1.4 Results

Figure F2-11 illustrates the reduction in residual risk achieved through successive control measures plotted against their cumulative sacrifice. The baseline measures provide the greatest risk reduction, reflecting established protocols and compliance with MARPOL and other maritime legislation. The addition of streamer recovery units and the deployment of a support vessel provide incremental risk reductions, though with increasing cost and complexity. The trendline clearly shows a flattening trajectory, indicating diminishing returns, and supports the conclusion that the most effective and proportionate measures have already been adopted. The ALARP threshold is shown at a cumulative sacrifice of 2.0, and all control measures fall below this, demonstrating they are proportionate.

Figure F2-12 is a combined ALARP chart that validates the assessment for the accidental release of materials or waste overboard risk pathway. It presents the residual risk reduction (bar) delivered by each control measure and the cumulative sacrifice (line) associated with implementing them. The baseline measures contribute the greatest reduction in risk, with additional benefits provided by streamer recovery units and support vessel deployment. While the incremental risk reductions are modest, all adopted measures remain within a reasonable sacrifice range. The steady rise in the cumulative sacrifice curve supports the conclusion that further measures would be grossly disproportionate relative to the low remaining risk.

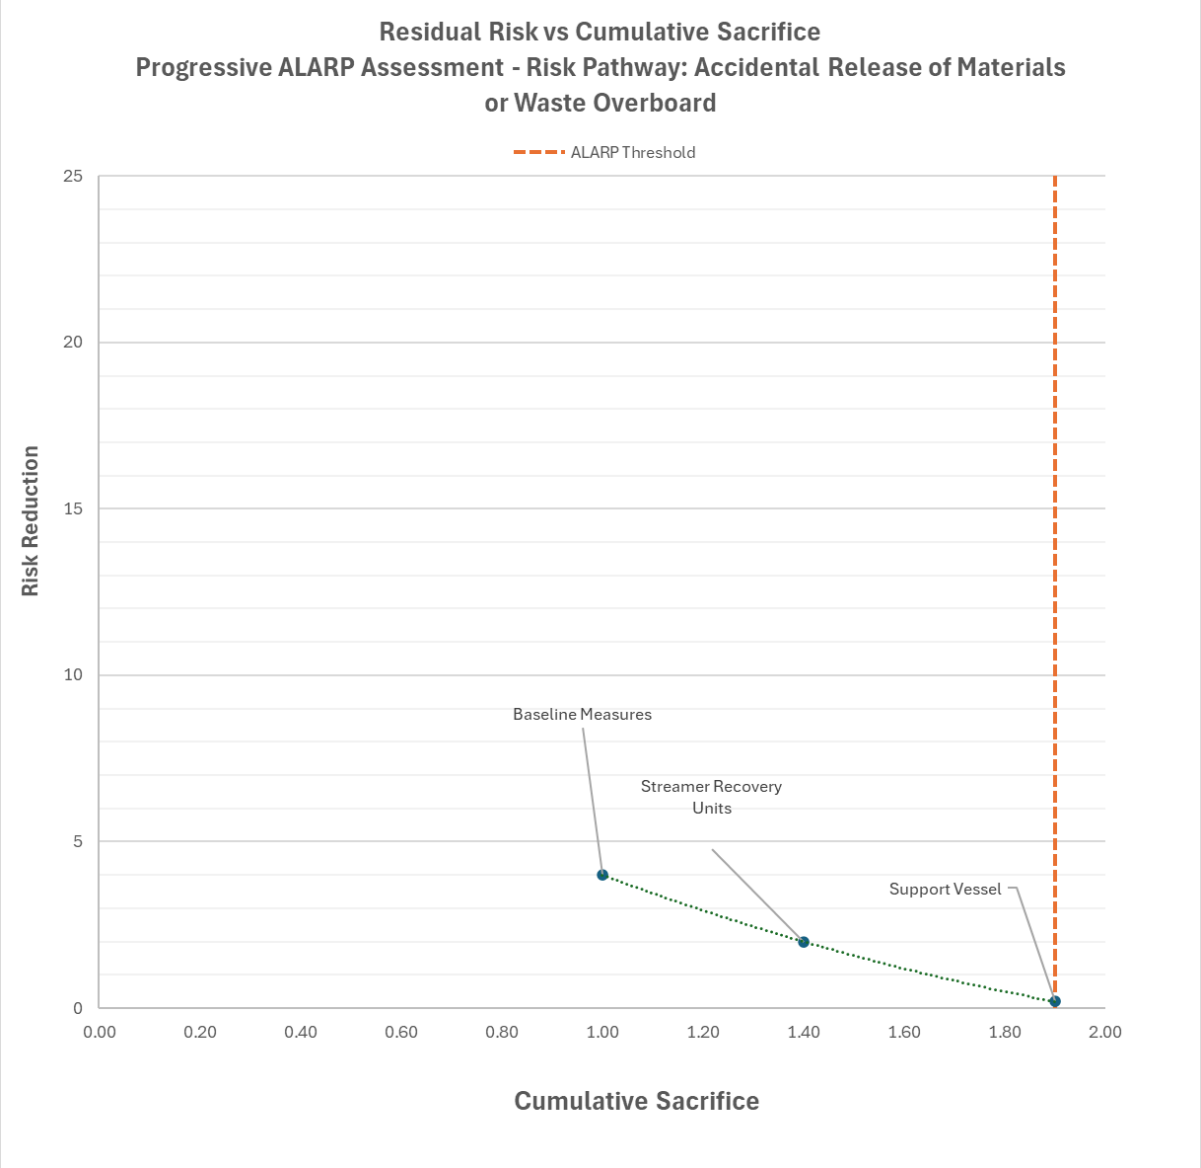

Figure F2-11 - ALARP chart showing residual risk reduction versus cumulative sacrifice for the Accidental Release of Materials or Waste Overboard risk pathway.

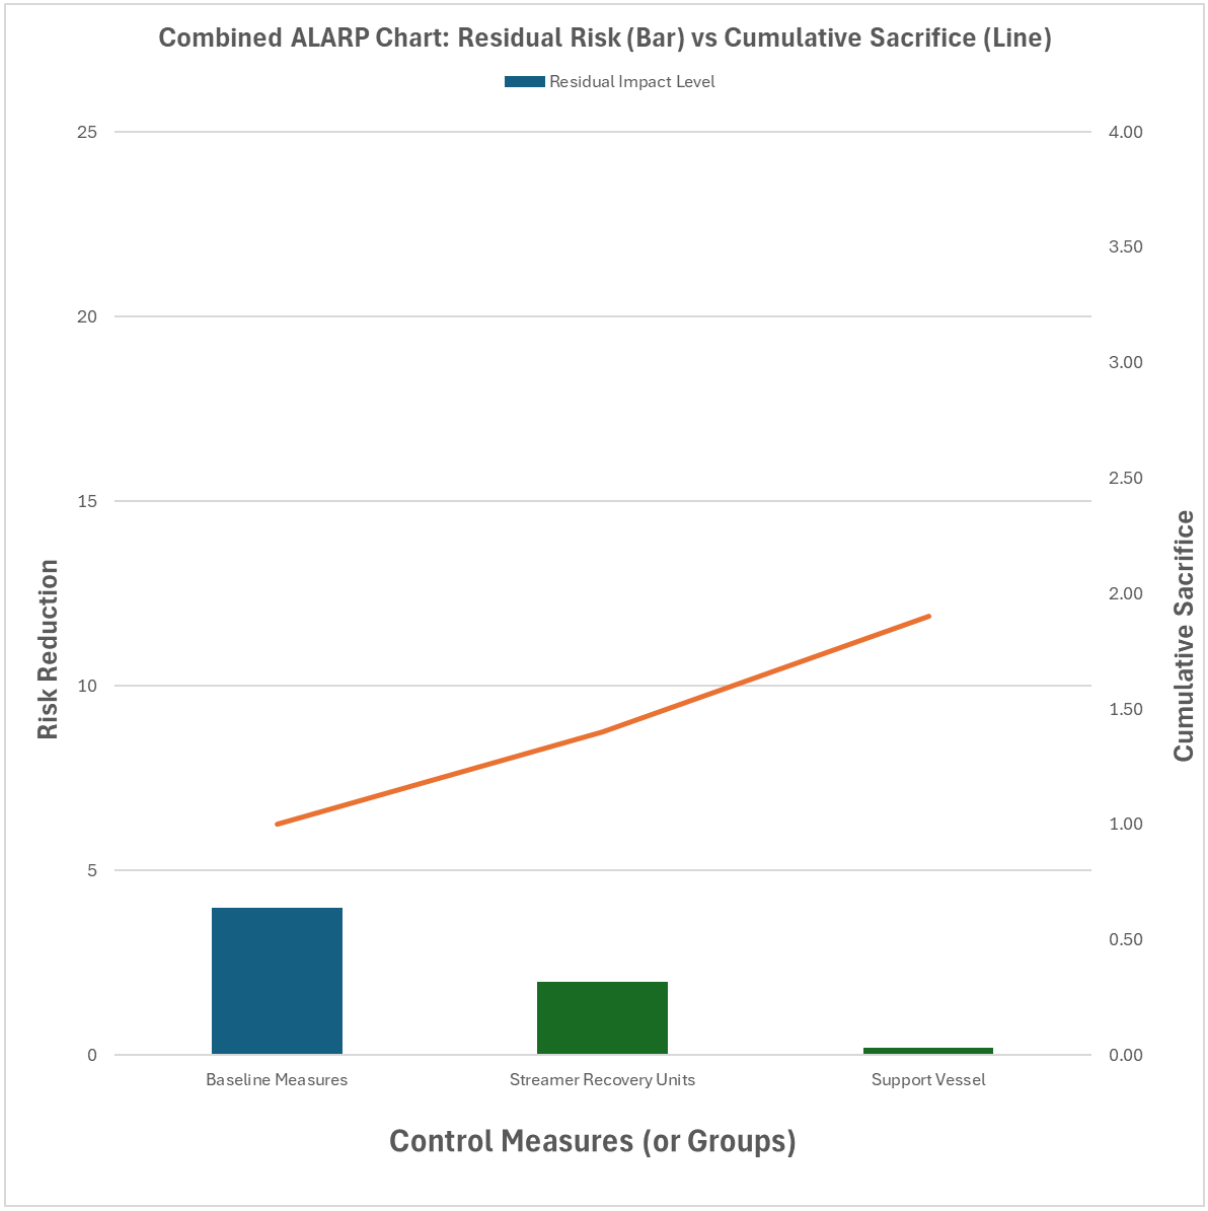

Figure F2-12 - Combined ALARP chart showing residual risk level (bars) and cumulative sacrifice (line) for the Accidental Release of Materials or Waste Overboard risk pathway.

7.2 Collisions with Marine Fauna

7.2.1 Baseline

Table F2-19 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline risk level and baseline quantum of sacrifice.

Table F2-19 - Baseline Measures – Collisions with Marine Fauna

Baseline Measure	Inclusion Rationale	Intrinsic Effectiveness
Vessel Speed Restriction	Seismic and support vessels limited to ≤6 knots during acquisition to reduce likelihood and severity of collisions with fauna, supported by national strategies and species-specific plans.	High – Lower vessel speed allows more time for fauna to detect and avoid the vessel, and for vessel operators to respond to sightings, reducing the probability and severity of collisions.
Fauna Management Plan	Implementation of Fauna Management Plan consistent with EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with Cetaceans and EPBC Act Policy Statement 2.1.	High – Clearly defined legal requirements provide a structured, enforceable approach to avoid and manage interactions with marine fauna, particularly cetaceans.
Activity Limitations (Timing)	Acquisition planned in shoulder periods for most whale abundance times. Avoidance of summer months is key.	High – Spatial and temporal planning minimises overlap with migrating whales, significantly reducing the likelihood of interactions during sensitive periods.
Marine Fauna Observers (MFOs)	Use of Marine Fauna Observers (MFOs) to maintain visual detection during operations. This includes MFO's on the spotter vessel.	High – Real-time detection of fauna enables immediate response, including shut-downs or course changes, to prevent interactions.

The outcome of the risk assessment for collisions with marine fauna was that the likelihood was ranked as rare (1) and the consequence ranked as major (4). Therefore, the residual risk after the application of baseline measures is medium (4).

The quantum of sacrifice for complying with the baseline has been calculated and includes the following:

- Operational speed limitation to ≤6 knots – This is the speed of the survey vessel as part of the acquisition; however, it does introduce some costs for other vessels fuel efficiency.
- MFO resourcing and training – Requires allocation of personnel with specialised skills, including pre-survey training and dedicated observer roles during acquisition, adding to staffing and operational expenditure.
- Compliance with separation zones under Fauna Management Plan – May necessitate course adjustments or activity pauses when fauna is detected within exclusion zones, potentially disrupting survey flow and efficiency.
- Seismic line planning and sequencing in high-risk seasons – Reduces scheduling flexibility and may require more complex operational planning to prioritise safer spatial-temporal windows.

The outcome of the risk assessment for accidental release of materials or waste overboard was that the likelihood was ranked as major (4) and the consequence ranked as rare (1). Therefore, the residual risk after the application of baseline measures is medium (4).

The cumulative quantum of baseline sacrifice is normalised to 1.0. All further control measures will be evaluated relative to this.

7.2.2 Assessment

Table F2-20 shows the step-by-step process followed for the ALARP assessment of collisions with marine fauna. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-20.

7.2.3 Consideration of Alternative, Additional, or Improved Control Measures

No further control options are considered necessary. The baseline includes all identified measures from the risk assessment that deliver high effectiveness with proportionate cost. This includes extensive mitigation to reduce impacts from underwater sound, which serves as a deterrent to marine fauna and decreases the likelihood of vessel interactions. These acoustic and procedural safeguards, along with visual and acoustic detection measures, ensure that the likelihood of collisions is already low. Therefore, no further practicable measures were identified that would lower the residual risk without incurring disproportionate sacrifice.

7.2.4 Results

Figure F2-13 presents the progressive ALARP assessment for the *Fauna Collisions* risk pathway, mapping residual risk reduction against cumulative sacrifice. The baseline measures account for most of the risk reduction and establish a strong initial risk profile. A turtle entrapment mitigation measure delivers a moderate additional benefit at a proportionate cost and is therefore adopted. A third measure, Passive Acoustic Monitoring (PAM), while technically feasible, offers only marginal improvement in this risk reduction relative to the increased sacrifice required. Despite being positioned well beyond the point of diminishing returns, it has been adopted due to is application to other impact pathways. The ALARP threshold is clearly defined, and the curve confirms that the accepted measures fall within the range of proportionality.

Figure F2-14 is a combined ALARP chart which validates the progressive assessment for the fauna collisions risk pathway by displaying both the residual risk reduction (bar graph) and cumulative sacrifice (line graph) for each control measure. Again, baseline measures deliver most of the risk reduction, establishing a low initial residual risk level. The turtle entrapment mitigation measure contributes additional reduction at a proportionate cost. Passive Acoustic Monitoring, while technically feasible, provides only a marginal further reduction at a sharply increased cumulative sacrifice, placing it beyond the range of proportionality and confirming the rationale for rejection in the progressive assessment, though it is adopted to manage other impact pathways and thus will be adopted anyway. The steady rise in the cumulative sacrifice curve supports the conclusion that further measures would be grossly disproportionate relative to the low remaining risk.

Table F2-20 - Step-by-step ALARP Assessment – Collisions with Marine Fauna

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	4	1.0	1.0	See individual ratings in previous tables.	1.0 (baseline normalised) – This represents the cumulative sacrifice across all baseline controls, including operational inefficiencies (e.g., low-speed transit), MFO labour and training costs, potential survey delays due to exclusion zones, and planning constraints.
2	Turtle Entrapment Mitigation	Tail buoys or streamers with no entrapment risk	4	60%	2.4	1.6	0.05	1.05	Addresses a rare but documented turtle entrapment risk by upgrading or modifying equipment that interacts with fauna near the surface. The 60% effectiveness rating reflects the ability of these equipment changes to eliminate a specific but low-frequency hazard. The rating is not higher because it is only one fauna group protected. The measure is targeted, effective in its narrow scope, and eliminates a known hazard when implemented correctly.	0.05 – This value is driven by the need to either retrofit or replace existing tail buoys with entrapment-safe alternatives. The cost is limited to equipment procurement or retrofit labour and applies only to vessels still using legacy buoys, making it low but not negligible.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
3	Passive Acoustic Monitoring	Use of PAM during periods of low visibility or night-time to detect vocalising cetaceans and trigger mitigation action	1.6	40%	0.64	0.96	0.15	1.20	Moderate – PAM provides valuable detection capability during low-visibility conditions when visual observers are ineffective. It enhances detection of vocal species like baleen whales but is less effective for non-vocalising or deep-diving species. The 40% effectiveness rating reflects this selective capability. While PAM does not detect all fauna types, it provides strong coverage in conditions where visual monitoring fails, making it a meaningful but partial addition to detection capacity.	0.15 – This includes costs associated with equipment rental or purchase, deployment and calibration on vessels, additional staff or training to operate the system, and data interpretation. Cost is considered moderate due to specialised hardware and integration requirements already being adopted to manage other pathways.

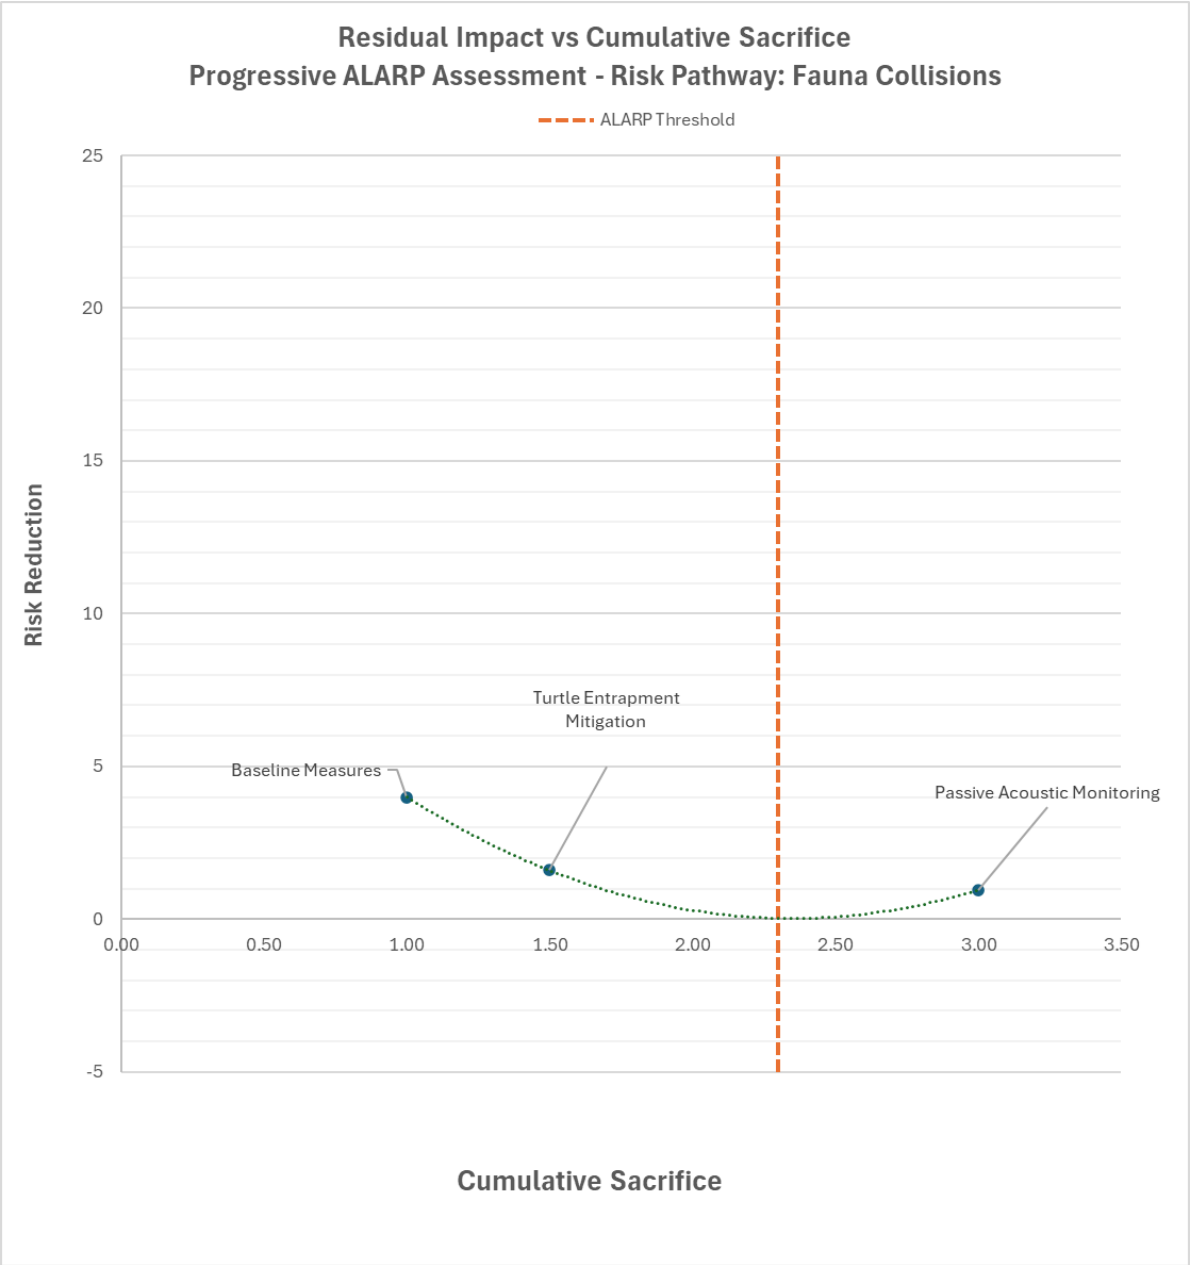

Figure F2-13 - Progressive ALARP assessment graph showing residual risk versus cumulative sacrifice for the Fauna Collisions pathway.

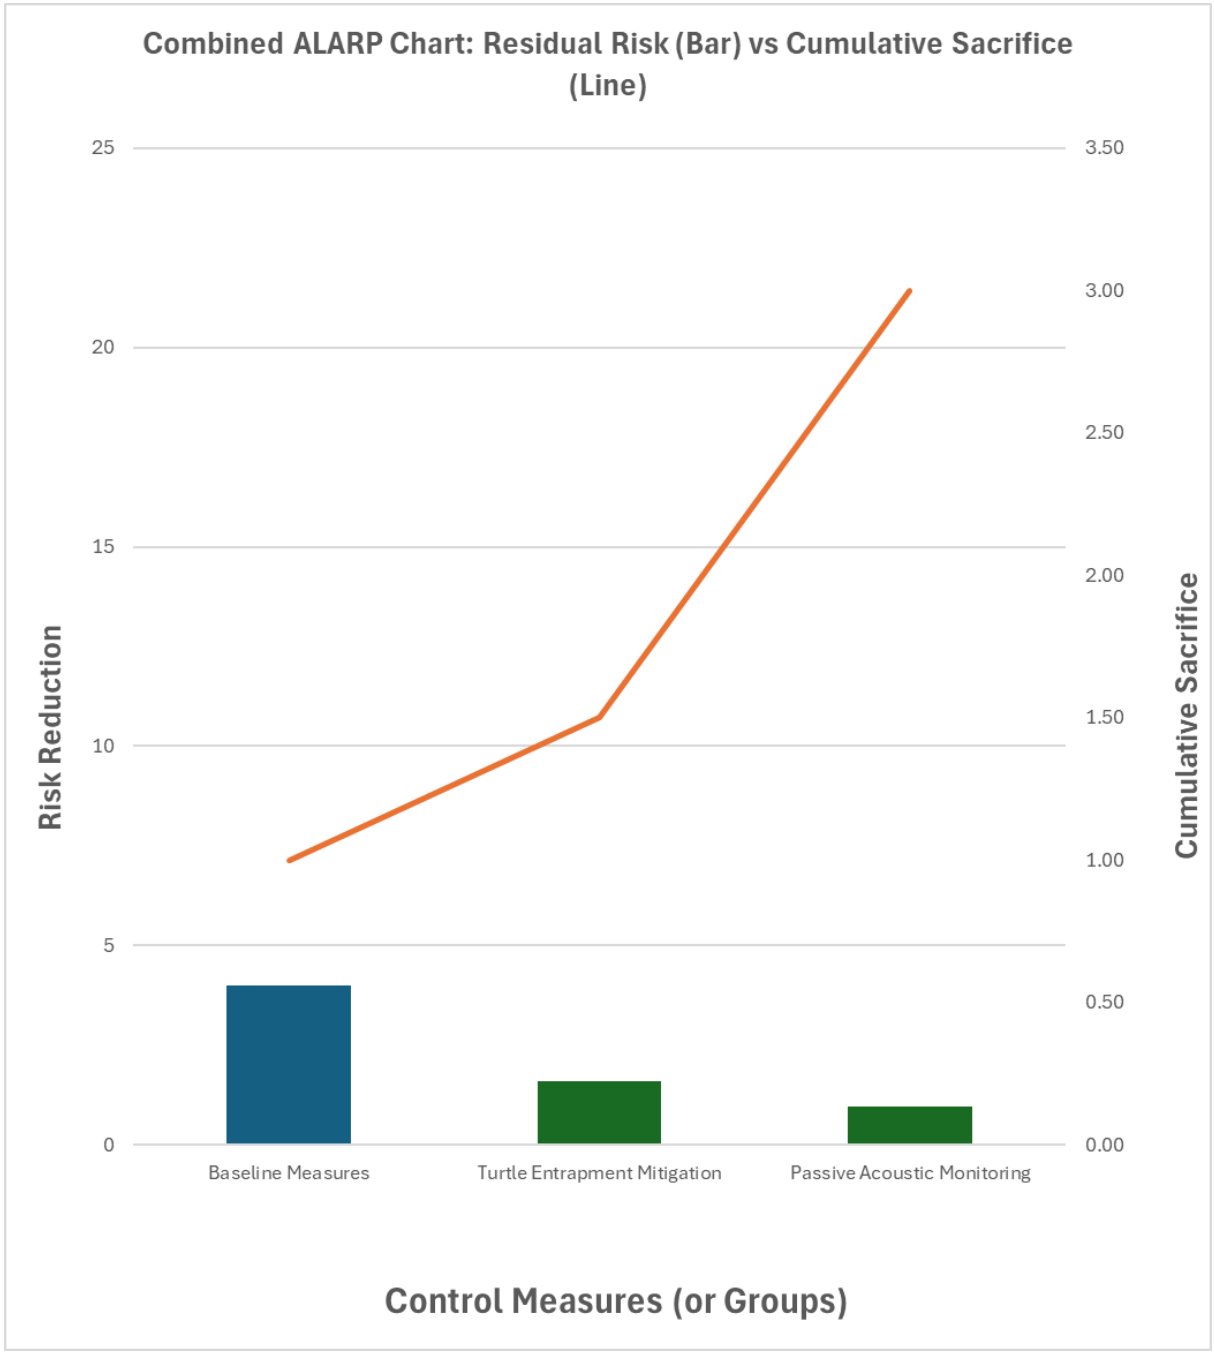

Figure F2-14 - Combined ALARP chart showing residual risk (bar) and cumulative sacrifice (line) for the Fauna Collisions risk pathway.

7.3 Introduction of Marine Pest Species

7.3.1 Baseline

Table F2-21 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline risk level and baseline quantum of sacrifice.

Table F2-21 - Baseline Measures – Invasive Marine Species

Baseline Measures	Inclusion Rationale	Intrinsic Effectiveness
Vessel contractor pre-qualification assessment	This measure ensures that only vessel contractors with acceptable biofouling management procedures and practices are considered for use. It aligns with internal environmental protection standards (GM-STD-MA-003) and acts as a proactive filter to reduce IMS risk at the earliest stages of planning and procurement. This pre-qualification assessment includes the preference for local vessels to reduce IMS risks.	This control ensures that only vessels with appropriate biofouling controls are used, reducing the risk of pest introduction by excluding unsuitable vessels at the planning stage.
OVID-style inspections	These inspections occur pre-port entry and provide assurance that marine pests are not present on vessels or associated subsea equipment. They include visual and documentary checks, cleaning verification, and adherence to vessel-specific mitigation procedures.	Real-time verification of vessel condition and cleanliness, including immersible equipment, significantly reduces the chance of live organisms being transported and introduced.
Operational Area Controls	Survey operations are excluded from zones of heightened sensitivity such as the Twelve Apostles Marine Park. Ballast water exchanges will be conducted outside of Marine Protected Areas. This reduces the potential for invasive species to enter high-value conservation areas and addresses specific concerns raised by regulators and stakeholders.	This measure eliminates the risk of IMS introduction into a nearby protected area and was adopted due to regulator and stakeholder concern.
Activity Design	The survey method avoids seabed contact by prohibiting anchoring and requiring all equipment to be stored on deck. This eliminates a major vector of pest translocation from vessel to marine habitat.	Equipment remaining on deck and absence of anchoring significantly reduces translocation opportunities for pests to reach the benthic environment.

The outcome of the risk assessment for invasive marine species was that the likelihood was ranked as Rare (1) and the consequence ranked as Major (4). Therefore, the residual risk after the application of baseline measures is Medium (4).

The quantum of sacrifice for complying with the baseline has been calculated and includes the following:

- Pre-deployment and port inspections: These require scheduling vessel access and personnel time, conducting physical inspections, and reviewing documentation for all vessels prior to mobilisation. This draws on internal resources, introduces potential delays, and requires coordination with port authorities and contractors.
- Survey design restrictions and procedural controls to minimise IMS introduction risk: These include route planning that avoids sensitive areas, procedural limitations on anchoring and equipment deployment, and dry-deck stowage requirements. They result in operational

limitations, require pre-mobilisation planning effort, restrict flexibility during operations, and may extend overall survey duration.

- Contractor management overheads: Additional effort is required to vet, select, and liaise with contractors that meet marine pest mitigation expectations. This includes clarifying standards, managing compliance documentation, and enforcing pre-qualification requirements.
- Regulatory compliance checks and documentation: Ensuring all necessary documentation for ballast water, biofouling, and other marine pest-related compliance is obtained, validated, and stored imposes administrative burden and coordination time.
- Internal coordination and assurance: Interdisciplinary coordination across environmental, operations, and logistics teams is needed to implement and oversee baseline controls, adding planning and review hours.

These combined costs and efforts form the cumulative baseline sacrifice, which is assigned a unit value of 1.0 in the ALARP assessment. This allows subsequent discretionary control measures to be evaluated proportionally.

7.3.2 Assessment

Table F2-22 shows the step-by-step process followed for the ALARP assessment of invasive marine species. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-22.

Table F2-22 - Step-by-step ALARP Assessment – Invasive Marine Species

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion	-	-	-	4	1.0	1.0	See baseline table	See baseline discussion
2	Anti-fouling Systems	All contracted vessels must have properly maintained anti-fouling systems in compliance with international standards	4	80%	3.2	0.8	0.2	1.2	The 80% effectiveness rating reflects that anti-fouling systems, when properly maintained and certified, provide a significant barrier to marine pest settlement and survival on vessel hulls. This high rating accounts for their broad coverage of vessel surfaces and prolonged effectiveness in limiting fouling if regularly inspected and reapplied. The increased rating reflects confidence in newer technologies and the industry's maturity in applying them.	The sacrifice is rated moderate (0.2) because antifouling is already a regulatory requirement for international shipping and most petroleum vessels. Additional cost comes from ensuring records are up-to-date, maintenance is current, and periodic inspections and certifications are maintained beyond standard operating requirements.
3	CGG Marine Assurance System	Governance framework ensuring implementation and verification of vessel and operational biosecurity controls through prequalification, inspections, and record keeping	0.8	65%	0.52	0.28	0.2	1.4	The CGG Marine Assurance System provides a structured governance mechanism to confirm that vessel-based controls (e.g., biofouling management, inspection regimes) are being properly implemented. A 65% rating reflects its central role in verifying compliance and integrating assurance into the planning cycle, though its effectiveness depends on the quality of oversight and the willingness of contractors to comply.	The incremental sacrifice is moderate (0.2), reflecting the effort involved in administration, audits, documentation, and corrective actions. However, much of the infrastructure is already embedded in CGG systems and represents an extension of existing assurance functions.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
4	IMS Risk Assessment Procedure	Structured assessment aligned with national standards, ensures inspections of vessels and immersible equipment	0.28	70%	0.20	0.08	0.3	1.7	A 70% effectiveness rating is justified because the IMS Risk Assessment Procedure systematises checks across vessels and immersible equipment, ensuring compliance and reducing the likelihood of oversight or inconsistency. This structured process adds discipline and repeatability, particularly in complex multi-vessel operations.	A moderate sacrifice value of 0.3 is assigned, reflecting the resources needed to develop, administer, and audit the procedure across operations. While the cost is non-negligible, it delivers a proportionate benefit through improved assurance, documentation, and rigour.

7.3.3 Consideration of Alternative, Additional, or Improved Control Measures

A structured feasibility scan was conducted as part of the IMS risk review. Additional or alternative measures such as deploying IMS-detection technologies or stationing a dedicated marine pest observer onboard were considered but found to deliver negligible additional benefit relative to their cost and operational burden.

Ballast water and biofouling compliance checks were considered at Step 4 and have been adopted as part of the IMS Riak Assessment Procedure. These checks ensure vessels comply with national and international legislation (e.g., Ballast Water Management Convention). The inclusion ensures discharge and hull fouling risks are actively managed in line with regulatory obligations and industry best practice. These checks directly prevent common vectors of marine pest transmission, including ballast water discharge and unmanaged hull biofouling, and provide coverage across all key pathways.

Hull cleaning and/or new antifouling coat application to vessel hull and niche areas prior to the Regia MSS was also considered. While this measure offers some environmental benefit, it was rejected on the grounds that the benefit is marginal when extensive existing measures are already in place. The cost of undertaking inspections and hull cleaning could range from tens to hundreds of thousands of dollars, depending on vessel size and operational logistics. Implementing this requirement uniformly across all vessels was considered disproportionate to the residual level of risk, especially where vessels already demonstrate low IMS risk profiles. The sacrifice associated with this measure was estimated at 2.0, well beyond what is considered reasonably practicable given the minor additional effectiveness.

Improved IMS risk assessment procedure specific to the Regia MSS was also considered. The existing procedure already mandates that an IMS risk assessment be conducted on vessels and immersible equipment by a qualified IMS inspector prior to mobilisation to the operational area. As such, creating a procedure specific to the Regia MSS was assessed to provide no additional environmental benefit. The associated cost was modest, estimated at 0.01, but the measure was still rejected as unnecessary given the strength of the existing risk management process.

The control measures assessed were found to achieve an overall risk reduction from medium to low and were assessed as reasonably practicable. No further measures were found to offer proportionate environmental benefits to justify their adoption at the current residual risk level.

7.3.4 Results

Figure F2-15 presents the risk reduction achieved through the implementation of control measures for the invasive marine species risk pathway, plotted against the cumulative sacrifice incurred. The baseline measures deliver the largest initial reduction in risk and represent mandatory compliance with biofouling and ballast water management requirements. Additional control measures—including the CGG Marine Assurance System, use of anti-fouling systems, and an Invasive Marine Species (IMS) Risk Assessment Procedure—deliver smaller incremental improvements in risk reduction. However, all measures are adopted prior to the point of diminishing returns, with the IMS Risk Assessment Procedure sitting just before the ALARP threshold. The curve remains downward sloping, indicating continued effectiveness, though with reduced marginal gains per unit of sacrifice.

Figure F2-16 validates the assessment of the pathway by displaying residual risk reduction (bar) alongside the cumulative sacrifice (line) for each successive control measure. The greatest reduction is delivered by the baseline measures, while the incremental environmental benefit of anti-fouling systems, the CGG Marine Assurance System, and the IMS Risk Assessment Procedure is modest by comparison. The cumulative sacrifice increases with each additional measure, but all adopted controls remain below the ALARP threshold, confirming their proportionality and value in further

reducing risk. This is despite a significant disproportion between the final measure and the cumulative sacrifice.

Based on this evaluation, and considering the high cumulative effectiveness of baseline and adopted control measures, the pathway is assessed to be reduced to ALARP.

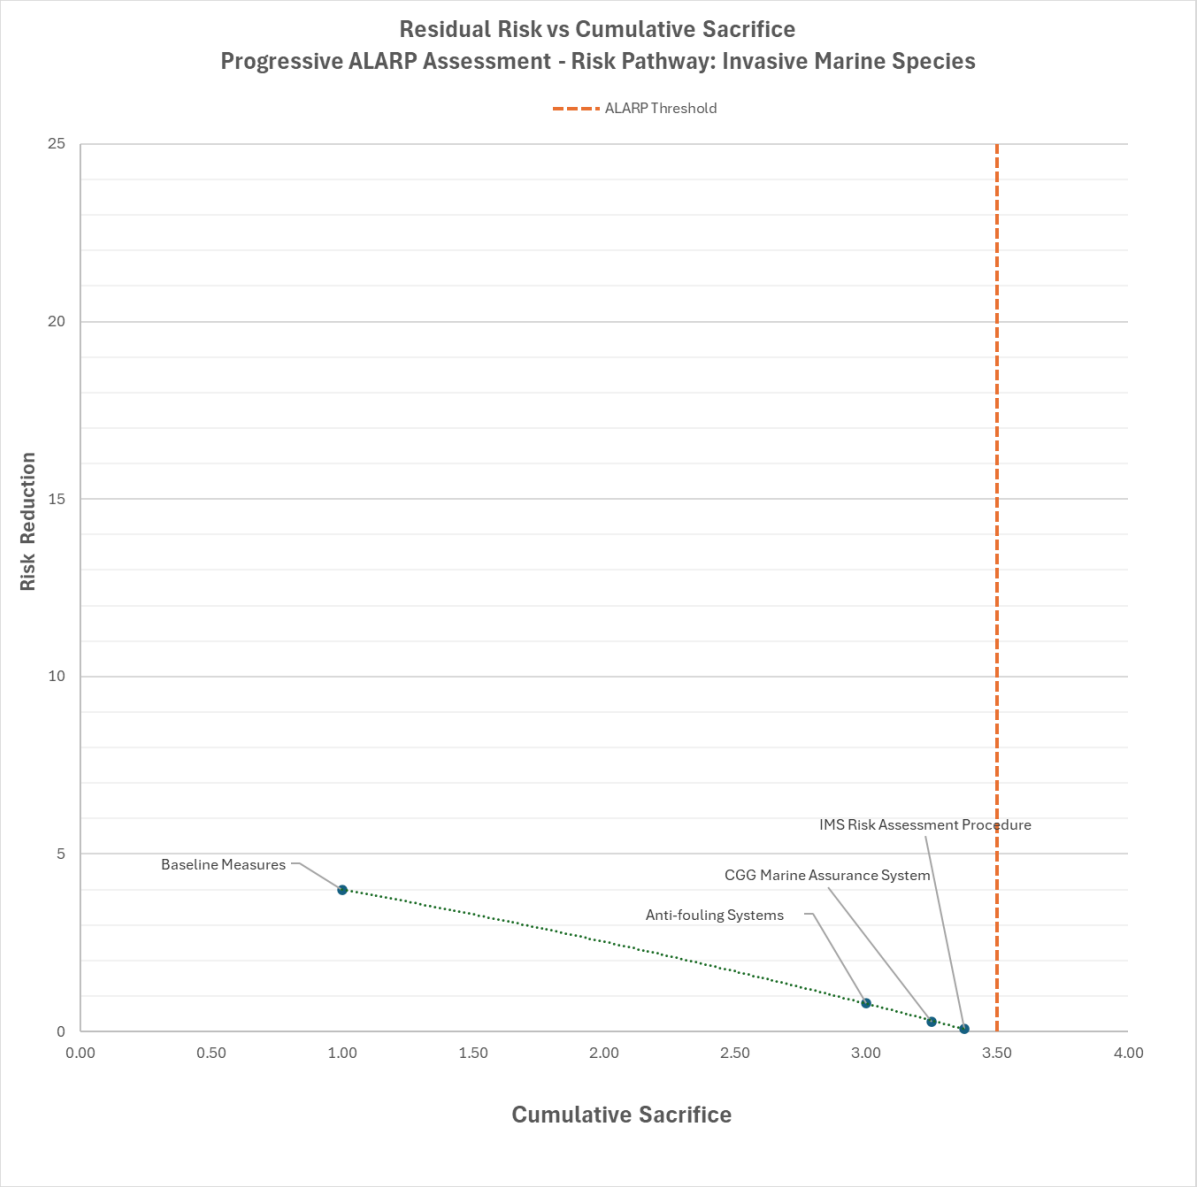

Figure F2-15 - Progressive ALARP assessment for the Invasive Marine Species risk pathway showing residual risk reduction versus cumulative sacrifice.

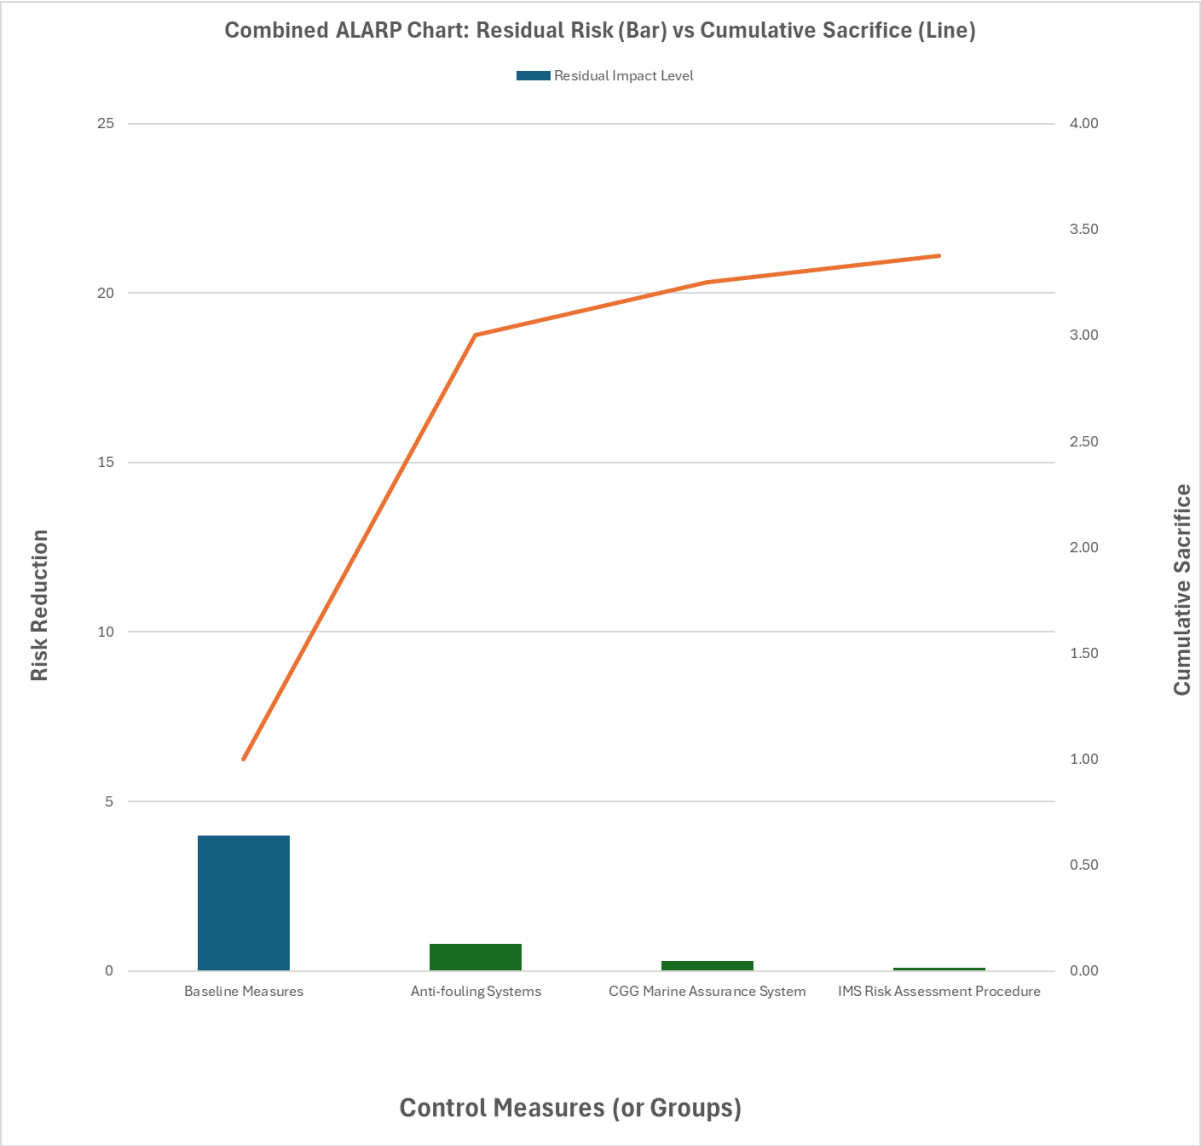

Figure F2-16 - Combined ALARP chart showing residual risk reduction (bars) and cumulative sacrifice (line) for the Invasive Marine Species risk pathway.

7.4 Accidental Release of Fuel

7.4.1 Baseline

Table F2-23 specifies the activity limitations, legislative requirements, and components of the implementation strategy that have been considered in the establishment of a baseline risk level and baseline quantum of sacrifice.

Table F2-23 - Baseline Measures – Accidental Release of Fuel

Baseline Measure	Inclusion Rationale	Intrinsic Effectiveness
Fuel inventory capped at 250 m³	Fuel tank inventories limited to 250 m³ to reduce maximum credible spill volume.	Limiting the fuel tank inventory directly constrains the worst-case volume of spill in the event of a loss of containment, reducing potential impact footprint and aiding spill response effectiveness.
No bunkering within 50 km of marine parks	Bunkering restrictions reduce the risk of fuel exposure to sensitive marine environments in the unlikely event of a spill.	Limiting bunkering locations spatially near marine parks protects biodiversity values and minimises the consequence of a potential release.
Compliance with marine legislation	Compliance with Navigation Act, MARPOL, COLREGS and Marine Orders ensured by CGG Marine Assurance System.	Legislative compliance is critical in ensuring industry-accepted safe vessel operation standards are adhered to, thereby minimising the risk of vessel incidents that could lead to fuel spills.
Use of dry-break couplings during refuelling	Use of dry-break couplings during refuelling to limit maximum credible release. Whilst this is an item of equipment it is also a legislative requirement for at-sea bunkering.	Dry-break couplings minimise the volume of release in the event of a refuelling hose failure, offering both preventative and containment benefits.
Spill response equipment and crew training	Vessel spill response equipment and training in place for immediate containment and response.	Readily available response equipment and trained personnel provide the ability to quickly contain a spill, minimising its spread and potential impact.
Emergency Plans	The Shipboard Oil Pollution Emergency Plan (SOPEP) and Oil Pollution Emergency Plan (OPEP) are legislative requirements detailing the role of vessel masters, CGG and AMSA in the event of an oil spill.	The SOPEP and OPEP ensure a coordinated and compliant emergency response in line with national expectations, ensuring roles, communication, and resourcing are clear during an incident.
Operational and Scientific Monitoring Plan (OSMP)	Operational and Scientific Monitoring Plan (OSMP) developed to identify effects of a fuel release. It is a legislative requirement.	Monitoring allows for timely detection of environmental effects and informs escalation or remediation actions, supporting environmental protection outcomes.

The outcome of the impact assessment for accidental release of fuel was that the likelihood was ranked as Rare (1) and the consequence ranked as Moderate (3). Therefore, the residual risk after the application of baseline measures is Medium (3).

The quantum of sacrifice for complying with the baseline has been calculated and includes the following:

- Engineering, design, and operational constraints to limit fuel tank capacity to 250 m³, ensuring that potential spill volume remains within manageable limits.

- Development, acceptance, and ongoing implementation of a NOPSEMA-compliant Oil Pollution Emergency Plan (OPEP), including scenario planning, response escalation, and stakeholder coordination protocols.
- Procurement and installation of dry-break coupling systems across relevant fuel transfer lines, minimising potential release volumes during hose or valve failure.
- Purchase, placement, and maintenance of vessel spill response kits, including absorbents, booms, and portable containment, along with regular crew training in their deployment.
- Integration of fuel containment and transfer risk controls within the CGG Marine Assurance System, encompassing routine inspections, audit procedures, and contractor compliance obligations.
- Design and deployment of an Operational and Scientific Monitoring Plan (OSMP) tailored to hydrocarbon release scenarios, supported by contingency arrangements for escalation to AMOSC and/or scientific advisors.

The baseline for this risk pathway is intentionally set at a high level because any accidental release of fuel is considered unacceptable. In this context, investment in preventive controls delivers the highest environmental return and is a necessary foundation for achieving ALARP. These baseline measures represent a comprehensive package of activity limitations, legally mandated requirements, and established good practice measures. As a result, the additional controls assessed in this ALARP process build upon an already low residual risk. This means their relative incremental sacrifices appear small in comparison. However, this does not mean they are low-cost or trivial to implement. The cumulative quantum of baseline sacrifice is normalised to 1.0. All further control measures will be evaluated relative to this.

7.4.2 Assessment

Table F2-24 shows the step-by-step process followed for the ALARP assessment of Accidental Release of Fuel. The reasons to support assigning percentage values for the intrinsic effectiveness (or environmental benefit) and the incremental sacrifice are provided in Table F2-24.

Table F2-24 - Step-by-step ALARP Assessment – Accidental Release of Fuel

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
1	Baseline Measures	See baseline table and discussion.	-	-	-	4	1.0	1.0	See discussion above.	See discussion above.
2	Support Vessel	Additional vessel support prevention of collision	4	95%	3.80	0.20	0.4	1.4	The support vessel provides navigational safety by front-running the seismic vessel, clearing potential hazards and actively communicating with oncoming traffic. It also holds the capability to tow the seismic vessel in case of mechanical failure, significantly reducing the likelihood of a scenario that could lead to an accidental release of fuel. This high intrinsic effectiveness score (95%) reflects its proactive role in avoiding both collision and loss-of-position incidents.	The sacrifice reflects the high operational cost of chartering, crewing, fuelling, and maintaining a dedicated support vessel for the duration of the survey. Although it provides multiple safety functions, the investment is substantial, particularly as the risk has already been reduced through previous procedural controls. However, the full cost of the support vessel wouldn't be the correct allocation as it functions to reduce other impacts and risk. A score 0.4 has been assigned to this sacrifice.
3	CGG Marine Assurance System	Contractor vessel vetting system for safety, pollution, and refuelling standards	0.20	50%	0.10	0.10	0.2	1.6	The CGG Marine Assurance System introduces a structured vessel vetting process focused on pollution prevention and refuelling safety. The environmental benefit is modest, given overlap with baseline legal obligations, but it strengthens consistency and quality assurance across contractors. It is highly effective because it must always be applied by CGG and includes pre-survey audits and inspections but due to the overlap with legislative measures only receives a score of 50%.	The associated sacrifice includes moderate administrative and financial burdens such as audit coordination, vessel pre-qualification, and potential scheduling delays if vessels fail assurance. This is not a one-off or periodic investment relative to operational scale, justifying a small sacrifice rating of 0.2.

Step	Short Title	Detail of Control Measures	Res Previous	IE (%)	MR	Res After	Incremental Sacrifice	Cumulative Sacrifice	Intrinsic Effectiveness	Sacrifice Quantum
4	Vessel Bunkering Procedure	Procedure for supervision and hose integrity checks during fuel transfers.	0.10	90%	0.09	0.01	0.3	1.9	The Vessel Bunkering Procedure introduces formal checks for hose integrity, spill trays, and supervision during all refuelling activities. It significantly reduces the likelihood of small operational spills, which represent the most credible release scenario for this pathway. Its high effectiveness score (90%) reflects its clear and targeted function, ease of implementation, and strong compatibility with baseline controls.	The sacrifice primarily arises from additional crew time during refuelling, adherence to procedure, and minor scheduling adjustments. These are modest increases in operational burden and are easily absorbed by vessel crews. Given its high effectiveness and practical implementation, a moderate incremental sacrifice of 0.3 is justified.
5	Petroleum SIMOPS Plan	Requires coordination across all petroleum activities in the region.	0.01	20%	0.002	0.008	0.3	2.2	The Petroleum SIMOPS Plan sets out procedures for managing simultaneous operations between vessels, with specific attention to coordination during refuelling. While its effectiveness (20%) is lower than previous measures due to its indirect role, it helps reduce confusion and human error in multi-vessel operations, particularly during bunkering. It integrates well with the baseline measures and supports procedural clarity during higher-risk transfer activities.	The sacrifice is associated with upfront planning effort, crew training, and inter-vessel communication protocols. While not resource-intensive, it requires alignment between different operational teams and regular updates, especially during dynamic offshore campaigns. The procedural overhead and ongoing coordination needs justify a moderate sacrifice rating of 0.3. For this risk alone the measure would be grossly disproportionate. However, it is adopted for management of other impacts and risks so will be useful for management of this risk too.

7.4.3 Consideration of Alternative, Additional, or Improved Control Measures

One additional control measure was considered:

Double-Walled or Internal Fuel Tanks

Double-walled or internal fuel tanks offer an additional barrier against fuel loss in the event of a hull breach or collision. These are increasingly found on modern vessels and can materially reduce the likelihood of a release due to external damage. However, retrofitting vessels with such tanks is not reasonably practicable due to prohibitive costs and technical complexity. Therefore, this measure has only been partially adopted by giving preference to vessels with double-bottomed or double-walled tank configurations during vessel selection as part of the CGG Marine Assurance System. The associated sacrifice was estimated at 4.4, reflecting the significant financial and scheduling implications of requiring double-walled tanks. This approach achieves a partial benefit by incorporating the measure at the procurement stage without imposing retroactive modification obligations.

7.4.4 Results

Figure F2-17 illustrates the results of the progressive ALARP assessment for the risk pathway accidental release of fuel, plotting residual risk reduction against cumulative sacrifice. The baseline measures deliver most of the risk reduction, with the addition of the support vessel, CGG Marine Assurance System, and the vessel bunkering procedure offering further reductions. The Petroleum SIMOPS Plan contributes only marginal additional reduction, with increasingly disproportionate costs. The trendline confirms the presence of diminishing returns, with the inflection point reached prior to adoption of the final measures. Due to small additional benefit, the SIMOPS Plan falls just below the ALARP threshold and is retained due to their broader impact and risk management utility. The analysis shows that most of the effective risk reduction is achieved early, reinforcing the efficiency of the baseline controls.

Figure F2-18 shows a combined ALARP chart for the accidental release of fuel risk pathway validates the results of the progressive assessment by displaying both residual risk reduction (bar) and cumulative sacrifice (line) for each control measure. The baseline measures deliver the largest reduction in risk, while successive measures such as the support vessel, CGG Marine Assurance System, and vessel bunkering procedures contribute incremental improvements. The Petroleum SIMOPS Plan, while offering minimal additional reduction, incurs a substantial cumulative sacrifice. The vertical reference line indicates where costs become grossly disproportionate, confirming that this final measure lies at the margin of acceptability and should be scrutinised carefully. The chart supports the earlier finding that diminishing returns are reached quickly and reinforces the value of early-stage control measures.

Based on this evaluation, and considering the high cumulative effectiveness of baseline and adopted control measures, the pathway is assessed to be reduced to ALARP.

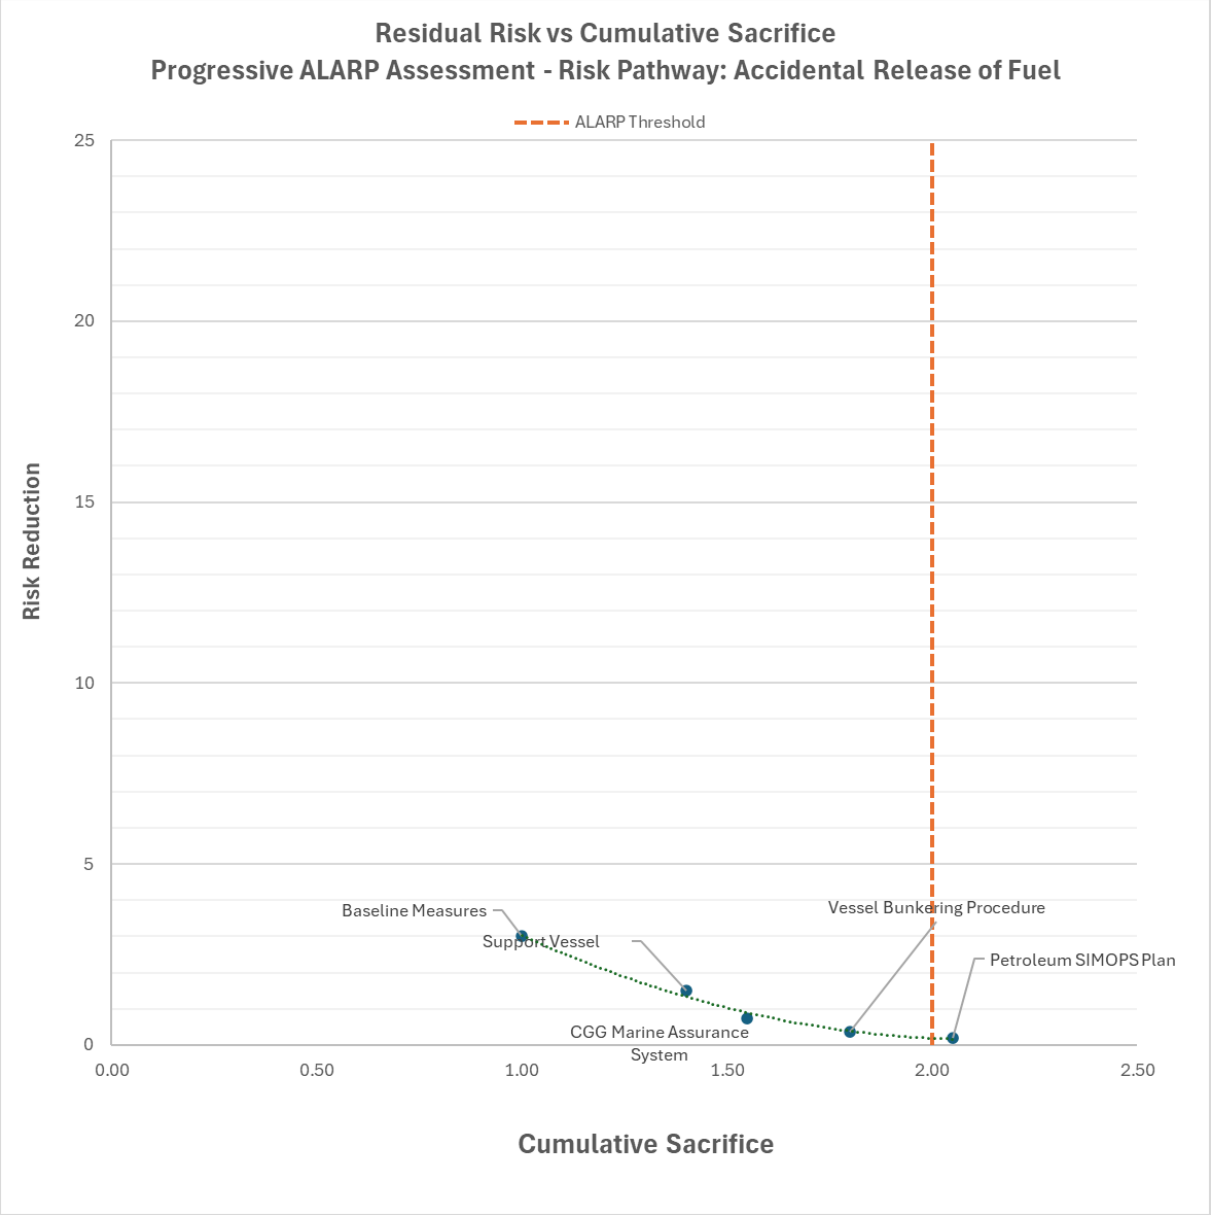

Figure F2-17 - Residual Risk vs Cumulative Sacrifice for the Accidental Release of Fuel risk pathway, demonstrating that most of the risk reduction is achieved through baseline and early-stage controls, with later measures yielding marginal gains approaching the ALARP threshold.

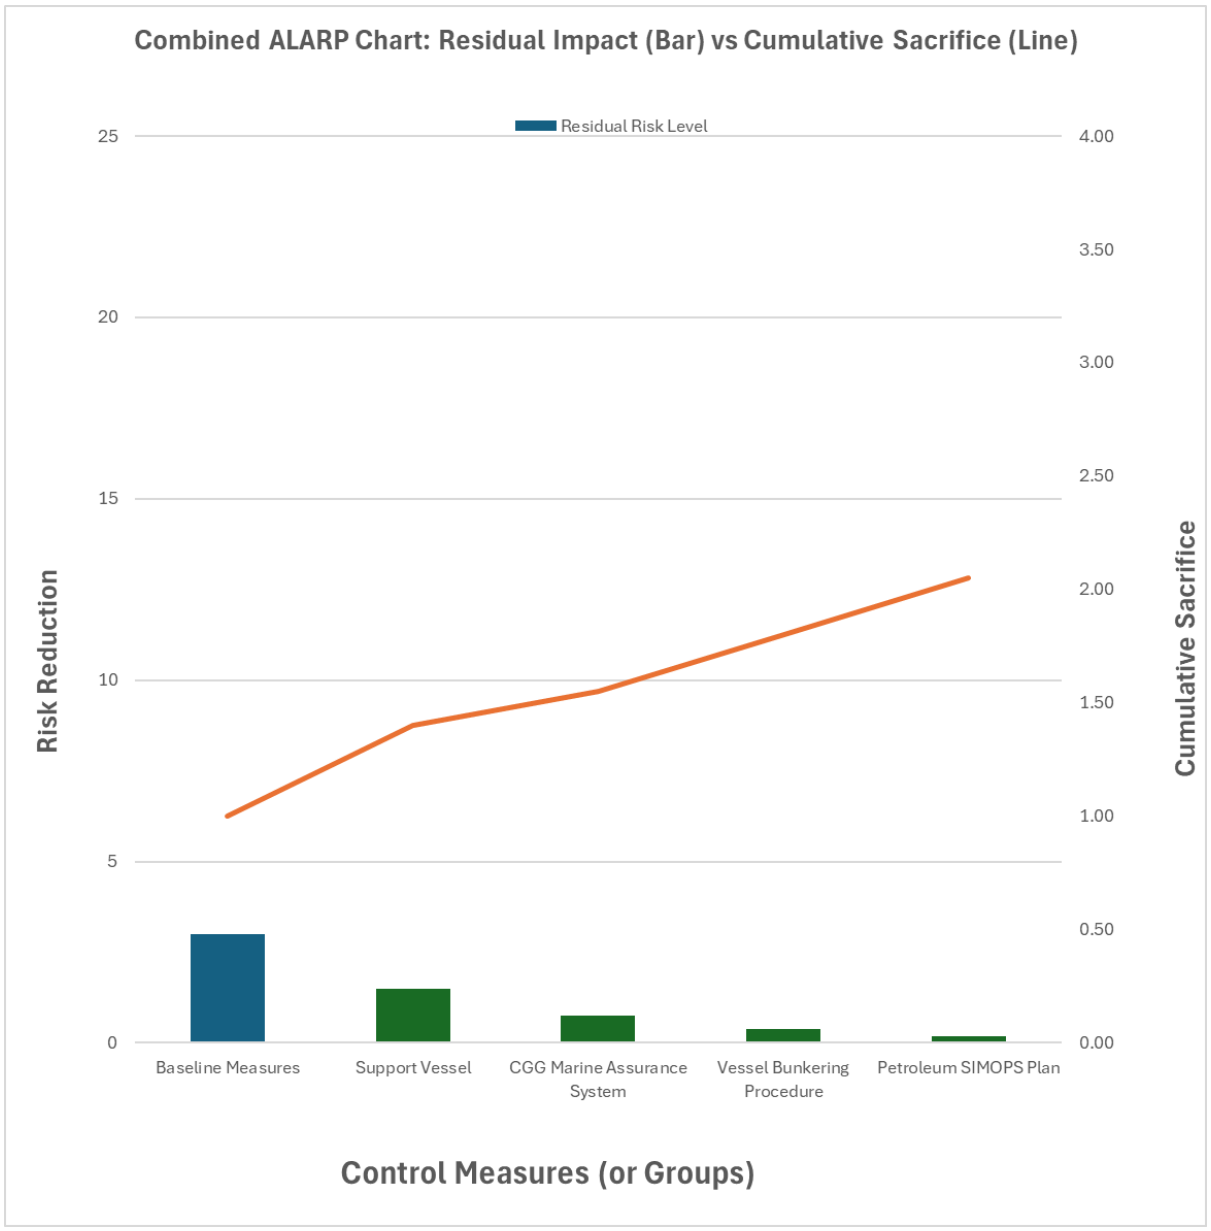

Figure F2-18 - Combined ALARP chart showing residual risk reduction (bar) and cumulative sacrifice (line) for the Accidental Release of Fuel risk pathway, highlighting diminishing returns and validating the ALARP threshold for identifying grossly disproportionate measures.

8 Conclusion

CGG have used a semi-quantitative approach that shows how much environmental benefit is achieved for every unit of sacrifice we invest - reduction per unit of sacrifice. In simple terms this is like the term '*return on investment*', but for environmental performance. It allows us to compare across all the different environmental impact and risk pathways and present a strong demonstration that each is managed to ALARP.

Figure F2-19 presents the environmental impact/risk reduction per unit of sacrifice across all assessed cause effect pathways. The value is calculated by dividing the total reduction in residual impact or risk by the cumulative sacrifice (expressed as a relative unit) associated with the implementation of adopted control measures. This metric highlights the relative return on investment for each pathway in terms of environmental benefit per unit of cost, time, or operational complexity.

Higher values indicate pathways where significant environmental improvements were achieved with a commensurately higher degree of sacrifice. For example, Planned Discharges and Atmospheric Emissions show low returns (i.e. a lower reduction per unit of sacrifice) because the baseline measures achieved almost complete mitigation with minimal additional sacrifice. Conversely, Underwater Sound and Physical Presence exhibit higher returns due to the large reduction per unit of sacrifice required to reduce impacts that are inherently difficult to manage, reflecting both the complexity and the uncertainty involved.

This analysis complements the ALARP assessments completed for each pathway by illustrating the comparative efficiency of mitigation efforts, helping to validate that resources were allocated in a proportionate and defensible way.

The calculation of impact/risk reduction per unit of sacrifice (i.e. total reduction divided by cumulative sacrifice) provides a normalised measure of efficiency across different impact and risk pathways. It tells you how much environmental benefit is being gained for every unit of effort, cost, or time invested.

This is especially valuable because:

1. It allows for comparison across pathways: Each impact or risk pathway is different in scale, consequence, and complexity. By normalising the return on sacrifice, this calculation shows where investments in control measures are most efficient — and where they may offer diminishing returns.

2. It validates proportionality: ALARP assessments must demonstrate that impacts and risks are reduced in proportion to their significance. This metric helps show that greater effort has been applied where potential harm is greatest, aligning with the core principle of focusing resources where they matter most.

3. It supports decision-making: When determining whether further control measures are warranted, this value helps to identify when additional effort would result in marginal benefit — a key consideration in recognising the point of gross disproportion.

4. It's defensible: If challenged, this ratio helps explain and justify why some measures were adopted and others were not. It shows that decisions were not arbitrary but grounded in a consistent, semi-quantitative framework.

5. It is visually communicative: When plotted in a figure, it provides a compelling illustration of where value was achieved — and helps non-technical audiences understand the logic used in environmental protection.

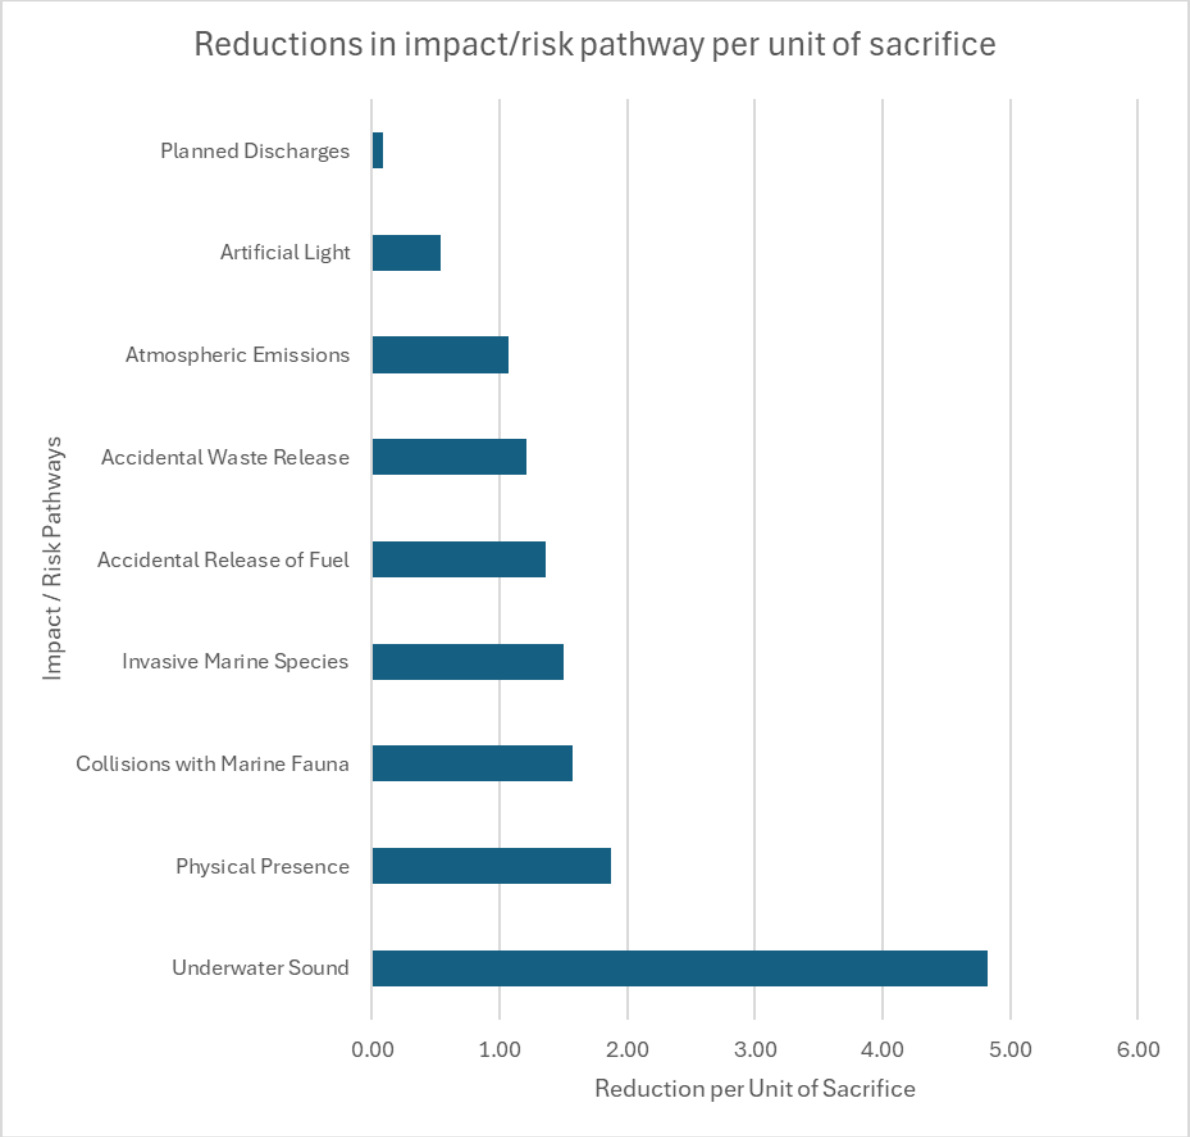

Figure F2-19 - Environmental Impact/Risk Reduction per Unit of Sacrifice for Each Assessed Pathway.

The ALARP assessments presented in this report demonstrate that control measures have been applied with appropriate proportionality across all impact and risk pathways. The analysis shows that pathways associated with the greatest potential for environmental harm — such as underwater sound and physical presence — received the most significant investment and yielded the highest levels of risk and impact reduction per unit of sacrifice. Conversely, for pathways where residual impacts / risks were already very low after baseline measures, further reduction would have required disproportionate sacrifice for limited benefit and was therefore not pursued.

This outcome reflects a systematic, thorough, disciplined and evidence-based application of the ALARP principle, ensuring that each control measure adopted contributes meaningfully to impact and risk reduction and that cumulative effort has been directed where it matters most. The framework applied throughout this assessment supports a conclusion that impacts and risks have been reduced to a level that is as low as reasonably practicable.

Annex 1- Public Comment

The completed EP was published for public comment on the NOPSEMA website on 25 Jan 2024 for a 30-day period, closing 26 February 2024. Table F2-25 shows how this feedback has been incorporated into the environmental assessments.

Table F2-25 - Public comment input into the preparation of the EP.

Matter	Matter ID	Changes made arising from public comment
Matter: Consideration of alternative survey technology	O01	CGG acknowledges claims regarding the consideration of alternative survey technologies and EP Appendix F2 (ALARP Assessment) has been updated to include additional information on this assessment.

Annex 2- Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table F2-26. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table F2-26 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4137	Mention of installing sound curtains underwater to reduce destructive sound.	Bubble curtains are not suitable for a moving activity, nor are other measures such as acoustic blankets. This has been included in the ALARP assessment.	2830
4297	The stakeholder requested to know the total cost of the MSS so they could ascertain if ALARP had been reached, as a cost-benefit analysis. The information provided by the titleholder to date was deemed insufficient to know if ALARP had been achieved.	Outlined the concept of 'costs' is more than the narrow interpretation of a monetary value, it includes money, time and trouble. Outlined that the 'cost' of a control measure could be weighed against total costs of the survey for context but that this point of reference fails to consider the environmental benefit of adopting the control. Agreed that the current presentation of ALARP could be improved and that CGG would prepare a dedicated report explaining how we have reached decisions about what measures needed to be adopted (Event ID 4062).	4062
4339	What new technologies are CGG considering for reducing impacts?	Provided the reasons that these technologies are currently not proposed, however acknowledge that they aren't explicitly excluded and if they become viable as the design of the activity is refined, they'll be considered (Event ID 4280).	3705
4359	Request for seismic blasting to be limited to 12 hours out of any 24-hour period and not carried out at night	The titleholder acknowledged this concern, however undertaking the seismic survey only in daylight hours would have a disproportionate cost without a significant environmental benefit. The survey would take twice as long, potentially resulting in cumulative effects to sensitive species.	2821
4178	Seismic should not be used; use alternative methods to seismic blasting to map the seabed.	No measures were adopted because of this claim. Utilising acoustic sources for marine seismic surveying provides a framework grounded in extensive research and practical experience. Their environmental impacts, both short-term and long-term, have been studied, facilitating the development of effective mitigation strategies. On the other hand, marine vibriosis, while holding promise as a newer technology, is not only more expensive but also shrouded in technical and environmental uncertainties. Its long-term effects, particularly concerning particle motion and its potential impact on marine ecosystems and sensitive aquatic species, remain inadequately explored. Exploring these environmental impacts is unlikely until the technology is commercially competitive. Until we have a comprehensive grasp of these implications, it is prudent to rely on technology with known and manageable impacts rather than embracing potentially riskier avenues	3145

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		with unforeseen or highly uncertain environmental impacts.	
4375	Claims that threats from the survey to SRW and their migration routes and HCTS means that impacts from the Regia survey are not ALARP.	Event ID 6529 - ALARP (As Low As Reasonably Practicable) is a criterion used to determine whether control measures should be implemented by balancing the environmental benefit with the sacrifice required for their adoption. NOPSEMA guidance and the Regia MSS EP provide details on how to demonstrate that environmental impacts and risks are reduced to ALARP. The stakeholder claims that "such threats do not pass the ALARP test," but its statements about SRWs and the eastern SRW population, some of which are directly copied from the SRW National Recovery Plan, fail to address control measures, their benefits or costs, or critique the ALARP demonstration presented in the Regia MSS EP. As a result, this claim is unclear in its application of the ALARP concept. CGG is open to further educating the stakeholder on the ALARP concept, assuming they are trying to provide information that might lead CGG to reconsider the control measures implemented or rejected, which have already demonstrated that environmental impacts and risks of the proposed Regia MSS have been reduced to ALARP.	6410
4488	Claims that CGG has not incorporated effective control measures to reduce impacts and risks to ALARP or to ensure those impacts will be acceptable. It maintains that several control measures in the Environment Plan (EP) are inconsistent or conflicting, making them difficult or impossible to implement. GMTOAC further contends that CGG has weakened its mitigation framework compared with the November 2024 EP by replacing required sound-source shutdowns with an undefined “low power zone” when Karntubul (Southern Right Whales) are present. Also, that CGG has not ensured its activity will avoid unacceptable impacts on Koorn Moorn, which feed in Nyamat Mirring waters extending 200 m around Deen Maar Island. It claims CGG has not used the best available science in its noise modelling and has relied on comparative analyses rather than updated models, making results difficult to interpret. Additionally, GMTOAC argues	CGG maintains that the Environment Plan (EP) incorporates effective control measures and satisfies the legal requirements for demonstrating that impacts and risks have been reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. It asserts compliance with Regulation 34 and emphasises that its environmental performance outcomes and controls are grounded in the best available science and tailored to the identified ecological and cultural sensitivities. Culturally significant species and features, including Karntubul and Koorn Moorn, are included in impact and cumulative risk assessments using a methodology intended to reflect both scientific evidence and cultural. CGG argues that GMTOAC’s objections substitute personal disagreement for the regulatory test, noting that the legislation does not require stakeholder agreement or grant veto powers over EP design decisions. While GMTOAC criticises the revised ALARP assessment methodology (April 2025 EP), CGG reiterates that its approach satisfies the regulatory criteria. In response to claims that mitigation measures have “weakened”, particularly the shift from sound-source shutdowns to a “low power zone”, CGG characterises these changes as part of a normal, adaptive, and consultation-driven refinement process. It describes the evolution of the activity as a progressive reduction in operational footprint, increasingly targeted controls, and strengthened performance-based measures, noting that core protections such as timing restrictions to avoid Karntubul birthing seasons remain in place.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	that the revised ALARP assessment methodology introduced in the April 2025 EP, intended to address flaws in the November 2024 version, is inadequate, less systematic, and less defensible than the earlier approach.	CGG states that cultural and ecological sensitivities associated with Karntubul, Wuuloc, and Koorn Moorn have been integrated into the assessment, with Appendix F3 acknowledging their cultural significance and informing mitigation commitments. CGG reiterates that its control measures are based on contemporary scientific evidence and incorporate cultural and ecological sensitivities throughout the EP.	
4489	Claims that CGG cannot determine what constitutes an "acceptable" level of impact or risk to Gunditjmara cultural values in Nyamat Mirring. States the April 2025 Environment Plan contains flawed cumulative impact assessments due to this lack of consultation. GMTOAC identifies several shortcomings: CGG's interpretation of potential impacts to Gunditjmara and other First Nations cultural heritage is too narrow; CGG wrongly assumes that acceptable ecological impacts equate to acceptable cultural impacts; and CGG's cumulative impact assessment for Karntubul (Southern Right Whale), previously criticised by NOPSEMA in its February OMR, remains unchanged.	CGG rejects GMTOAC's claim that inadequate consultation prevents CGG from determining "acceptable" levels of cultural impact, asserting that it fully met its consultation obligations. CGG argues that the legal test is whether the Environment Plan demonstrates impacts and risks are reduced to ALARP and to an acceptable level. It maintains that GMTOAC's critiques conflate subjective opinion with the regulatory standard under Regulation 34 and emphasises that the law does not grant stakeholders a veto over design decisions. In response to the assertion that its interpretation of cultural heritage is too narrow, CGG maintains that GMTOAC has already articulated its cultural values clearly and extensively through published materials and received during consultation. These values, encompassing ceremony, obligations, kinship systems, spiritual relationships, and ecological connections are thoroughly integrated across the EP. The EP references the Nyamat Mirring Plan 2023–2033, incorporates cultural values and sensitivities into Appendix F3, and identifies culturally significant species and places as sensitive receptors with tailored management measures, for example, timing restrictions to avoid birthing seasons. CGG states that it has incorporated analysis of cumulative effects on Sea Country, including those arising from the survey in combination with other activities. It confirms that Karntubul is included in cumulative risk assessments with corresponding mitigation commitments.	EVT352
4507	GMTOAC objects to the ALARP methodology used in CGG's April 2025 Environment Plan (EP). In that EP, CGG adopts a "semi-quantitative" approach that begins with a baseline of assumed controls, including legal requirements and activity limitations, and then applies additional measures to which CGG assigns its own "effectiveness scores." GMTOAC argues this framework is even less systematic, transparent, or reproducible than the ALARP method rejected by NOPSEMA in 2024, as it allows CGG to define both the starting level of predicted impacts and the magnitude of their reduction.	GMTOAC's critique of the Regia MSS ALARP assessment is based on misunderstandings of the regulatory framework, the ALARP principle, and the methodology set out in Appendix F2. CGG clarifies that the ALARP baseline includes all legally required control measures and activity limitations, which cannot be altered or removed. Assertions that the baseline is arbitrarily constructed or manipulable are therefore incorrect. CGG also notes that GMTOAC's arguments are internally inconsistent, for example, claiming the baseline is both too rigid and too flexible. CGG rejects GMTOAC's claims that only measures reducing source noise can reduce noise impact, explaining that acoustic impact management relies on avoiding exposure through detection tools, shutdown zones, and real-time monitoring. Similarly, CGG clarifies that support personnel and the Whale Expert Panel are not "double counted" but serve as additional assurance mechanisms beyond baseline staffing.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	GMTOAC notes that CGG's selected "baseline" already incorporates key operational controls, shutdown procedures, exclusion zones, and seasonal timing restrictions, that CGG itself has full discretion to modify or strengthen. By embedding these controls in the baseline rather than treating them as adjustable mitigation measures, CGG effectively limits the scope for further impact reduction and risks underestimating the true level of harm. Despite this favourable baseline, CGG still predicts "High" impacts on marine mammals from underwater sound. The reduction of these impacts to "acceptable" levels is achieved by applying effectiveness scores to additional measures such as increased personnel, enhanced detection equipment, or expanded monitoring. GMTOAC argues this is flawed because these measures do not physically reduce noise exposure; they only increase the likelihood of detecting whales. In several cases, CGG appears to "double count" controls, treating them as part of the baseline while also awarding them separate effectiveness scores, which artificially reduces the predicted level of harm. GMTOAC highlights particularly problematic examples, such as CGG assigning an 80% effectiveness rating to "support personnel" and then reducing predicted harm by 80%, even though those personnel merely enable measures already included in the baseline. Similarly, CGG gives towed passive acoustic monitoring (PAM) a 50% effectiveness score and cuts predicted impacts in half, even though PAM cannot detect silent whales and has no ability to reduce noise levels themselves. Overall, GMTOAC concludes that the ALARP methodology	CGG notes that PAM is appropriately assessed and contributes to reducing exposure risk, with effectiveness ratings justified in the EP. Overall, CGG concludes that GMTOAC's critique lacks evidentiary support and overlooks the structured, transparent, and regulator-aligned approach presented in Appendix F2.	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	used by CGG lacks scientific defensibility and systematically underestimates risk. GMTOAC expresses deep concern that this approach may not genuinely reduce impacts to Nyamat Mirring, its ecosystems, culturally significant species, or cultural values to acceptable or legally required levels.		

Annex 3- Ensuring Integrity in ALARP Assessments

Guidance for Assessors

Assessors are responsible for ensuring that ALARP assessments are conducted with transparency, conservatism, and discipline. While the methodology provides structure, it still relies on subjective judgments, particularly when assigning intrinsic effectiveness and estimating sacrifice. These areas are vulnerable to manipulation, whether intentional or inadvertent. To ensure the assessment remains robust and credible, assessors should:

- **Avoid Overestimating Intrinsic Effectiveness:** Resist the temptation to assign high effectiveness scores without strong justification. When there is uncertainty in the measure's performance (e.g. due to operational limitations, environmental variability, or limited evidence), a conservative estimate should be used. This ensures that the assessment does not prematurely conclude that further control measures are unnecessary.
- **Strengthen and Clarify Sacrifice Justifications:** Sacrifice should be expressed in clear, comparable terms—ideally in monetary value, but also in time and operational effort where appropriate. Avoid vague or speculative estimates. Ensure it is clear whether the sacrifice is incremental to the baseline and whether all relevant costs (e.g. training, maintenance, or implementation complexity) have been considered.
- **Document the Rationale Clearly:** Intrinsic effectiveness and sacrifice are not standalone numbers. They must be supported by detailed justification that references functionality, availability, reliability, independence, and compatibility (for effectiveness), or cost components and practical implications (for sacrifice). If a value cannot be substantiated, reassess its inclusion.

Guidance for Reviewers

Reviewers play a critical role in ensuring the ALARP assessment is applied with rigour and that conclusions are genuinely justified. When reviewing an assessment, be alert to signs of poor discipline or potential manipulation. These include:

- **Repeatedly High Effectiveness Scores:** Be cautious where multiple measures are assigned very high intrinsic effectiveness (e.g. 80–90%) without clear justification. This pattern may indicate that the assessment has been structured to reduce residual impact/risk too quickly, limiting the evaluation of other reasonable measures.
- **Vaguely Justified or Inflated Sacrifice:** Sacrifice estimates should be well explained and broken down into their component parts. Watch for measures rejected with minimal or speculative reasoning, or costs that seem out of proportion to the control measure and baseline sacrifice described.
- **Rapid Plateauing of Impact/Risk:** If the residual risk or impact drops sharply within the first few measures and the trendline flattens early, this may suggest an overly optimistic treatment of effectiveness or sacrifice. Review whether the residual values and polynomial trendlines genuinely reflect diminishing returns.

By applying these checks, reviewers can verify that the ALARP conclusion is based on a balanced and evidence-based assessment and not the result of subjective inputs skewed to justify doing less.

1 Introduction

This document is part of Stage 3 of CGG's assessment of the environmental impacts and risks arising from the Regia Marine Seismic Survey (**Regia MSS**). This document records further assessment of key environmental values and sensitivities. The key environmental sensitivities have been selected following a self-assessment by CGG of whether the preliminary and secondary assessments have resulted in all environmental impacts and risks being reduce to ALARP and an acceptable level, and the criteria for acceptance being met. A further assessment was also undertaken if there was significant interest from relevant persons, or high levels of predictive uncertainty remaining after the secondary assessment.

2 Purpose

The purpose of this document is to further assess environmental impacts and risks and support the demonstration that environmental impacts and risks arising from the activity will be of an acceptable level. This additional assessment was either required because:

- CGG self-identified that the result of the environmental assessment:
  - Had some residual uncertainty about whether impacts or risks were of an acceptable level; and/or
  - Contained environmental values and sensitivities (species) of key importance due to their protection status or commercial value; and/or
- Consultation with relevant persons revealed a particular value or sensitivity required further attention and material to support the consultation.

The content aims to demonstrate that a thorough assessment of environmental values and sensitivities that may be affected by the activity has been undertaken in accordance with the environmental assessment methodology (Appendix B3). Further assessments have been undertaken for the reasons outlined in Table F3-1.

Once these further assessments have been completed, any modifications required to the originating environmental assessments will be briefly described in Section 6 and any modifications required shall be made in the relevant impact or risk assessment.

Table F3-1 - Further assessments undertaken in stage 3 of the Regia assessment process.

Further Assessment Topic	Reasons for Further Assessment
Southern Right Whales / Koontapool (*Eubalaena australis*)	The species is listed as threatened (Endangered) under the EPBC Act. The species was identified as culturally important.
Blue Whales / Wuulok (*Balaenoptera musculus*)	The species is listed as threatened (Endangered) under the EPBC Act. The species was identified as culturally important.
Australian Sea Lion (*Neophoca cinerea*)	The species was identified to be of concern to relevant persons.
Little Penguin (*Eudyptula minor*)	The species was identified to be of concern to relevant persons.
Southern Rock Lobster (*Jasus edwardsii*)	The species was identified as of key commercial value. The impacts of elevated levels of sound were identified as one of the few to have permanent physiological effects. The species was identified to be of concern to relevant persons.
Giant Crab (*Pseudocarcinus gigas*)	The impacts of elevated levels of sound were identified as one of the few to have permanent physiological effects. The species was identified to be of concern to relevant persons.
Glass Eels / Kooyong (*Aquilla australis*)	The species was identified as culturally important.
Gould's Squid (*Nototodarus gouldi*)	The species was identified to be of concern to relevant persons.

Further Assessment Topic	Reasons for Further Assessment
Pale Octopus (*Octopus pallidus*)	The species was identified to be of concern to relevant persons.
Blacklip Abalone (*Haliotus rubra*)	The species was identified to be of concern to relevant persons.
Pink Snapper (*Chrysophrys auratus*)	The species was identified to be of concern to relevant persons.
King George Whiting (*Sillaginodes punctatus*)	The species was identified to be of concern to relevant persons.
Plankton Communities and the Bonney Upwelling System	The impacts of elevated levels of sound were identified as one of the few to have permanent physiological effects. The species was identified to be of concern to relevant persons.
Spawning Patterns	The value was identified to be of concern to relevant persons.
Budj Bim Cultural Landscape	This sensitivity was identified as culturally important by relevant persons.
Cultural Features of the Environment	This sensitivity was identified as culturally important by relevant persons.

3 Further Assessment of Key Environmental Values and Sensitivities

This part of the demonstration underscores the importance of conducting a thorough evaluation of key environmental values and sensitivities as part of our overall assessment of impacts and risks associated with the Regia MSS. Focusing on key values and sensitivities enables us to:

- Continue the assessment of higher order impacts and risks.
- Change perspective to increase confidence in the assessment process.
- Put the magnitude of impacts and risks into their proper context.
- Address specific concerns raised by relevant persons.

The following detailed evaluations not only enhances the robustness of our overall environmental assessments but also serves to test and validate the appropriateness of our preceding analysis. For each of the key values and sensitivities identified through the environmental assessment process this evaluation will address:

- **Species-Specific Sensitivity:** Assess the vulnerabilities of each species to the seismic activity, including breeding, feeding, migration patterns, and habitat preferences.
- **Magnitude of Effect:** Evaluate the potential scale of impact on each key value and sensitivity, considering both direct and indirect effects.
- **Cumulative Impacts:** Consider the combined effects of the seismic survey with other existing or planned activities in the area.
- **Recovery Potential:** Assess the ability of species or ecosystems to recover from potential impacts.
- **Conservation Status:** Factor in the conservation status of species, especially those that are endangered or protected.
- **Mitigation Effectiveness:** Evaluate the effectiveness of proposed mitigation measures specific to each key value and sensitivity.

3.1 Southern Right Whales / Koontapool (*Eubalaena australis*)

In the assessments completed to date (Appendix E7), CGG have used a defined threshold as the basis for understanding when a behavioural response may occur and predicted an effect distance. To demonstrate that any elevated sound exposures beyond this predicted distance are of an acceptable level assumes that no behavioural response occurs beyond the predicted distances. In other words, the traditional dose-response model assumes that above a certain SPL threshold, animals will exhibit predictable behavioural responses.

However, real-world observations do not support this assumption. For example, in Ellison et al. (2012), Gray whales altered their migration paths in response to a sound source only when it was positioned within their typical travel corridor, even when sound exposures remained similar across different trials. This suggests that context matters more than a fixed threshold. Similarly, Southall et al. (2023) emphasise that vulnerability varies between species and populations, meaning that different species can react differently to the same exposure regime depending on their ecological and physiological characteristics.

A recent study by Darias-O'Hara et al. (2025) derived a median behavioural threshold of 139 dB for low-frequency cetaceans using expert elicitation informed primarily by humpback whale data and adjusted for other species. The authors emphasise substantial uncertainty due to limited data, a lack of global consensus on appropriate behavioural thresholds, and the context-specific nature of their findings, figure

Considering that the thresholds apply only under the assumptions and Antarctic scenarios assessed. While the values provide a conservative indication of where behavioural responses may begin, their biological significance depends on multiple external factors, and the study is positioned as an early step requiring further research to strengthen regulatory assessment.

Southall 2024 demonstrated that simple received-level thresholds are inadequate for predicting behavioural responses of marine mammals to noise. This paper highlights that all-or-nothing thresholds fail to account for the substantial variability observed between species, individuals, and contexts. Instead, a probabilistic, context-dependent approach has emerged as more scientifically robust, reflecting the reality that behavioural responses are influenced not only by received sound levels but also by factors such as behavioural state, exposure history, and proximity. This shift supports the development of more ecologically meaningful noise exposure criteria, particularly for acute noise events, and lays the foundation for improved assessment of both individual and population-level impacts.

Another flaw in selecting a fixed behavioural response threshold is that it ignores chronic noise effects. The dose-response model focuses on acute, immediate responses, but does not account for cumulative impacts from prolonged exposure, such as communication masking, stress-related physiological changes, or gradual displacement from key habitats. Even at relatively low levels, if noise is persistent, it can disrupt essential behaviours over time. This means that using a single threshold to predict behavioural impacts could be misleading, as it fails to capture these long-term effects.

Instead of relying on a single threshold, both Ellison et al. 2012, Southall et al. 2023, and Southall 2024 advocate for a multi-factor assessment that includes various threshold levels alongside context-dependent variables. This means incorporating species-specific sensitivity assessments, evaluating exposure severity relative to background noise conditions, and considering behavioural context to determine the likelihood and severity of responses. This approach allows for more accurate and ecologically meaningful assessments of how noise affects marine mammals, rather than assuming a universal threshold applies across all situations. Therefore, this further assessment will focus on the residual uncertainty from the impact assessment on marine mammals (Appendix E7), namely on whether impacts to any SRW within the reproduction BIA are of an acceptable level and what additional measures may need to be incorporated to increase predictive certainty.

3.1.1 Acoustic Species-Specific Sensitivity

Baleen whales, which include SRW, are categorised as low-frequency cetaceans. The acoustic repertoire of right whale species is similar, comprising of a variety of short, low frequency (<1 KHz) vocalisations (DCCEEW 2023, DOSITS 2023). Vocalisations have a fundamental frequency range of 50 to 500 Hz, with modelled hearing range between 10 Hz to 22 kHz (functional range of 15 Hz to 18 kHz), and source levels ranging from 132 to 192 decibels (Parks & Tyack 2005, Parks et al. 2007, Nielsen et al. 2019).

SRW mother-calf pairs on a Western Australia breeding ground were found to produce low amplitude vocalisations; acoustic tags measured received levels between 123 and 134 decibels at low rates (< 10 calls per hour, 1 call per dive) (Nielsen et al. 2019a). Calls were more likely to occur during dives, indicating that these signals function to coordinate movements between mothers and calves.

SRW mothers tend to bring their calves close to the shore into the surf zone as the higher levels of ambient noise from crashing waves provides a refuge from potential predators (Nielson et al. 2019a).

The frequency of the sound produced from each seismic pulse is primarily less than 2 kHz, with the highest levels at frequencies in the range of 10-500 Hz (McCauley 1994). Thus, there is an overlap with low-frequency cetaceans hearing frequencies.

Interestingly, the SRW source level of 132 to 192 decibels means that SRW calls can be louder than the current noise assessment criteria for behavioural disturbance of 160 decibels.

The National Recovery Plan for SRW (DCCEEW 2024) assessed threats to SRWs through a risk assessment process. For the eastern population of SRWs, which are relevant to the Regia MSS, the consequence of seismic surveys was assessed as moderate, which is defined as population recovery slows or stalls. The risk assessment outcome for threats to the eastern population of SRWs from underwater noise from seismic surveys stated, "the likelihood of occurrence was assessed as likely, expected to occur at least once every five years, resulting in a risk level of high, requiring additional mitigation action and an adaptive management plan required; the precautionary principle should be applied."

The risk assessment is deemed to be conservative as the National Recovery Plan for SRW (DCCEEW 2024) details there is an increase in long-term population trend for SRW, albeit slowly for the eastern population.

Other threats assessed as having a moderate consequence and a likelihood of occurrence of almost certain are:

- Anthropogenic underwater noise; industrial noise.
- Habitat degradation; infrastructure of coastal development.
- Habitat degradation; infrastructure of offshore development.

Other threats assessed as having a major consequence and a likelihood of occurrence of almost certain are:

- Entanglement: active fishing or aquaculture equipment.
- Collisions; vessel strike.
- Anthropogenic climate variability and change.

3.1.1.1 Behavioural Ecology in the Reproduction BIA

Observations of female southern right whale births are rare, Christiansen et al. (2022) noted in many cases large, fat females are observed pregnant, and days later, they are resighted with a calf.

During the last month of gestation, southern right whale foetuses' grow between 3 and 4 cm per day (Christiansen et al. 2022). At birth, calves can typically range from 4.5 to 5 meters in length, with the largest calves being born to the largest mothers, measuring approximately 35% of the mother's total length (Christiansen et al., 2022). Giving birth to such sizable offspring requires a significant energy investment from the females. The primary energetic demand during pregnancy is generating the heat needed for gestation (74%), followed by foetal growth (21%) and the placenta's energy requirements (5%). This overall energy expenditure continues to rise during the 12-month gestation period and is at its highest during the last 4 months (Christiansen et al. 2022).

Christiansen et al (2018) examined the relative cost of lactation in female southern right whales in relation to growth rates in their calves over a breeding season, at the Head of the Bight in South Australia. They found over the first 3 months of lactation, females lost around 25% of their body volume. This suggests females invest as much energy as they can into their calves.

Nielson et al (2019b) studied the developmental behaviour in SRW calves over a period of 2.5 months on their breeding grounds, at the Head of the Bight in South Australia. SRW calves were in the nursing position for 10% of their time on the breeding grounds, and this increases with calf size, back-riding composed ~5% of the total observation time in SRW mother– calf pairs. This behaviour decreased by 9% during the 2.5 months of observations (Nielson et al. 2019b). Surface active behaviours such as tail

and pectoral fin slapping, breaching and rolling remained low and did not increase with calf size. Calves were within an adult body length to its mother for 90% of the time (Nielson et al. 2019b).

For the Regia MSS, detecting the departure of SRW from the reproduction BIA at the end of their utilisation of the area is important. Dickenson (2018) investigated the factors that influence the migration of SRW calf cow pairs from their wintering breeding grounds at the Head of the Bight, South Australia. Diurnal period was the best indicator of migration timing for SRWs leaving the wintering grounds. Diurnal periods are consistent year to year; therefore, it is logical for taxa to align their internal rhythms and crucial life history stage with this predictable environmental cue. Most mother calf pairs departed the wintering grounds at a mean day length of 11.6 hours. The authors suggest calf length was the second-best predictor of migration timing, the mean length of SRW calves at the time of migration was 7.63m. Sea surface temperature was a poor indicator of SRW migration and surprisingly, maternal body condition was the poorest indictor of migration (Dickenson, 2018). Although the author acknowledged the limitations of this study, understanding the factors that trigger southern right whale migration is crucial for the recovery of the species. Due to the proximity of SRW to the coast when they are utilising the reproduction BIA, there is a high degree of certainty that, with the appropriate measures in place, CGG will be able to monitor the presence of SRW within the BIA prior to the survey and detect the departure from the reproduction BIA, into the migration BIA. Once departure is confirmed, it becomes certain that sound exposures from the Regia MSS will be of an acceptable level.

3.1.1.2 Timing of Residence in BIA

A recent study by Charlton et al. (2025) examined SRW residency and site fidelity along the south coast of Australia. Mean residency for female and calf pairs at the Head of the Bight was approximately 3.5 months and site fidelity remained consistent with 57.6% of females identified between 1984–2019 resighted in multiple years (Charlton et al. 2025).

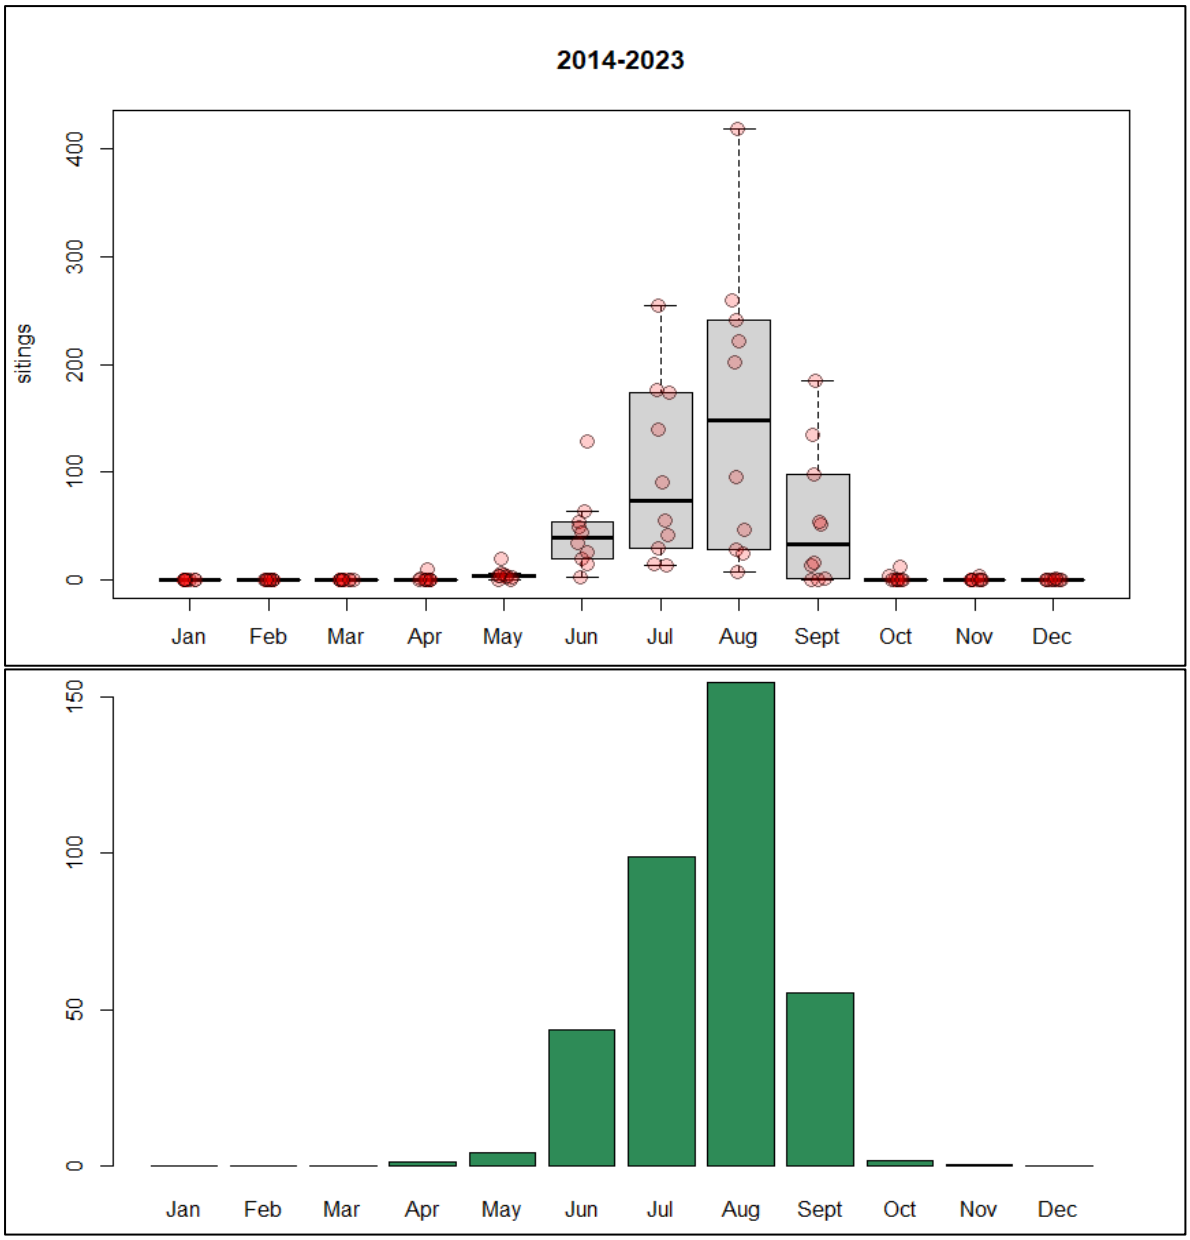

Figure F3-1: Monthly sightings of SRW along the Otway coast for the 10 years between 2014-2023. Top - boxplots illustrating the range of counts for each month, Bottom – Bar plot of 10 year average of sightings for each month.

CGG examined long term sighting records of southern right whales recorded in the WhaleFace Southern Right Whale photo identification project, located on the SWIFFT website. The data underlying these observations was extracted from the NatureKit online database (https://maps2.biodiversity.vic.gov.au/Html5Viewer/Index.html?viewer=NatureKit). This database contains observations of SRW presence along the entire Victorian coastline for over 40 years and has been used for multiple published scientific studies (e.g. Stamation et al 2020, Watson et al 2021). CGG extracted a spatial subset of the data encompassing all observations between Apollo Bay and 30km NW of Cape Duquesne off Portland. From this data it can be seen that June – September is the core period for SRW residence along the Otway coast. Arrival is predominantly in June while their migration from the BIA is usually complete by September. SRW have only been seen in October twice over the past 10 years with no sightings for the previous 5 years (see Figure F3-1). The SRW Research and monitoring Project hosted on the SWIFFT website has stated that there were no sited SRW after 26th August for the 2024 season. The sightings data are demonstrating that migration out of the BIA is usually complete by October but will often be complete weeks earlier.

In 2025, Klarite undertook a SRW monitoring program from Cape Otway Light Station to Cape Bridgewater as Whaleface data for 2025 may not be available for 2 years.

The monitoring program resulted in just over 466 hours of observation effort from July through to October 2025. Most SRWs observations were at Logans Beach Whale nursery. The 2025 reproduction season concluded with a total of four confirmed SRW calf-cow pairs utilising the south-west portion of the Victorian SRW reproduction BIA between July and September 2025. These calf-cow pairs were identified at Logans, Beach, Cape Bridgewater and Portland Bay, with Logans Beach being the most visited site by one calf-cow pair in particular. The calf-cow pair at Logans Beach was identified as a regular breeding female named Tripod and her calf. Tripod was first identified at Logans Beach in 1995 (Whaleface, 2025). No calf-cow pairs seemed to remain resident in any one location with detection being sporadic and often weeks between sightings.

Klarite tested the tested the feasibility of using onshore MFO's to detect SRWs in the Reproduction BIA and found this to be a successful detection method. Klarite also found the use of local citizen science platforms provide near real time alerts of SRW detections and SRW movements in the BIA.

3.1.1.3 Behavioural Effects to SRW From Other Stressors

Sprogis et al. (2023) examined the behavioural impacts to Southern Right Whales from whale-watching activities in South Australia at 300 m from the mother-calf pairs. No significant reduction was observed on the whales' respiration rate, swim speed, nursing rate and duration, maternal rate of active behaviours, tactile contact or calf pectoral fin contact. There was a significant reduction in resting during some phases of the study, for both mothers (halved) and calves (to near null). The rate of active behaviours for calves was also observed to be significantly higher prior to the whale-watching vessel approaching. This was noted as may having been due to the calf hearing the whale-watch vessel upon approach and reacting to the vessel in the before phase, and/or due to other external factors. Sprogis et al. (2023) suggest that whale resting behaviours may have been disturbed in the presence of the vessel and this disturbance was sustained once the vessel departed. It is unknown if this cumulative reduction in resting on mother and calf pairs is sustainable, or could lead to long-term energy deficits (by increasing energy expenditure). Sprogis et al. (2023) suggest it might also be possible for mothers and calves to compensate for this disturbance by resting at other times in the day, and/or at night.

An exclusion zone is in place from 1 June until 31 October to protect migrating Southern Right Whale mother-calf pairs in the Logans Beach Nursery. Recreational boaters must remain 200 metres from whales during this period (GoV 2022). Evidence exists however to suggest that behavioural impacts from recreational activities occur within 300 m from the mother-calf pair.

Currently, there are no noise standards for whale-watching vessels, thus, a loud vessel is able to approach whales at the same distance as a quieter vessel, even though there are known disturbance effects from louder vessels (Arranz et al. 2021; Sprogis et al. 2020)

Short-term negative impacts from behavioural responses to whales can include bioenergetic consequences like reduced energy intake or increased energy expenditure, associated with altered respiration rates, nursing, and resting due to the disturbance (Arranz et al. 2021; Sprogis et al. 2020; Christiansen et al. 2013). If resting is frequently disturbed by anthropogenic impacts, the cumulative effects could have significant long-term consequences on the bioenergetics of the whales (Sprogis et al. 2023).

Charlton et al (2023) studied the impacts associated with implantable tagging SRWs at their wintering grounds at the Head of the Australian Bight in South Australia. They noted there was no observed difference in body condition between two tagged and non-tagged females. Nielson et al (2019) tagged female calf cow pairs at Flinders Bay and found the typical behavioural response to be a slow dive, with the calf moving into a back-riding position, while the pair moved slowly away from the tagging boat. After a short period of time (about 15 min) during which the whales were diving slowly, the mother–calf pair resumed their original behaviour. Christiansen et al (2020) examined behavioural responses from southern right whale calf cow pairs of using a UAV (Unmanned Aerial Vehicle). They found flying the UAV at 5m altitude for 10 minutes, elicited no behavioural responses from mother calf pairs as they likely did not hear the UAV.

3.1.2 Magnitude of Effect

3.1.2.1 Behavioural Impacts of Seismic on Baleen Whales and Calf Cow Pairs

Dunlop et al (2017a) noted 'for a change in behaviour to be considered biologically significant, it should have an effect on one or more life functions (e.g. migration, survival, mating), affecting individual vital rates (e.g. maturation, reproduction) and ultimately leading to population effects. For example, an animal that is under stress can exhibit behaviours outside their normal behavioural repertoire and/or cease to exhibit typical behaviours. If this stressor is chronic, then the animal is likely to have a reduced likelihood of surviving and reproducing.'

Richardson et al (1999) examined the effects of seismic on migrating bowhead whales and found migrating bowhead whales avoided the seismic source within 20km of the operating guns with received sound levels of between 120–130 dB re: 1 μ Pa. Wood et al (2012) defined behavourial response categories for sensitive species and migrating mysticetes using the Richardson et al (1999) study. Wood et al (2012) proposed a graded probability of response for impulsive sounds using a frequency weighted SPL metric, and graded the probability of mysticetes to respond at 140 dB re: 1 μ Pa as 90%.

Robertson et al (2016) sought to determine the extent to which analyses of the distribution of bowhead are affected by changes in visual 'availability' caused by seismic operations. Roberston et al (2016) found no evidence of changes in distribution of whales exposed to sound levels up to ~150 dB re 1 μ Parms, whereas Richardson et al. (1999) found evidence of avoidance behaviour. The authors suggested earlier analyses of displacement by bowhead whales of seismic operations are likely to have overestimated displacement because the numbers of whales in areas ensonified by seismic operations may have been as much as 33–68% higher than were previously estimated, implying some whales are not avoiding those areas as previously suggested.

McCauley et al. (2003) found resting humpback female-calf pairs showed avoidance responses at a considerably lower level 11km from the array. The calf cow pairs moved 3km to the south of the array (mean of 140 dB re 1 µPa). There were no indications of increased stress on a cow-calf pair which allowed the operating seismic vessel to pass three km to the North. This contrasts with migrating humpbacks which showed clear course changes at received levels of 144–151 dB re 1 µPa.

From 2010 to 2015, BOEM funded the Behavioural Response of Australian Humpback Whales to Seismic Surveys (BRAHSS) to investigate the effects of seismic surveys on humpback whales. Studies were conducted off the coast of Queensland at Peregian Beach on the southeast coast of Australia. Humpback whales were likely to avoid airgun arrays within 3km when the received level was greater than about 140 re. 1 µPa2 s (Dunlop et al 2017b). Another study as part of the BRAHSS project used a 3130 cubic inch airgun array to examine effects of seismic on migrating humpback whales. The authors found none of the groups exhibited any behaviours that were outside their normal repertoire of behaviours (e.g. continuous surface activity, female–calf separation) and none of the groups ceased to migrate or turned and continued to head northwards after the trial was over. Groups continued to generally move southwards and socially interact during active and control treatments (Dunlop et al 2017a). There were also no abnormal behaviours, such as instances of a female separating from her calf or sustained bouts of high energy surface behaviours (which are considered abnormal behaviour indicative of a stress response in humpback whales), were observed (Dunlop et al 2017b). The authors continued to observe typical behaviours including singing, socializing with conspecifics, using social signals such as surface slapping, and general migratory travel southwards. Since no abnormal behaviours were observed and there was no clear evidence that the whales were experiencing stress, humpback whale behaviours seemed to be primarily influenced by social interactions and their need to migrate, with minimal impact from the seismic vessel and airguns (Dunlop et al 2017a).

Bröker et al (2015) developed and examined the effectiveness of an extensive monitoring program to investigate the effects of a 4D seismic survey on a critically endangered population of foraging gray whales off Sakhalin Island, Russia. The authors used a behavioural threshold of 156 dB re μ Pa2-s. They found with a monitoring program and mitigation measures in place, some individual responses in movement patterns were observed, however the results from the behavioural analysis suggested the seismic survey did not have a large impact on the movement or respiration patterns of the population of gray whales as a whole.

3.1.2.2 Acute and Chronic Noise Exposure

Southall et al (2021) sought to make distinguishes between acute and chronic noise exposures. Southall et al (2021) defined acute exposure as short term, often high noise events with identifiable exposure to known individuals or groups (e.g. Military sonar, seismic airguns, pile driving, and sudden

vessel pass-bys. Southall et al (2021) noted behavioural responses from acute noise can range from brief orientation to prolonged avoidance, or separation of mother-calf pairs. Acute exposure responses can be studied using Controlled Exposure Experiments (CEEs) or direct observations.

Chronic exposure as defined as sustained or repeated exposure over weeks, seasons, or years—usually at lower intensity but over longer durations (e.g. whale watching operations, ongoing vessel traffic, long-term seismic surveys, and industrial coastal activities) (Southall et al 2021). To study the effects of chronic noise exposure, Southall recommends using ecological models, UAVs and energetic modelling and systematic reporting of exposure context, species traits, and potential stressors.

The Regia MSS will only occur during one season when SRWs are present in Australia waters, the noise exposure associated with the survey is acute. The Regia Operational Area does not overlap with the SRW Reproduction BIA. The Regia MSS has been planned to ensure there is only a 20% overlap with the SRW calving season. The Regia MSS will only overlap with half of the migration period for SRWs in one season. The survey will not lead to long term sustained repeated exposures to SRWs.

3.1.2.3 Thresholds and Criteria for Behavioural Disturbance

The 160 dB re 1 μ Pa SPL threshold for behavioural disturbance is a commonly applied regulatory benchmark derived from empirical studies, particularly those examining mysticete responses to seismic sources. This threshold is widely recognized in national (NOAA) and international guidelines, including the National Marine Fisheries Service (NMFS) criteria. However, emerging research challenges the universality of this fixed threshold. Southall et al. (2021) and Ellison et al. (2012) argue for a contextual interpretation of behavioural responses, highlighting that the same sound exposure level (SEL) can result in different behavioural outcomes depending on factors such as behavioural state (e.g., nursing vs. migrating), group composition (e.g., mother-calf pairs), and habitat importance (e.g., reproductive BIAs).

Another major flaw in selecting a fixed behavioural threshold is that it ignores chronic noise effects. The dose-response model focuses on acute, immediate responses, but does not account for cumulative impacts from prolonged exposure, such as communication masking, stress-related physiological changes, or gradual displacement from key habitats. Even at relatively low SELs, if noise is persistent, it can disrupt essential behaviours over time. This means that using a single SEL-based threshold to predict behavioural impacts could be misleading, as it fails to capture these long-term effects.

The dose-response approach, while useful for predicting the likelihood of a response based on exposure level, fails to account for these ecological nuances. It assumes a uniform reaction to sound across individuals and settings, which does not reflect observed variability. The context-based model proposed by Ellison et al. (2012) considers behavioural ecology and situational variables, offering a more precautionary and biologically relevant framework. This is particularly important for SRWs, where low-level disturbances in critical reproductive habitats may still have significant energetic and developmental consequences.

This approach, whilst complex and not yet adopted by regulators, CGG believes that the behavioural context assessment approach does have greater merit than the more simplistic dose-response approach. This is particularly true in circumstances such as those found for the Regia MSS and the reproductive BIA for SRW.

Additional work has been commissioned by CGG to provide some further analysis and discussion around the application of the 160 dB threshold in project contexts and its overall suitability. They also consider the continuing relevance of the 160 dB threshold in contemporary acoustic modelling applications, evaluating whether it remains an appropriate benchmark considering current scientific understanding and technological advancements. See Appendix B7c. for this report.

3.1.2.4 Behavioural Disturbance Within and Adjacent to the SRW Reproduction BIA

Behavioural disturbance to Southern Right Whales (SRW) within or adjacent to the reproduction Biologically Important Area (BIA) is a central consideration of the National Recovery Plan for the Southern Right Whale (DCCEEW 2024). The requirements placed on CGG's actions have been adopted as defined acceptable levels of the Regia MSS and they establish two clear and measurable expectations near the reproduction BIA:

1. SRWs must be able to continue utilising the area, and
2. Behavioural disturbance must be minimised.

While modelled thresholds for behavioural disturbance are informative, the scientific literature shows that behavioural responses can still occur at received sound levels below 140 dB re 1 µPa SPL(e.g. Southall et al. 2016). Studies indicate that responses at these lower levels tend to be of low severity, but may still occur (Affatati & Camerlenghi 2023), although SRW-specific studies remain limited.

For the Regia MSS:

- Modelled results show no exceedance of the 140 dB threshold in the SRW reproduction BIA (See MAP-REG-EPM-188).
- Modelled results show sound levels within the BIA fall within ~120–140 dB re 1 µPa SPL (See MAP-REG-EPM-187, MAP-REG-EPM-188 and MAP-REG-EPM-189).
- Modelled sound level results within the BIA overlap with natural ambient sound levels in the Otway region, which have been found across multiple studies to vary between 90–158 dB, with a mean around ~110 dB (Beach Energy 2022 and references therein).

This overlap means that modelled effect thresholds alone cannot reliably distinguish natural variability from activity-related sound within the BIA. SRW mothers and calves may occupy the BIA for extended periods, where even low-severity behavioural responses could compromise the Recovery Plan requirement that utilisation be maintained and behavioural disturbance minimised.

To meet the Recovery Plan obligations and the defined acceptable levels, the management approach must ensure that SRWs can continue to utilise the reproduction BIA and that the risk of behavioural disturbance is minimised in practice – not just in modelling. Given the uncertainties described above, CGG has adopted a precautionary approach based on the following principles:

1. Where natural ambient levels and modelled results overlap, modelled thresholds alone may not ensure behavioural disturbance is minimised.
2. An ambient sound management framework to monitor sound in the reproduction BIA provides a more reliable, real-time assurance of protection.
3. Real-time monitoring of SRWs within the BIA provides a direct, species-specific control measure that is fully aligned with the Recovery Plan.

To operationalise these principles, CGG will manage to an EPO whereby, 'No behavioural disturbance will occur to any SRW within the reproduction BIA as a result of the Regia MSS.

To support this approach, CGG will:

- Characterise ambient (~baseline) sound levels within the reproduction BIA recognising natural variation across weather, sea state, biological activity and anthropogenic activities not associated with the MSS
- Conduct sound source verification as close as practicable to the reproduction BIA to confirm that activity-related sound does not elevate received levels above defined ambient-based ranges during sampling periods.
- Use this verification to guide real-time decision-making, providing a direct, measurable basis for ensuring behavioural disturbance is minimised.

By adopting the measured ambient seascape as our reference for the management framework, CGG removes reliance on modelled behavioural effect distances as the primary control measure. This increases predictive certainty and strengthens confidence that SRWs within the reproduction BIA will not be exposed to sound levels capable of causing behavioural disturbance.

To inform this approach CGG will deploy a suite of monitoring measures including shoreline observations, offshore monitoring platforms, aerial surveys, and acoustic detection systems.

Under this framework:

- If any SRW is detected within the reproduction BIA, the seismic source will be shutdown,
- Restart of the seismic source will only occur once monitoring confirms that SRWs have departed the reproduction BIA, ensuring actions must not prevent whales from utilising the area.
- Uncertainty regarding behavioural thresholds is removed entirely, ensuring that the activity is conducted in a manner that minimises behavioural disturbance.

More detail on mitigation effectiveness is discussed below.

3.1.3 Recovery Potential

The life history traits of Southern Right Whales such a long-life span, low reproductive output, late sexual maturity, and strong fidelity to calving areas, make them vulnerable to anthropogenic threats. These life history traits mean that any long-term response to disturbance and impacts from threats that may affect recovery are unlikely to be detectable, or even reliably identified to a specific threat, over short timescales (i.e., 1 to 3 years).

As SRWs recover from commercial whaling and their distribution and abundance increases, anthropogenic underwater noise may have the potential to displace and/or deter SRWs from habitats critical to the species or currently unused but historically important areas (DCCEEW 2023).

Based on the magnitude of effect from the Regia MSS to SRWs, which is limited to behavioural avoidance for migrating SRWs for one season, no long-term disturbance are impacts that may affect their recovery are predicted.

3.1.4 Conservation Status

The SRW is listed as threatened (*Endangered)* under the EPBC Act because population numbers have been severely reduced by historical commercial whaling (DCCEEW 2024). SRWs are also listed as Migratory. The National Recovery Plan for SRW (DCCEEW 2024) identifies the Commonwealth legislation and management arrangements that relate to the protection of SRWs in Australian waters.

Two populations of SRW occur in Australian waters: the western and eastern. SRW occur seasonally in all State coastal waters, with sightings ranging from Hervey Bay in Queensland on the east coast, along the entire southern coastline and including Tasmania, to Exmouth Gulf in Western Australia. The geographical boundary between the Australian populations is unclear. For management purposes, the western population includes Western Australia and South Australia waters, whereas the eastern population comprises the coastal waters of Victoria, Tasmania, New South Wales, and Queensland (DCCEEW 2024).

SRWs predominantly occur in aggregations in coastal water reproductive areas where they calve and nurse their young from May to October, primarily occupying shallow waters (< 10m depth) within 1 km of the coastline (Charlton et al. 2019).

Is there serious or irreversible harm to SRW from the Regia MSS requiring action under the Precautionary Principle?

In evaluating the threat (impacts) of seismic surveys on marine species, it is crucial to distinguish between different levels of harm—specifically, what constitutes serious or irreversible harm. The Regia MSS EP has shown that only behavioural effects are predicted to occur and that those effects are below the threshold for underwater level B harassment.[1]

The full range of possible behavioural effects has been acknowledged and shown to likely be at the lower end of the severity scale proposed in Southall et al 2021. These behavioural effects often do not meet the threshold for serious or irreversible harm for several reasons:

1. Behavioural changes in marine species in response to acoustic disturbances are typically reversible. Once the sound source ceases, the affected species are predicted to return to their normal behavioural patterns. This reversibility indicates that the changes do not result in long-term detrimental effects on any individual nor at the population level.
2. Behavioural effects are distinct from physical injuries that can cause immediate and lasting harm to individuals. Physical injuries can directly impact the health, reproductive capabilities, and survival of marine animals. In contrast, behavioural changes are less likely to have direct physiological consequences that could be considered serious or irreversible, particularly in circumstances such as the Regia MSS where sound exposures are impulsive (i.e. not continuous) and episodic due to survey downtime and the location changes of survey sail lines.

[1] Level B harassment is a defined term from the Marine Mammal Protection Act (MMPA) 1972 (US) which Southall 2007 et al state "would almost certainly not constitute biologically significant disturbance (or consequently level B harassment under the MMPA)."

3. Marine species often exhibit adaptive behaviours that allow them to cope with and adjust to changes in their environment, including sound. These adaptations can mitigate the potential negative effects of behavioural disturbances, further reducing the likelihood of serious or irreversible harm.
4. The scientific consensus (i.e. excluding outliers or adopting worst-case scenario thinking) indicates that while behavioural responses can be significant, they rarely translate into population-level impacts that would be considered serious or irreversible. This distinction is critical in applying the precautionary principle appropriately; the principle is intended to prevent significant harm, and its application must be supported by evidence of potential serious consequences (i.e. not hypotheticals, worst-case thinking, or scientific outliers).
5. Effective management and mitigation measures, including real-time monitoring and adaptive management strategies, are in place and are designed to reduce the intensity and duration of disturbances, thus preventing them from reaching a threshold that could be considered serious or irreversibly harmful.
6. The precautionary principle requires a proportionate response. Applying the highest level of precaution—reserved for preventing serious or irreversible damage—to relatively low-risk behavioural effects can lead to unnecessary restrictions and may divert resources from addressing more significant environmental threats. Thus, while precaution is necessary, it must be balanced with the actual level of harm presented by the behavioural effects.

CGG has shown in the impact and risk analysis documents that regulatory requirements relevant to the Regia MSS and SRW will be met. Relevantly, the National Recovery Plan for SRW (DCCEEW 2024) has significant weight in CGG's assessment due to the involvement of Commonwealth and State regulatory agencies, threatened species managers, and scientific experts in the development of the recovery plan. As such, recommended actions from the plan relevant to the Regia MSS have been implemented as detailed in Section 3.1.5 Mitigation Effectiveness.

3.1.5 Mitigation Effectiveness

CGG has already adopted a suite of mitigation measures that address most of the impact pathways for effects to SRW. These have been detailed in Appendix E7. However, no one measure is entirely effective and there are uncertainties in the assessment which will be addressed in this section.

Assessment of Uncertainty

This section explains how CGG has identified the key sources of uncertainty relevant to predicting and managing the environmental impacts and risks of the Regia MSS on SRW, and how those uncertainties are reduced through a structured suite of activity limitations, monitoring programs, detection platforms, and strict procedures for managing to below acceptable levels.

The tables presented in this section serve a specific function. Each Commitment is an activity limitation or management measure adopted to remove or materially reduce a defined source of uncertainty, and each Rationale explains why that measure ensures impacts remain within defined acceptable levels.

Where uncertainty exists, CGG will implement activity limitations, monitoring programs, validation mechanisms, and conservative procedures that remove or materially reduce that uncertainty. This demonstrates that CGG is managing uncertainty proactively so that environmental impacts and risks are maintained below acceptable levels.

Identifying Types of Uncertainty

A range of uncertainties are inherent when trying to predict environmental responses to offshore seismic activities, particularly for SRW and other cetaceans in the Otway region. We have categorised these uncertainties as follows:

1. *Ecological uncertainty*- reflects natural variability in whale arrival timing, utilisation of the reproduction BIA, migration pathways, and behavioural sensitivities to sound.
2. *Model uncertainty* or *Predictive uncertainty* - arises because underwater sound propagation models rely on assumptions and environmental inputs that are not always clearly defined or easily measured. Factors such as source-level variability, bathymetry resolution, and sound-speed structures can influence model accuracy. In addition, there is

inherent uncertainty in how well modelled thresholds translate to real-time sound fields during survey operations.

3. *Detection uncertainty,* - relates to the likelihood of observing whales reliably across multiple detection platforms. All detection systems have inherent probabilities of false negatives, especially when weather or sea-state conditions reduce visibility or acoustic performance. Spatial and temporal gaps in coverage can also occur, particularly during migration peaks or poor weather windows, creating uncertainty in whether cetaceans are present but undetected.
4. *Operational uncertainty* - arises from variable conditions and vessel behaviour during the survey. Weather-driven changes in sailing patterns, line turns, vessel repositioning, and equipment handling can influence sound propagation or detection system performance. Contractor variability and operational constraints also contribute to this uncertainty, requiring robust procedures and real-time adaptability.

Management of Uncertainty

The most effective way to reduce uncertainty in the impact assessment is to reduce the nature and scale of the activity itself. CGG acknowledges that maintaining two potential acquisition windows (April–June and September–December) creates operational uncertainty, particularly because these windows overlap with periods of high SRW sensitivity. The April–June period is especially critical, as it coincides with the arrival of pregnant females and mothers with newborn calves. For this reason, CGG has eliminated the April–June window entirely, representing a major reduction in ecological uncertainty. This change is now formalised as a new activity limitation in Appendix A2 (Description of Activity).

Additional activity limitations adopted through this further assessment to reduce uncertainty include:

- *24-hour shutdown for any SRW detections within the migration or reproduction BIA*: In the September window, SRWs observed in the BIA are typically preparing for southbound migration. A shutdown for every confirmed detection, regardless of distance, is a highly precautionary measure that provides sufficient time for the animal to move naturally away from the area. Given the long sail lines and racetrack acquisition pattern, there is high confidence this approach prevents interference with migration and ensures SRWs are not displaced from using the BIA.
- *Extending the northern activity limitation from the most northerly 20 lines to the most northerly 30 lines while SRWs are using the reproduction BIA*: This restriction is strongly protective, as it ensures received sound levels in the reproduction BIA stay within the ambient statistical window, well below 140 dB re 1 µPa SPL and far below the NMFS 2024 recommended 160 dB re 1 µPa SPL behavioural threshold. These refinements have been implemented across the relevant EP appendices.

Below summarises the specific measures adopted by CGG to reduce key ecological, detection, modelling and operational uncertainties relevant to SRW management. The commitments are structured as a stepwise sequence that begins prior to the survey and progressively builds the evidence base required to validate modelling assumptions, strengthen detection performance, and confirm operational readiness. Early-season activities focus on establishing empirical baselines and verifying SRW presence, distribution and behaviour, while subsequent phases apply validated thresholds, precautionary shutdown procedures and real-time monitoring to actively prevent unacceptable impacts. Each stage builds upon the information obtained in the previous one, reducing uncertainty and enabling CGG to progressively tighten environmental control measures as biological sensitivity increases, thereby supporting a robust demonstration that impacts and risks will be of an acceptable level.

Uncertainty	Commitment	Rationale why the commitment is necessary to manage uncertainty and supports a demonstration that impacts will be managed to an acceptable level	EP Cross Reference
Pre-Survey – In Season SRW Detection and Management Program (May 2025 – October 2025)			
Ecological Uncertainty	Commence Season 1 of a SRW monitoring program	Real-time, on-country monitoring reduces ecological uncertainty by validating suitable SRW observation locations and independently corroborating citizen-science sighting information, which cannot be relied upon alone because publicly available databases (e.g., Whaleface) are updated post-season and therefore provide no in-season verification capability.	This commitment has been completed. This document (F3) has provided a summary of the findings.
	Carry out SRW monitoring in the season prior to the survey.	This pre-survey dataset reduces ecological and detection uncertainty by establishing verified SRW presence and distribution patterns for the 2025 season, identifying suitable locations for shore-based MFOs and drone deployment, and assessing the reliability of local citizen-science sighting platforms as real-time information sources.	
Pre-Survey – Out-of-season Monitoring Program (October 2025 – April 2026)			
Model Uncertainty	Undertake extended logging of underwater sounds between Cape Otway and Cape Bridgewater.	Long-term pre-survey ambient sound recordings reduce modelling uncertainty by providing empirically derived baseline distributions of central tendency, variability, and upper-tail levels across relevant spatial and temporal scales. These baselines enable accurate differentiation between natural soundscape conditions and any MSS-related contributions, and are required to establish defensible, acceptable thresholds for deviation during operations. This aligns with the SRW Recovery Plan action to "Improve understanding and characterisation of marine soundscapes, including the application of new technologies for data processing, within southern right whale BIAs to facilitate quantification of anthropogenic noise in the marine soundscape"	This commitment is captured in the Sound Source Verification Procedure (Appendix G6). As this is a procedural control measure the relevant performance standards can be found in Appendix G1.

Uncertainty	Commitment	Rationale why the commitment is necessary to manage uncertainty and supports a demonstration that impacts will be managed to an acceptable level	EP Cross Reference
Detection Uncertainty	Aerial surveillance preparation.	Finalising the aerial surveillance strategy reduces detection uncertainty by ensuring that all permitting, operator competencies, and platform capabilities are validated prior to operations, thereby confirming that aerial surveillance methods and technologies can reliably detect SRW at the ranges and conditions required for effective environmental management.	This commitment occurs before commencement of the activity, so it is captured in the Implementation Strategy (Appendix B3) and in the Coastal SRW Monitoring Programme Implementation Plan (Appendix G5).
Pre- survey – In Season SRW Monitoring Program (1 May 2026 – 30 July 2026)			
Ecological Uncertainty	Commence Season 2 of monitoring of SRW presence between Cape Otway and Cape Bridgewater	This monitoring reduces ecological and detection uncertainty by generating current-season data on SRW presence and abundance within the scope area, ensuring CGG is accurately informed leading up to and throughout the acquisition period, and providing empirical validation of improvements made to SRW detection methods prior to commencement of the survey. This is best practice as required by the SRW Recovery Plan 2025: "Baseline surveys and monitoring undertaken during activity implementation are conducted in accordance with best practice standards and guidelines to ensure standardised datasets are obtained and suitable to inform environmental management decision making that can reduce the risk of threats to southern right whales."	This commitment is captured in the implementation strategy (Appendix B3) and has an associated implementation plan in Appendix G6.
	Pre-survey aerial surveillance of nearshore/SRW reproduction BIA.	This commitment aligns with, and directly implements, the SRW Recovery Plan requirement that "Baseline surveys and monitoring undertaken during activity implementation are conducted in accordance with best practice standards and guidelines to ensure standardised datasets are obtained and suitable to inform environmental management decision making that can reduce the risk of threats to southern right whales."	This commitment fits under the *Pre-survey and aerial surveillance procedure* control measure. Performance standards that reflect this commitment can be found in Appendix G1.

Uncertainty	Commitment	Rationale why the commitment is necessary to manage uncertainty and supports a demonstration that impacts will be managed to an acceptable level	EP Cross Reference
Model Uncertainty	Undertake ongoing sound logging of nearshore/SRW reproduction BIA.	Ongoing nearshore sound logging reduces modelling and ecological uncertainty by quantifying ambient sound levels within areas routinely used by SRW, providing empirical reference conditions necessary to distinguish natural variability from any survey-related contributions during operations.	This commitment is captured in the Sound Source Verification Procedure (Appendix G6). As this is a procedural control measure the relevant performance standards can be found in Appendix G1.
Pre survey – In Season SRW Monitoring Program – Pre-Activity Operations Phase (1 August – 15 September)			
Ecological Uncertainty	Expand monitoring of SRW presence between Cape Otway and Cape Bridgewater to commence all platforms and programs.	Expanded pre-activity monitoring reduces ecological and detection uncertainty by providing up-to-date information on SRW presence and abundance during the expected peak period, thereby validating the survey start criteria and confirming that all detection programs and platforms are performing effectively before acquisition begins.	This commitment is captured in the implementation strategy (Appendix B3) and has an associated implementation plan in Appendix G6.
Detection Uncertainty	Deploy and calibrate Sound Source Verification Buoys (SSV Buoys)	Deployment and calibration of the SSV buoys reduce modelling and operational uncertainty by confirming correct buoy operation, quantifying and adjusting for any mooring-related noise, verifying reliable communication pathways between the buoys and shore, and ensuring each buoy can continuously transmit full-spectrum acoustic data via satellite/4G, and Wi-Fi prior to the commencement of acquisition.	This commitment is captured in the Sound Source Verification Procedure (Appendix G6). As this is a procedural control measure the relevant performance standards can be found in Appendix G1.
Operational Uncertainty	Run the Acquire Seismic On Paper (ASOP) workshop	The ASOP workshop reduces operational and management uncertainty by ensuring all teams have a shared understanding of roles, expectations, and decision pathways across a range of credible survey scenarios, and by testing and validating the response actions required for SRW detections before the activity commences.	This is an existing component of the Implementation Strategy (Appendix B3) and contributes directly to the management of uncertainty.
Ecological Uncertainty	Conduct pre-survey aerial surveillance (likely by onshore drones)	Pre-survey aerial surveillance reduces ecological and detection uncertainty by extending visual coverage beyond the limits of land-based observers, improving the accuracy of SRW presence and abundance estimates, and validating the reliability of existing monitoring datasets before acquisition begins. This aligns with the SRW Recovery Plan action to "Establish effective monitoring techniques for the eastern population and implement a targeted long-term monitoring program capable of measuring and evaluating population recovery."	This commitment is captured in the implementation strategy (Appendix B3) and has an associated implementation plan in Appendix G6.
During survey – In Season SRW Monitoring Program – Activity Operations Phase (16 September - 31 October)			

Uncertainty	Commitment	Rationale why the commitment is necessary to manage uncertainty and supports a demonstration that impacts will be managed to an acceptable level	EP Cross Reference
Ecological Uncertainty	Continue monitoring of SRW presence between Cape Otway and Cape Bridgewater.	Ongoing in-season monitoring reduces ecological and detection uncertainty by providing current information on SRW presence and abundance within the scope area, thereby ensuring that whale-related shutdown decisions are based on accurate, real-time data during acquisition.	This commitment is captured in the implementation strategy (Appendix B3) and has an associated implementation plan in Appendix G6.
Ecological Uncertainty	Shut down the sound source if impulsive noise levels exceeding 120 dB SPL are repeatedly detected by the SSV buoys. In October, if there have been 14 consecutive days without a confirmed SRW detection, the shutdown trigger for repeated impulsive-noise exceedances increases to 140 dB SPL.	Context is essential when considering behavioural disturbance. For the Regia MSS: • The NMFS (2024) threshold for behavioural disturbance is 160 dB SPL. • Existing shutdowns extend to 13km which corresponds to the 140 dB SPL threshold. • Shutdowns also occur for any confirmed detection of a single SRW. Despite these unprecedented control measures, CGG recognises that the scientific literature acknowledges some behavioural responses may occur at or below 140 dB SPL. Given the uncertainty in the literature, the data showing reducing numbers in September, and no observations in October since 2018, CGG will implement this ultra-precautionary shutdown measure. This approach will ensure that impacts to SRWs remain of an acceptable level also addressing uncertainties regarding behavioural responses and thresholds. The conditional part of this measure can only be applied in October if there have been no detections of SRWs from any detection platform for a period of two weeks. This two-week timeframe was determined to be appropriate based on the Whaleface sightings data, which shows that there have been no SRW sightings in October over the past five years. In the unlikely event that a SRW were to be detected in October, which has historically occurred, then the threshold for impulsive sound detection would return to 120 dB SPL for a minimum period of 2 weeks. Applying this conditional shutdown measure ensures that any remaining SRWs in the BIA can continue to utilise the area without experiencing behavioural disturbance because of the Regia MSS, thus ensuring impacts are of an acceptable level.	A new EPO will be adopted to address this uncertainty: *Underwater sound emissions from the Regia MSS are empirically measured and validated through the sound source verification procedure to ensure they remain within levels that do not cause injury or unacceptable disturbance to Southern Right Whale.* Additions have been made to the Environmental Performance for the survey including shutdown and restart procedures. They can be found in Appendix G1, in the Fauna Management Plan (Appendix G2). This procedure and metrics associated with this measure are defined in Appendix G6 (Sound Source Verification Procedure).

Uncertainty	Commitment	Rationale why the commitment is necessary to manage uncertainty and supports a demonstration that impacts will be managed to an acceptable level	EP Cross Reference
Operational Uncertainty	Shutdown the sound source upon "confirmed detection" of any SRW from any detection platform. Soft restart of the survey can only commence when there have been no confirmed detections of a SRW across all the platforms for a period of 24 hours.	Applying an immediate shutdown for any confirmed SRW detection eliminates the potential for behavioural disturbance or TTS within the Reproduction BIA by ensuring that all shutdown triggers are based on verified detections, defined as observations confirmed by a qualified MFO, an expert scientist, or time- and date-stamped photographic evidence.	Additions have been made to the Environmental Performance Standards for the Shutdown and Restart Procedures. They can be found in Appendix G1 and in the Fauna Management Plan (Appendix G2).
Operational Uncertainty	Investigate all "unconfirmed detections" of SRW from any information platform or program within 12 hours.	Investigating all unconfirmed SRW detections reduces detection uncertainty by ensuring that any claimed sighting (defined as an observation not yet verified by a qualified MFO, an expert scientist, or time- and date-stamped photographic evidence) is rigorously validated before triggering a shutdown or extending an existing shutdown, thereby preventing false positives and ensuring that management actions are based solely on confirmed, reliable detections.	Additions have been made to the Environmental Performance Standards for the Shutdown and Restart Procedures. They can be found in Appendix G1 and in the Fauna Management Plan (Appendix G2).
Model Uncertainty	Gather ambient and received sound levels throughout the survey from locations just outside the reproduction BIA via SSV buoys.	Real-time SSV data reduces modelling and operational uncertainty by providing continuous empirical information on ambient and received sound levels adjacent to the Reproduction BIA, enabling informed management decisions about vessel positioning and line acquisition, and validating modelled sound predictions against measured field conditions.	This commitment is captured in the Sound Source Verification Procedure (Appendix G6). As this is a procedural control measure the relevant performance standards can be found in Appendix G1.
Model Uncertainty	Investigate potential causes for pre-defined exceedances of ambient sound levels as detected by any SSV buoy.	Investigating any detected sound levels above the established historical maximums reduces modelling and operational uncertainty by confirming whether anomalous peaks are attributable to Regia MSS impulsive sound, triggering immediate shutdown where required, and providing empirical data necessary to test the hypothesis that acquisition along lines 31–67 will not produce statistically significant deviations from ambient sound levels within the Reproduction BIA while SRW may be present.	

Uncertainty	Commitment	Rationale why the commitment is necessary to manage uncertainty and supports a demonstration that impacts will be managed to an acceptable level	EP Cross Reference
Operational Uncertainty	Soft (re)start of the survey can only commence if the sound source detected by SSV buoys is confirmed not to be from the Regia MSS and it is during daylight hours.	This requirement ensures that, irrespective of visual detection limitations within the Reproduction BIA, the survey will not elevate received sound levels above ambient conditions, thereby managing residual uncertainty in both the effectiveness of detection platforms and the predictive accuracy of sound-propagation modelling.	Additions have been made to the Environmental Performance Standards for the Start-up Procedure. This can be found in Appendix G1 and in the Fauna Management Plan (Appendix G2).
Operational Uncertainty	The spotter vessel will travel parallel to the seismic vessel, 20km away and on the northerly side, while it is acquiring lines 31-67.	Positioning the spotter vessel between the survey vessel and the expected SRW distribution within the Reproduction BIA reduces detection uncertainty by maximising the probability of visually or acoustically detecting migrating whales before they approach the survey footprint, thereby supporting timely and precautionary shutdowns.	Additions have been made to the Environmental Performance Standards for the Spotter Vessel Procedure. This can be found in Appendix G1 and in the Fauna Management Plan (Appendix G2).

Taken together, the measures in the tables form a conservative, multi-layered framework that progressively eliminates or controls uncertainty at every stage of the activity. High-uncertainty periods are removed entirely through temporal exclusions, and spatial buffers ensure that the highest-sensitivity zones remain insulated from potential exposure. Model assumptions are then validated in real time through the Sound Source Verification program and continuous comparison of measured and baseline ambient sound levels, ensuring that predictions remain accurate under operational conditions.

At the same time, detection probability is maximised by deploying overlapping, independent platforms across visual, acoustic, and aerial domains. This redundancy ensures that no single point of failure can compromise the system. Any residual uncertainty is absorbed through deliberately conservative procedures, including mandatory shutdowns, confirmation protocols, and relocation triggers that apply long before behavioural or auditory thresholds could be approached.

Collectively, these layers ensure that SRW are not prevented from utilising biologically important areas, and that no individual is exposed to sound levels capable of causing auditory injury or sustained behavioural disturbance. The approach also ensures that the activity is not inconsistent with the SRW National Recovery Plan. Most importantly, by managing uncertainty at its source and validating real-time conditions as the survey progresses, CGG ensures the predictions of the impact and risk assessments remain robust and reliable under real-world conditions.

Demonstration that behavioural impacts to SRW from underwater sound are of an acceptable level

Through application of the most up-to-date modelling, direct real-time sound management, and verification by calibrated SSV buoys, CGG can demonstrate that impulsive sound emissions from the Regia MSS will not exceed acceptable levels of impact for SRW, which are defined as:

1. Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate they do not prevent any southern right whale from utilising the area or cause auditory impairment.
2. Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that they minimise behavioural disturbance.
3. Sound exposures to southern right whales must be below a TTS per pulse and TTS 24 hr SEL threshold of 216 dB and 168 dB respectively.

The Environmental Performance Outcome states that:

> *As a result of the implementation of real-time monitoring and activity limitations, SRW are not exposed to sound levels that cause behavioural disturbance within or adjacent to BIAs or HCTS.*

The acceptable levels of impact can be demonstrably met because sound levels within the reproduction BIA will remain within the statistical window of ambient sound levels, as established by pre-survey baseline monitoring and verified through a running baseline during operations.

Moreover, this approach exceeds standard industry practice, provides a transparent and scientifically defensible basis for demonstrating environmental protection, and fully aligns with the Regulations, the SRW National Recovery Plan, and NOPSEMA's decision-making guidelines.

3.2 Blue Whales / Wuulok (*Balaenoptera musculus*)

3.2.1 Species-Specific Sensitivity

Blue whales are categorised as low-frequency cetaceans. Blue whales produce high-intensity, low frequency vocalisations which can be detected over large distances (Miller et al. 2021). Blue whale calls last up to 18 s and generally consist of three segments: a 9-s-long, 27-Hz tone, followed by a 1-s downsweep to 19 Hz and another, longer-lasting downsweep to 18 Hz (Širović et al. 2004, Rankin et al. 2005).

Antarctic blue whale source levels have been estimated to be 189 underwater decibels (Širović et al. 2007), although a more recent study has estimated source levels to be between 188-191 decibels (Miller et al. 2021).

Gavrilov and McCauley (2013) found pygmy blue whales in Australian waters display a diel pattern in vocalisation, noting pygmy whales are more vocally active during hours of darkness compared to daylight hours. Tripovich et al. (2015) noted Antarctic blue whales calls were more prevalent in the night to early morning.

The frequency of the sound produced from each seismic pulse is primarily less than 2 kHz, with the highest levels at frequencies in the range of 10-500 Hz (McCauley 1994). Thus, there is an overlap with low-frequency cetaceans hearing frequencies.

The blue whale source level of 188 to 191 decibels means that blue whale calls can be louder than the current sound effect criteria for behavioural response of 160 decibels.

The Blue Whale Conservation Management Plan 2015-2025 (DoE 2015c) assessed threats to blue whales through a risk assessment process. For both the pygmy blue whales and Antarctic blue whales, which are relevant to the Regia MSS, the consequence of seismic surveys was assessed as moderate, which is defined as population recovery slows or stalls. For pygmy blue whales the likelihood of occurrence was assessed as almost certain, expected to occur every year, resulting in a risk level of very high for which immediate additional mitigation action is required. For Antarctic blue whales the likelihood of occurrence was assessed as possible, the event might occur at some time, resulting in a risk level of high requiring additional mitigation action and an adaptive management plan required; the precautionary principle should be applied.

The risk assessment is deemed to be conservative as the Blue Whale Conservation Plan 2015-2025 (DoE 2015c) details that given the behavioural impacts of noise on blue whales are largely unknown, a precautionary approach has been taken regarding assignation of possible consequences.

Other threats assessed as having a moderate consequence and a likelihood of occurrence of possible are vessel collisions. Other threats assessed as having a major consequence and a likelihood of occurrence of possible are climate variability and change.

3.2.2 Magnitude of Effect

The Conservation Management Plan for Blue Whales (DoE 2015c) details that impacts from anthropogenic noise can include hearing impairment (e.g. permanent and temporary threshold shifts) masking of communication, displacement, and other significant behavioural changes (including to vocal behaviour). There have been no recorded mortal injuries to blue whales from seismic surveys.

The Conservation Management Plan for Blue Whales 2015-2025 (DoE 2015c) details the potential for impacts from anthropogenic underwater noise is of particular concern within biologically important areas at biologically important times. CCG will implement an activity limitation where the seismic source will only be operated in the pygmy blue whale foraging BIA from 16 September and during October, November and December.

During this time permanent or temporary hearing loss and/or displacement of blue whales is not predicted based on the implementation of detection systems and actions as described in the Fauna Management Plan (Appendix G2). Furthermore, it has been suggested that blue whales may

continue to forage within 2.5 km of an operating seismic survey if resources are abundant enough to outweigh the physical and energetic costs of acoustic disturbance (Burton et al. 2023).

As the Regia MSS will only occur during one season when blue whales are present in Australia waters, potential impacts to individual blue whales will not impact on the recovery of the population.

3.2.3 Recovery Potential

Blue whales exhibit long life history traits reaching sexual maturity at 10 years old and calve every 2 or 3 years, making their population recovery slow and vulnerable to anthropogenic threats, although it is thought that blue whale populations are recovering.

Estimates of pre- and post-whaling abundance of Antarctic blue whales indicate that they have been increasing in abundance since the cessation of whaling. The estimated original population size was 239,000 (95% interval 202,000 – 311,000) (Branch et al. 2004). A more recent estimate of the Antarctic blue whale population was 2,280 (95% interval 1,160 – 4,500) individuals in 1996 (estimated from the circumpolar International Decade of Cetacean Research, Southern Ocean Whale and Ecosystem Research survey conducted from the 1992/1993 to 2003/2004 season) (Branch 2007).

There is little knowledge of the pre-exploitation abundance of Australian pygmy blue whales, making it difficult to assess population recovery. Pygmy blue whales in the sub-Antarctic are estimated to have reduced from 7,598 at the start of the 1960/1961 season to 3,996 at the end of the 1971/1972 season, however this is based on out-of-date methodology and the population identity of these sub-Antarctic blue whales is unknown (Zemsky and Sazhinov 1982). Preliminary estimates of the number of pygmy blues caught are 13,022 though this encompasses all catches from South Africa to New Zealand and the northern Indian Ocean for which the extent of connectivity is unknown (Branch et al. 2008).

Based on the magnitude of effect from the Regia MSS to blue whales, no long-term disturbance impacts that may affect their recovery are predicted.

3.2.4 Conservation Status

The blue whale is listed as endangered under the EPBC Act as population numbers have been severely reduced by historical commercial whaling (DoE 2015c). The Conservation Management Plan for Blue Whales (DoE 2015c) identifies the Commonwealth legislation and management arrangements that relate to the protection of blue whales in Australian waters.

There are two sub-species of blue whale found in the Southern Hemisphere. The Antarctic blue whale *(B. musculus intermedia*) which occurs in the southern hemisphere and averages 27 m in length and the pygmy blue whale (*B. musculus brevicauda*), occurs in waters of the southern Indian Ocean, eastern South Atlantic Ocean and western South Pacific Ocean, and averages 22 m in length (Victorian State Government, 2009). The Pygmy Blue Whales give birth in the tropical waters of the Banda Sea migrating to and from this area to reach the cool temperate waters of the Southern Ocean.

Antarctic blue whales breed and calve in warm water (latitude 20° S) during the southern hemisphere winter. They then migrate to cold Antarctic waters (60 - 70° S) during the southern hemisphere summer to feed, mainly on krill. Pygmy blue whales occur only in the southern hemisphere (southern Indian Ocean, eastern South Atlantic Ocean and western South Pacific Ocean). They do not migrate as far south as Antarctic blue whales, and in summer are generally found north of latitude 55 °S (DoE 2015c).

Important foraging grounds for blue whales include the Great Australian Bight, South Australia, and off Portland Victoria. Research to date has found that Pygmy Blue Whales occupy the western area of the Bonney Upwelling system in the Eastern Great Australian Bight and adjacent to the Kangaroo Island canyons from November and December (DoE 2015c). Pygmy Blue Whales then move south-east to the Bonney Upwelling system off eastern South Australia and Victoria (e.g., between Robe, SA and Cape Otway, Vic). This occurs predominately between January to April (DoE 2015c) though they have been recorded in the Otway area as early as October and as late as June.

CGG has shown in the impact and risk analysis documents that regulatory requirements relevant to the Regia MSS and blue whales will be met. Relevantly, the Conservation Management Plan for Blue Whales (DoE 2015c) and Guidance on Key Terms within the Blue Whale Conservation Management

Plan (DAWE 2021) have significant weight in CGG's assessment due to the involvement of Commonwealth and State regulatory agencies, threatened species managers, and scientific experts in the development of the conservation management plan and guidance. As such, recommended actions from the conservation management plan relevant to the Regia MSS have been implemented as detailed in Section 3.2.5 Mitigation Effectiveness.

3.2.5 Mitigation Effectiveness

Mitigation of the Regia MSS effects can be best implemented with regards to blue whales by temporal exclusions to avoid the periods of time when blue whales are most likely to be present in the foraging BIA. Thus, CGG will implement an activity limitation where the seismic source will only be operated in the pygmy blue whale foraging BIA from 16 September and during October, November and December.

The Conservation Management Plan for Blue Whales (DoE 2015c) details the following in relation to marine seismic surveys:

- The risk of physical impacts to blue whales is minimised by implementation of the practical measures outlined in the *EPBC Act Policy Statement 2.1— interaction between offshore seismic exploration and whales*.

CGG will implement the requirements of *EPBC Act Policy Statement 2.1— interaction between offshore seismic exploration and whales* for the Regia MSS as detailed in the Fauna Management Plan. In addition, detection methods above typical industry standards, such as passive acoustic monitoring and in-water acoustic detection monitoring systems for low-frequency whales will be implemented. This will result in an effective mitigation system for detecting blue whales and taking actions to prevent acoustic injury or displacement to foraging blue whales in vicinity of seismic survey operations.

Additionally, the Conservation Management Plan for Blue Whales (DoE 2015c) identifies actions that are relevant to the Regia MSS and underwater noise. CGG has considered each of these actions in the completion of an assessment of the activity (action) according to the principle of ESD (Appendix F4), and the application of a Fauna Management Plan (Appendix G2) which includes minimising the risk of injury and displacement of blue whales.

3.3 Australian Sea Lion (*Neophoca cinerea*)

[Section added in response to Matter I17 and updated in response to Matter F17].

3.3.1 Species-Specific Sensitivity

The Australian Sea Lion is an otariid pinniped with Southall et al. (2019) categorising the species within the *other marine carnivores in water* hearing group. Otariid pinnipeds have a generalised hearing range of 60 Hz to 39 kHz (NMFS 2018). Little data exists on sounds produced by the Australian Sea Lion, or on the effects of noise on their behaviour (Pidcock et al. 2003) with available literature mostly referring to the California Sea Lion in the northern hemisphere. This species is considered to show some similar characteristics to the Australian Sea Lion. California Sea Lions make both airborne and underwater sounds, including barks, whinnies and buzzing associated with social interactions (Pidcock et al. 2003). The frequency of these sounds underwater is below 4 kHz. Most energy for these sounds is projected between 0.25 and 2 kHz (Richardson et al. 1995). Underwater source levels for the Australian Sea Lion are unknown as according to Erbe et al. 2017 there are no subsea recordings for the species.

The frequency of the sound produced from each seismic pulse from the Regia MSS is primarily less than 2 kHz, with the highest levels at frequencies in the range of 10-500 Hz (McCauley 1994). Thus, there is an overlap with the Australian Sea Lion hearing range.

The impacts to the Australian Sea Lion population which are relevant to the Regia MSS, were assessed as medium. The assessment predicted the Regia MSS to have some effect to seals and sea lions, but the effect is not considered significant or at a level to affect the population.

The Issues Paper for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaCa 2013a) and Recovery Plan for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaCa 2013b) list noise as a secondary threat to the Australian Sea Lion. However, research into the vulnerability of the Australian Sea Lion to noise disturbance has not been undertaken with studies only conducted on similar species (e.g. harbour seal and grey seal) in the Northern Hemisphere (DSEWPaCa 2013b).

Historically, the main anthropogenic threat to the Australian Sea Lion was hunting and overharvest through sealing activities during the 1700s, 1800s and early 1900s. Although this activity was stopped in the 1920s, the Australian sea lion population has not recovered to pre-exploitation levels (AFMA, 2010). Estimating the abundance of the Australian Sea Lion is difficult. Techniques used are based on estimates of pup production and the use of population models. Using these techniques, the best estimate for the 2011 population was approximately 14,700 Australian sea lions, with most (86 per cent) occurring in South Australian waters (Shaughnessy, et al. 2011). Population trends at studied colonies varies with some showing decline, with others showing growth. No population data post 2011 could be sourced.

Primary threats to the Australian Sea Lion, (DSEWPaCa 2013a, 2013b) are not activities connected with the Regia MSS. In summary these are:

- interactions with commercial gillnetting operations resulting in drowning.
- interactions with commercial pot fishing for rock lobster resulting in drowning.
- entanglement in marine debris resulting in drowning or causing extensive wounds.

In addition, secondary threats to the Australian Sea Lion (DSEWPaC 2013a, 2013b) which are also not connected to activities during the Regia MSS are:

- loss of habitat due to marine aquaculture.
- entanglement in subsurface equipment from marine aquaculture.
- 32
- land based run-off causing habitat degradation.
- human disturbance from either deliberately or accidentally being near Australian sea lions.
- direct killing because of fishers or aquaculture operators shooting animals that are perceived to be a threat to their operations.
- disease.

- pollution (research is ongoing with to date no supporting evidence).
- oil spills leading to hypothermia if fur is affected and poisoning if toxic hydrocarbons are ingested.
- competition and prey depletion from resulting from human activities and other marine predators.
- climate change associated to events such as sea level rise and 'wave wash' resulting from extreme weather patterns.

3.3.2 Magnitude of Effect

The Issues Paper for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaCa 2013a) and Recovery Plan for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaCa 2013b) details that anthropogenic noise can cause avoidance behaviour and/or hearing threshold changes in pinnipeds. In addition, seismic pulses may affect marine mammal prey species.

Permanent (PTS) or temporary (TTS) threshold shift (hearing loss) to otariid pinnipeds is not predicted based on underwater noise modelling (Appendix B7 – Sound Modelling Reports). The effect criteria for PTS for otariid pinnipeds was not reached. In addition, the per pulse effect criteria for PTS and TTs for these species was reached at 51m-55m and 63m-68m respectively, from the sound source. The PTS cumulative effect criteria for these species was reached at 50m-55m from the sound source and TTs cumulative criteria was reached at 660m-1.02 km from the sound source. It is highly unlikely that a seal or sea lion would stay within 1.02 km of the sound source for up to 24 hr, thus TTS impacts are not predicted.

The impacts to otariid pinnipeds, resulting from noise generated by the Regia MSS, are limited to avoidance behaviour within an area between 3.12 km-6.96 km depending on where in the Operational Area the Regia MSS is being undertaken. As Australian Sea Lions are not dependent on any specific area and typically forage up to 60 km and can forage up to 190 km from their colony, impacts may occur to individuals but not at a level to reduce fitness.

The Australian Sea Lion is a specialised benthic forager, primarily feeding on the sea floor (DSEWPaC 2013b). They typically feed on a range of prey including fish, cephalopods (squid, cuttlefish and octopus), sharks, rays, rock lobster and penguins (DSEWPC 2013b). Underwater noise modelling (Appendix B7 – Sound Modelling Reports) and assessment (Appendix E4 - Underwater Sound: Invertebrates) does not predict mortality or physiological damage to cephalopods. In addition, the predicted effect level to Southern Rock Lobster is assessed as minor as impacts are predicted to have some effect, but the effect is not considered significant or at a level to affect the population given.

Mortality of fish (both immediate and delayed) is not predicted based on lack of documented cases of mortality in free-swimming fish exposed to seismic source emissions under experimental or field conditions (DFO 2004; Boeger et al. 2006; Popper et al. 2014; Popper et al. 2016; Carroll et al. 2017; Popper and Hawkins 2019). Site-attached fish species are species that rely on the benthic habitat and demonstrate a very high degree of site fidelity to the extent that they are unlikely or unable to flee an approaching seismic source and are likely to remain and/or seek refuge within habitat structures. However, impacts to site-attached fish were studied by Woodside at Scott Reef during the Maxima 3D MSS activities (Miller and Cripps 2013) and no lethal or sub-lethal effects on fish were experienced nor any significant decreases in the diversity and abundance of fish after the seismic survey, compared with the long-term temporal trend before the survey.

As the Regia MSS will only occur during a limited period in Australia waters (maximum 60 days acquisition), potential behavioural impacts to individual Australian Sea Lions will not impact on the recovery of the population. Population impacts to prey species for the Australian Sea Lion are also not predicted.

3.3.3 Recovery Potential

Slow recovery of populations due to the extreme philopatry of females and limited dispersal of males between breeding colonies make Australian Sea Lions vulnerable to anthropogenic threats. The removal of only a few individuals annually may increase the likelihood of decline and potentially lead to the extinction of some of the smaller colonies (DSEWPaCa 2013b).

Based on the magnitude of effect from the Regia MSS to Australian Sea Lions which is limited to behavioural avoidance for the duration of the activity (maximum 60 days acquisition), no long-term disturbance that may affect the recovery of the species are predicted.

3.3.4 Conservation Status

The Australian Sea Lion is listed as endangered under the EPBC Act which was based on declining population trends, the life history characteristics of the species and the fact that the species was still under pressure from some sectors of the Australian commercial and recreational fishing industries at the time of listing. The Australian Sea Lion population underwent a massive decline in numbers caused by seal harvesting (DSEWPaC 2013).

The Australian Sea Lion is the only endemic, and least abundant, pinniped that breeds in Australia (DSEWPaC 2013). Breeding colonies for the Australian Sea Lion are found only in South Australian and Western Australian waters; however, the species is known to forage in Commonwealth waters adjacent to these states. The population can be broadly separated into three main metapopulations (Goldsworthy et al. 2009):

- one in SA accounting for ~84% of pup production
- one on the south coast of WA accounting for ~10% of pup production
- one on the west coast of WA accounting for ~6% of pup production.

The Australian Sea Lion uses a variety of shoreline types but prefer the more sheltered side of islands and typically avoid rocky exposed coasts (Shaughnessy 1999).

CGG has shown in the impact and risk analysis documents that regulatory requirements relevant to the Regia MSS and Australian Sea Lions will be met. Relevantly, the Recovery Plan for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaC 2013) has significant weight in CGG's assessment due to the involvement of Commonwealth and State regulatory agencies, threatened species managers, and scientific experts in the development of the recovery plan. As such, recommended actions from the recovery plan relevant to the Regia MSS have been implemented as detailed in Section 3.3.5 Mitigation Effectiveness.

3.3.5 Mitigation Effectiveness

Mitigation of the Regia MSS effects can be best implemented with regards to Australian Sea Lions by limiting the spatial boundaries of the survey to avoid the sound source being discharged within 11.8 km of Lady Percy Julia Island / Deen Maar. This distance is the furthest distance to the sound effect criteria for pinnipeds (seals and sea lions). This criterion was used as Deen Maar is the largest Australian Fur Seal breeding colony in Australia with and the Australian Sea Lion may occur within the area.

The Issues Paper for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaCa 2013a) and Recovery Plan for the Australian Sea Lion (*Neophoca cinerea*) (DSEWPaCa 2013b) lists noise as a secondary threat to the Australian Sea Lion. However, neither publication provides practical measures on the interaction between offshore seismic exploration and the Australian Sea Lion.

CGG has assessed potential cumulative noise impacts (Appendix F1) of other activities within the Otway Basin and identified additional mitigations to ensure cumulative noise impacts are within acceptable levels.

Assessment of the Regia MSS activities are consistent with the principles of ESD (Appendix F4).

3.4 Little Penguin (*Eudyptula minor*)

3.4.1 Species-Specific Sensitivity

Little penguins are found only in Australia and New Zealand where they are widely distributed along the coastlines of New Zealand and along the southern half of Australia. While the majority of little penguin colonies are located on islands - often cohabiting with other seabird species such as shearwaters and petrels – there are multiple colonies to be found on the mainland and this is the case

along the Otway Coast where up to seven colonies have previously been identified (Norman et al. 2017)(see Figure F3-2 below).

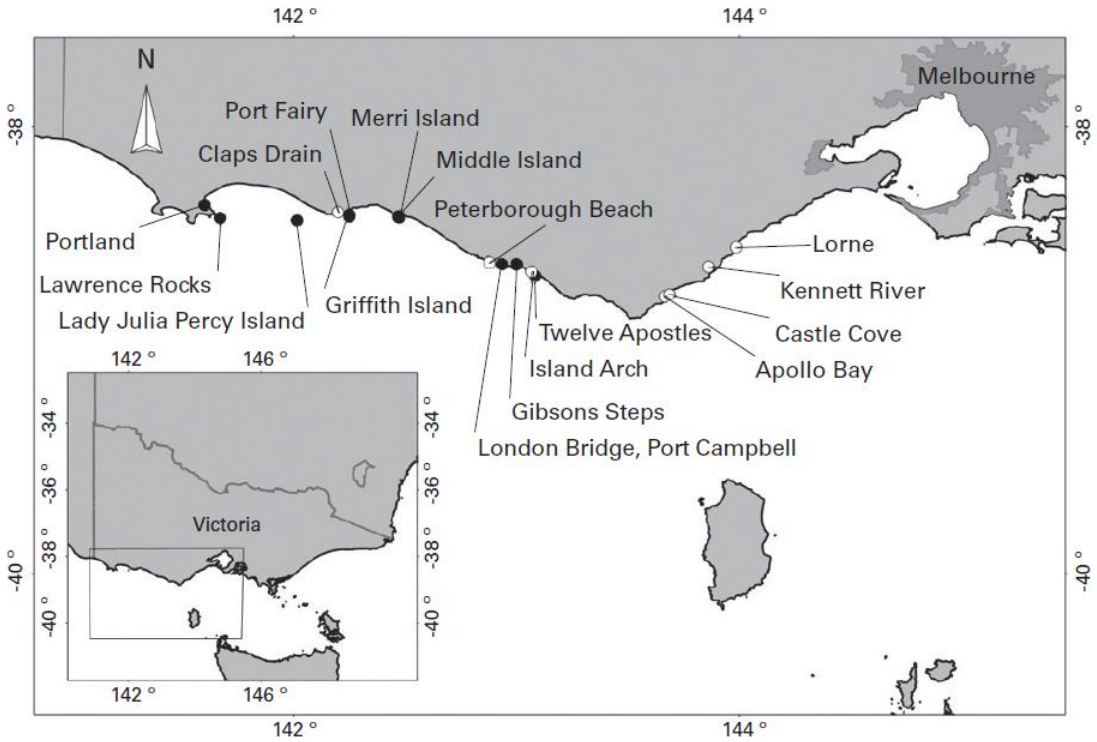

Figure F3-2 - Locations of past and present breeding sites across Western Victoria (from Norman et al 2017). Past or present breeding sites shown as ●, other sites as ○.

Mainland colonies are subject to large changes in the number of breeding animals which has been principally attributed to predation from foxes, dogs and cats (Norman et al. 2017). Most mainland colonies in New Zealand and Australia are in decline because of such impacts, while island colonies are faring much better. Food limitation has been seen previously with the collapse of the Anchovy population across southern Australia in the mid 1990's (Dann et al. 2000) however stocks of Anchovy and Sardines are currently considered healthy and not limiting (Grammer, Bailleul and Ivey, 2023). Philip Island remains the epicentre of the little penguin population in the region with current estimates of ~32,000 individuals (Philip Island Nature Parks; https://www.penguins.org.au/about/). Compare this with estimates of 7 individuals for Middle Island (` 2020-21; reports from 2021/22 and 2022/23 did not provide population estimates), 317 active burrows on Lady Julia Percy Island in 2000 (Dann et al. 2004) and 70 nests at London Bridge in 2012/13 (Berlincourt and Arnould, 2014)[2].

Norman et al (2017) updated estimates to 300 burrows in 1981 at Gibson Steps. There was a small colony in Portland located in clay cliffs on Henty Beach, however this colony decreased due to predation from dogs (Norman et al 2017). There were small colonies located at Lawrence Rocks (109 burrows, Harris and Norman (1981)), and Merri Rocks (5 burrows Dann and Norman 2006)), however they cannot be used to define current colony existence and/or size. It is understood the colony located at Griffiths Island has disappeared in recent times as a result of fox predation (Dann and Norman, 2006). CGG has contacted several government and local bodies but could not obtain more recent population estimates for these colonies.
Little penguins are resident central-place foragers that remain tied to their colony throughout the year, not just in the breeding season. They visit the colony to moult, breed and rest. Most little penguin colonies are located on islands where terrestrial predators are usually absent. It is these islands,

[2] These counts represent the most recent numbers we could find from the literature.

together with the food resources around them that limit and determine the distribution of colonies, population size of colonies and foraging ranges of penguins (Wiebkin 2012). Little penguins can store prey, which gives them the flexibility to forage for the entire day before returning to their chicks at dusk. Diet studies indicate that they are generalist predators that target whichever small schooling prey are abundant near their colony (Klomp and Wooller, 1988; Montague and Cullen, 1988; Gales and Pemberton, 1990; Cullen, Montague and Hull, 1991; Chiaradia, Costalunga and Kerry, 2003; Eberle, 2003). There is large variability in diet amongst colonies and even between years at the same colony. They feed mainly on clupeids, such as anchovy and sardines, when feeding chicks, but they may also feed on krill and several species of cephalopods at all stages of breeding (https://datazone.birdlife.org/species/factsheet/little-penguin-eudyptula-minor/text).

Studies into daily feeding range limits for nesting penguins have found forays out to 30+ km however the vast majority of feeding during this period is occurring within 15-20 km of their nesting sites and this has been confirmed across multiple studies from multiple locations (e.g. Montague and Cullen, 1988; Hoskins et al. 2008; Berlincourt and Arnould, 2014; Pelletier et al. 2014; Phillips et al. 2019, 2022). Feeding dynamics can be very different between locations and is correlated with prey abundance and distribution patterns. Feeding range limits can also change outside nesting season. When adults no longer need to return to the nest each day, they can venture out over 100km from the colony to feed. As has been demonstrated with references throughout the EP, the Otway region is well supplied with sardines and squid, with quality of food resources correlated with nearness to upwelling areas (Norman et al. 2017).

Because penguins feed on mobile prey species such as fish, squid and krill they must be able to regularly expend considerable searching effort and flexibility in foraging behaviour (Chiaradia et al 2007). Tagging studies conducted over three breeding seasons have revealed that little penguins are flexible in their foraging behavior and can adjust their activity budgets in relation to breeding stage and local environmental conditions (Berlincourt and Arnould, 2015). Little penguins tagged at London Bridge decreased their foraging efforts during periods of rough sea states and increases in wave heights, The authors suggested two potential reasons for this: high sea states and swells may increase foraging efforts of penguins or rough sea states may modify prey behavior, alternating the penguins ability to find prey (Berlincourt and Arnould, 2015). This study did note that although little penguins at London Bridge would have increased their foraging efforts, individuals at London Bridge did not vary in their body condition between breeding seasons. This suggests that individuals breeding at London Bridge may have more scope for increasing their foraging effort to compensate for reductions in prey availability. During the chick guard stage, close to their colony Little penguins at London Bridge mainly foraged at hotspots primarily located south-west of the colony. The maximum foraging distance during the chick guard stage was 16.9km (Berlincourt and Arnould, 2015). During the post guard stage, core foraging areas were located up to 15 km from the colony to south-west and south south-west, and in some instances, it was also very close to the shore. Maximum foraging distances in the post guard stage for the colony at London Bridge ranged from 12.5km to 25.9km (Berlincourt and Arnould, 2015).

A subsequent tagging study conducted on breeding colonies at Gabo Island and London Bridge confirmed little penguins are shallow divers and inshore foragers at these study sites (Camprasse et al. 2017). This study found a lack of short-term consistency in bearings to maximum distance, indicating that over subsequent days, little penguins foraged in different locations within their home range. These findings confirm that little penguins are behaviourally highly plastic (Camprasse et al. 2017). The study also found individual consistency in foraging metrics was only present over subsequent foraging trips, with no consistency detected for longer timescales. This suggests that little penguins are adapted to feed on prey that is temporally unpredictable on timescales longer than multiple consecutive days. This study concluded, although little penguins have a limited foraging range during their breeding season, foraging behaviour and its consistency varied extensively across sites, years, breeding stages and clutches, showing that little penguins are highly plastic and have high flexibility in foraging behaviour (Camprasse et al. 2017).

Egg-laying and chick raising covers the period from August to February which is the most critical time for obtaining sufficient food to sustain developing chicks (see Figure F3-3 below).

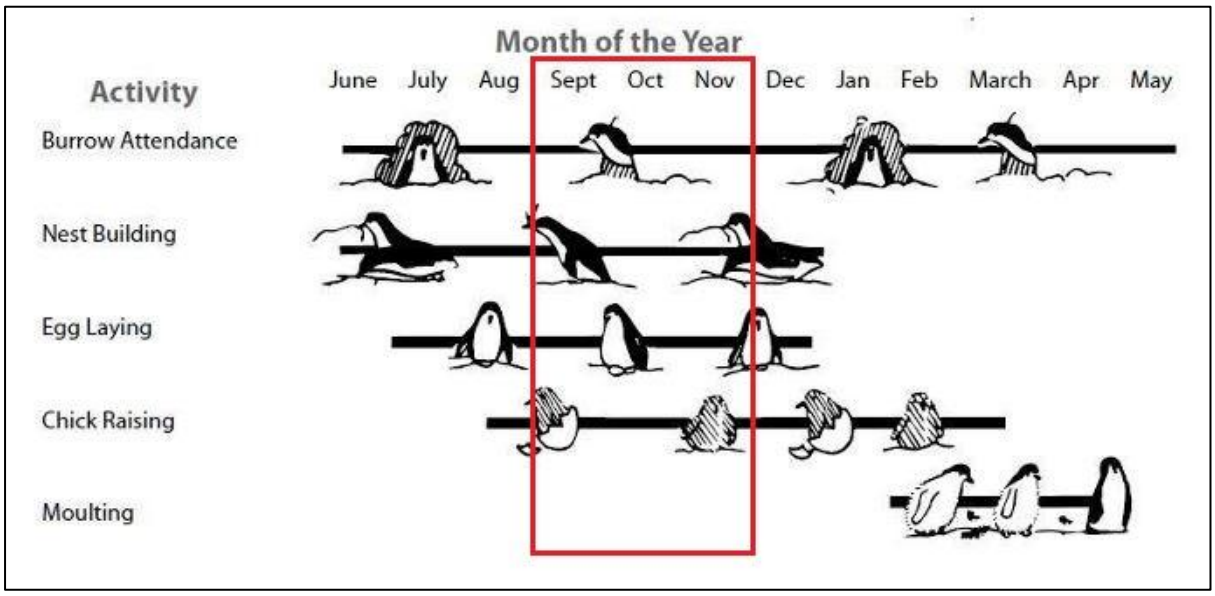

Figure F3-3 - Schematic of reproductive cycle in little penguins at Philip Island (from https://penguins.org.au/conservation/education/nature-notes/little-penguins/).

***** *Red box highlights the Regia MSS windows.*

During consultation with relevant persons, it was noted that as referenced by the Middle Island Project (Event ID 6412) there were instances of breeding cycles beginning as early as June.

There have been no studies looking at seismic effects on little penguins specifically, so we have looked for seismic studies on other penguin species. A study by Pichegru et al. (2017) investigated the behavioural response of endangered African penguins (*Spheniscus demersus*) before, during and after a seismic survey conducted within 100 km of their breeding colony in South Africa, using a multi-year GPS tracking dataset. They found penguins foraging within 100 km of the active seismic operations showed a change of foraging direction during seismic periods, increasing their distance between their feeding area and the location of the seismic vessel. While the avoidance behaviour observed in this study was unable to be definitively attributed it was most likely to have been due to penguins responding directly to the noise. Small-scale acoustic fish surveys assessing distribution and abundance of small pelagic fish in Algoa Bay around both penguin colonies did not however, show a significant change in distribution and/or abundance of small pelagic fish in the region in March 2013 compared to a few months prior to or after the seismic operations. Moreover, further monitoring as part of this study highlighted that the African penguins quickly reverted to normal foraging behaviour after cessation of seismic activities, indicating a relatively short-term influence of seismic activity on these birds' behaviour and/or that of their prey.

While no seismic studies exist for little penguins, recent research has modelled sound reception and hearing in little penguins through anatomical analysis of the head structures of deceased individual penguins (Wei and Erbe, 2024). They predicted the hearing capabilities of little penguins across a broad frequency range (100 Hz – 10kHz) (see Figure F3-4 below).

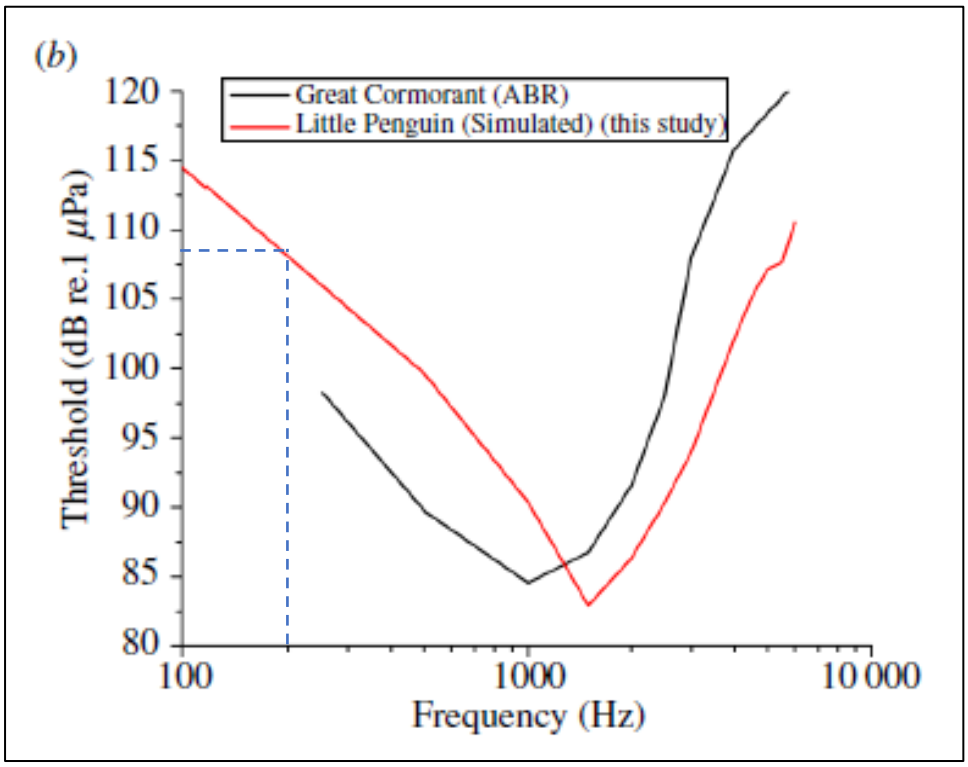

Figure F3-4: Predicted underwater audiogram of the Little Penguin (from Wei & Erbe 2024). Overlaid dashed lines represent the hearing threshold relative to the expected frequency level of the Regia MSS.

Sound modelling undertaken for the Regia MSS used 200kHz frequency for the MSS and extrapolating this from Figure F3-4 indicates a hearing threshold of ~107-112 dB re.1 µPa. Wei & Erbe (2024) indicate that humans have strong behavioural responses at 50dB above thresholds while for whales it is as high as 100dB above threshold hearing levels. Using this range as a guide and noting that little penguin hearing is most sensitive in the 1000-2000 Hz range we can extrapolate to a potential SEL TSS threshold of 170 dB re.1 µPa and this is the threshold level modelled for impacts by SLR. It remains the case that more research is needed into penguins and sound however it is reassuring to see that the modelled thresholds are in line with current research. With behavioural effects, Sorensen et al. (2020) found a response by Gentoo Penguins at 120 dB re.1µPa but this appears too low for Little Penguins given it is only 5dB above their calculated hearing threshold. It must also be highlighted that Sorensen et al. (2020) obtained their outcomes from penguins enclosed in a pool which is not reflective of normal conditions. Testing of seismic effects through caging of subjects remains a significant weakness of current experimental approaches and limits extrapolation of effects to real-life applications.

3.4.2 Magnitude of Effect

The limited science around Penguin responses to seismic surveys indicates they respond to the presence of active seismic by moving away from the area. The same science also indicates they return to previous areas once seismic moves away. The most recent study examining hearing thresholds based on skull morphology (Wei and Erbe, 2024) indicates a TTS hearing threshold in the region of 180 dB re. 1µPa is appropriate for understanding thresholds distances (i.e. an additive on top of the calculated minimum hearing threshold of ~115 dB re. 1µPa at 200Hz frequency). At this level penguins would have to be within 600m of the seismic source for 24 hrs to sustain temporary damage. Given the limited time that seismic will be active within the potential feeding halos of Little Penguins, the intermittent timing of seismic in those areas and the extensive nearshore feeding grounds available to Little Penguins we expect the magnitude of any effects to be small and temporary.

If the seismic survey occurs in the chick rearing stage (September to November), it is understood little penguins will be provisioning for chicks and foraging close to their colonies. CGG acknowledges some penguins may be behaviourally impacted and may have to extend their foraging times . However, there have been numerous studies on the foraging flexibility exhibited by little penguins and increasing foraging effort does not lead to impacts to the fitness and survival of penguins, CGG anticipates any potential impacts to little penguins during the chick provisioning stage to be temporary, localised and recoverable.

The Regia MSS is expected to collect seismic data for 60 days within a 90-day timeline, which provides flexibility to accommodate stoppages due to scheduled and/or unscheduled events. Such events may include adverse weather conditions or mitigation measures as part of the EP (see Appendix A2 for Description of Activity).

A seismic survey acquires data by running parallel sail lines towing streamers back and forth within the defined Activity Planning Area. The survey can be carried out in sections and the sail lines acquired in any order. Acquisition is a continuously moving process hence seismic sound levels are not static and will increase when moving to a point in space and then decrease as it moves away. This is strictly true for sessile animals but not for mobile ones. Mobile animals such as penguins can actively respond to seismic sources and will move away from the activity, as has been noted by researchers (Pichegru et al. 2017).

In response to concerns raised by a relevant person, CGG sought to conduct some analysis on how much of an overlap the Regia MSS has with little penguin foraging areas. By overlaying the proposed sail line plan with 20km core feeding halos centred around nominated penguin colonies (from literature and consultation) we can calculate the amount of time and proportion of core foraging habitat that the Regia MSS will intersect with. Of the 5 main colonies identified through community consultation only the colony on Deen Mar will intersect with active sail lines within the 20km feeding halo.

The area within the halo that will be traversed with active seismic is ~32km^2 which is ~3% of the total feeding halo area of ~1006km^2. There will be 11 lines that will be actively acquiring seismic within the halo for a portion of their path. However, because the acquisition process involves running parallel lines extending the length of the total acquisition area, the time each relevant line spends inside the Deen Maar feeding halo is very short and is not cumulative (see Figure F3-5 and Table F3- 2below).

Figure F3-5- Map illustrating core penguin foraging areas for all identified colonies (in red) relative to the location of the Regia MSS survey lines (green).

Table F3- 2: Proportion of time and distance that survey lines will be acquiring within the 20km Deen Mar core feeding halo. Line #'s corresponds to distance from shore, i.e. line 1 is closest to shore. The survey does not actually start at line #1 so number position in the table reflects the likely survey path to be taken.

Line #	High Power (km)	Time Acquiring (min@9.3kmh^{-1})	Return Time (hrs)
2	4.2	27	31
3	3.9	25	48
1	3.6	23	326
11	1.9	12	25
10	4.0	26	25
9	5.8	37	25
8	6.7	43	24
7	5.8	37	24
6	5.0	32	24
5	4.4	28	24
4	4.2	27	

For example, the first entry into the halo will be running at full power for ~4.2km (see Line # 2 in Table F3- 2) and will leave the halo after 27 min at an average speed of 4-6 knots. The second entry into the halo will not occur for another 31 hours. It will be running at full power for ~3.9 km (Line # 3) and will exit the halo after 25 min. The third entry into the halo will not occur for another 48 hours. It will be running at full power for ~3.6 km and will leave the halo after 23 min. The 4th entry will not occur for another 13.5 days as the MSS is operating further offshore. This process will continue like this for the other 8 entries into the halo. The very short time inside the halo followed by extended time away between each seismic line drastically reduces the likelihood of any impacts whether singular or cumulative in nature. Total time acquiring seismic in the Deen Mar feeding halo is only ~5.3 hours spread over 3.5 weeks.

With significant overlap of halos around each colony we suggest that all the habitat running parallel to the coast out to 20km will provide suitable feeding opportunities. This equates to ~ 3370 km2 of suitable area for fishing of which the seismic area constitutes < 1 %. CGG acknowledges some little penguins may be behaviourally impacted and displaced from their foraging areas which may impact the fitness of an individual. There have been multiple studies examining little penguin foraging behaviours. Camperasse et al (2017) examined tagged breeding little penguins at Gabo Island and London Bridge. This study revealed an absence of short-term consistency in bearings to the maximum distance, suggesting that over the following days, little penguins foraged in various locations within their home range. This confirms that little penguins exhibit high plasticity and flexibility in their foraging behaviours. The study also found differences in foraging behaviour across space and time arose from differences in the local distribution and abundance of Clupeiformes, thought to be associated with different environmental conditions, rather than from differences in prey types. Berlincourt and Arnould (2015) noted rough sea conditions caused little penguins at London Bridge to increase their foraging effort. These individuals did not vary in body condition suggesting breeding individuals at London Bridge may have a greater ability to increase their foraging effort in response to declines in prey availability. Little penguins have also been documented group foraging to increase foraging success (Sutton et al. 2015). Given that Little Penguins exhibit high flexible foraging behaviours and tend to prey on species that is temporally unpredictable, if little penguins are temporarily displace from foraging areas impacts to penguin fitness and survival are not expected.

A dedicated study of little penguin diving behaviours during nesting season and across their whole distribution range, clearly shows that they prefer to constrain their diving to shallow water (Chiaradia et al 2007). Across 4 widely separated colonies they found almost all Little Penguin dives were less than 50m deep with the overwhelming majority less than 30m deep (Figure F3- 6). When the bathymetry of the Otway coastline is examined, it can be seen that the 50m contour line lies within 15km of the coast and the 30m contour line lies within 5km of the coast.

While studies into daily feeding range limits for nesting penguins have found forays out to 30+ km the vast majority of feeding during this period is occurring within 15-20 km of their nesting sites and this has been confirmed across multiple studies from multiple locations (e.g. Montague and Cullen, 1988; Hoskins et al. 2008; Berlincourt and Arnould, 2014; Pelletier et al. 2014; Phillips et al. 2019, 2022).

The study by Chiaradia et al (2007) demonstrates that all chick-rearing Little Penguins face similar diving and dispersal limitations across their distribution range. These dispersal limitations are heavily influenced by the water depth and geographical features of the foraging zones. When applied to the Otway coast region encompassing known penguin colonies it can be seen that the majority of foraging will be occurring within 15km of the coast with less occasional forays out to 20km.

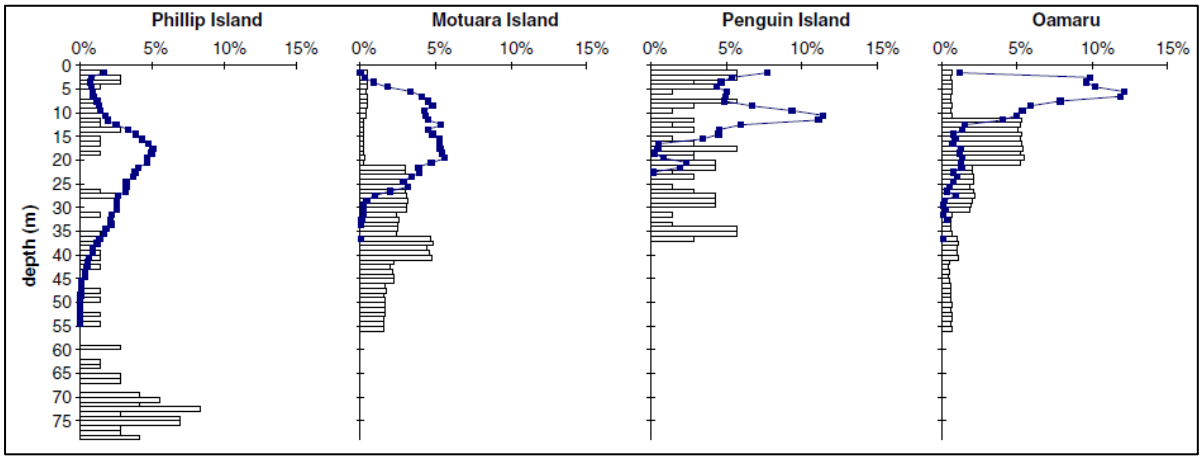

Figure F3- 6 - The proportion of foraging area depth (bathymetry, clear bars) and diving depths (dark squares and lines) per 1 m interval for Little Penguins in Australia (Phillip Island and Penguin Island) and New Zealand (Motuara Island and Oamaru). From Chiaradia et 2007)

Consequently, we assess the likelihood of any significant impact to food resources and feeding opportunities for little penguin colonies as low. CGG believe any behavioural impacts to little penguins are of an acceptable level as any knock-on effects from the survey will not impact the foraging success penguins, their ability to rear their chicks and their overall fitness.

3.4.3 Recovery Potential

While there is no research into seismic effects on little penguins there is enough parallel/ complementary research to make an informed assessment of the scale of any impacts to little penguin colonies from seismic activity. Coastal colonies in the region have undergone major fluctuations in abundance over the past 30 years which reflects the influence of a multitude of factors. Mainland colonies have faired poorly in most locations as they have succumbed to predation from feral animals and nearness to human populations. Multiple mass mortality events in the 1990's of their preferred food source, the Australian Anchovy, also caused substantial declines in colony sizes of little penguins across the south coast. Current anchovy stocks are in good health however and this species is commonly distributed along the shelf. There is also a very large coastal foraging area available so food limitation will not be an issue throughout the duration of the proposed Regia MSS. While behavioural responses can be expected, previous research has shown penguin species exposed to seismic will quickly revert to normal foraging behaviour after cessation of seismic activities, indicating a relatively short-term influence of seismic activity (Pichegru et al. 2017). Additionally, the specific

source used in the Pichegru et al. (2017) study had a total volume of 4,230 in^3 compared to the 2,630 in^3 proposed for the Regia MSS hence the size of the seismic source is ~45% less here.

3.4.4 Conservation Status

There is no conservation status assigned to little penguins (*Eudyptula minor*) as noted on the Species Profile and Threats Database (http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=1085). They are considered a species of Least Concern under the IUCN Red List, with the last assessment undertaken in September 2020. The global population estimate at this time was 469,760 animals (https://www.iucnredlist.org/species/22697805/202126091)

3.4.5 Mitigation Effectiveness

There are multiple processes that will contribute to mitigation of any effects of seismic surveys on Little Penguins. They include, "soft start" procedures and timing the survey to avoid the most sensitive parts of their lifecycle e.g. summer months. The survey program avoids the core feeding areas with the exception of limited time within the outer edge of the Deen Mar zone. Additionally, the seismic within this area is being undertaken in short sections separated by at least 24 hrs between successive survey lines. There are also mitigation measures for feeding birds which will indirectly support mitigation for Little Penguins, namely reducing to low power within 500m of feeding birds.

3.5 Southern Rock Lobster (*Jasus edwardsii*)

3.5.1 Species-Specific Sensitivity

Substantial research on the interaction between seismic surveys and the Southern Rock Lobster (*Jasus edwardsii)* has confirmed that while lethal effects are not seen, sub-lethal effects are likely to impact all stages of their life cycle that are within ~700m of a seismic system when it is firing (see Appendix B8 and references therein). In adults/juveniles, these effects are principally manifest as an impaired righting reflex and/or delayed progression through the moulting cycle. However, due to seismic signal attenuation over distance, its interaction with variability in individual vulnerability, habitat complexity, and time spent within proximity to the seismic source points, these effects are neither ubiquitous nor consistent. The larval stage of *J. edwardsii* is long (up to 2 years) and subject to persistent and high natural mortality during this time. Any effects on individual animals will not be measurable against the natural mortality rates that exist, and which operate over far greater spatial and temporal scales than the intended MSS schedule.

A recent experimental study used cages to assess seismic effects on Western Rock Lobster (*Panulirus cygnus*) in shallow reef habitat adjacent to Dongera on the central WA coast (de Lestang et al. 2024). Juvenile lobsters were confined to cages and subject to seismic pulses from very close quarters (2-5m metres) after which they were released. A recapture program was followed to determine what effects seismic might have on catches. Results indicated a short-term reduction in catchability for the first month of the recapture program which subsequently disappeared. The recapture rates after the first month were very low (e.g. max of 1-3 animals per treatment) and not appropriate to draw any further conclusions from, as highlighted by the breadth of the 95% CI's associated with the analysis (6-68%). Treatment was not reflective of normal seismic activity nor normal activity and domiciles of WRL. Natural mortality rates of WRL are also very high with density-dependent mortality between the time that pueruli settle on inshore reefs and the time they move offshore as juveniles to recruit to the fishery estimated to be as high as 80–98% during the first year after settlement (Phillips et al 2003).

3.5.2 Magnitude of Effect

Individual adult and juvenile animals within proximity to a seismic system when firing is occurring will likely be impacted in a non-lethal way as described above and in Appendix E4. The effects will vary across individuals and reduce with distance from source of the disturbance.

Puerulus settle into their preferred benthic habitat from June – September each year so potential seismic effects on the most vulnerable stage of the life cycle can be drastically reduced by scheduling the MSS for outside this window. Most mortality happens in the larval stages of marine organisms that incorporate a planktonic phase in their life cycle. Estimates can vary widely however > 90% mortality is common (Morgan 1995 - Life and death in the Plankton) hence reducing or minimising impact at time of settlement will provide more powerful mitigation of any potential seismic effects.

All SRL (Southern Rock Lobster) located within the MSS operational area are considered part of a single genetic stock spread across southern Australia (Ovenden et al. 1992; Thomas & Bell 2013). The huge geographical spread of this species means that larval supply to any individual area, such as the MSS operational area, comes from many other areas and hence is not linked to the number of reproductively active animals in any one place. Research has highlighted the complex processes affecting settlement strength in SRL which indicate that environmental conditions that reduce settlement strength in one region of the fishery often increase settlement strength in other regions. A system such as this is extremely resistant to localised disturbances as it receives larvae each year from what is effectively, a 'bank' of SRL stretching across southern Australia. Output from modelling of larval supply as seen in Figure F3-7 and Figure F3-8 clearly shows the dispersal extent of larvae released from locations in Victoria and Western Australia.

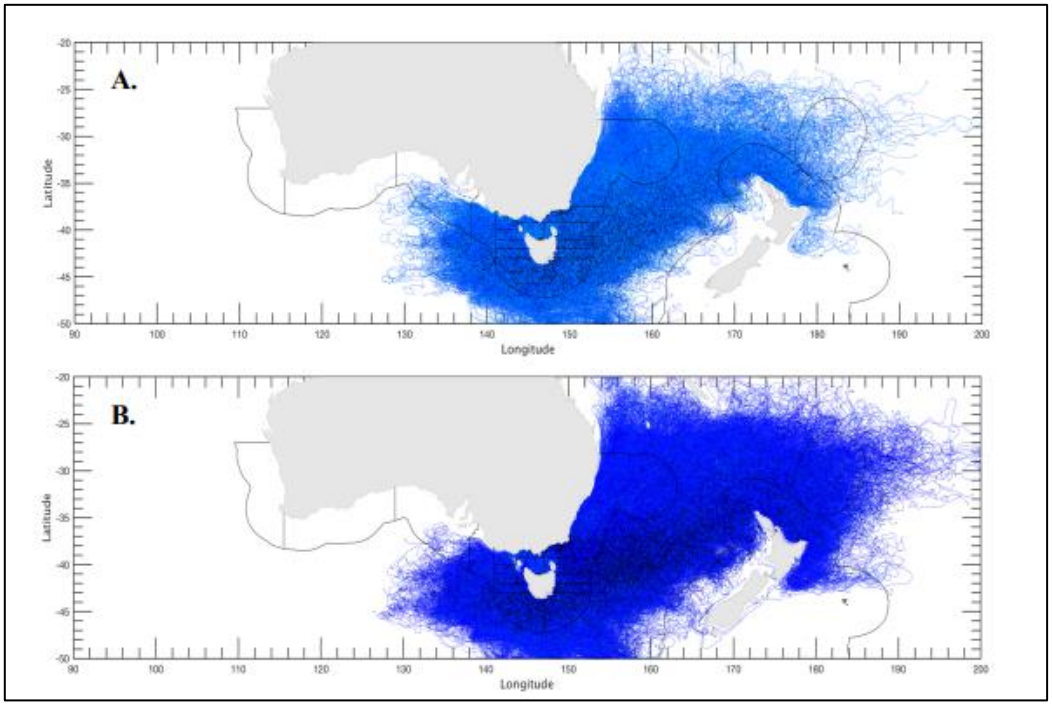

Figure F3-7 - Simulated trajectories of larvae released from Victorian fisheries: A. VIC_W fishery, B. VIC _ E fishery. The location of larvae at the end of the dispersal simulation is marked with black dots (from Vasile 2018 PhD thesis).

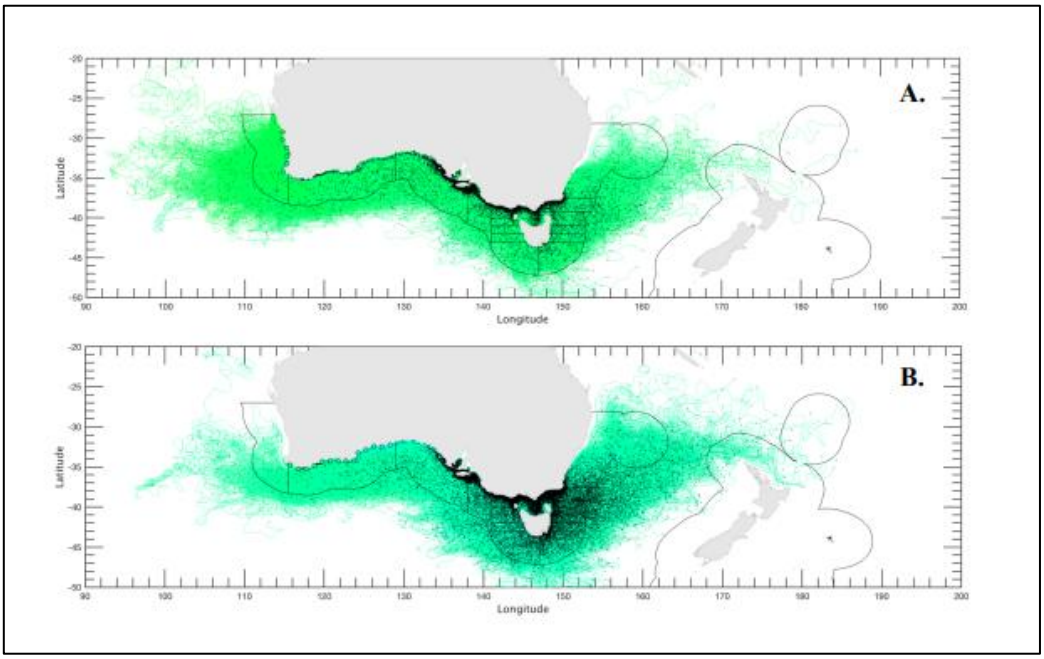

Figure F3-8- Simulated trajectories of larvae from Western Australia fisheries A. WA _ W fishery, B. WA_ S fishery. The location of the larvae at the end of the dispersal simulation is marked with black dots (from Vasile 2018 PhD thesis).

During consultations several commercial rock lobster fishers claimed there were cumulative effects from seismic surveys that were adversely affecting the Southern Rock Lobster stock. Following the first round of consultations, CGG agreed to undertake a case study on the effects of seismic activity on the Southern Rock Lobster population in the Victorian western rock lobster zone over time. Historical catch data would be used to look at the whole of the fishery over the last 20 years and determine if there was any correlation between the previous seismic surveys that have occurred in that timeframe.

CGG made an additional request from the Victorian Fisheries Authority to aggregate data over three previous seismic surveys which fishers identified as particularly damaging to their activities (Investigator in 1999; Enterprise in 2002/03; and Crowes Foot in 2016). The aggregated data was received by CGG however there were inconsistencies in the totals rendering the data unusable.

Instead, CGG obtained the records of monthly catch between 2006 and 2023 (to June) and completed an analysis of this data with respect to the following surveys:

- Astrolabe MSS
- La Bella MSS
- Enterprise MSS
- Flanagan MSS
- Crowes Foot MSS
- Schlumberger MSS
- Sequoia MSS

Both landed catch in kilograms was analysed as well as monthly catch rates. Table F3-3 and Figure F3-9 show the landed catch with the relevant surveys timing shown in the colour coded months. Table F3-4 and Figure F3-10 show the monthly catch rates for the western zone over the same period.

Table F3-3 - Monthly landed catch for western zone rock lobster 2006 to 2023 (kilograms).

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Nov	Dec

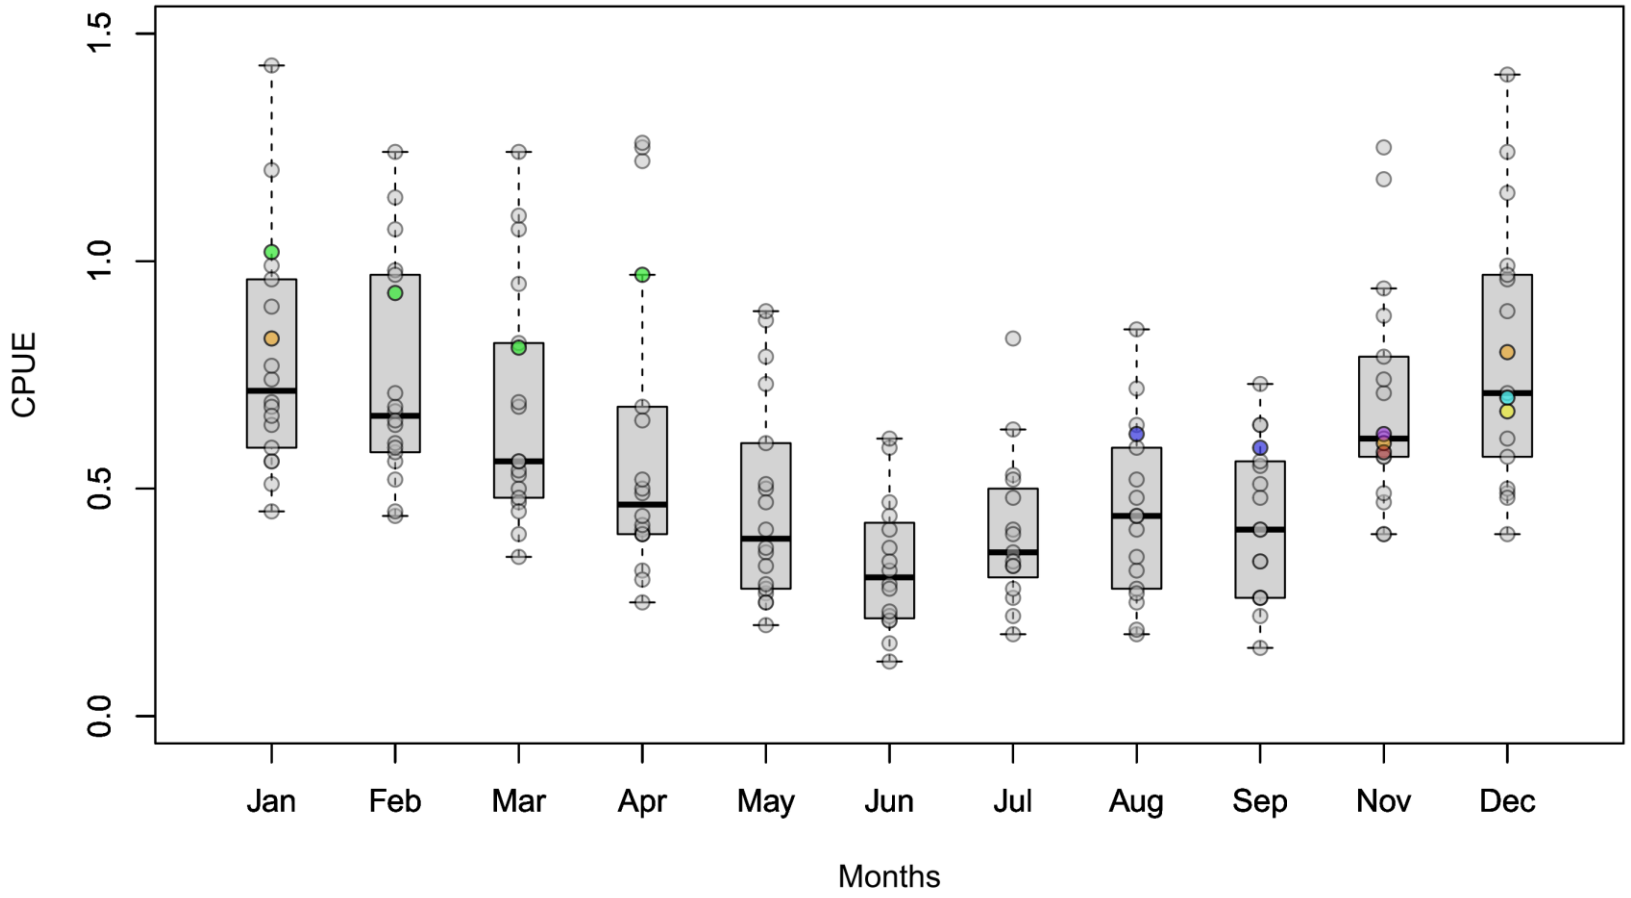

Figure F3-10 - Box plot of catch rates (CPUE) month by month with each year represented by a circle, coloured circles represent months seismic was acquired. Colour corresponds to the survey colour code in Table F3-4.

This analysis shows a general and unsurprising decline in catch in the winter months when males only may be taken, with a slight dip in September (note the fishery is closed on 16th September and opens on the 15th November). The data shows, at the whole of western zone level, the catch rates remain within normal distributions both in the month(s) of the survey and in the subsequent months, and in the subsequent years. This extends to more than 7 years post surveys, the timeframe claimed by fishers that catch rates and populations would take to recover.

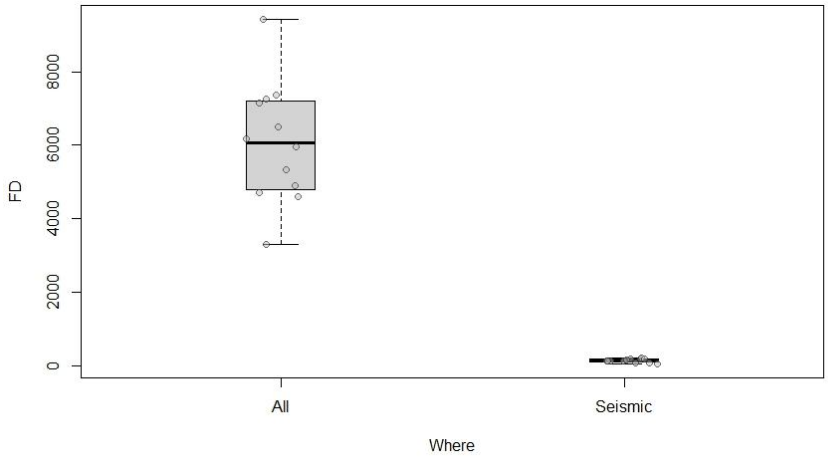
The data shows only one statistical anomaly in February 2020 in the landed catch. This is likely to be due to Covid-19 affects in Victoria and a subsequent reduction in fishing effort. The corresponding months CPUE shows that those who were able to fish did not suffer a reduction in CPUE beyond normal distribution. This data is conclusive that there are no detectable long-term effects to catch rates, and presumably the population of Southern Rock Lobster, in the western zone SRL fishery attributable to seismic surveys. Therefore, cumulative impacts to the SRL populations and the knock-on effects to fishers from sub-lethal effects are not measurable.

The MSS will be a pulse event with a timeline of 60 days within 90 days. For site attached SRL, individual animals will be exposed to high intensity seismic on a reducing exposure curve which will be defined by the closeness of the individual to the source, the depth of habitat where the individual is residing (defines the minimum distance from the seismic source), the complexity and density of the (limestone) habitat they are inhabiting and the direction and speed of the seismic survey. Hence impacts will be extremely varied and inconsistent. There will likely be a reduction in overall fitness of the population of animals exposed to the MSS which may influence adult mortality for a period, but the scale of any potential impact will be subsumed into the far larger natural and fishing mortality schedules that already exist.

Impacts to larval SRL will be confined to those animals in the plankton present in the area at the time the array is working. Plankton is highly variable in both space and time (Robinson et al 2021) which favours affected larvae being subsumed into a larger planktonic assemblage containing larvae not exposed to the MSS. The nett effect will be any affected larvae will be spread out within a greater pool of non-affected larvae, mitigating the probability of significant localised effects.

The Bureau's (BOM) long-range forecasts indicate warmer than average Sea Surface Temperatures (**SST**s) (up to around 2 °C warmer than average) off the coast of south-east Australia will likely continue through the southern hemisphere summer 2023–24 (http://www.bom.gov.au/climate/enso/). Such large-scale climate changes will exert a much greater influence on population dynamics than the Regia MSS given they can operate at the scale of the entire population. Warming temperatures attributed to climate change have already been shown to increase growth of animals in temperate waters and lead to larger-size-at-maturity (McLeay et al 2019).

Commercial fishing statistics from the VFA 20/21 season Stock Assessment Report highlight that CPUE has almost tripled from 2009/10. While some of these gains have come from fleet modernisation and associated efficiencies, standardised catches have continued to increase, reflecting a stable and relatively healthy fishery. Commercial fishing is a press disturbance and exerts a much greater and clearly quantifiable effect on populations than a pulse disturbance over a defined space. Despite this, the assessment concluded the fishery is stable with increasing recruitment over the past few years from a long-term trend of lower-than-average recruitment. Additionally, within the MSS operational area fishing effort is extremely low with only ~2% of total fishing days occurring within this area over the past 12 years (see Figure F3-11).



** Box encompasses 50% of the data points. Black line indicates median value. Whiskers encompass full range of values.*

Figure F3-11 - Comparison of the number of fishing days (FD) undertaken within all designated fishing blocks across Victoria (All) with number of fishing days undertaken within those blocks encompassed by the proposed MSS (Seismic). Individual data points are yearly.

While seismic operations have been shown to cause injury to SRL at the level of individuals there is no evidence that supports population level effects. A large part of this conclusion is based on the research base that exists for SRL and which clearly shows the size of the 'population' of SRL is very large and well connected. The MSS area is a very small component of this system and the SRL population within is resilient because of this.

3.5.3 `Recovery Potential

Research has indicated that some of the physical and chemical changes seen in SRL exposed to seismic may be permanent. For those individuals their fitness will likely be reduced and their susceptibility to predation may increase. For those animals whose exposure window is smaller there is evidence of recovery although there are no definitive time frames known.

The largest effects on SRL populations are from fishing and climate drivers such as increased water temperatures. Nevertheless, management of the fishery in the state indicates it is stable and improving over the past few years. This indicates a population that can recover even under sustained fishing pressure. Effective management underpinned by continued collection of appropriate data is key to this outcome.

3.5.4 Conservation Status

The Fisheries Research and Development Corporation (FRDC) recognises SRL *Jasus edwardsii* as a sustainable species found broadly across Southern Australia. Unlike the Western Rock Lobster in Western Australia whose habitat is a Key Ecological Feature (KEF), SRL have no elevated level of conservation protection.

3.5.5 Mitigation Effectiveness

Mitigation of MSS effects to SRL can best be implemented by limiting the spatial boundaries of the survey to minimise interaction with areas of high SLR density and fishing activity, which is predominantly located shoreward of the 40m depth contour. Additionally, timing the MSS to avoid the June-September period when peurulus are settling is also advisable. The period after release of fertilised eggs is the preferred window as this is when natural mortality is extremely high and localised seismic effects are likely to be subsumed into this mortality schedule.

3.6 Giant Crab (*Pseudocarcinus gigas*)

3.6.1 Species-Specific Sensitivity

Giant crabs are a long-lived slow growing species that inhabit soft sedimentary environments and feed on sessile or slow-moving benthic species including gastropods, asteroids, and other decapods. The species is found across all southern Australia and up into Southern NSW, generally occupying depths between 120-370m but can be found from 20-600+m. Key stages in the life history of *P. gigas* appeared to be synchronised across southern Australia suggesting that factors operating at a large scale are influencing the species' distribution and life cycle off southeast Australia (Levings 2008). These large-scale drivers are responsible for population level changes with small-scale disturbances buffered by connectivity and dispersal across large scales. Genetic studies have indicated that the species is effectively a single stock with little evidence of sub populations. This is likely due to the 3–4-month larval phase and the ability of individual adults to move up to 400km (Currie & Ward 2009).

Climate change is expected to cause a southerly shift of the austral subtropical high-pressure belt, with models predicting more upwelling-favourable winds. This would likely provide *P. gigas* with increased access to benthic food resources and their growth rate may increase in some regions (Levings & Gill 2010). This has the potential to increase productivity at the population level.

Multiple studies have looked at seismic effects on crustacean larvae amongst other taxa, and results have been mixed, with any mortality limited to very close proximity to the source. Adult crab species that have been tested have shown very little response to seismic pulses (Appendix E4 and references therein).

Based on the evidence available the sensitivity of giant crabs to the MSS is likely to be small and immeasurable relative to normal population variance. The species undergoes annual cross-shelf movements to align with favourable temperatures and feeding opportunities (see Figure F3-12 and Figure F3-13) which provides a temporal window for minimising any potential seismic effects.

Fishing for female crabs is banned between June 1st and November 15th to protect the peak timings of their reproductive cycle (see Figure F3-14). If Giant Crabs were the only receptor of concern, then potential effects from the MSS could be avoided by excluding activities over this period to align with fisheries protections already in place. However, the overlap of with female crabs is lessened because:

- The 200 m depth limitation for acquisition means only a partial overlap with depths female crabs are likely to be present.
- More than half of the period is already avoided because:
    - Two of the five-and-a-half period is already excluded due to weather limitations (July and August).
    - At least a further month of no overlap will occur because the Regia MSS cannot occur in both June and September to December.

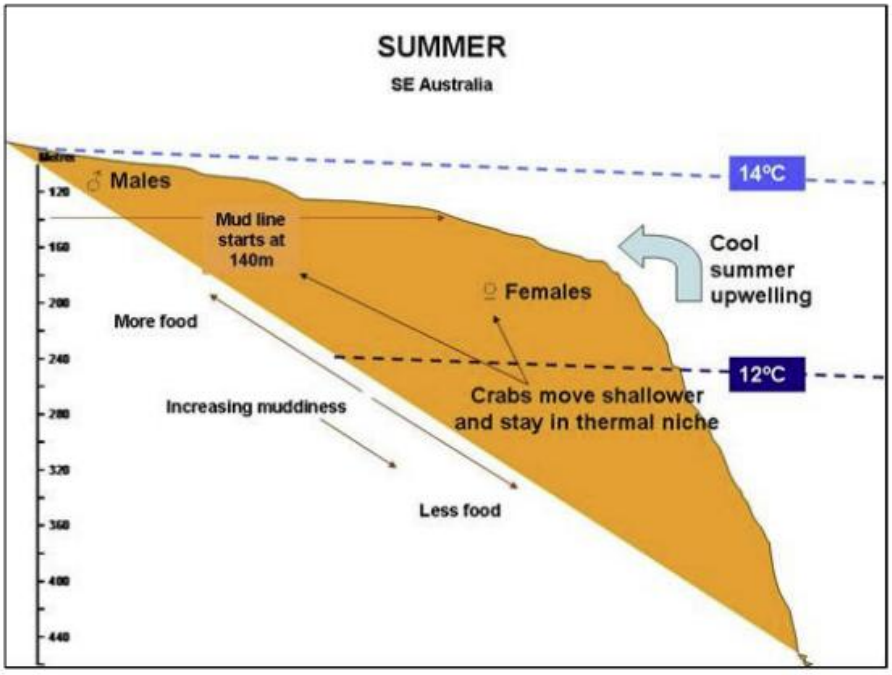


Figure F3-12 - Summer model for P. gigas off south-east Australia (Levings 2008).

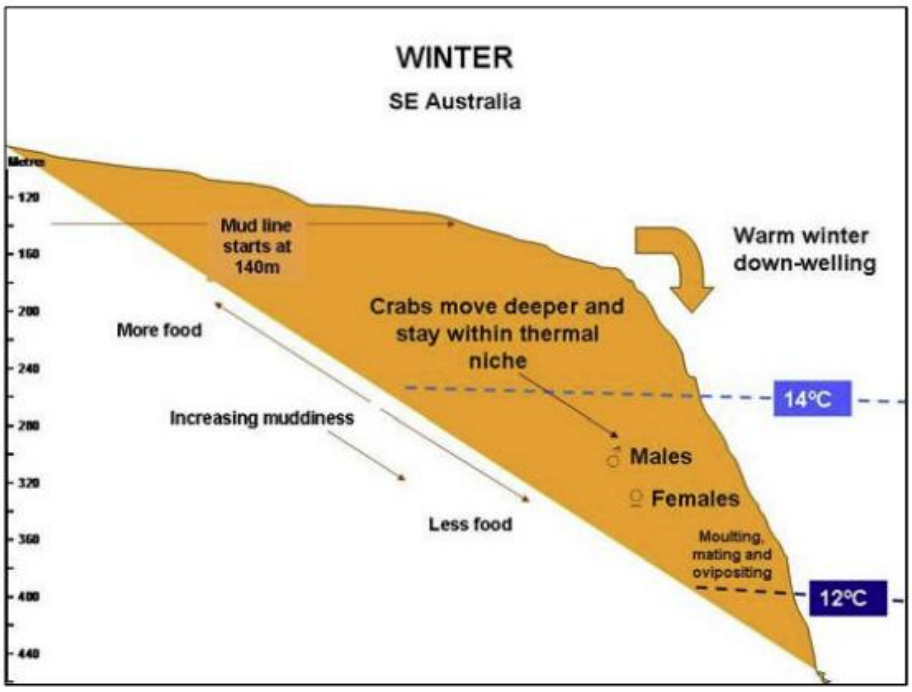

Figure F3-13 - Winter model for P. gigas off south-east Australia (Levings 2008).

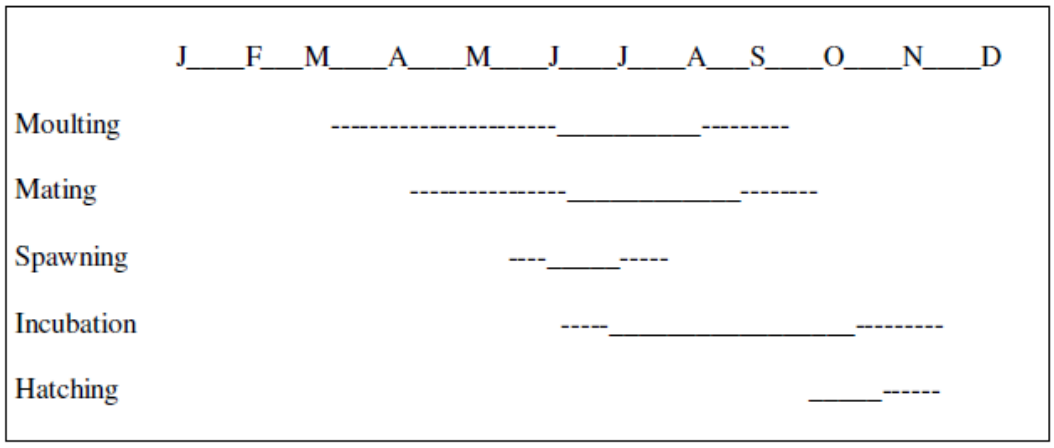

Figure F3-14 - Reproductive cycle of P. gigas based on extensive field observations. Solid lines represent peak periods, while broken lines represent temporal extent of observations (from Levings 2008).

3.6.2 Magnitude of Effect

Seismic effects on individuals have been shown to be limited to larvae within very close proximity to the discharge source.

Timing the MSS to avoid the peak period in the reproductive cycle period will mitigate any potential impacts.

Fishing days within the Regia MSS Active Source Area averaged out at 17.3 % of total fishing days from 2011-2022. However, fishing effort in the Active Source Area over recent times has shrunk to 7.5% of total fishing days from 2018-2022.

As discussed above there is no evidence to support an expectation of significant and measurable cumulative impacts to *P. gigas* because of the MSS. Large scale environmental drivers driven by a changing climate, and fishing effort, will continue to be the major influences on the population health of giant crab.

Regarding any impacts on the giant crab fishery, the targeted catch in 2021/22 of 0.95kg per 24 hour was a substantial reduction from 1.27kg/24-hour pot-lift in 2017–18 but still remained well above the limit reference point of 0.52 kg/24-hour pot-lift for the fishery (VFA 2022). Factors including the lack of fishery independent surveys, limited length frequency data, the significant decline in the number of operators targeting giant crab and a decrease in the spatial distribution of the fishery, all add to the uncertainty in the assessment of the Victorian component of the Giant Crab stock. More data is needed from the fishery to better understand the changes to catch rates and to better determine the size of the fishable stock available.

3.6.3 Recovery Potential

The population stocks of *P. gigas* have been declared sustainable across 75% of their range (WA, SA, Victoria) however the Tasmanian population is considered depleted and not sustainable at current fishing levels. Data collection remains insufficient to more accurately assess future trends (FRDC Report 2020 Giant Crab 2020 (fish.gov.au)). Fishing effort is the major anthropogenic driver of changes to populations, and it is this interaction with a changing climate that will drive population changes in the future.

3.6.4 Conservation Status

Based on the evidence presented above, the Giant Crab Fishery (Victoria) management unit is classified as a sustainable stock and there are no conservation concerns. Temperature is a primary driver of their life-history strategy and this, along with fishing effort will be the drivers of population dynamics of this species.

3.6.5 Mitigation Effectiveness

With most of the reproductive cycle occurring in the June-December period ensuring the MSS is undertaken outside this period would provide the most effective mitigation approach to minimising effects from seismic surveys.

3.7 Short-finned Eel / Kooyang (*Anguilla australis*)

3.7.1 Species-Specific Sensitivity

There are two species of freshwater eels that inhabit the southeast and east coasts of Australia, *Anguilla australis* and *A. reinhardtii* known colloquially as the short-fin and long-fin eel respectively. Only *A. australis* is relevant to the MSS because the westward edge of distribution for the long-finned eel is around Wilsons Promontory which is 300 km from the nearest edge of the MSS survey path (see Figure F3-15).

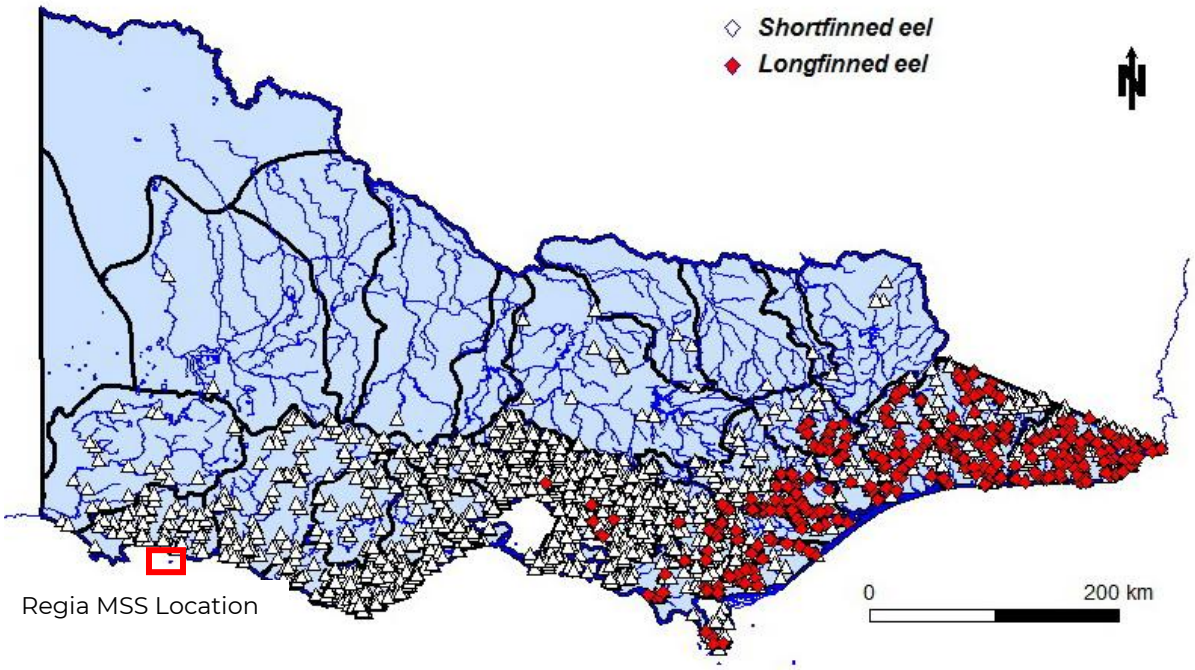

Figure F3-15 - Spatial distribution of both species of freshwater eel across Victoria (VFA Eel Fishery Management Plan) and the location of the proposed Regia MSS survey.

The short-fin eel has a complicated but spectacular life cycle. The juveniles and adults live in freshwater rivers but when reproductively mature the adults migrate many thousands of kilometres to spawning grounds in the Coral Sea (Gooley et al 1999). Once spawning has finished the adults perish and never return. The life cycle is then continued by the many trillions of larvae who attempt to make their way back to river systems over 200 plus days using prevailing currents and an evolving swimming ability. There is no homing into river systems as seen with salmon, rather larvae will randomly enter river systems they encounter. Adult migration out of the estuaries to the spawning grounds occurs from January to May while the returning glass eels stage occurs during the July-September period (Figure F3-16).

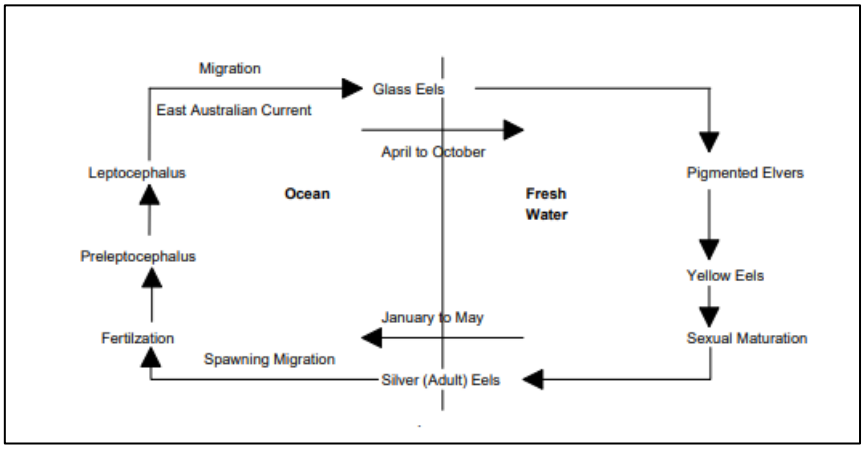

Figure F3-16 - Life cycle of Anguilla australis eels. After Gooley et al. (1999).

This life cycle predisposes this species to very large mortality rates both as larvae and as adults. Adult mortality has been estimated to be at least 30% for migrating adults (Koster et al 2021) and while there have been no direct measurements of larval mortality in eels, as a broadcast spawner it likely exceeds >95 % as could reasonably be expected from a larval life-history which encompasses 200+ days at sea and many thousands of kms of travel from spawning grounds to river systems (Figure F3-17) For example, modelling work by Bonhommeau et al. (2009) on A. anguilla indicated <0.2 % of larvae survived the trans-Atlantic migration.

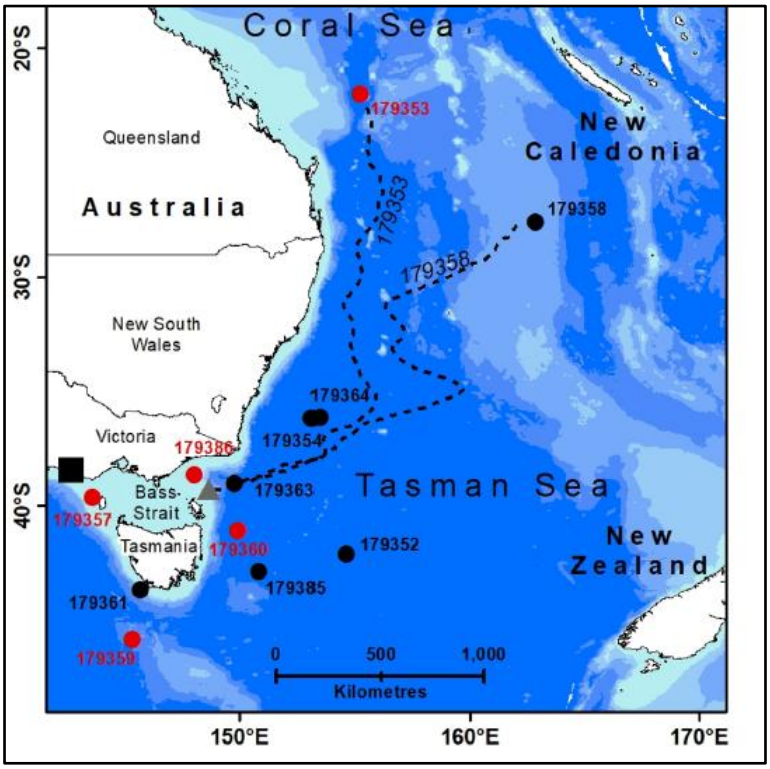

Figure F3-17 - Map indicating locations of tagged adult eels originating from Otway coast region (from Koster et al 2021)

Australasian short-finned eels are listed as 'near threatened' on the IUCN Red List of Threatened Species, with barriers to riverine movement and freshwater habitat loss identified as key threats. In addition, changes in ocean currents, primary production, and thermal regimes may affect eel migration, spawning success, and recruitment (Koster et al. 2021). These processes operate at landscape scales and are heavily influenced by long term climate trends. Changes to riverine flows

and water quality are affected not only by changing climates but also land management regimes adjacent to riverine systems.

Changes in the size of the spawning stock (i.e. adults) have been identified as the most likely cause of declining recruitment of eels (see review by Jellyman 2022) and so it is factors affecting the adult population that will have the largest effect on the population health of *A. australis*. As previously mentioned, climate related changes and modification of the landscape are affecting the carrying capacity of rivers to support populations of eels and other species. Fishing is also a major pressure on eel stocks and there has been a commercial fishery for short-finned eels across Southern Victoria since the 1950's.

Pre-migrating adults have been found to spend a lot of time in the estuaries of rivers before starting their migrations, making them more vulnerable to net fisheries than was previously thought (Crook et al. 2014). Catches reached a peak in the mid 1990's with a low in 2009, but have since stabilised around 30-80 tonnes/year (Southern Shortfin Eel 2020 (fish.gov.au)) (see Figure F3-18). The massive decline in catches from 1993 was related to the so-called millennium drought throughout the late 90's and early 2000's (van Dijk et al 2013) illustrating the powerful links between eel health and environmental conditions.

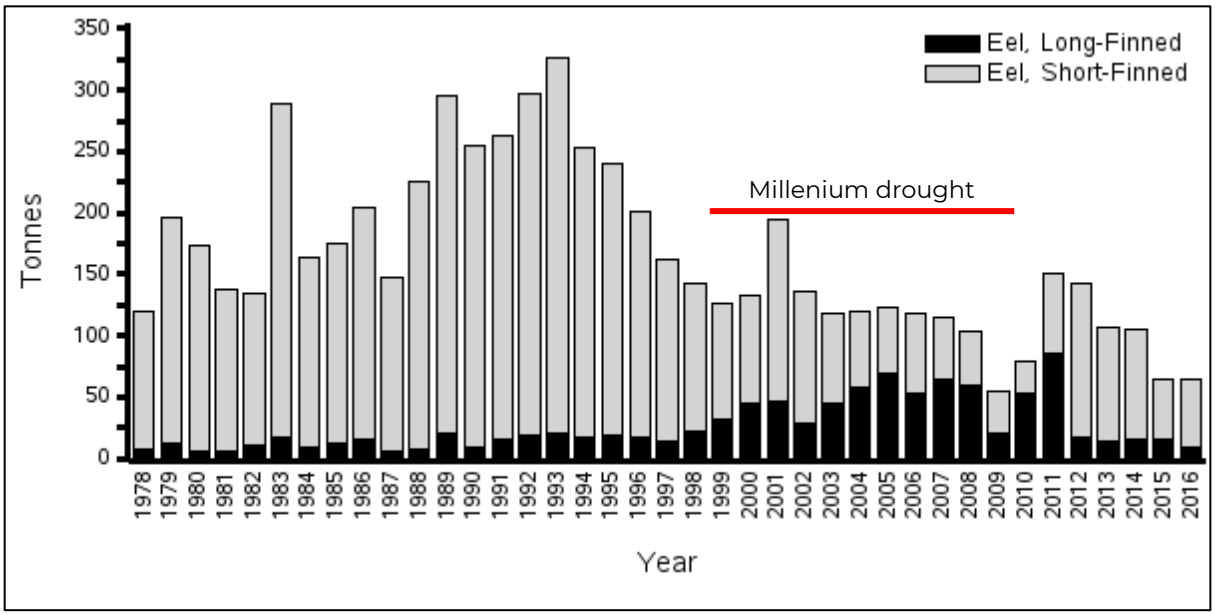

Figure F3-18 - Annual commercial catches of eels in Victoria (VFA 2017). Red line encompasses those years when extended drought conditions prevailed.

Once adults begin migrating to their spawning grounds they travel quickly, with migration speeds averaging 30.8 ± 7.3 km/day although one individual was found travelling at 80km/day (Koster et al 2021). The annual timing of adult migrations is from January to May each year.

There are no scientifically derived studies indicating mortality effects on eels from seismic surveys, which we group with fish containing swim bladders when assessing seismic effect studies. Adult eels are undertaking their migrations over an extended period of 5 months and the work of Crook et al (2014) indicates that migration from estuaries is a highly variable process. Given the extended and volatile timing of migration from estuaries and the high mobility of individual animals we do not anticipate any critical effects to the local populations of eels from the Regia MSS.

3.7.2 Magnitude of Effect

If any individual adult eels are within proximity to the seismic arrays when acquisition is occurring, there will likely be non-lethal impacts. However, given the mobility of adult eels, their intrinsic drive to get to their spawning grounds, and the soft startup procedures of the Regia MSS the risks

associated with this event are extremely low and impossible to distinguish from the large-scale changes inherent in the population each year and driven by multiple factors as previously described. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04].

For the larval leptocephelae and glass eel stages, they are most prevalent in regional waters during the winter-spring months. If the Regia MSS is scheduled outside this timeframe, then all interactions with this stage of the life cycle will be avoided.

3.7.3 Recovery Potential

There is no identified recovery plan for this species, nor do we anticipate impacts of sufficient scale to be considered for future recovery plans. The species has proven resilient to fishing and other anthropogenic pressures for millennia.

3.7.4 Conservation Status

The short-finned eel *Anguilla australis* is not under any conservation status. However, short-finned eels are of cultural significance to First Nations people. The Gunditjmara people of south-western Victoria built and used sophisticated aquaculture systems throughout the Budj Bim Cultural Landscape to exploit eel migrations at least 7,000 years ago. Budj Bim Cultural Landscape is listed as a World Heritage Area and is protected by Victoria's Aboriginal Heritage Act 2006. One of the values of this World Heritage Area is the Budj Bim lava flows, which provides the basis for one of the world's most extensive and oldest aquaculture systems developed by the Gunditjmara, based on deliberate redirection, modification and management of waterways and wetlands (UNESCO 2023). There is no direct effect, and no measurable indirect effect, from the Regia MSS to the Budj Bim Cultural Landscape (see section 3.15).

3.7.5 Mitigation Effectiveness

Potential impacts could be minimised or avoided by scheduling of the Regia MSS to outside the period when elvers are returning to the river systems along the Southwest coast during the months of April to October. However, this measure would increase the effects on other more sensitive species. No petroleum activity will be carried out between 1 January and 15 September, so the overlap with this period is reduced.

3.8 Gould's Squid (*Nototodarus gouldi*)

3.8.1 Species-Specific Sensitivity

There remains minimal research completed on the effects of seismic surveys on squid. Two key sources have been the work of McCauley et al (2000) and Fewtrell & McCauley (2012). Startle or alarm responses out to 4-5 km from the seismic source were the only consistent outcomes from the experimental work, and these were shown to reduce with amount of exposure i.e. habituation to the sound. Potential effects from damage to the tissue surrounding the statoliths were not evident as experimental animals showed consistent responses even after multiple seismic pulses.

Gould's Squid which is the primary targeted species in the Southern Squid Jig Fishery (SSJF), is short-lived (<1 year) and has been found to spawn up to 4 times a year. They also display highly variable growth rates and size and age-at-maturity. Populations with life-history characteristics like these have high turnover rates and are consequently much more resilient to fishing pressure. Moreover, with fishing concentrated over the few months of summer there remains multiple other spawning events to provide new recruits for the population.

Research has shown that squid populations are highly responsive to variations in environmental conditions from year to year, however it has been difficult to pinpoint whether any factor is more important than another. This is borne out by the correlation between all the fisheries across SE Australia having peak catches around the same time. A final model for all zones of the SSJF sector combined included Year, zone, depth, and the interaction of depth and moon phase as the variables of most influence with Year explaining the greatest source of variation in CPUE (15.1%; see Figure F3-19) (Koopman et al 2018). Genetic studies support the hypothesis of a single biological stock of Gould's Squid throughout southeastern Australian waters (Jackson and McGrath-Steer 2003) which provides another layer of resilience at the population level.

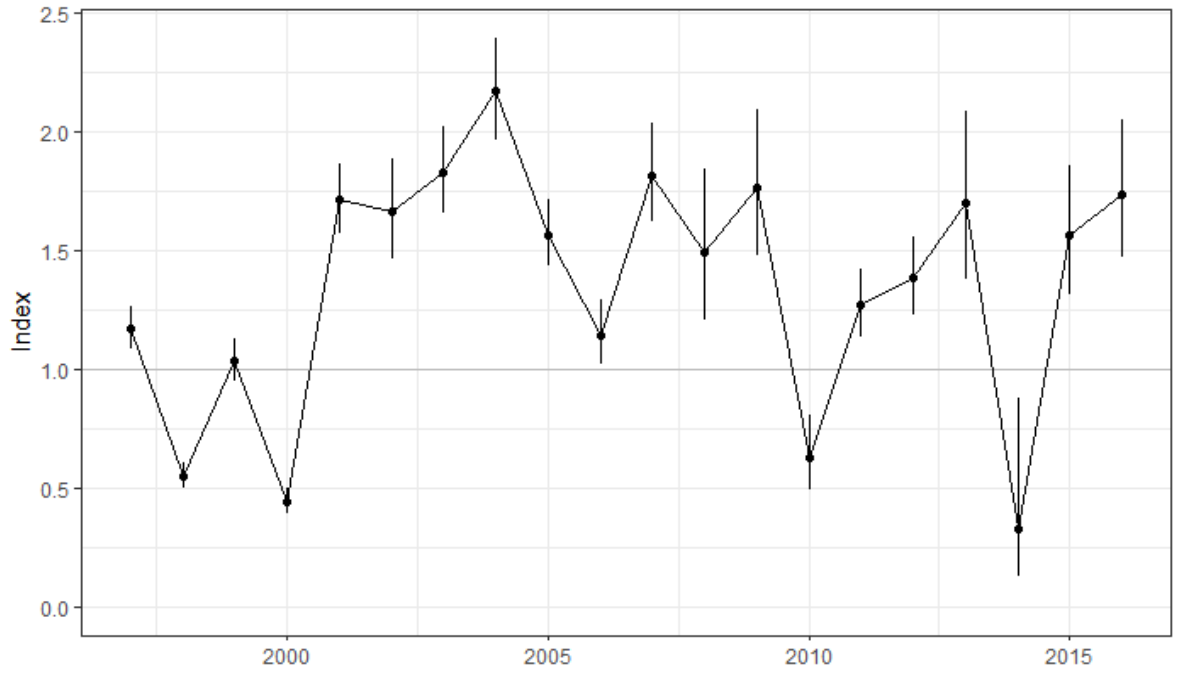

Figure F3-19 - Final model showing annual variation of Standardized CPUE for all catches of Gould's squid.

Very large catches were taken by foreign vessels in the 70's and 80's without appearing to reduce available biomass in subsequent seasons. Modelling of heavy fishing in the GAB fishery has also shown that even when biomass is reduced to 10% of original size, recovery still occurs (Virtue et al 2011). The overall productivity of the region is the likely key driver of dynamics.

3.8.2 Magnitude of Effect

Fishing remains the largest anthropogenic impact on populations and this source has been shown to carry less impact on standing biomass of the population than environmental parameters. Hence any potential impacts from seismic activity on the resilience of the squid population in the region is not going to be measurable against the backdrop of annual variation that is naturally occurring.

3.8.3 Cumulative Impacts

Studies have not identified any large-scale impacts to squid from seismic blasting. Short term behavioural changes as observed are not likely to have any impacts on the squid population in the vicinity of the seismic surveys. Soft starting will provide a catalyst for squid to move and provide scope for a learned response such that subsequent seismic pulses will not illicit as strong a response from individual animals. In this context there is a very low probability of cumulative impacts occurring. However, once the source passes, animals will be free to move back into the habitat that they departed from. [Paragraph updated in response to Matter I04].

3.8.4 Recovery Potential

As outlined in the previous sections current knowledge indicates only temporary localised effects to individual squid and no evidence of effects that could cascade into population level impacts. Squid populations are highly dynamic and responsive to larger scale environmental influences.

3.8.5 Mitigation Effectiveness

While the probability of adverse consequences for squid populations from seismic is extremely low it is appropriate to reduce any probability to as low as possible. The timing of peak catches has centred around February/ March in the Western Victoria fishery hence avoiding seismic during this period is advisable.

3.9 Pale Octopus (*Octopus pallidus*)

[Section added in response to Matters: F11 and F12]

3.9.1 Species-Specific Sensitivity

While there are a number of species of octopus that can be caught in Victorian waters (e.g. Maori Octopus, *Macroctopus maorum* and Gloomy Octopus, *Octopus tetricus*) the most abundant species and focus of commercial fishing, is the Pale Octopus, *Octopus pallidus*. This species is most commonly found on sandy substrates, often near beds of sponges or sea squirts (VFA website).

The pale octopus is found from the Great Australian Bight across to Tasmania and up into Southern NSW. It has a typical life span of 12 months but can live for up to 18 months. It is a benthic species with no pelagic stage in its development. They spawn throughout the year but with an optimal spawning period during late summer (Leporati et al. 2008). Lack of a pelagic cycle is correlated with strong spatial genetic structuring in populations, with connectivity mostly through movement of adults between locations (Higgins et al 2013)

Cephalopods are increasingly being identified as highly dynamic organisms that grow and mature with great degrees of individual variability, often influenced by external factors such as temperature and diet (Moltschaniwskyj 2004).

Sensitivity of the pale octopus to seismic has been specifically tested through a dedicated research program funded by the Fisheries Research and Development Corporation (FRDC), with the final report recently released (Day et al 2023; Examining the potential impacts of seismic surveys on Octopus and larval stages of Southern Rock Lobster, FRDC). The key findings were that exposure to seismic airgun signals did not kill adult octopus and nor was there any indication of harm to offspring. There were some observed behavioural changes but no indications that this would translate to sustained and deleterious changes in the health of exposed populations.

3.9.2 Magnitude of Effect

Fishing and climate changes are the largest impacts to fisheries in general. A stand-alone octopus fishery commenced in Victoria as recently as 2020 and is focussed on Eastern Victoria. Octopus fishing in central and western Victoria is less established and is managed through exploratory, temporary permits. A fishing experiment found that continual local fishing pressure appeared to have altered the age and reproductive structure of the female *O. pallidus* population, reflecting size selective fishing mortality, which could lead to smaller sizes at maturity, fecundity, and ultimately recruitment (Leporati 2008). A recent and substantive meta-analysis of studies looking at climate-change impacts on cephalopods (Borges et al. 2023) has highlighted that ocean warming poses a clear threat to cephalopods with impacts seen across all stages of the life cycle. There is no evidence to support significant impacts to pale octopus from the proposed Regia MSS.

3.9.3 Recovery Potential

There is no evidence to support significant impacts to pale octopus from the proposed Regia MSS such that Recovery Potential has to be assessed.

3.9.4 Conservation Status

There are no conservation consequences associated with the Pale Octopus in Australian Waters. Stocks in Victoria are classified as undefined with a dedicated octopus' fishery only starting in 2020 in eastern Victoria.

3.9.5 Mitigation Effectiveness

While the probability of adverse consequences for pale octopus' populations from seismic is extremely low, scheduling the Regia MSS outside of summer months, when spawning peaks, would reduce this probability even further.

3.10 Blacklip Abalone (*Haliotus rubra)*

[Section added in response to Matters: F12 and F16]

3.10.1 Species-Specific Sensitivity

Blacklip Abalone stocks in Victoria are in relatively poor condition having suffered greatly from disease and overfishing. In addition, the southeast coast of Australia is in a climate change 'hot-spot' where sea surface temperatures are experiencing rapid warming at rates 3–4 times the global average. These increasing SSTs are predicted to have negative impacts on the abundance of *H. rubra* in South coast waters. Modelling work has identified summer SST as the most influential variable on density distribution of *H. rubra*, with smaller sizes and lower catches coinciding with warmer SST's (Young et al 2020 and refs therein).

The pelagic larval duration of abalone is short at ~10 days, nevertheless genetics studies have found that abalone stocks along Victorias south coast are well connected, with high levels of gene flow within and between reef patches. Larval supply and recruitment success may therefore not depend predominantly on local reef sources. The marine physical environment of the south coast is highly variable, driven by converging ocean currents, strong environmental gradients, habitat discontinuities and varying degrees of exposure to wave energy (Miller et al 2016).

Regia MSS will be operating at depths greater than 50m. While almost all diver-harvested abalone will come from depths <30m the majority will come from depths <20m, hence there is approximately 15-20km distance between the 20m and 50m depth contours adjacent to where the proposed Regia MSS will approach the coast.

There has not been any direct testing of seismic effects on Abalone, so a weight-of-evidence approach is taken where we use results from testing on other molluscs, notably scallops and pearl oysters. Testing outcomes on scallops were consistent with studies on seismic effects to other invertebrates, with impacts clearly noted within very close proximity to seismic pulses (i.e. hundreds of metres) but then rapidly dissipating (see response to Matter F09). Estimated mortality rates in all cases remained well below natural mortality rates. A recent, major study into seismic effects on silverlip pearly oysters found no evidence of reduced productivity or mortality (Parsons et al 2024).

We do not therefore, find compelling evidence for a high likelihood of significant lethal or sub-lethal effects to abalone stocks from the proposed Regia MSS. As already stated, Abalone stocks are being influenced by climate, overfishing and disease and these remain the primary areas of concern.

3.10.2 Magnitude of Effect

There is no evidence to support significant impacts to black-lip abalone from the proposed Regia MSS. There is a possibility for impacts to abalone divers working in the fishery, however this has been recognised and appropriate measures put in place based on feedback from the Abalone Fishers in the region (see Appendix E8: Underwater Sound – Divers).

There is no evidence to support the Regia MSS causing significant impacts to black-lip abalone stocks in the region. Cumulative impacts to Abalone stocks are coming through climate, overfishing and disease and these remain the primary areas of concern. Rebuilding biomass has been proposed through a combination of conservative catch and minimum size limits, spatial management of fishing and catch, and a combination of fishery-independent and fishery-dependent data collection to demonstrate ongoing recovery and guide future TAC setting (Peeters et al 2023). Climate change will however pose further challenges to management objectives as temperature increases have been linked to fitness reductions in abalone along with smaller size and lower catches (Young et al 2020 and refs therein).

3.10.3 Recovery Potential

There is no evidence to support significant impacts to black-lip abalone from the proposed Regia MSS such that recovery potential must be assessed.

3.10.4 Conservation Status

There is no conservation status classification with black lip abalone in Australian Waters. However, stocks in 2 of 3 fishing zones in Victoria are classified as depleting while the western zone is considered sustainable.

3.10.5 Mitigation Effectiveness

While the probability of adverse consequences for black lip abalone from Regia MSS is extremely low, scheduling the Regia MSS for outside of the summer months, when spawning peaks, would reduce this probability even further.

3.11 Pink Snapper (*Chrysophrys auratus*)

[Section added in response to Matter: F12]

3.11.1 Species-Specific Sensitivity

Pink Snapper are widely distributed in the Indo-Pacific and an important species for both recreational and commercial fisheries in Australia and New Zealand. The reproductive biology of the snapper has been studied in several places across its distribution and is well understood However, there is geographic variation with respect to the timing of spawning, length of season and the environmental conditions associated with spawning, such as water temperature and photoperiod (Saunders et al 2012). Such geographic differences indicate the need to understand the reproductive biology of the species at the local scale to understand regional population dynamics.

Most adult snapper recruiting into the major fisheries in Port Phillip Bay (PPB), Western Port, and Western Victorian coastal waters originate from one major spawning/nursery area in PPB. Spawning happens between November and February with larval durations of ~ 18-32 days. Settlement will start to occur from 1 month after spawning occurs and will continue through to early winter. Therefore, it is the strong fluctuations in juvenile recruitment within PPB that dominate the population dynamics of the entire western Victorian snapper stock (Hamer & Jenkins 2007). Young snapper (1–4 years of age) born in PPB can migrate large distances (100's km) to replenish populations in coastal waters and other bays.

The latest assessment of stock health (Bell et al 2022) classifies snapper as sustainable and highlights the extremely strong recruitment cohorts of 2018 and 2022 which should result in increased adult fish in the system over the following years. Recruitment patterns have been highly variable over the years and are more influenced by local-scale processes e.g. at the estuary level.

Testing of seismic effects on adult snapper has found damage to the sensory epithelia within their ears, for fish exposed to a towed single seismic array <15m away (McCauley et al 2003). However there have been no reports of mortality in adult fish of any species nor evidence to support population-level effects on fish stocks from seismic surveys. A review of the potential impacts of marine seismic surveys on fish & invertebrates (Carroll et al 2017) found that while there was some evidence to support lethal and semi-lethal effects to fish larvae near a seismic source, these effects dissipated with distance and were not consistent between taxa.

Annual counts of snapper recruitment to Port Philip Bay were also compared with counts of annual seismic surveys in the region to see if there was any correlation between the two. We found no evidence of a link, with high recruitment of snapper equally likely to coincide with low or high seismic activity levels (see Figure F3-20).

In summary we find that the species-specific sensitivity to seismic is low for *Chrysophrys auratus* and further reduced because of spatial and temporal distance from the proposed location and timing of the Regia MSS.

3.11.2 Magnitude of Effect

Because the key parts of the lifecycle of snapper are centred on PPB and its surrounds and this is ~170km from the proposed Regia MSS zone any possible effects will be substantially diluted. Management of timing for the proposed survey to avoid the peak recruitment period over Dec -Jan - Feb will further mitigate any possible effects.

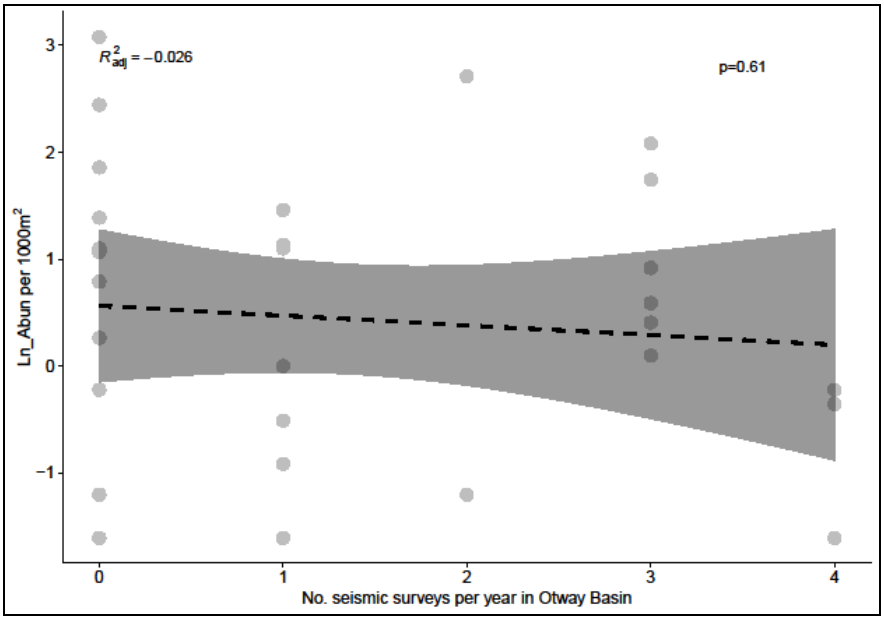

Figure F3-20 - Snapper recruit abundance (transformed) versus level of seismic activity each year for all basins combined (top) and for Otway basin only (bottom).

The dynamics of the entire western Victorian snapper fishery, encompassing over 500km of coastline from Portland to Wilsons Promontory, are linked to recruitment variation in PPB. The focus is therefore on maintaining the processes/habitats that support the production and survival of juvenile snapper in PPB. This dynamic demonstrates the importance of the spawning adults that migrate into PPB from coastal waters during spring/summer, and the potential implications of over-fishing of this spawning aggregation. Hence the main impacts to snapper stocks in the region are fishing and the ongoing health of PPB.

3.11.3 Recovery Potential

Recent strong recruitment with two high peaks observed during the past 5 years is expected to reverse any declining biomass trends and drive a rebuilding of adult biomass consistent with forecasts from Port Philip Bay creel showing an expected improvement in fishery performance over the next 5–10 years. Length compositions are not showing signs of truncation, and commercial fishing pressure has reduced substantially in recent years due to the Port Phillip Bay buy-outs and reduced landings by South Australian and Commonwealth operators. The available evidence indicates that the biomass of this stock is unlikely to be depleted and that recruitment is unlikely to be impaired.

3.11.4 Conservation Status

Pink Snapper are not under any conservation protection status other than state and commonwealth fishing regulations. Snapper populations in Victoria are currently classified as sustainable and improving based on a successful recruitment year in 2018.

3.11.5 Mitigation Effectiveness

As noted, the key dynamics of pink snapper stocks in Victoria are centred around PPB and to a lesser extent Westernport Bay. Their distance from the proposed Regia MSS area provides an inherent buffer to any potential effects of seismic. In addition, there are multiple adaptions to the MSS protocols to further reduce risk of seismic effects. This includes soft starting procedures with seismic and depth limitations (>50m). Recruitment dynamics, the health of spawning populations and the interaction with fishing effects remain the main drivers of population health in pink snapper stocks.

3.12 King George Whiting (*Sillaginodes punctatus*)

[Section added in response to Matter: F14]

3.12.1 Species-Specific Sensitivity

King George Whiting are found within the bays, estuaries, and coastal waters of Victoria. They are a popular target of recreational fishers with most fish taken within the semi-sheltered waters of Port Phillip Bay (PPB), Corner Inlet-Nooramunga (CI) and Western Port (WP), where commercial fishers are also located. Population dynamics are strongly influenced by climatic factors determining numbers of larvae transported to bay and estuarine nurseries from coastal spawning areas in spring [Jenkins and May 1994, Hamer and Jenkins 1996, Jenkins et al. 2000, Jenkins 2005]. As most King George Whiting leave the bays and inlets permanently by four years of age (prior to adulthood) [Hamer et al. 2004], these fisheries are based on just a few age classes at any one time, making catches highly variable over relatively short time scales. Over the past 60 years catches have shown peaks and troughs at about 10 to 12-year intervals. These cycles are thought to be related to variation in westerly winds driving larval transport and survival (Jenkins 2005). Because fishing effort is concentrated in bays and inlets, adults in coastal waters are likely subject to low fishing mortality.

King George Whiting has a complex life history, exhibiting ontogenetic shifts in habitat at different life history stages (Fowler and Jones, 2008). Spawning occurs during late autumn and early winter at offshore reefs, shoals, and mounds in relatively deep water (30–100 m) in exposed locations (Fowler, 2000, Fowler et al., 1999, Steer et al., 2018). The larvae of King George Whiting can be advected across hundreds of kilometers over a prolonged pre-settlement period (3–5 months), dispersing larvae from the offshore spawning grounds to the shallow water nursery areas in protected shallow bays (Fowler et al., 2000b, Rogers, 2019). Juvenile fish develop and grow in the vicinity of these nursery areas until 3-4 years of age (Fowler et al., 2000a) when they move to their offshore spawning grounds to repeat the cycle (Fowler et al., 2000a, Fowler et al., 1999).

Most of the investigative research into seismic effects on fish (and invertebrates) has been from laboratory, or field-based studies where the animals are confined and hence not representative of a normal environment. A recent scientific publication conducted a systematic literature review of the effects of marine seismic surveys on free-ranging fauna only (Affatati & Camerlinghi (2023)). Frontiers in Marine Science Vol 10: 1222523). Unlike many review papers, they looked only at field studies on wild animals to provide the most realistic context for interpreting effects, ending up with 6 relevant publications for fish. Results described either no changes or temporary changes in behaviour/distribution of populations of animals. Studies were constrained to the North Sea and two solitary studies in the NE (Meekan et al. 2021) and SE (Bruce et al. 2018) corners of Australia, reflecting areas with appropriate resources to conduct ‘natural’ experiments.

The scientific evidence is clear that individuals within very close proximity to seismic sources will potentially face lethal or sub-lethal damage. There is, however, no evidence to support levels of disturbance greater than natural rates of mortality, for those species that may encounter the proposed Regia MSS. As such any potential effects will be immeasurable. Long term cumulative drivers of change in KGW fish populations remain closely linked to commercial and recreational fishing pressure and changing climate with little evidence to suggest seismic testing is driving population changes.

3.12.2 Magnitude of Effect

To further investigate the potential influence of seismic on KGW populations we sought to understand if there was any relationship between the annual frequency of seismic programs running in Victorian waters and the annual recruitment levels of King George Whiting in Port Philip Bay (PPB). PPB is the main area for KGW stocks in Victoria and hence where any correlations would be most likely to show up.

One of the arguments used by both sides of the “effects of marine seismic testing” issue is that the persistent presence of seismic testing in Victoria over a prolonged period has either been a primary driver of declines in fishing catches or it is evidence that the systems are relatively resilient to the scale of these effects. Providing a direct cause and effect is virtually impossible given the scale of the operating environment and the large number of confounding factors that are also acting at any given point in time and/or space.

In lieu of this, one approach is to look at long term datasets of a resource such as fish and see if the patterns revealed have any coherency with long-term patterns of MSS in the greater region. If seismic testing is having a significant effect on a stock at population level, then it might be argued that the more seismic testing that is done then the greater any likely impact will be. Hence in years of multiple seismic there will be a greater impact than in years where there has been little or no seismic.

To investigate this hypothesis CGG compared a long-term dataset of annual counts of newly settled King George Whiting recruits within Port Philip Bay (as described in VFA 2021 – Review of key Victorian fish stocks) with a similarly long-term dataset on annual seismic surveys in Victorian waters. Patterns of recruitment into this bay are representative of the other 2 catchments of Western Port Bay and Corner inlet as described in multiple papers and reports already submitted as part of the EP.

A simple linear regression approach was used to test for any correlations between the annual recruitment of KGW to Port Philip Bay and the annual count of seismic surveys across Victorian waters. This data was further subdivided to test for correlations with only seismic conducted in waters of the Otway Basin region which is more closely linked to offshore spawning behaviours of KGW in Victorian waters. For each of the two seismic datasets CGG compared KGW recruitment counts in the same year and then also lagged by 1 year, 2 years and 3 years. This is a test to look for delayed effects of seismic. For example, with a 1-year lag CGG compare the seismic accounts from 1999 with the recruitment counts in 2000, 2000 with 2001, 2001 with 2002 and so on. For a 2-year lag CGG compared seismic in 1999 with KGW recruitment in 2001 and so on. This analysis is shown in Figure F3-21.

CGG found no evidence of a relationship between annual recruitment levels of KGW to PPB and annual seismic levels, whether in the same year or lagged by multiple years. High recruitment of KGW was just as evident during years with high seismic activity or low seismic activity.

As analysed and described in the previous sections we do not foresee any measurable impact on KGW stocks in Victoria from the proposed Regia MSS. Analysis of long-term seismic frequency versus long term KGW recruitment records finds no evidence of linkages between these two outcomes. Therefore, we conclude that the risk of the proposed Regia MSS causing an impact of sufficient scale and intensity as to cause synergistically greater impacts to KGW than already exist, is low.

3.12.3 Recovery Potential

Indicators of stock status for King George Whiting are all directly related to juvenile life stages and are highly variable, being primarily driven by recruitment dynamics – which CGG could not link to annual seismic frequency. None of the fishery CPUE or pre-recruit time series show persistently declining trends, providing reassurance that the poorly known and lightly fished adult stock in coastal waters is continuing to be replenished at rates that are sufficient to prevent declines in recruitment potential/egg production. Recent modest post-larval recruitment is expected to result in a decline in fishery performance, but it is expected to remain within historical bounds so the stock should remain sustainable (Bell et al 2022).

3.12.4 Conservation Status

King George Whiting is not under any conservation protection status other than state fishing regulations. King George Whiting populations in Victoria are currently classified as sustainable.

3.12.5 Mitigation Effectiveness

As noted, the key dynamics of KGW stocks in Victoria are centred around PPB, WPB and CI. Recruitment dynamics, the health of spawning populations and the interaction with fishing effects remain the main drivers of population health in KGW stocks.

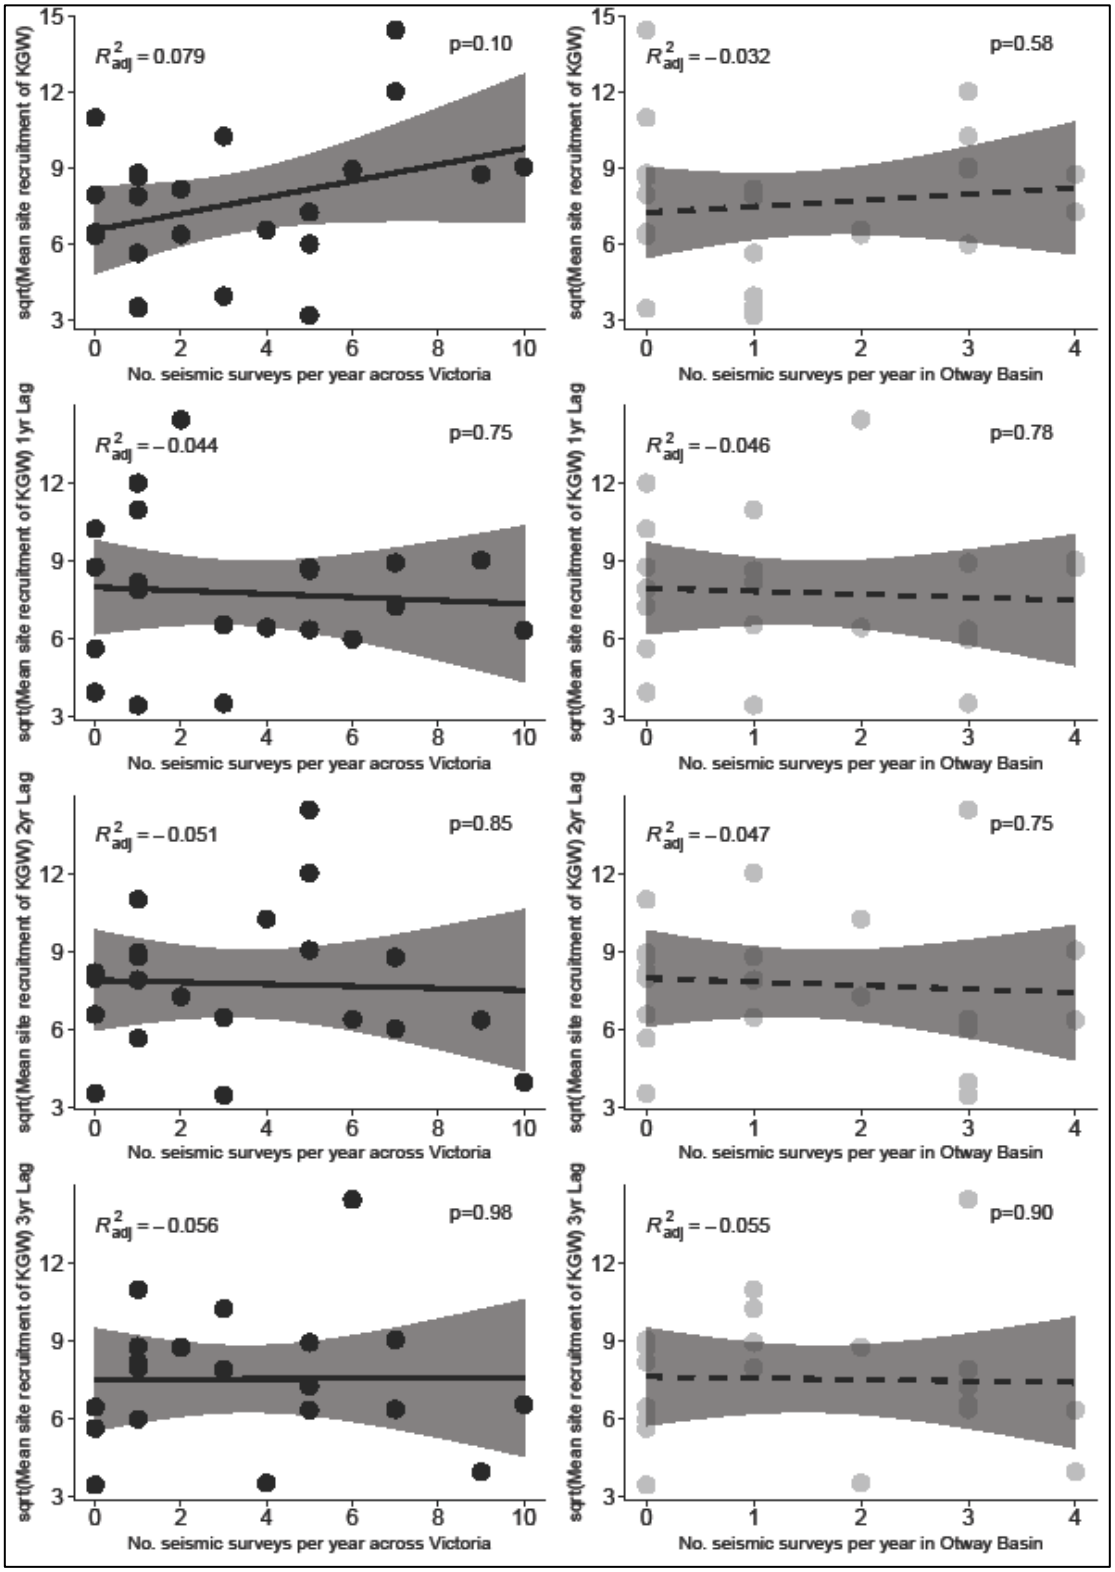

Figure F3-21 - Relationship between frequency of seismic surveys and KGW recruitment levels in PPB. Left hand column includes seismic surveys across Victoria, Right hand column is seismic surveys conducted in the Otway Basin only. Rows represent a lag effect of 0, 1, 2 and 3 years respectively.

3.13 Plankton Communities and the Bonney Upwelling System

3.13.1 Species-Specific Sensitivity

The plankton communities of the general region encompassing the Regia MSS area are dominated by copepods, cladocerans, euphausids (Krill) and chaetognaths amongst others (Kampf & Chapman 2016; Van Ruth & Ward 2009). Much of the work on direct effects of seismic to plankton has focussed on copepods, krill and fish/invertebrate larvae. Results are mixed, with the consensus indicating a range of effects, including mortality, for individuals within close proximity to the seismic pulses at the time of discharging. However, the evidence is much less compelling for large scale mortality and potential population level effects to plankton communities at ever increasing distances from the seismic discharges. A pivotal study cited as definitive proof of large-scale mortality of krill (McCauley et al 2017) presented an outcome more extreme than previous research, concluding that there was large-scale mortality out to 1.2 km from the source. A subsequent study was conducted by three highly cited CSIRO modellers/ researchers (Richardson et al 2017) to model the effects of a seismic survey on zooplankton in a hypothetical survey conducted off the NW Shelf of Australia. This work was also suggested by McCauley et al (2017),

> "*There is an urgent need to conduct further study to mitigate, model and understand potential impacts on plankton and the marine environment…*"

The model outcomes demonstrated substantial impact within 15 km of the seismic in keeping with previous empirical research, but unlike McCauley et al (2017) they found no likely population level effects, with recovery of zooplankton populations within 26 days of the survey completion. Modelling is a proven tool for investigating systems that are difficult to study at large scales and the model outcomes were closely aligned with previous research outcomes across a range of plankton species. As with all models there were numerous caveats due to insufficient information to inform aspects of the model. Richardson et al (2107) however also identified multiple outcomes from the McCauley et al (2017) study that cannot be taken as absolute, especially the apparent lack of any attenuation by distance effects on mortality rates. The obvious conclusions were that there needs to be an independent, rigorous, largescale follow up study to see if the results of McCauley et al (2017) can be verified and validated.

Sensitivity of individual plankton species across multiple studies have all indicated maximum mortality rates from Regia MSS to be below estimated natural mortality rates, with reduced impact at increasing distances/depth from the seismic source (multiple references in the EIA doc on UWS – Plankton).

A significant component of plankton community dynamics in the region is collectively known as the Great Southern Upwelling which mostly refers to three distinct upwelling centres located off the Bonney coast, the southwest coast of Kangaroo Island and the west coast of the Eyre Peninsula. While these centres are not seen as being connected (see Huang and Wang 2019) there is evidence of upwelling at a lower level across the greater shelf region and blue whales are known to aggregate for feeding along the Otway coast SE of Cape Nelson (Gill et al 2011). There is also evidence of sub-surface phytoplankton blooms occurring along the shelf region (Shute et al. 2022, Kampf & Kavi 2017).

Upwelling is a key driver of seasonal biomass enhancements of mesozooplankton (Van Ruth and Ward, 2009), sardine (*Sardinops sagax*) (Ward et al. 2006) and other small pelagic fishes (e.g. *Arripis georgianus*, *Etrumeus teres*, *Trachurus declivis*, *T. novaezelandiae*, *Scomber australicus*, *Emmelichthys nitidus* and *Scomberesox saurus*) (Ward et al., 2008), which are in turn important in the trophic webs of higher order predators in the region (Goldsworthy et al., 2013). Productivity associated with the Bonney Upwelling is also linked to enhancements of euphausiid (*Nyctiphanes australis*) biomass and associated blue whale (*Balaenoptera musculus*) feeding aggregations (Gill, 2002).

In the case of the euphausiid *N. australis*, while its highest abundance is found in summer in response to the upwelling, this species is short-lived and extremely productive, reaching maturity within 4 months and reproducing continuously throughout the year (UTas, IMAS website).

When the upwelling season starts during late spring and early summer (November and December), the influence of the Bonney coast upwelling is often restricted to the coast. During the mid-summer

and early autumn (January to March) when the upwelling is the strongest (measured by AoI), the upwelling influence often extended to the shelf break before retreating in April. At the height of the Bonney coast upwelling during February and March, the upwelling's area of influence often exceeds 12,000 km^2, its SST anomaly often exceeds 1 °C, and its chlorophyll-a concentrations are often >1.5 times of its adjacent areas (All part of Huang and Wang 2019).

The upwelling area of influence is affected by ENSO events, especially at inter-annual level (Huang and Wang 2019). El Nino or La Nina events tend to increase or reduce, respectively, the upwelling's area of influence. It has even been suggested that La Nina events could potentially stop the upwelling events from happening altogether. For example, the Bonney coast upwelling season in 2008–09 was restricted to February only. Interannual variation in areal extent (AoI) can be as high as 50 % from year to year. At the Bonney Coast Western Victoria (BCWVIC) area, the highest annual means in 2009–10 (13,029 ± 5894 km^2) and 2015–16 (12,414 ± 7794 km^2) were more than twice the lowest two in 2004–05 (5378 ± 3184 km^2) and 2012–13 (5184 ± 4838 km^2).

The inherent variability in the dynamics of plankton productivity and the oceanographic processes that drive their life cycles, including concentrating food in upwelling systems, is driven by global-scale climate cycles such as the El Nino Southern Oscillation, with rising SST's also impacting at regional scales. While the direct effects of seismic pulses are felt by individual animals within proximity to the Regia MSS the impacts on population dynamics of these communities are insignificant relative to the scales of change that operate normally.

Krill is a key component of the plankton communities of the region. Because of its primary role in the regional food chains, many species long term sustainability is closely linked to the annual upwelling events that drive the krill blooms upon which animals converge to feed. Because upwelling is the key driver of krill population dynamics, it follows that the huge shifts in temporal and areal extent of the GSU both within and between years will cause krill populations to shrink and expand in a similar way. Such changes, as previously noted, can be as much as 50%. The animals that rely on this system (e.g. whales) for their survival must therefore have evolved to survive and thrive within a system that changes markedly in scale and extent. When put into this context the scale of any potential impacts to plankton communities from the proposed Regia MSS will have no measurable effect on the population health of plankton communities. By extension the risk associated with reduced krill biomass available to feeding animals as a result of the proposed Regia MSS is immeasurably low. [Paragraph added in response to Matter: M10].

The Bonney Upwelling is also identified as culturally significant to the Gunditjmara People (Appendix F3, Section 3.16.1), with its current bringing cold nutrient-rich waters that support culturally significant species such as phytoplankton, fish, squid, seals, dolphins, whales, penguins, gannets and other sea birds (GMTOAC, 2023).

3.13.2 Magnitude of Effect

As noted in Appendix E2 (Underwater Sound – Plankton) there are multiple studies detailing the effects of seismic on fish larvae (see also Sivle et al 2021) and other inhabitants of the plankton. The results consistently indicate that there are deleterious effects on plankton in close proximity to seismic sources however the scale of the impacts is varied and species specific. There is a general relationship of decreasing effects with increasing distance from the seismic sources, although the work of McCauley et al (2017) disputes this relationship.

There has been a constructive assessment of the work of McCauley et al (2017) by Richardson et al (2017) which highlights the need for more research into the findings of this work, especially the apparent lack of attenuation in responses with distance from the seismic source. There is much variation in experimental and study methodologies undertaken to assess seismic effects, and most do not replicate 'real-life' scenarios adequately. Hence more targeted research is needed.

The outcomes discussed by McCauley et al (2017) have indeed catalysed further research into the effects of seismic on planktonic assemblages. Norway has a long history of oil and gas exploration and a concomitant program of research into its effects on the environment (Sivle et al 2021). As a direct result of this work the Norwegian Research Council has funded a 4-year project (ZoopSeis) aimed at uncovering the effects of seismic sound on zooplankton (https://www.hi.no/hi/nettrapporter/toktrapport-en-2022-9). This work is designed to investigate effects under realistic seismic survey conditions and finishes at the end of 2023. Peer-reviewed papers of the research are being completed, with the first publication now available. Mortality rates and

reduced growth of copepod larvae of *Acartia* spp were found to be high in the vicinity of the airgun discharges however the actual rates were significantly lower than normal population mortality rates and hence would likely not be detected (Vereide et al. 2023). They did not test for the effects of distance-from-seismic in this work, but their results remain consistent with most of the other research already published in this area.

A second publication derived from the ZoopSeis work (Vereide et al. (2024a)) has also found that while there was significant damage at close quarters to seismic discharges, there was not extensive and unattenuated mortality out to 1 km + as reported by McCauley et al (2017). Mortality levels reported were also lower than natural mortality rates and hence are predicted to be difficult to separate from background mortality. As well as experimental work a review was conducted as part of the ZoopSeis program and highlighted the vexed issue of extrapolating experimental results to real-life situations (Vereide et al 2024b). They noted that although a seismic survey may cover up to 3000 km^2 and shoot continuously for many weeks the animals will not be constantly exposed throughout that period. The duration of exposure in the reviewed studies lasted for a maximum of 3–4 days, which could be considered too long to be transferred into a real-life setting, considering advection and migration processes that typically occur in the plankton. [Paragraph added in response to Matters: P04 and P06].

Zooplankton will be exposed to airgun discharges when a seismic survey is conducted but over varying time durations and sound levels. In addition, seasonal, diel, and species-specific changes in copepod distribution, both within and among species (Hygum et al., 2000; Thor et al., 2005), will influence exposure level and, therefore, the overall impact of seismic discharges. Dongen-Vogels et al (2011) found up to 4 magnitudes of difference in the abundance of picophytoplankton communities in GAB which highlighted the role of localised physical events including upwelling, downwelling, water column stratification and eddy formations.

A recent study attempted to quantify the patchiness of planktonic assemblages off Florida and clearly demonstrated the multi-scale nature of this phenomenon – see Figure F3-22 below (Robinson et al 2021).

While effects of seismic will be felt by plankton assemblages at localised scales the highly dynamic nature of populations in space and time will ensure there are no population level effects hence the magnitude of any effects will be minor.

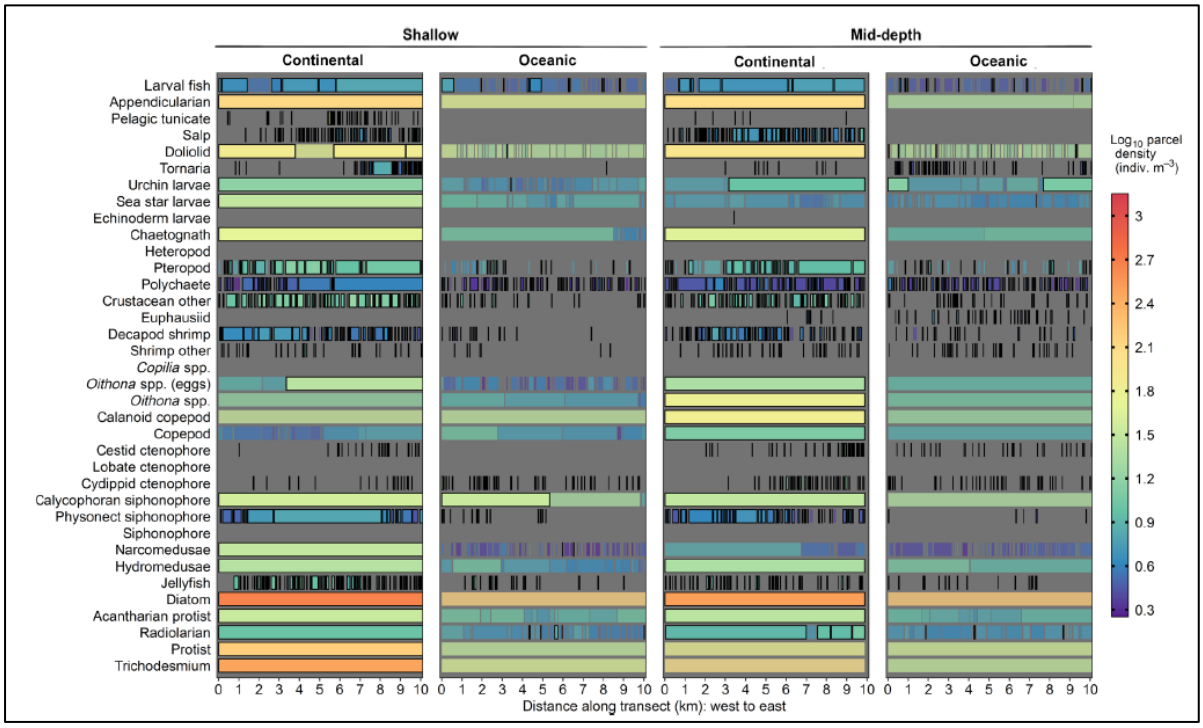

Figure F3-22 - Position and length of plankton catches for 36 taxa. The position and length of patch (coloured bars with black outline) and aggregated parcel (opaque coloured bars) for each taxonomic group along with a single example set of 10-km ISIIS transects in the shallow and mid-depth waters of continental oceanic regions of the SOF. The bar colour gradient indicates the log $_{10}$ – transformed density of individuals (individuals per cubic meter). Multiple groups had patches of aggregate parcels that extended the entirety of the 10-km transects (e.g. diatom).

3.13.3 Recovery Potential

The scale of seismic effects relative to natural background mortality and patchiness of planktonic communities precludes any impacts on such a scale that 'recovery' would be a process specifically applied to a seismic event.

3.13.4 Conservation Status

Planktonic communities of themselves are not given any conservation status. The Bonney Upwelling has been recognised as a Key Ecological Feature however this has no formal legal standing. Whale conservation and management plans may indirectly confer a conservation status on plankton communities in the same area.

3.13.5 Mitigation Effectiveness

Plankton exists in the oceanic environment off the Otway coast and greater south coast region all year round. Localised areas of extremely high plankton density such as upwelling areas should be avoided, however they do not exist within the Regia MSS area. Mitigation might otherwise be better targeted towards avoidance of aggregations of animals that either feed on plankton or who target those species that are feeding on plankton.

3.14 Spawning Patterns

3.14.1 Species-Specific Sensitivity

The commercially important fish species that occur proximate to the survey are largely broadcast spawners (i.e. species that release vast numbers of sperm and eggs into the water column, or in some cases scatter them on the substratum), with several species forming spawning aggregations on the continental shelf, shelf break and slope.

The commercially important crustacean species fished in the vicinity of the Operational Area (i.e. southern rock lobster and giant crab) also spawn eggs but incubate them under their abdomen until hatching. Some species may aggregate at locations to spawn all their eggs and sperm at a specific time within a certain period, batch spawn across a region multiple times during certain seasons (e.g. pink ling and Australian sardine) or spawn continuously throughout the year (e.g. Gould's squid). Significant spawning aggregation areas are not known to occur in the vicinity of the Operational Area, although information regarding fish spawning in offshore regions of the Otway Basin is generally not well documented.

Spawning periods for key species of Commonwealth and State managed fisheries (as identified in B6) overlapping the Operational Area are shown in Table F3-5 with Table F3-6 providing more spawning detail for those species most likely fished in the operational area. Austral spring-summer is the predominant spawning period for most species as it coincides with warmer conditions although many of the deeper water species prefer winter/spring for spawning.

Table F3-5 - Commercial fisheries species spawning timings and depths.

	Spawning Timing												
Fish species	**J**	**F**	**M**	**A**	**M**	**J**	**J**	**A**	**S**	**O**	**N**	**D**	**Depth Range**

Tiger flathead	■	■	■								■	■	10-400 m

Table F3-6 - Fish species potentially spawning in Regia MSS Operational area.

Fish species	Spawning activity	Impacted by survey
Blue Grenadier	Main spawning areas located off the central west coast of mainland Tasmania (Gunn et al. 1989b) and eastern VIC / southern NSW (Bruce et al. 2001).	Main spawning areas outside of the active source area and overlap of spawning limited to one month at end of spawning period
Elephant fish	Only partly known. Females migrate to shallow coastal waters in spring to lay their eggs (AFMA 2024).	Broad distribution across southern Australia but only incidental catches in SESSF. No aggregations known in OA.
Gummy shark	Similar to elephant fish	A continuous stock across southern Australia (ABARES Fishery Status Reports 2024).
Saw sharks	Also similar to elephant fish although timing of migration is in winter	Biological structure unknown but found across southern Australia.
School sharks	Pups and juveniles aggregate in shallower 'nursery' waters during the spring and summer.	Found across southern Australia. Stocks are considered overfished. No known aggregations inside OA.
Tiger Flathead	Mature fish migrate to shallow continental shelf waters (<200 m depth) prior to the spawning period (AFMA 2017).	Minimal overlaps at start of general spawning season. OA not a major location for TF
Eastern School Whiting	Spawning is regionally variable but peaks in summer for the region. Spawning is twice a year in deep water.	Minimal overlaps at start of general spawning season. OA not a major location for TF
Blue Warehou	Major spawning areas are located off the west coast of mainland Tasmania.	Main spawning areas outside of active source area and overlap of spawning limited to two months at end of spawning season
Blue Grenadier	Major spawning areas are located off the west coast of mainland Tasmania.	Main spawning areas outside of active source area and overlap of spawning season limited to a month at end of spawning season
Pink Ling	Mature fish migrate to shallow continental shelf waters (<200 m depth) prior to the spawning period (CSIRO 2002).	Main spawning areas deeper than survey and overlap of spawning limited to two months at end of spawning season.
Blue-eye Trevalla	Spawning occurs in summer and autumn where they move into shallower depths (320–400 m) and form spawning aggregations over rough ground and drop-offs on the continental slope, as well as over seamounts (Kailola et al., 1993).	No overlap with spawning period. Spawning is widespread across the South-east Marine Region (CSIRO, 2002) although most spawning activity occurs in waters from central NSW to north-eastern TAS (AFMA, 2017).
Ribaldo	Spawning occurs in winter and early spring. Ribaldo are not thought to form large spawning aggregations.	No overlap with spawning period.
Jack Mackerel	Spawning occurs near the edge of the continental shelf with eggs and sperm released among schooling fish deep in the water column (CSIRO, 2002). Larvae are thought to be carried inshore by currents (Marshall et al. 1993).	No overlap with spawning period. Multiple spawning events over areas outside of acquisition timing.
Redbait	Spawns on outer continental shelf, mostly at night, once every three to five days over the spawning period between Sept. – Nov..	Multiple spawning events over an extensive area between Tasmania and King Island. Spawning is confined to narrow corridor along the shelf break including within the active source area. Minor component of CSPF with no state catches reported.

Fish species	Spawning activity	Impacted by survey
Australian Sardine	Spawns on continental shelf (200 m) with larvae moving Inshore towards bays and inlets during a planktonic period of around 120 days after hatching.	Multiple spawning events over the spawning season. Overlaps the active source area. Stock is spread over >6000km and assessed as highly abundant in 2024.
Orange Roughy	Usually found at depths of 700 - 1400 m where it forms dense spawning aggregations around pinnacles in winter	No spawning or feeding aggregation areas have been identified in the Operational Area. Major spawning locations located on the east coast of Tasmania
Gould's Squid	Spawn throughout the year with 2-3 peaks of spawning activity (AFMA website)	Spawning is continuous throughout year with multiple intra-year peaks that can vary from year-to-year depending on inter- and intra-year variability of environmental conditions. Highly resilient stock that can be subject to 90% mortality.
Southern Rock Lobster	Mating is in autumn with fertilised eggs released from Sept – Nov. where they spend 12-24 months in the plankton.	SRL are considered a single stock across their entire range with high connectivity. Extremely resilient to episodic disturbances.
Giant Crab	Spawning occurs in June-July	No overlap with spawning period

Overlapping Spawning Species

Australian Sardine

Some locations identified as Australian Sardine spawning areas overlap with the Regia MSS area with timing of spawning centred around spring-summer months. Mapping of egg densities along the south coast shows the distribution and abundance of sardine spawning locations is centred around Kangaroo Island and the Cape Otway region (Ward et al. 2018). However, Ward et al. (2018) state that these results are underestimates of the total spawning biomass of the south coast region. This has recently been confirmed by Ward et al (2023) who have discovered that the size of the SE Australian Sardine stock is substantially bigger than previously estimated. This species is recognised as one genetically identical stock, subdivided into meta-populations that are still connected but more self-regulating (Izzo et al. 2017). The distribution of spawning areas is extensive across the south and southeast coast and connected at a much larger scale than the Regia MSS area (Figure F3-23 and Figure F3-24). As such, the scale of any effects to the spawning output of sardines across the greater region are expected to be immeasurable.

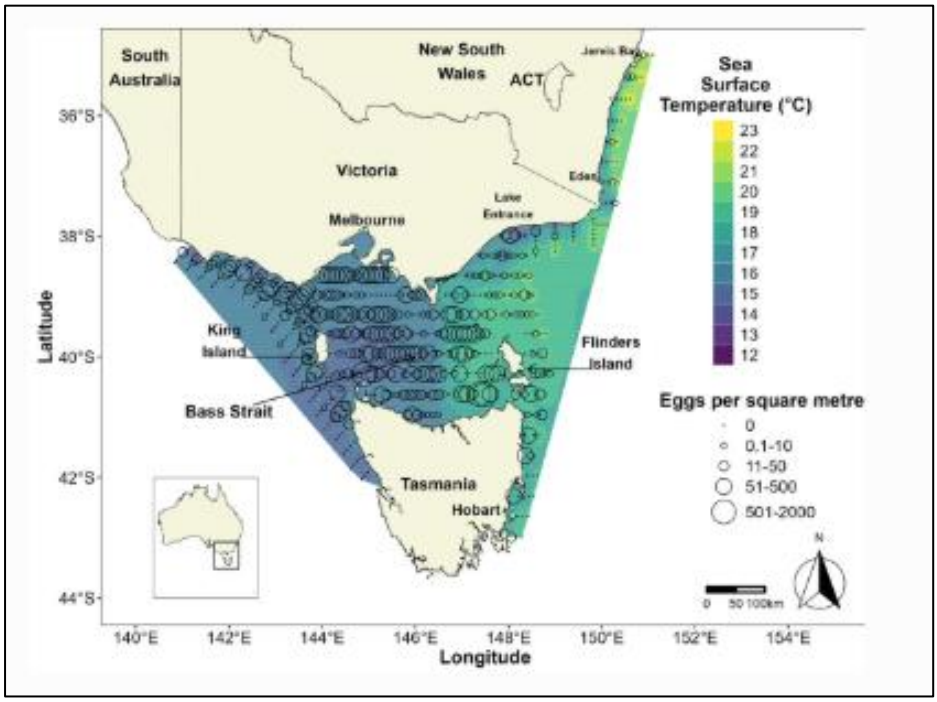

Figure F3-23 - Spatial patterns and density of Sardine eggs between December 2023 and January 2024. Along with the corresponding sea surface temperature (Credit: Tim Ward UoT 2024).

Redbait

There is overlap of redbait spawning locations with the Regia MSS area (Table F3-6) with timing of spawning during spring/early summer (Table F3-5). However, distribution of redbait eggs was found to be greater to the west and east of the Regia MSS area with highest concentrations off the west coast of Tasmania and the Bonney Upwelling region (Ward et al 2019) (Figure F3-24).

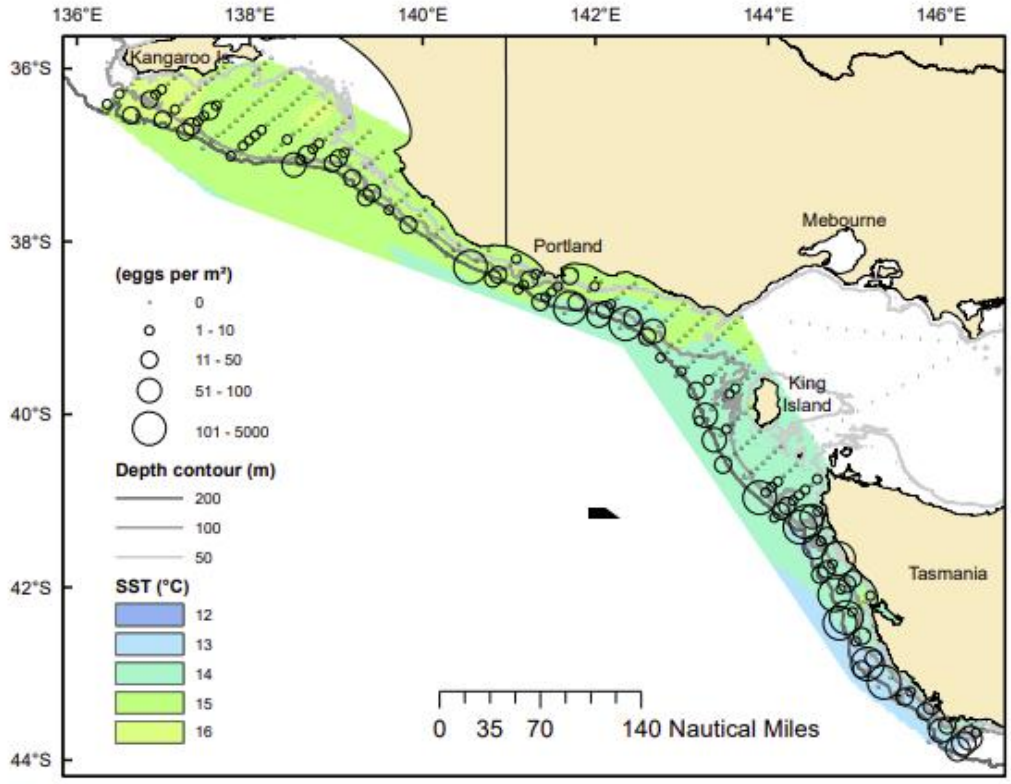

Figure F3-24 - Distribution and abundance of Redbait eggs between western Tasmania and Kangaroo Island in October 2017 (from Ward et al. 2019).

3.14.2 Magnitude of Effect

An effect on spawning from the operation of the seismic source could only happen if seismic is occurring at the time of spawning and is within the threshold distances for each particular species. . Moreover the levels of energy and scale of effects that marine biota will be exposed to within the ensonified area will vary by species and by individual according to their closeness to the sound energy source, their behaviour and physiology, the complexity and density of their preferred habitat and the speed and direction of the survey. Actual near-field and far-field received sound levels are influenced by several factors including the overall size (capacity) of the acoustic source, the array configuration, water depths in the area, position in the water column, distance from the source and geo-acoustic properties of the seabed.

Appendices B7 and B8 highlight that the distance thresholds selected for understanding the effects of elevated levels of sound on fish eggs and larvae are defined as the active source area plus 740 m. In selecting impact thresholds, the EP considers an extensive list of different studies which have investigated the effects of underwater sound on plankton (which includes the eggs and larvae of finfish and invertebrates). Guideline thresholds for mortality to eggs and larvae have been drawn from the sound exposure guidelines of the ANSI-Accredited Standards Committee S3/SC 1, Animal Bioacoustics Working Group (Popper et al. 2014). The critical level proposed for mortality in eggs and larvae is 207 dB re 1 µPa Lpk and this is based on the maximum sound levels measured from repeated pile driving that indicated no damage to the larvae of the common sole (Bolle et al. 2012). This level has been used for the assessment of underwater sound from seismic on plankton including fish larvae and eggs (see Appendix E2). The spatial extent within which effects are being assessed is conservative in keeping with the precautionary approach because it encompasses all physiological and behavioural disturbance effects to all the marine fauna considered, at the seabed and in the water column.

In general, there have been few studies into the effects of marine seismic surveys on plankton. Up until recently, studies on the effects of noise from airguns on plankton have indicated that any effect

is likely to be highly localised (<10 m from the source and typically within 0.5 to 5 m) (Kostyuchenko 1973; Matishov 1992; Booman et al. 1996; Payne 2009). These studies indicated that impacts would be insignificant compared with the naturally high turnover rates of zooplankton.

Scale of impacts is also closely linked to the size of the population. Species with high abundance and a large, interconnected distribution will be resilient and robust to a spatially and temporally constrained seismic survey. Any localised mortality will be buffered by the scales of advection and dispersal that are intrinsic to highly connected populations. Recent work has demonstrated the abundance of sardine stocks across the region (Ward et al 2023) while Redbait populations are also spatially extensive and relatively abundant across southern Australia, occurring continuously at the shelf break between southern NSW and south-western Western Australia (Ward et al 2019). potential mortality of larval fish that rely on zooplankton for food is difficult to predict but is not expected to affect a significant proportion of larvae based on the assumptions that not all zooplankton are killed by exposure to airguns (Richardson et al. 2017) and only a very small proportion of the plankton would be exposed at any one time.

No population level effects are predicted from an individual survey, however there is the potential for an overlap with the TGS Otway 3D MSS. TGS and CGG have committed that both surveys will not occur at the same time. The two surveys are targeting acquisition in different water depths such that cumulative effects are not predicted to species whose spawning distributions are depth limited. The only species with depth ranges affected by both surveys have such broad distributions that cumulative effects remain within acceptable levels. The recoverability of populations and levels of natural mortality are such that no effect is predicted to commercially caught species, or to their catch rates as an indirect result of impacts on eggs/larvae.

3.14.3 Recovery Potential

Although the work by McCauley et al. (2017) and Richardson et al. (2017) suggests that the zone of impact for zooplankton may be two orders of magnitude higher than previously thought, there is still evidence that for certain components of the plankton effects are likely to be limited to <10 m. Further, for many components of the zooplankton and phytoplankton, recovery is expected to be rapid (in the order of days), so the effects are expected to be limited and within the range of natural variability.

Richardson et al. (2017) showed that zooplankton communities can begin to recover during the survey period during periods of good oceanic circulation (and periods of upwelling). Hence, a continuous decline in zooplankton throughout the survey period is not anticipated, and parts of the Active Source Area would progressively recover as the survey proceeded. It is unlikely therefore that localised patches of reduced food availability for plankton feeders would occur over the period of the survey and during the 3-day recovery period (as modelled by Richardson et al. (2017)).

3.14.4 Conservation Status

Fish eggs and larvae are not protected in Australia.

3.14.5 Mitigation Effectiveness

There are no known critical spawning areas (i.e. species with restricted distribution and/or a relatively large-scale event) for any commercially important fish species within the Regia MSS area-of-effect and the survey will not have population level impacts on spawning output of commercially important fish and invertebrate species. Given the broad distribution and high natural mortality of spawning and the potential mortal injury effects the only viable mitigation measures are avoidance of spawning timing. In all cases, the avoidance of minor impacts to spawning should not be traded off against higher order effects of moving to other times.

In consideration of the spatial and temporal extent of this predicted impact it is also important to consider the following:

- Any plankton, including fish eggs and larvae, present in the water column within the Active Source Area will not be evenly distributed with substantial spatial patchiness the most likely (e.g. Robinson et al 2021).
- The seismic source will be constantly moving, and plankton populations are constantly being replenished by currents from non-impacted areas. Plankton populations' recover quickly due

to their fast growth rates, and the dispersal and mixing of plankton from both inside and outside of the impacted area.

- Any mortality or mortal injury effects to fish eggs and larvae resulting from seismic noise emissions are likely to be inconsequential compared to natural mortality rates of fish eggs and larvae, which are very high (exceeding 50% per day in some species and commonly exceeding 10% per day). For example, in a review of mortality estimates (Houde and Zastrow 1993), the mean mortality rate for marine fish larvae was M = 0.24, a rate equivalent to a loss of 21.3% per day.

3.15 Budj Bim Cultural Landscape

The Budj Bim Cultural Landscape, located in the traditional Country of the Gunditjmara Aboriginal people in south-eastern Australia and comprises three components: Budj Bim – Northern Component (Budj Bim IPA and National Park), Kurtonitj – Central Component (Budj Bim IPA) and Tyrendarra Southern Component (Budj Bim IPA and Tyrendarra IPA) (GMTOAC, 2023). Budj Bim is recognized for its world heritage values due to its ancient and sophisticated aquaculture systems. The Budj Bim lava flow is recognised as an attribute contributing to the Outstanding Universal Value of the Budj Bim World Heritage Site which extends into Portland Bay (Wheeler et al., 2023). These systems are among the world's oldest, dating back at least 6,600 years.[3] The Gunditjmara people utilized the lava flows from the Budj Bim volcano to create one of the largest and oldest freshwater aquaculture systems in the world. This system comprises of an extensive network of channels (yereoc), weirs (stone and wood), dams, ponds and sinkholes. This network was ingeniously designed to manage floodwaters and create basins for the systematic trapping, storing, and harvesting of Kooyang (short-finned eel - Anguilla australis), providing a sustainable economic and social base for their society over millennia.[4] More recently, acoustic tagging of Kooyang from 2008 to 2020 traced their migration from Tae Rak out to sea before spawning, with tags recorded near Tasmania, Sydney and New Caledonia. In 2019, the Kooyang Killara Water Project also piloted a six-tub, solar-powered aquaculture facility that strengthened participants' skills in feeding Kooyang, monitoring water levels and flows, and recording results.

The landscape embodies the continuing and evolving relationship between the Gunditjmara people and their land, showcasing a unique interrelationship of cultural and environmental systems. This connection is evidenced through the continuation of traditional knowledge, practices, and cultural traditions expressed through oral traditions, dance, landscape management methods such as cultural burning, and resource utilisation, such as basket weaving and rock building. This connection is also physically evidenced both archaeologically and contemporarily via the extensive aquaculture systems and interconnected geological, hydrological and ecological systems.

3.15.1 Sensitivity (World Heritage Outstanding Universal Values)

The World Heritage values of Budj Bim are recognized under two specific criteria:

Criterion (iii): This criterion highlights the Budj Bim Cultural Landscape as an exceptional testimony to the cultural traditions, knowledge, practices, and ingenuity of the Gunditjmara people. Their aquaculture system serves as a testament to their engineering skills and sustainable fishing practices, which have been passed down through generations.

Criterion (v): Under this criterion, the Budj Bim Cultural Landscape is acknowledged as an outstanding example of human interaction with the environment. The Gunditjmara's manipulation and management of the landscape through their aquaculture system demonstrate a profound understanding and relationship with their natural surroundings, emphasizing the dynamic ecological-cultural relationships that have been maintained over thousands of years.

The integrity and authenticity of the site are maintained through the intact and operational nature of the aquaculture systems, the ongoing connection of the Gunditjmara to their land, and the continuation of cultural practices. The landscape is managed to respect the rights and obligations of

[3] UNESCO 2019 https://whc.unesco.org/en/list/1577/
[4] Budj Bim website https://www.budjbim.com.au/about-us/world-heritage/

the Gunditjmara Traditional Owners. The preservation of its cultural and natural values are currently managed by the Ngootyoong Gunditj Ngootyoong Mara South West Management Plan (2015), the Gunditj Mirring Budj Bim Indigenous Protected Area Plan of Management 2022 – 2027 (Event ID 352), the Budj Bim Cultural Landscape Master Plan 2022 – 2030, a GMTOAC Budj Bim World Heritage Unit and a Steering Committee that includes membership from GMTOAC, Winda-Mara, World Heritage experts and state and federal agencies. The 'Tyrendarra Indigenous Protected Area Management Action Plan 2015–2018' is a strategic document outlining the conservation, protection, and management of the Tyrendarra Indigenous Protected Area (IPA) (Event ID 352)

3.15.2 Magnitude of Effect

CGG undertook a review of the World Heritage Listing information on the UNESCO website, the Budj Bim and GMTOAC websites, the Ngootyoong Gunditj Ngootyoong Mara South West Management Plan, the Gunditj Mirring Budj Bim Indigenous Protected Area Plan of Management 2022 – 2027 (Event ID 352), the Budj Bim Cultural Landscape Master Plan 2022 – 2030, Tyrendarra Indigenous Protected Area Management Action Plan 2015–2018' and social media posts related to the cultural values in the region. CGG has also undertaken a tour of the Budj Bim site and consulted with GMTOAC and other Traditional Owner groups in the region to better understand the significance of cultural heritage features of the environment in and around the area in which it proposes to operate.

The management plans (listed above in section 3.15.1) for the Budj Bim Cultural Landscape integrate requirements to protect the site's UNESCO Outstanding Universal Value, describing the World Heritage aims for the landscape to be universally recognised and protected as a dynamic living place with internationally recognised cultural heritage and sustainable ecological systems, with a specific long-term target of zero substantial decline in natural or cultural heritage values. Other fundamental indicators and goals focus on preventing significant decline in the condition and function of the aquaculture features (channels, weirs, dams, and ponds), including ensuring water flows are within the range that enables the aquaculture system to function sustainably, increasing native fauna populations, the development and implementation of a long-term kooyang and fish monitoring program, and building the resilience of the landscape to the impacts of climate change

The cultural values documented in the UNESCO listing and the Management Plans identified the Budj Bim Cultural Landscape and the example of human interaction with that environment. CGG subsequently considered the environmental aspects arising from the Regia MSS on the World Heritage values of the Budj Bim Cultural Landscape. The understanding CGG had of the values were analysed from both direct and indirect perspective.

Direct effects

Since Budj Bim's World Heritage values are tied to its ancient aquaculture systems, cultural traditions at the site, and the deep historical connection between the landscape and the Gunditjmara people, a seismic survey undertaken over 20km offshore will not change the physical characteristics or resources of the Budj Bim Cultural Landscape. Culturally important species, places, and practices can continue without disruption to their role, accessibility, or long-term viability, in alignment with the related Management Plans.

Indirect effects

Indirect effects could potentially be more significant, especially concerning the marine environment and its interconnectedness with the cultural practices and values of the Gunditjmara people. Since the Gunditjmara's traditional practices and cultural significance associated with the Budj Bim Cultural Landscape include the management and harvesting of aquatic resources, changes in marine ecosystems could indirectly impact these cultural practices.

CGG understood from our consultations the cultural significance of the Kooyang eel (Short-finned Eel - *Anguilla australis* – also known as Glass Eels when they are ocean bound before they migrate to inland freshwater systems). CGG undertook a detailed assessment of the effects of short-term seismic surveys on this species which can be found in Section 3.7 Short-finned Eel / Kooyang (*Anguilla australis*)

3.15.3 Recovery Potential

Due to the absence of direct effects and immeasurable indirect effects, this is no recovery potential to assess.

3.15.4 Conservation Status

As a World Heritage Listed environmental value it was important for CGG to thoroughly assess the Outstanding Universal Value of the Budj Bim site. This assessment has found no threat to the values of the site from the proposed activity.

3.15.5 Mitigation Effectiveness

Whilst there are no direct effects, and immeasurable indirect effects, from the Regia MSS on the World Heritage Values of Budj Bim, CGG recognises that there may be other indirect effects to spiritual values held by the Gunditjmara people and that this information may be sensitive such that it cannot be shared.

In acknowledgement of the ongoing sovereignty of the Gunditjmara people, and CGG's willingness to find ways to protect cultural heritage, a Sea Country Protection Plan will be implemented to facilitate the identification and management of new information, relevant to the activity, through collaboration of First Nations people who decide to be part of the program.

3.16 Cultural Features of the Environment

3.16.1 Sensitivities

Following review of relevant literature, case law, and information provided through consultation, the following environmental values and sensitivities were identified as cultural features of the environment that may be affected by the Regia MSS. Where an impact and risk on a cultural feature has been identified, environmental assessment has been undertaken and can be located as per the 'Reference to Evaluation' column in Table F3-7 below.

Table F3-7: Table showing the cultural features that may be impacted by the Regia MSS.

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
Tangible				
Koontapool Woorrkngan Yakeen	Whale Birthing Dreaming Sites, are in coastal bay areas from Port Campbell to Portland, including Warrnambool. These places on Gunditjmara Country are known resting and feeding sites for mothers and calves and are directly related to Gunditjmara Neeyn (midwives), explaining why Gunditjmara is a Matrilineal Nation.	DCCEEW 2024 Appendix C3, Desktop Research: Org ID 316 & Person ID 1163	**Planned:** Underwater sound Physical Presence **Unplanned:** Fauna interactions Accidental release of fuel Accidental release of materials or waste overboard	Underwater Sound (Marine Mammals), Appendix E7 Fauna Interactions, Appendix D2 Accidental release of fuel, Appendix D4, *(cited in section 9.3.6).* Release of materials or waste overboard, Appendix D1 Physical Presence, Appendix E1

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
Whale	Southern Right Whales (*Eubalaena australis*) and Blue Whales (*Balaenoptera musculus*) have been identified as a culturally significant species for Indigenous peoples. The GMTOAC Nyamat Mirring Plan 2023-2033 describes the spiritual connection Gunditjmara maintain with all species of whale that travel through their sea country, with the arrival of Karntubul signifying the start of the big wet season. Their whale ancestors and kin, Koontapool, the southern right whale, and Wuuloc, the pygmy blue whale, are sacred to the Gunditjmara and hold a significant place in their cultural practices. [This sentence has been updated follow public comment FN01] Koontapool are a culturally significant species for the Eastern Maar people. Blue Whales, Southern Right Whales and Killer Whales use Wadawurrung Warre (sea country).	Event ID 3678Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023 Wadawurrung Traditional Owners Aboriginal Corporation, 2020 Event ID 6624 Feedback ID 4389 Appendix C3, Desktop Research: Org ID 316 & Person ID 1163	**Planned:** Underwater sound Physical Presence **Unplanned:** Fauna interactions Accidental release of fuel Accidental release of materials or waste overboard	Underwater Sound (Marine Mammals), Appendix E7 Fauna Interactions, Appendix D2 Accidental release of fuel, Appendix D4, *(cited in section 9.3.6)* Release of materials or waste overboard, Appendix D1 Physical Presence, Appendix E1

Native Title Areas & Rights	In July 2011 the Eastern Maar and Gunditjmara peoples were recognised as the native title holders for an area of their Traditional Country in south-west Victoria between the Shaw and Eumerella Rivers and from Yambuk in the south to beyond Lake Linlithgow in the north. For the Gunditjmara People, their recognised native title rights and interests include the non-exclusive right to: • have access to or enter and remain on the land and waters • camp on the land and waters landward of the high water mark of the sea • use and enjoy the land and waters • protect places and areas of importance on the land and waters • take resources of the land and water Native Title rights and interests are non-exclusive and sit alongside the broader community's right to enjoy these places. A significant site of early conflict in Gunditjmara Country was at a place now known as the "Convincing Ground". In 1832 – 33, when Kilcarer Gunditj came together at a beached whale, whalers used the gathering, murdering approximately 60 people at the Convincing Ground. Only two members of the clan survived the massacre. 'The 'Convincing Ground' is located in Portland Bay and is listed on the Victorian Heritage Register. Deen Maar and its surrounding area hold deep spiritual significance	https://easternmaar.com.au/about/ https://www.gunditjmirring.com/nativetitle Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023	**Planned:** Light Emissions Physical Presence Diving, Surfing and Swimming **Unplanned:** Accidental release of materials or waste overboard Accidental release of fuel	Light Emissions, Appendix E9. Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
	A story associated with Deen Maar Island is that the spirits go first to Deen Maar and then up to the stars, as Bunjil had done (Eastern Maar Aboriginal Corporation, 2015). The island is where the Gunditjmara believe the spirits of their dead travel to wait to be reborn. Ancestral creation beings revealing themselves in the landscape: erupting volcanoes; tsunamis; mountains forming; sea country creeping up onto the land. (Weir 2009). Deen Maar holds cultural significance (Event ID 1891, Feedback ID 1103) Deen Maar (Lady Julia Percy Island) is the point where two creator deities, Punjil and Pallian left this earth. Pallian was the creator deity of the sea and fish and the governor of the oceans (after William Thomas, Letters from Victorian Pioneers, in National Oceans Office 2003:12). This island holds and creation story holds significance for both the Gunditj Mara and Eastern Maar. (Appendix B12)			
Point Nepean & Mornington Peninsula	During consultation with Bunurong Land Council Aboriginal Corporation (Org ID 144) identified Mornington Peninsula, and particularly Point Nepean, as an area of high cultural significance.	Event ID 2371, Feedback 1170 Thomas et al. (2017)	**Planned:** Physical Presence Light Emissions **Unplanned:**	Physical Presence, Appendix E1 Release of materials or waste overboard, Appendix D1

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
	With significant input from Dan Turnbull of Bunurong Land Council Aboriginal Corporation, Thomas et al., describe Point Nepean/Monmar as a culturally significant and sacred site on the Mornington Peninsula, which is itself culturally significant with values including tradition, story and song. Stating that within Point Nepean is a special women's place, used for birthing, ceremony and initiation. Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
Marine Mammals – General	Marine mammal species are identified by the Gunditjmara people as culturally significant as important resources, particularly as food sources, and as a feature in dreaming stories, ceremony, song and dance. Relating to Koorn Moorn (seals) and Karntubul (whales), dolphins. The Wadawurrung People recognize marine mammals, including Blue Whales, Southern Right Whales, Killer Whales, and seals, as culturally significant species. During consultation, whales, seals and sea lions are identified by the Eastern Maar people as culturally significant species.	Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023 Wadawurrung Traditional Owners Aboriginal Corporation, 2020. Event ID EVT272	**Planned:** Physical presence. Underwater sound. **Unplanned:** Release of waste overboard. Fauna interactions. Accidental release of fuel.	Underwater Sound (Marine Mammals), Appendix E7 Physical Presence, Appendix E1 Fauna Interactions, Appendix D2 Accidental Release of Fuel, Appendix D4 *(cited in section 9.3.6)* Release of materials or waste overboard, Appendix D1
Fish - General	Two freshwater species, blackfish and eels continue to be harvested by the Gunditjmara people Fishing is described as a cultural activity in The Wadawurrung Country Plan 2020 – 2030, with eel (buniyak) caught in tubular-shaped baskets (buniya). Eeling also remains an important traditional, social and economic practice among the Eastern Maar People. They continue to fish for perch, blackfish.	Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023 Wadawurrung Traditional Owners Aboriginal Corporation, 2020. Eastern Maar Aboriginal Corporation, 2015.	**Planned:** Underwater sound. Light emissions. **Unplanned:** Fauna interactions. Accidental release of fuel.	Underwater Sound (Fish), Appendix E3 Light Emissions, Appendix E9. Blackfish, eels and perch species are not identified as being potentially affected by light emissions (Appendix E9, Annex 3). Fauna Interactions, Appendix D2. Blackfish, eels and perch species are not identified as being potentially affected by fauna interactions (Appendix D2). Accidental Release of Fuel, Appendix D4 *(cited in section 9.3.3)* Blackfish are an inland river fish (VFA 2024b) and therefore outside of the Operational

				and Planning Areas.
Invertebrates - General	Coastal shellfish harvested from the sea, intertidal reefs and beaches are important resources, particularly as food sources to the Gunditjmara People. They hold strong cultural value as evidenced by cultural heritage sites and current practices. Shellfish species central to ongoing connection include torbos, pipis, abalone, limpets, mussel, elephant snail, crayfish/lobster, and crabs. Several invertebrate species are identified as important resources, particularly as food sources to the Wadawurrung People. Species include barnabeel (oyster), murrabal (mussel), bam (crayfish), abalone and pipis. Invertebrate species are an important traditional, social and economic resource for the Eastern Maar People. Abalone, cockles and crayfish are collected as tucker along the coast.	Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023 Wadawurrung Traditional Owners Aboriginal Corporation, 2020. Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
Totemic Value and Kinship	Individuals may have kinship to specific species and/or a responsibility to care for particular species. Kinship arises from totemic associations within First Nations "skin group" systems. It is forbidden for an individual to kill or eat a species who is from the same "skin group". They may also have certain obligations linked to caring for Country. For Aboriginal Peoples, plants and animals are totems and central to their cultural responsibility, providing food, health, shelter, and spiritual wellbeing. Their relationship with these species is fundamental to cultural practices and expression. Caring for plants, animals, and their habitats is a keyway of expressing culture. Indigenous ecological knowledge, passed down for tens of thousands of years, is unique to each Aboriginal clan and language group in Victoria. (AHC) In addition to this uniquity, knowledge may also be kept within Traditional Owner groups. However, the tangibles section of this table lists, describes, and references the cause-and-effect pathways, of the species identified as having cultural values.	Smyth, 2008; Juluwarlu, 2004; Muller, 2008. Aboriginal Heritage Council Victoria, 2025	*Refer to identified tangible species above*	*Refer to identified tangible species above*

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
Sea Country Knowledge	Knowledge of and familiarity with the features of Sea Country is itself a "value". The inherent potential for restricted or secret knowledge (or information that is not wished to be shared) makes this difficult to assess even through consultation with Traditional Custodians. However, aspects such as limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Transfer of knowledge includes continuing traditional practices to pass on practical skills. This transfer of knowledge may be integral to managing a group's intangible cultural heritage.	UNESCO, 2003	Indigenous tangible and intangible values are interconnected (see section 3.16.2), relying on the health of Country, for cultural values to be maintained and passed down to future generations. Therefore, holistic assessment through the principles of ESD is appropriate.	Acceptable Levels Assessment, Intergenerational Equity Principle, Appendix F4
Songlines	Cultural knowledge, as expressed through songlines, dreaming, dance and other cultural practices, can be associated with tangible objects and physical sites that are culturally important to First Nations people. The land's physical features are instrumental in maintaining songlines because this is how ancestral spirits journeyed through, and interacted with, the physical landscape leaving shared knowledge behind.	Ardler, 2021; Bursill et al., 2007. Event ID 842 Feedback ID 4216 Appendix C3, Desktop Research: Org ID 316 & Person ID 1163	Indigenous tangible and intangible values are interconnected, relying on the health of Country, for cultural values to be maintained and passed down to future generations. Therefore, holistic assessment through the principles of ESD is appropriate. (See also the identified tangible culturally significant	Acceptable Levels Assessment, Intergenerational Equity Principle, Appendix F4 (See also the identified tangible culturally significant species in this table above)

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
	The effects from the proposed activity lie at the interconnection between the physical and spiritual and this is where songlines become intrinsically tied to significant places across Country. As a result, geographical landforms are recorded within songlines and become sacred places. Such landforms can include inter alia: rocks, mountains, rivers, caves, and hills.	Higgins, 2021	species in this table above)	
	Physical sites that have been identified as comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. The region is located within the ancient landscape where prominent landscape features (e.g., rocks, mountains, rivers, caves and hills) would have been visible or used by Traditional Custodians and therefore likely to be incorporated in songlines. In Australia, songlines can stretch thousands of kilometres, making up a complex and organic network of stories containing cultural knowledge of First Nations communities across the land.	Neale and Kelly, 2020		

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
	Songlines can also extend out to Sea Country and contain cultural knowledge that is tied to geographic features, atmospheric phenomena and marine plants and animals. Often songlines containing references to a seascape or Sea Country make mention of mythical events occurring around marine life, fishing areas, submerged rocks or coral. Songlines that embody seascapes can reflect how a group may relate to, or value, Sea Country—for example connections to nearby islands that they once inhabited in their songlines.	Smyth and Isherwood, 2016		
	Songlines can become lost, fragmented, or broken when there is a loss of Country or impact to culturally important physical features.	Neale and Kelly 2020:30		
Connection out to the continental shelf	The connection with Sea Country extends well beyond the current shoreline to the edge of the continental shelf with Songlines across the land and out to sea (Eastern Maar Aboriginal Corporation, 2015).	Eastern Maar Aboriginal Corporation, 2015.	Indigenous tangible and intangible values are interconnected, relying on the health of Country, for cultural values to be maintained and passed down to future generations. Therefore, holistic assessment through the principles of ESD is appropriate.	Acceptable Levels Assessment, Intergenerational Equity Principle, Appendix F4

Connection to Country	This describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. It is also an aspect of personal identity for many First Nations people. In the case of Sea Country this can mean identifying as a Saltwater person, where "essence of being a 'Saltwater' person is ontological… it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people" The proposed activity is situated in important Sea Country for the Gunditjmara people, who have enduring spiritual and cultural connections to the area and marine life that lives within it [This sentence has been updated follow public comment FN01] Nyamat Mirring is an intrinsic part of their (*Gunditjmara*) culture, law, Lore, and custom (Event ID 352) In the video 'Bunurong Land Council @ Point Nepean in HD', representatives from the Bunurong Land Council talk about their connection to Country and ancestors. Gunditjmara have a strong connection, and responsibility, to Nyamat Mirring. Wadawurrung describe the interwoven relationship they have with Dja (Country), and the connection to their past, cultural practices and stories. Country represents a deep, intrinsic connection to the land, a source of identity, nurturing individuals and communities through	McDonald and Phillips, 2021 Bunurong Land Council, 2016 Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023 Wadawurrung Traditional Owners Aboriginal Corporation, 2020. Eastern Maar Aboriginal Corporation, 2015. Event ID 352	Indigenous tangible and intangible values are interconnected, relying on the health of Country, for cultural values to be maintained and passed down to future generations. Therefore, holistic assessment through the principles of ESD is appropriate.	Acceptable Levels Assessment, Intergenerational Equity Principle, Appendix F4,

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
	shared knowledge, stories, values, and traditions passed down through generations. For those who live away, the bond remains strong, with frequent returns to reconnect with both the land and the community, reinforcing their role in caring for and preserving Country.			

Cultural Features	Description	Source	Cause and Effect Pathway	Reference to Evaluation
	Seasonal knowledge. The Eastern Maar seasonal calendar follows six distinct seasons, Larneuk, Gwangal moronn, Petyan, Kooyang, Chinnup, and Ballambar, each marked by ecological signs that indicate changes in weather, animal behaviour, and the availability of important food resources, guide the Eastern Maar in caring for Country, aligning their activities with natural cycles rather than fixed Western seasons. The Gunditjmara follow a six-season calendar that guides their understanding of Country and informs when different natural cycles occur. The seasons are known (in English) as: Big Dry, Early Wet, Big Wet, Flowering Time, Fattening Up, and Drying Out. Changes in rainfall, water levels, wetlands, plants flowering, insect and animal behaviour guide Gunditjmara land-management, harvesting, and cultural activities. This calendar, rooted in careful observation of environmental rhythms rather than fixed dates, helps the Gunditjmara maintain a living, responsive relationship with their Country, ensuring that practices align with ecological and cultural cycles.l	Eastern Maar Aboriginal Corporation, 2015. Gunditj Mirring Traditional Owners Aboriginal Corporation RNTBC, 2023 Event ID EVT352	Traditional Owner seasonal calendars differ from the Western four-season model by using ecological cues, such as plant flowering, eel movement, whale migration, or bird nesting, to define the transitions between seasons. These seasons are specific to Country and reflect local ecological rhythms, whereas Western calendar seasons are fixed by date and do not adjust to environmental variability.	Annex 1 – 'Presence/Absence Analysis for Species within the Environment Planning Area' of the EP incorporates species "biological calendars," the distribution of their habitats, and the identification of environmentally sensitive areas, including breeding grounds, migration pathways, and resting areas.
	Access to Country is highly valued and a key aspect of cultural maintenance.	Woods (2020)	**Planned:** Physical Presence	Physical Presence, Appendix E1, *(cited in section 8.2.5)*

3.16.2 Magnitude of Effects

McConnell, et al, describes Indigenous tangible and intangible values as symbiotic and inseparable, explaining that Songlines depend upon the continued health of Country, including access and connection (McConnell, 2021). The tangible value must persist for the intangible value to continue to be maintained and passed down through future generations of Indigenous peoples. UNESCO (2003) and ICOMOS (2013) recognise that tangible and intangible cultural heritage are inseparable and mutually reinforcing: physical places, species and landscapes embody cultural memory and identity, while intangible traditions, meanings and practices give those tangible elements their significance and rely on them as the setting for their practice and transmission.

CGG's proposed management approach reflects this relationship. In CGG's impact and risk framework, cultural values and sensitivities are therefore treated as an integrated receptor. Impacts on the biophysical environment, such as changes to species behaviour, water quality or access to Sea Country, may also generate non-physical cultural impacts by affecting the meanings, practices, associations and obligations associated with those places and species. Accordingly, the impact pathways, risk evaluation and control measures consider both the potential effects on tangible cultural features and the intangible values that rely on their presence, condition and continuity. The Sea Country Protection Plan has been put in place to provide an ongoing opportunity for identification and management of any new cultural information that may emerge.

In addition, as Appendix F4 – Acceptable Levels Assessment, Section 5.10, demonstrates, the Regia MSS EP aligns with the principles of ESD. From the precautionary approach to intergenerational equity and the conservation of biological diversity, the EP process consistently reflects a commitment to safeguarding the marine environment, reducing environmental impacts and risks, and preserving the interests of future generations.

Throughout the environmental impact and risk assessment chapters, CGG established Environmental Performance Outcomes (EPOs). These EPOs act as key performance indicators to guide the activity's environmental goals. All EPO's are therefore relevant to safeguarding social, economic, and cultural features and values, ensuring protection across all areas. In addition, a specific social, cultural and economic features EPO has been put in place, reinforcing the protection and sustainability of these values.

3.16.3 Recovery Potential

There will be no interference with the knowledge of Sea Country or the practices and rituals that allow the knowledge to be shared and preserved, including access to Country. Songlines management of intangible cultural heritage can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003; ICOMOS 2013). Therefore, measures that promote the preservation of stories and songlines in the area would be suitable for managing these features. Regarding the intangible values of connection to Sea Country and the related knowledge, due to the absence of direct effects and immeasurable indirect effects, this is no recovery potential to assess.

3.16.4 Conservation Status

Conservation status of the identified tangible cultural features is described on a receptor level, within this document and the relevant impact and risk appendices (Appendix E1, E2, E3, E4, E5, E7, E9, D1, D2, D3, D4)

3.16.5 Mitigation Effectiveness

Mitigation measures are in place to protect marine fauna from the effects of elevated levels of underwater sound, minimise impacts from physical presence and artificial light, and decrease the likelihood of unplanned events. All apply to the protection of intangible cultural features and can be found in Appendix E1-E5, E7, E9. These measures are effective to ensure impacts are temporary and localised such that impacts on intangible cultural heritage values and sensitivities are not predicted.

CGG has adopted a Sea Country Protection Plan (SCPP). The SCPP is a mechanism that facilitates the identification and management of new information, relevant to the activity, through collaboration with First Nations people who decide to be part of the program.

4 Temporal Alignment of Key Environmental Values/Sensitivities

With many competing environmental values to be considered within the EP, a key approach to mitigation is to ascertain whether there are appropriate temporal windows within which disturbances could be minimised and/or avoided. To determine such windows, we ranked all identified key environmental values/sensitivities according to a 3-point scale for every month of the year.

For each individual group, taxa or sensitivity we ranked the importance of each month according to whether they were concentrated or aggregated relative to other months of the year. This was intended to capture spawning/reproductive behaviour and/or feeding behaviour that produces densities above yearly averages, including upwelling periods.

We used a 3-point ranking system;

1 - widely dispersed not displaying aggregating behaviour

2 – months surrounding peak aggregating i.e. shoulder periods

3 – months when aggregating behaviour is highest, such as spawning or upwelling

The resulting matrix was analysed to determine if there were natural patterns in the data reflecting monthly periods of high or low activity. A similarity index was calculated using the Gower coefficient for ordinal data such as ours (see Podani 1999). Clustering and non-metric multidimensional scaling (Clarke et al 2014) was then applied to the similarity matrix to produce a dendrogram and ordination. A heat map was also produced to further illustrate and clarify what groups are driving the observed temporal patterns in the data.

4.1 Results

The clustering analysis identified four distinct time periods across the year (Figure F3-25). The most heavily utilised time period was peak summer between January - March with April still significant enough to be grouped with the summer period but clearly becoming less important to a range of groups, reflecting the tail-end of the summer spawning period. November and December months while considered part of the austral summer period are more closely aligned to the larger grouping of May to October which encompasses non-summer spawners of which there are far less. These two months are shoulder months reflecting the start of the summer breeding season when environmental triggers for species to engage in aggregation behaviour have not reached peak levels.

The shade plot and ordination (Figure F3-26) together provide the detail about what species or sensitivities are linked to particular periods of the year. Twelve of the identified 15 key taxa/sensitivities are most closely aligned to the summer period between December and April. Only three are more closely aligned to the winter months. While numbers alone are not the deciding factor it is notable that in making decisions about timing of the Regia MSS there are far less of the identified groups reliant on the winter-spring-early summer period for their key reproductive and/or feeding behaviours.

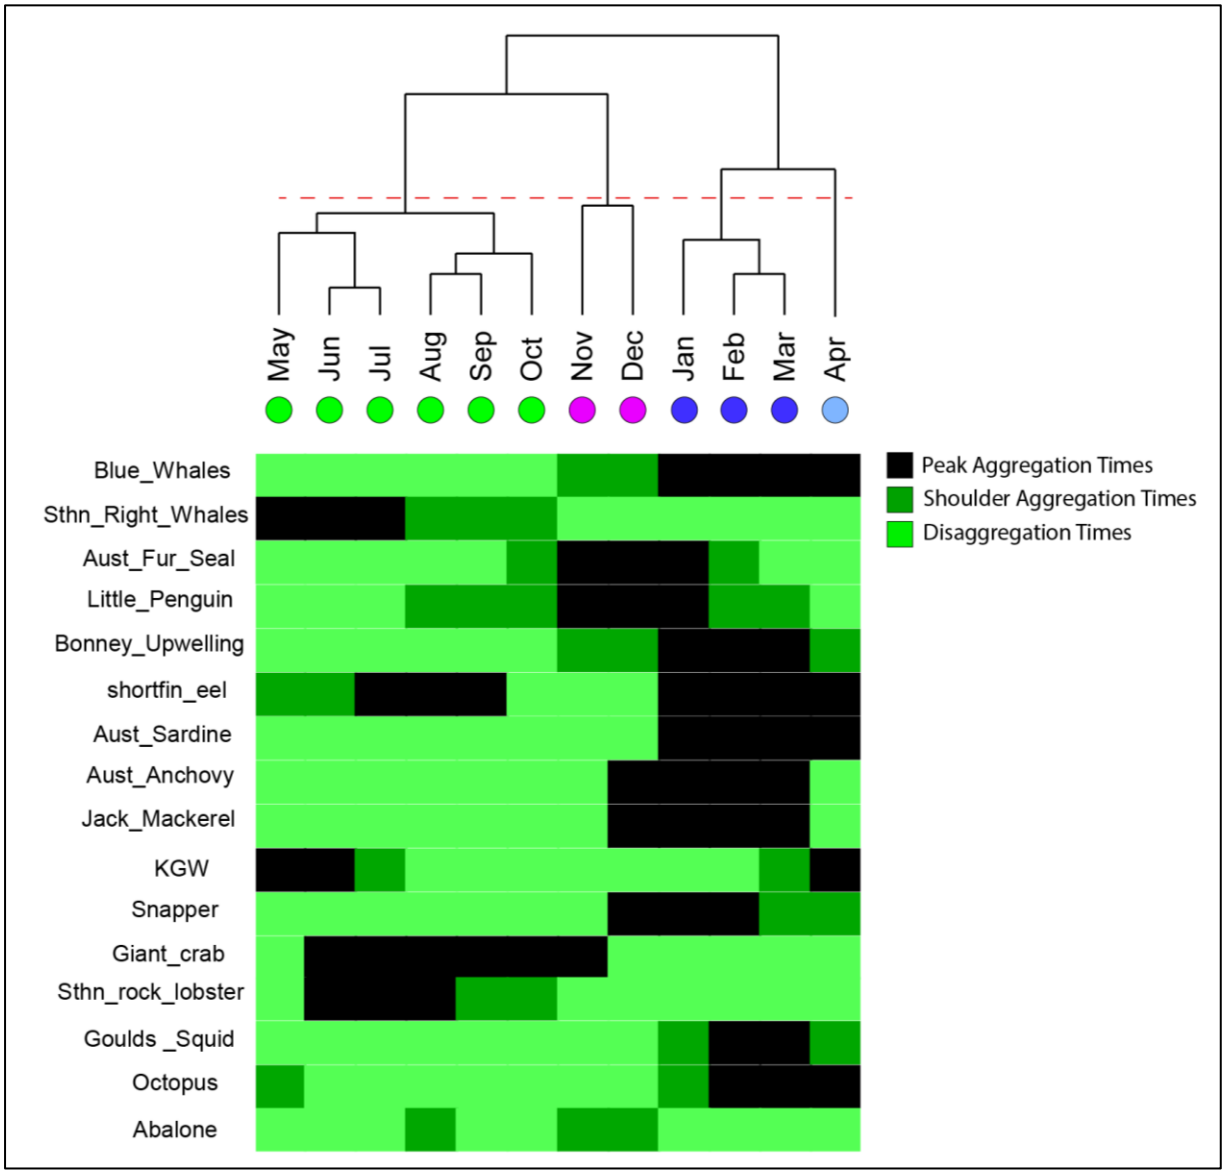

Figure F3-25 - Dendrogram from the cluster analysis indicating the grouping of months across the year according to their importance to the key sensitivities. The associated shade plot (~heat map) provides a clear visual picture of which species are influencing the groupings with the black boxes hjghlighting the most important times for each group.

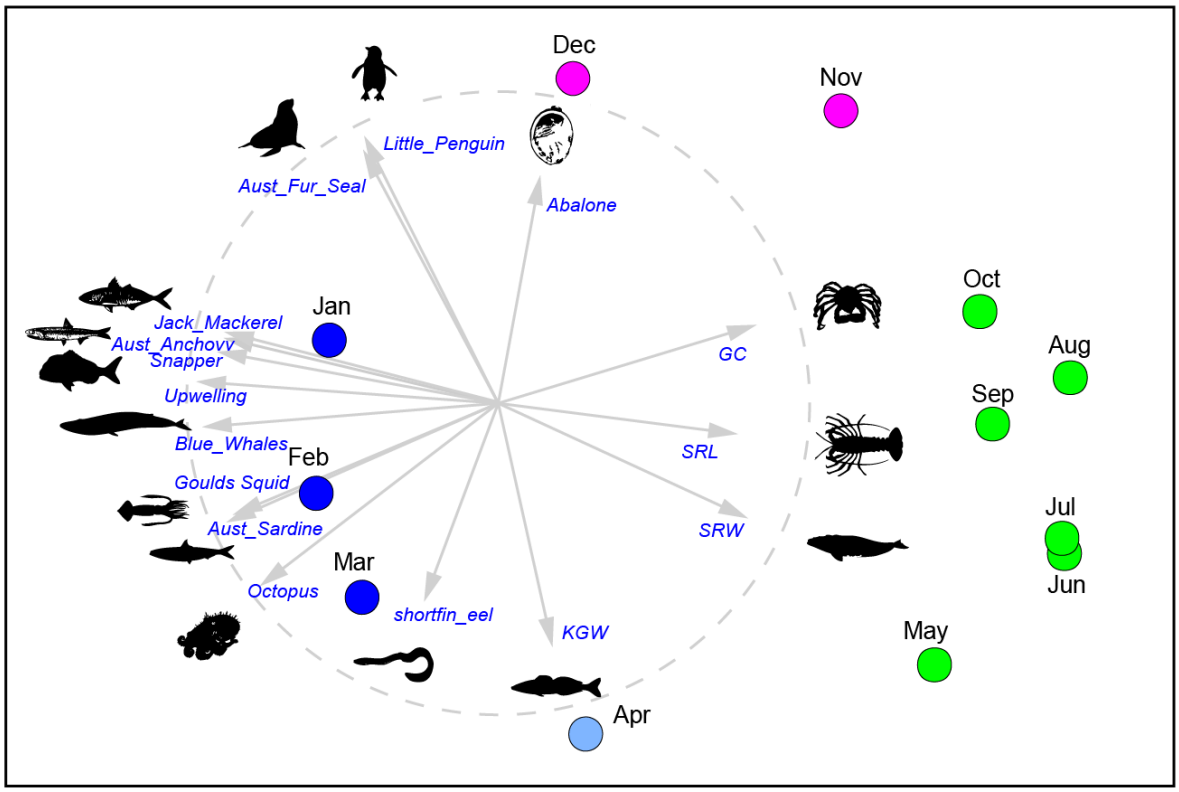

Figure F3-26 - A non-metric multidimensional scaling ordination illustrating the relationships between key values/sensitivities and months of the year. Months are coloured according to their groupings in the cluster analysis. Vectors representing the correlation with months of the year for each taxa/sensitivity are overlaid with arrows indicating the direction of strongest correlation. For example, the most important months of the year for Giant Crab (GC), Southern Rock Lobster (SRL) and Southern Right Whales (SRW) are the winter months ranging from May-October.

5 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in Annex 2.

6 Environmental Assessment Modifications Required

Following completion of the further assessments in this document, in line with the iterative nature of the process followed to prepare this EP, CGG has considered whether modifications are required to the originating environmental assessments (Appendices D1-D4 and E1 – E9). This feedback loop ensures that the environment assessments remain contemporary, accurate, and reflects feedback from the regulator and relevant persons.

Further Assessment Topic	Outcome of Further Assessments
Southern Right Whales / Koontapool (*Eubalaena australis*)	Further assessment identified the uncertainty of applying simplistic thresholds to managing behavioural disturbance, particularly to critical life stage activities. Further analysis of the sound propagation modelling led to the design of activity limitations that effectively eliminate the overlap of any sound exposures thought to have any significant behavioural effects to SRW.
Blue Whales / Wuulok (*Balaenoptera musculus*)	
Australian Sea Lion (*Neophoca cinerea*)	CGG has assessed the impacts of the Regia MSS to these receptors in detail throughout this EP and is satisfied through the implementation of mitigation measures and activity limitations, impacts have been reduced to below acceptable levels. As a result, no further assessment or mitigation is recommended.
Southern Rock Lobster (*Jasus edwardsii*)	
Giant Crab (*Pseudocarcinus gigas*)	
Glass Eels / Kooyong (*Aquilla australis*)	
Gould's Squid (*Nototodarus gouldi*)	
Pale Octopus (*Octopus pallidus*)	
Blacklip Abalone (*Haliotus rubra*)	
Pink Snapper (*Chrysophrys auratus*)	
King George Whiting (*Sillaginodes punctatus*)	
Plankton Communities and the Bonney Upwelling System	
Spawning Patterns	
Budj Bim Cultural Landscape	
Cultural Features of the Environment	CGG has assessed the impacts of the Regia MSS to this receptor in detail throughout the EP and has concluded the defined acceptable levels and EPOs for this receptor were not sufficiently detailed. As such, CGG has re-assessed and added more defined acceptable levels and EPO's relating to this receptor in the impact and risk appendices (D1-D4 and E1-E9).
Little Penguin (Eudyptula minor)	CGG has assessed the impacts of the Regia MSS to this receptor in detail throughout the EP and has concluded the defined acceptable levels and EPOs for this receptor are not sufficiently detailed. As such, CGG has set additional defined acceptable levels and EPO's for each life cycle stage for little penguins in EP Appendices E5 and

	update the environmental performance commitments in Appendix G1.

8 Revision History

Version	Date of Revision	Author/Reviewer	Summary of Changes
0.0	2 October 2023	MS	Table of contents established and commenced evaluation.
0.1	6 December 2023	MS/AH/SJ/CT	Concluded demonstration of whether environmental impacts and risks from the Regia MSS were of an acceptable level.
0.2	20 December 2023	MS	Review and update following comments.
1	5 January 2023	MS	Formatting complete and published for public comment.
2	15 May 2024	MS	Review and update following public comment
3	4 November 2024	AH/RH/CT/MS	Added further assessments of Budj Bim, cultural features, and little penguins. Updated following feedback from NOPSEMA.
4	16 April 2025	MS	Updated following NOPSEMA OMR 1 Letter
5	6 December 2025	MS/EOR	Updated following NOPSEMA OMR 2 Letter

Annex 1

Public Comment

Table F3-8 shows how the Matters raised during public comment have been incorporated into the EP in this document.

Table F3-8 - Public comment input into the preparation of the EP.

Matter	Matter ID	Changes made arising from public comment
Matter: Flawed argument regarding animals moving away	I04	CGG has considered these claims and has updated the EP Impact Assessments (Appendices E, and F where relevant) to clarify that, while some displacement is expected from mobile taxa during the Regia MSS, the survey will not preclude animals from the Operational Area in its entirety. Instead, animals are expected to temporarily move away from the active acoustic source, but once the source passes, animals will be free to move back into the habitat that they departed from.
Matter: Impacts to whales' food source	M10	CGG has undertaken further investigation and provided an additional detailed responses related to these this matter in EP Appendix F3, Section 5.2.10.1.
Matter: Limitations of MFOs/MMOs when detecting marine mammals	M43	CGG has considered these claims and has updated EP Appendix G2 (Fauna Management Plan) and Appendix F3 (Acceptability Assessment) and EP Appendix G1 (Environmental Outcomes) to include an additional MFO/ PAM operator to ensure fatigue management is appropriately addressed with allowance for 24/7 coverage.
Matter: MFOs/MMO's do not have a 360-degree view, the use of one MFO/MMO is inadequate.	M45	CGG has considered these claims and has determined that additional MFO coverage is appropriate to further mitigate the potential for whales to go undetected within the 3 km observation zone. Consequently, CGG has updated EP Appendix G2 (Fauna Management Plan), EP Appendix F3 (Acceptability Assessment) and EP Appendix G1 (Environmental Performance) to include an additional MFO/ PAM operator will be present on the vessel to support fatigue management. In addition to the two MFOs on the seismic vessel, two dedicated, trained and experienced MFOs will be always onboard a dedicated spotter vessel. In addition, officers of the watch on the attending support vessels will be trained to identify whales during daylight hours to support the visual detection of marine mammals.
Matter: The use of two PAM operators is inadequate.	M49	CGG has considered these claims and has updated EP Appendix G2 (Fauna Management Plan) and Appendix F3 (Acceptability Assessment) and EP Appendix G1 (Environmental Outcomes) to include an additional MFO/ PAM operator to ensure fatigue management is appropriately addressed with allowance for 24/7 coverage.
Matter: No modelling of impacts to zooplankton	P04	CGG has considered these claims and is satisfied that all available and relevant modelling studies on seismic effects have been included in the knowledge base used to develop the EP, and the EP has been updated to include reference to recent publications.
Matter: Extent of impacts to zooplankton	P06	CGG has considered these claims and is satisfied that the extent of seismic effects on zooplankton have been appropriately assessed, and the EP has been updated to include reference to recent publications.
Matter: Impacts of underwater sound on octopus	F11	CGG has considered these claims and to ensure that the most up-to-date assessment has been made has provided an extra Acceptability Assessment within Appendix F3 of the EP, which more clearly defines the levels of risk to Octopus from the proposed Regia MSS.

Matter	Matter ID	Changes made arising from public comment
Matter: Impacts on Fisheries (general)	F12	CGG has considered these claims and has added specific analyses of further species including Abalone, Snapper, and Octopus to the Acceptability Assessment within Appendix F3 to ensure all concerns have been investigated and the level of risk has been clarified according to the available evidence.
Matter: Impacts on spawning aggregation areas for King George Whiting	F14	CGG has considered these claims and has added specific analyses for King George Whiting to the Acceptability Assessment within Appendix F3 to ensure all concerns have been investigated and the level of risk has been clarified according to the available evidence.
Matter: Impacts on abalone fisheries	F16	CGG has considered these claims and is satisfied that through scheduling management of the proposed Regia MSS any potential interaction with abalone stocks can be minimised and has conducted a further assessment on abalone in EP Appendix F3 (Acceptability Assessment), Section 5.2.8, which provides a more detailed species-specific examination of impacts.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and M#01: Activity limitation, to reflect that the sound source will not be discharged at full power from areas which have been predicted to result in an exceedance of the safety criterion human health safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, G1 and G2).
Matter: Lack of detail on EPBC-listed species and enforceable measures	I17	CGG has updated EP Appendix F3 (Acceptable Levels Assessment) to include an assessment for the Australian sea lion in response to these claims.

Annex 2

Objections or claims raised through consultation

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4002	Risks to the lives of ancient marine mammals	The titleholder acknowledged the feedback, noting that impacts and risks to marine mammals are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to marine mammals are outlined in the EP in E7 and G1.	5114
4334	This statement opposes seismic blasting in areas designated as Sacred Birthing Grounds for Southern Right Whales, underlining the cultural and environmental significance of these grounds. It also expresses solidarity with the Gunditjmara Traditional Owners, acknowledging the cultural heritage and environmental stewardship of this region by Indigenous communities. The feedback emphasises the perceived risks to both marine life and Indigenous heritage in the area.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country (Event ID 2101).	2101
4332	This statement calls for a respectful approach, urging stakeholders to engage deeply with Indigenous knowledge and perspectives, including the views of Elders and Traditional Owners. It emphasises empathy and a meaningful understanding of the environmental and cultural impact of activities on marine life.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country.	2101
4280	The stakeholder expresses strong opposition to the exploration for gas near Deen Maar (Lady Julia Percy Island), emphasising its significance to the local Indigenous community, comparable to the cultural importance of Uluru. They highlight its unique status as Australia's only offshore volcano and assert that such an exploration would be inappropriate in a site of sacred significance, arguing against the project's alignment with respecting Indigenous heritage and environmental integrity.	We are aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how we protect and preserve the values of this site (Event ID 2108).	2108

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4303	The stakeholder stated that they were concerned about both tangible and intangible cultural heritage, as well as submerged underwater archaeology.	Indicated that we will be performing non-invasive work in a site survey and could work with the TO's to help identify culturally significant sites (Event ID 1891).	1891
4271	The stakeholder asserts that seismic blasts will have a direct negative impact on marine life, specifically mentioning that an “exclusion zone” will not effectively prevent the effects of the blasts from travelling through the ocean.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable. The titleholder is aware of the environmental, cultural, and spiritual importance of Deen Maar and will talk with local traditional owners to learn more about Deen Maar and understand how to protect and preserve the values of this site.	2108
4216	Stated that they feel a sense of reparability to listen to the Guntijimara people and what they wish for their sea country and ancient song lines.	Titleholder responded to the individual confirming consultaiton was currently being attempted with First Nations Custodians of Country and to engage with them on the activity. Titleholder requested that the individual encourage any potentially relevant people they may know to contact the consutlation team and advised that consultation is an important aspect of the marine seismic survey planning process, community input and feedback will be considered in the planning and execution of the survey.	842
4035	Comment about the impact of human activities on wildlife habitats and calls for a halt to such destruction for profit. It emphasises the negative consequences of competing interests in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2109
4036	Comment claims that seismic activity is known to cause significant harm to marine life, arguing that the proposed project will lead to further degradation of the coastal environment and should be abandoned as a result.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2098
4038	Commenter highlights that fish populations have been adversely affected by seismic testing over the past few years, leading to a decline in their numbers. This decline could also impact other marine species and have negative effects on whale populations.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. A fauna management plan is in place to manage whale interactions.	1432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4004	Seismic blasting in our ocean so close to our beautiful home is deeply concerning given the toll will inevitably take on sea life and further unknown impacts.	The titleholder acknowledged the feedback, noting that impacts and risks to sea life are assessed in the Environmental Plan (EP) and can be found in E1 to E9 and F3. Measures to minimise adverse impacts to sea lufe are outlined in the EP in G1.	2757
4006	A call for a moratorium on seismic surveying in biologically important areas during times when whales are present, emphasizing the need to protect vulnerable species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine mammals are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to marine mammals are outlined in the EP in E7 and G1.	612
4008	Acceptable levels are subjective and based mostly on limits set by proponent.	Agreed, noting the subjectivity in the process as a whole. Agreed to include more information on the acceptability argument as a whole and not just aspect-by-aspect. Provided ALARP report (Event ID 4280)	3705
4009	Activities are timed to avoid species' peak migration and foraging behaviors.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in E7 Section 8 and G1.	653

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4010	Activities that may prevent or displace Pygmy Blue Whales or Southern Right Whales' use of BIAs are avoided.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales and ensures The Regia MSS does not prevent SRW and BW utilising their BIAs include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in E7 Section 8 and G1.	653
4012	AMCS critiques the proposed monitoring plan for detecting foraging whales and Southern Right Whales in Biologically Important Areas (BIAs), which relies on two marine fauna observers (MFOs) aboard the survey vessel during daylight hours. They note that this approach may not reliably detect whales that are submerged, in low visibility conditions, or during nighttime operations. Given the potential for seismic surveys to cause temporary and permanent injury to EPBC-listed cetaceans, AMCS requests that CGG provide a comprehensive monitoring plan that ensures reliable detection of whales in all weather conditions and throughout the entire operational schedule, rather than just during daylight or optimal visibility.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in E7 Section 8 and G1.	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4018	Any assessment of potential mortality or injury effects on plankton must consider natural mortality rates. However, relying on natural mortality rates is irrelevant, as seismic survey-induced mortality will compound existing natural mortality, thereby increasing overall mortality rates. The Environmental Impact Assessment (EIA) does not acknowledge that this additional mortality could significantly affect plankton reproduction. The continuous nature of the blasting (every 10-15 seconds for 60 days) will likely hinder zooplankton recovery more than indicated in the EIA, which treats seismic-induced mortality as separate from natural mortality. AMCS requests that CGG explicitly evaluate the cumulative and additive impacts of continuous seismic surveys on plankton communities to provide a more comprehensive assessment of their effects on this critical trophic level and overall ecosystem health.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E2 and F3. Contrary to this feedback our intent within the assessment has been to expressly consider the compounding effect that the sound emissions would have on plankton - as it is stated in the quote provided. We have provided references for our application of recovery rates (Huntley and Lopez 1992, Richardson et al 2017) and respectfully request that AMCS provide your references for the claim that "The continuous nature of the blasting (i.e. every 10-15 seconds for 60 days in a row) will affect the ability of zooplankton communities to recover beyond what is presented in the EIA" so that we can consider them.	3384
4022	Attendees voiced concerns about how seismic activities could impact the sustainability and fish-ability of the immediate and nearby areas.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1529
4023	Behavioural Response Threshold & Seismic Sound Avoidance: If CGG conducts seismic blasting within 82.8 km of any Fairy Penguin colony during the breeding season, the penguins may experience discomfort and hearing interference, leading them to alter their behavior to avoid the seismic source. This distance combines the maximum foraging range for a single day trip and the modelled distance for behavioral response thresholds.	CGG has included the study by Pichegru et al. (2017) on penguins in the EP and has referred to this study multiple times across multiple documents See specific examples below: B8 Seismic Study Report, Section 7, Birds: E5 Underwater Sound- Birds Section 6 F3 Section 4.4.1, 4.4.3 and 4.4.4.	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4024	Birds and the little Penguin Colony having to travel further away for food and shelter during seismic testing times, causing stress and fatigue.	The titleholder acknowledged the feedback, noting that impacts and risks to penguins are assessed in the Environmental Plan (EP) and can be found in E5 and F3. F3 focuses on foraging capabilities in the area and the potental oerlap with the Regia MSS. There is an overlap between the foraging range of Little penguins at Deen Maar and the Regia MSS. This overlap is ~5.3 hours spread over 3.5 weeks, therefore, we do not belive little penguins will be displaced from foraging areas.	1784
4025	Bodily harm to Fairy Penguins: Fairy penguins can be harmed and killed by shock waves from underwater blasts.	The Cooper (1982) paper mentioned here is referring to injury/mortality cases with bird species as the result of underwater explosions triggered to fragment limestone. Use of an explosive charge such as dynamite does lead to significant changes in the seabed, sedimentation, and harm to marine life in close vicinity. Underwater detonations are an unconstrained, omnidirectional force of greater intensity and destructive capability than a highly controlled and directed seismic pulse (Koschinski 2011). No comparable effects can be associated with the proposed Regia MSS. CGG therefore does not believe that impacts from explosive blasting and exploratory seismic activity in the marine environment can sufficiently and accurately be compared, and CGG does not believe the threats to Little Penguins highlighted in this section have the potential to occur as a result of the Regia MSS. As a result of this relevant persons claims, CGG carried out an additional assessment on Little Penguins in F3.	5117
4026	Catch rate decreased significantly after the survey was conducted.	The titleholder acknowledged the feedback, noting that this claim was assessed in F3 where historical data was analysed for any correlation between historical seismic survey and a reduction in catch rates. No such correlation was found as shown in the analysis in F3.	5190

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4027, 4385	Central Place Foraging Limitations: All five Western Victorian Fairy Penguin colonies are likely to be directly impacted during the breeding season when adult penguins have limited foraging ranges. The Middle Island population is expected to be the most affected, as it is centrally located within CGG's Active Source Area for seismic blasting. Due to the coastline's geography, this population has the least ocean area available for foraging, with a significant portion of their range falling within the Active Source Area. Consequently, regardless of their foraging direction, the penguins will struggle to avoid the impacts of CGG's seismic activity.	When describing home ranges for feeding it is important to distinguish between maximum distances, total distance travelled and mean/median distances. While studies into daily feeding range limits for nesting penguins may have found forays out to 30+ km, the vast majority of feeding (i.e. mean distance travelled) is occurring with 15-20 km of their nesting sites. Longer distance forays are the exception not the norm and this has been confirmed across multiple studies from multiple locations (e.g. Berlincourt & Arnould 2014, Pelletier et al 2014, Philips et al 2019, Philips et al 2022). Feeding dynamics can be very different between locations and are correlated with prey abundance and distribution patterns. As we have demonstrated with references throughout the EP the Otway region is well supplied with sardines and squid, with quality of food resources correlated with nearness to upwelling areas (Norman et al. 2017). The proposed survey lines for the Regia MSS that will be closest to the coast are outside the core feeding areas for feeding penguins during nesting periods. Moreover, each successive line (lines will run parallel to the coast) will be located further and further away from the coast, hence the time spent within proximity to the coast will be small and continuously diminishing. It is anticipated that MS acquisition will occur over a total of 2-3 days in the distance range of 25-40km declining in intensity - relative to the coast - with every pass. The extent of the disturbance will be limited to a few hours each day over a maximum of 3-4 days at a distance NOT encompassing the main feeding ranges of nesting birds. The scale of such an impact is not predicted to impact on the viability of any local fairy penguin colonies.As a result of this relevant persons claims, CGG carried out an additional assessment on Little Penguins in F3.	5117
4033	Claim that seismic testing is proven to damage and kill marine life.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1024
4035	Comment about the impact of human activities on wildlife habitats and calls for a halt to such destruction for profit. It emphasises the negative consequences of competing interests in the area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2109

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4036	Comment claims that seismic activity is known to cause significant harm to marine life, arguing that the proposed project will lead to further degradation of the coastal environment and should be abandoned as a result.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	2098
4038	Commenter highlights that fish populations have been adversely affected by seismic testing over the past few years, leading to a decline in their numbers. This decline could also impact other marine species and have negative effects on whale populations.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. A fauna managment plan is in place to manage whale interactions.	1432
4046	Concern about potential impacts to environmental assets and cultural heritage within Bunurong Country.	Titleholder acknowledged this concern and noted that potential impacts to cultural features from physical presence is assessed in E1 of the EP and in F3 Section 4 . CGG will implement a Sea Country Protection Program to ensure impacts to cultural heritage are minimised.	2371
4047	Concern about spawning activity of the Giant Crab, rather than the impact of the fishing overlap given exclusion of surveying at +200m water depths.	Titleholder acknowledged this concern andcarried out an additional impact assessment for Giant crab and spawning species has been included in F3. There is expected to be no measurable effect on giant crab populations as a result of the survey.	4076
4048	Concern about sustained noise impact on cetaceans in the area.	CGG has conducted a thorough impact assessment relating to underwater sound and marine mammals, with mitigation measures and management adopted as a result of both this assessment (which includes relevant marine mammal species) (E7) and a further assessment (which includes two key whale species: Blue Whale and SRW) (F3). A comprehensive fauna management plan was also established as part of this EP development (G2).	1835

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4050	Concern about the destruction of smaller sealife and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures are outlined in the EP.	1669
4057	Concern about the long-lasting impacts of the proposed activity on marine life and coastlines, highlighting ecological and cultural repercussions.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation nor interfere with cultural practices or values. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1022
4061	Concern about the welfare of whales, seals, and birds due to the activity.	The titleholder acknowledged concerns outlined in email regarding welfare of whales, seals and birds due to the activity. Outlined approach to assessment that included demonstrating that impacts to these species will be of an acceptable level and advised that it had been determined that is acceptable to have a temporary behavioural change such as moving away from the survey vessel and that injury or long-term impacts were not acceptable.	835
4063	Concern for various birds and little penguins and the effects of sound and light.	Impacts from underwater sound and artificial light on birds, including little penguins, are assessed in the Environmental Plan (EP) and can be found in E5 and E9. Further assessment of little penguins was also undetook by CGG to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level. Measures to minimise adverse impacts on birds in the region are also outlined in the EP.	1783
4065	Concern regarding comparing spaital placement of the previous surveys	This concern has already been considered in the analysis provided to this relevant person and CGG notes that the placement of the previous surveys is not a determining factor in the assessment because of the broad spatial dispersion of fish eggs and larve associated with this fishers concern.	4639

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4066	Concern regarding the potential effects of the proposed activities on zooplankton populations and the subsequent impacts on marine ecosystems.	The only effects to zooplankton come from elevated levels of sound. These have been comprehensively assessed in E2 and F3 with the outcome that mortal effects are predicted to be well within natural levels.	2027
4067	Concern regarding the repeated seismic blasting in the area, which may have effects on marine life. Stakeholder is questioning the impact of multiple blasts and the potential for further exploration by other companies, particularly regarding the sale of seismic data.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Cumulative impacts are also assessed as negligible.	879
4069	Concerned about the harm being inflicted on oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1673
4070	Concerned about the harm to King George Whiting species and disagreement with the provided information of having no impacts on the mentioned species in the region.	The titleholder agreed to undertake further analysis noting the issues raised needed some further evidence. This analysis can be found in F3 Section 4 of the EP	4497
4071	Concerned about titleholder analysis and King George whiting advection pathway and impact of proposed activity on their business. Stated a spatial and temporal comparison is required.	The titleholder agreed to undertake further analysis noting the issues raised needed some further evidence. This analysis can be found in F3 Section 4 of the EP	4967
4074	Concerns about implications for the population of Rock Lobsters in the area going forward.	This claim has been thoroughly assessed in E1 and E5, and F3 for southern rock lobsters. The known effects to individual lobsters are not predicted to have any measurable effect on population levels or dynamics.	2773
4075	Concerns about marine life and ecosystems.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for various marine fauna (see G1)	2117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4076	Concerns about potential disturbance to the marine environment, including marine parks and areas of Biological Importance.	The titleholder acknowledged this concern and noted that potential impacts to the marine environment including marine parks and biologically important areas as a result of the Regia MSS is assessed in E1 to E9 and F3 of the EP. There will be will be no activities with Australian Marine Parks. All areas of biologic importance have been identified and assessment in the respective impact and risk assessments.	2278
4077	Concerns about potential harm to zooplankton, whales, dolphins, sharks, seals, the Bonney Upwelling, rock lobster fishery and other local fishing industries.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identiifed with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	722
4079	Concerns about the impact of seismic activities on the Bonny upwelling.	The Bonney Upwelling is subject to further assessment in F3 and the values (plankton) of the Key Ecological Feature have been assessed in E2. There are limitations in place to ensure there is no discharge of the sound source within the Bonney Upwelling KEF and the effects to zooplankton are well within natural mortality levels.	2997
4083	Concerns about why more seismic needed and what time of the year was the survey going to be done to minimise impacts to fishing for sharks, lobsters, squid	Titleholder acknowledged this concern and each of the species within this claim has been subject to extensive assessment in E1, E3, E4 and F3 with various measure adopted to limit the sound exposure to the lowest level possible to meet geophyiscal objectives and to protect marine fauna (see G1).	740
4084	Concerns for reduced landed catch during the survey due to displacement. Have historical data going back many years to show if changes.	The titleholder has acknowledged this concern and note that displacement is assesed in the EP E1 and F3 as a potential impact of the physical presence of the activity. Control measures to reduce impacts to commercial fishers as a result of displacement are outline in EP. The Adjustment Protocol stipulates an adjustment process will be implemented if a commercial fisher has a financial loss due to the Regia MSS. The adjustment process will be developed in consultation with the fishery associations that represent the commercial fishers that fish within the Operational Area. While onshore fish processing is not covered by NERA protocol a claim will be considered based on appropriate historical evidence.	4108
4085	Concerns of damage to the marine environment by seismic blasting and gas extraction	All available scientific evidence is used to inform the environmental assessment on seismic impacts. There are no impacts identified that will affect the population stability of any taxa.	825

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4086	Concerns raised by specific fishers about King George Whiting.	The titleholder acknowledges this concern and carried out an additional impact assessment for King George Whiting and spawning species that has been included in F3. There is expected to be no measurable effect on KGW populations as a result of the survey.	4627
4088	Condemns seismic testing, asserting that it is deadly to marine life and unacceptable for ocean ecosystems. Call for a total ban, citing the large number of marine animals harmed by the practice. Argument that the destruction of marine ecosystems and the fishing industry is unjustifiable and express frustration, telling the parties responsible to stop.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	422
4092	Do not disrupt their whale songlines.	The cultural features of the environemnt have been assessed in E1 and further in F3. The effects to physical receptors are temporary and localised and there is no interference with the practices or rituals required to maintain a spiritual connection to Country. Songlines have been explicitly considered in these assessments.	2254
4093	Doubted the effectiveness of mitigation measures, and believed the reports/information provided were absent of action /intention.	The mitigations applied by CGG are industry standard and comply with government policy. They have been proven to be as effective as reasonably practical for a number of years. The measures adopted to protect species from the aspects of the activity are found in the respective impact and risk assessments.	2830

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4096	Environmental Risk: Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artifical light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity.The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures are outlined in the EP.	2766
4102	Expresses opposition due to proximity to local fishing industries. Emphasises concern about potential risks this testing poses.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Adjustment protocol in place for fishers to seek compensation if impacted by MSS.	428
4106	Feedback raises concern for the welfare of whales that come to calve in local waters, emphasising the need to consider the impact of proposed activities on these vulnerable marine animals.	We will not survey while SRW mothers and calves are in the area. Oil and gas has successfully co-existed with wildlife in this area for 25 years and we are doing everything we can do protect the wildlife and natural beauty of the area (Event ID 1781).	1781
4112	Highlights concern for the disregard of wildlife and humans in environmental decisions, emphasising that extinction is irreversible.	The impact and risk assessments undertaken by CGG have not identified any effects that will led to extinction of any species. A search for unacceptable impacts was undertaken in F4 and found no pathway this these types of significant effects.	1781
4116	Ignoring reputable scientific studies showing harm from seismic testing	CGG refuted this claim and provided the relevant person with 44 peer review studies directly relevant to their concerns as well as a thorough assessment of the effect on spawning and recruitment to their fishery.	4551

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures have been outlined in the EP.	2274
4120	Indigenous Heritage: Advocacy for the protection of the sacred Sea Country of the Otway Basin and objections to the proposal's potential destruction of indigenous cultural heritage.	The cultural features of the environemnt have been assessed in E1 and further in F3. The effects to physical receptors are temporary and localised and there is no interference with the practices or rituals required to maintain a spiritual connection to Country.	2383
4121	Indigenous Heritage: Objection to the proposal due to the potential destruction of a sacred indigenous location in the Otway Basin.	There is no physical interaction with the seabed or coastlines which would lead to destruction of any location. The cultural features of the environemnt have been assessed in E1 and further in F3. The effects to physical receptors are temporary and localised and there is no interference with the practices or rituals required to maintain a spiritual connection to Country.	2766

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4122	Indirect Impact: Changes To Prey Availability: CGG cannot assure that the proposed seismic blasting will not reduce the prey available in the breeding season foraging areas of the Fairy Penguins. Therefore, seismic blasting should be prohibited in these critical areas due to the negative impact it would have on the prey species that the penguins rely on for survival and feeding their young.	We refer you to E - Impact Assessments - E2 – Underwater Sound – Plankton, and F – Decision Making – F3 – Acceptability Assessment - Sections 4.2.7 – Goulds Squid, 4.2.12 – Plankton Communities and Bonney Upwelling, and section 4.2.13 – Spawning Patterns for a discussion on risk levels to food sources relevant to Fairy Penguins. Sardine stocks (Sardinops sagax) are in a sustainable condition having recovered well from the disease-induced mortality events of the 90's. Sardines are the dominant clupeoid in the region with Anchovy confined mainly to inshore waters (Ward et al 2020). Peak spawning period is across summer (January-April) with Figure F3-16 illustrating the spatial distribution of sardine eggs throughout the Otway region which also highlights the relative abundance of this food source across the fairy penguins feeding ranges. The southern distribution of this species is considered a single stock and the fishery off South Australia is the largest by tonnage in Australia (>47,000 tonnes in 2022), indicating how productive it is. Behaviorally, pelagic schooling species such as sardine are highly mobile in space and time which makes them highly resistant to localized and/or transient disturbances. It is also the case that Australia's less-productive pelagic ecosystems means predators are less dependent on only one prey species and can feed opportunistically across a wider variety of species. This has been seen with dietary examinations of Fairy Penguins who can switch between sardines, anchovies and squid as encountered. Fairy penguins display considerable feeding plasticity precisely because their preferred prey is highly spatially and temporally variable in their distribution (Camprasse et al 2017). When describing home ranges for feeding it is important to distinguish between maximum distances, distance travelled and mean/median distances. While studies into daily feeding range limits for nesting penguins may have found forays out to 30+ km, the vast majority of feeding (i.e. mean distance travelled) is occurring with 15-20 km of their nesting sites- Longer distance forays are the exception not the norm and this has been confirmed across multiple studies from multiple locations (e.g. Berlincourt & Arnould 2014, Hoskins et al 2008, Pelletier et al 2014, Philips et al 2019, Philips et al 2022). Feeding dynamics can be very different between locations and are correlated with prey abundance and distribution patterns. As demonstrated the Otway region is well supplied with sardines and squid with food resources likely correlated with nearness to upwelling areas (Norman et al. 2017).	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4127	Lack of Acknowledgement of the Fairy Penguin Breeding Colonies in Western Victoria in CGG's Environment Plan, as well as No Acknowledgement of their Biologically Important Foraging Areas.	We believe there is some confusion here on what Biologically Important Areas are. Biologically Important Areas are regions where aggregations of individuals of a particular species are known or likely to display important behaviours such as breeding, foraging, nesting or migration. They have been identified from the literature and using expert scientific knowledge about species' distribution, abundance and behavior (Australian Marine Parks, 2024). Biologically Important Areas were established to guide decision-making under the Environmental Protection and Biodiversity Conservation Act of 1999. These areas have been designated for a specific group of protected species, selected based on their conservation status and the availability of dependable spatial and scientific data. There are two sources we would use to identify Biologically Important Areas, the Protected Matters Search Tool and the National Conservation Values Atlas website. The closest Fairy Penguin BIA is around Christmas Island (off the northeast coast of King Island), and it is a designated foraging BIA. Nonetheless, just because the colonies are not BIA's doesn't mean they don't deserve consideration in our Environmental Plan. Little Penguins are discussed in detail in E56 Section 4.5, here we have acknowledged the breeding colonies on both Middle Island and Lady Julia Percy Island. See excerpt from E5 below: "The Little Penguin was identified as breeding known to occur within the area potentially affected by underwater sound (Annex 2). Within this area, breeding occurs on Lady Julia Percy Island and Middle Island." CGG will amend the Environmental Plan to include references to fairy penguins located at London Bridge, Gibson Steps and Lawrence Rocks.	5117
4128	Lack of adequate monitoring of species present or likely to be impacted.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions regarding species that may be affected by the Regia MSS. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	3237
4130	Lasting and unrecoverable damage mentioned.	The titleholder acknowledged the feedback, noting that risks and impacts are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on marine life are outlined in the EP in G1.	4808

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures have been outlined in the EP.	2274
4135	Mention of being heavily impacted by the whales in the tourism industry.	Title holder has undertaken a thorough analysis and assessment of all relevant literature related to Marine Mammals to inform its decisions. The MSS will not impact the population stability of marine mammals within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1244
4136	Mention of considerable damage to marine life outweighing the benefits of mapping seafloors for gas drilling.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	1389
4137	Mention of installing sound curtains underwater to reduce destructive sound.	Bubble curtains are not suitable for a moving activity, nor are other measures such as acoustic blankets. This has been included in the ALARP assessment.	2830

4138	Mitigation Deficiencies: CGG lacks a reliable method to consistently detect the presence of Fairy Penguins. To minimize impact, seismic blasting should occur during their breeding season when their foraging range is limited to shorter daily trips, and it should be conducted at least 82.8 km away from each colony, assuming the JASCO sound modeling is accurate for the species.	CGG has undertaken an extensive assessment of all the available scientific literature and other relevant information sourced from reports and websites. Our process is 'live', meaning we are continually checking and updating our plans if new information comes to light which is relevant to assessments. For example, we have been able to add a recent paper, Wei and Erbe (2024) Sound reception and hearing capabilities in the Little Penguin (Eudyptula minor): first predicted in-air and underwater audiograms. Royal Society Open Science 11(8): 240593 which has calculated sound threshold levels of Little Penguins and provides a more robust estimate than has previously been used. It was reassuring to then see that our modelled sound thresholds were appropriate, based on this newly published estimate. The principal aims of the environmental assessment are to ensure there is no impact to population stability and to reduce any potential impacts to "As Low as Reasonably Practicable". The assessment has concluded that there is not a significant risk to the stability and resilience of the Little Penguin population in the region. This outcome is derived from the cumulative effects of mitigation that the Regia MSS has committed to and which includes • Timing of the survey – avoiding the prime egg-laying and chick raising period • Location of survey outside core feeding areas – the majority of feeding is undertaken within 20km of nests as borne out from multiple studies cited in our EP. The seismic is occurring outside this zone with the exception of a very small section adjacent to Deen Maar which is within 17.5 km of the island. However, sum exposure for this area is 5 hours over 3 weeks which is immeasurably low exposure. • Minimal time in proximity to core feeding zones – the seismic acquisition is a continually moving process and will not ever be at full power while stationary. This provides ample opportunity for individual animals to move away from a source even as the source is also moving hence expanding the gap as quickly as possible. • Feeding is equally possible along the coast hence the area available for feeding is substantially larger than implied. • Anchovy stocks are in good health at the moment according to state fishery statistics and these are the core food source for Little Penguins. • If feeding birds are found within 500m of an active seismic line then the source will be switched to low power until outside 500m again. This measure is not expected	5117

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		to capture all penguin feeding movements however it does provides a mitigation measure to allow birds feeding to continue doing so with minimal disturbance. The total sum of mitigation measures provides a level of impact that fulfills ALARP and importantly does not provide a pathway to population impacts.	
4140	No mention of ceasing activities when whales are present in the area.	CGG has conducted a thorough impact assessment relating to underwater sound and marine mammals, with mitigation measures and management adopted as a result of both this assessment (which includes relevant marine mammal species) (E7) and a further assessment (which includes two key whale species: Blue Whale and SRW) (F3). A comprehensive fauna management plan was also established as part of this EP development (G2).	1835
4145	Opposes seismic exploration claiming it is dangerous to all marine life. Cannot ensure zero risk.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	427
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high-decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4148	Opposition to seismic blasting and frontier gas due to community and traditional custodian concerns.	The cultural features of the environemnt have been assessed in E1 and further in F3. The effects to physical receptors are temporary and localised and there is no interference with the practices or rituals required to maintain a spiritual connection to Country.	2632

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4151	Potential cumulative impacts upon species are addressed.	The titleholder responded by informing the stakeholder that the Regia MSS team were currently undertaking the cumulative impact assessment and will ensure that it covers previous and planned seismic surveys within the area and assesses impacts to cetaceans (behaviour, PTS, TTS) and their food source (krill).	653
4154	Questions a previous statement that indicated there would be no mortal effects from seismic activities.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2088
4158	Reference to the destruction and degradation of the marine environment observed during diving trips.	The titleholder acknowledged the feedback, noting that impacts and risks to the marine environment are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts on the marine environment are outlined in the EP in G1.	2830
4160	Rejects claim that proposed survey will have immeasurably small impact on fishery, states this is not supported by the evidence in the peer reviewed paper provided	Provided further assessments and information on the methodology used. Provided stakeholder with copies of all papers referenced.	4484
4161	Related to the effects of seismic testing on various birds, in particular the Little Penguin colony at Middle and Griffith Islands.	The titleholder provided information regarding the update of the environment plan to reflect the inclusion of various seabirds, including the Little Penguin, at the location of concern, not previously accounted for in the environment plan. The titleholder responded with some summarised information from the paper the stakeholder provided about foraging penguins and its relevence to the Regia MSS (Event ID 2910).	2908
4162	Related to the effects of sesmic testing on various birds, in particular the Little Penguin colony.	The titleholder responded with a provision of a document link to the titleholders preliminary impact and risk assessment relevent to shorebirds, some information regarding light being a likely cause of effect on nesting seabirds, and the titleholder has explained the process by which they conducted the relevent impact assessment in line with government guidelines (Event ID 1792). The titleholder provided information regarding the update of the environment plan to reflect the acknowledgement of various seabirds, including the Little Penguin, not previously accounted for in the environment plan (Event ID 2910).	1783

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4167	Risks are considered too high, impacting cultural and spiritual wellbeing of the populace.	The cultural features of the environemnt have been assessed in E1 and further in F3. The effects to physical receptors are temporary and localised and there is no interference with the practices or rituals required to maintain a spiritual connection to Country.	2118
4170	Scientific evidence indicates that seismic blasting using air guns has chronic impacts on whales. These effects include the exclusion of marine mammals from crucial areas during important times, interference with migration, habitat degradation, disruption of vital behaviors, and increased stress levels. Statement that such findings underscore the unacceptable risks associated with seismic testing in marine environments.	The titleholder acknowledged the feedback, noting that impacts to whales are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to whales are outlined in the EP in E7 and G1.	2073
4175	Seismic blasting is harmful and disruptive to marine life of many species.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	3343
4176	Seismic blasting negatively affects not only whales but also crucial marine life, including fish, crustaceans, and zooplankton, all of which play vital roles in the marine ecosystem.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	2074
4177	Seismic blasting would have a significant negative effect on marine creatures and ecosystems.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts ont marine life are outlined in the EP in G1.	3343
4186	Stakeholder expressed concern about the destruction and depletion of the ocean due to the activity.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2963

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4187	Stakeholder expressed concern about the potentially devastating impact of seismic testing on ocean marine life.	The titleholder acknowledged the feedback, noting that impacts and risks to marine life are are assessed in the Environmental Plan (EP) and can be found in D1 to D4 and E1 to E9, and F3. Measures to minimise adverse impacts to marine life are outlined in the EP in G1.	3209
4189	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1653
4190	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1655
4191	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1659

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4192	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1661
4193	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1662
4194	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1663
4195	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1665

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4196	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1667
4197	Stakeholder noted concern for harm being inflicted on our oceans by unnecessary gas exploration.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1670
4200	Stakeholder noted that dolphins use clicks and whistles as a complex form of communication, with observations of bottlenose dolphins using distinctive whistles for individuals within their pod, similar to how humans use names. Claimed that blasts from seismic testing could cause temporary and permanent hearing loss in dolphins and whales, citing instance near Peru, where some 900 long-beaked common dolphins and black porpoises washed up dead along a stretch of beach, shown to have had fractures in their ear bones and signs of bleeding from their middle ears. - LINK provided.	A Preliminary Environmental Impact and Risk Assessment is undertaken during an impact assessment process (our PEIRA is available here). The PEIRA is compiled to identify environmental values and sensitivities, to provide an evaluation of the environmental impacts and risks associated with the project. The PEIRA is then used to inform the environmental assessment documents, and as above, the environmental impact and risk treatments, which are being uploaded in the document library. The draft Environmental Impact Assessments are in the document library now, for review and feedback. For transparency we are uploading the entire documents, however if there is a concern you would like a summary or specific information on, please let us know. Further information on marine mammal treatments are covered below in response to concern 6.	2886

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4203	Stakeholder outlined impacts to marine animals from seismic testing. It was noted that to communicate with other whales, humpbacks use a complex combination of noises in beautiful melodics and that seismic airguns emit a wide range of frequencies with sounds in the lower frequency ranges which can travel long distances being particularly troublesome sounds with humpback whales known to stop singing when subjected to the sound of a seismic airgun near Scotland. Ending the humpback's haunting song could impact migration, breeding and feeding. (Credit: NOAA's National Ocean Service.) LINK provided.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of dolphins ir whales within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	2886
4205	Stakeholder raised concern regarding amount of spatial placement effect from previous studies causing lag effect or reduction in catch/recruitment and noted titleholder analyses shows this may be hard to detect. Concerned if seismic study done over bulk of larval advection pathway, this could significantly impact fishery.	This concern has already been considered in the analysis provided to this relevant person and CGG notes that the placement of the previous surveys is not a determining factor in the assessment because of the broad spatial dispersion of fish eggs and larve associated with this fishers concern.	4638
4210	Stakeholder stated they were concerned at the impact the activity will have on the nearby whale nursery and marine sanctuary. We need to be protecting our oceans and marine life from further disruption and climate change not attempting to extract more gas through seismic blasting.	The Regia MSS will be undertaken in a manner that does not prevent or displace Pygmy Blue Whales or Southern Right Whales' use of BIAs. This will be done by implementing spatial and/or temporal zones and where these cannot be implemented mitigation controls will be implemented. Controls will be evaluated with expert opinion from acoustic specialists and whale researchers to ensure they are effective.	870
4211	Stakeholder stated they were extremely concerned about the risks, damage and destruction caused by exploration activities in the marine environment.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1049

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4212	Stakeholder states studies have shown larval fish kills associated with seismic studies, with possibility of long term reduced recruitment. Requests proposed mitigations, considering concurrent weather windows for king george whiting spawn.	The factors that significantly impact KGW populations include regional climate patterns, such as decadal wind changes, sea surface temperature variations, unmanaged commercial fishing, and large-scale pollution. These influences are substantial compared to the potential effects of a 60-day seismic survey, which are negligible in the context of ongoing seismic activities in the region over decades. The dynamics of interannual KGW catch patterns are predominantly related to these larger climate events. Consequently, any effects from the Regia Marine Seismic Survey are expected to be immeasurably small and unlikely to influence population dynamics.	4355
4218	Strong opposition to seismic testing in the ocean due to its effects on both wildlife and the fishing industry. Individual firmly disapproves of the practice.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	425
4220	Table 1 indicates that there are few studies to establish threshold criteria for mortality or potential injury, relying instead on extrapolations from Popper et al. (2014). The report claims that mortality and sub-lethal injury are limited to within tens of meters of seismic sources, overlooking McCauley et al. (2017), which found a 2-3-fold increase in zooplankton mortality up to 1.2 km from the source. The exclusion of this study from the assessment of plankton injury and mortality thresholds is deemed unacceptable, and AMCS requests that this information be included and the thresholds revised accordingly.	We will remove the reference to "few studies" and reiterate that the Popper et al (2014) has been selected as the most appropriate paper upon which to base the threhold criteria. The McCauley et al (2017) paper has been considered in the chapter as a whole and it is incorrect to claim its omission from the assessment	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4224	The EIA claims that impacts to the Bonney Coast Upwelling KEF and the broader Great Southern Australian Upwelling System, which the Regia MSS overlaps, are not predicted because the effects on zooplankton mortality are within natural mortality rates. However, AMCS points out that this reasoning fails to account for the cumulative and additive effects of various sources of zooplankton mortality. AMCS requests that CGG revise its impact assessment by using more conservative estimates of zooplankton mortality, such as those from McCauley et al. (2017).	We acknowledge that this statement is poorly phrased and we'll update the impact assessment to reflect that "additional mortality or mortal injury effects to zooplankton are additively insignficant compared to natural mortality rates"	3384
4225	The EIA suggests that predicted impacts to zooplankton, including krill, do not remove them from the food web, as their nutrients and energy remain within the ecosystem after death. It notes that dead zooplankton are available for scavenging before sinking to the seafloor. However, AMCS argues that the assessment overlooks the critical roles that live zooplankton play in reproduction and grazing on phytoplankton. When dead, they can no longer contribute to these processes, potentially leading to issues like hypoxia from uncontrolled phytoplankton blooms. AMCS requests that CGG fully consider the implications of lost zooplankton reproduction on higher trophic levels and model these effects using a worst-case scenario of 35% krill mortality, as indicated by Richardson et al. (2017). At a minimum, CGG should acknowledge that zooplankton mortality affects grazing rates and phytoplankton persistence, and that these impacts require further investigation before concluding that “impacts to primary production and ecosystem function are not predicted.”	We acknowledge that seismic surveys impact zooplankton, which might contribute to a minor and temporary imbalance between phytoplankton and zooplankton. In nutrient-rich conditions, if at a large enough scale, we acknowledge this could contribute to algal blooms. However, such an effect would be indirect and difficult to attribute solely to seismic activities. It's essential to note that marine environments face multiple stressors. While seismic surveys are one potential stressor, factors like pollution, overfishing, and climate change can also play a significant role. Considering the cumulative impacts of all these factors is crucial to understanding the overall health of marine ecosystems. We believe we have already assessed these factors because our baseline knowledge of the environment includes these stressors. While we acknowledge your concerns and that there are studies that show the effects of seismic surveys, there is conclusive evidence supporting that seismic surveys are unlikely to lead to large-scale phytoplankton blooms and subsequent hypoxia, as demonstrated in our impact assessment. Once again, we have provided our consideration of may papers, including Richardson et al. (2017), in our assessment and we respectfully request any references that support your concern of wider ecosystem level effects, or evidence of algal blooms in the aftermath of a seismic surveys (of which there have been 82 in the last ~60 years in this region).	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4231	The feedback expresses concern that the project might disrupt blue whale migration, movements, and natural behavior due to potential interference in their habitat.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for blue whales and an extensive detection area. These measures have been assessed in E7, F3 and G2.	2081
4236	The feedback questions priorities, suggesting that profit motives may overshadow environmental concerns. It calls for a reconsideration of project locations to avoid populated areas and protect wildlife.	We will not survey while SRW mothers and calves are in the area. Oil and gas has successfully co-existed with wildlife in this area for 25 years and we are doing everything we can do protect the wildlife and natural beauty of the area (Event ID 1781).	1781
4238	The feedback raises concern about the foraging distance penguins travel at night to feed themselves and their young, urging consideration of this range in seismic planning.	We are studying the little penguins and will put in place protections for them. The detail of our impact assessment of the effects of elevated levels of sound will be published shortly. We will consider all life-cycle stages of the penguin and the ecosystem effects, including those pressures on the food chain (Event ID 2079).	2079
4241	The fisher expressed concerns about the adverse effects of seismic activities on the stocks he relies on, indicating that the surveys have negatively impacted fish availability.	This claim was thoroughly assessed both in E3 and in F3. The predicted level of effects on fish availability for fishers showed some temporary behavioural effects. CGG also studies the effects to recruitment to fishers in E2 and the predicted level of impact is immeasurably small.	2026
4246	The fishing industries in Port Fairy and King Island have reported significant impacts without financial compensation.	Through our extensive research we have not found any evidence of causation between seismic survey and mortal effects on molluscs. In fact, the evidence we have found (which we will publish in full) suggests seismic and fishing can happily co-exist. Please provide references, evidence, or testimonials for your claims so that we can take them into consideration in the proper process (Event ID 2084).	2084
4250	The last time the activity was conducted, it destroyed the fishery for 2 years. I have catch history for this.	This claim was assessed in F3 where historical data was analysed for any correlation between historical seismic survey and a reduction in catch rates. No such correlation was found as shown in the analysis in F3. This fisher was asked to provide their catch history to substantiate their claim and no data has been received to date.	5190

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4253	The possible effects to marine life and ecosystmens is my primary concern	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2117
4256	The presence of other fishermen displaced by operations in the area has led to a noticeable decline in catch rates.	CGG analysed the data provided to examine this claim. The analysis shows that catch rates (catch per unit effort) was actually increasing year over year.	2037
4258	The project has the potential to impact within the RAP Area, Bunurong Country.	The titleholder has acknowledged this feedback by highlighting that impacts to cultural heritage are thoroughly assessment in E1 and F3.	2371
4259	The proposed works will harm and damage the climate and ocean life.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2256
4260	The protection of wildlife in the Otway Basin is directly affected by drilling and seismic surveying.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	1901

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4262	The random placement of animats representing Southern right whales (SRW) and pygmy blue whales (PBW) is inappropriate, as whale presence in the area is not random. SRWs and PBWs migrate significant distances for calving and feeding in the waters of the OA. Assuming a random distribution in a model meant to reflect complex animal behavior influenced by environmental factors is flawed. Additionally, the proposed spacing of four animats per square kilometer underestimates the likely higher density of SRWs, particularly in aggregation and calving areas from May to October.	We understand the concern regarding the random placement of animats in the model. The animat modelling creates a foundational understanding of potential whale response to sound emissions once they are in or near the OA. We recognize and agree that the overall migratory and behaviour patterns of the SRWs and PBWs are far from random. The decision to start with a random distribution was in fact a conservative first step to ensure we didn't inadvertently overlook potential areas of concern. Recognizing the specific migratory and behavioral patterns of SRWs and PBWs, is completed in the subsequent impact assessment. Regarding the spacing of animats at 4 per sq km, your feedback is valuable. We believe that a 4 per sq km is a significantly conservative density for the model to take given the population levels of these species and their observed behaviours.	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4263	The recognition of plankton diversity in the proposed OA and EMBA, combined with the lack of comprehensive data for the area, suggests that the precautionary principle should be applied due to the crucial role of plankton in overall ecosystem function.	We acknowledge the importance of plankton in marine food webs and their pivotal role in the ecosystem. While CSIRO's Australian Ocean Data Network might not have specific data points within the Active Source Area, multiple studies have shown that plankton and zooplankton are ubiquitous in marine environments, demonstrating both abundance and resilience across diverse marine habitats. For instance, Beaugrand et al. (2019) and Hays et al. (2018) have highlighted the pervasive distribution of these organisms throughout the world's oceans, including regions similar to the Bass Strait [1,2]. Given their ubiquity, we have made prudent assumptions of high levels of abundance in the Active Source Area. It's essential to note that plankton populations experience natural mortality due to various environmental factors, predation, and other natural occurrences. Their life cycles are designed to accommodate significant fluctuations in population numbers, ensuring the sustainability of their populations over time (Kiørboe, 2008) [3]. Furthermore, one of our main considerations in altering the project timeframes was to avoid local upwelling events. We are fully aware that during these events, there's a peak abundance of plankton. Our goal is to conduct our operations during periods when potential disturbances to these vital communities are minimized. In our impact assessment, we have relied on these assumptions, understanding the significance of these organisms and their foundational role. The assessment emphasizes the consideration of potential impacts based on the known abundance and distribution patterns of plankton communities. Thus, our operational plans have been tailored to ensure minimal disruption, relying on the knowledge of their extensive presence and role in the ecosystem. (2008). A Mechanistic Approach to Plankton Ecology. Princeton University Press	3384

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4264	The report states that the area of impact is predicted to extend a maximum of 230 meters from the sound source during survey acquisition, with a severity rated as Minor (2). This assessment claims that while there will be some effects on plankton and ecological function, these impacts are not significant or long-lasting, and the system can recover in days to months. AMCS challenges this conclusion, citing evidence from McCauley et al. (2017), which was excluded from the assessment. That study indicates impacts can occur at distances at least six times greater than the 230 meters cited. Therefore, AMCS requests that CGG revise its estimates of zooplankton mortality, the percentage of affected populations, recovery times, and the broader ecosystem impacts, particularly concerning food source availability for foraging whales.	We have acknowledged the findings of McCauley et al. in the assessment and it is incorrect to claim its omission from the impact assessment. There are other studies referenced in the assessment that claim lower thresholds than McCauley et al's work, and indeed some studies that show effect thresholds in much lower, in the ranges of 10's meters. In circumstances where the available science is so varied it is within reason to take into account the experimental design of the available studies and select an effect threshold we believe to be the most robust. We note also that the Popper et al. (2014) thresholds have been routinely applied by titleholders, and accepted by NOPSEMA, further emphasising that this threshold is likely the most appropriate to use.	3384
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4267	The Stakeholder also objected to the project on the basis that it would impact every marine creature and sea bird.	Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2064

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4269	The stakeholder asserted that they have all necessary catch history data to justify the cessation of seismic, expressing concern about its impact on their fishing operations.	This claim was assessed in F3 where historical data was analysed for any correlation between historical seismic survey and a reduction in catch rates. No such correlation was found as shown in the analysis in F3. This fisher was asked to provide their catch history to substantiate their claim and no data has been received to date.	5189
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures have been outlined in the EP.	3343
4272	The stakeholder asserts that the survey will have a harmful effect on millions of sea creatures.	It would be unacceptable to have long-term or permanent/unrecoverable impacts, fortunately, impacts from marine seismic surveys are short-term, temporary, and recoverable. (Event ID: 3419)	3343
4274	The stakeholder claims that seismic exploration poses a significant danger to marine life in general. This claim suggests a strong opposition to the practice due to its perceived harmful effects on the marine ecosystem as a whole.	The titleholder publically responded to this interactive map comment explaining that legislative framework in Australia permits some impact from offshore petroleum if it is managed and of an acceptable level. We believe that responsible development of gas is essential for maintaining the current quality of life we all enjoy and ensuring we pass that quality of life on to future generations. Gas is part of the Labour governments energy transition plan.	2107
4275	The stakeholder did not support the project due to the impact it will have on the significant whale nursery at Logan's Beach.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of whales within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	2250
4276	The stakeholder does not accept the blasting activity as beneficial or more important than existing marine life and structures.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	2255

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4278	The stakeholder expresses an active interest in the wellbeing of the coastline and its flora and fauna, indicating a general concern for environmental conservation.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	1325
4279	The stakeholder expresses concern that the proposed seismic blasting will disrupt the travel paths of whales, particularly after efforts have been made to allow their populations to recover. They emphasise the potential harm to these animals from creating explosions in their migratory routes, arguing against any activities that threaten their sustainability.	We are working hard to design our survey so that we limit our impacts to acceptable levels. Our activity is no more than 90 days so we'll find an appropriate window to operate in. We will not destroy any wildlife habitat as a result of our activity (Event ID 2109).	2109
4284	The stakeholder noted concern regarding impacts to zooplankton and the marine ecosystem.	The only effects to zooplankton come from elevated levels of sound. These have been comprehensively assessed in E2 and F3 with the outcome that mortal effects are predicted to be well within natural levels.	1890
4286	The stakeholder noted their concern regarding short and long term effects to recruitment of King George Whiting into Corner Inlet.	An additional impact assessment for King George Whiting and spawning species has been included in F3. There is expected to be no measurable effect on KGW populations as a result of the survey.	4433
4288	The stakeholder objected to the project on the basis that it would impact the Stakeholder personally and every person in the community who love the ocean. Stakeholder noted that they do not support the activity and find it distressing to even think about the damage that could be caused for thousands of creatures and the future of herself, other people of Port Fairy and the greater community.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan.	2064
4292	The stakeholder raised concern about the sound level from the survey and its effect on marine mammals and other species.	Outlined the predicted effects of sound levels of different species of marine mammals including difference between high and low frequency cetaceans, sound propagation and modelling, and different effect level thresholds. Outlined the whale management and mitigation measures in place for Southern Right Whales and Blue Whales including timing of the activity, vessel-based monitoring (MMO's and PAM Operators), detection technology trails, and citizen science program access. Outlined the effects on zooplankton and the case for acceptability of these impacts noting the movement of the survey timing to avoid the upwelling period. (event ID 3697)	3697

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4294	The stakeholder raised concerns regarding the precautionary principle and criticised the aspect-by-aspect approach currently published and suggested that a key matters report for matters of national environmental significace would be a preferred way to review information.	Outlined why the aspect lead approach was followed and acknowledged that for species with elevated levels of protections a key matters report (or similar) that was receptor-focussed could be prepared. (Event ID 3697)	3697
4297	The stakeholder requested to know the total cost of the MSS so they could ascertain if ALARP had been reached, as a cost-benefit analysis. The information provided by the titleholder to date was deemed insufficient to know if ALARP had been achieved.	Outlined the concept of 'costs' is more than the narrow interpretation of a monetary value, it includes money, time and trouble. Outlined that the 'cost' of a control measure could be weighed against total costs of the survey for context but that this point of reference fails to consider the environmental benefit of adopting the control. Agreed that the current presentation of ALARP could be improved and that CGG would prepare a dedicated report explaining how we have reached decisions about what measures needed to be adopted (Event ID 4062).	4062
4299	The stakeholder stated that elevated sound levels are an unnacceptable impact to marine mammals.	The titleholder acknowledged the feedback, noting that impacts to marine mammals are assessed in the Environmental Plan (EP) and can be found in E7 and F3. Measures to minimise adverse impacts to marine mammals are outlined in the EP E7 and G1.	1890
4301	The stakeholder stated that the proposed activity is environmentally unsound irrespective of the assessment process and predicted environmental risk.	Petroleum activities do not operate to a no-impact standard. Instead, the Regia MSS is required to define the acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan	1747
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in G1.	3152

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevant receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevant mitigation measures have been outlined in the EP.	2273
4313	The statement challenges that seismic blasting will harm shellfish like scallops, citing research by Ryan Day et al. (2017) that demonstrates physiological harm and altered behavior in scallops due to exposure to seismic air gun signals.	We understand that there are impacts of seismic surveys. The findings of the paper have been used to define the distance at which some effects may occur. Our current understanding is that the effects are initially sub-lethal, that increased mortality was observed post exposure, and that increased mortality was within natural variation. Our draft assessments will be published soon (Event ID 2078).	2078
4315	The statement suggest that the significant harm caused by seismic activity to marine life and commercial fisheries, along with the existing natural gas supplies and climate change issues, renders the industrialisation of Port Fairy's coastline unacceptable. It emphasises community disapproval of allowing major oil companies to profit at the expense of the local environment and tourism.	We believe impacts from our activity can be managed to below acceptable levels. Further development of the offshore area would be subject to multiple future approvals. The visual impact from this survey would be temporary and similar to the shipping/fishing activity that already occurs in the region (Event ID 2076).	2076
4319	There are concerns regarding the potential impacts of seismic surveys on penguins, diving birds, and other marine fauna. Stakeholders are particularly worried about how the noise and disturbance from these surveys could affect the breeding and foraging behaviours of these species.	This effects of sound on birds was initially assessed in E4 and further assessments for penguins can be found in F3. Birds can also be affected by artifical light, which has been assessed in E9. The conclusion is that the measures adopted to protect foraging birds will mean that impacts are of an acceptable level.	2006
4320	There are concerns regarding the potential impacts on intangible cultural values, particularly those related to the Koontapool (Southern Right Whale) and eels.	Agreed that Sea Country, including spiritual values, should be protected. Stated that input into the design and implementation is needed from Traditional Owners to achieve this (Event ID 3678).	3678
4322	There is measurable damage done to one species which will be an an example of potential damage to others in the vicinity of King Island and surrounds	While the claim was noted the REGIA EP has conducted an extensive assessment of the literature and found no evidence of measurable damage to populations of invertebrates or fish in the vicinity of King Island and surrounds. The seismic acquisition area is also located ~100km from nearest King Island landfall.	2773

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4326	This feedback challenges a response (that was taken out of context), that there would be no mortal impacts on plankton from seismic testing. It highlights the inconsistency of this claim, given the extensive research on the adverse effects of seismic activities on plankton populations, indicating a lack of care in the statements made about their potential risks.	Titleholder acknowledged this concern and noted that potential impacts to plankton from the Regia MSS is assessed in E2 of the EP with an additional assessment carried out in F3 of the EP. Any potential mortality or permanent injury effects to plankton must be assessed in the context of natural mortality rates. Mortality and/or mortal injury impacts to plankton assemblages (including fish eggs and larvae) resulting from seismic surveys are likely to be inconsequential relative to natural daily mortality rates, which can range from 11.6% (average minimum) to 59.8% (average maximum) as reported by Tang et al. (2014). Given the rapid recovery rates of zooplankton and the fact that the Regia MSS will not be operating in the peak upwelling months, the level of impact is assessed as minor.	5210
4327	This feedback claims the negative impacts of seismic noise on marine ecosystems, including zooplankton mortality, hearing damage, physiological harm to larger marine animals, and disruptions to essential behaviors like feeding, breeding, and escape responses.	We acknowledge that there may be mortal effects on zooplankton within a few meters of the sound source. However, given natural mortality rates of 20-50% along with their abundance the population effects to zooplankton are considered negligible (Event ID 2097). There are significant protections in place for effects on large marine animals which we will detail in our full impact assessments. The acceptable levels of impacts to whale species are defined in their conservation management plans. It is unacceptable to injure a Blue Whale or displace it from its foraging area. it is unacceptable to injure or disturb a Southern Right Whale. Humpback Whales are recovering and no longer on the endangered list and we are required to protect them along with all other marine life. This project is in the early stages of exploration and the purpose of the survey is to determine if commercially viable deposits of petroleum are even present (Event ID 2097).	2097

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4327	This feedback claims the negative impacts of seismic noise on marine ecosystems, including zooplankton mortality, hearing damage, physiological harm to larger marine animals, and disruptions to essential behaviors like feeding, breeding, and escape responses.	We acknowledge that there may be mortal effects on zooplankton within a few meters of the sound source. However, given natural mortality rates of 20-50% along with their abundance the population effects to zooplankton are considered negligible (Event ID 2097). There are significant protections in place for effects on large marine animals which we will detail in our full impact assessments. The acceptable levels of impacts to whale species are defined in their conservation management plans. It is unacceptable to injure a Blue Whale or displace it from its foraging area. it is unacceptable to injure or disturb a Southern Right Whale. Humpback Whales are recovering and no longer on the endangered list and we are required to protect them along with all other marine life. This project is in the early stages of exploration and the purpose of the survey is to determine if commercially viable deposits of petroleum are even present (Event ID 2097).	2097
4329	This feedback highlights the uncertainty regarding the long-term impacts of seismic blasting on abalone populations, particularly emphasising that the effects may not be immediately observable and could depend on the juvenile stages at the time of blasting.	We have recently installed an exclusion zone down to the 40m bathymetry contour primarily as a result of discussions with abalone fishers who dive down to 30m. This will help protect early life-cycle stages of abalone. Further, seismic surveys have occurred in this region for many years and the two industries (fishing and petroleum) have successfully coexisted over time (Event ID 2095).	2095
4330	This feedback questions the accuracy of claims regarding the safe distance of seismic blasting impacts, contrasting reported effects from previous studies in Western Australia that indicated zooplankton mortality within a 1.2 km radius. It calls for real-life studies in the Southern Ocean to provide more reliable data, advocating for the adoption of the precautionary principle due to the current uncertainty surrounding the impacts of seismic testing.	Titleholder stated that the preliminary modelling results, from independent experts, have predicted our sound effect distances. For zooplankton this is 220m. Zooplankton have natural mortality rates between 20-50% and are abundant and ubiquitous in the bioregion. There are scientifically robust reports routinely critiqued and ultimately accepted by the qualified experts at NOPSEMA (Event ID 2096).	2096
4331	This feedback raises concerns about the negative impact of seismic blasting on local commercial rock lobster and scallop fishing industries.	This claim has been thoroughly assessed in E1, E5, and F3 for southern rock lobsters. There is no commercial scallop industry in the region. The known effects to individual lobsters are not predicted to have any measurable effect on population levels or dynamics.	2097

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4333	This statement expresses a strong feedback to the potential impacts of seismic activities on whale communication and hunting abilities, emphasising the unacceptable risks to marine life and local ecosystems for the sake of gas company profits. It reflects concerns about environmental responsibility and the prioritisation of corporate interests over ecological health.	The Federal Department of Environment, through the EBPC Act, protect matters of national environmental significance. Whale species have specific levels of protected enacted through legal instruments such as Conservation Management Plans. These plans often contain information about the levels of impact that is unacceptable and we must adopt them to comply with the law (Event ID 2099).	2099
4335	This statement opposes the disruption of marine habitats, migratory patterns, and cultural songlines due to perceived corporate exploitation. It reflects a strong stance against environmental harm driven by profit, emphasising the cultural and ecological importance of these areas.	The titleholder acknowledged this concern and confirmed that CGG will not carry out the survey whilst Southern Right Whales are present in their reproductive biologically important area. Confirmed that CGG are engaging with the local traditional owners and look forward to hearing their stories, learning about their culture, and protecting sea country (Event ID 2101).	2101
4339	What new technologies are CGG considering to reduce impacts?	Provided the reasons that these technologies are currently not proposed, however acknowledge that they aren't explicitly excluded and if they become viable as the design of the activity is refined they'll be considered (Event ID 4280).	3705
4342	Attendees stated that the fishery has seen significant improvement, marking its best condition in about six years, since the last seismic activity in the region. This feedback highlights concerns regarding the potential negative impacts of upcoming seismic activities on the current health of the fishery.	The titleholder acknowledged the feedback, noting that impacts are assessed in the Environmental Plan (EP) and can be found in E1 and F3. Measures to minimise adverse impacts on functions, interests and activities on fisheries are outlined in the EP.	1529
4343	Questions possibility of compensation for the abalone industry if their stocks are depleted as a result of seismic testing, drawing a parallel to the scallop industry near King Island that was adversely affected. It highlights concerns regarding accountability and the financial implications for local fisheries in the event of ecological harm.	The titleholder acknowledged this concern and noted that potential impacts to the abalone industry. It would be unacceptable to have mortal effects on any marine species from our or any marine seismic survey. We do not predict mortal effects to molluscs (including scallops, abalone, oysters, clams, mussels, limpets, squids, octopus and cuttlefish etc.). Our full assessment of predict impacts on molluscs can be found in E1 Section 8, E4 Section 8 and F3 Section 4.	2093

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4345	The stakeholder asked how we can be sure that seismic blasting will not harm penguins when conducted 60 meters away, expressing concern that this distance might be insufficient for safety.	The titleholder has acknowledged this feedback relating to underwater sound and penguins. The results from the underwater sound modelling (see E5 Section 6) show the TTS criteria was reached within 60 m of the source. This is a 24 hour cumulative result, meaning the penguin would have to remain within 60m of the sound source to experience TTS. It would be highly unlikely for a diving bird or penguin to be within that distance of the source for 24 hours. As the seismic source will be slowly ramped up to full power over 30 minutes this further reduces the risk of a diving bird or penguin being close to the seismic source at full power.	2079
4346	Requested details on the proximity of seismic blasting to Middle Island, with a specific concern for the range penguins travel offshore to forage at night.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions relating to penguins. The MSS will not impact the foraging abilities of fairy penguins within the area of operation, and CGG has acknowledged breeding colonies of Fairy Penguin along the coast of Victoria (EP E7 Section 4 and 8). CGG undertook an additional assessment of Fairy Penguins in EP F3 and outlined the overlap of foraging colonies along the coast with the Regia MSS. The foraging range of the Middle Island colony does not overlap with the Regia MSS. There is a small overlap with one of the breeding colonies and the Regia MSS, the overlap equates to only ~5.3 hours spread over 3.5 weeks. Mitigation plans are in place to reduce any impacts to as low as practicable.	2079
4347	Enquired about whether the potential impacts on the Fairy Penguin colony have been evaluated, specifically regarding how far they travel to forage and the depths to which they dive. Raises concerns about the effects of seismic activity on this important wildlife species.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions relating to penguins. The MSS will not impact the foraging abilities of fairy penguins within the area of operation, and CGG has acknowledged breeding colonies of Fairy Penguin along the coast of Victoria (EP E7 Section 4 and 8). CGG undertook an additional assessment of Fairy Penguins in EP F3 and outlined the overlap of foraging colonies along the coast with the Regia MSS. There is a small overlap with one of the breeding colonies and the Regia MSS, the overlap equates to only ~5.3 hours spread over 3.5 weeks. Mitigation plans are in place to reduce any impacts to as low as practicable.	2077

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4348	Asks if the seismic blasting will occur during the breeding season of the Fairy Penguin colony, emphasising that the penguins forage after dusk, making them less visible at night. It highlights the need to consider the timing of the project to avoid disrupting this vulnerable wildlife population.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions relating to penguins. The MSS will not impact the foraging abilities of fairy penguins within the area of operation. The Regia MSS is scheduled to take place putside of the Fairy Penguin breeding season. CGG undertook an additional assessment of Fairy Penguins in EP F3 and outlined the overlap of foraging colonies along the coast with the Regia MSS. There is a small overlap with one of the breeding colonies and the Regia MSS, the overlap equates to only ~5.3 hours spread over 3.5 weeks. Mitigation plans are in place to reduce any impacts to as low as practicable.	2077
4349	Raises a concern about whether the sound levels from seismic blasting could be harmful or uncomfortable for Fairy Penguins during their foraging activities.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the foraging abilities of fairy penguins within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2077
4353	Concerns about the impact of oil and gas exploration on the marine environment, particularly in regards to seismic testing and its harmful impacts on whales.	Titleholder responded that a detailed assessment has been completed of all available relevant scientific literature to inform the management and mitigation of MSS and their interaction with whales. Spatial and temporal zoning in conjunction with mitigation measures will ensure that interactions will minimise disturbances to whales.	612
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4359	Request for seismic blasting to be limited to 12 hours out of any 24-hour period and not carried out at night	The titleholder acknowledged this concern, however undertaking the seismic survey only in daylight hours would have a disproportionate cost without a significant environmental benefit.The survey would take twice as long, potentially resulting in cumulative effects to sensitive species.	2821
4361	Stakeholder shared concern about whales ceasing to visit the South West coast to give birth and nurture calves.	The titleholder has undertaken a thorough review of the effects of seismic on whales - see E7 Section 8 and F3 Section 4.1 and 4.2. There is no evidence to suggest whales will cease to visit, give birth and nurture their calves in the south west as a resutl of the Regia MSS.	1255

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4362	Concerns about the lack of environmental reviews of seismic surveys at necessary scales to assess, mitigate and monitor impacts.	The titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The titleholder responded providing links to large scale studies on seismic undertaken in Australian waters and offered to provide individual with impact assessments when they became available.	1389
4363	Stakeholder noted opposition to the harmful effects on marine life and the pristine coast.	The titleholder provided information on identifying potential impacts and risks and putting mitigations in place such as, conducting survey during time of year marine mammals are less likely to be in area, reducing sound source to lowest setting and reducing number of times activated, implementing marine mammal and fish monitoring programs, exclusion zones, following strict NOPSEMA guidelines. Provided link to PEIRA and document library on website.	786
4364	Concern about the future of ocean health for children and sea life, including whale children.	Titleholder responded in Event ID: 1416, describing CGG's commitment to safeguarding marine mammals, the assessment process, regulations and measures currently in place. The stakeholder was provided with consultation information and invited to engage.	1410
4365	Concerns about the lack of definitive clarification on how seismic testing affects the marine environment and the clash between economic interests and environmental risks.	The titleholder acknowledged the feedback, noting that they have undertaken a thorough analysis and assessment of all relevant literature to inform the impact assessments conducted to assess potential impacts from underwater sound to relevant receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals in the Environmental Plan (EP). These findings can be found in E2, E3, E4, E5, E6, and E7 under Section 8: Predicted Levels of Impact. Additional assessments of key receptors was also completed to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level (F3). Titleholder also conducted an assessment to investigate potential impacts to other marine users from physical presence resulting from the activity (E1).	2383

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4377	Stakeholder claims that the lack of consultation with local experts and scientists could lead to adverse effects on the Fairy Penguin colonies and other species.	Event ID 6882 (Doc ID 9096) - CGG consulted with Parks Victoria (PV) during the planning of the proposed survey, meeting on 11/08/2023. The consultation records are available in the EP (Appendix C2). PV raised concerns about the survey's proximity to the Twelve Apostles Marine Park, leading to a refinement of the survey area. Fairy Penguins were not mentioned in this meeting. CGG also consulted with the Warrnambool Coastcare Landcare Network and their Middle Island Penguin Project. A referenced expert in scientific literature was consulted about penguin foraging ecology and at-sea movements. They advised against relying on outdated population estimates for penguins due to rapid ecosystem changes and predation pressures. CGG has sent the F3 assessment from the Regia EP to the Professor for feedback and is awaiting a response. CGG also reached out to DECCA but has not received any information. Regarding the other individuals mentioned, they were consulted, with records available on the public website. The Regia MSS EP includes extensive references to studies by blue whale (EP E7 and F3) and Southern Right Whale experts. Additionally, a professor's work on Fairy Penguins is referenced, along with the Middle Island Penguin Project. CGG based its impact assessment on peer-reviewed literature, including studies by the scientists mentioned, and disagrees with any suggestion that knowledge was bypassed or cherry-picked. The process has been fully transparent, and CGG has actively sought additional relevant literature. CGG also met with Warrnambool City Council to discuss the Middle Island Penguin Project and is looking to support efforts to gather data on penguin populations.	6412

4383	Stakeholder objects to the seismic blasting program, stating that it could negatively impact the penguins' prey base.	EVENT ID 6320- Previously responded to in Feedback ID 4122: "We refer you to Appendix E - Impact Assessments - E2 – Underwater Sound – Plankton, and Appendix F – Decision Making – F3 – Acceptability Assessment - Sections 4.2.7 – Goulds Squid, 4.2.12 – Plankton Communities and Bonney Upwelling, and section 4.2.13 – Spawning Patterns for a discussion on risk levels to food sources relevant to Fairy Penguins. Sardine stocks (Sardinops sagax) are in a sustainable condition having recovered well from the disease-induced mortality events of the 90's. Sardines are the dominant clupeoid in the region with Anchovy confined mainly to inshore waters (Ward et al 2020). Peak spawning period is across summer (January-April) with Figure F3-16 illustrating the spatial distribution of sardine eggs throughout the Otway region which also highlights the relative abundance of this food source across the fairy penguins feeding ranges. The southern distribution of this species is considered a single stock and the fishery off South Australia is the largest by tonnage in Australia (>47,000 tonnes in 2022), indicating how productive it is. Behaviorally, pelagic schooling species such as sardine are highly mobile in space and time which makes them highly resistant to localized and/or transient disturbances. It is also the case that Australia's less-productive pelagic ecosystems means predators are less dependent on only one prey species and can feed opportunistically across a wider variety of species. This has been seen with dietary examinations of Fairy Penguins who can switch between sardines, anchovies and squid as encountered. Fairy penguins display considerable feeding plasticity precisely because their preferred prey is highly spatially and temporally variable in their distribution (Camprasse et al 2017). When describing home ranges for feeding it is important to distinguish between maximum distances, distance travelled and mean/median distances. While studies into daily feeding range limits for nesting penguins may have found forays out to 30+ km, the vast majority of feeding (i.e. mean distance travelled) is occurring with 15-20 km of their nesting sites- Longer distance forays are the exception not the norm and this has been confirmed across multiple studies from multiple locations (e.g. Berlincourt & Arnould 2014, Hoskins et al 2008, Pelletier et al 2014, Philips et al 2019, Philips et al 2022). Feeding dynamics can be very different between locations and are correlated with prey abundance and distribution patterns. As demonstrated the Otway region is well supplied with sardines and squid with food resources likely	6412

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		correlated with nearness to upwelling areas (Norman et al. 2017)."	
4388	Concerned about the impacts of the seismic survey on Southern Right Whales.	Event ID 6878 - The Regia team explained in-meeting that there were multiple lines of evidence approach in relation to fauna management. Discussed that the Regia team were doing the most any titleholder had previously done for a seismic survey. Stated that there would be at least one aerial flight survey and that there would be a secondary spotter vessel. Discussed the tethered buoy experiment and that the Regia team were taking advice on what the best location would be to maximise results.	6878
4389	The relevant person was concerned about the timing of the proposed survey and impacts to the sourthern right whale.	Event ID 6878 - The Regia team provided an overview of the Regia seismic survey timings and that they were notional dates as there are criteria for whale detections. Explained that there were multiple lines of evidence approach in relation to fauna management. Also discussed the tethered buoy expriment and that they were taking advice for the best location to maximise results.	6624

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4391	Stakeholder claims there is a threat of serious harm to the regional krill population if the Regia seismic survey occurs and a lack of full scientific certainty on the effects, therefore the Precautionary Principle should be applied.	The precautionary principle needs only be applied when there is a threat of serious or irreversible harm and a lack of full scientific certainty. In relation to the effects of sound on plankton and larval krill it is CGG's view that neither of these preconditions are met. Nevertheless, we have adopted precautionary measures as evidenced by: 1. >39% reduction in acquisition area. 2. Avoidance of the key summer months despite this time providing the best conditions for survey. 3. The 60-day limitation on acquisition. (Event ID 5304) The NOPSEMA quote they have used to support their case has been misinterpreted by the stakeholder, that encourages a precautionary approach rather than describes principle: s391(2): The precautionary principle is that lack of full scientific certainty should not be used as a reason for postponing a measure to prevent degradation of the environment where there are threats of serious or irreversible environmental damage. (Event ID 6517) The Regia EP provides scientific estimates on the natural variations in plankton (including krill) communities globally and regionally, as well as mortality levels in these communities.Based on the long history of seismic surveys in the region, there is no evidence of significant harm to plankton populations, suggesting that serious harm is unlikely. These findings help define what constitutes "serious harm." The stakeholder lacks valid data to support their claim of large-scale harm to regional krill populations. (Event ID 6815)	6432
4392	Claims there will be impact to Bonney Upwelling via krill larvae originating from within the MSS zone.	The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4393, 4409, 4411, 4413	As krill is a critical food source for whales, no seismic should be done between the months of November to April.	The claim that krill is a critical food source for whales is well-established, as whales migrate to upwelling areas to support sufficient densities of their preferred food source. However, the stakeholder provides no scientifically supported cause-and-effect pathways or evidence to justify the prohibition of seismic surveys from November to April. The Regia EP offers scientific evidence showing the fluctuating abundance of krill and its connection to whale feeding patterns. While upwelling events can occur at various times and locations, there is a clear understanding of what constitutes major upwelling events and when they occur – as has been identified clearly in the EP. Whales feed throughout the upwelling season, primarily when krill density is highest, and continue their migrations each year despite significant fluctuations in krill abundance between years. (Event ID 6815)	6432
4390, 4414	The relevant person was concerned about the evidence related to potential regional population impacts of seismically induced krill mortality within the ASA.	In the online meeting, Regia's marine scientists explained that the natural variation in the ecosystem was much larger than the potential impacts their model suggested. They also pointed out that the literature did not support the stakeholder's model and that there was no evidence of a population collapse or catastrophic effects on krill from seismic activity. The stakeholder was encouraged to refine his work, particularly regarding the historical effects of seismic surveys, and consider the scale and natural variability of the ecosystem (Event ID 6890).	6420

4394, 4412	Stakeholder claims their modelling indicates that by actively monitoring currents across the Active Source Area (ASA) and defining appropriate operational limits (no active source if mean currents across ASA (stratified) are > 0.5m/s), CGG can reduce mortality of larval Nyctiphanes australis by up to 80%, as stronger currents increase the volume of water exposed to lethal doses of seismic. This would, in turn, minimize the impacts on the blue whale feeding zone and the broader Bonney Upwelling ecosystem.	The stakeholder's model does not consider the following points: Plankton and larval krill abundance and density are not uniformly distributed in the water column either vertically or horizontally. The meso-scale biological and physical characteristics that are the more appropriate scale for investigating flow-on effects on whale populations or other relevant taxa (i.e. at the population level and not the effect to individuals). The vast differences in abundance of plankton (~krill) month-by-month and year-by-year and the significance of CGG's decisions: To avoid the peak upwelling times, where there is traditionally the highest abundance of plankton and larval krill (January, February and March). To limit the survey duration to 60 days of total acquisition. Any of the 30+ peer-reviewed scientific papers beyond the McCauley and Richardson papers about the Bonney Upwelling and the effects of impulsive sound on plankton and krill. The ecological context and purpose of zooplankton and larval krill: In primary productivity in the region regardless of the state of their physical condition, evidenced by the high levels of natural mortality. As a primary food source for Blue Whale. The ± 50% interannual variation in area extent of upwelling (~population abundance of krill) which is driven mostly by climate influences and within which whale populations continue to recover. In austral summer 2008/09 the upwelling season was constrained to the single month of February – we cannot find any scientific literature that describes this season as catastrophic for the visiting whale population. In addition, assumptions are made about krill behavior, distribution, and density, as well as how the model accounts for patchiness and current speeds. The model's treatment of water and krill as uniformly distributed contradicts scientific understanding of their distribution in space and time. The Regia EP provides evidence of the natural variability in marine systems and highlights the resilience of zooplankton communities, including krill, due to high birth, growth, and mortality rates. These communities exhibit high turnover and production-to-biomass ratios, making them resilient to disturbances. Citing the work of Hosie (1982), the EP emphasizes that Nyctiphanes species have higher turnover rates than Euphausid krill, and that similar mortality rates (88-90%) can be expected in both. The assumptions about krill mortality	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		in the EP are based on well-established scientific literature. (Event 6815)	
4395	The project is adjacent to Warrnambool's Logans Beach Whale Nursery for Southern Right Whales and upstream of the Bonney Upwelling Key Ecological Feature, which could be affected.	The titleholder acknowledges this and has spent two years preparing a comprehensive Environmental Plan (EP). This process included ongoing consultations with communities and individuals, summarizing the EP into webinars, information sheets, and holding in-person meetings. The team recognizes the Otway region's marine environment as both spectacular and dynamic and believes environmental assessments must be thorough and detailed to respect its importance. Impacts are assessed in the Environmental Plan (EP) and can be found in Appendix E7 and F3. Measures to minimise adverse impacts to whales and ensures the Regia MSS does not prevent SRW and BW utilising their BIAs include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in Appendix E7 Section 9 and G1. The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4396	Stakeholder objects to Regia's dismissal of the importance of current strength in mitigating impact on krill and Bonney Upwelling biomass as both currents and krill distribution vary with depth, making monitoring at multiple depths beneficial. In the ASA, where water depth is typically less than 200m, larval krill are likely exposed to lethal seismic doses, as noted by McCauley et al. (2017). This region serves as a transport corridor for larval N. australis heading toward the Bonney Upwelling, with a westward current from November to April likely transporting larval krill into nutrient-rich upwelling zones.	The suggestion to monitor all depths lacks a clear rationale or explanation. The assumption that all krill within a specific volume of water will be killed by seismic activity is not supported by evidence. Given the lack of observed effects from past seismic surveys in the region, the model's conclusions are unsupported. If krill and currents are not uniform throughout the water column, the model's assumption of uniform distribution is flawed. The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. The model, which originally aimed to show massive krill mortality, takes a simplistic approach based on basic physical principles, such as the effect of current speeds, but ignores the complexity and scale of regional ecosystem dynamics. The model lacks validation and fails to account for key factors in the region's ecology. (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4397	Stakeholder objects to the idea that meso-scale biological and physical characteristics are more appropriate for assessing impacts on whale populations or other taxa at the population level, not individual effects, claiming that individual krill disturbances can scale up to affect whale foraging success and overall population dynamics, quoting Williams 2016, Lagos 2022, Guilpin et al 2020, Santora 2011, and Kampf 2024.	Williams (2016) has been used superficially by the stakeholder. A more thorough reading reveals that the paper pertains to Humpback Whales, which show minimal response to food source reductions below 50%. The paper is useful for demonstrating the variability of ecosystems, which is discussed in detail in the Regia EP. Lagos (2022) is cited by the stakeholder to support a general statement about stress, but the thesis actually focuses on ocean warming and UV radiation impacts on krill—large-scale factors, which the Regia EP identifies as primary drivers of population changes. A small-scale disturbance like the MSS does not align with these larger impacts, which the stakeholder dismisses despite citing related studies. The stakeholder also references Guilpin et al. (2020) (not included in the bibliography). This study models how changes in krill density affect blue whale foraging success, but it highlights that climate change and fishing, not seismic surveys, drive population changes. This supports the Regia EP's focus on large-scale impacts. The stakeholder's citation of Santora (2011) on California upwelling misrepresents the information. The Bonney Upwelling area is well-defined, and the stakeholder is encouraged to consult the DCCEEW website for clarification. Kampf (2024) is used by the stakeholder to suggest upwelling outside the Bonney area, a known fact. The Regia EP addresses how Blue Whale interactions with the MSS will be managed. Kampf's work builds on existing knowledge of upwelling mechanisms, and the stakeholder is encouraged to consider it as a model for understanding ocean dynamics. (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4398	Objects to CGG's actions to avoid peak upwelling (misinterpreted as January–March) and limit survey duration to 60 days, stating that krill populations do not recover linearly after intense disturbances and the life cycle of N. australis is not necessarily aligned with the phytoplankton blooms of the Bonney Upwelling.	The stakeholder cites a study by Rau (2019) to argue that even small disruptions can affect the Southern Ocean food chain. This citation is a clear example of selective use of literature. Rau (2019) is based on aquarium experiments in a freshwater lake in Berlin, and the stakeholder is invited to clarify the relevance of Lake Muggelsee to the Southern Ocean. It appears the stakeholder did not properly review the paper. The peak upwelling season for the Bonney region is well-established through various studies, as noted in the Regia EP. Upwelling is defined by sea surface temperatures (SSTs) and chlorophyll-a (Chl_a) levels, not by wind patterns, as confirmed by the cited Barlow et al. (2021). The stakeholder's assertion that krill exist before upwelling occurs is self-evident. The stakeholder's reference to the Gill (2011) study is also inappropriate, as it does not discuss the lack of synchronization with Bonney upwelling. Furthermore, the stakeholder argues that krill are not closely linked to phytoplankton blooms in the region, contrary to established scientific knowledge. Krill rely on phytoplankton as a primary food source, and upwelling conditions concentrate this food, boosting krill reproduction and survival, which is critical for baleen whales such as Blue Whales.The stakeholder also suggests that whales are not synchronized with upwelling events, despite clear evidence that whales feed in areas where localized upwelling occurs. The Bonney Upwelling is the main upwelling center, but other regions also experience upwelling, albeit less intense, as documented in the Regia EP. Recent work by Kampf (2024, 2025) has provided insights into the mechanisms behind these upwelling events. (Event ID 6815)	6432
4399	Stakeholder claims that with the potential impact on krill mortality and EPBC protected Blue Whales, the proponent excluding current modelling is not consistent with ALARP framework.	The criticism raised by the stakeholder is unfounded and reveals a misunderstanding of ALARP principles. ALARP involves assessing control measures by balancing environmental benefits with the costs of implementation. The stakeholder's arguments are flawed as they incorrectly suggest mitigation measures should be evaluated independently, only to contradict this by stating that ALARP is about layering controls to reduce risk and they assume their model is a reliable predictor of impacts, yet the model lacks credibility, and there is no justification for assuming mitigation measures will provide any environmental benefit. Timeframe limitations are not control measures but are self-imposed to comply with legislation and support coherent assessments. (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4400	The stakeholder claims that CGG's statement fails to consider cumulative effects of seismic blasting, which can push krill populations beyond their ability to recover and disrupt population dynamics. have ecosystem level impacts, disrupting the balance of an evolved system that ensures population stability.	The key point about natural mortality rates is that plankton populations can naturally endure high mortality rates, sometimes exceeding 90%, and still thrive despite large-scale environmental changes like temperature and wind variations. This is well-documented in the Regia EP. There is no evidence to suggest that a single, spatially and temporally limited seismic survey could cause ecosystem changes at the implied scale. The Regia EP explains that planktonic communities can withstand high natural mortality rates and changes in key environmental factors. The comparison of seismic impacts to other natural events, like predation is irrelevant, as predation is a natural process. While climate change and fishing are the most significant drivers of change in marine ecosystems, seismic activity does not pose a comparable threat. The claims about seismic activity's impact on breeding krill lack any relevant scientific support, along with statements about the ripple effects of localized krill reduction. (Event ID 6815)	6432
4401	Objects to CGG's claim that impacts won't be "measurable", arguing that the absence of immediate measurable effects doesn't mean there isn't significant harm.	The case for acceptability does not rely on calculated mortality and recovery levels. Instead, the case is based on the immense size and dynamic nature of the ecosystem. The effects of the seismic survey are considered negligible because they are completely overshadowed by natural variations and dynamics, making any measurable calculation impossible. This argument is further supported by the fact that the survey avoids peak upwelling times, which are when krill populations are expected to be most productive. Additionally, when considering cumulative impacts, any extra mortality caused by the survey is expected to be quickly absorbed by the natural variations and dynamics of the ecosystem, likely within days of the survey's completion. (Event ID 6514)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4402	Stakeholder claims that equating seismic mortality with natural mortality overlooks the fact that natural mortality is an inherent part of an evolved system that maintains population stability. In contrast, human-induced mortality disrupts this balance by targeting individuals indiscriminately, including those crucial for reproduction and survival.	The Regia EP does not equate seismic mortality with natural mortality. Instead, it defines the scales of natural mortality in plankton populations to provide context for seismic effects. It is clearly stated that the two are not equivalent in any way. The stakeholder seems to misunderstand marine population dynamics, espousing a view of the natural world that was debunked in the 1970s, namely the idea of a stable or climax community where any disturbance disrupts balance. As demonstrated by Connell (1978), high diversity in ecosystems like tropical rainforests and coral reefs is only maintained in a non-equilibrium state. Wu and Loucks (1995) further emphasized that the classical equilibrium view fails because equilibrium conditions are rare in nature, and stability should consider heterogeneity and scale multiplicity. Stability, in ecological terms, is better measured by the ability of a population to continue reproducing through time, ensuring its persistence. For plankton communities like krill, this stability is defined by life-history traits such as rapid population turnover rates, enabling them to withstand extreme fluctuations in numbers and persist over time. Large variations in krill biomass are a fundamental characteristic of stable populations. (Event ID 6815)	6432
4403	Claim of ecosystem impact, as any Krill killed by seismic will become unavailble to predators.	Food chain dynamics in the open ocean are primarily supported by detritus, which serves as the foundation for energy transfer up the food chain. This detritus is mainly composed of dead plankton, with krill carcasses being a significant component, including those potentially killed by seismic activity. Such organic material is consumed by bacteria and other organisms, contributing to the marine food web. However, as demonstrated scientifically, the act of krill falling as marine snow does not cause a large-scale impact. In fact, some models suggest that this process can trigger a positive feedback loop, resulting in a surge in phytoplankton and zooplankton productivity (Skartsaeterhagen et al., 2024). (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4404, 4408, 4410	Stakeholder claims that disruptions to krill populations can directly affect Blue Whale feeding, as these whales depend on dense krill aggregations for their energy requirements. Reduced prey densities may impact whale migration and breeding success.	Krill are naturally subject to mortality rates as high as 90%, and their food source fluctuates spatially and temporally, shrinking by up to 50% between and within years. The size, duration, and location of krill swarms also vary. Whales continuously feed across this dynamic space and return annually. The Regia EP argues that there is no evidence suggesting a spatially and temporally constrained MSS would cause a disturbance greater than what already naturally occurs. The stakeholder demonstrates a lack of understanding of how stability is measured in marine environments. The energy whales derive from krill fluctuates month to month and year to year due to natural dynamics in the food chain. The scale of disruption to whale feeding energy when upwelling shrinks by 30% or 50% is far greater than any MSS disturbance. The stakeholder's general statements regarding the MSS's impact lack scientific support. (Event ID 6815)	6432
4405	objects to the assertion that ± 50% interannual variation in upwelling extent, mostly climate-driven, has not constrained whale population recovery.	Whales have evolved to handle significant fluctuations in their food source, with some years yielding more biomass and others less. The Regia EP provides references to support this argument. Upon closer examination of Wiedenmann et al. (2011), which the stakeholder cites, it becomes clear that while whales can adapt to decreases in krill abundance in a particular area, the net effect on their population vital rates is negligible. Wiedenmann et al. (2011) also suggest that blue whales may adjust their foraging behaviors in response to changes in local environmental conditions, mitigating the impacts of declines in krill abundance. They note that blue whales exploit different feeding areas based on large-scale prey abundance and can concentrate in productive areas when prey is scarce, such as during El Nino years (Benson et al. 2002, Bailey et al. 2010). Furthermore, Wiedenmann et al. (2011) propose that blue whales are better equipped to cope with environmental changes than species with more restricted foraging areas, thanks to their adaptive foraging behaviors and ability to travel long distances in a foraging season. (Event ID 6815)	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4406	The sender claims that the absence of a defined acceptable threshold for krill mortality in the Regia EP is a core issue.	The case for acceptability does not rely on calculated mortality and recovery levels. Instead, the case is based on the immense size and dynamic nature of the ecosystem. The effects of the seismic survey are considered negligible because they are completely overshadowed by natural variations and dynamics, making any measurable calculation impossible. This argument is further supported by the fact that the survey avoids peak upwelling times, which are when krill populations are expected to be most productive. Additionally, when considering cumulative impacts, any extra mortality caused by the survey is expected to be quickly absorbed by the natural variations and dynamics of the ecosystem, likely within days of the survey's completion. (Event ID 6514)	6507
4415	The percentage figure in Appendix E2, Section 4.1 has errors.	The Tang et al. (2014) paper was referenced to discuss non-predatory mortality in zooplankton samples from various marine environments. The stakeholder claimed that this rendered the estimated numbers used in the comparison irrelevant. However, Tang et al. provides a range estimate for non-predatory zooplankton mortality (11.6% to 59.8%) in these samples, which is relevant to the impact assessment. While CGG agree that directly extrapolating these mortality ranges to the entire Otway marine region might be overly simplistic and therefore doesn't carry significant weight in our overall argument, it is still a reasonable and relevant consideration. These ranges can be compared with the potential additional mortality resulting from factors such as predation, other anthropogenic sources, and the proposed survey. (Event ID 6518)	6890
4416	The Relevant Person was concerned that the Regia graph did not consider the spatial placement of the seismic tests relevant to the King George Whiting recruitment success, stating they are directly over the larval advection pathway .	This claim has previously been addressed in Feedback ID 4205: This concern has already been considered in the analysis provided to this relevant person and CGG notes that the placement of the previous surveys is not a determining factor in the assessment because of the broad spatial dispersion of fish eggs and larve associated with this fishers concern.	6325
4437	Relevant person was concerned about impacts of seismic to rock lobsters.	Event ID 6595 - The titleholder responded that they had undertaken a thorough assessment of potential impacts on SRL, including a further assessment on the effectiveness of the mitigations in place.	6592
4438	Relevant person was concerned about the impacts of seismic surveys on lobster populations.	Event ID 6875 - The Regia team responded in-meeting and explained that there is an impact of the seismic activity on lobster associated with their righting reflex. Discussed that they needed to look at what the resource tolerates. Discussed research boat in Tasmania and directed relevant person to recent research paper "Boom, Shake the Room."	6875

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4441	Concerned about the impacts of seismic activities on crab populations.	Event ID 6876 - The Regia team responded in-meeting that seismic can cause a physiological reaction in crab - delayed righting. Discussed that they will only go to 200m.	6876
4443	Concerned that the Regia team said there will be zero effect and that every historical seismic activity has had a worse effect.	Event ID 6876 - The Regia team responded in-meeting that they did not say there would be zero effect. Offered to analyse fishing data provided by commcercial fishers and reproduce long-term catchability analysis. An analysis is also included in Appendix F3, section 3.5.3	6876
4444	Concerned that there are no studies about the effect of seismic after adult malting.	Event ID 6786 - The Regia team responded in-meeting and discussed UTAS study which looked into effects of seismic during different stages of juvenile development. Explained that the sample size was very small. Study showed that there is a repairing period. Asked relevant person about malting seasons.	6876
4447	Asserted that non-productive catch areas are a result of seismic activity.	Event ID 6876 - The Regia team responded in-meeting that they could re-run their long-term catchability analysis with data provided by commercial fishers. Stated that they could reduce block size and make it granular.	6876

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4378	Stakeholder described the anthropogenic impacts on the Victorian Fairy Penguin populations, such as direct human interference, predation by dogs, cats, foxes and rats, trampling of burrows by humans and stock, plastic product pollution, oil spills, accidental entrapment, inundation of burrow sites from climate induced sea level rise and drowning in fishing nets and competition with fisheries. Claims that seismic blasting will be an additional pressure to these challenges and threats that marine life and the Fairy Penguins already face, and may result in local population reproduction failure or extintion if sufficient protections are not put in place.	Event ID 6882 (Doc ID 9096)- CGG agrees that predation from feral animals, particularly dog attacks, poses a significant threat. Recent research by Blamey et al. (2024) identifies dog attacks as the largest threat to Little Penguin colonies in Tasmania, and similar threats have been reported along Western Victoria (Norman et al., 2017). In response to the claim that CGG compared the potential impacts of the Regia MSS to the serious threats faced by penguins, CGG clarifies that such a comparison has never been made. CGG seeks clarification on the origin of this statement. CGG acknowledges the potential for behavioural impacts on Little Penguins but asserts that these impacts are of an acceptable level, as detailed in the EP. The justification for this conclusion includes: • Sound exposure results in only short-lived changes, which penguins can quickly habituate to. • There is no evidence suggesting a reduction in overall fitness, as demonstrated by their extensive foraging ranges and capabilities. • Breeding success and survival rates are unaffected, as breeding occurs on land and no mortal or potential injury (PTS) from sound exposure has been observed. This conclusion is based on an extensive review of scientific literature, alongside the mitigation measures implemented by CGG. While sound may act as a deterrent, CGG acknowledges that the sound source moves. To further mitigate any potential effects on Little Penguins, CGG has committed to using a low power setting if foraging flocks (which may indicate feeding penguins) are observed within 500 m of the sound source. Full power will only be employed when the seismic source is more than 500 m away from such flocks, ensuring that foraging birds are not startled and can continue to forage after the vessel has moved on.	6412

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4379	Claims that the proposed activity may cause chicks to be underfed or abandoned due to the seismic blasting activity meaning less access to food supply, leading to death and reproductive failure as Fairy Penguins can be potentially behaviourally affected up to 77km away from the airgun source, forcing them from their natural colony foraging area and impacting caring for their young during breeding season (June-February), as forced into more concentrated areas of limited breading season foraging range. This could result in eggs and chicks being abandoned due to lack of food and uncomfortable sound pressure.	Event ID 6882 (Doc ID 9096) - Previously responded to in Feedback ID 4138. Titleholder re states several studies related to penguin foraging behavior, outlining the following key points about the home range and feeding behavior of penguins, their foraging distances, and the lack of evidence suggesting seismic surveys have caused penguin chick mortality. 1. Feeding Range and Foraging Distances: o It is essential to distinguish between maximum, total, and mean/median foraging distances when describing home ranges. o Studies show that while penguins may occasionally travel distances exceeding 30 km from their nesting sites, the majority of their foraging occurs within 15-20 km of the nest (Berlincourt & Arnould 2014, Pelletier et al. 2014, Philips et al. 2019, Philips et al. 2022). o The longer foraging distances are exceptions rather than the norm, and this is consistent across multiple studies and locations. 2. Food Resources and Foraging Areas: o The Otway region is rich in sardines and squid, with food quality improving closer to upwelling areas, which are known to enhance the availability of these resources (Norman et al. 2017). o The presence of abundant food resources may allow penguins to meet their nutritional needs more efficiently without needing to travel far. 3. Penguin Condition and Foraging Effort: o Berlincourt and Arnould (2015) found that penguins breeding at the London Bridge colony did not show variation in body condition despite an increase in foraging effort. This could imply that these penguins have a greater capacity to increase foraging efforts if prey becomes scarcer. 4. Fledgling Weight: o Overeem Wallis (2003) reported that the mean fledgling weight at Middle Island was 1081.4g. Fledgling weight is an important indicator of the health and success of young penguins. 5. Seismic Surveys and Penguin Mortality: o There is no scientific literature to support the claim that seismic surveys result in the death of penguin chicks. o Despite numerous seismic surveys and other petroleum-related activities in the Otway region since the 1960s, no evidence of direct harm to penguins, including chick mortality, has been observed. o On the other hand, studies highlight that the primary threat to penguins, especially little penguins, comes from feral animal predation.	6412

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4386	objects to CGG's claim that the disturbance will be “short term” and “temporary”, stating that the seismic blasting project may disrupt the penguins' foraging behavior and potentially impact the population health of penguin colonies in the area, including increased competition and less area in which to forage.	Event ID 6882 - Whilst the Titleholder continues to acknowledge there may be some behavioural impacts to little penguins, there is no scientific evidence to support the claim that young chicks may be abandoned as a result of the survey. CGG has described the disturbance as being short term and temporary as this accurately reflects the activity relative to other disturbances, for example the continuous predation by feral animals.	6412
4387	Claims that CGG’s Environment Plan needs to be updated to the correct normal breeding season commencement time of June/July for the Fairy Penguins of Western Victoria.	Event ID 6882 - CGG agrees to amending the EP to reflect this: During consultation with relevant persons, it was noted that as referenced by the Middle Island Project (Event ID 6412) there were instances of breeding cycles beginning as early as June.	6412
4445	Concerned that divers had noticed a reduction in marine activity after a seismic activity.	Event ID 6876 - The Regia team responded in-meeting and went through their box plot analysis. Explained that the data used was landed catch data each month from 2016 - 2023. Also went through CPUE data set and stated that the analysis showed although landed catch was lower, CPUE was still in range in 2020. Explained the Regia team are looking at recruitment of the fishery. Explained that the fishers take 30% of the fishery. Stated there was evidence there was no stock level effect.	6876
4446	Raised concern that catch will drop off 5 years after seismic activity.	Event ID 6876 - The Regia team responded in-meeting and went through their box plot analysis. Explained that the data used was landed catch data each month from 2016 - 2023. Also went through CPUE data set and stated that the analysis showed although landed catch was lower, CPUE was still in range in 2020. Explained the Regia team are looking at recruitment of the fishery. Explained that the fishers take 30% of the fishery. Stated there was evidence there was no stock level effect.	6876

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4382	Claims that the 20km halo is insufficient for the penguin populations to forage without direct impact disturbance and questions the intent behind the 20km seismic-free halos around each Fairy Penguin colony apart from the Deen Maar colony which does not have the same exclusion buffer.	As described in Appendix F3, section 3.4, studies have shown that while little penguins can forage up to 30 km from their nesting sites, the majority of feeding during the nesting season occurs within 15–20 km. This pattern has been confirmed across multiple locations and studies. Research also shows that little penguins are highly adaptable foragers. Tagging studies at London Bridge revealed changes in foraging effort in response to sea conditions, yet body condition remained stable, suggesting the capacity to increase effort as needed. A tagging study confirmed that little penguins are shallow divers and forage close to shore. The study found that while individual penguins showed some consistency in foraging behaviour over short periods, their foraging locations varied across days, suggesting they adapt to shifting prey availability. There was no long-term consistency in their foraging patterns, indicating an ability to respond to prey that is unpredictable over time. Overall, the findings highlight little penguins' high behavioural plasticity and flexibility, with variation in foraging behaviour influenced by location, year, breeding stage, and clutch (Camprasse et al. 2017).	6412
4452	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	7136
4453	Stakeholder claims that potential impacts on World Heritage Values of Budj Bim and the life-cycle of Kooyang have not been properly assessed or addressed.	Regia team responded by referencing the relevant impact assessments in the Environment Plan (EP) (EVT070), this information was also provided in Event ID 7363. Previously provided in Event ID 2521, 2356, 2357, 2358, 2359, 2360, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417.	EVT070
4460	Claims that seismic blasting adds cumulative pressure to Fairy Penguins, leading to additional adverse effects beyond existing threats that could lead to population declines or local extinction, and that this cumulative impact has not been considered.	Species sensitivity, including threats from existing predation and robustness of food stocks, was included in Appendix F3, section 3.4, as per previous feedback (FB ID 4378).	7135
4461	Objection to the acceptability of behavioural impacts and displacements of Fairy Penguins from core foraging areas caused by seismic noise.	Assessment using up to date and relevant science has concluded that any impacts would be temporary and short-term with no population level impacts, as per previous feedback (FB ID 4386).	7135

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4462	Objection to claim that breeding and chick rearing is unaffected due to being on land, emphasing the need for adult penguins to forage at sea.	Assessment using up to date and relevant science has concluded that any impacts would be temporary and short-term with no population level impacts and no scientific evidence to support the claim, as per previous feedback (FB ID 4386).	7135
4463	Claims that mitigation measures for Fairy Penguins are insufficient to protect breeding success and health.	That the justification for the mitigation measures has been outlined in prior feedback (IDs 4027, 4119 and 4138). The environmental assessment aims to ensure population stability is not affected and that impacts are reduced to ALARP. The assessment concludes that the Little Penguin population is not at significant risk, based on the combined effect of the mitigation measures. These include scheduling the survey outside the core egg-laying and chick-rearing period, locating the survey outside primary feeding areas (typically within 20 km of nests), and exposure near Deen Maar to just five hours over three weeks. Because the seismic vessel is always moving, penguins have continuous opportunity to avoid the sound source. Feeding grounds extend widely along the coast, and anchovy stocks—the main food source—are currently healthy. In addition, if feeding flocks are observed within 500 m of an active seismic line, the source will be reduced to low power until the vessel is again beyond this distance. Collectively, these measures reduce impacts to ALARP and avoid any pathway to population-level effects.	7135
4464	Objection to proceeding with seismic surveys in the absence of published studies, based on precautionary principle.	The precautionary principle requires action to prevent environmental degradation even when full scientific certainty is lacking, but only where there is a threat of serious or irreversible harm. CGG states that the Regia EP demonstrates that, with the measures applied, the Regia MSS does not pose such a threat. Therefore, in CGG's view, uncertainty does not trigger the precautionary principle in this case, making debates about the extent of uncertainty irrelevant to its legal application.	7135
4465	Claims insufficient assessment of indirect effects on penguin food supply (Cluepid fish) from seismic activity.	This assessment has been undertaken and provides the EP reference, Appendix F3, section 3.4.1. States that the outcome (impacts are of an acceptable level) has previously been shared with the stakeholder (Feedback IDs 4378 & 4122). Confirms that the core food stocks for Little Penguin (Anchovy) are in good health, as confirmed via state fishing statistics.	7135
4466	Claims the EP does not provide consideration of how penguins, both chicks and adults, may be directly or indirectly affected during the guard and post-guard stages of the breeding season.	The guard and post-guard stage is already considered in assessment Appendix F3, section 3.4, quoting Berlincourt and Arnould's 2015 paper, as per previous feedback (FB ID 4228).	7135

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4467	Claims the EP underrepresents the early onset of egg-laying at colonies beyond Middle Island, despite previously provided evidence showing that breeding at other locations, such as the London Bridge colony, regularly begins as early as June or July. The stakeholder suggests that CGG has omitted relevant scientific data already shared with them, resulting in an incomplete picture of the species' breeding phenology in the region.	This is in the EP, as per the following reference in App F3, section 3.4.1, from Event ID 6412: During consultation with relevant persons, it was noted that as referenced by the Middle Island Project (Event ID 6412) there were instances of breeding cycles beginning as early as June.	7207
4468	Objection to claim that breeding and chick rearing is unaffected due to being on land, emphasizing the need for adult penguins to forage at sea.	Assessment using up to date and relevant science has concluded that any impacts would be temporary and short-term with no population level impacts and no scientific evidence to support the claim, as per previous feedback (FB ID 4386).	7207

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4469	Objects to the negative effects of seismic testing on the short-finned eel.	CGG undertook scientific assessment for underwater sound impacts on Fish (Appendix E3 and F3), including short-finned eels. Short-finned Eels possess a swim bladder and were grouped with other fish having swim bladders for acoustic impact analysis, following the guidance of Popper et al. (2014). For fish in general, and eels in particular, the key impact mechanisms considered were potential for hearing damage or physiological injury from intense sound close to the source, and behavioural disturbance (e.g. startle responses or avoidance movement) at various distances. The EP concluded that no fish, including eels, would be close enough to the seismic source to suffer mortality or physical injury, with measures in place such as soft-starts the free-swimming fish are able to move away from the sound source, and that they anticipate no direct fatalities or lasting injuries to adult eels in the water. The titleholder acknowledges that fish may exhibit behavioural reactions to seismic noise and they assumed a conservative scenario where fish might show avoidance responses at substantial distances. In the worst case, an eel migrating through the area might detect the seismic pulses at distance and alter its course or depth to avoid the highest sound levels. The EP considered such avoidance to be a temporary and localised effect and that any diversion would likely be on the scale of hundreds of meters to a few kilometres at most. Given that migrating eels travel thousands of kilometres to reach spawning grounds, a short detour or a brief pause is not expected to jeopardize their overall journey. The EP's finding was that behavioural changes would be temporary and would not have long-term impacts on individuals or the population. (Responded to in EVT346)	EVT178
4470	Objects to the insufficient consideration of the physical presence and migration interference caused by seismic activities in eel migratory pathways.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. The titleholder acknowledged that the Regia MSS Operational Area is offshore in the Otway Basin (south-west of Vic), which is adjacent to, with some limited overlap, to the potential migration corridor for these eels heading toward the western Tasman Sea. Appendix E3 identified "Eels (Anguilla spp.)" as a receptor in the environment that could be affected by underwater sound (section 4.1.6), precisely because Short-finned Eels are present in coastal catchments adjacent to the survey area and undertake marine migrations. (Responded to in EVT346)	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4471	Objects to the insufficient consideration of daily vertical migrations of the short-finned eel.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. CGG recognises that Short-finned Eels spend most of their life in freshwater/estuarine environments and undertake a once-in-a-lifetime spawning migration to the ocean. Specifically, the EP notes that mature adults (typically 8–20 years old, depending on sex) depart their rivers in late summer to autumn to migrate to oceanic spawning grounds. The EP also describes the return journey of the progeny: eggs hatch into larvae that drift southward on currents, metamorphose into “glass eels” and eventually enter coastal estuaries (with peak recruitment in winter–spring), which is consistent with established literature and references cited by the stakeholder (e.g. Gooley et al. 2002 , Jacoby et al. 2015). Appendix E3 incorporated the latest research on eel migration behaviour, notably Koster et al. (2021). The EP explicitly references Koster et al. and confirms the phenomenon of diel (daily) vertical migration in migrating eels: tagged eels from the Hopkins and Fitzroy Rivers exhibited a pattern of surfacing at night and diving deeper during the day while at sea. CGG acknowledges that this is a crucial behavioural detail that the EP does acknowledge. (Responded to in EVT346)	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4472	Objects to the insufficient consideration in Regia MSS Environment Plan's of the cultural value of the short-finned eel in South-West Victoria and South Australia beyond Budj Bim.	The Regia MSS EP was prepared and assessed under an objective based regulatory regime, which requires the titleholder to consider a broad definition of the environment which may be affected, including cultural heritage. The EP recognises the intangible cultural or spiritual connections to Sea Country and undertook research and assessment, including consultation with Traditional Owner groups, within the relevant Sea Country. While no significant impact is predicted, they remain committed to respectful ongoing engagement with Indigenous stakeholders regarding any spiritual or cultural concerns. Cultural heritiage to the eels is stated in Appendix E3 section 4.6.1, Appendix F3 section 3.7 and 3.16. Titleholder also explained that the EP contains a dedicated assessment of the Budj Bim Cultural Landscape (World Heritage Site) and its connection to Short-finned Eels and directed the stakeholder to Appendix F3 (Section 3.15). They stated that the conclusion of that assessment was that no threat or damage to Budj Bim's heritage values is expected from the proposed activity and that the cultural practices and eel stocks that underpin Budj Bim's value will not be materially affected. They stated that the EP goes further to acknowledge that beyond formally listed World Heritage values, there may be intangible cultural or spiritual connections to Sea Country that are difficult to quantify and that the Titleholder has regognised these and consulted Traditional Owner groups to better understand them.	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4473	Objects to the inadequate consideration of the habitat and lifecycle of the short-finned eel as their habitat includes all the areas essential to its lifecycle.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. The titleholder acknowledged that the Regia MSS Operational Area is offshore in the Otway Basin (south-west of Vic), which is adjacent to, with some limited overlap, to the potential migration corridor for these eels heading toward the western Tasman Sea. Appendix E3 identified "Eels (Anguilla spp.)" as a receptor in the environment that could be affected by underwater sound (section 4.1.6), precisely because Short-finned Eels are present in coastal catchments adjacent to the survey area and undertake marine migrations. The EP outlines the broad geographic distribution of Anguilla australi, extending from Queensland through Victoria, Tasmania, South Australia, and New Zealand, to demonstrate that eels from various regions may pass through or near the survey area. Accordingly, the EP did not overlook the potential for eels originating from rivers west of the survey area (such as the Glenelg River, Coorong, and Murray River) to travel along the continental slope. Instead, it treated the Short-finned Eel as a wide-ranging species and assessed it on that basis. The EP did not list each river individually because it considered the species at a regional population level. The evidence and conclusions therefore apply to all Short-finned Eels in the area, irrespective of origin, as their marine behaviour and sensitivities are expected to be consistent across populations. The EP also includes detailed description of lifecycles, referencing the latest science, including the migrations in these lifecycles. (Responded to in EVT346)	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4474	Claims that seismic sounds can cause sublethal and lethal impacts on short-finned eels, such as disorientation, reduced energy budgets, stress or mortality.	Appendix E3, and additional species-specific assessment in F3, provides a thorough summary of short-finned eel biology, aligned with the best available science and fisheries data. The titleholder acknowledged that the Regia MSS Operational Area is offshore in the Otway Basin (south-west of Vic), which is adjacent to, with some limited overlap, to the potential migration corridor for these eels heading toward the western Tasman Sea. Appendix E3 identified "Eels (Anguilla spp.)" as a receptor in the environment that could be affected by underwater sound (section 4.1.6), precisely because Short-finned Eels are present in coastal catchments adjacent to the survey area and undertake marine migrations. The EP outlines the broad geographic distribution of Anguilla australi, extending from Queensland through Victoria, Tasmania, South Australia, and New Zealand, to demonstrate that eels from various regions may pass through or near the survey area. Accordingly, the EP did not overlook the potential for eels originating from rivers west of the survey area (such as the Glenelg River, Coorong, and Murray River) to travel along the continental slope. Instead, it treated the Short-finned Eel as a wide-ranging species and assessed it on that basis. The EP did not list each river individually because it considered the species at a regional population level. The evidence and conclusions therefore apply to all Short-finned Eels in the area, irrespective of origin, as their marine behaviour and sensitivities are expected to be consistent across populations. The EP also includes detailed description of lifecycles, referencing the latest science, including the migrations in these lifecycles. (Responded to in EVT346)	EVT178
4475	Objects to the inconsistent consideration of short-finned glass eels arriving during April to October as they have been recorded to arrive throughout the year.	The EP describes the Short-finned Eel migration from Victoria largely occurring during late summer through autumn consistent with prevailing scientific theory. (Responded to in EVT346)	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4476	Objects to the lack of consideration of glass eel feeding, or the potential of having to 'swim out of the way' of seismic testing on energy budgets.	The Environment Plan (EP) fully considered potential effects of seismic activity on Short-finned Eels, particularly in relation to their ability to detect, avoid, and respond to underwater sound while migrating. The assessment followed internationally recognised scientific frameworks (e.g., Popper et al. 2014) and incorporated conservative sound-modelling to determine thresholds for injury and behavioural disturbance. The assessment concluded that no eels would be close enough to the seismic source to suffer injury or mortality, as eels are free-swimming and capable of moving away from noise. A soft-start procedure will also allow animals to detect and avoid the source gradually. Behavioural responses such as temporary avoidance or course adjustment were acknowledged and assessed as the most likely effect. Any such diversion would be localised and short-term, on the scale of hundreds of metres to a few kilometres, and would not meaningfully affect the eels' long-distance migration or energy reserves, given their natural capacity for endurance. The EP therefore determined that behavioural changes would be temporary, reversible, and of low intensity, with no population-level consequences. Supporting evidence from global studies shows no recorded cases of eel mortality or population decline linked to seismic surveys, including in the Otway Basin, where over 80 surveys have occurred in the past six decades. The assessment concludes that Short-finned Eels may move away from the survey area when exposed to sound, but will resume migration without harm or delay, and that predicted impacts are minor, transient, and not significant at individual or population scales. (Responded to in EVT346) Appendix E3 section 4.1.6 has been updated to include: It has been noted by Van Wichelen, et al (2022) that glass eels feeding during their migration is highly restricted, therefore when discussing impacts to glass eels, this has been considered.	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4477	Objection about the lack of adequate recognition and consideration of non-lethal, cumulative, and long-term impact of seismic noise on short finned eel.	Short-finned Eels possess a swim bladder and were grouped with other fish having swim bladders for acoustic impact analysis, following the guidance of Popper et al. (2014). For fish in general, and eels in particular, the key impact mechanisms considered were potential for hearing damage or physiological injury from intense sound close to the source, and behavioural disturbance (e.g. startle responses or avoidance movement) at various distances. The assessment concluded that no fish, including eels, would be close enough to the seismic source to suffer mortality or physical injury, with measures in place such as soft-starts the free-swimming fish are able to move away from the sound source, and that they anticipate no direct fatalities or lasting injuries to adult eels in the water. The titleholder also acknowledged that fish may exhibit behavioural reactions to seismic noise and that they assumed a conservative scenario where fish might show avoidance responses at substantial distances. In the worst case, an eel migrating through the area might detect the seismic pulses at distance and alter its course or depth to avoid the highest sound levels. The EP considered such avoidance to be a temporary and localized effect and that any diversion would likely be on the scale of hundreds of meters to a few kilometres at most. Given that migrating eels travel thousands of kilometres to reach spawning grounds, a short detour or a brief pause is not expected to jeopardize their overall journey. The EP's finding was that behavioural changes would be temporary and would not have long-term impacts on individuals or the population. The Titleholder noted that the EP acknowledges the existing pressures on the Short-finned Eel population and was developed to demonstrate that the proposed seismic survey would not materially increase the cumulative impact on the species. The cumulative impact assessment concluded that, even when accounting for other regional activities, the incremental effect of the survey on overall conservation values would be neutral to negligible. (Responded to in EVT346)	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4478	Objection to CGG's statements of 'no predicted mortality' on short finned eels is not supported.	This conclusion is supported by conservative modelling, peer-reviewed scientific research, and a precautionary evaluation of worst-case scenarios. No new scientific information was identified in the submission that had not already been considered in the Environment Plan. References such as Koster et al. (2021) were already incorporated into the EP, which includes the IUCN listing of near threatened. CGG notes that while Jacoby et al. (2015) raised conservation concerns for the species, the EP's findings are consistent with ensuring that the proposed activities do not exacerbate those concerns. (Responded to in EVT346)	EVT178
4479	Objection to CGG's statements about proposed mitigation measures in relation to the short finned eel.	The Environment Plan (EP) adopts an evidence-based, risk-weighted, and precautionary approach, consistent with both the letter and spirit of the precautionary principle in Australian law. The EP concludes that the impacts and risks to Short-finned Eels have been reduced to As Low As Reasonably Practicable (ALARP) and remain acceptable, meeting the requirements for EP acceptance under Regulation 34. While recognising that NOPSEMA's independent review will make the final determination on the EP's adequacy, CGG's view is that the document meets the regulatory acceptance tests, including demonstrating no unacceptable impacts on World Heritage values and consistency with the principles of Ecologically Sustainable Development (ESD). (Responded to in EVT346)	EVT178
4480	Objection to CGG's frequency range of 0-200Hz on migrating eels, stating the EP minimises how seismic testing may affect the eels.	Short-finned Eels possess a swim bladder, though it is not primarily used for hearing, and were therefore grouped with other fish possessing swim bladders for the purpose of acoustic impact assessment. The Environment Plan (EP) applied the internationally recognised framework of Popper et al. (2014) to establish scientifically validated thresholds for potential injury and behavioural disturbance. The assessment considered possible hearing damage, physiological effects from intense sound near the source, and behavioural responses, such as avoidance or startle reactions, at varying distances. As no specific audiograms exist for Short-finned Eels, the EP adopted a conservative approach, assuming they would respond similarly to other fish with comparable anatomy. (Responded to in EVT346)	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4481	Claims that content provided in the Regia Environment Plan is inconsistent, incomplete, misleading and has multiple errors in logic and critical thinking and does not accurately represent the evidence about the life cycle of the short-finned eel.	The version of the EP referenced by the stakeholder (June 2024) had been substantively updated with multiple iterations during NOPSEMA's assessment and following public comment which addresses all scientific and policy related claims. Titleholder also explained that the Regia MSS EP was prepared and assessed under an objective based regulatory regime, which requires the titleholder to consider a broad definition of the environment, including cultural heritage and social values, not just the immediate onshore operational area.	EVT178
4482	Claims the inadequacy of the Regia MSS Environment Plan in applying the precautionary principle and using transparent, comprehensive evidence for impact assessment.	The claim that the process lacked transparency is not supported by record as the project ran an unusually open process where the EP and appendices were published on the Consultation Hub, and the public were provided with updates at every revision. The EP's approach is fully consistent with Australian regulatory requirements for EP's which demand evidence-based assessment and precaution in the face of uncertainty and that the Regia MSS EP applied conservative assumptions and safety margins wherever scientific uncertainty existed. CGG are confident that the EP's evidence-based, risk-weighted approach – supplemented by precautionary, worst-case scenarios – meets both the letter and spirit of the precautionary principle in Australian law. The EP applies precaution through conservative assumptions, rigorous modelling, and layered safeguards, while also ensuring that conclusions remain scientifically defensible and evidence based. CGG have taken precautionary measures without abandoning accuracy or overstating unverified threats.	EVT178
4483	Claims insufficient monitoring and need for application of conservation recommendations and the IUCN's ongoing monitoring advice.	The EP applies the precautionary principle and ESD, using a conservative risk assessment that predicts negligible impact and is consistent with avoiding any deterioration in the species' conservation status. The EP acknowledges the conservation concerns highlighted in scientific literature, noting that the Short-finned Eel is classified as Near Threatened on the IUCN Red List. However, this classification is attributed primarily to freshwater habitat issues, not marine threats. The EP did not propose species-specific monitoring for eels because the predicted impacts were deemed so low (minor, transient disturbances with no lasting harm to individuals or the population), however would be open to assisting researchers.	EVT178

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4484	Claims that the Regia MSS assessment on mortality of eels shows a critical thinking error, confirmation bias, logical fallacy and exaggerated language.	CGG maintains that the EP contains no fundamental logical flaws and expresses confidence that NOPSEMA, as the independent regulator, would identify any such issues in fulfilling its statutory role. The EP applies a structured weight-of-evidence approach, drawing on multiple lines of scientific information rather than selectively minimising impacts; where uncertainty was identified, the EP adopts precautionary assumptions. CGG states that the EP meets all regulatory requirements by describing the activity and environment, identifying all credible impacts and risks, and demonstrating that they are reduced to ALARP and acceptable levels. Regarding eel mortality, CGG notes that the EP explicitly predicts no mortality or injury based on modelled sound levels. Acoustic modelling shows the distance at which injury could occur is limited (60–230 m), and because eels are mobile, combined with the soft-start procedure, the likelihood of harm is extremely low. In response to concerns about confirmation bias or minimising language, CGG explains that terms such as “low risk” and “no measurable impact” are technical descriptors supported by evidence, not value judgments. They state that contextual information—such as the species’ resilience and broader existing pressures—is provided to ensure accuracy rather than diminish concerns. CGG also acknowledges minor typographical errors in species names but clarifies that these do not affect the scientific assessment.	EVT178
4485	Claims the activity will exacerbate existing pressures on freshwater eel.	The EP directly acknowledges the conservation concerns identified in the scientific literature and states that its impact conclusions are designed to ensure the proposed activity does not exacerbate those threats. It contextualises the Short-finned Eel’s resilience by noting that the species faces far greater long-term pressures, such as overfishing, river barriers, drought, and climate-driven changes to ocean currents, and that its Near Threatened status on the IUCN Red List is primarily due to freshwater habitat issues rather than marine impacts. Within this broader context, the EP concludes that the Regia MSS survey will not materially add to the cumulative pressures on the eel population. The cumulative impact assessment predicts the survey’s incremental effect to be neutral to negligible, and that any impacts will be minor and temporary, with no risk of jeopardising migration success or the species’ viability.	EVT200

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4486	Claims that the overall ecological health of systems is impacted by stressors affecting the short finned eel.	The EP recognises the ecological significance of the Short-finned Eel within the wider system. It notes that the species plays an important dual role in aquatic food webs, as both predator and prey, and is an ecologically connected component of marine and freshwater ecosystems. The EP describes the species' resilience, highlighting that Short-finned Eels are broadly distributed, migratory, and have persisted through natural environmental fluctuations over millennia. The EP assesses whether any predicted impacts could translate into population-level or ecosystem-level consequences. It concludes that Short-finned Eels are expected to experience only minor and temporary behavioural disturbance from the seismic survey, with no lasting harm to individuals or the population. Because abundance and function are predicted to remain intact, the species' ecological roles are not expected to change. Consistent with defined acceptable impact criteria, the assessment finds that effects will be temporary, reversible, small-scale, and low intensity at the population level. On this basis, the EP concludes there will be no ripple effects on predators, prey, or ecosystem processes. The document further supports this conclusion by noting that more than 80 seismic surveys have taken place in the Otway Basin over six decades, with no recorded decline in Short-finned Eel populations attributable to seismic activity.	EVT200

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4487	Claims that CGG's proposed activities are inconsistent with the Recovery Plans made under the EPBC Act, the Southern Right Whale Recovery Plan and the Blue Whale Recovery Plan. GMTOAC states that these activities pose known physical and behavioural risks to the Eastern Population of Southern Right Whales and to Pygmy Blue Whales. These risks include impacts from anthropogenic underwater noise, particularly seismic noise, vessel strikes, climate-driven changes in prey availability, and the cumulative effects of these pressures, all of which have the potential to injure or kill individuals and affect populations. GMTOAC notes that under the EPBC Act Program and NOPSEMA's decision-making guidelines, an Environment Plan cannot be accepted if it is inconsistent with a recovery plan. It emphasises that both Recovery Plans contain "Very High" importance actions requiring that Blue Whales and Southern Right Whales must be able to continue using their Biologically Important Areas (BIAs) without auditory impairment, injury, or displacement. The plans also call for preventing disruption and displacement of Karntubul (Southern Right Whales) from BIAs due to anthropogenic noise such as seismic surveys.	CGG maintains that its approach aligns with statutory obligations and industry best practice. It asserts that all regulatory requirements under Regulation 34 have been met, and that its environmental performance outcomes and control measures are grounded in the best available science and tailored to the ecological and cultural sensitivities revealed through consultation. The Regia MSS Environment Plan (EP) was designed to ensure impacts and risks are reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. Regarding whale protection, CGG highlights that the EP includes specific mitigation measures for culturally and ecologically significant marine fauna, including species noted in relevant Recovery Plans. Early correspondence in February 2023 identified Southern Right Whales and Pygmy Blue Whales as key sensitivities, and the EP commits to spatial and temporal avoidance measures, sound-source shutdowns, and exclusion zones to protect them. These measures explicitly consider cultural significance, such as timing restrictions to avoid the Karntubul (Southern Right Whale) birthing period. The whales, Karntubul and Wuuloc, are identified in the EP as sensitive receptors with dedicated protective measures. CGG confirms that these cultural and ecological sensitivities were incorporated into the environmental assessment. The EP acknowledges the sacred cultural status of Koontapool (Southern Right Whale) and Wuuloc (Pygmy Blue Whale) for the Gunditjmara people and includes them in impact and cumulative risk assessments. Appendix F3 references the Nyamat Mirring Plan 2023–2033 and recognises Gunditjmara spiritual connections, including to Karntubul. CGG substantively addresses the relevant issues, including underwater noise, vessel interactions, and cumulative effects. The EP sets out noise-management frameworks, timing restrictions, and cumulative impact analyses consistent with the concerns raised.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4488	Claims that CGG has not incorporated effective control measures to reduce impacts and risks to ALARP or to ensure those impacts will be acceptable. It maintains that several control measures in the Environment Plan (EP) are inconsistent or conflicting, making them difficult or impossible to implement. GMTOAC further contends that CGG has weakened its mitigation framework compared with the November 2024 EP by replacing required sound-source shutdowns with an undefined "low power zone" when Karntubul (Southern Right Whales) are present. Also, that CGG has not ensured its activity will avoid unacceptable impacts on Koorn Moorn, which feed in Nyamat Mirring waters extending 200 m around Deen Maar Island. It claims CGG has not used the best available science in its noise modelling and has relied on comparative analyses rather than updated models, making results difficult to interpret. Additionally, GMTOAC argues that the revised ALARP assessment methodology introduced in the April 2025 EP, intended to address flaws in the November 2024 version, is inadequate, less systematic, and less defensible than the earlier approach.	CGG maintains that the Environment Plan (EP) incorporates effective control measures and satisfies the legal requirements for demonstrating that impacts and risks have been reduced to As Low As Reasonably Practicable (ALARP) and to an acceptable level. It asserts compliance with Regulation 34 and emphasises that its environmental performance outcomes and controls are grounded in the best available science and tailored to the identified ecological and cultural sensitivities. Culturally significant species and features, including Karntubul and Koorn Moorn, are included in impact and cumulative risk assessments using a methodology intended to reflect both scientific evidence and cultural. CGG argues that GMTOAC's objections substitute personal disagreement for the regulatory test, noting that the legislation does not require stakeholder agreement or grant veto powers over EP design decisions. While GMTOAC criticises the revised ALARP assessment methodology (April 2025 EP), CGG reiterates that its approach satisfies the regulatory criteria. In response to claims that mitigation measures have "weakened", particularly the shift from sound-source shutdowns to a "low power zone", CGG characterises these changes as part of a normal, adaptive, and consultation-driven refinement process. It describes the evolution of the activity as a progressive reduction in operational footprint, increasingly targeted controls, and strengthened performance-based measures, noting that core protections such as timing restrictions to avoid Karntubul birthing seasons remain in place. CGG states that cultural and ecological sensitivities associated with Karntubul, Wuuloc, and Koorn Moorn have been integrated into the assessment, with Appendix F3 acknowledging their cultural significance and informing mitigation commitments. CGG reiterates that its control measures are based on contemporary scientific evidence and incorporate cultural and ecological sensitivities throughout the EP.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4489	Claims that CGG cannot determine what constitutes an "acceptable" level of impact or risk to Gunditjmara cultural values in Nyamat Mirring. States the April 2025 Environment Plan contains flawed cumulative impact assessments due to this lack of consultation. GMTOAC identifies several shortcomings: CGG's interpretation of potential impacts to Gunditjmara and other First Nations cultural heritage is too narrow; CGG wrongly assumes that acceptable ecological impacts equate to acceptable cultural impacts; and CGG's cumulative impact assessment for Karntubul (Southern Right Whale), previously criticised by NOPSEMA in its February OMR, remains unchanged.	CGG rejects GMTOAC's claim that inadequate consultation prevents CGG from determining "acceptable" levels of cultural impact, asserting that it fully met its consultation obligations. CGG argues that the legal test is whether the Environment Plan demonstrates impacts and risks are reduced to ALARP and to an acceptable level. It maintains that GMTOAC's critiques conflate subjective opinion with the regulatory standard under Regulation 34 and emphasises that the law does not grant stakeholders a veto over design decisions. In response to the assertion that its interpretation of cultural heritage is too narrow, CGG maintains that GMTOAC has already articulated its cultural values clearly and extensively through published materials and received during consultation. These values, encompassing ceremony, obligations, kinship systems, spiritual relationships, and ecological connections are thoroughly integrated across the EP. The EP references the Nyamat Mirring Plan 2023–2033, incorporates cultural values and sensitivities into Appendix F3, and identifies culturally significant species and places as sensitive receptors with tailored management measures, for example, timing restrictions to avoid birthing seasons. CGG states that it has incorporated analysis of cumulative effects on Sea Country, including those arising from the survey in combination with other activities. It confirms that Karntubul is included in cumulative risk assessments with corresponding mitigation commitments.	EVT352
4490	CGG has failed to adequately assess the impacts of its proposed activity on the Budj Bim World Heritage Cultural Landscape. GMTOAC further states that CGG did not sufficiently evaluate impacts on Kooyang, a culturally significant species whose lifecycle and migration underpin the world heritage values of the Budj Bim Cultural Landscape and extend well beyond its physical boundaries.	Culturally significant features, including the Budj Bim landscape, were included in both impact and cumulative risk assessments using a methodology that blends scientific evidence with cultural narratives. Regarding Kooyang (Eel), CGG maintains that this culturally important species, whose lifecycle is central to the world heritage values of Budj Bim, was addressed within the EP's impact and cumulative assessments. These assessments include both Kooyang's cultural significance and ecological role. CGG reiterates that its EP is consistent with statutory obligations, based on best-available science, and tailored to the cultural and ecological sensitivities identified. CGG maintains that the Budj Bim Cultural Landscape and Kooyang have been incorporated into the EP and that this inclusion meets regulatory standards for demonstrating ALARP and acceptable levels of impact.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4491	Claims about the SRW and BW BIAs. States proposed activity will cause unacceptable impacts to all Karntubul species, including temporary & permanent hearing loss, displacement from BIAs, vessel strike, prey depletion during peak feeding/migration period, calving interruption, and impact to ecosystems and cultural landscapes as a result of the cumulative impact of these.	CGG has identified all Biologically Important Areas (BIAs) relevant to blue whales (BWs) and southern right whales (SRWs) and incorporated seasonal BIA use into the survey design through substantial temporal and spatial restrictions detailed in the EP. Predicted underwater-sound impacts on these Karntubul species, along with mitigation measures presented in Appendices E7 and F3, demonstrate impacts will remain acceptable and will avoid auditory impairment or displacement from BIAs or Habitats Critical to Survival (HCTS). CGG further notes that vessel-strike risk is already extremely low during seismic surveys and that additional controls in Appendix D2 ensure this risk is prevented and acceptable. It concludes that no changes to ecosystem structure, diversity, or function are expected from the one-off survey, with sound exposure too limited in extent and duration to affect prey, food webs, or predator–prey relationships. A cumulative impact assessment found residual cumulative effects to be low, reduced to ALARP, and acceptable, with no impacts predicted for regional marine parks. CGG also asserts consistency with the National Recovery Plan for Southern Right Whales and the Blue Whale Conservation Management Plan, stating that their objectives and recommended measures have been incorporated. Finally, CGG maintains that all marine mammal species likely to occur in the region have been adequately assessed using up-to-date EPBC Protected Matters data, and that mitigation measures ensure impacts to all listed species will remain acceptable and not inconsistent with EPBC Act protection provisions.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4492	Claims that the eastern population of the Southern Right Whale, estimated at only 200–300 individuals, is at particularly high risk because its migration and reproduction Biologically Important Areas (BIAs) overlap directly with CGG's Operational Area and sound propagation footprint. According to the Southern Right Whale Recovery Plan, these whales use the affected region for reproduction between May and September and for migration between April and October. The Recovery Plan also notes that Southern Right Whales do not feed in coastal waters but are expected to feed, and possibly conceive, within the Australian Whale Sanctuary—an area entirely overlapped by the proposed Regia MSS activity. As a result, the seismic survey could occur within, or affect, conceiving, calving, and feeding grounds for this critically endangered sub-population. The species is particularly vulnerable to human impacts due to its low reproductive rate, long lifespan, and strong site fidelity to key habitats. The submission therefore emphasises the relevance of underwater noise, habitat degradation, and vessel-strike risks in the context of the proposed seismic activities.	The Recovery Plan explains that BIAs can be designated for key behaviours such as reproduction, foraging, migration, and resting. While Southern Right Whale BIAs in the Plan cover reproduction and migration, the Plan notes that foraging occurs across a much broader offshore latitudinal range (30°S–65°S) and is not linked to these BIAs. Because the Regia MSS is not located in Antarctic waters, it will not affect cetaceans that forage there. CGG states the survey will avoid peak SRW abundance in the mapped BIA and apply mitigation measures to ensure no SRWs are harmed, injured, or interfered with.	EVT352

4494	The claim highlights guidance from the Blue Whale Recovery Plan, which stresses the need for a precautionary approach when assessing threats at the population level. It notes that blue whales may continue feeding despite disturbance if alternative feeding grounds are limited, meaning that anthropogenic noise may still present significant risk even when behavioural responses are subtle. Drawing on the Recovery Plans, the submission identifies key threats relevant to assessing potential impacts of the Regia MSS activity: underwater anthropogenic noise, climate change, habitat degradation, vessel strikes, prey depletion, and the cumulative effects of these pressures. GMTOAC argues that CGG has not adequately assessed these threats, either individually or cumulatively, given that consultation on these matters remains ongoing. The submission states that, based on CGG's own impact metrics, the proposed seismic activities may result in moderate to major impacts from underwater noise, major risks of vessel strikes, major impacts associated with climate change, and potentially more severe cumulative impacts. It references the Commonwealth's Significant Impact Guidelines, which define significant impact and list criteria for determining when an action may threaten an endangered species' survival or recovery. GMTOAC concludes that moderate to major impacts, especially when cumulative effects are considered, meet the threshold of significant impacts and are therefore unacceptable. Finally, the submission notes that both Recovery Plans and EPBC Act Policy Statement 2.1 emphasise that seismic surveys should avoid biologically important areas during biologically important times and assess 3-4 years of baseline data. GMTOAC argues that this principle is not met in the timing and location of the proposed Regia MSS survey,	The EP is consistent with the Blue Whale Conservation Management Plan, which identifies seismic noise as a threat, by implementing measures that ensure blue whales can continue using the area without injury or displacement. This includes using MFOs and PAM, shutting down the seismic source if whales enter behavioural, or TTS-impact ranges, and complying with EPBC vessel-operation requirements such as maintaining a 300-metre caution zone. CGG states it will also avoid peak-abundance periods by commencing the survey after most SRWs have left the BIA and during months when blue whale numbers are low. Drawing on current scientific literature, the recovery plans, and detailed impact assessments, CGG maintains that all risks and impacts have been reduced to acceptable levels. While Appendix E7 initially identifies major impacts for SRWs and BWs due to their threatened status, CGG notes that both species were reassessed in Appendix F3, which added further measures for SRWs; Appendix F3 concludes that residual impacts to both species are reduced to an acceptable level.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	increasing the potential for displacement from critical habitats essential to whale survival and recovery.		
4496	GMTOAC objects to CGG removing a previous control measure limiting seismic discharge in the Pygmy Blue Whale foraging BIA during periods of low whale presence, replacing it with a vague condition requiring CGG to determine whether whale presence is "compatible" with proceeding. GMTOAC argues this new measure lacks detail on how whale presence or "unacceptable disturbance" will be assessed, and that it fails to reference Recovery Plans which define unacceptable impacts. GMTOAC warns that the proposed survey timing (April–June 2026) coincides with peak Pygmy Blue Whale foraging season and Southern Right Whale migration and calving periods, meaning the seismic survey is likely to occur when both species are using their BIAs. Preventing whales from accessing these areas, or exposing them to injury while they remain, would constitute unacceptable impacts inconsistent with Recovery Plan objectives.	CGG has further reduced the likelihood of interactions with marine mammals by excluding the April–June period and commencing the survey only after 15 September. Because blue whales typically do not arrive from Western Australia until November, CGG argues that most of the survey will occur when blue whales are absent from the area. It adds that sighting data show very few blue whales in November and December, with peak abundance occurring later, from January to March during the Bonney Upwelling.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4501	GMTOAC objects that the EP sets out CGG's own "Defined Acceptable Levels" for cultural impacts arising from underwater sound on marine mammals, concluding that any such impacts would be short-term, temporary, and recoverable. GMTOAC and Gunditjmara reject this assessment, emphasising that CGG did not properly consult them on what levels of harm to cultural values, including impacts to culturally significant species such as Karntubul, would be acceptable. As these standards were developed unilaterally, GMTOAC and Gunditjmara do not accept CGG's conclusions regarding cultural impacts.	PROPOSED RESPONSE SUMMARY - CGG applied a comprehensive, transparent, ISO 31000:2009-aligned risk-assessment methodology, drawing on peer-reviewed literature and approaches accepted in numerous Environment Plans, to determine acceptable levels of environmental impacts and risks on both tangible and intangible values. Environmental aspects were systematically identified, impact severity and duration were assessed, and mitigation measures were evaluated using evidence and consultation. Acceptable impact levels (Appendix B1) and the assessment method (Appendix B9) were publicly released in May 2023. CGG concluded that impacts and risks are acceptable because risks were fully identified, lower-level risks were eliminated or controlled, major risks were examined in detail, activity limitations constrain operations, predictions were assessed against defined acceptable levels, uncertainty was considered, and the activity complies with the EPBC Act and ecologically sustainable development principles. CGG also relied on relevant sources, including peer-reviewed studies and UNESCO guidance describing the deep interdependence of tangible and intangible values, to inform acceptable levels where Traditional Owner input has not yet been provided. GMTOAC and Gunditjmara have been invited to contribute to cultural-value management, and the EP includes an Implementation Strategy embedding a Sea Country Protection Plan to support ongoing engagement and adaptive management. The Regulations (Regs 17–18) further ensure that any significant new cultural or environmental information must trigger revision of the EP. CGG remains ready to continue collaboration with GMTOAC and Gunditjmara throughout the activity.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4502	GMTOAC objects to the seismic survey's potential impacts on krill populations, including larval krill, which form a foundational part of the marine food web in Nyamat Mirring and are a critical food source for culturally significant species such as Pygmy Blue Whales and Southern Right Whales. They state that CGG's EP downplays potential impacts by comparing them to natural fluctuations in krill abundance, a framing GMTOAC considers inappropriate because it subsumes an anthropogenic disturbance within natural variability rather than assessing it cumulatively. GMTOAC emphasises that Nyamat Mirring and the broader oceanic system are already under significant stress from climate change and other human impacts. They point to the catastrophic Karenia mikimotoi algal bloom in South Australia as an example of how cumulative pressures can destabilise marine ecosystems. GMTOAC also references the recent failure of the Panama Upwelling, the first such event recorded in over 40 years, as further evidence that natural oceanographic processes are increasingly vulnerable to cumulative stressors. They argue that these examples undermine CGG's assumptions about the robustness of the system and highlight the need for a more precautionary, cumulative-impact-focused assessment.	CGG undertook an extensive review of the scientific literature to understand regional upwelling systems and their dynamics, assessing more than 65 publications to support the confidence of its analysis. Detailed assessments of upwelling and krill are provided in Appendices E2 and F3 of the EP. CGG does not agree with the suggestion that the assessment is trivial and remains confident in the robustness of its findings. CGG also remains open to receiving questions or new relevant information. Additionally, CGG notes that references to Panama upwelling processes are not applicable to the Regia MSS assessment and maintains confidence in the supporting literature base.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4506	GMTOAC claims that NOPSEMA has repeatedly raised concerns about deficiencies in CGG's noise modelling, first in August 2024, and again in its February and June 2025 OMRs. Despite this, the April 2025 EP appears to rely on noise models last updated in May 2023 and June 2024, and GMTOAC notes that it is unclear how these outdated models could address NOPSEMA's concerns. NOPSEMA specifically found that CGG's modelling was not based on the best available science because it failed to incorporate the updated 2024 US NMFS noise-injury thresholds. Rather than rerunning its full acoustic models using the updated criteria, CGG instead hired a consultant to compare the new NMFS thresholds with its older modelling. NOPSEMA criticised this approach, stating it was unclear whether such a comparison could reliably be applied to historical model outputs, particularly since the consultant did not provide the underlying input data used to generate the new results. GMTOAC argues that under the precautionary principle, CGG should adopt whichever modelling outputs predict the greatest potential harm, rather than relying on older, less precautionary models. They express serious concern that foundational flaws in the noise-modelling approach mean the impacts to marine mammals may be significantly underestimated, calling into question the accuracy of the EP's impact conclusions and the adequacy of its proposed protective measures for Nyamat Mirring and its species and ecosystems.	CGG notes that how the titleholder responds to NOPSEMA's information requests is a matter between the titleholder and the regulator. CGG has completed updated acoustic modelling using the latest science, including NMFS 2024 guidance, and has refined the Regia MSS design to be more environmentally conservative. These updated results are included in the current EP, which remains robust and based on the best available information. CGG notes that GMTOAC may be relying on an outdated EP version or may not have fully considered the updated material.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4508	GMTOAC claims inadequate assessment of noise on culturally important Kooyang. GMTOAC notes that CGG's EP groups Kooyang with other fish possessing swim bladders, and acknowledges that fish with swim bladders may be more susceptible to physiological trauma from seismic noise. However, while the EP claims no studies have demonstrated direct mortality of adult fish from seismic emissions, GMTOAC highlights that it has repeatedly requested an independent study on Kooyang specifically, a request CGG has refused. Across multiple appendices, CGG's assessment appears inconsistent. Some sections state that eels fall within the category of fish whose hearing directly involves a swim bladder, while other parts of the EP fail to mention this heightened sensitivity or cross-reference relevant acoustic impact studies. GMTOAC argues these inconsistencies obscure the true risk profile and hinder meaningful evaluation of proposed controls. Finally, GMTOAC challenges CGG's conclusion that risks to adult Kooyang will be "extremely low" and indistinguishable from natural population variation. GMTOAC notes that this claim lacks scientific justification and appears to rely on the eel's behavioural avoidance or instinctual drive to migrate rather than on concrete control measures to prevent harm.	CGG recognises kooyang as a profoundly important Gunditjmara cultural value and not just an ecological species. The Environment Plan explicitly protects kooyang by applying culturally defined acceptability criteria, including ensuring no material reduction in kooyang abundance, recruitment, or sustainable harvesting that could impact Budj Bim practices or World Heritage values. This cultural framing underpins the entire assessment. CGG rejects claims that its underwater-noise assessment is inadequate, noting that it is detailed, conservative, peer-reviewed, and fully compliant with best-practice standards. Kooyang are assessed using the highest-sensitivity category under EPBC Policy 2.1, and predicted noise-effect zones are extremely small. The survey timing has been shifted to September–December, avoiding: peak adult silver-eel migration (Feb–May), most glass-eel recruitment (Oct–Feb), and juveniles that would already be inside river/estuary systems. This means minimal temporal or spatial overlap with key life stages. There is no credible pathway for population-level or culturally significant effects, and global evidence shows no seismic survey has ever been linked to effects on anguillid eel recruitment. Overall, the assessment is precautionary, culturally informed, and reduces risks to ALARP. CGG remains open to incorporating additional Gunditjmara knowledge or scientific evidence, but based on current information, no material impact on kooyang is credible.	EVT352

4509	GMTOAC claims that CGG's approach to assessing impacts on Kooyang is inconsistent with the precautionary principle under the EPBC Act, especially given Kooyang's cultural significance and its central role in the World Heritage–listed Budj Bim Cultural Landscape. GMTOAC states that CGG has repeatedly asserted, without scientific evidence, that juvenile eels will not be near the seismic activity, despite the absence of data tracking their migration from the Coral Sea to Gunditjmara Sea Country. They outline the well-established seasonal migration patterns of adult and juvenile Kooyang and state that these movements directly link the open ocean to the Budj Bim aquaculture systems. UNESCO inscribed Budj Bim as a World Heritage property because of Gunditjmara's long-standing eel aquaculture, which relies on the uninterrupted migration of Kooyang. GMTOAC highlights that published research, co-authored by Gunditjmara Elders and scientists, shows adult eels travel through areas that overlap with CGG's Operational Area and EMBA, meaning migrating Kooyang are likely to encounter the seismic survey if undertaken in April 2026. GMTOAC also raises concerns regarding CGG's framework for assessing impacts on World Heritage values. They argue that CGG wrongly limits its definition of "direct effects" to the physical boundaries of the property, failing to recognize that Kooyang moving through the marine environment outside the site are essential to the World Heritage values themselves. GMTOAC rejects CGG's categorisation of impacts to Kooyang and Gunditjmara cultural practices as merely "indirect," and notes the EP provides no explanation for its claim that such impacts are "immeasurable."	CGG affirms the deep cultural importance of kooyang to the Gunditjmara People and agrees that any activity causing a population-level decline in kooyang that recruit into the Budj Bim wetland systems would be unacceptable. However, the claims in paragraphs 118–132 are based on legal and factual misunderstandings. The World Heritage property is strictly limited to the freshwater Budj Bim wetlands on the lava flow and does not include estuarine, coastal, or oceanic waters. Under UNESCO rules, World Heritage protection applies only within the fixed site boundaries and cannot extend to migratory species outside them. No World Heritage site has ever been interpreted the way GMTOAC suggests. CGG clarifies that the OUV attribute "ecology and life-cycle of kooyang" refers specifically to the parts of the life cycle occurring within the engineered aquaculture systems inside the property, not the entire oceanic migration. International precedents—such as the Monarch Butterfly Reserve, the Yellow Sea Migratory Bird Sanctuaries, and the Wadden Sea, show that impacts outside property boundaries are not considered direct impacts on World Heritage values. Scientifically, the EP uses best-practice criteria, with predicted noise effects on kooyang limited to very small distances (<300 m), and the survey timing (Sept–Dec) avoids overlap with major migration and recruitment periods. No tracking data show a kooyang migration corridor through the survey area, and the contribution of one 60-day survey to cumulative pressures is negligible. Appendix F3 confirms alignment with relevant management plans, which only consider impacts inside the property's boundaries. CGG states it remains open to further Gunditjmara knowledge and evidence, and has updated the EP to consider the provided management plans, but concludes that no credible pathway exists for material impact on kooyang abundance within the Budj Bim wetlands or on the property's Outstanding Universal Value. The EP is therefore lawful, scientifically robust, and compliant with Australia's World Heritage and EPBC Act obligations.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	Further, GMTOAC states that CGG has only referenced one of the required Budj Bim management plans and has not demonstrated engagement with the others. They contend that CGG has not shown how the proposed activities align with or avoid contravening the management goals, especially those aimed at restoring healthy Kooyang populations. GMTOAC concludes that CGG's failure to properly account for the cultural, ecological, and World Heritage significance of Kooyang is unacceptable to Gunditjmara, whose stewardship of Budj Bim spans millennia and underpinned the site's World Heritage listing.		
4510	GMTOAC claim that CGG's proposed seismic survey would elevate chronic ambient noise levels and disrupt acoustic-dependent functions such as reproduction, feeding, navigation, predator avoidance and maintaining social structures. While CGG has acknowledged that an ambient noise assessment may be required to inform its impact analysis, GMTOAC contends that such a baseline must begin with an understanding of the natural, pre-industrial soundscape before incorporating existing anthropogenic sources such as shipping and offshore petroleum activity. GMTOAC suggests that this assessment could form part of a Gunditjmara Cultural Values Assessment (CVA). However, in the absence of a comprehensive baseline and analysis of how CGG's operations would contribute to cumulative noise levels, GMTOAC remains concerned that the Environment Plan does not adequately describe the affected environment, as required by the Regulations, and cannot reliably assess or reduce impacts on Nyamat Mirring, including chronic noise exposure, to acceptable or ALARP levels.	CGG acknowledges GMTOAC's concerns about acoustic impacts on Nyamat Mirring but notes that the EP already includes a rigorous, science-based assessment of underwater sound and its interaction with culturally and ecologically significant species. The assessment incorporates five years of ambient noise data, current international scientific guidance, calibrated sound-field modelling, and real-time acoustic monitoring during operations. CGG has also committed to additional pre-survey ambient noise monitoring in sensitive nearshore areas, such as Southern Right Whale nursery habitat. The EP demonstrates that the survey's noise contribution will be temporary, spatially limited, and tightly managed through shutdowns, PAM, exclusion zones, and adaptive scheduling. Overall, CGG maintains that GMTOAC's suggestion that the EP lacks adequate baseline information or understanding of acoustic impacts is incorrect, and that the approach integrates strong science, cultural input, and real-time validation to ensure responsible management of any acoustic effects.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4511	GMTOAC claims that, without proper consultation and completion of a Gunditjmara Nyamat Mirring Cultural Values Assessment (CVA), CGG cannot legitimately determine what constitutes an "acceptable" level of impact on Gunditjmara cultural values. They highlight deficiencies in CGG's cumulative impact assessment, which adopts an unduly narrow definition of First Nations cultural heritage. In the EP, CGG limits cultural impacts largely to obligations to maintain spiritual connections and care for culturally significant species, despite having access to far broader definitions through documents it relied upon, such as the Gunditjmara Nyamat Mirring Plan and native title determinations. These sources make clear that Gunditjmara cultural responsibilities encompass Country, Ceremony, Lore, language, relationships, and rights to use and manage resources. GMTOAC also challenges CGG's unsubstantiated assumption that ecological acceptability equates to cultural acceptability, noting that this equivalence has never been expressed or endorsed by Gunditjmara.	CGG has relied on peer-reviewed literature, management plans, policy documents, and guidance to define acceptable levels for cultural values, including sources such as McConnell et al., which outlines the interdependence of tangible and intangible cultural values. CGG emphasises that it does not claim these values are equal in weight, and has repeatedly invited GMTOAC and the Gunditjmara to contribute directly to how their cultural values should be managed. The EP includes an Implementation Strategy with a Sea Country Protection Plan to ensure ongoing involvement of Traditional Owners and to enable adaptive management if new information emerges. Regulations 17 and 18 require CGG to revise the EP if any new or increased cultural or environmental impacts arise, ensuring that future cultural information can be formally incorporated. Appendix F3 (section 3.16) draws on documents such as the Nyamat Mirring Plan and native title determinations to describe cultural features and assess related impacts and risks. CGG remains willing to continue collaborating with GMTOAC and the Gunditjmara in ongoing consultation and environmental management.	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4512	GMTOAC claims significant concerns about CGG's definition of "acceptable levels" of impact on Blue Whales and Southern Right Whales. CGG maintains that impacts are acceptable so long as each offshore operator conducts activities in a manner consistent with relevant Conservation and Recovery Plans, ensuring whales can continue using the area without injury or displacement. However, NOPSEMA has already criticised this approach, noting that measures designed for individual projects cannot simply be assumed to prevent cumulative impacts from overlapping noise fields without a clearer understanding of combined exposure regimes. Despite this critique, CGG appears to have carried this same rationale forward from its November 2024 EP into the April 2025 version, without addressing the deficiencies identified by NOPSEMA. GMTOAC argues that this is inadequate, especially in light of current environmental pressures affecting Nyamat Mirring.	CGG notes that GMTOAC appears to have referenced an outdated version of the Environment Plan. In the current EP, acceptable impact levels for Blue Whales and Southern Right Whales are defined using each species' Recovery Plan, and these levels are assessed through rigorous, literature-supported impact assessments in Appendices E7 and F3. In response to NOPSEMA's advice, the cumulative impact assessment was updated to include the sound sources and timing of all future and reasonably foreseeable activities. This added detail ensures that any potential cumulative impacts from additive sound exposure are assessed with appropriate contextual information.	EVT352

4514	GMTOAC objects to CGG refusing to address how its seismic survey, being the first step in a chain of petroleum exploration and production, will contribute to climate change impacts on Nyamat Mirring. When asked about future gas extraction or data purchasers, CGG dismissed these questions as "speculation" or commercially irrelevant, but GMTOAC argues that such information is essential for assessing indirect risks arising from the activity, as required by the Regulations. GMTOAC emphasises that Gunditjmara, not CGG, will live with the long-term consequences of industrialisation, environmental degradation, and climate impacts. They highlight that climate change already disrupts Gunditjmara cultural obligations, seasonal knowledge systems, native title rights, and their broader responsibilities to Country. Because seismic surveys are the initiating step enabling gas expansion, GMTOAC argues that CGG must evaluate the indirect environmental risks associated with likely future production and emissions. GMTOAC notes that international legal developments, including the recent ICJ Advisory Opinion on climate obligations, support the need to consider how exploration licensing contributes to harmful downstream emissions. They argue that CGG's refusal to disclose who it plans to sell seismic data to undermines transparency and prevents informed assessment by Traditional Owners in accordance with UNDRIP and Gunditjmara's Consultation & Negotiation Protocol. GMTOAC also challenges CGG's claim that exploration aligns with intergenerational equity under the principles of ESD. They assert that expanding gas fields contradicts both the EPBC Act's definition of intergenerational equity and	CGG explains that the Environment Plan (EP) is legally required to assess only the environmental impacts of the seismic survey itself, not hypothetical future emissions from possible gas developments by other parties. The Regulations and NOPSEMA's guidelines confirm that downstream combustion emissions, occurring years later, at unknown locations, by unknown proponents, are outside the scope of a non-production seismic survey EP. CGG's activity will not extract hydrocarbons, will not emit industrial greenhouse gases beyond normal vessel operations, and cannot predict whether any future development will occur. GMTOAC's request for CGG to quantify emissions from future gas fields is scientifically impossible, as it depends on unknown variables such as reserve size, technology, production emissions, market conditions, policy settings, and end-use combustion pathways. Producing such an assessment would be speculative and indefensible. Australia already regulates climate impacts through national GHG accounting, the Safeguard Mechanism, fuel and emissions policies, and export regulations—frameworks designed for activities that actually produce emissions, not exploration surveys. CGG also refutes the idea that the ICJ's 2025 climate advisory opinion applies to seismic surveys. The opinion concerns State obligations regarding global greenhouse gas emissions and does not mention seismic activities. It is nonbinding and cannot override Australia's existing regulatory framework. Where courts have restricted seismic surveys, they have done so under marine biodiversity law, not climate law. Similarly, GMTOAC's claim that ESD (ecologically sustainable development) blocks the survey is incorrect. ESD guides how development proceeds, not whether it is allowed. CGG has transparently assessed its impacts, addressed vessel-related emissions, and applied all practicable mitigation, consistent with ESD principles. Finally, the demand that CGG disclose future seismic data purchasers is both legally baseless and irrelevant to environmental risk. Such information is unknowable, commercially sensitive, and has no bearing on the impacts of the survey. Any future project would require its own approvals and environmental assessments. Overall, CGG concludes that GMTOAC's claims misinterpret the law, expand the EP scope beyond what the Regulations allow,	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	scientific consensus requiring rapid emissions reductions. In GMTOAC's view, presenting exploration as beneficial to future generations is misleading, particularly when climate change is the primary threat identified in the Gunditjmara Nyamat Mirring Plan. They add that providing information about data purchasers would be essential for enabling future generations of Gunditjmara to make informed decisions about resource use in Nyamat Mirring.	and rely on speculative links that have no legal or scientific basis. Appendix F3, section 3.16.1 has been updated to include First Nations seasonal calendar.

1 Introduction

This document is a collection of demonstrations that the Regia Marine Seismic Survey (**Regia MSS**) is an activity that can be carried out in a manner:

- In which the environmental impacts and risks of the proposed activity will be of an acceptable level.
- Consistent with the principles of ecologically sustainable development (**ESD**).

The principles of ESD play an important role in responsible decision-making. ESD encompasses the integration of economic, social, and environmental considerations in pursuit of a shared goal: meeting the needs of the present without compromising the ability of future generations to meet their own needs. Although ESD lacks a precise, accepted definition, it is generally recognised as an important concept as it ensures environmental factors and future generations are considered in assessing a current development, in this case the Regia MSS.

Readers of this document are encouraged to have read and understood the following documents at a minimum which provide important context to this assessment and underpinning evidence.

1. Description of the Activity (Appendix A2)
2. Environmental Assessment Process (Appendix B3 – Implementation Strategy)
3. Environmental Performance (Appendix G1)

The remaining documents that make up the Regia MSS Environment Plan (**EP**) also provide context to this assessment.

2 Purpose and Scope

This document was prepared prior to first submission of the EP, and has been updated for each new submission to address any new information, changes in assessment outcomes and feedback from relevant persons and the regulator. This document assesses the Regia MSS EP preparation process, through multiple methods to demonstrate how this activity will have environmental impacts and risks that will be of an acceptable level and can be carried out in a manner consistent with the principles of ESD.

3 Consultation Input

CGG carried out the consultations required by the regulations to:

- Improve the predictive quality of this assessment by seeking relevant person input into the preparation of the EP.
- To verify the description of the environment that CGG produced as part of its environmental assessment process through information provided to CGG by relevant persons.
- Receive objections or claims about the adverse effects of the activity on a relevant person's functions, interests, or activities.

The information received from relevant persons can be found in each relevant person consultation report. It has been considered in the preparation of this assessment.

Objections or claims about the adverse of the effects of the activity can also be found in each relevant person's consultation report. They have been assessed for merit and CGG has written a statement of its response to each objection or claim. Any objection or claim relevant to this assessment and subsequently considered in its preparation can be found in

Annex 1.

4 Defining Acceptable Levels

This section outlines the framework for defining acceptable levels of environmental impact and risk for the Regia MSS. Our approach aligns with best practices and regulatory requirements. Figure F4-1 is a copy of the conceptual framework for defining acceptable levels and establishing levels of environmental performance from NOPSEMA guidance documents. CGG has adopted this framework in application to the Regia MSS EP.

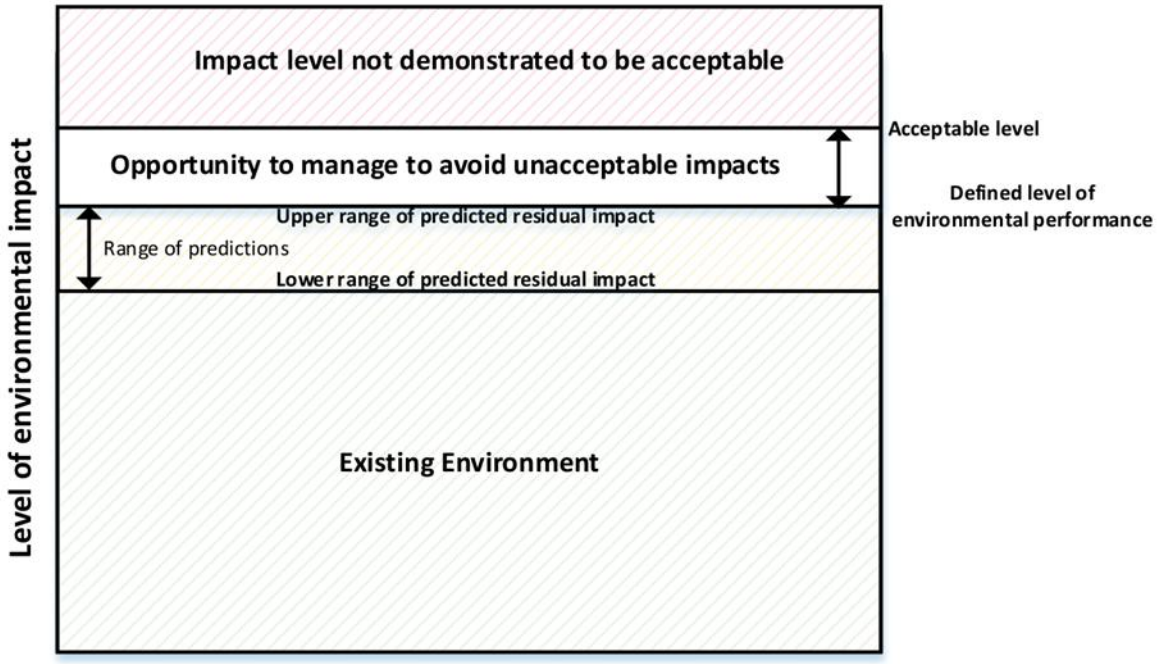

Figure F4-1 - Framework for defining acceptable levels of impact and associated levels of environmental performance (N-04790-GN1663).

In Figure F4-1, the terms used have the following meaning:

- ***Existing environment*** is the condition of the existing environment before the implementation of the project.
- ***Range of predictions*** illustrates that impact prediction processes can result in a range of residual impacts after the implementation of control measures due to a degree of uncertainty attributed to limitations in impact prediction tools, shortfalls in knowledge in the way that the environment responds to pressures.
- ***Opportunity to manage*** is the window that the titleholder must undertake responsive management measures to prevent the impact exceeding the defined acceptable level.
- ***Defined level of environmental performance*** is a level of performance of a proponent in relation to environmental performance outcomes (and environmental performance standards in EPs).
- ***Acceptable level*** is the maximum level of change in environmental parameters before the environmental effects become unacceptable.

- ***Unacceptable impact*** is the change in the environment that has exceeded the acceptable level and usually indicates that a change has occurred that is not acceptable from a socio-economic, ecological, biological, or cultural values perspective.

This conceptual framework considers the defined acceptable level, accounts for limitations in the impact and risk analysis undertaken (Appendices D1 – D4 and E1 – E9) and helps to establish levels of environmental performance in a manner that enables management response to prevent the acceptable level of impact from being exceeded. This framework highlights the opportunity for titleholders to manage their activities to prevent environmental impacts from becoming unacceptable by setting levels of environmental performance such that they represent a level that is better than or at least equivalent to the 'acceptable level' and therefore a precursor to unacceptable impact. By applying this approach, inaccuracies in the impact prediction process and uncertainties in the effectiveness of management controls can be accounted for using responsive management to avoid exceeding the acceptable level.

Table F4-1 establishes five parts of the framework used in this EP as the basis of defining acceptable levels. CGG used specific, defined acceptable levels of impact and risk for the Regia MSS based on these contexts. These levels are tailored to the unique aspects of our project, ensuring a responsible and well-informed approach to environmental management.

Table F4-1 - Framework for defining acceptable levels.

Acceptable Levels Framework	Description
Principles of ESD	We considered the principles of ESD, as set out in the Environment Protection and Biodiversity Conservation Act (EPBC Act), into our impact and risk assessment processes. These principles guide our efforts to manage environmental impacts and risks responsibly, ensuring long-term sustainability. The assessment of the consistency of CGG's decision making with the principles of ESD can be found in Appendix F4 Section 5.11.
Environmental Context	We considered the biological, ecological, economic, social, and cultural features relevant to the Regia MSS in each impact and risk assessment (Appendices D1-4 & E1-9). This comprehensive approach allows us to understand and respect the environment's inherent values and sensitivities.
Legislative Context	Our acceptable levels are consistent with legislation and other regulatory requirements, including relevant policy documents, guidelines, and conservation plans. This ensures our activities align with national standards and objectives.
Company (Internal) Context	Management of the activity is aligned with CGG's impact and risk assessment process and implementation strategy. This internal alignment ensures consistency and reliability in our environmental management practices.
External Context	We assess, respond to, and adopt measures in response to objections and claims received from relevant persons, attempting to satisfactorily address concerns in our environmental management strategies.

CGG applied a comprehensive and transparent methodology in defining acceptable levels of impacts and risks for the activity. CGG's impact and risk management method is grounded in the principles, framework, and processes defined by ISO 31000:2009 Risk Management. The method included steps for:

- Identifying and analysing environmental aspects associated with the activity for environmental impacts and risks.
- Predicting the extent, duration, and severity of those environmental impacts and risks.
- Assessing mitigation and management measures.

This process was systematic and evidence-based, incorporating consultation at all stages. Furthermore, the methodology placed a significant emphasis on establishing the context of assessments, incorporating both internal and external environmental factors. This included a detailed examination of the activity description, as well as preliminary information gathered through

independent assessments and relevant person feedback. This ensured that acceptable levels of environmental impact and risk are not only in line with legislative requirements but also consider the specific environmental, social, and economic contexts of the Otway Basin.

The defined acceptable levels in Appendix B1 were published in May 2023 on the Consultation Hub alongside our environmental assessment process (Appendix B9) to provide an opportunity to the community and relevant persons to understand the assessment process and influence the criteria used in the assessment process. The opportunity to comment was open for 60 days.[1]

5 Acceptable Level Demonstrations

The environmental impacts and risks of the activity are of an acceptable level because:

1. All environmental impacts and risks have been identified and assessed.
2. Lower order impacts and risks have been screened and eliminated or managed.
3. Higher order impacts and risks have been assessed by:
    a. Gathering knowledge about relevant environmental values and sensitivities.
    b. Defining acceptable levels for relevant environmental values and sensitivities.
    c. Predicting the levels of impact and risk.
    d. Evaluating the effectiveness of measures that protect the environment.
4. Activity limitations comprehensively bound the activity and environmental assessment.
5. Predicted impacts and risks of the activity have been compared to acceptable levels of impact and risk.
6. The titleholder has considered predictive uncertainty in the environmental assessments.
7. The environmental assessments are appropriate to the nature and scale of the activity.
8. Once managed, no pathways to unacceptable impacts were identified.
9. The proposed activity will comply with the requirements of the EPBC Act.
10. The proposed activity is consistent with the principles of ecologically sustainable development.

Each of these reasons is explained below, in detail, to demonstrate that environmental impacts and risks arising from the proposed activity are of an acceptable level.

5.1 Identification of all Impacts and Risks

CGG commissioned a Preliminary Environmental Impact and Risk Assessment (**PEIRA**) to identify all impacts and risks of the activity. Appendix B4 documents this first stage of the environmental assessment process and demonstrates that all environmental impacts and risks of the activity will be of an acceptable level because:

- Proper identification allows for a thorough assessment of the impacts and risks. This includes understanding both direct and indirect impacts, ensuring that all potential pathways to marine life, ecosystems, and socio-economic factors are considered.
- Identifying all impacts enables the development of targeted mitigation measures reduces the likelihood of unforeseen consequences that could exceed acceptable impact levels.
- Accurate identification of environmental impacts supports the analysis of the legislative and other requirements that apply to the activity. Demonstrating compliance with environmental

[1] Appendices B1 and B9 have since been merged into Appendix B3.

laws, regulations, and guidelines, which often specify that impacts must remain within acceptable limits. This has been completed in Appendix B2.

- Proper identification of impacts increases transparency and builds trust among relevant persons, including local communities, Traditional Owners, and environmental groups. This helps prevent conflicts and ensures that all concerns are addressed before the survey begins.
- Identifying all impacts allows for data-driven decisions regarding when, where, and how to conduct seismic activities to minimise impacts and risks. This includes selecting appropriate survey timings (e.g., avoiding breeding seasons) and using technologies that reduce sound intensity or directionality.

5.2 Screening and Control of Lower Order Impacts and Risks

The PEIRA also performed a screening of all impacts and risks to understand those that were negligible and those which required further assessment. Benthic disturbance, atmospheric emissions, and planned discharges were identified as lower order environmental aspects that could be treated with legislative requirements and industry standards. These required no further assessment because:

- By categorising impacts and risks into higher-order and lower-order, it becomes easier to prioritise the most critical issues. This ensures that efforts and resources are focused on managing and mitigating impacts that have the greatest potential to cause significant harm.
- Environmental assessments often involve limited resources in terms of time, budget, and manpower. Screening helps in allocating resources efficiently by focusing more detailed studies and mitigation efforts on higher-order impacts, while lower-order impacts can be managed with simpler, standardised measures.
- Screening helps organise the environmental assessments by breaking down complex interactions into manageable components. This separation makes it clearer to relevant persons and decision-makers which impacts and risks are more pressing, allowing for better understanding and informed decision-making.
- Higher-order impacts typically require more stringent, tailored mitigation strategies, while lower-order impacts may be managed with generic or standard procedures. This differentiation allows for more precise and effective mitigation planning, reducing unnecessary measures for minor risks.
- Environmental systems can be highly complex, with numerous interacting variables. Screening simplifies the assessment by categorising impacts, which makes the analysis more manageable and reduces the cognitive load on assessors. It helps break down the assessment into bite-sized pieces that are easier to evaluate.
- Without screening, assessments can become bogged down by minor details that detract from significant issues. Screening filters out lower-order impacts from intensive analysis, ensuring that the assessment remains focused and concise, without overwhelming readers with excessive details on low-significance data.

5.3 Higher Order Impacts and Risks have been Comprehensively Assessed

CGG then commissioned experts to undertake specific analysis of the higher order impacts and risks, including quantitative modelling and analysis to underpin the understanding of the environment and reinforce a demonstration that environmental impacts and risks will be of an acceptable level. The higher order assessments found in Appendix D1 to D4 and E1 to E9 are comprehensive because:

- Comprehensive baseline data was relied upon to establish the existing environmental conditions. This data served as a reference point for predicting and assessing the potential magnitude and significance of higher-order impacts. High-quality data on species, habitats, ecosystem functions, and socio-economic factors demonstrate a robust foundation for assessment.

- A combination of quantitative (e.g., modelling, statistical analysis) and qualitative (e.g., expert judgment, relevant person input) methods have been employed to assess higher-order impacts. This ensures that complex interactions are examined from multiple perspectives, providing a thorough understanding.
- Experts in relevant fields (e.g., marine biology, ecology, geology, socio-economic) have been employed during the assessment process to provide insights into the significance of higher-order impacts. Their expertise helps identify the most significant impacts and risks and supports evidence-based conclusions.
- Recognised frameworks and methodologies have been applied to categorise, rank, and analyse higher-order impacts. This provides a structured and reproducible approach to assessing the risks and impacts of the proposed activity.
- A cause-effect analysis has been conducted to identify the pathways through which activities may lead to significant environmental changes. Understanding the chain of events that link project activities to environmental outcomes shows that potential higher-order impacts have been explored in depth.
- Worst-case scenarios have been considered to evaluate the most severe potential outcomes of higher-order risks. Assessing worst-case scenarios helps ensure that even rare but high-consequence impacts are accounted for and appropriately mitigated.
- Relevant persons, including local communities, Traditional Owners, regulatory authorities, and industry experts, have been consulted throughout the assessment process. Their input provided insights into perceived higher-order impacts and ensure that all significant concerns were addressed.
- Best available science, industry standards, and technological tools have been used to evaluate higher-order impacts. This includes advanced modelling, simulations, and remote sensing technologies, demonstrating that the assessment is based on cutting-edge and reliable information.
- Specific, measurable, and enforceable mitigation measures for higher-order impacts have been developed. The presence of well-defined management plans, including monitoring programs, contingency plans, and adaptive management strategies, shows that potential impacts and risks have been fully evaluated and prepared for.
- A comprehensive monitoring plan has been established to track higher-order impacts during and after the activity. This includes baseline comparisons, performance indicators, and triggers for adaptive management, demonstrating a commitment to monitoring and managing risks over time.
- The assessment has included a detailed cumulative impact analysis that considers other existing and potential future projects in the area. This demonstrates that the evaluation is not limited to isolated impacts but addresses the broader environmental context.
- Clear and transparent documentation, including methodologies, assumptions, data sources, and limitations, has been provided in the assessment report. This demonstrates that the process is rigorous, unbiased, and subject to scrutiny, supporting the credibility of the conclusions about higher-order impacts and risks.
- The assessment has been conducted in accordance with local, national, and international regulatory requirements, guidelines, and best practices. Meeting or exceeding these standards provides confidence that higher-order impacts have been assessed comprehensively and responsibly.
- Independent peer reviews or third-party verifications have been conducted to validate the findings of the assessment. External validation ensures that higher-order impacts have been evaluated from multiple perspectives and meet scientific and regulatory standards.

- The assessment has evaluated alternative project designs, locations, and technologies to avoid or reduce higher-order impacts and risks. Applying the mitigation hierarchy - eliminate, minimise, administrate - demonstrates a commitment to managing higher-order impacts and risks responsibly.
- A focused assessment of impacts on sensitive and vulnerable environmental receptors (e.g., endangered species, critical habitats, protected areas) has been conducted. This ensures that the most ecologically and socially significant aspects have been given appropriate attention.

The assessment explicitly addresses uncertainties and the level of confidence in the predictions. This includes sensitivity analysis, consideration of data gaps, and conservative assumptions to account for uncertainty, showing that higher-order impacts have been carefully evaluated even in the face of unknowns.

5.4 Activity Limitations Comprehensively Bound the Activity and the Environmental Assessment

CGG has adopted several activity limitations that provide the scope and boundaries of the proposed activity. Activity limitations also provide the scope and boundaries of the environmental assessment. They eliminate or substitute environmental impacts and risks and are the most effective way of management environmental aspects.

The adoption of activity limitations was for one or more of the following reasons:

1. To design an activity that fulfilled the geophysical objectives of the survey.
2. To reduce an impact or risk because of the findings from the environmental assessments.
3. Required because of meritorious objections or claims raised by a relevant person.

Activity limitations proposed through consultation or identified through the NOPSEMA assessment process were identified and assessed with some being discarded and others being included to bound the activity.

Crucially, compliance with these activity limitations is a significant part of managing environmental impacts and risks of the activity to an acceptable level. As such, they are included in the Environmental Compliance Register and form part of the ongoing audit and inspection program in the Implementation Strategy (Appendix B3).

5.5 Predicted Impacts and Risks are of an Acceptable Level

Throughout the preparation of the EP, CGG reviewed and reassessed whether the impacts and risks of the proposed activity could be managed to an acceptable level. That process can be found in Appendix B3 and included:

- Publishing defined acceptable levels at the beginning of the consultation and preparation process.
- Sharing with the public the assessment process we would undertake and how impacts and risks would be quantified.
- Publishing draft impact and risk assessments and inviting input.
- Creating additional assessments so that more detail could be assessed and communicated with relevant persons.
- Detailing the scientific literature being relied on.
- Considering all EPBC Act literature, policies, advice, and plans and demonstrating that the activity (action) is consistent with them.
- Comparing the predicted levels of impact with the defined acceptable level (general and aspect-specific).

- Adopting environmental performance outcomes and control measures that ensure all impacts and risks will be of an acceptable level.

There is evidence in each assessment (Appendix D1-4 and E1-E9) that this process was followed and with each submission, an opportunity to improve the content, context, and decision-making associated with environmental management of the activity was taken to improve environmental outcomes.

The further assessments undertaken in Appendix F3 evaluated the quality of the previous assessments with a focus on levels of predictive certainty. Those assessments either resulted in confirmation of the adequacy of the original assessment or the adoption of further improvements in environmental management of the activity. Any necessary modifications were subsequently incorporated into the original assessments. This feedback loop demonstrates the iterative process that was followed.

5.5.1 Release of materials or fuel overboard

Category	Predicted Level of Risk
Principles of ESD	An accidental release of materials or waste is not predicted.
	Available literature and government management plans, recovery plans and conservation advice were used to inform the risk assessment. There is high confidence in the prediction of risks to environmental components that are at risk from an accidental release of materials or waste.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans as detailed in Appendix B2.
Biological	The risks of an accidental release of materials or waste to biological features would be temporary and small scale and would not result in environmental damage at population levels.
Ecological	The risks of an accidental release of materials or waste to ecological features is not predicted.
Economic	The potential risks of an accidental release of materials or waste is predicted to be confined to a one-off event that would not result in affected persons being worse off because of the activity. As per the Adjustment Protocol an adjustment process will be implemented in the event there is a financial loss to marine users from an accidental release of materials or waste.
Cultural	The risks of an accidental release of materials or waste is predicted to be confined to a one-off event that would have a temporary / reversible, small scale, and low intensity risk to cultural values.
Company	All reasonably practicable measures have been adopted to reduce environmental risks as detailed in the following section.
	The predicted risk level is medium.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the risk.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons as per the following stakeholder feedback; - We want to be assured that your activities out at sea will not result in increased rubbish washing up. The dominant form of rubbish we collect is from ocean sources such as rubbish discarded from international shipping and fishing boats. We would like to see your waste management plan and have assurances that you will commit to zero rubbish disposed of at sea. - A whale and seal and bird watch for pelagic and shorebirds along the southwest coast of Victoria and are concerned about their welfare in relation to the Regia MSS. The CGG Marine Assurance System will be implemented to ensure no waste material is disposed of overboard and all vessels used for the Regia MSS will be required to have a Garbage Management Plan. The risk assessment undertaken predicted that if an accidental release of materials or waste did occur and impacted marine fauna, it would be restricted to an individual and not affect the

	species at a population level. Thus, impacts to marine fauna watching along the southwest coast of Victoria is not predicted to be affected.
	No public comments have been received in relation to an accidental release of materials or waste.

5.5.2 Collisions with marine fauna

Category	Predicted Level of Risk
Principles of ESD	Predicted risks are low intensity environmental damage as risks would be restricted to individual fauna and will not affect the species at a population level.
	Available literature and government management plans, recovery plans and conservation advice were used to inform the risk assessment. Serious or irreversible environmental damage is not predicted as risks would be restricted to individual fauna and will not affect the species at a population level. There is high confidence in the prediction of risks to species that are at risk from vessel collisions.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans.
Biological	Predicted risks are low intensity environmental damage as risks would be restricted to individual fauna and will not affect the species at a population level.
Ecological **Economic**	Predicted risks to ecological features associated with marine fauna are temporary / reversible, small scale, as risks would be restricted to individual fauna and will not affect the species at a population level.
Cultural	Predicted risks to cultural features associated with marine fauna are temporary / reversible, small scale, as risks would be restricted to individual fauna and will not affect the species at a population level.
Company	All reasonably practicable measures have been adopted to reduce environmental risks as detailed in the following section.
	The predicted risk level is medium.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the risk.
Social	To date no objections or claims in relation to fauna and vessel collisions have been made by relevant persons. A relevant person raised that they whale and seal watch along the southwest coast of Victoria and are concerned about their welfare in relation to the Regia MSS. A collision with a whale or seal is a rare event and has not been reported during seismic surveys. The implementation of the Fauna Management Plan will ensure that fauna collision risk is as low as reasonably practicably. The risk assessment undertaken predicted that if a collision did occur with marine fauna, it would be restricted to an individual and not affect the species at a population level. Thus, risks to marine fauna watching along the southwest coast of Victoria is not predicted to be affected.
	To date there have been no views from the public in relation to fauna and vessel collisions.

5.5.3 Introduction of marine pest species

Category	Predicted Level of Risk
Principles of ESD	The introduction and establishment of marine pests is not predicted.
	Available literature and government management plans, recovery plans and conservation advice were used to inform the risk assessment. The introduction and establishment of marine pests is not predicted. There is high confidence in the prediction of risk to environmental components that are at risk from the introduction of marine pests.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans.
Biological **Ecological**	The introduction and establishment of marine pests could lead to reduced native species diversity, displacement and shifts in ecosystem dynamics. The likelihood of a marine pest being present on a Regia MSS vessel and becoming established is assessed as rare due to the implementation strategy. The predicted level of risk is assessed as low. The introduction and establishment of marine pests is not predicted.
Economic	The introduction and establishment of marine pests could lead to reduced native species diversity, displacement and shifts in ecosystem dynamics impacting commercial fisheries. The likelihood of a pest being present on a Regia MSS vessel and becoming established is assessed as rare due to the implementation strategy. The predicted level of risk is assessed as low.
Cultural	The introduction and establishment of marine pests could lead to reduced native species diversity, displacement and shifts in ecosystem dynamics. If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. The likelihood of a marine pest being present on a Regia MSS vessel and becoming established is assessed as rare due to the implementation strategy. The predicted level of risk is assessed as low.
Company	All reasonably practicable measures have been adopted to reduce the risk of introducing a marine pest as detailed in the following section.
	The predicted risk level is medium.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the risk.
Social	To date no objections or claims in relation to marine pests have been made by relevant persons.
	To date there has been no views from the public in relation to marine pests.

5.5.4 Accidental release of fuel

Category	Predicted Level of Risk
Principles of ESD	A vessel oil spill is not predicted to occur but if it occurred impacts would be temporary / reversible, small scale, and/or low intensity environmental damage due to the low volumes and light nature of marine diesel.
	Available literature and government management plans, recovery plans and conservation advice were used to inform the risk assessment. A vessel oil spill is not predicted. There is high confidence in the prediction of risks from a vessel oil spill.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans.
Biological **Ecological** **Economic** **Cultural**	A vessel oil spill is not predicted to occur but if it occurred risks would be temporary / reversible, small scale, and/or low intensity environmental damage due to the low volumes and light nature of marine diesel.
Company	All reasonably practicable measures have been adopted to reduce the risk of a vessel oil spill.
	The predicted consequences range from Minor to Moderate depending on the report with the likelihood of a vessel collision considered rare as it would only occur in exceptional circumstances. Thus, the risk level ranges from Low to Medium.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the risk.
Social	Some relevant persons reported finding oily residues and tar balls on beach walks along the Otway coastline. This information has been included in this risk assessment and is expected given the hydrocarbon prone geology of the area. From relevant person consultation, objections and claims have been made regarding: Impacts to beaches and shorebird nesting areas. This risk assessment shows that impacts to beaches and shorebird nesting area would be temporary / reversible, small scale, and/or low intensity environmental damage due to the low volumes and light nature of marine diesel. Balls of crude oil along beaches and how these will be disposed. Diesel being a light fuel is not prone to forming crude oil balls. Notification to the DNP in the event of oil/gas pollution incidences which occur within a marine park or are likely to pose a risk to a marine park as soon as possible. This requirement is covered in the Regia MSS Implementation Strategy and Oil Pollution Emergency Plan.
	To date there has been no views from the public in relation to a vessel oil spill.

5.6 Predicted impacts are of an acceptable level

In evaluating the proposed activity against acceptable levels of environmental impact and risk, CGG has followed its Decision-Making Criteria as outlined in its environmental assessment process.

Category	Defined Acceptable Level
Principles of ESD	The petroleum activity results in temporary / reversible, small scale, and/or low intensity environmental damage.
	The impact and risk assessment process are based on sufficient information to understand if: Serious/irreversible environmental damage is predicted; or The application of the precautionary principle is applied in the presence of scientific uncertainty.
	Environmental management of the activity must not be inconsistent with EPBC Act Management Plans and Recovery Plans.
Biological	Impacts and risks to biological features will be temporary / reversible, small scale, and/or low intensity environmental damage at population levels.
Ecological	Impacts and risks to ecological features will be temporary / reversible, small scale, and/or low intensity damage to the overall health, diversity, or functioning of the ecosystem.
Economic	Affected persons will not be worse off because of the activity.
Cultural	Impacts and risks to cultural features including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts and risks.
	Environmental impacts and risks are consistent with the CGG impact and risk assessment process such that for an impact or risk the effect/ consequence rating is medium or below.
	The implementation strategy includes specific measures to ensure that measures adopted continue to be effective in managing the impact or risk.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons.
	The views of public have been considered in the impact and risk assessment.

Comparing the predicted levels of impact or risk from the environmental assessments with the pre-defined acceptable levels was completed for each aspect and carried significant weight in CGG determining whether the activity complied with its corporate policies and the Regulations. These comparisons are shown in the below sections using the category as the link to the defined acceptable level.

5.6.1 Physical presence

This table provides a self-assessment of the predicted levels of impact assessed in Appendix E1 against the defined acceptable levels in the table above.

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts are temporary, reversible, and small-scale. The predicted impacts from physical presence are 90 days, absent when the activity is concluded and limited to the moving geographic footprint of the survey. Therefore, the impacts confirm to be below the defined acceptable level.
	Available literature and government data were used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts to marine users.
Biological	Not applicable.
Ecological	Not applicable.
Economic	Predicted impacts are temporary and in most cases avoidable. A compensation process will be implemented in the event displacement cannot be avoided and there is a financial loss to the marine user.
Cultural	Impacts to cultural features including cultural values, traditions, or practices, are not predicted. This distance of the activity offshore means that no Traditional Owners will be excluded from Sea Country. No indirect impacts to connection to Country is predicted as no displacement or affects to species at populations levels, to ecosystem integrity, or biodiversity preservation.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in Appendix F2.
	The predicted effect level is moderate.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	Measures have been adopted based on the consultation process to address relevant objections and claims of relevant persons as per the stakeholder feedback of: Ensure continued liaison with the Australian Hydrographic Service (AHS) for Notices to Mariners (NOTMAR), ensure that the AHS is notified three weeks prior to the actual commencement of activities. This information is critical to maritime safety and reduces negative impacts on other maritime users. This is addressed in the Consultation Plan. CCG have adopted an adjustment protocol that will ensure that no fisher will be worse off because of the Regia MSS and that reasonable, evidence-based claims will be paid.
	No public comments have been received in relation to the physical presence of the vessels and equipment in relation to impacts to marine users.

5.6.2 Underwater sound – Plankton

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts to zooplankton will be temporary, reversible, small-scale, and/or within natural variations in mortality.
	Available literature was used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts which is based on peer reviewed and published literature.
	No EPBC Act Management Plans and Recovery Plans were identified relevant to plankton.
Biological	Predicted impacts to zooplankton are temporary, reversible, small-scale, and within natural variations in mortality.
Ecological **Economic** **Cultural**	If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. As predicted impacts to zooplankton are temporary, reversible, small-scale, and within natural variations in mortality, impacts to primary production and ecosystem function are not predicted.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in Appendix F2.
	The predicted effect level is minor.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation the following objections and claims have been made: Impact of the survey on the Bonney Upwelling. - The impacts of the noise on marine ecosystems, can kill zooplankton. - Seismic blasting will kill zooplankton which have a fundamental role for ecological integrity as food for krill and subsequently krill are food for whales. Impacts to zooplankton and the Bonney Coast Upwelling and the role they both play in ecosystem function and productivity, are not predicted as: • Impacts to phytoplankton are not predicted. • Mortality or injury effects to zooplankton will be well within natural mortality rates. Upwelling systems in the region are highly dynamic with large variations in biomass a normal process. Zooplankton communities demonstrate high rates of turnover and will be constantly replenishing even as the seismic survey occurs. • Mortality or mortal injury effects to zooplankton, including krill, do not impact on marine fauna being able to feed on them as they will still be available within the water column.

5.6.3 Underwater sound – Fish

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts to EPBC Act listed fish species are temporary / reversible and small-scale behavioural response or recoverable temporary threshold shift. Predicted impacts to fish are low intensity damage at population levels and within currently accepted levels of impact to these species as applied by the commercial fishing industry.
	Available literature was used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts which is based on peer reviewed and published literature.
	No EPBC Act Management Plans and Recovery Plans identified for fish identified underwater sound as a threat and no actions relevant to the seismic survey were identified.
Biological	Predicted impacts to fish are low intensity damage at the population level and within currently accepted levels of impact to these species as applied by the commercial fishing industry.
Ecological	Impacts to ecological features are not predicted.
Economic	Via stakeholder consultation commercial fishers have raised concerns in relation to seismic impacts to commercial fisheries and the Otway Adjustment Protocol will be implemented to ensure that affected fishers will not be worse off because of the activity.
Cultural	If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Via consultation, impacts to the Budj Bim Cultural Landscape World Heritage Area eel traps and *kooyang* (Short-finned Eel) from the seismic survey has had been raised. The eel traps are protected under the World Heritage Area listing, the eels themselves are not. No impacts to the World Heritage Area are predicted. The predicted impacts to eels are low intensity at a population level and within current accepted levels of impact as applied to the commercial fishing industry.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in the following section.
	The predicted effect level is minor.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation the following objections and claims have been made: - Commercial fishers and some other marine users have raised concerns about the impacts to fish populations and the long-term effects of seismic on the sustainability of the fisheries. The impacts of the Regia MSS have been assessed and the predicted levels of impact to each commercial fish species are all sub-lethal and mostly behavioural. There is no evidence of reduced fecundity nor developmental effects in any fish species, so long-term effects over multiple fishing seasons are not predicted. This has been communicated to the individuals who raised these concerns.

5.6.4 Underwater sound – Invertebrates

Category	Predicted Level of Impact
Principles of ESD	Of the invertebrates known to be present within the Operational Area and predicted to be impacted by seismic sound, individual Southern Rock Lobster within close proximity to the seismic may suffer permanent injury and individual Giant Crab may suffer similarly. However, there is no evidence for scaling of effects to population levels. Impacts to molluscs are not predicted while impacts to octopus and squid are predicted to be behavioural only. Whilst the impacts may be irreversible for individual Southern Rock Lobsters and Giant Crabs the extent of impacts will not affect population levels. Fishing removes up to 30% of adult standing stock each year and the population is resilient to this. The impacts to molluscs, octopus, and squid are predicted to be negligible.
	Available literature was used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts which is based on peer reviewed and published literature.
	No EPBC Act Management Plans and Recovery Plans were identified relevant to invertebrates.
Biological	Predicted impacts to molluscs, octopus, and squid are temporary, reversible, and small-scale. Predicted impacts to Giant Crab and Southern Rock Lobster are low intensity damage at population levels and well within currently accepted and sustainable levels of impact to these species as applied by the commercial fishing industry.
Ecological	Impacts to ecological features are not predicted.
Economic	Through consultation commercial fishers have raised concerns in relation to seismic impacts to commercial fisheries and the Otway Adjustment Protocol will be implemented to ensure that affected fishers will not be worse off because of the activity.
Cultural	If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Predicted impacts to molluscs, and squid are temporary, reversible, and small-scale. Predicted impacts to Giant Crab and Southern Rock Lobster are low intensity damage at population levels and well within currently accepted and sustainable levels of impact to these species. From consultation to date no cultural features including cultural values, traditions, or practices have been identified associated with invertebrates that may be impacted.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in the following section.
	The predicted effect level is minor.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation the following objections and claims have been made: - Some fishers have raised a claim that they will be worse off because of the activity either through direct displacement, loss of gear, through knock-on effects, or through long-term effects to stock levels. A compensation process will be adopted to pay reasonable, evidence-based claims. - Local businesses and interested individuals have claimed unacceptable levels of impact to fish stocks and the ripple effects that this would have to the coastal developments of the Otway.

	Local businesses once removed from the fisher (i.e., fish markets or point of sale handlers) will be able to submit claims under the compensation process.

5.6.5 Underwater sound – Birds

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts to diving birds and penguins are temporary / reversible and small-scale behavioural responses that are likely to be within natural variation of foraging behaviours.
	Available literature was used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts which is based on peer reviewed and published literature.
	No EPBC Act Management Plans and Recovery Plans identified for birds identified underwater sound as a threat and no actions relevant to the seismic survey were identified.
Biological	Predicted impacts to diving birds and penguins are temporary / reversible and small-scale behavioural response that are likely to be within natural variation of foraging behaviours.
Ecological	Impacts to ecological features are not predicted.
Economic	Impacts to economic receptors are not predicted.
Cultural	If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Predicted impacts to short-tailed shearwaters with implemented controls are temporary / reversible and small-scale behavioural responses or recoverable temporary threshold shifts, with no impacts at a population level are predicted. Impacts to cultural receptors are not predicted.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts.
	The predicted effect level is minor.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation the following objections and claims have been made: - Behavioural disturbance impacts to Little Penguin colony at Middle Island resulting in further distance to forage and impacting breeding success. The active seismic area will be at least 25km distant from Middle Island at its closest point and ever further away after that. Key foraging habitat and access to regular food sources will not be affected.

5.6.6 Underwater sound – Turtles

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts to EPBC Act listed turtle species are temporary / reversible and small-scale behavioural response or recoverable temporary threshold shift. No impacts at a populations level are predicted.
	Available literature was used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts which is based on peer reviewed and published literature.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans as detailed in Annex 1 of this document.
Biological	Predicted impacts to EPBC Act listed turtle species are temporary / reversible and small-scale behavioural response or recoverable temporary threshold shift. No impacts at a populations level are predicted.
Ecological	Impacts to ecological features are not predicted.
Economic	Impacts to economic features are not predicted.
Cultural	If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Predicted impacts to EPBC Act listed turtle species are temporary / reversible and small-scale behavioural response or recoverable temporary threshold shift. Impacts to cultural features are not predicted.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in the following section.
	The predicted effect level is minor.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation no objections and claims have been made regarding underwater sound and turtles. A single individual raised awareness about the presence of marine turtles in the Otway region and this information was included in this impact assessment.

5.6.7 Underwater sound – Marine Mammals

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts to marine mammals with implemented controls are temporary / reversible and small-scale behavioural responses or recoverable temporary threshold shifts. No impacts at a population level are predicted.
	Available literature was used to inform the impact assessment. Serious or irreversible environmental damage is not predicted. There is high confidence in the prediction of impacts which is based on peer reviewed and published literature. There is medium confidence in the prediction of when foraging whales and Southern Right Whales are present in BIAs and thus monitoring will be undertaken to validate the presence and/or absence of whales.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans.
Biological	Predicted impacts to marine mammals with implemented controls are temporary / reversible and small-scale behavioural response or recoverable temporary threshold shift. No impacts at a populations level are predicted.
Ecological	Impacts to ecological features are not predicted.
Economic	Impacts to economic features are not predicted.
Cultural	Impacts to cultural features are not predicted. If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Predicted impacts to marine mammals with implemented controls are temporary / reversible and small-scale behavioural responses or recoverable temporary threshold shifts. No impacts at a population level are predicted. Via stakeholder consultation the cultural value of Deen Maar (Lady Julie Percy Island) has been raised, hence, an activity limitation has been implemented such that no acquisition will occur (i.e. full power discharge of the sound source) within 17 km of Deen Maar. [Distance updated in response to Matters M31, M32, M33 and F17].
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in the following section.
	The predicted effect level is minor to moderate.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation, objections and claims have been made regarding underwater sound and marine mammals. These have been addressed by changing the Regia MSS temporal and spatial boundaries to: Avoid the period when Blue Whale and other foraging whales are present in the Blue Whale foraging BIA in significant numbers. Not operating the sound source within 17 km of Deen Maar. Distance updated in response to Matters M31, M32, M33 and F17. Not operating the sound source within 42 km of the SRW Reproduction BIA when SRW's are present in the BIA, ensures the activity does not affect calving, resting, nursing, or any other biologically important behaviour for calf-cow pairs No discharge of the sound source in the Southern Right Whale reproduction BIA at any time.

5.6.8 Underwater Sound – Divers, Swimmers & Surfers

Category	Predicted Level of Impact
Principles of ESD	Impacts to divers, surfers and swimmers are not predicted as the Regia MSS has been redesigned so that the received sound level at 13 representative coastal locations and at Deen Maar is below the human health safety criterion for divers and swimmers of 145 dB re 1 µPa.
	Available literature was used to inform the impact assessment. There is high confidence in the prediction of impacts which are based on peer reviewed and published literature. The sound modelling was revisited with a deliberate effort to assess received sound levels at 13 representative coastal locations and at Deen Maar adjacent to the Survey Acquisition Area. The outcomes showed that the survey could not exceed the safety criterion on the coastline except from a small area. This area has now been removed from the acquisition area where the sound source would operate at full power.
	No EPBC Act Management Plans or Recovery Plans were identified that are relevant to divers, surfers or swimmers.
Biological	Impacts to biological features are not predicted.
Ecological	Impacts to ecological features are not predicted.
Economic	Impacts to economic receptors are not predicted. The sound source will not be discharged at full power in areas from where it is determined that exceedances of the human health safety criterion may occur.
Cultural	Impacts to divers, surfers and swimmers are not predicted as the Regia MSS has been redesigned so that the received sound level at 13 representative coastal locations and at Deen Maar is below the human health safety criterion for divers and swimmers of 145 dB re 1 uPa. The distance of the activity offshore means that no Traditional Owners will be excluded from Sea Country. Impacts to cultural receptors are not predicted.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in the following section.
	The predicted effect level is negligible.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	From relevant person consultation the following objections and claims have been made: - Impacts to divers and surfers from underwater acoustic impacts. A second modelling report was commissioned which deliberately assessed whether exceedances of the human health safety criterion could be realised on the coastline adjacent to the Survey Acquisition Area or at Deen Maar. The discharge of the sound source at full power has been constrained and the Survey Acquisition Area will not include the area from where exceedances on the coastline were predicted.

5.6.9 Artificial light

Category	Predicted Level of Impact
Principles of ESD	Predicted impacts are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation.
	Available literature and government management plans, recovery plans and conservation advice were used to inform the impact assessment. Serious or irreversible environmental damage is not predicted from light emissions. There is high confidence in the prediction of impacts to light sensitive receptors.
	Management of the activity is consistent with EPBC Act Management Plans and Recovery Plans.
Biological	Predicted impacts to biological receptors (fish, invertebrates, birds, turtles) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation.
Ecological	Predicted impacts to ecological receptors (e.g. zooplankton) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation.
Economic	Predicted impacts to economic receptors (e.g. squid) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation, thus commercial squid fishers will not be worse off as a result of the activity.
Cultural	If the potential ecological impact or risk to a culturally important species is deemed acceptable, it is likely that the corresponding impact on cultural heritage will also be considered acceptable, as the physical presence and health of these species are key for preserving their cultural significance. Predicted impacts to biological receptors (fish, invertebrates, birds, turtles) are temporary, reversible, small-scale, and light emissions will be reduced to minimum levels for safe operations and navigation. Light emissions are not predicted to impact cultural receptors.
Company	All reasonably practicable measures have been adopted to reduce environmental impacts as detailed in the following section.
	The predicted effect level is minor.
	The adopted measures will be implemented and monitored as detailed in the implementation strategy to ensure they are effective in managing the impact.
Social	To date no objections or claims in relation to light emissions have been made by relevant persons. - A relevant person raised that they bird watch for pelagic and shorebirds along the southwest coast of Victoria and were concerned about their welfare in relation to the Regia MSS. The impact assessment undertaken identified several pelagic and shorebird species, including BIAs, that occur within the area potentially affected by light. Some of the species identified are threatened or migratory species with a subset of species identified as undertaking biologically important behaviour such as breeding and/or foraging/feeding. As such the CGG Marine Assurance System will ensure that vessels implement a Vessel Lighting Management Plan to ensure light emissions do not impact on pelagic and shorebirds. Thus, impacts to bird watching for pelagic and shorebirds along the southwest coast of Victoria are not predicted.
	To date there has been no views from the public in relation to the activity's light emissions.

5.7 Consideration of Predictive Uncertainty

In any environmental impact assessment process, predictive uncertainty plays a pivotal role in shaping our understanding and management of potential impacts. This section delves into the complexities and inherent uncertainties associated with predicting environmental effects on sensitive marine species and habitats.

It outlines our methodologies for quantifying and managing these uncertainties, emphasising the limitations of current predictive models. By transparently addressing these uncertainties, we aim to enhance the robustness of our environmental assessments and decision-making processes, ensuring a responsible and adaptive approach to environmental management.

Each impact analysis (Appendix E1 – E9) explicitly considered the levels of uncertainty in our predictions of impact in accordance with the process outlined in Appendix B9. Through this consideration it has been possible to identify areas where uncertainty is highest, or confidence in the predictions is low. In such circumstances there has been a further consideration of whether the uncertainty levels can be reduced prior to the proposed commencement of the activity, during the activity, of afterward.

Application of the precautionary principle is required when there are threats of serious or irreversible environmental damage and a lack of full scientific certainty. There are examples in the analysis where a lack of full scientific uncertainty was identified, however, there were no instances where threats to environmental values and sensitivities were serious or irreversible. Despite this CGG routinely applied precaution in its assessment; selecting conservative effect thresholds for sound, adjusting the activity design to avoid overlap with sensitive species protected areas (e.g. KEFs), and implementing buffers around marine protected areas.

Ultimately, the Implementation Strategy in Appendix B3 is how all uncertainties are managed adaptively. Appendix B3 discusses various parts of the environmental management system that facilitate adaptive management strategies to ensure there is a dynamic approach to manage and mitigate environmental impacts and risks effectively. Adaptive management is pivotal in this context, allowing for flexible responses to changes and uncertainties identified during the survey. It involves continuous monitoring, evaluation, and modification of management strategies based on real-time data and feedback.

5.8 Quality of the Environmental Assessments

The analysis completed in Appendices D1 – D4 and E1 – E9 are appropriate to the nature and scale of the activity because they:

- Cover all environmental aspects, and all environmental components including air, water, land, flora, fauna, and human health including the social, economic, and cultural features of these.
- Follow a structured methodology to identify environmental impacts and risks.
- Clearly document the assessment process and findings for relevant person review and they have been publicly available for months prior to submission.
- Apply caution in uncertainty, preferring preventative measures and properly applying the hierarchy of controls concept.
- Will be maintained in a ‘live’ status throughout the duration of the EP to enable the incorporation of new data and adjust management and mitigation measures as needed.
- Have applied greater effort to analysis of impacts and risks with lower predictive confidence and higher effect/consequence meaning the EP has prioritised actions based on the severity of impacts and risks.
- Comply with relevant laws and regulations.
- Address the social and cultural impacts on local communities.

The analyses completed derive their credibility through evidence gathered from peer-reviewed scientific literature, utilisation of high-quality and verifiable data (e.g. fisheries), use of rigorous and

established scientific methodologies, and full transparency regarding methods and data sources. Thus, ensuring reproducibility of results. It also exercises objectivity, avoiding any conflicts of interest by using qualified external experts, and follows international standards for environmental impact assessments. Comprehensive documentation throughout the assessment process further underpins its scientific integrity.

5.9 Compliance with the EPBC Act

The primary environmental legislation within Australia is the *Environmental Protection and Biodiversity Conservation Act* 2002 (**EPBC Act**). NOPSEMA's authorisation processes have a Part 10 approval that applies to offshore petroleum activities as per the NOPSEMA EPBC Act Program. This program ensures that impacts on matters protected under Part 3 of the EPBC Act are not unacceptable.

Matters protected by the EPBC Act that have been considered in this EP include:

- World Heritage properties
- National heritage values of declared National Heritage Places.
- Wetlands of international importance.
- Listed threatened species and ecological communities.
- Listed migratory species.
- Commonwealth marine environment.

CGG maintains a register of all legislation, including all EPBC Act materials, which has been provided in Appendix B2 of the EP. This appendix has been reviewed prior to each submission and will be updated in accordance with the requirements in the Implementation Strategy (Appendix B3).

Each impact and risk analyses has considered relevant matters from Appendix B2 and provides evidence backed by appropriate primary information sources, that the proposed activity is not in conflict with any recovery plans or threat abatement plans for listed threatened species or ecological communities. It respects the management plans in place for Commonwealth reserves, such as Australian Marine Parks, and upholds the Australian IUCN Reserve Management Principles. It shows that the activity will not have unacceptable impacts on the values of these protected areas.

Moreover, the EP content confirms that the proposed activity does not contravene any management plans for World Heritage properties, National Heritage places, or Ramsar wetlands. In the absence of specific management plans, the EP shows that all reasonable steps have been taken to ensure consistency with the Australian World Heritage Management Principles, National Heritage Management Principles, Australia Ramsar Management Principles, and Commonwealth Heritage Management Principles.

The EP also demonstrates due regard for relevant policy documents, guidance, bioregional plans, wildlife conservation plans, management plans, gazettal instruments under the EPBC Act, conservation advice, marine bioregional plans, and other pertinent information, including spatial data, available on the DCCEEW website.

Objectives and values of the relevant south-east marine parks, presented in the South-east Marine Parks Network Management Plan (DNP 2025) are described and discussed in Table F4-2 and Table F4-3 below – to demonstrate that the activity is not inconsistent with the relevant management plan, and that impacts will be of an acceptable level.

Table F4-2 - Demonstration that the activity is not inconsistent with the objectives of the South-east Marine Parks Network Management Plan

Goals/Visions/Objectives – *South-east Marine Parks Network Management Plan (DNP 2025)*	**Demonstration of Consistency with this Goal/Vision/Objective within the Regia MSS EP**
Management program goal: Respect and support the ongoing cultural responsibilities and connections of First Nations people to care for and manage Sea Country in marine parks	The following activity limitation is set: • No activities within a designated Australian Marine Park (State and Commonwealth).
Management program goal: Reduce the impacts of pressures and environmental changes on marine species, habitats and ecosystems	
Vision: The South-east Marine Parks are healthy and resilient for current and future generations	The methodology applied for all impact and risk analyses (Appendices D1-D4 and E1-E9) involved the consideration of all relevant matters protected by the EPBC Act. This process also involved providing evidence that the proposed activity is not in conflict with any recovery plans or threat abatement plans for listed threatened species or ecological communities. It respects the management plans in place for Commonwealth reserves, including Australian Marine Parks. It shows that the activity will not have unacceptable impacts on the values of these protected areas.
Objective (a): To protect and conserve biodiversity and other natural and cultural values	The following Environmental Performance Outcomes are set: • No death or injury to fauna, including listed threatened or migratory species, from the activity. • No disruption to critical life-cycle behaviours. • Biologically important behaviours within a BIA or outside a BIA can continue while the activity is being undertaken.
	The Regia MSS EP is assessed under a Part 10 approval under the EPBC Act, and an endorsed Program implemented by NOPSEMA.
	Appendix F2 demonstrates that all reasonably practicable measures to protect relevant receptors have been adopted and therefore minimised.
	Where potential impacts or risks relating to cultural features have been identified, these potential impacts/risks including cultural values, traditions, or practices, will be temporary / reversible, small scale, and/or low intensity.

Goals/Visions/Objectives – *South-east Marine Parks Network Management Plan (DNP 2025)*	**Demonstration of Consistency with this Goal/Vision/Objective within the Regia MSS EP**
	The following points include relevant legislation and other requirements that currently apply to environmental management of the proposed activity (full list available in Appendix B2): • Underwater Cultural Heritage Act 2019 - The act provides for the protection of underwater cultural heritage, which may be affected by the activities associated with seismic surveys. • National Parks Act 1975 - This act establishes a framework for the protection and management of national parks in Australia. It provides for the conservation of natural and cultural resources, the provision of recreational opportunities, and the management of park use. • Victorian Marine National Parks and Sanctuaries Management Plan - The management plan provides guidance on the management of marine national parks and sanctuaries in Victoria, including the protection and conservation of marine environments that may be impacted by seismic surveys. • EPBC Act Policy Statement 1.1 – Significant Impact Guidelines – Matters of National Environmental Significance - The policy statement provides guidance on the assessment and management of activities that may have a significant impact on matters of national environmental significance, including marine habitats and species. • All conservation and listing advice, and management and recovery plans for relevant EPBC Act-listed receptors were considered to inform and identify actions required for conservation and recovery of the threatened species or ecological community.
Objective (b): Ecologically sustainable use and enjoyment of the natural resources within marine parks, where this is consistent with objective (a) (above)	The proposed Regia MSS activity is consistent with the principles of Ecologically Sustainable Development as assessed in Section 5.11.

Table F4-3 - Demonstration that the activity is not inconsistent with the values of the South-east Marine Parks Network Management Plan.

	Apollo Marine Park Values	Franklin Marine Park Values	Nelson Marine Park Values	Zeehan Marine Park Values	Justification for why the activity will not have unacceptable impacts on the values of AMP values
Ecosystems, habitats, communities, and notable features	The park contains habitats, species and ecological communities associated with the 2 provincial bioregions – Western Bass Strait Shelf Transition and Bass Strait Shelf Province – and the Central Bass Strait mesoscale bioregion.	The park contains habitats, species, and ecological communities associated with 2 provincial bioregions – Tasmanian Shelf Province and Western Bass Shelf Province – and the Otway and Franklin mesoscale bioregions.	The park contains habitats, species and ecological communities associated with the West Tasmanian Transition provincial bioregion.	The park contains habitats, species, and ecological communities associated with 3 provincial bioregions – the West Tasmania Transition, the Western Bass Strait Shelf Transition, and the Tasmania Province – and the Otway mesoscale bioregion.	There are no pathways for direct impact to ecosystems, habitats, communities, or notable features within AMPs that are permanently located within the boundaries of the park, given their sessile/permanent nature. Relevant predicted impacts to these in the greater region are assessed and discussed in Appendices E1-E9.
		Ecklonia radiata kelp forests, brown and red macroalgae, sponges, gorgonians, hard bryozoans and tube worms.		Benthic communities of fan worms, sponges, sea whips, and hard bryozoans, diverse sessile fauna and associated mobile fauna, including giant crabs, ascidians (sea squirts), corals, hydroids, crustaceans, sea stars, brittle stars, molluscs and fish.	
				The biodiversity and productivity in the park are influenced by the southward-flowing Zeehan Current (an extension of the Leeuwin Current from Western Australia) interacting with the canyons.	

	Apollo Marine Park Values	Franklin Marine Park Values	Nelson Marine Park Values	Zeehan Marine Park Values	Justification for why the activity will not have unacceptable impacts on the values of AMP values
Biologically Important Areas	Shy albatross, Black browed albatross, Campbell albatross, Indian yellow nosed albatross, Wandering albatross, Bullers albatross, Common diving petrel, Wedge-tailed and short-tailed shearwaters - Foraging	Antipodean albatross, Black browed albatross, Campbell albatross, Indian yellow nosed albatross, Wandering albatross, Bullers albatross, White faced storm petrel, Common diving petrel, Little penguin, Australasian gannet, and Short-tailed shearwater - Foraging	None identified	Antipodean albatross, Black browed albatross, Campbell albatross, Indian yellow nosed albatross, Wandering albatross, Bullers albatross, Common diving petrel, Wedge-tailed and short-tailed shearwaters - Foraging	No direct impacts to this species or its BIA within the AMP are predicted due to absence of any overlap with relevant EMBAs. Relevant predicted impacts to these in the greater region are assessed and discussed in Appendices E1-E9.
	Pygmy Blue Whale - Foraging	Pygmy Blue Whale - Foraging		Pygmy Blue Whale - Foraging	
	Southern Right Whale - Migration	Southern Right Whale - Migration		Southern Right Whale - Migration	
	White Shark - Foraging	White Shark - Foraging		White Shark - Foraging	
Key Ecological Features	Shelf rocky reefs and hard substrate – includes the mesophotic and rariphotic reefs in the north-west corner of the park.	Shelf rocky reefs and hard substrate – includes the mesophotic and rariphotic reefs in the north, east and south sections of the park.	None identified	West Tasmanian canyons • shelf rocky reefs and hard substrate – includes the rariphotic reefs on the mid and outer shelf.	There are no pathways for direct impact to KEFs within AMPs that are permanently located within the boundaries of the park, given their sessile/permanent nature.

	Apollo Marine Park Values	Franklin Marine Park Values	Nelson Marine Park Values	Zeehan Marine Park Values	Justification for why the activity will not have unacceptable impacts on the values of AMP values
Species and key behaviours	Benthic communities dominated by sponges, with some octocorals, bryozoans and encrusting macroalgae, and southern rock lobsters.	The park is a core foraging area for early incubating Tasmanian Shy albatross from the nearby Albatross Island breeding colony.	Many whales migrate through the park when travelling between the cold food-filled southern waters and the warmer waters north where they breed.	The park is a core foraging area for early incubating Tasmanian Shy albatross from the nearby Albatross Island breeding colony.	No direct impacts to these species or their key behaviours within AMPs are predicted due to the absence of any overlap with relevant EMBAs. Predicted impacts to relevant species and associated behaviours in the greater region are assessed and discussed in Appendices E1-E9.
	Fish communities are dominated by velvet leatherjackets, Degen's leatherjackets, six spine leatherjackets, jackass morwong, rosy wrasse, butterfly perch, bluethroat wrasse, pink snapper, common gurnard perch, barracouta, sand flathead, draughtboard shark, spikey dogfish, and gummy shark.				
Native Title, Sea Country, and Cultural Heritage	The MV City of Rayville shipwreck, an American freighter, lies near the western boundary of the park in a depth of 80 m.	None identified	None identified	None identified	There are no pathways for impacts to this shipwreck due to its fixed location within an AMP that is not predicted to be directly impacted by the activity.

	Apollo Marine Park Values	Franklin Marine Park Values	Nelson Marine Park Values	Zeehan Marine Park Values	Justification for why the activity will not have unacceptable impacts on the values of AMP values
Other marine park users, including other planned or existing offshore petroleum activities	Commercial fisheries operating in the park include: • South-east Scalefish and Shark Fishery – gillnet, hook and trap sector • Southern Bluefin Tuna Fishery • Victorian Rock Lobster Fishery • Victorian Ocean General Fishery • Victorian Wrasse (Ocean) Fishery • Victorian Commercial Permit and Small Sales Commercial Permit Fishery.	Commercial fisheries operating in the park include: South-east Scalefish and Shark Fishery – gillnet, hook and trap sector • Tasmanian Octopus Fishery • Tasmanian Rock Lobster Fishery • Tasmanian Giant Crab Fishery • Tasmanian Scalefish Fishery.	None identified	Commercial fisheries operating in the park include: • Tasmanian Rock Lobster Fishery • Tasmanian Giant Crab Fishery	There are no pathways for direct impact to commercial fisheries operating within AMPs due to the absence of any overlap with relevant EMBAs. Predicted impacts to relevant targeted species and fisheries in the greater region are assessed and discussed in Appendices B6 and E3.
	Commercial shipping routes into and out of Melbourne			Six existing petroleum titles (exploration permits at the commencement of this DNP (2025) plan) overlap the northern section of the park.	There are no pathways for direct impact to shipping routes operating within AMPs due to the absence of any overlap with relevant EMBAs. Relevant predicted impacts to other marine users are assessed in Appendix E1.

Under the EPBC Act, a National Recovery Plan exists for the endangered Southern Right Whale (*Eubalaena australis*). This plan identifies anthropogenic underwater noise as a Very High priority threat and sets out Action Areas designed to meet recovery targets, address key pressures, and guide species-specific conservation efforts. Action Area A5, also identified as Very High priority, focuses on the need to *"assess, manage, and mitigate impacts from anthropogenic underwater noise."*

This threat is classed as likely and a moderate consequence for the eastern portion of the population. The Recovery Plan also states that the behavioural impacts of sound to southern right whales is largely unknown and, therefore, a precautionary approach should be taken to the management of potential impacts, particularly in the context of cumulative impacts.

As detailed in Appendix E7 and shown in Map 085 (MAP-REG-EPM-085_C), the acquisition area overlaps a migratory BIA for SRWs. SRWs are likely to migrate through this area from April through October. Pregnant cows may pass through early in the season as they travel to aggregation areas, while cows with calves are likely to pass through later in the season as they depart for summer foraging grounds. Isolated individuals may be present outside this period. The acquisition area does not overlap the reproduction BIA; however, sound propagation may overlap this area when acquiring. Consequently, actions have been considered below based on effects to reproduction and effects to migration.

Only those actions within Action Area A5 that are applicable to the Regia MSS and within CGG's sphere of influence have been considered in this assessment. CGG has evaluated each relevant action and demonstrated that the Regia MSS is not inconsistent with these actions, as outlined below.

Action 1: CGG will improve baseline understanding of southern right whale acoustic communication to better inform potential impacts from anthropogenic underwater noise because:

1. The survey will deploy hydrophones, PAM systems, and fixed buoys that may detect low-frequency SRW calls, generating a spatially resolved dataset of SRW vocal activity in the western Otway region.
2. These systems will record ambient noise, sufficient to attempt identification and measurement of communication space, natural variability in noise levels, and in-situ signal-to-noise ratios relevant to mother–calf communication (if present and detected).
3. By analysing SRW calls (if present and detected) alongside environmental and oceanographic conditions, CGG will collect data to support an understanding of when and where SRWs are acoustically active and possibly how well calls propagate under local conditions.
4. Collected data will reduce uncertainty in the assessment of masking, disturbance thresholds, and the reliability of detection systems, strengthening future ALARP decisions and allowing more precise mitigation tailored to SRW acoustic ecology.
5. All data collected will be used to calibrate and assess the effectiveness and appropriateness of current models of sound transmission in the region. Filling data gaps with empirically derived location specific data will improve the quality of such models.

This monitoring will be published to contribute to the Recovery Plan priority to improve understanding of SRW communication and interactions with anthropogenic noise, providing empirical data to support regional cumulative assessments and future protection measures.

Action 2: This EP has demonstrated that the Regia MSS does not prevent any southern right whale from utilising the migration BIA nor the reproduction BIA or cause auditory impairment because:

1. The activity will not occur during April – August, avoiding the period when mothers and calves are most likely to arrive in and utilise coastal habitats and hence are most sensitive to disturbance.
2. While the Regia MSS overlaps with the final six weeks of the SRW presence window (mid-September–October), the activity is not predicted to prevent any southern right whale from utilising the Reproduction BIA because:

a. By the final six weeks of the season, most biologically important behaviours relevant to presence within the Reproduction BIA are expected to have already occurred, as approximately 75% of the reproduction season will have already elapsed by the time the Regia MSS commences.
    i. Arrival, initial migration into the BIA, calving, early calf-cow bonding, and the early developmental period for calves are all more likely to take place earlier in the season, as per the SRW National Recovery Plan.
    ii. Very late in the season in the latter stages of September, most SRW calf-cow pairs have completed the most sensitive life-stages and are departing the Reproduction BIA.
    iii. Migration from the reproduction BIA can occur at any time and a 10,500 km^2 shutdown zone is in place for SRW during this movement, with significant detection capability deployed such that detection is likely before threshold effect distances for PTS and TTS are reach and behavioural disturbance may occur.

b. Acquisition will commence in deeper waters, greater than 42 km from the reproduction BIA, and will not progress into shallower waters where sound may overlap the reproduction BIA until SRW's have been confirmed to not be present in the relevant section of the reproduction BIA. SRWs within the BIA will not be exposed to levels that would cause auditory injury or displacement. Modelling for deeper waters >42 km from the reproduction BIA shows:
    i. No exceedance of SRW injury thresholds within the reproduction BIA, and
    ii. Received levels within the reproduction BIA remain below a conservative behavioural disturbance threshold of 140 dB SPL.

    In addition, shutdown measures are in place if there is detection of an impulsive sound signature above an ultra-conservative threshold of 120 dB in the reproduction BIA in September or October.

c. As outlined in the National Recovery Plan, SRWs using the Reproduction BIA in late season predominantly engage in resting, nursing, and preparing for offshore departure.
    i. These behaviours occur in shallow, nearshore habitats (<20 m depth).
    ii. The seismic survey will be conducted in deep offshore water, spatially separated from the Reproduction BIA, while calf-cow pairs are present in this area.

    Therefore, utilisation of the reproduction BIA is predicted to continue unimpeded, as the survey will not alter habitat quality, accessibility, or suitability while SRW are present.

d. Calves later in the season are larger, more mobile, resilient and capable of accompanying their mothers into deeper waters, reflecting reduced reliance on the highly sheltered conditions required during the early weeks post-birth, as described in the Recovery Plan.

e. SRWs can continue to ulitise the migration BIA as the Regia MSS does not overlap the period when SRWs begin arriving from April onwards. The survey area overlaps less than 1% of the migration BIA, and 24-hour shutdown and relocation procedures are in place should a migrating whale be detected. The Reproduction BIA remains entirely undisturbed due to the activity limitations and control measure in place. Accordingly, the activity does not:
    i. prevent SRWs from utilising the migration BIA, and to arrive and enter the reproduction BIA.

ii. prevent SRWs from remaining within or utilising the reproduction BIA during calving and nursing.

iii. prevent SRWs from undertaking reproductive behaviours within the reproduction BIA.

iv. cause auditory impairment to SRWs within either the migration or reproduction BIAs.

v. cause displacement from HCTS or the reproduction BIA; or

vi. prevent SRWs from utilising the migration BIA to depart the region at the end of the season.

3. The sound source will not operate within 42 km of the SRW Reproduction BIA when SRW's are present in the BIA, ensuring the activity does not affect calving, resting, nursing, or any other biologically important behaviour for calf-cow pairs given:

    a. Auditory injury effects may begin to occur within 59 m of the sound source.

    b. TTS effects may begin to occur within 2.9 km of the sound source, assuming the whale remains within that distance for 24 hours.

    c. Behavioural responses may occur within:

        i. 3.15 km of the sound source at the 160 dB SPL threshold used in the NMFS guidance.

        ii. 12.43 km of the sound source at the more precautionary effect threshold of 140 dB SPL.

        iii. 30.97 km of the sound source at the ultra-precautionary effect threshold of 120 dB SPL.

    Multiple effective methods in place to detect SRWs before these distances are reached and will trigger immediate shutdown of the sound source. None of the predicted effect distances overlap with the SRW reproduction BIA when the survey is >42 km from the reproduction BIA.

4. Regarding underwater sound effects within the migration BIA, real-time monitoring (MFOs, spotter vessel, towed PAM, sound source verification, and aerial observations) ensures high detection probability, enabling shutdowns prior to migrating whales encountering distances associated with auditory impairment.

5. Shut down measures will occur if any SRW is detected anywhere within a 10,500 km^2 (Map 193). This ensures shutdowns occur well before auditory injury or TTS could occur whether the SRW is utilising the migration or reproduction BIA.

Based on independent expert modelling, underwater sound from the Regia MSS is not predicted to result in a deviation of natural soundscape within the reproduction BIA, to an extent that would prevent biologically important reproduction behaviours, as defined in the SRW Recovery Plan from occurring (courtship, mating, birthing, nursing or accompanying a dependent young). Therefore, SRW are not predicted to be prevented from utilising the BIA or be exposed to auditory impairment.

Action 3: The Regia MSS EP has demonstrated that the risk of behavioural disturbance is minimised because:

1. The required actions contained within the National Recovery Plan were used as the defined acceptable levels of impact, along with other levels in the impact assessment, ensuring all efforts and environmental performance outcomes were aligned with the National Recovery Plan from the commencement of the environmental assessment.

2. The survey footprint, timing and operating envelopes have been substantially reduced through iterative design, and extensive consultation, resulting in far less overlap with the migration BIA and peak biological periods than originally proposed.

3. The sound source will never operate within 17 km of the SRW reproduction BIA nor within 42 km of it while SRW are expected to be present, eliminating potential impacts during the most sensitive life-cycle stages.
6. Independent expert sound modelling predicts that PTS/TTS thresholds for SRW are not exceeded within the reproduction BIA, and shutdowns will occur well beyond the predicted ranges within the migration BIA noting that:
    a. A conservative approach has been taken in the modelling, such that the received sound levels and effect distances are likely to be lower than those predicted. The modelled outputs will be verified throughout the survey.
    b. The impact assessment has been informed by contemporary peer-reviewed literature and internationally accepted, conservative effect thresholds.
    c. The shutdown procedures are based on even more conservative effect threshold distances.
7. The shutdown zones applied for migrating SRWs are highly conservative, far exceeding EPBC Act requirements.
8. A multi-layered detection system (involving MFOs, spotter vessel, PAM, sound source verification, aerial surveillance, and external PAM detections) maximises detection probability across visual and acoustic ranges, materially reducing the likelihood of undetected close approaches. A full list of control measures and associated environmental performance standards can be found in Appendix G1.
9. A dedicated PAM-enabled spotter vessel will operate in dynamic 'sentry' and 'scouting' modes, targeting SRW movement pathways by adjusting positions based on real-time detections.
10. Adaptive management, with oversight from a Whale Expert Panel, applies real-time expert judgement to detections, trends, environmental cues, and uncertainty, increasing the reliability of behavioural protection measures.
11. Soft-start and low-power modes will prevent sudden introduction of sound into the environment, giving migratory SRW the opportunity to avoid the source voluntarily.
12. Night-time operations are managed by acoustic monitoring and extended shutdown periods, reducing residual uncertainty in low-visibility conditions.
13. Capped speed limits (up to 6 knots) reduce the risk of vessel-related disturbance and allow more time for detection and shutdowns.
14. Pre-survey seasonal acoustic and visual monitoring validates presence/absence expectations and ensures environmental conditions match predictive modelling.
15. The activity's acoustic impacts are temporary, reversible, and spatially limited, with modelling showing that behavioural responses would be short-lived and not sustained.
16. Cumulative impacts have been assessed as low, owing to staggered timing of other Otway Basin activities, minimal temporal overlap, and industry-wide mitigation commitments.
17. The EP incorporates relevant requirements of Recovery Plans, Conservation Advice, and the Australian National Guidelines, ensuring species are not prevented from utilising BIAs or subjected to auditory impairment.
18. Mitigation measures have been taken through ALARP and other 'acceptable level' assessments, demonstrating that no reasonably practicable additional measures are available that would further reduce behavioural disturbance.

Collectively, the points above demonstrate that this EP ensures the Regia MSS has minimised the risk of behavioural disturbance (as defined in the SRW National Recovery Plan) to SRWs within the reproduction BIA.

Action 4: CGG has ensured its environmental assessments associated with underwater noise generating activities include consideration of national policy (e.g., EPBC Act Policy Statement 2.1) and guidelines related to managing anthropogenic underwater noise and implement appropriate mitigation measures to reduce risks to southern right whales to the lowest possible level because:

1. CGG has adopted a 10,500 km^2 shutdown area (Map 193) well in excess of the shutdowns that must occur at a minimum of 5 km for PTS, TTS, and behavioural disturbance. These far exceed EPBC Act Policy Statement 2.1, which recommends a 500 m shutdown zone for all whales.
2. CGG's assessment relies on detailed numerical sound modelling calibrated to site-specific bathymetry, propagation, and species-specific thresholds rather than the generic source-level assumptions in Policy Statement 2.1, providing a more accurate, conservative prediction of exposure risk. Additionally, CGG has committed to in-field sound source verification of the modelling predictions and adaptive management should these distances have been underestimated.
3. CGG applies multi-platform detection (including MFOs, spotter vessel, PAM, sound source verification, aerial surveillance, and external PAM detections), exceeding the minimum single-platform visual monitoring described in Policy Statement 2.1, thus reducing the probability of undetected close approaches. A full list of control measures and associated environmental performance standards can be found in Appendix G1.
4. Shutdown procedures are triggered earlier, under more conservative conditions, and for a wider set of effects than required under Policy Statement 2.1, ensuring SRW are protected long before exposure to thresholds that could cause disturbance or auditory impairment.
5. By employing ambient noise monitoring and multiple detection systems, CGG can adjust mitigation beyond the approaches contemplated by Policy Statement 2.1.

The combination of spatial exclusions, ultra-conservative shutdown zones, multi-layered detection, and timing limitations results in a risk profile that is substantially lower than that assumed under Policy Statement 2.1.

Action 7: CGG will improve understanding and characterisation of marine soundscapes, including the application of new technologies for data processing, within southern right whale BIAs to facilitate quantification of anthropogenic noise in the marine environment because:

1. CGG will deploy a network of hydrophones, a PAM network capable of long-duration, broadband (including low-frequency) acoustic monitoring, generating a spatially and temporally detailed soundscape within and adjacent to the SRW reproduction BIA in southwest Victoria.
2. These systems measure ambient (~baseline) noise, biological noise, and anthropogenic noise allowing CGG to characterise the soundscape, including diel, weather-driven, and seasonal variability across the SRW communication band.
3. The hydrophone array enables source separation, allowing CGG to distinguish seismic pulses, other anthropogenic sources, biological signals, and natural geophysical sounds, which is important for quantifying the proportion of anthropogenic noise in the wider soundscape.
4. Sensors will operate before and during, the survey, so that CGG can quantify changes in soundscape composition attributable to the activity, enabling assessment of incremental anthropogenic noise contributions relative to baseline conditions.
5. The monitoring locations are positioned to capture propagation into the SRW reproduction BIA, meaning the resulting data will improve understanding of how offshore noise transmits toward SRW calving and migration habitats.
6. The integrated dataset (ambient noise metrics, PAM detections, species-call presence, and vessel activity logs) will support the development of empirical noise budgets, quantifying anthropogenic contributions across frequencies important for SRW communication.

The Recovery Plan identifies improved understanding of anthropogenic noise in SRW habitats as a priority, and the baseline and impact-related acoustic information required will be published to meet support meeting this objective.

Rationale for why a biological response is consistent with the SRW National Recovery Plan

The National Recovery Plan for the Southern Right Whale (2024) defines an impact as "*a biologically significant effect that reflects a change whose direction, magnitude and/or duration is sufficient to have consequences for the fitness of individuals or populations*" (Glossary, p.1). The Plan further explains that, due to the species' life-history traits, "*any long-term response to disturbance and impacts… are unlikely to be detectable, or even reliably identified to a specific threat, over short timescales (i.e. 1 to 3 years*)" (p.13). Accordingly, only effects that alter fitness or population trajectory, or disrupt biologically important behaviours within key habitats, constitute impacts relevant to recovery planning. The National Recovery Plan identifies that the risk from anthropogenic underwater noise is greatest "*within or close to southern right whale reproductive BIAs and HCTS, where whales… are resident for long periods… and young calves are present*" (Action A5, p.71).

The Regia MSS:

- Temporally overlaps with 2 weeks of SRW's likely presence in the reproduction BIA at the end of the reproduction season.
- Occurs entirely outside the reproduction BIA and will come no closer than 42 km during SRW utilisation months.
- Has shown sound propagation will be verified to be below 120 dB (an ultra-precautionary threshold).

Therefore, the Regia MSS cannot interfere with calving, nursing, or the prolonged residency behaviours that define reproduction BIAs. Action A5 requires that proponents "*demonstrate that [the action] does not prevent any southern right whale from utilising the area or cause auditory impairment*" (A5.2, p.71), and independent expert modelling confirms that received levels within the reproduction BIA remain below thresholds for auditory injury or behavioural disruption of biologically important behaviours.

Disturbance is separately defined as "*behavioural changes in response to an activity that can result in disruption to biologically important behaviours (i.e., reproduction, foraging, migration, resting)*" (Glossary, p.1).

The EP has put in place stringent measures to ensure that behaviours that meet this definition will not occur because of the Regia MSS. Any remaining behavioural responses observable may or may not be attributable to the Regia MSS. Hypothetically, if a behavioural response below 'disturbance' were attributable to the Regia MSS these effects are still consistent with the National Recovery Plan because they don't meet the definition of 'disturbance' and therefore cannot met the definition of 'impact'. On a strict reading of the Recovery Plan, a biological response to the Regia MSS (if one were to occur) does not constitute an impact, because it does not affect fitness, does not occur or emit sound at unacceptable levels within the reproductive BIAs or HCTS where sensitive behaviours occur, does not prevent use of critical habitat, does not cause auditory impairment, and does not disrupt reproduction, calving, nursing, or resting. Accordingly, the activity remains fully consistent with the Recovery Plan's objectives and specific actions relating to anthropogenic underwater noise.

While the Regia MSS EP conservatively acknowledges behavioural changes may occur at received levels below 120 dB SPL, this does not imply such responses are ecologically or regulatorily meaningful. Based on the best available evidence, and consistent with the behavioural variability typical of large mysticetes, any such responses are unlikely to constitute disruption to biologically important behaviours as defined by the National Recovery Plan. Moreover, where behavioural response probabilities have already been incorporated into impact predictions through conservative modelling and empirical thresholds, invoking residual uncertainty in the absence of demonstrable harm is neither necessary nor proportionate because:

- It is impossible to show or measure the point at which a behavioural change becomes a behavioural disturbance. The permissible behavioural changes under the National Recovery

Plan are those behaviours that do not result in disruption to biologically important behaviours.

- The following studies indicate that the transition between a behavioural change (i.e. within the expected behavioural repertoire) and a behavioural disturbance likely occurs somewhere between the ~110 dB SPL and >160 dB SPL thresholds. Behavioural changes in response to sound exposures below 120dB SPL are unlikely to be distinguishable from the normal range of biological behaviours as demonstrated by numerous scientific studies:
  - In an early field study, Malme et al. (1984) exposed gray whales to industrial sounds during migration and feeding. Migrating gray whales avoided a single airgun in their path starting around 164 dB re 1 µPa (rms), with about half deflecting course by ~170 db. In feeding areas, playbacks of continuous drillship noise suggested a much lower disturbance threshold. Whales showed no clear avoidance below ~110 dB and only began to possibly move away as levels approached ~119 dB. Malme et al. recommended 120 dB re 1 µPa as the received level at which there is a 50% probability of feeding gray whales interrupting feeding and leaving the area. This study, albeit with limited sample size, became a key benchmark for regulation, implying that sound below ~120 dB is unlikely to cause noticeable disturbance in baleen whales. For Southern Right Whales, which are also large mysticetes, these findings support the idea that maintaining received levels under 120 dB would avoid significant behavioural disruption (though the 120 dB criterion is recognized as a precaution based on sparse data). It must also be pointed out that the 120 dB level only applied to continuous noise with the same 50% probability estimate for seismic noise set at 170dB, some 50dB or 41% louder.
  - A series of studies in the 1980s and 1990s observed bowhead whale reactions to airgun noise in the Alaskan Beaufort Sea. In controlled exposure trials with a single airgun, migrating bowheads began orienting away from the approaching source at distances ~7–8 km (received levels roughly in the 120+ dB range) and all whales showed clear avoidance by 2 km, where received levels were at least 134 dB re 1 µPa. In contrast, no overt responses were detected when whales were exposed to distant seismic operations (received levels 107–158 dB) that were not directly in their path. During playbacks of airgun sounds, normal behaviour was observed at 3–5 km from the source (118–133 dB) until some whales finally moved away at ~124–134 dB (at closer ranges ~0.2–4 km). These studies show that bowheads can tolerate moderate noise if not directly confronted, but individuals will actively avoid an oncoming source once levels exceed roughly 120–130 dB. These studies concluded that contextual factors (whether the whale is feeding or migrating, and the nature of the approach) mediate the response threshold. In effect, 120 dB re 1 µPa was a conservative lower bound for disturbance. Most bowheads were unperturbed below this level, though a few sensitive individuals might react slightly above it. Applied to Southern Right Whales, this suggests sound under ~120 dB is unlikely to cause disturbance, especially if the noise source is not closing distance (which it is not), supporting the use of 120 dB as a precautionary criterion (Richardson 1985, 1986, 1999). It must also be pointed out that Richardson et al 1986 concluded the following: On 21 occasions in the summers of 1980–84, general activities of bowheads exposed to pulses of underwater noise (107–158 dB re: 1 μ Pa) from seismic vessels 6–99 km away were observed. Activities were indistinguishable from those without seismic noise; there was no detectable avoidance. In general, bowheads exhibit avoidance reactions when they receive seismic pulses stronger than about 160 dB re: 1 μ Pa. Evidence of reactions to lower received levels remains inconclusive.
  - Nowacek et al (2004) conducted playback experiments on North Atlantic right whales (*Eubalaena glacialis*) and revealed that the nature of the sound can be as important as its level. Tagged right whales were exposed to three stimuli – an approaching ship noise, a conspecific social call, and an artificial “alert” signal – all at similar received levels (~130–140 dB range). Strikingly, the whales did not show any significant avoidance or interruption of normal diving when they heard the actual ship noise (or the social sounds). In contrast, 5 out of 6 whales exposed to the alert signal (a complex tone designed to get their attention) dramatically changed behaviour: they prematurely aborted their foraging dives, rapidly ascended at shallow angles with increased fluke

strokes, and then stayed near the surface abnormally long. This response, which represents a disturbance (cessation of feeding and atypical surfacing), occurred at received levels around 133 dB re 1 µPa, statistically indistinguishable from the ship noise levels that produced no reaction. The authors concluded that right whales tend to ignore continuous low-frequency noise from vessels even when they can hear it, yet a novel or alarming sound can trigger an immediate disturbance response at similar or even lower levels. A limitation is the small sample size and the fact that the "alert" sound was not a typical environmental noise. Nonetheless, the study highlights that received level alone (e.g. 120 vs 130 dB) is not the sole predictor of behavioural disturbance and sound characteristics matter. In terms of management, the science supports the position that most low-level anthropogenic noises (<120 dB) are unlikely to disturb Southern Right Whales. The lack of response to ship noise around 130 dB supports the notion that sub-120 dB noise would rarely cause disturbance in right whales.

- Controlled exposure work on migrating humpback whales exposed to airguns has reported startle or brief orienting responses at received levels around 110–120 dB SPL, with more consistent avoidance or changes in movement patterns becoming evident at ≥130 dB SPL when animals were within a few kilometres of the source. These studies also reported no "abnormal" behaviours such as abandoning migration or sustained high-speed flight, highlighting that responses were modest adjustments within the normal behavioural repertoire (McCauley et al., 2000, Dunlop et al., 2018).
- Bowhead and grey whale studies further illustrate this pattern and the importance of context. Migrating bowheads have shown avoidance and course deflection at approximately 120–130 dB SPL, whereas feeding bowheads tolerated substantially higher levels (~158–170 dB SPL) before showing comparable displacement, indicating that the same species can respond quite differently depending on behavioural state (Weilgart 2013). Similarly, migrating grey whales altered course in response to airgun exposures around 110–130 dB SPL but continued their migration and did not abandon the area altogether (Gomez et al., 2016). Western gray whale studies off Sakhalin also detected changes in movement and respiration associated with higher received levels, while emphasising that detecting population-level effects requires very large sample sizes and that many responses remain within natural variability (Gailey et al 2016).
- McCauley et al., (2000) conducted a controlled study in Western Australia that tracked migrating humpback whales during exposure to a single airgun. Avoidance behaviour (deflection of course and/or increased speed) was observed once whales experienced about 140 dB re 1 µPa (rms) – for example, at 1.3 km from the source (received ~143 dB) whales consistently veered away. Notably, when the airgun was first fired, some humpbacks showed a startle or sudden dive response at relatively low levels (~112 dB), but they did not flee at that level. Mother–calf pairs resting near the surface were more sensitive. They avoided the source at greater distances (up to 7–12 km away, corresponding to received levels still on the order of 140 dB). A key limitation is that the vessel could not approach closer than 1.2 km for ethical reasons, so true threshold distances were estimated by extrapolation. McCauley et al. (2000) concluded sustained avoidance in humpbacks begins around 140 dB, with lower-level reactions limited to brief startle responses. This finding indicates that humpbacks (and by analogy, right whales) are unlikely to be disturbed by received levels below ~120 dB; indeed, the whales in this study showed no lasting displacement at such low exposures. In the Regia MSS context, McCauley's results reinforce that a 120 dB cutoff is very conservative – well below the ~140 dB level where humpbacks altered course. It must also be pointed out that the methodology of McCauley et al (2000) did not use soft-start procedures for the seismic tests. It is unlikely that an initial startle response would have been observed under a soft-start procedure, which is now an entrenched part of seismic survey methodology.
- Gailey et al (2016) found a gray whale changed its behaviour from feeding/travelling in a northeast direction to travelling in a northwest direction and increased its swim speed at received sound levels ranging from 127 to 139dB SEL. The authors noted the response was observed in conjunction with other factors such as direction of the sound source relative to the whale's position combined with increasing sound exposure levels. This

study was part of a seismic survey in Russia which implemented an extensive monitoring program to examine the effects of a 4D seismic survey on an endangered gray whale population. The authors theorised the lack of evidence that the whales responded to seismic survey sound and vessel traffic by changing either their movement or respiration patterns could indicate that the mitigation strategy was effective. This study used linear modelling to try and quantify the contribution of seismic amongst other variables to behavioural patterns in grey whales. After considering natural variation, none of the response variables were significantly associated with seismic survey or vessel sounds. A whale's distance from shore and its orientation relative to the closest vessel were found to be significantly influenced by vessel proximity, which suggested some non-sound related disturbance.

- Wood et al. (2012) provided an expert review and updated recommendations on noise impact criteria, building on studies like Malme (1980s) and Southall et al. (2007). For behavioural disturbance, they advocated a dual-threshold approach that many regulators (e.g., NOAA) had adopted: for impulsive noise (such as seismic airguns), use ~160 dB re 1 µPa (rms) as the threshold for potential disturbance in baleen whales, whereas for continuous or non-impulsive noise, use ~120 dB re 1 µPa. These values were not derived from new field experiments but rather from the consensus of earlier data – notably the 120 dB level traces back to Malme et al.'s findings for gray whales response to continuous noise only, and 160 dB to observations that pulses above that tend to provoke avoidance in various species. Wood et al. noted that the 120 dB criterion had become a de facto standard despite the "paucity of our knowledge" about its precision. They treated it as a conservative, broadly protective threshold to trigger mitigation, given the uncertainties. The authors' conclusion was essentially to retain these precautionary thresholds for management until better species-specific data are available. Legally and scientifically, this positions <120 dB exposures as unlikely to cause more than minor or transient behavioural changes in low-frequency cetaceans. In the context of the Regia MSS and Southern Right Whales, the Wood et al. (2012) guidance supports the assertion that keeping noise below 120 dB will avoid disturbances. It is in line with international best practice and provides a defensible, although ultra-conservative rule for protecting whale behaviour in the absence of more refined data.
- Blackwell et al. (2013) monitored calling behaviour of bowhead whales during seismic surveys in the Arctic, providing insight into gradual behavioural responses over a range of sound levels. They discovered two behavioural response thresholds in calling rates. At lower noise exposures, bowheads increased their call output – reaching a plateau of elevated calling when 10-minute cumulative sound exposure level (CSEL) was around 94 dB re 1 $\mu Pa^2 \cdot s$ (a likely reaction to mild noise by calling more). However, once noise exposure exceeded an upper threshold (approximately 127 dB re 1 $\mu Pa^2 \cdot s$ CSEL, over 10 minutes), the whales' calling rates began to drop significantly. At the highest exposure levels (CSEL >160 dB), bowheads almost fell silent, indicating a strong avoidance or cessation of normal communication. This study, based on extensive acoustic monitoring, links biologically significant behaviour (calling associated with migration and socialising) to received levels. A key point is that the initial adverse effect – reduced calling – corresponded to moderate received levels (the 127 dB SEL threshold likely equating to SPL on the order of 115–125 dB for the intermittent airgun pulses). The authors suggest that the drop in calling reflects disturbance (whales either left the area, stayed silent, or both), which could impact breeding or migration if prolonged. One limitation is that calling rate changes are an indirect measure of disturbance, but in bowheads vocal silence is strongly associated with area abandonment. Blackwell et al. (2013) conclusions support the idea that responses can initiate at low exposure levels, in this case, well below traditional 160 dB criteria for impulses. For Southern Right Whales, which are also vocal baleen whales, this implies that subtle behavioural changes (like altered calling or listening behaviours) could begin at or below 120 dB in some cases. However, the more overt disturbance (ceasing calls and presumed avoidance) occurred at higher levels (on the order of >120 dB). In practice, this study underscores using caution: while prolonged sound below 120 dB is unlikely to drive whales away, even mild noise can have small effects. It overall does not contradict the 120 dB threshold adopted for the Regia survey

for avoiding clear disturbance and indeed supports using it as a conservative threshold to protect normal communication in right whales.

- Pirotta et al. (2022) provide one of the most sophisticated mechanistic models to date linking individual behavioural responses in marine mammals to population-level consequences. Using blue whales exposed to sonar in the eastern North Pacific as a case study, the authors integrated multi-year biologging data, prey density, controlled exposure experiments, and simulations of disturbance scenarios. They demonstrated that while behavioural responses such as feeding interruptions were frequently observed during exposure to mid-frequency sonar, these did not translate into measurable reductions in survival or reproductive success under the current sonar regime. Their findings reinforce that observable behavioural change is not inherently indicative of biological significance, and that the spatial-temporal overlap between sound exposure and biologically sensitive activity is a more critical driver of population-level effect than received level alone. Importantly, Pirotta et al. (2022) emphasise the need to quantify cumulative energy loss, recovery capacity, and prey availability to assess fitness impacts, rather than if any behavioural response constitutes disturbance. In the context of the Regia MSS, where exposures within SRW BIAs remain below the 120 dB SPL behavioural threshold and spatial-temporal overlap is limited, these findings support the conclusion that any behavioural responses, if they occur, are unlikely to have population-level consequences or meet the definitions of impact or disturbance under the National Recovery Plan.
- Southall et al. (2023) provide the most comprehensive synthesis to date of behavioural response studies in marine mammals exposed to anthropogenic sound, including seismic airguns. Their review confirms that behavioural responses are highly variable and context-dependent, influenced by factors such as behavioural state, prior exposure history, group composition, environmental setting, and proximity to important habitat. Crucially, they highlight that while received sound level is one of many contributing factors, it is not a reliable predictor of behavioural outcome on its own. The authors caution against over-reliance on single-value thresholds, such as the frequently cited 120, 140, or 160 dB re 1 µPa SPL values, which they note have often been "erroneously applied as step-change indicators of biological effect." Instead, Southall et al. (2023) advocate for probabilistic, dose–response approaches that acknowledge uncertainty, individual variability, and the importance of response severity and duration when assessing ecological significance. With respect to low-frequency cetaceans, they summarise evidence that the probability of any behavioural response begins to increase above ~120 dB re 1 µPa SPL, with stronger or more sustained reactions becoming more likely above 140 dB. Responses at or above 160 dB are more consistently observed but remain variable in type and consequence. Most importantly, Southall et al. (2023) distinguish between observable responses (e.g. slight changes in orientation, surfacing intervals, or dive behaviour) and biologically significant disturbance stating clearly that not all responses constitute disturbance, and that significance must be evaluated in terms of whether the response disrupts biologically important behaviours such as calving, resting, or migration.

  In the context of the Regia MSS, the findings of Southall et al. support the use of 120 dB SPL as an ultra-conservative, precautionary threshold for managing the risk of behavioural disturbance to Southern Right Whales. When considering the small temporal overlap, the modelled sound levels within the reproduction BIA, the shutdown rules, and spatial exclusions, Southall et al. (2023) conclusions reinforce the assessment that any potential behavioural response would be minor, reversible, and highly unlikely to meet the National Recovery Plan's definition of disturbance.
- Darias-O'Hara et al. (2025) derived a median behavioural threshold of 139 dB for low-frequency cetaceans using expert elicitation informed primarily by humpback whale data and adjusted for other species. Although this study did not include calf-cow pairs, the authors suggested mother-calf pairs more likely to elicit more adverse, and quicker responses to sound sources than their conspecifics. As the Regia MSS has adopted a precautionary 140 dB threshold for October and an ultra-precautionary threshold of 120

dB for September, extended shut down measures, and excluding 75% of the calving season, CGG is confident a behavioural response (if any) experienced by a SRW would not result in *disturbance* or *impact* as per the National Recovery Plan.

While numerous behavioural response studies have been conducted on mysticetes exposed to seismic and other underwater sound sources, none demonstrate a direct causal relationship between received noise levels and biologically significant disturbance. These studies rely on inference rather than proof, using observed patterns of movement, dive behaviour, or vocalisation as proxies for disruption. However, whale behaviour is naturally variable, driven by a complex mix of environmental, social, and physiological factors that make attribution to a single source of noise inherently complex (Southall et al., 2007, Nowacek et al., 2007, Ellison et al., 2012, National Academies of Sciences 2017, Southall et al., 2023, Darias-O'Hara et al., 2025). As a result, the evidence base depends on constructs such as probability curves, threshold estimates, and expert elicitation. These are tools which help identify patterns but also increase epistemic uncertainty. This makes it difficult to determine the biological relevance of observed responses with confidence. The work of Pirotta et al (2022) comes closest to addressing the biological relevance of disturbance to whales. By utilising multiple sources of data on environmental parameters, food source dynamics and military sonar they were able to model the predicted effects on female blue whale vital rates and whether this translated into effects on the fitness of individuals and populations. They found environmental changes (~disturbances) were able to severely affect long term health while sonar activities did not. This type of study provides a more insightful analysis of what constitutes a disturbance that translates into an impact. Clearly there can be multiple disturbance scenarios around sound that do not translate to changes in fitness.

Despite this, at the precautionary exposure levels adopted for the Regia MSS, there is evidence of a decreased probability of behavioural changes equating to a disturbance noting that such responses are context-dependent, typically short-lived and reversible, and unlikely to constitute biologically significant disturbance as defined by the National Recovery Plan. Given the extensive control measures and temporal exclusions implemented by CGG, any behavioural change from a SRW can confidently be said to be unlikely to constitute a disturbance as defined by the National Recovery Plan.

In short, the Regia MSS EP has demonstrated that any behavioural changes observed during the Regia MSS will fall within the normal behavioural repertoire of the species such that the Regia MSS:

- is not an impact as defined by the National Recovery Plan.
- is not disturbance as defined by the National Recovery Plan.

This is further evidence that the environmental impacts of the Regia MSS will be of an acceptable level.

Table F4-4 below describes how acceptable levels for impacts to SRWs is being met regarding the Regia MSS.

Table F4-4 - Demonstration that behavioural impacts to SRW from underwater sound are consistent with the SRW National Recovery Plan.

Action (Acceptable Levels)	Environmental Context	Activity Context	Supporting Facts and Evidence	Residual Uncertainty	Management of Uncertainty	Conclusion/Claim
Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment (Commonwealth of Australia 2024).	SRW migrate from Antarctica to Southern Australia, starting in May. SRW migrate from Southern Australia to Antarctica ending in October. Between May and October, SRW utilise the reproduction BIA/HCTS for courting, breeding, birthing, and rearing. Data shown in Figure F3-1 confirms that sightings are significantly lower in October, and zero in the last 6 years. Ambient sound levels are variable between 90 dB and 158 dB, with a 110 dB mean.	The Regia MSS will not occur in May, June, July, August or the first 2 weeks of September. This leaves the last 2 weeks of September and October as the only months of potential overlap. The survey overlaps with <1% of the migration BIA with overlap expected on SRW departure from the reproduction BIA, likely in September/October. The survey does not overlap with the reproduction BIA and is never closer than 41 km in September of October.	75% of the temporal overlap with the known presence of SRW in the BIA/HTCS has been avoided. The survey is never closer than 23 km from the reproduction BIA. The survey will acquire lines 30-67 in September and October, resulting in a minimum 41 km separation from the reproduction BIA. Modelling results predict SRW behavioural effects at 13 km (140 dB).	No activity proposed from April to August, therefore no uncertainty during this period. Remaining uncertainty about SRW presence in September and October. Sound modelling is a predictive process which, may have errors. Effects that prevent utilisation behaviours may occur below 140 dB (see Appendix F3 for details).	Received sound level monitoring acquired in near real-time through SSV buoys, and if statistically significant increase from stated threshold is exceeded, then implementation of shut down procedures or relocation of survey in September and October. Monitoring of the SRW reproduction BIA/HCTS from May to end-August to estimate total numbers, estimate calf/cow pairs, track patterns of movements of SRW, monitor residency to inform/confirm departure from reproduction BIA.	There is no uncertainty about being able to meet the acceptable level in the months of April, May, June, July, August or the first half of September. In later September, the Regia MSS will not prevent any SRW from utilising the migration or reproduction BIAs and that behavioural response is not attributable to the survey. It has been demonstrated that the Regia MSS will not have impacts of an unacceptable level to SRW.

Action (Acceptable Levels)	Environmental Context	Activity Context	Supporting Facts and Evidence	Residual Uncertainty	Management of Uncertainty	Conclusion/Claim
Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it minimises behaviour disturbance.	SRW migrate to Southern Australia starting in May. Common reproductive behaviours in the absence of impulsive sound are known and documented in Southall 2023 (though they are not tied to received level thresholds). SRW residency/ high site fidelity, is a common assumption in the literature. NMFS 2024 recommends activities use a 160 dB SPL as the starting point for management.	The Regia MSS may result in elevated sound levels in the SRW migration BIA and HCTS for the southern migration only. The Regia MSS may result in elevated sound levels in the SRW reproduction BIA and HCTS between Cape Otway and Cape Bridgewater, which is <2% overlap with the reproduction BIA.	Peak sound levels above 120 dB may be exceeded within the reproduction BIA between Cape Otway and Cape Bridgewater. Peak sound levels above 140 dB may be exceeded within the reproduction BIA between Logans Beach and Portland Port. Peak sound levels above 160 dB are not predicted to reach the reproduction BIA. Preliminary results from monitoring in 2025 have returned 1 resident cow/calf pair at Logans Beach with 8 days of detections for the season to date. (Detections between July 16 to Aug 7).	Behavioural responses can occur below the recommended NMFS threshold of 160 dB SPL. There is no consensus on a relationship between any threshold of impulsive sound and a nominated behavioural response. Therefore, any sound above ambient levels may cause a behavioural disturbance. SRW presence in the reproduction BIA at commonly observed sites is insufficient to monitor behavioural disturbance. Observed behaviours in ambient noise settings are difficult to distinguish from disturbed behaviours. Therefore, an in-situ behavioural monitoring program with appropriate shut down procedures cannot be feasible implemented.	In-field sound source verification through the SSV buoys to confirm predicted attenuation. Position of SSV buoys near entry to BIA to monitor received sound levels and implement shutdown/relocation procedures if exceedance triggers are met within September and October. As a result, sound levels within the reproduction BIA are not predicted to exceed baseline levels	As the monitoring focus is now using pre-determined and ultra-conservative threshold levels for ambient sound levels, sound exposures within the reproduction BIA will not exceed statistically significant levels, and if exceedance did occur, the source of sound will be eliminated, thus ensuring no behavioural response attributable to the Regia MSS. This meets the requirement to ensure behavioural disturbance is minimised.

5.10 Search for Unacceptable Environmental Impacts

Whilst all the impacts arising from the Regia MSS have been evaluated looking at the cause-effect pathways to environmental components, it is also important to evaluate impacts from the survey more holistically to understand if there are unacceptable impacts. This search looked for unacceptable impacts by considering whether the Regia MSS maintains biological diversity and ecosystem integrity.

5.10.1 Maintenance of Biological Diversity

Biological diversity underpins resilient and durable ecosystems. High biodiversity is closely linked to ecosystem functions and services, with more diverse systems being seen as more resilient to change (Oliver et al 2015 and references therein). A primary mechanism allowing species to endure and thrive in complex environments is heterogeneity. This occurs in a multi-dimensional framework as reflected in the spatial and temporal differences that exist in all aspects of a species' environment (Wu & Loucks 1995).

Preferred habitat is usually never uniformly available and will be shared and competed for by other species and individuals. For invertebrates and fish with a planktonic larval stage, recruitment back to a location is highly variable in space and time with usually weak stock-recruitment relationships (e.g. Cury et al 2014). Strength of recruitment pulses are often correlated with better-than-usual environmental conditions during their larval phase resulting in more food and greater survival. These conditions are themselves highly variable in space and time. For marine mammals that aggregate to feed on concentrations of krill, these food sources are equally variable in space and time with strong intra and inter year variations in the upwelling systems that drive the production of krill.

The environmental assessments considered all key organisms likely to interact within the Operational Area and Survey Acquisition Area and have indicated that these areas are not primary habitat within the ecosystem. There is no evidence to support the Survey Acquisition Area as either a major source-or-sink for species inhabiting the greater area. This heterogeneity is key to population stability with minimal reliance on the Survey Acquisition Area as a key provider to the greater population of species in the region.

Direct disturbance to those species that are site attached within the Active Source Area is the most likely manifestation of impact from use of seismic. However, there has been no experimental evidence of mortality to fishes and invertebrates from this type of activity. Seismic surveys have been conducted across the greater region for many years however existing long-term datasets on key species within the area have not been able to identify impacts that can be unequivocally linked to seismic activity. While some individuals may suffer permanent injury as discovered in experimental work, these effects will be highly variable in space and time due to changes in habitat across areas and the continual movement of the seismic array. The size of impacts will be negligible at a population level and will be virtually impossible to quantify once natural variations and other anthropogenic effects, primarily from fishing, are accounted for.

5.10.2 Maintenance of Ecosystem Integrity

Maintenance of biological diversity leads naturally to an expectation that ecological integrity will be maintained. At its most fundamental, ecological integrity means the ability of all species within an ecosystem to survive and reproduce such that the overall health of their ecosystem is maintained. Population structures should persist, supported by processes such as connectivity and dispersal that are key to sustaining systems. Associated habitat must also remain capable of supporting critical population levels.

By looking for ecosystem vulnerabilities and comparing these to impacts from the Regia MSS it may be possible to identify unacceptable impacts. Table F4-5 identifies the potential ecosystem vulnerabilities were considered in the context of the Regia MSS.

Our assessments have identified that no measurable changes to ecological integrity or population structures are likely because of the Regia MSS. Any potential changes to standing stock will not be measurable relative to the scale of changes that are manifest through fishing, or relative to the degree

of uncertainty that already exists around quantifying abundance and health of large highly mobile marine animals. The one-off, "spatially constrained", and highly mobile nature of the survey will not by-definition cause population level impacts. The highly connected nature of stocks along the south coast ensures a regular supply of new recruits will be available to settle into habitat that has been surveyed by sonar arrays. Stocks are historically limited by recruitment levels rather than habitat shortages. Seismic surveys will not damage habitat given there is no interaction with the seabed proposed by this activity.

Table F4-5 - Potential ecosystem weaknesses and unacceptable impacts.

Potential Ecosystem Vulnerabilities	Description of potential unacceptable impacts
Low Biodiversity	Ecosystems with few species lack ecological redundancy, meaning there are fewer species that can perform similar roles. This makes the ecosystem more susceptible to disturbances because the loss of any single species can have disproportionate effects on the ecosystem's overall functionality.
Simplified Food Webs	Simple food webs have fewer connections among species, which means energy and nutrients have fewer paths to flow through the ecosystem. This simplicity can lead to instability if a link in the chain is disrupted, as there are fewer alternative pathways to compensate for the loss.
Non-native or Invasive Species	The introduction of species from other ecosystems can create weaknesses by disrupting established relationships among native species. Invasive species often have no natural predators in the new ecosystem, allowing them to outcompete and displace native species, which can lead to reduced diversity and altered ecosystem functions.
Degraded or Fragmented Habitats	Damage to or division of habitats can isolate species populations, limit resource availability, and disrupt the interactions necessary for ecosystem processes. This can weaken the ecosystem's ability to support species diversity and maintain ecological functions.
Overexploited Resources	Overexploitation occurs when the rate of resource use exceeds the ecosystem's capacity to regenerate. This can lead to a decline in species, as well as a decrease in the ecosystem's ability to provide goods and services, such as food and clean water.
Climate Change Vulnerabilities	Ecosystems that are particularly sensitive to temperature changes, sea-level rise, or alterations in weather patterns may struggle to adapt to the rapid pace of climate change. This can lead to shifts in species distributions, loss of habitat, and increased susceptibility to diseases.
Limited Genetic Diversity within Species	When species have limited genetic variability, they may not have the necessary traits to adapt to changing environmental conditions or to resist diseases and parasites, making the species and the ecosystem more vulnerable.
Lack of Keystone Species	Keystone species have a disproportionate influence on their ecosystem. Their removal can lead to significant changes in ecosystem structure and function, which may not be easily reversible and could lead to ecosystem collapse.
Over-dependence on Keystone Species	Heavy reliance on a single keystone species makes the ecosystem vulnerable to any changes that affect that species. If the keystone species declines or goes extinct, there may not be another species that can fill its role, leading to ecosystem degradation.
Insufficient Regenerative Capacity	If an ecosystem cannot recover from disturbances such as natural disasters or human activities, it can become stuck in a degraded state (often known as a phase-shift), losing its ability to support a diverse community of organisms and provide ecological services.
Overfishing and Unsustainable Fishing Practices	Overfishing reduces populations of key species to below sustainable levels, disrupting the balance of the marine food web. Practices like bottom trawling can also cause irreversible damage to marine habitats, further weakening the ecosystem.
Narrow Timing of Important Life-Cycle Events	Species that rely on specific environmental cues for timing critical life-cycle events, such as breeding or migration, can be thrown off by changes in climate or habitat conditions. This can lead to mismatches in timing that disrupt reproduction and survival rates.
Areas of Concentrated Abundance	Regions with high densities of organisms are critical for the ecosystem but can become points of vulnerability if conditions supporting these concentrations change or if these areas are disproportionately affected by human activities.

Potential Ecosystem Vulnerabilities	Description of potential unacceptable impacts
Narrow Distribution or Ranges	Species with limited geographical distribution are at a higher risk of extinction due to habitat loss or environmental changes that directly affect their small living area.
Sensitive Life-Cycle Stages of Species	Certain life-cycle stages may be more vulnerable to environmental stresses and impacts on these stages can affect the survival and recruitment of individuals into the population, thereby affecting the overall health of the ecosystem.

5.11 Consistency with the Principles of ESD

ESD is a foundational concept in environmental decision-making and management, with its principles deeply rooted in international agreements and enshrined in Australian legislation. The core tenet of ESD is to ensure that the needs of the present generation are met without compromising the ability of future generations to meet their own needs. Several key principles guide the application of ESD:

1. **Precautionary Principle:** In cases where there are threats of serious or irreversible environmental damage, a lack of full scientific certainty should not delay measures to prevent environmental degradation. This principle acknowledges the inherent limitations of scientific knowledge and encourages a proactive approach to environmental protection.
2. **Inter-generational Equity:** ESD mandates that the current generation acts as stewards of the environment, maintaining or enhancing its health, diversity, and productivity for the benefit of future generations. It underscores the moral obligation to preserve the planet's natural wealth for those to come.
3. **Conservation of Biological Diversity and Ecological Integrity:** Biodiversity, including ecosystem, species, and genetic diversity, forms the foundation of social and economic systems. The conservation of biological diversity and ecological integrity should be fundamental considerations in all environmental planning and decision-making processes.
4. **Valuation, Pricing, and Incentives:** Environmental factors should be included in the valuation of assets and services. The "polluter pays" principle holds that those responsible for pollution should bear the costs of containment, avoidance, or abatement. Pricing should reflect the full life cycle of costs, including natural resource use and waste disposal. Moreover, environmental goals should be pursued through cost-effective incentive structures and market mechanisms.
5. **Integration of Considerations:** ESD emphasizes the effective integration of social, economic, environmental, and equitable considerations in decision-making processes. It recognizes that decisions must balance both short-term and long-term perspectives.

These principles are integral to Australia's environmental legislation, including the federal Environment Protection and Biodiversity Conservation Act 1999 (**EPBC Act**). They guide the evaluation of projects, ensuring that they align with the principles of ESD, protect biodiversity, and promote sustainable development. Consistent adherence to these principles is essential for responsible and sustainable environmental management in Australia. There follows and assessment of each principle of ESD having regard to the Regia MSS and the preparation process of the EP.

5.11.1 Precautionary Principle

The precautionary principle is an approach in environmental management that suggests taking proactive action to prevent harm to the environment when there is scientific uncertainty about potential negative impacts. It is often invoked as a guiding principle in decision-making processes for various activities that have the potential to affect the environment adversely. However, the application of this principle is not always straightforward or appropriate, particularly when considering the impacts of a single activity within a larger environmental context.

Consider, for instance, the case of a minor activity whose potential impact on marine biodiversity is not fully understood. The principle might dictate that in the absence of clear evidence of

harmlessness, action should be taken to prevent the activity or mitigate its potential impacts. However, when the levels of natural variation in the marine environment are demonstrably high - such as variations in salinity, temperature, and currents that can have significant effects on marine life - the effects of a single, limited-duration activity may be demonstrably low, even when the uncertainties are factored in.

In such scenarios, the baseline environmental variability can often dwarf the impact of a single activity. For example, the migration patterns and breeding cycles of marine life may be subject to greater influence from natural seasonal changes than from the noise generated by a seismic survey. The introduction of noise into the marine environment from a survey may be a minor addition to the existing soundscape, which includes not only anthropogenic sources like shipping traffic but also natural sources like storms or the vocalizations of marine animals.

It is crucial to clarify that the precautionary principle does not equate to preparing for the worst-case scenario. The precautionary principle advocates for measures that are proportional to potential harm and the level of scientific uncertainty, not necessarily the most extreme outcomes. It is based on examination of the full corpus of relevant literature and aligning with the scientific consensus whilst acknowledging the extremes (or the range) of scientific outcomes.

Conceiving of the worst-case scenario involves planning or making decisions based on the most severe possible outcome in each situation, often regardless of the probability of such an outcome occurring. This method is typically used in contexts where the cost of failure is exceedingly high, such as in emergency preparedness or nuclear safety, and may lead to measures that go beyond what the precautionary principle would dictate.

There are clear examples of this in the context of the Regia MSS. There has been much conjecture about which effect threshold distance to use as the basis for the impact assessment for underwater sound effects to plankton. Relevant persons have advocated for application of McCauley et al (2017) which would have seen adoption of a 1.2 km effect distance when most other scientific papers have a reduced distance, in some cases down to meters from the sound source. Applying the precautionary principle does not mean one should take a scientific outlier and manage to that outcome. Rather, having considered the range of outcomes across the body of relevant research, application of a consensus or modal outcome is the appropriate and proportionate position to take.

Similarly, for protection of Southern Right Whales, one could take a view that behavioural disturbances to low frequency cetaceans have been observed at levels below the adopted behavioural effect threshold of 160 dB re 1 μPa^2 SPL (i.e. HESS 1999 and McCauley 2003). However, doing so in isolation would ignore Southall et al (2007) findings that behavioural response from sound exposure below 160 dB re 1 μPa^2 SPL “would almost certainly not constitute biologically significant disturbance.” This matter is discussed in detail in other parts of the Regia MSS EP and serves in this instance to show that the starting point of any impact assessment is to select and justify the use of appropriate (i.e. consensus or modal) scientific outcomes as the starting point for later considering whether a threat may result in serious or irreversible harm.

In this context, it is essential to consider the proportionality aspect of the precautionary principle. The principle should not be applied in isolation but rather in consideration of the relative scale of impact. If the contribution of an activity to the overall environmental impact or risk is minimal and the natural resilience and variability of the ecosystem are high, the application of the precautionary principle may not be warranted. This is particularly relevant when there is an absence of significant threat or when the threat is negligible compared to the baseline environmental variability.

The principle is most relevant when there is a possibility of serious or irreversible damage, and the activity in question contributes significantly to that impact level. When the activity's impact is minimal and the environmental system exhibits high levels of inherent variability, applying the precautionary principle without the context of the significance of the harm would be disproportionate and could potentially divert resources from addressing more significant environmental threats.

Thus, the application of the precautionary principle should be calibrated to the scale and significance of potential impacts in relation to the broader environmental context. This ensures that environmental management remains focused on significant threats and does not become an

impediment to activities with lower order impacts, especially when these activities are conducted responsibly.

The Regia MSS EP preparation process is consistent with the Precautionary Principle because:

1. The EP preparation process recognised the presence of environmental impacts and risks associated with the activity, particularly in terms of underwater sound impacts, atmospheric emissions, and accidental fuel releases. It acknowledged that these impacts and risks, if unmitigated, could lead to serious or irreversible environmental harm.
2. In response to the identified impacts and risks, the process took proactive measures to minimise and mitigate potential harm. It did not rely solely on full scientific certainty before acting but instead acted in anticipation of possible adverse effects.
3. The EP preparation process resulted in the implementation of robust monitoring and evaluation strategies (Appendix B3). It recognised that ongoing assessment and monitoring were essential to detect any unforeseen impacts or changes in environmental conditions promptly.
4. Acknowledging the uncertainty surrounding certain impacts and risks, the process kept flexibility in its mitigation strategies. It is shown through evolution of the activity design and through the consultation process that CGG was prepared to adapt and adjust its survey objectives and proposed mitigation measures based on emerging information and changing circumstances.
5. The process implemented a range of safeguards and best practices to ensure that environmental impacts and risks, particularly underwater sound emissions, were kept within acceptable levels of impact and risk. It recognised that taking precautionary steps was appropriate in preventing potential harm to marine ecosystems and species.
6. The EP preparation process engaged with scientific experts and researchers to assess environmental impacts and risks. It sought advice from specialists who could provide insights into the best available science and mitigation technologies related to the project's environmental aspects (Appendices B4, B5, B6, B7, B8, and F5).
7. To uphold the Precautionary Principle, the process kept transparency in its decision-making and reporting. It ensured that relevant persons, regulatory authorities, and the public were informed about the identified impacts and risks, the measures taken, and any updates regarding the project's environmental impact.
8. In line with the Precautionary Principle, the EP preparation process prioritised the prevention of irreversible harm to the marine environment. It recognised that some environmental damage, once done, might be impossible to reverse or remedy, and therefore acted prudently to avoid such scenarios.

In summary, the Regia MSS EP preparation process aligned with the Precautionary Principle by acknowledging the presence of environmental impacts and risks associated with the proposed activity. CGG has proactively taken steps to prevent harm, monitor environmental conditions, and remaining flexible in its approach. It prioritized the protection of the marine environment whilst meeting enough of the original geophysical objectives to ensure a viable project. CGG has acted to appropriately to avoid serious or irreversible environmental damage, even in the face of scientific uncertainty.

5.11.2 Intergenerational Equity Principle

The Regia MSS EP preparation process adhered to the Inter-generational Equity Principle through the key actions and considerations described below:

1. The process acknowledged that the marine environment, including its ecological and biological diversity, is a shared resource. It recognised the responsibility to manage and conserve these resources for the benefit of both present and future generations (Appendix B1).

2. During its decision-making and planning, a long-term perspective was adopted, ensuring that actions taken today would not compromise the ability of future generations to enjoy the same environmental benefits. It considered the consequences of activities on a multi-generational timescale (Appendix B1).
3. To protect the health, diversity, and productivity of the marine environment, the process implemented a range of safeguards and mitigation measures (Appendix G1). These measures were designed to minimise negative impacts of the Regia MSS on the environment, ensuring that it will remain intact and functional for future generations.
4. The EP preparation process engaged with scientific experts and conducted comprehensive assessments to understand associated environmental impacts (Appendices B4, and E1 to E9) and environmental risks (Appendices B4, and D1 to D4). The EP provided robust scientific evidence, essential for informed decision-making to safeguard the environment for generations to come.
5. Consistent with inter-generational equity, the process prioritised identifying and preventing irreversible environmental damage. CGG understood that once certain ecological harm occurred, it might be impossible to rectify or restore, disproportionately affecting future generations. Consequently, there is no irreversible environmental damage predicted from the Regia MSS.
6. The process actively consulted with indigenous communities, other marine users, policy and regulatory authorities, and the public, regarding environmental values and sensitivities and protection measures. CGG put no restrictions on who could self-identify as a relevant person recognising that the voices and perspectives of current and future generations needed to be heard and considered in shaping the EP.
7. The process kept transparency in its actions, decisions, and reporting, demonstrating accountability to current and future generations. The EP documents CGG's commitment to preserving environmental values and ensuring that actions taken today will benefit those who come after.
8. Recognising that unforeseen circumstances and new information might emerge over time, the process incorporates a mean of adapting to changing circumstances in its environmental management system (Appendix B3). This approach allows for the ongoing adjustment of strategies and actions to align with the evolving understanding of environmental impacts.
9. The process implemented mitigation strategies to minimise the environmental footprint of the Regia MSS. It actively sought ways to reduce ecological harm, particularly in sensitive areas and habitats, with a view to preserving these areas for the enjoyment of future generations.
10. Impacts to marine plants, animals and other cultural features associated with culturally important non-tangible values might impact the intergenerational transmission of knowledge of Sea Country, including connection to Country and songlines when individuals can no longer witness or interact with the cultural features tied to Country. Therefore, managing tangible cultural features required mitigation to protect species at a population level, including songline related migratory routes. Physical features comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. This was achieved through identification and assessment of values and adoption of the Sea Country Protection Plan to allow ongoing consideration of cultural values.

In conclusion, the Regia MSS EP preparation process prioritised responsible management and ecological conservation, demonstrating commitment to the Inter-generational Equity Principle by safeguarding the marine environment, actively engaging with the community, and ensuring that actions taken today promote the well-being and environmental quality of future generations.

5.11.3 Conservation of Biological Diversity and Ecological Integrity Principle

Ecological integrity refers to the ability of an ecosystem to maintain its structure, functions, and processes, including its biodiversity, dynamics, and resilience. It is important in environmental assessments because it is crucial to understand how proposed activities might affect the natural balance and health of ecosystems. The Regia MSS EP preparation process consistently upheld the Conservation of Biological Diversity and Ecological Integrity Principle through various actions and considerations as described below:

1. Throughout the EP preparation process, there was a clear commitment to preserving the biodiversity of the marine environment. This included changing the economically preferred timing of the activity to move to a time of the year when biodiversity will be lower (Appendices A2 and G1). The process recognised the intrinsic value of diverse ecosystems and species, understanding that they contribute to ecological integrity and overall environmental health.
2. Detailed ecological assessments and studies were conducted to evaluate the impacts of the activity on marine biodiversity. These assessments aimed to identify sensitive habitats, critical species, and potential threats to ecological integrity (Appendices D1 – D4 and E1 – E9).
3. The process incorporated protection measures to safeguard key biological diversity and maintain ecological integrity. These measures included activity limitations (Appendix A2) and control measures (Appendix G1) designed to minimize any disturbances to marine habitats, breeding grounds, and migratory routes of sensitive species. Further commitments have been made to the protection of cultural heritage and other key receptors.
4. Areas of high ecological significance, including critical habitats and migration corridors, were identified and marked for additional attention. The process recognized the importance of these areas in maintaining ecological integrity and prioritised their protection. Further scientifically justified impact management zones were adopted because of consultation and to eliminate scientific uncertainty.
5. To mitigate potential harm to biodiversity, the process implemented a range of mitigation measures (Appendices A2 and G1). These measures aimed to reduce the footprint of the seismic survey in sensitive zones, minimise disruption to marine life, and prevent significant adverse effects on species and ecosystems.
6. The process engaged with experts in marine biology, ecology, and conservation to inform decision-making. This collaboration ensured that the EP's provisions were aligned with the best available scientific knowledge regarding biodiversity and ecological integrity.
7. The process sought to avoid activities that could harm biological diversity and ecological integrity wherever possible. This included planning the survey timing, sail lines and other operations to avoid critical areas and sensitive habitats.
8. Acknowledging the dynamic nature of ecosystems, the process incorporated an adaptive management approach to both the management of the activity holistically and to key receptors. This approach will allow for real-time adjustments during the survey to respond to unexpected ecological conditions and ensure minimal disruption to biodiversity.
9. Comprehensive monitoring and reporting systems have been put in place to assess the survey's impact on biological diversity and ecological integrity. This data-driven approach will track changes, identify potential issues, and support the implementation of corrective actions as needed.
10. The process engaged with relevant authorities and environmental agencies to align its efforts with broader conservation goals and regulations aimed at preserving biodiversity and ecological integrity.

In conclusion, the Regia MSS EP preparation process demonstrated a strong commitment to the Conservation of Biological Diversity and Ecological Integrity Principle. It proactively addressed potential impacts on marine biodiversity, incorporated protective measures, and relied on scientific expertise to ensure that the seismic survey is conducted with minimal harm to ecosystems, species, and overall ecological health.

5.11.4 Valuation, Pricing, and Incentives Principle

The Valuation, Pricing, and Incentives Principle has reduced relevance within the context of the Regia MSS EP preparation process. However, it is important to emphasise that the process remains consistent with this principle, albeit to a lesser degree because of the nature of the activity. Several factors contribute to this alignment:

- The primary goal of the Regia MSS project is to identify gas reserves beneath the seabed. While the immediate emphasis is on scientific exploration rather than commercial exploitation, the project's success in locating potential gas reserves is inherently linked to the future valuation and pricing of these resources. Thus, the EP preparation process indirectly contributes to the long-term considerations associated with this principle.
- The Regia MSS project acknowledges the importance of inter-generational equity, recognising that present actions must consider the well-being of future generations. By responsibly exploring and identifying potential gas reserves, the EP preparation process ensures that future generations can make informed decisions regarding the utilisation of these resources. This aligns with the principle's objective of protecting natural and human capital for the benefit of future generations.
- The project's commitment to ecological sustainability and environmental protection indirectly addresses the Valuation, Pricing, and Incentives Principle. By safeguarding the marine environment and adhering to precautionary measures, the EP preparation process contributes to maintaining the natural capital that underpins any future valuation or pricing of ecosystem services.
- In cases where the Regia MSS project may unavoidably interfere with commercial fishing activities, it incorporates a compensation protocol. This protocol ensures that any potential financial impacts on fishing communities are addressed through calculated and negotiated agreements. While not directly related to traditional pricing mechanisms, it reflects a commitment to fair compensation and social considerations.

In summary, while the Valuation, Pricing, and Incentives Principle may hold reduced relevance in the specific context of the Regia MSS EP preparation process, the approach taken is consistent with the principle to the extent possible. The focus on responsible exploration, inter-generational equity, environmental stewardship, and fair compensation aligns with the broader goals of ensuring that ecological and social values are adequately considered, even though immediate valuation and pricing mechanisms are not central to the project's current phase.

5.11.5 Integration Principle

The Regia MSS EP preparation process demonstrates consistency with the Integration Principle of ESD as described below:

1. The Regia MSS EP preparation process included a thorough impact assessment considering economic, environmental, and social impacts. It identified and assessed potential positive and negative consequences of the seismic survey on these dimensions, ensuring that decision-makers had a comprehensive understanding of the project's implications.
2. The EP preparation process actively engaged with relevant persons, including indigenous communities, environmental organizations, and local communities. It sought their input and considered diverse perspectives, ensuring that relevant persons were given the opportunity to have their say in the decision-making process, and their concerns were considered.
3. In cases where uncertainties or risks were identified regarding potential environmental harm, the Regia MSS EP preparation process adopted a precautionary approach. It took proactive measures to prevent harm, even in the absence of full scientific certainty, aligning with the precautionary principle.
4. The process assessed how the seismic survey impacted future generations. It ensured that the decisions made did not compromise the ability of future generations to meet their needs and enjoy a healthy marine environment.

5. The EP preparation process integrated the conservation of biological diversity and ecological integrity into decision-making. It involved detailed environmental assessments and implemented measures to protect biodiversity within the operational area.
6. Environmental and social factors were incorporated into economic analyses. The process considered the costs and benefits of the seismic survey, considering its impact on the environment and society, thus fulfilling economic integration (Appendix F2).
7. The EP preparation process maintained clear documentation of the decision-making process. It transparently outlined how economic, environmental, social, and equitable considerations were integrated into the planning and execution of the Regia MSS, ensuring transparency and accountability. This was primarily achieved by using the Environmental Assessment Method (Appendix B9) and the Decision-Making Criteria (Appendix B1).
8. Mechanisms for ongoing review and monitoring of the seismic survey decisions were established in the Implementation Strategy (Appendix B3). This ensures the project will continue to align with ESD principles, with adjustments made as new information becomes available or circumstances change.
9. The process provided transparent and comprehensive reporting on how economic, environmental, social, and equitable considerations were integrated into the decision-making process. This information was shared with relevant persons through the Regia MSS website to uphold transparency and foster trust.

By addressing these aspects, the Regia MSS EP preparation process has demonstrated its commitment to and consistency with the Integration Principle of ESD. This approach ensured that the seismic survey will be conducted in a manner that balances economic, environmental, and social factors, ultimately contributing to ecologically sustainable development.

6 Conclusion

In conclusion, the assessment of the Regia MSS EP preparation process against the principles of ESD demonstrates a strong commitment to responsible and sustainable offshore petroleum activities in Australian waters. The adherence to ESD principles, as enshrined in the Regulations, underscores the importance of integrating economic, social, and environmental considerations into the decision-making processes surrounding petroleum operations.

Throughout this assessment, it becomes evident that the Regia MSS EP preparation process aligns with these principles. From the precautionary approach to intergenerational equity and the conservation of biological diversity, the EP process consistently reflects a commitment to safeguarding the marine environment, reducing environmental impacts and risks, and preserving the interests of future generations. While the valuation, pricing, and incentives principle may have reduced relevance within this context, the focus remains on ensuring that the cost of protecting natural and human capital is adequately considered.

This document has provided a comprehensive assessment of the Regia MSS EP preparation process, incorporating iterative updates based on evolving information, feedback, and regulatory requirements. Through the application of multiple assessment methods, it has been demonstrated that the activity can be undertaken in a way that manages environmental impacts and risks to an acceptable level, and ensures that the EP is robust, responsive, and fit for purpose across all stages of its implementation.

Annex 1

Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table F4-6 If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table F4-6 - Objections and Claims raised from consultation.

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4078	Concerns about seismic testing and drilling rigs impacting marine life and fishing activities.	Titleholder has undertaken a comprehensive assessment of all available scientific literature to develop an appropriate EP. All potential risks have been identified with appropriate mitigation methods applied where necessary. There are no identified levels of harm that would endanger the population stability of any taxa.	917
4254	The precautionary principal needs to apply, due to lack of evidence of damage.	A full assessment of the precautionary principle will be undertaken outside of the aspect-by-aspect approach currently taken. Noted that the preconditions for the precautionary principles are two-fold and there need to be evidence of a serious or irreversible threat to the environment which is not present once control measures have been applied to the Regia MSS. However, precaution has been routinely used in the activity design.	3415
4254	The precautionary principal needs to apply, due to lack of evidence of damage.	A full assessment of the precautionary principle will be undertaken outside of the aspect-by-aspect approach currently taken. Noted that the preconditions for the precautionary principles are two-fold and there need to be evidence of a serious or irreversible threat to the environment which is not present once control measures have been applied to the Regia MSS. However, precaution has been routinely used in the activity design.	3415
4439	Concerned about impacts to squid, octopus and scallops.	Event ID 6875 - The Regia team responded in-meeting with a discussion about the assessment work undertaken on impacts to squid, octopus and scallops.	6875
4381	Even though the months April/May/June have the least ecological impact, it does not mean the impact is acceptable.	Event ID 6882 (Doc ID 9096)- CGG has always acknowledged that this is not a 'no impact' activity, and this is not what the environmental assessment is intended to achieve. Rather ensuring impacts are of an acceptable level (meaning that overall ecosystem integrity and resilience is not irreparably damaged) while also reducing impacts to as low as reasonably practicable. Timing has been selected in an effort to avoid the time of year when the ecosystem is most active and the majority of animals are breeding, which is the summer months. It is not appropriate to cease the activity, which occurs at a minimum 20km offshore, for animals laying eggs onshore.	6412

4489	Claims that CGG cannot determine what constitutes an "acceptable" level of impact or risk to Gunditjmara cultural values in Nyamat Mirring. States the April 2025 Environment Plan contains flawed cumulative impact assessments due to this lack of consultation. GMTOAC identifies several shortcomings: CGG's interpretation of potential impacts to Gunditjmara and other First Nations cultural heritage is too narrow; CGG wrongly assumes that acceptable ecological impacts equate to acceptable cultural impacts; and CGG's cumulative impact assessment for Karntubul (Southern Right Whale), previously criticised by NOPSEMA in its February OMR, remains unchanged.	CGG rejects GMTOAC's claim that inadequate consultation prevents CGG from determining "acceptable" levels of cultural impact, asserting that it fully met its consultation obligations. CGG argues that the legal test is whether the Environment Plan demonstrates impacts and risks are reduced to ALARP and to an acceptable level. It maintains that GMTOAC's critiques conflate subjective opinion with the regulatory standard under Regulation 34 and emphasises that the law does not grant stakeholders a veto over design decisions. In response to the assertion that its interpretation of cultural heritage is too narrow, CGG maintains that GMTOAC has already articulated its cultural values clearly and extensively through published materials and received during consultation. These values, encompassing ceremony, obligations, kinship systems, spiritual relationships, and ecological connections are thoroughly integrated across the EP. The EP references the Nyamat Mirring Plan 2023–2033, incorporates cultural values and sensitivities into Appendix F3, and identifies culturally significant species and places as sensitive receptors with tailored management measures, for example, timing restrictions to avoid birthing seasons. CGG states that it has incorporated analysis of cumulative effects on Sea Country, including those arising from the survey in combination with other activities. It confirms that Karntubul is included in cumulative risk assessments with corresponding mitigation commitments.	EVT352

Desktop Study: An Assessment of Available Whale Detection Technologies as Additional Management Procedures for the Regia 3D Marine Seismic Survey

The author gratefully acknowledges the assistance of each of the equipment vendors that provided detailed information relating to their individual equipment offerings. This report has been compiled directly from many web-based sources, including government, research organisations, private enterprise, equipment manufacturers and vendors plus AI-based search research results. The views and opinions expressed in this document, based on the research conducted, are those of the author and do not necessarily reflect the views of the Regia 3D MSS survey proponents or its sponsors.

A list of most (but not all) of the sources of data used can be found in the References section at the end of this document.

Introduction

Klarite Pty Ltd (Klarite), on behalf of CGG Australia (CGG), has commissioned Millodon Consulting (Millodon) to conduct a desktop study on the available technologies, both current and in development stages, of systems designed to detect and alert the presence of marine mammals to aid in mitigation measures during seismic surveys.

CGG is planning a 3-Dimensional Marine Seismic Survey (3D MSS) offshore Victoria, to be conducted sometime during 2024. As part of the environmental management planning for the survey CGG is seeking to identify, procure and eventually deploy, suitable systems to mitigate interactions with Species of National Environmental Significance (SNES), with a particular focus on the Blue and Southern Right Whales, known to frequent the survey operational area at certain times of the year, or potentially even all year round.

The systems included within this study are being reviewed for suitability and practicality for consideration as Additional Management Procedures, in addition to those already defined and mandated in the Environment Protection and Biodiversity Conservation (EPBC) Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales. Additional Management Procedures are required in Australian waters where there is a moderate to high likelihood of encountering whales.

This study is not intended to be a full and thorough description of each system's operational or technical intricacies. Where available, URL links will be included to manufacturer's own web-based literature to better cover those subjects. The study is designed to help inform CGG on the most practical system, or combination of systems, to best reduce the risk of marine mammal interactions to as low as reasonably practicable (ALARP), based on information available in the public domain.

Assessment Summary

Millodon Consulting reviewed a range of different technologies for marine mammal detection that are either currently available or in advanced stages of development. Where there are multiple vendors for similar technologies each vendor's equipment was assessed independently.

Detection Technologies Considered

The range of technologies considered for review consisted of the following: -

1. Passive Acoustic Monitoring (PAM)
    a. Towed streamer PAM
    b. Supplementary vessel towed PAM
    c. Fixed/tethered PAM buoys
    d. Unmanned/Uncrewed Surface Vessels (USV)
    e. Unmanned/Autonomous Underwater Vessels (UUV/AUV)
    f. Distributed Acoustic Sensors (fibre optic)
2. Satellite imagery
3. Aerial surveys
    a. Manned Aircraft
    b. Drones
4. Camera-based monitoring systems

Assessment Criteria

Assessment of each system was based on five simple criteria: -

- Availability
- Prior deployment histories and reported effectiveness.
- Practicality of implementation
- Safety & environmental concerns
- Cost versus benefit

Assessment Results

The following list includes assessment summaries of each detection technology or methodology, as reviewed by the author. Systems have been either deemed worthy of implementation or further investigation/consideration, or rejected based on safety and environmental concerns or failing the cost versus benefit criteria.

1. Towed streamer PAM using Sercel's QuietSea in-streamer PAM hydrophones and QuietSea monitoring and automatic detection software is a proven and tested solution that will already be installed and operational on the survey vessel prior to mobilisation. It is recommended the QuietSea system be fully deployed and operational throughout the survey activity. Dedicated PAM Operator personnel, either CGG or contracted, would be considered necessary, with a minimum requirement for full-time PAM monitoring during the hours of darkness.

2. If using supplementary PAM vessel(s) the use of the Seiche towed PAM hydrophone arrays and onboard recording/analysis equipment is considered both practical and cost effective. However, the cost and associated risks of additional vessels and crew need to be considered against the potential benefits gained.

3. Tethered buoy PAM to provide real-time remote monitoring using data telemetry to an onshore or offshore monitoring hub is considered a feasible option. It would appear that the bandwidth requirements for real-time audio frequency spectral signal data via satellite is prohibitive for onshore monitoring at any significant distance offshore, but the use of VHF radio, 2.4GHz Wifi or GSM cellular phone are common options for local telemetry back to a monitoring vessel.

   All buoy-based PAM systems reviewed have the ability to operate autonomously, with real, or near real-time monitoring possible remotely from the buoy. The Sercel manufacture PAM buoy is, at time of writing, still in its late development stage but could be deployed pre-survey for sea trials and performance testing.

   Seiche Ltd has a long history of PAM equipment development and their Modular Buoy Detection System has proven offshore performance for whale detections, though their effective use during seismic surveys has yet to be confirmed by Seiche. The Jasco Ocean Observer Buoy, like the Seiche offering, is a smaller, more light weight option (45Kg) than the large and relatively heavy (220Kg) Sercel Buoys, so would be more easily deployed and recovered. The Jasco Ocean Observer Buoy is also the only unit reviewed that can perform onboard, in-situ processing of detections, with the spectrograms converted to frequency contours for transmission via satellite to the survey vessel or to a shore-based monitoring station for confirmation of detections and relaying of detection information to the survey vessel.

   If a tethered buoy PAM system is to be considered as an option for the Regia 3D survey further investigation into the telemetry ranges involved and the number of buoys needed to provide a ringfence around the active survey area to detect whales entering. The Jasco Ocean Observer Buoy would appear to have the best options available for either onshore or offshore monitoring of detections.

   It is important to note that whilst the majority of the Regia 3D active survey area, as currently mapped, is in water depths of less than 200 metres, the south western survey margin does extend beyond the continental shelf and into water depths exceeding 1300 metres, including the West Tasmania Canyons Key Ecological Feature. Whilst not impossible, the use of tethered buoys in such depths does create additional logistics problems for deployment and recovery. It may, therefore, be worthwhile considering the use of a hybrid PAM array using a combination of tethered buoys in the shallower waters and unmanned surface vessels or underwater gliders in the deeper waters, in order to provide adequate detection coverage from all directions of approach.

4. If considering a hybrid deployed remote PAM array, in order to maintain consistency in monitoring and detection software and associated systems, it would be logical to look at unmanned vessels provided by the same manufacturer/vendor as the selected tethered PAM equipment. Seiche's Autonaut USV can carry the same PAM and telemetry payload as its Modular Buoy Detection System, whilst JASCO's use of the Slocum Autonomous Underwater Glider, integrated with the OceanObserver intelligent acoustic monitoring system is another viable option.

Both vessels can maintain station, within a given radius, by circling (or traversing straight line routes) around a target location. The Autonaut, being a surface vessel, can continually transmit its current location and accept new instructions via an Iridium satellite link. Real-time detection data can be transmitted continually through RF or Wifi link, with a resultant limitation in reception range from the survey vessel monitoring equipment based on the PAM system radio transmitter's effective range.

The Slocum Glider, being an underwater vessel, can only transmit positioning and detection data during preset surfacing periods. However, the Jasco OceanObserver system installed on the glider can, in contrast to the Seiche system, transmit in-situ processed detections to any location via Iridium satellite. However, there would be a variable delay between the vocalisation detection, processing and transmission of detection data to the monitoring station, either onshore or offshore. This may affect the usefulness of any detection if the transmission delay proved to be longer than the transit time of a whale into the active survey area. In any case, the use of a hybrid remote PAM platform array can be considered a feasible option for consideration during the Regia 3D MSS.

5. For manned aerial whale detection survey flights there are several air charter services located in Warrnambool, the closest commercial airport to the Regia 3D MSS survey area. Aircraft available include small, single engine propellor planes, like the Piper Cherokee 150, turboprops like the Pilatus PC-12, up to small private jets. There are currently no designated landing points for helicopters, although the Helicopter Emergency Medical Service (HEMS 4) is based at the airport. Although manned flights for whale detections have been assessed as an option for the Regia 3D MSS, it is felt that the operational limitations, such as bad weather groundings, added safety risks and significant costs of regular sighting flights during survey operations, does not warrant further consideration.

6. Aerial surveying for visual detection of whales using suitably equipped drones is considered a more practical, safe, and cost-effective method than manned aircraft visual detection. A suitably qualified drone pilot may need to be engaged for this option, or additional pre-survey training provided to MMO personnel for the chosen drone equipment. The use of a thermal image capable drones could also provide the option for low-visibility/night flights for visual detection.

   One drone reviewed for this study, the DJI Matrice 30T, is considered a very viable option due to its advanced features, including thermal imaging, extreme optical zoom capacities (200x), laser ranging, dual control capable, weather resistance and more. With the addition of the "DJI Dock" system the drone can operate semi-autonomously, returning to the weatherproof dock to recharge batteries. The author feels this drone warrants further investigation by the Regia survey proponents as an additional whale mitigation management procedure.

7. Survey vessel mounted dual camera-based systems are also considered a viable option to be used to supplement MMO visual detections, especially during poor/night visibility periods. Again, additional MMO personnel may be required for this option to be implemented.

   Of the two systems reviewed, the Seiche Smart Visual Detection System is the more commercially developed system than Thaum's WhalePOD, but both are similar in function and features. The WhalePOD system is an Australian designed and developed unit that, at time of writing, was in the initial stages of its commercialisation phase. Initial field-testing results were positive and industry interest was reported as being high. If the WhalePOD system is a

commercially available system in time for deployment on the Regia 3D MSS it would be a valuable platform for early adoption and feasibility testing for use during marine seismic surveys. Based on initial contact with Thaum's WhalePOD team, early adoption could also result in more beneficial commercial terms, making the cost versus benefit assessment a simple task.

8. The use of DAS fibre optic detection systems as a mitigation tool has been investigated and is considered impractical for use during the Regia 3D MSS. Limitations include the need to connect to existing telecommunications infrastructure, or to deploy dedicated cables on the seafloor and physically interface them to the monitoring equipment. Interfacing to existing commercial fibre optic cables is only feasible when the cable is located within proximity to the survey area and has an uninterrupted light path (no electronic repeater nodes) between the DAS control/record unit and the distributed acoustic sensors setup along the cable's length.

Background

Australian Regulatory Framework for Marine Seismic Surveys

Marine seismic surveys involve the use of sound waves to gather information about the seafloor and subsurface geology. These surveys are often conducted in offshore areas for various purposes, including oil and gas exploration, scientific research, and environmental studies. Given the potential environmental impacts of such activities, regulatory frameworks are in place to ensure that they are conducted responsibly and in compliance with relevant laws.

National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA)

In Australia, the regulation of marine seismic surveys falls primarily under the regime of the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA). NOPSEMA is Australia's independent expert regulator for health and safety, structural (well) integrity and environmental management for all offshore energy operations and greenhouse gas storage activities in Commonwealth waters, and in coastal waters where regulatory powers and functions have been conferred. NOPSEMA operates and regulates under the Australian Governments legislation and regulations.

a. **List of legislation**
   i. Public Governance, Performance and Accountability Act 2013
   ii. Offshore Petroleum and Greenhouse Gas Storage Act 2006
   iii. Offshore Petroleum and Greenhouse Gas Storage (Regulatory Levies) Act 2003
   iv. Environment Protection and Biodiversity Conservation Act 1999
b. **List of regulations**
   i. Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011
   ii. Offshore Petroleum and Greenhouse Gas (Safety) Regulations 2009
   iii. Offshore Petroleum and Greenhouse Gas (Environment) Regulations 2023
   iv. Offshore Petroleum and Greenhouse Gas (Regulatory Levies) Regulations 2022

As with any other human activity, marine seismic surveys have the potential for some level of impact on the environment. The type and degree of environmental impact from a seismic survey is influenced by:

- the nature of the biological, social, economic, and cultural features of the marine environment where the survey is proposed to take place,
- the level of spatial and temporal overlap with environmentally sensitive areas and times and
- the individual survey design (e.g. the nature of the sound source and acquisition line spacing).

The Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (OPGGS Environment Regulations) require companies who wish to conduct a marine seismic survey to address these factors through an environmental impact assessment (EIA) for their specific proposed activity circumstances.

The key requirements that apply in Australia are:

- the Environment Protection and Biodiversity Conservation (EPBC) Act Policy Statement 2.1, which sets out procedures for managing interactions with whales
- recovery plans for listed threatened species (particularly where noise is identified as a threat), which define objectives and actions to ensure effective threat mitigation and species recovery
- Australian marine park management plans, which prescribe rules for where seismic surveys can and can't occur, as well as objectives for environmental protection.

There are also a range of international requirements that should be considered, such as:

- the Convention on the Conservation of Migratory Species (CMS) Family Guidelines on Environmental Impact Assessment for Marine Noise-generating Activities (CMS Guidelines)
- various technical guidelines on applying thresholds for the impact of received sound levels, e.g. marine mammal acoustic technical guidance
- various guidelines and codes of conduct for effectively managing environmental impacts from marine seismic surveys, e.g. IUCN guidance on effective planning of geophysical surveys.

NOPSEMA's environmental assessment processes consider all project and activity-specific environmental impacts and risks, including but not limited to those relevant to matters protected under Part 3 of the EPBC Act. Decision-making ensures that environmental impacts and risks, including to matters protected under Part 3 of the EPBC Act, will be of an acceptable level and reduced to as low as reasonably practicable (ALARP).

The object of the Environment Regulations is also to ensure that any petroleum activity or greenhouse gas storage activity is carried out in a manner consistent with the principles of ecologically sustainable development as set out in section 3A of the EPBC Act.

Of direct relevance to the subject of this report is NOPSEMA's. role as compliance regulator of the EPBC Act, with particular a focus on *Policy Statement 2.1 - Interaction between offshore seismic exploration and whales*, as described in the following section.

EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales

About the policy statement

The aim of the policy is to:

1. provide practical standards to minimise the risk of acoustic injury to whales in the vicinity of seismic survey operations,
2. provide a framework that minimises the risk of biological consequences from acoustic disturbance from seismic survey sources to whales in biologically important habitat areas or during critical behaviours, and

3. provide guidance to both proponents of seismic surveys and operators conducting seismic surveys about their legal responsibilities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

Scope of the Policy Statement

Under the EPBC Act, a number of whale species are listed as threatened and/or migratory species and are, subsequently, protected under the Act as matters of national environmental significance (NES). Whale species are also part of the Commonwealth marine environment, another matter of NES.

Whales and other cetaceans also have additional protections in the *Australian Whale Sanctuary*. The EPBC Act provides for offences for certain actions that adversely affect whales in the Australian Whale Sanctuary. The Act also provides for permits to be obtained in relation to actions affecting whales in the Australian Whale Sanctuary.

Applicable Species

Not all whales hear the same acoustic frequencies. Seismic survey sound sources are generally focussed at frequencies below 200Hz. Based on the best available scientific information, it is generally understood that baleen whales and some toothed whales are likely to be sensitive to sounds in this lower frequency range.

Due to the difficulties in identifying whales to the species level, particularly at distance, appropriate management procedures (as recommended in Part A Standard Management Procedures and Part B Additional Management Procedures) should be applied whenever **whales** are, or might be, encountered. **'Whales'** includes baleen whales and larger toothed whales, such as, sperm whales, killer whales, false killer whales, pilot whales and beaked whales.

Smaller dolphins and porpoises that have peak sensitivities in the higher frequency ranges are likely to be less disturbed by these lower frequency sounds and less vulnerable to acoustic trauma. Accordingly, this Policy Statement does not apply to encounters with the smaller dolphins and porpoises.

Legislative Responsibilities

If the likelihood of encountering whales is low, the chance of a seismic survey having a significant impact on a whale species should be minimal, provided that the proponent and the operator of the seismic survey adopt the measures outlined in Part A Standard Management Procedures.

While Part A Standard Management Procedures may be sufficient in locations where the likelihood of encounters with whales is low, the proponent may need to consider additional avoidance and mitigation measures for areas and/or seasons where the likelihood of encountering whales is moderate to high. In these circumstances, the proponent should not only apply Part A Standard Management Procedures, but should also consider measures like those outlined in Part B Additional Management Procedures.

Part A Management Procedures

Part A Management Procedures are to be implemented as a minimum requirement for all marine seismic survey activities conducted in Australia where the likelihood of whale interactions is considered low. Part A Management Procedures include: -

1. **Pre-Survey Planning:** to avoid scheduling seismic surveys in areas where and when whales are likely to be breeding, calving, resting or feeding.
2. **Trained Crew:** The survey proponent should ensure that there is sufficient trained crew to fulfil the basic requirements of whale observation, distance estimation and reporting.
3. **During Surveys:** All seismic survey vessels operating in Australian waters must undertake the following basic procedures during surveys irrespective of location and time of year of survey:

    - Pre-start-up visual observation
    - Soft start
    - Start-up delay
    - Operations
    - Power- down and Stop work
4. **Compliance and Sighting Reports:** It is the responsibility of the proponent to maintain a record of procedures employed during operations. Such records should be auditable and account for aspects of the operation that relate to legislative approvals and regulations.

Detailed specifics of the requirements for Part A Standard Management Procedures, such as soft-start durations and mitigation zone distances, can be found in the policy statement document that can be found online at the DCCEEW web site.

Part B Additional Management Procedures

For seismic surveys operating in areas where the likelihood of encountering whales is **moderate to high**, the application of additional measures, to ensure that impacts and interference are avoided and/or minimised, are necessary. The following measures are recommended, however, application of all these measures may not be necessary, applicable or possible for all seismic survey operations.:-

1. **Marine Mammal Observers (MMO):** Whilst listed as an additional management procedure in the policy statement it is now considered standard practice for marine seismic surveys to employ at least one MMO during any seismic survey activity. MMOs should be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters. The MMOs should assist other observers (e.g. trained crew) and be available to provide advice, should whales be encountered.
2. **Night-time/Poor visibility:** For surveys in areas where whales are expected to be encountered, the proponent should include appropriate management measures to detect (or predict) whale presence and apply measures to reduce the likelihood of encounters. Depending on the situation a range of measures may be appropriate, possible measures include:

    - Limiting initiation of soft start procedures to conditions that allow visual inspection of the precaution zone;
    - Daylight spotter vessel or aircraft searches of the night-time survey area to determine if whales are present; and
    - Pre survey research (including surveys) to detect and identify likely whale concentration areas, such as: peak migration paths and times, key feeding sites (e.g. shelf breaks, sea mounts and trenches), or other aggregation areas.
3. **Spotter Vessel(s) and Aircraft:** Where the likelihood of encountering whales is high, spotter vessels/aircraft could be used to assist in detecting the presence of whales. Spotter vessels and aircraft may be usefully employed to determine the presence and likelihood of encountering whales during day and night-time operations; information that can then be used to re-design

the survey or tracks to be run to avoid whales that are in the vicinity. Spotter vessels/aircraft should maintain continuous contact with the seismic survey vessel. An MMO should be employed on board both the survey vessel and the spotter vessel/aircraft.

4. **Increased Precaution zones and Buffer zones:** In some locations and circumstances it may be advisable to apply increased distances for the instigation of power-down procedures from those outlined in Part A Standard Management Procedures.
5. **Passive Acoustic Monitoring:** Deployment of PAM with appropriate technologies and programs to detect whales in real time may provide an additional method of detecting and avoiding whales during surveys and may be particularly useful during night-time and low visibility operations.
6. **Adaptive Management:** Where a survey is proposed in an area that is spatially and temporally on the edge of areas considered to provide biologically important habitat, the proponent may consider implementing adaptive management procedures to manage the potential increased likelihood of encountering whales. Adaptive management could include implementation of daytime only operations if there are three consecutive days on which operators experience three or more whale-instigated shut down/power down situations. Adaptive management may also be used in conjunction with other measures described in Part B. For example, if aerial surveys identify whales in the region, increased buffer zones are implemented.

One of the core objectives of this report is to provide details of whale detection and mitigation systems that could be implemented as part of the Additional Management Procedures that will be implemented during the Regia 3D MSS due to the known presence of both Blue and Southern Right Whales in the vicinity of the Survey Planning Area. The most practical and effective additional management procedures/equipment will, where adopted by the survey proponents, be included as mitigation measure commitments within the Regia Seismic Survey Environment Plan.

Detection Technologies Overview

Introduction

The following section provides a broad overview of the technologies and implementation procedures that have been considered for adoption as Additional Management Procedures during the Regia 3DMSS. Advantages and disadvantages have been provided where an assessed technology is regarded as having both.

Passive Acoustic Monitoring

PAM History

Passive Acoustic Monitoring (PAM) for marine mammal detection has a history that spans several decades. The technique relies on the use of underwater microphones, known as hydrophones, to listen to and record the sounds produced by marine mammals. Here's a brief overview of the key milestones in the history of PAM:

1. **Early Observations (1950s-1960s):** The use of hydrophones to study marine life, including marine mammals, dates back to the 1950s and 1960s. Researchers began recording underwater sounds, but the technology was limited and the focus was primarily on general oceanography rather than specific marine mammal studies.
2. **Navy's Interest (1960s-1970s):** The United States Navy became interested in the use of passive acoustic techniques for detecting submarines. While conducting these naval operations, they unintentionally recorded marine mammal sounds, which led to increased awareness of their vocalisations.
3. **Whalesong Discoveries (1960s-1970s):** Researchers studying humpback whales made significant discoveries in the 1960s and 1970s. They found that humpback whales produced complex and repetitive songs, which piqued scientific interest in using passive acoustics for studying marine mammal behaviour.
4. **The Development of PAM Tools (1980s):** During the 1980s, advancements in hydrophone technology and signal processing capabilities made it easier to detect and analyse marine mammal sounds. This led to the development of dedicated PAM tools and software, making the process more efficient and accurate.
5. **International Whaling Commission's Involvement (1980s):** The International Whaling Commission (IWC) recognised the importance of passive acoustics in studying and conserving marine mammals. They initiated efforts to standardise PAM methodologies and data analysis techniques.
6. **Wide Application (1990s-2000s):** In the 1990s and 2000s, PAM gained broader recognition and became an essential tool for marine mammal researchers worldwide. It was used to study various species, including cetaceans (whales, dolphins, and porpoises) and pinnipeds (seals and sea lions), and assess their distribution, abundance, and behaviour.
7. **Integration with Autonomous Systems (2000s-2010s):** With advancements in underwater autonomous systems, such as autonomous underwater vehicles (AUVs) and gliders, PAM techniques were integrated with these platforms to expand coverage and improve data collection.

8. **Industry Applications (2010s):** PAM found applications beyond scientific research. Industries like offshore oil and gas exploration, renewable energy, and shipping began using PAM as part of their environmental monitoring efforts to reduce the impact of their activities on marine mammals.
9. **Real-time PAM (2010s-2020s):** Real-time PAM systems evolved, allowing researchers and operators to monitor marine mammal activity continuously. These systems could detect vocalisations and other sounds, provide alerts for specific species detections, and help mitigate potential risks for marine life.

Overall, passive acoustic monitoring has become an essential tool in marine mammal research and mitigation, offering a non-invasive and effective means of detecting vocalising marine mammals. Ongoing advancements in technology continue to improve the accuracy, efficiency, and scope of PAM use in a broad range of applications.

PAM During Marine Seismic Surveys

PAM is a valuable tool used during marine seismic surveys to monitor and mitigate the impact of seismic operations on marine life, especially marine mammals. Seismic surveys involve the use of airguns to generate powerful acoustic signals, which may be harmful to marine organisms if not properly managed. PAM helps in minimising the potential negative effects by providing real-time monitoring and detection of marine mammal presence within the detectable range of the acoustic energy source.

Here's how PAM is utilised during marine seismic surveys:

1. **Marine Mamal Detection:** PAM systems are installed on seismic survey or energy source vessels and/or in the vicinity of the seismic survey area to continuously monitor for the presence of marine mammals. These systems consist of hydrophones (underwater microphones) or an array of hydrophones that can detect and record the vocalisations and other acoustic signals produced by marine mammals.
2. **Real-time Monitoring:** The hydrophones are connected to onboard or shore-based monitoring stations, where specialised software analyses the recorded acoustic data in real-time. Some PAM software is capable of automatic identification of individual species of marine mammals based on their vocalisation signatures. If marine mammal sounds are detected during survey, operations can be adjusted or halted temporarily to prevent potential harm to the animals.
3. **Mitigation Measures:** PAM allows for the implementation of mitigation measures when marine mammals are detected. These measures can include shutting down the airguns or altering the survey activity to minimise potential impacts on marine life. The mitigation measures are often guided by the likely species present and environmental regulations and guidelines specific to the area of operation.
4. **Data Collection and Analysis:** The data collected through PAM systems during seismic surveys are also essential for assessing the effectiveness of mitigation measures and studying the behaviour of marine mammals in response to seismic activities. This information helps researchers and regulatory authorities make informed decisions about future seismic operations.
5. **Compliance with Regulations:** Many countries and international organisations have strict regulations and guidelines to protect marine life during seismic surveys. In some countries PAM has been mandated as a required mitigation tool during all seismic survey activities. In Australia PAM use is not yet mandated. However, it is considered best practice as an "Additional

Management Procedure" beyond the "Standard Management Procedure" requirements of the EPBC Act, Policy Statement 2.1.

It's important to note that the use of PAM is just one aspect of a comprehensive environmental monitoring and management plan that operators implement during seismic surveys. Other measures, such as visual monitoring, pre-survey assessments, and adherence to mitigation zones, also play significant roles in safeguarding marine life during seismic operations.

Regardless of the platform on which a PAM system is deployed during a seismic survey activity there is one common disadvantage, or limitation, being the ability to detect marine life acoustic signals in amongst the large impulse noise of seismic airgun arrays being discharged, as well as the engine and propellor noises generated by the survey vessel(s) themselves. During survey data acquisition a typical airgun array discharge repetition rate is between 7 to 10 seconds. This high amplitude noise is received directly by PAM hydrophones through the water column, overpowering lower amplitude sounds.

Dependent on the water depth and subsurface geology, the subsurface acoustic reflections from each seismic source impulse can still be returning to the sea surface whilst the next airgun array impulse is generated. This means that the actual "quiet" period where lower amplitude marine fauna noise source levels can be monitored, without background seismic signal data present, is either minimal or non-existent during active survey periods. Therefore, PAM systems need to be able to filter out, or differentiate between seismic energy returns. The best times for detection of marine mammal vocalisations are the short periods of lower noise levels between seismic airgun pulses and during transits between seismic survey transect lines (line changes).

Towed Streamer PAM

Towed streamer PAM has been utilised for many years and is the most common form of passive acoustic monitoring used during seismic surveys to date. This detection method involves using a dedicated array of underwater microphones, or "hydrophones", which are incorporated in a long cable or "streamer" that is towed behind a seismic survey or associated support vessel.

The hydrophones pick up sounds in the underwater environment, including the vocalisations and other noises made by marine animals, such as whales. The PAM hydrophone arrays are interfaced to bespoke electronic equipment that can filter, digitise, and condition the acoustic signals for analysis by specialist software, such as the Open Source "PamGuard" system.

More recently manufacturers of in-water seismic survey equipment, such as Sercel's "QuietSea", system has incorporated cetacean detection hydrophones within the same streamers used to receive subsurface acoustic reflection data from the seismic energy source. The PAM hydrophone data is fed back to the survey vessel independently of the seismic data and is interfaced to equipment designed to analyse received acoustic signatures and automatically detect and identify cetaceans, alerting survey operators of their presence within the vicinity so that suitable mitigation measures can be instigated.

By incorporating PAM sensors in the seismic streamers, the need for additional dedicated PAM hydrophone arrays is eliminated, removing the risk of entanglement of the PAM streamer with the seismic vessel's towed equipment. It also reduces exposure of personnel to risks associated with the deployment and recovery of third-party PAM streamers from the stern of seismic survey vessels.

The integration of PAM data within the seismic streamers also provides for far greater numbers of hydrophones listening for cetacean vocalisations over a much broader area of the ocean. Dependent on the geophysical objectives, a typical modern seismic streamer deployment configuration during a marine 3D survey is between ten and fourteen individual seismic streamers of up to ten or twelve kilometres in length, spaced between fifty and one hundred and fifty metres apart. This provides a PAM hydrophone array of up to two square kilometres or more. Such large, two-dimensional arrays provide the ability to better compute geographic locations of received vocalisations by comparing the arrival times of individual acoustic signatures across the array to determine bearing and distances to the sound source.

Supplementary Vessel Towed PAM

The use of one or more vessels, in addition to the seismic survey vessel, to deploy towed PAM systems during a seismic survey can add considerably to cetacean mitigation efforts by enabling marine mammal detections at greater distances from the seismic energy source.

Dependent on the species of concern and the regulatory requirements for mitigation buffer zone distances from the active energy source(s) it may be impossible for seismic vessel-based towed PAM to detect cetacean vocalisations out to the required mitigation zone radius. Survey vessel towed PAM receivers are positioned astern of the vessel and therefore offset from the centre of the acoustic energy source. Positioning another vessel with its own towed PAM system ahead of the survey vessel could increase the potential to detect cetaceans ahead of the survey vessel, in the direction of travel along pre-plotted seismic lines.

Advantages of one or more supplementary vessels equipped with towed PAM are:-

- Increased range for detection of cetacean vocalisations from the seismic vessel, potentially providing more advanced warning of whale presence ahead of the energy source.
- Additional platform(s) for visual detections, including using more MMOs and possibly extra automated camera-based detection systems.
- Increased distance from the energy source means a lower level of direct arrival impulse noise as the amplitude decays with distance.
- A secondary vessel can potentially offer verification of received vocalisations and may assist in determining the location of the sound source.

Some disadvantages include: -

- The need for additional people to install, deploy, recover, and operate the PAM equipment, leading to additional safety risks for personnel at sea.
- The costs of an additional vessel and its crew capable of accommodating the extra PAM/MMO personnel and being able to work alongside the survey vessel in all weather conditions is not insignificant.

Tethered Buoy PAM

A tethered buoy PAM system is a tool used in marine research and mitigation efforts to monitor and protect marine animals, particularly cetaceans like whales and dolphins.

Here's how a tethered buoy PAM system works:

1. **Buoy**: The system typically consists of a buoy that floats on the water surface. The buoy is designed to stay afloat and stable in various sea conditions.
2. **Tethered Design**: The buoy is tethered to an anchor or weight on the seafloor. The tether keeps the buoy in place, preventing it from drifting away with ocean currents.
3. **Underwater Hydrophones:** The buoy is equipped with underwater hydrophones. These hydrophones are sensitive to underwater sounds and can pick up a wide range of frequencies.
4. **Data Recorder:** The buoy is connected to a data recorder or logger, which stores the acoustic data captured by the hydrophones. Depending on the system, the data can be stored locally on the buoy or transmitted in real-time, via either radio frequency (including Wifi)or satellite-based data telemetry, to a shore-based monitoring station or onboard the seismic survey vessel.
5. **Acoustic Monitoring:** The tethered buoy PAM system operates continuously, listening for underwater sounds in the surrounding environment. It can detect various marine animal sounds, such as whale calls, dolphin clicks, and other vocalisations.
6. **Research:** Tethered buoy PAM systems are particularly useful for long-term monitoring in specific areas, such as migration routes or important feeding grounds.
7. **Non-Intrusive:** Since the PAM system does not emit any sounds, it is considered non-intrusive and does not disturb marine life during the monitoring process.

Tethered buoy PAM systems have been deployed in the field during marine seismic surveys to supplement the towed array PAM systems typically deployed from the seismic survey vessel and/or the energy source vessel. Buoys can be placed around the perimeter of the active seismic operations area in order to alert survey operations of the arrival of cetaceans within the area.

Dependent on the size of specified mitigation zones, when compared to the distances between the detected animals and the seismic energy source, actions can be taken to either heighten the level of alertness, such as increasing visual or acoustic monitoring efforts, or suspend survey operations until no further detections have been received within a pre-defined period, equivalent to the likely movement of detected whales outside the mitigation zone.

Tethered buoy PAM has the following advantages: -

- Buoys can be deployed around the perimeter of the seismic survey operations area to virtually ringfence the active source area, enabling detections of vocalising cetaceans prior to them entering the mitigation zone.
- Monitoring of real-time buoy PAM can be performed remotely at any location, either onshore or offshore, using satellite-based acoustic data telemetry. No additional personnel need to be assigned to a survey vessel, reducing risk and costs of travel as well as reducing pressure on survey vessel bunk space. Onshore monitoring provides more flexibility in shift timing and manning levels.
- Buoys can be used to compare received energy source sound levels at distances from the centres of sources with the modelled levels used to define the mitigation zones. Mitigation zone distances could be amended based on real-world sound level measurements.

Tethered buoy PAM disadvantages include: -

- Cost of buoy deployment and recovery is not insignificant.

- Corrective maintenance in the event of equipment failure is logistically difficult and costly due to the potential need for third party vessel charter to repair or replace buoys.
- Poor weather can affect buoy operational effectiveness. Buoy surface movement can affect hydrophone data quality through additional noise. Constant cloud cover can reduce solar panel effectiveness to charge system onboard batteries.
- Tethered buoys can become a navigation risk to other vessels. Buoy locations are required to be registered with government and military authorities and released in official Notices to Mariners.

Unmanned Surface Vessel PAM

USVs (Unmanned/Uncrewed Surface Vehicles) can be utilised for various purposes, including Passive Acoustic Monitoring (PAM). USVs can enhance PAM operations by serving as a platform to deploy and maintain the acoustic sensors, collect data, and transmit it to the operators or data centres. Here's how USVs can be beneficial for PAM:

1. **Autonomous operations:** USVs can be programmed to follow specific paths or patrol areas or keep station autonomously, reducing the need for constant human intervention. This autonomy enables extended monitoring periods and increased coverage of marine environments.
2. **Reduced cost and risk:** Using USVs for PAM reduces the need for manned vessels, thereby cutting down operational costs and minimizing risks to human personnel in challenging or dangerous marine conditions.
3. **Extended endurance:** Many USVs can operate for extended periods, even in remote locations, allowing for continuous monitoring of underwater sounds over long durations.
4. **Precise positioning:** USVs equipped with GPS technology can maintain accurate positions, ensuring that acoustic sensors are deployed at specific locations for precise data collection.
5. **Low acoustic interference:** USVs are generally quieter than traditional manned vessels, reducing the potential for acoustic interference with marine life and improving the quality of PAM data.
6. **Remote control and data transmission:** Operators can remotely control USVs and receive real-time data from the acoustic sensors, enabling quick analysis and decision-making.
7. **Flexibility:** USVs can be equipped with different types of sensors, allowing them to perform a variety of tasks beyond PAM, such as meteorological or oceanographic data collection.

-
-
- Configurable payloads and sensors
- Real-time data transfer via satellite telemetry.
- Potential alternatives to tethered buoys, especially in very deep water.

Some USV PAM disadvantages are: -

- Potential navigation risk to other marine users.
- Potential for entanglement of the towed hydrophone array with in-sea debris or fishing gear.
- Unmanned, so potential targets for theft or vandalism in certain deployment scenarios.

Unmanned Underwater Vessel PAM

Unmanned underwater vessels, often referred to as underwater drones or autonomous underwater vehicles (AUVs), can play a crucial role in conducting PAM efficiently. Here's how they could be used for this purpose:

1. **Data Collection:** Unmanned underwater vehicles equipped with hydrophones (underwater microphones) can collect audio data from different depths and locations in the ocean. These vehicles can travel to specific areas of interest and record underwater sounds without disturbing marine life.
2. **Extended Operation:** AUVs can operate for extended periods, covering large areas of the ocean. This allows for continuous or scheduled monitoring, which is especially useful for tracking the migration patterns and behaviours of marine species.
3. **Precise Localisation:** AUVs can be programmed to move to specific coordinates, enabling targeted acoustic data collection near underwater sources of interest, such as breeding or feeding grounds of marine animals.
4. **Real-time Data Transmission:** Some AUVs can transmit data in real-time to a monitoring station on the surface. This feature is advantageous for immediate analysis and decision-making based on the collected acoustic data.
5. **Adaptability:** AUVs can be programmed to follow predefined paths, adapt to changing environmental conditions, and navigate complex underwater terrain, ensuring optimal coverage of the monitored area.
6. **Reduced Human Interaction:** Using AUVs for PAM reduces the need for constant human presence at sea, minimizing the associated risks and costs.
7. **Integration with Other Sensors:** AUVs can carry additional sensors, such as environmental sensors or cameras, to gather more comprehensive data about the underwater environment and the marine life within it.
8. **Data Processing and Analysis:** The collected acoustic data can be processed to identify specific species based on their characteristic sounds. Machine learning algorithms can be employed to automate the analysis process and identify patterns in the recorded sounds.
9. **Reduced Environmental Impact:** Compared to traditional survey methods that involve larger vessels and potentially disruptive activities, AUVs produce minimal noise pollution and disturbance to marine life.

The advantages of autonomous underwater vessel use for PAM are similar to those of autonomous surface vessels, with the addition of the ability to submerge the hydrophone arrays to water depths where sea surface noise in greatly lessened. This provides a quieter environment for detecting distant whale vocalisations. However, this advantage comes at the cost of real-time data telemetry to the PAM monitoring station during periods of submersion, making it impractical as a mitigation option.

Fibre Optic Distributed Acoustic Sensors

Fibre optic distributed acoustic sensors (DAS) are a type of technology that utilises optical fibres to detect acoustic signals along the length of the fibre. These sensors are capable of converting the fibre optic cable into an array of virtual microphones, making them ideal for various applications in monitoring and surveillance.

Here's how fibre optic DAS generally works:

1. **Principle**: The basic principle behind fibre optic DAS is the interaction between light and sound. When an acoustic wave (sound) interacts with the fibre optic cable, it causes minute changes in the properties of the light traveling through the fibre.
2. **Optical Fibre:** The fibre optic cable used in DAS is typically a single-mode optical fibre, which allows only one mode of light to propagate along the fibre core. This is crucial for maintaining the integrity of the signal.
3. **Laser Interrogation:** A laser source is used to generate a continuous wave of light that travels through the optical fibre.
4. **Scattering:** When an acoustic wave interacts with the fibre, it causes minute changes in the refractive index of the fibre due to phenomena like Brillouin scattering or Rayleigh scattering. These changes result in the scattering of light along the fibre.
5. **Interference Measurement:** The backscattered light returns to the DAS unit, where it is analysed to detect changes in the phase and intensity of the light. By analysing these changes, the DAS system can pinpoint the location and characteristics of the acoustic disturbance.
6. **Data Processing:** The collected data from the DAS system is then processed using advanced signal processing algorithms to interpret the acoustic information accurately. This allows the system to distinguish between different types of acoustic events.

Fibre optic DAS has several advantages over traditional point sensors:

- **Continuous Monitoring:** Since the fibre optic cable acts as an array of virtual microphones, DAS provides continuous monitoring along its entire length, enabling the detection of acoustic events over long distances.
- **Sensitivity and Resolution:** DAS systems have excellent sensitivity and high spatial resolution, allowing for precise localization of acoustic events.
- **Versatility:** Fibre optic DAS can be used in various applications, such as pipeline monitoring, perimeter security, seismic monitoring, and structural health monitoring.
- **Immune to Electromagnetic Interference**: Fibre optic cables are not affected by electromagnetic interference, making DAS systems suitable for harsh environments.

Due to these advantages, fibre optic distributed acoustic sensors have gained popularity and are being employed in diverse industries for efficient and reliable acoustic monitoring applications.

An article published in Frontiers in Marine Science in July 2022 titled "Eavesdropping at the Speed of Light: Distributed Acoustic Sensing of Baleen Whales in the Arctic" *(Bouffaut et al)* detailed the successful use of a 120km long sub-sea telecommunications fibre optic cable, with sensing points every 4 metres, to identify and estimate the 3D positions of vocalising baleen whales. It also demonstrated the use of frequency modulated whale vocalisations recorded on the DAS to generate correlated subsurface seismic profiles down to a depth of around 2 seconds.

Disadvantages of DAS include:

- DAS can only operate over uninterrupted lengths of fibre optic cable. It cannot pass through repeater modules or other electronic nodes.
- Use of DAS with existing cables requires the assistance and cooperation of the telecommunications company that owns and/or operates the cables.
- DAS can only be used on dedicated fibres and therefore needs to utilise spare or unused fibres within any existing cable infrastructure.

- Deployment of dedicated DAS fibre optic cables on the seafloor may need some forms of regulatory approval prior to deployment.
- Deployed seafloor cables may be at risk of damage through external sources, such as trawling operations.
- Dedicated DAS cables needs to be physically connected to the recording equipment. In most cases this means the need to run the cable to a shore-based facility or possibly an offshore installation, such as an oil rig/platform. The logistics of this requirement are prohibitive.
- As at 2021, there is only one submarine telecommunications cable, Indigo Central, that passes through the Regia 3D survey area. This cable runs between Sydney and Perth, making the likelihood of potential utilisation due to the distances involved extremely slim.

Satellite Imagery

Satellite imagery has been utilised for various purposes, including environmental monitoring and wildlife conservation. However, using satellite imagery specifically for whale detection presents some challenges.

Whales are massive marine creatures that typically spend most of their time submerged underwater. While some whale species exhibit behaviours such as breaching (jumping out of the water) or spouting (blowing air and water from their blowholes), these activities can be relatively infrequent and challenging to capture from space.

Nevertheless, advancements in satellite technology and image processing algorithms have made it possible to detect large marine mammals, including whales, under certain circumstances. Here are some ways satellite imagery can be used for whale detection:

1. **Large Whale Detection:** Satellites equipped with very high resolution (VHR) optical sensors can detect large whales when they surface for air. These sensors can capture images of large whales like humpback whales, blue whales, and Southern Right whales when they breach or spout. While not continuous monitoring, these images can provide valuable data on whale distribution and migration patterns.
2. **Whale Migration Tracking:** Satellite-tagged whales can transmit signals when they surface, allowing researchers to track their movements and migration routes. This information can be used to understand whale behaviour and identify critical habitats.
3. **Whale Population Estimation:** Researchers can analyse satellite images to estimate whale populations in specific regions, such as areas where seismic survey activities are planned. This approach involves identifying and counting whales in the images, which can provide valuable insights into population trends and mitigation efforts.
4. **Detection of Human Activities Impacting Whales:** Satellite imagery can also be used to monitor human activities that may negatively impact whales, such as ship traffic, coastal development, and oil spills. By identifying potential threats, regulators can take appropriate measures to protect whale habitats.

However, it's important to note that satellite-based whale detection has its limitations. Cloud cover and weather conditions can obstruct the view from satellites, making consistent monitoring challenging. Moreover, smaller marine mammal species, or those that spend more time underwater, might be difficult to detect using current satellite technology.

The field of satellite imagery and marine mammal monitoring is continuously evolving, and there may be more advanced techniques and systems developed in the future. A German company, Space Whale, has developed a cetacean survey method, employing a convolutional neural network (CNN) to automate much of the VHR satellite imagery interpretation. Space Whale offers VHR satellite-based whale detection and monitoring as a service, with end users merely needing to provide corner coordinates for a rectangular area of interest, start and end dates for monitoring and the whale species of interest in order to obtain a quote for services.

At present though, real-time satellite imagery for use in whale detection as a real-time mitigation measure is not considered a practical option. It can certainly be considered as a means to establish whale population presence in a survey operational area over time in order to determine the best time to conduct a seismic survey.

Camera-Based Detection

Infrared Cameras

Infrared, or Night Vision cameras can be used for various purposes, including whale detection. Infrared cameras have been used to monitor and study marine mammal populations, including whales, in both research and mitigation efforts. Here's how infrared cameras are employed for whale detection:

1. **Thermal Imaging:** Infrared cameras are also known as thermal imaging cameras because they detect and capture infrared radiation (heat) emitted by objects, including living beings. Whales, like all warm-blooded animals, generate heat, and this thermal signature can be detected by infrared cameras even when the whales are underwater.
2. **Day and Night Vision:** Infrared cameras can operate in low-light conditions and even in complete darkness, making them valuable tools for marine research, especially in remote locations or during nighttime studies.
3. **Identification and Monitoring:** By using infrared cameras, researchers can identify and track whales without disturbing them or altering their natural behaviour. This helps in studying their movement patterns, behaviour, and population dynamics.
4. **Aerial Surveys:** Infrared cameras mounted on drones or aircraft can conduct aerial surveys of whale populations over large areas, making it easier to assess their numbers and distribution.
5. **Remote Monitoring:** Infrared cameras can be set up at specific locations, such as coastal areas or key migration routes, to continuously monitor whale activity. This allows researchers to collect data over extended periods without the need for direct human presence.
6. **Mitigation Applications:** Infrared cameras can play a role in marine mitigation efforts by providing valuable data on whale populations, migration patterns, and interactions with their environment. This information can be used to develop better mitigation strategies to protect these species.

It's important to note that while infrared cameras are a useful tool for whale detection, they are often used in conjunction with other monitoring techniques, such as acoustic monitoring (PAM) and visual observations (MMOs), for additional mitigation measures during marine seismic surveys.

Advantages of infrared cameras include: -

- Ability to identify whales in low light or dark conditions.

- Up to 360-degree, 24-hour remote scanning of the ocean around the monitoring platform out to the horizon.
- Systems are relatively inexpensive and are lightweight, easily transported, and relatively simple to install.
- Some camera systems incorporate Artificial Intelligence (AI) software to automatically identify whales through thermal imaging and blow detections.

Some disadvantages of infrared camera systems are: -

- Reduced effectiveness during periods of poor weather, including sea state and precipitation and during high sun glare situations. Fog and humidity can also adversely affect camera performance.
- If being used as an additional night time visual mitigation procedure, alongside the use of PAM detection systems, it may be necessary to engage additional MMO personnel to provide full 24 hour visual monitoring coverage onboard the survey or support vessel(s).

Dual Camera Systems

A Dual HD Image and Infrared Whale Detection Camera System is a specialised technology designed to monitor and detect the presence of whales using both high-definition visual imagery and infrared (IR) technology. This type of system is commonly used in marine research, conservation efforts, and environmental monitoring.

Here's how dual camera systems work:

1. **Dual Camera Setup:** The system consists of two types of cameras: high-definition (HD) visual cameras and infrared (IR) cameras. These cameras are typically positioned on a platform, such as a survey vessel or a fixed installation like an oil rig or platform.
2. **HD Image Cameras:** The HD cameras capture visible light imagery of the surrounding ocean. These images provide clear visual information about the appearance, behaviour, and location of whales. HD cameras are particularly useful for identifying specific species, observing behaviour patterns (breaching, swimming, etc.
3. **Distance Measurement:** Some dual camera systems can integrate automatic distance estimation analysis software, such as the Seisch Real Time Automated Distance Estimate at Sea (RADES) software.
4. **Infrared (IR) Cameras:** As detailed previously, IR cameras capture heat signatures emitted by living organisms, including whales, in the form of thermal radiation. Whales generate heat due to their metabolism, and this heat signature can be detected by IR cameras even when visibility is poor, such as in low light or adverse weather conditions. IR cameras are advantageous for night-time observations and in areas with reduced visibility.
5. **Image Processing and Analysis:** The system typically includes image processing software that can analyse the captured images and videos in real-time or post-capture. Machine learning algorithms can be employed to identify and classify whale species based on their visual features and heat signatures.
6. **Whale Detection Algorithms:** The core functionality of these systems lies in their ability to automatically detect the presence of whales within the captured images and videos. Detection algorithms are trained to recognise specific shapes, patterns, and characteristics of whales, both in visible light and in IR images. When a potential whale is detected, or an anomaly in the incoming images flagged, the system can trigger alerts for further observation or examination.

7. **Data Storage and Transmission:** The systems can store the captured images and videos for further analysis and research. Additionally, if a system is connected to a network, it can transmit real-time data to MMOs or a central database for instant analysis and response.
8. **Research and Conservation Applications**: A Dual HD Image and Infrared Whale Detection Camera System has numerous applications. It can aid in understanding whale migration patterns, assessing population sizes, monitoring the health of individual whales, and studying their behaviour. Furthermore, it can be used to support additional mitigation procedures, such as during marine seismic surveys, where they can be used as an additional source of real-time whale monitoring and detection to trigger required mitigation control measures.

This technology combines the advantages of high-definition visual imagery and infrared technology to provide a comprehensive and accurate method for monitoring and detecting whales. The advantages of a dual camera system include all of those previously listed for infrared cameras, plus the ability to better identify whale species and distances during daytime operations. The inclusion of automated distance estimation software further adds to the list of advantages.

The disadvantages of dual camera system use are also similar to those of a straight infrared camera option, being the limited effectiveness during poor sea state and weather conditions. Both systems are also limited by the location of the platform on which they are mounted, with a 360 degree uninterrupted view being almost impossible to achieve on most vessels due to the presence of the ship's mast(s) and any other upper deck superstructures, such as cranes, stacks and the like. Mast-top mounting, where the view is less obstructed, is impractical in most situations due to the height and the increased motion experienced at that height.

Aerial Surveys

Manned Aircraft

Manned aircraft aerial surveys for whale detections are a valuable method used by researchers to study and monitor whale populations in their natural habitats. These surveys involve using aircraft, such as airplanes or helicopters, equipped with specialised equipment and cameras to observe and document the presence of whales in a given area. Here's an overview of how aerial surveys for whale detections typically work:

1. **Survey Planning:** Researchers plan the aerial survey by defining the study area and identifying the target species of whales they want to observe. The study area can be a specific region, a migration route, or a known feeding or calving ground for the whales. For seismic survey planning purposes this would be the survey's Operational Area plus any prescribed mitigation zone buffers.
2. **Aircraft and Equipment:** A suitable aircraft is selected for the survey, considering factors such as range, speed, and altitude capabilities. The aircraft is often equipped with high-quality cameras and, in some cases, specialised sensors like infrared or thermal cameras that can aid in detecting whales more effectively.
3. **Flight Patterns:** Project planners determine the flight patterns based on the study objectives and the characteristics of the whales they are monitoring. The aircraft may fly along predetermined transects, circular patterns, or adaptive flight paths to cover the designated study area systematically.

4. **Detection and Documentation:** During the flight, trained observers/spotters scan the ocean surface for signs of whales, such as blows (exhalations), breaches, or fluke dives. When a whale is sighted, its location, behaviour, and species are recorded. Photographs and videos may also be taken for later analysis and identification.
5. **Data Analysis:** After the aerial survey, observers analyse the collected data to estimate whale abundance, distribution, and behaviour. They use statistical methods to extrapolate the observations to estimate the total whale population in the study area.
6. **Mitigation and Management:** The data gathered from aerial surveys help inform mitigation measures and management decisions related to whale populations. It aids in understanding population trends, identifying critical habitats, and assessing the impact of human activities on whale populations.

Advantages of Aerial Surveys:

- Aerial surveys allow spotters to cover large areas efficiently and rapidly.
- They provide a non-invasive method to study whales without disturbing their natural behaviours.
- Aerial observations can be used to complement data obtained from other survey methods, such as shipboard surveys, shore-based observations, or acoustic monitoring.
- Pre-activity aerial surveys can be used to help plan seismic survey timing to minimise exposure to periods of peak presence of whale species of concern.

Limitations of Manned Aerial Surveys:

- Weather conditions and sea state can affect survey flight operations and the ability to detect whales accurately.
- The altitude of the aircraft may limit the ability to identify smaller whale species or individuals.
- Aerial surveys can be expensive, especially if frequent or ongoing coverage is required.
- Aerial surveys are limited in duration and highly dependent on aircraft fuel endurance and distances from suitable air strips based within practical range of survey locations.

Overall, aerial surveys for whale detections can be a useful addition to marine seismic survey mitigation methods. However, the additional risks associated with personnel spending significant periods of time in low flying aircraft, plus the significant additional costs of this method, combined with the restrictions to flights in poor weather conditions, makes this option less desirable as a real-time mitigation method for a seismic survey, especially when located in areas of frequent bad weather.

Drones

Using drones for whale research and detection has become an increasingly popular and effective method in recent years. Drones offer numerous advantages for studying and monitoring whales in their natural habitats. Here are some ways in which drones are utilised for whale monitoring:

1. **Aerial Surveys:** Drones equipped with high-resolution cameras can conduct aerial surveys over large ocean areas, making it easier to spot whales and other marine mammals from above. This approach is especially valuable for species that spend a lot of time at the surface, like humpback whales and southern right whales.

2. **Behaviour Observation:** Drones allow researchers to observe the behaviour of whales without disturbing them. They can document social interactions, feeding behaviours, breaching, and other activities, providing valuable insights into the lives of these animals.
3. **Population Monitoring:** By flying over known habitats or migration routes, drones can help researchers estimate whale populations more accurately. Traditional survey methods may miss some individuals, but drones can cover larger areas and improve counting accuracy.
4. **Identification:** Drones equipped with specialised cameras, such as thermal or multispectral sensors, can aid in identifying whale species based on unique markings, colour patterns, or heat signatures.
5. **Tagging and Tracking:** Some drones are equipped with specialised dart guns or tagging devices that can safely attach tracking tags to individual whales. These tags allow researchers to monitor the movements and behaviours of specific whales over time.
6. **Acoustic Monitoring:** Drones can also carry hydrophones or other acoustic sensors to record whale vocalisations, helping scientists study their communication patterns and track their presence in areas with low visibility.
7. **Environmental Research:** Drones can be utilised to collect water samples, measure sea surface temperatures, and study other environmental factors that may influence whale behaviour and distribution.

When using drones for whale detections, it is essential to follow ethical guidelines and regulations to minimise disturbance to the animals and their environment. Observers must maintain a safe distance from the whales and ensure that the drone's presence does not cause stress or disruption to the animals. Additionally, adherence to local laws and permits related to drone operations and wildlife observation is crucial.

Advantages of drones:

- Drones are a cost effective and safe means of visual detection of whales. One or more drones can be deployed from either the survey or a support vessel at any time to scan a large area of ocean from heights capable of spotting whales at considerable distances.
- Modern consumer drones have flight times in excess 40 minutes and ranges up to 20km, with real-time, high-definition video streamed back to the drone pilot's video monitor or First Person View (FPV) goggles. Individual drones can be rotated as batteries are recharged, providing almost continual aerial monitoring, as long as flight conditions are suitable.
- Drones can be fitted with an additional infrared camera for use on low light or night detection flights. Some drones also include a laser range finder for accurate measurement of the geographic coordinates of a visual target.
- Drones can be quickly launched in response to acoustic whale detections to provide visual confirmation of presence and location of detected whales.
- Some drones can use dual controllers, with one controlling the flight while the other controls the cameras, allowing for MMOs to concentrate on species location and identification while the drone pilot focusses on the flight controls.
- Drones can be programmed to autonomously fly preset patterns around moving seismic vessels, such as circular flight paths at fixed offsets, or by using fixed routes around programmed geographic waypoints. They can also be used to scout well ahead of a seismic vessel along survey line transects, providing significant advanced notice of the presence of whales beyond the immediate mitigation zone.

- Drones can be used to electronically tag whales using drop tags to potentially add a valuable whale research data source during a seismic survey activity, in association with a third-party research organisation. This could result in improved PR for the survey operator.

Disadvantages of drones:

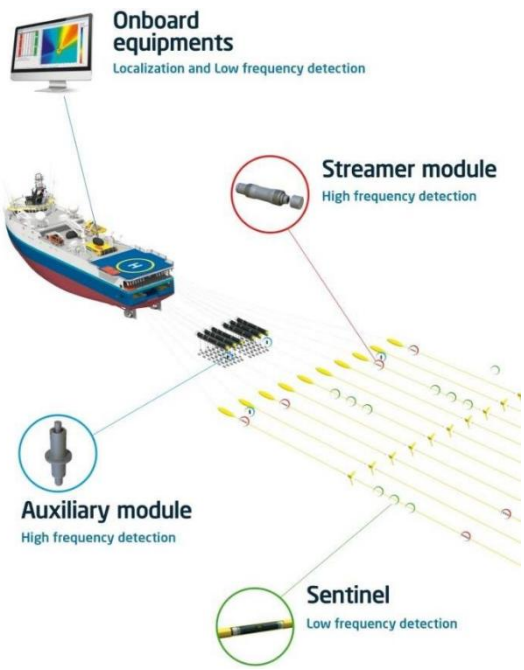
- Most drones cannot operate during periods of very poor weather, such as in strong winds or heavy rain although some high-end commercial drones, such as the DJI Matrice 30 and Autel Robotics EVO II Dual 640T Thermal drones, are weather resistant, including the controllers.
- Drones require trained pilots to get the best operational and safety performance from the aircraft. Pilots may also need to be trained as Marine Mammal Observers (MMOs) to aid in species identification and regulatory regimes. Alternately, MMOs may need to be trained as competent drone pilots.
- Drones can be subjected to attacks from bird species, causing loss of flight control and possible crash landings at sea.
- Drone flight limes are limited by battery life and regular landings are needed to replace batteries.

Vendor Equipment Reviews

Towed PAM

Sercel QuietSea

Conventional PAM (Passive Acoustic Monitoring) systems are composed of a separate PAM antenna at sea with a limited number of sensors. The Sercel system is an innovative PAM system integrated in the seismic acquisition system: for low-frequency detection, it is using up to 384 seismic hydrophones of the streamer sections and for high-frequency detection, up to 120 dedicated broadband hydrophones also integrated in the streamers (QuietSea Streamer Modules) and below impulsive source array (QuietSea Auxiliary Modules, intended to improve detection in the vicinity of the source).



This integrated system offers numerous advantages: good coverage of the exclusion zone (centered on the source) by many sensors, high precision of the marine mammal localization (by the mean of sensors positioning in real-time), reduction of the risk of accidents during deployment, easy retrieval and operation (no separate antenna at sea) and thus, significant reduction of operational downtime and possible equipment replacement costs.

Assessment Criteria	Comment
Availability	Immediate. Will be pre-installed on the survey vessel prior to mobilisation for the survey
Prior deployment histories and reported effectiveness.	Has been used worldwide since 2016 with demonstrated success.
Practicality of implementation	Easily implemented based on historical use
Safety & environmental concerns	No concerns raised
Cost versus benefit	Will be incorporated in survey activity budget. Benefits outweigh costs.

Seiche Towed PAM

The base system comprises a towed array cable, deck cable, electronic processing unit including data acquisition devices, computer and headphones. The physical spacing of hydrophones and the frequency response of the system provides optimal performance and the acoustic detection of species of interest. PAMGuard software is integrated as standard. Equipment is provided with 100% back-up.

The system can be readily configured to suit the project requirements. The array section includes either four or six hydrophones arranged in pairs of calibrated hydrophone channels with low noise preamplifiers, identical sensitivity and frequency response. An array depth sensor is integrated at the rear of the array. A 230 m heavy tow cable with a detachable 20-25 m array section may be preferred for harsh environments. A networked PAM station is available to enable the PAM system to be monitored and controlled from the most convenient location onboard.

Assessment Criteria	Comment
Availability	Systems available with advanced shipping notice ex-UK and USA
Prior deployment histories and reported effectiveness.	Many years of prior use on seismic surveys worldwide
Practicality of implementation	Practical for use on support or supplementary PAM vessels. Survey vessel will have Sercel QuietSea fitted.
Safety & environmental concerns	No significant concerns other than the need for additional in-water equipment deployment and recovery, with the potential for entanglement and personnel exposure to deck equipment.
Cost versus benefit	Cost of equipment and additional PAM operator personnel is not prohibitive

Tethered PAM

Sercel Buoy Solution

Automated & Real-time detections via QuietSea algorithms

- Connected via IRIDIUM or 4G
- Harbour porpoise detector available
- Other species under development
- Raw data available for post-processing 〉 High level integration
- Detections are visible on the seismic vessel

Specifications

- Diameter: 1200mm
- Height: 2182 mm
- Weight: 210 kg (without the anchoring)
- Navigational Aid: LED Lantern, AIS Transponder, Real Time GPS tracker
- Telemetry: AIS, Iridium, 4G and Wi-Fi as needed and relevant.

Assessment Criteria	Comment
Availability	Sercel are currently building 4 x buoys for potential deployment as a trail in the Regia 3D survey area.
Prior deployment histories and reported effectiveness.	No history of use during seismic surveys. One prototype buoy in use in the UK for Harbour Porpoise detection trials.
Practicality of implementation	Potentially expensive to ship from Europe and deploy/recover in Victorian waters due to size and weights..
Safety & environmental concerns	None
Cost versus benefit	Unknown cost element but potentially advantageous pricing due to the CGG/Sercel business association and beta test status of the units.

Seiche Modular Buoy Systems

The Modular Buoy Detection System uses Passive Acoustic Monitoring (PAM) to provide a flexible approach to monitoring vocalising marine mammals and underwater noise.

The system consists of a remote moored buoy with a multi-element detachable hydrophone array suitable for mitigation and anthropological noise capture. Signals can be captured up to a sampling rate of 500 ks/s at 16 bit depth. The system can be configured to record the data locally within the buoy or remotely at the receiving station, whichever is required.

Further options include:

- Remote on/off via Radio Frequency (RF) link (868 Mhz)
- Real-time remote monitoring of audio via RF link (2.4 Ghz)
- Truly global remote control via Iridium
- Truly global GPS via Iridium

Telemetry

The buoy has the necessary components to transmit signals received at the hydrophone (PAM data) to the survey vessel, as well as transmitting position information (from an Iridium GPS receiver on board the buoy).

- The telemetry system for the PAM data operates in the 2.4 GHz band
- The position telemetry system operates in the 1–2 GHz band
- The remote power control system operates in the 868 MHz band

Hydrophone

Due to the modularity of the array sections, Seiche can provide custom-made array sections to suit specific needs. However, we also offer an off-the-shelf option with the following specification:

- • Hydrophone element H1
- • Super Broadband 10 Hz to 200 kHz (3 dB points)

Assessment Criteria	Comment
Availability	Unknown availability. No response received from Seiche at time of writing.
Prior deployment histories and reported effectiveness.	Unknown for seismic surveys but many commercial deployments quoted.
Practicality of implementation	Use of RF audio data telemetry, rather than satellite-based, may prove problematic due to distances involved between deployed locations and survey line lengths. However, if the effective operating range is beyond the required detection range it may be possible to deploy an array of buoys to provide continuous coverage around the survey area.
Safety & environmental concerns	None
Cost versus benefit	Unknown cost but likely not prohibitive for the project.

JASCO Ocean Observer Buoy

A compact and powerful system for real-time passive acoustic monitoring (PAM), acoustic data collection, and non-acoustic measurements. Based on JASCO's OceanObserver electronics suite, it records data to removable memory with two classes of real-time telemetry options:

- Stream full bandwidth data via Wi-Fi, cellular, or VHF (short range, lifetime of days or weeks)
- Transmit processed information products via Iridium (long range, lifetime of weeks or months)

Collects data from acoustic and non-acoustic sensors and supports a variety of sensor and array options. Transmits full bandwidth data to nearby vessels or shore stations or performs in situ processing to transmit results via satellite, including marine mammal calls and clicks, pitch tracks for validation, vessel noise quantification, and ambient noise statistics. Typically fitted with up to three hydrophones, GPS, AIS, and Wi-Fi. Can be moored or free drifting.

Specifications

Mass:	45 kg , 99.3 lbs
Dimensions:	(D × H*)24 × 77 in [610 × 1956 mm]
Main platform:	JASCO Ocean Observer electronics suite
Local telemetry:	Wi-Fi, cellular, VHF
Global telemetry:	Iridium
Acoustic sensors:	Omnidirectional hydrophones
	Directional sensors
	Small linear or spatial arrays

Hydrophone suspension:	Straight cable or inverse catenary
Battery pack:	96 alkaline D-cells (internal)

Assessment Criteria	Comment
Availability	Unknown
Prior deployment histories and reported effectiveness.	Unknown
Practicality of implementation	Similar in size and functionality to the Seiche buoys, the Jasco units would be no less practical to deploy and operate. The use of satellite telemetry to transmit "in-situ processing" needs to be clarified as far as time lag between detection and receipt of notification at the monitoring station. Otherwise the use of VHF telemetry to the survey (or ancillary) vessel limits the real-time detection range to around 30km.
Safety & environmental concerns	None
Cost versus benefit	Costing has yet to be confirmed but it is unlikely to be prohibitive for the project.

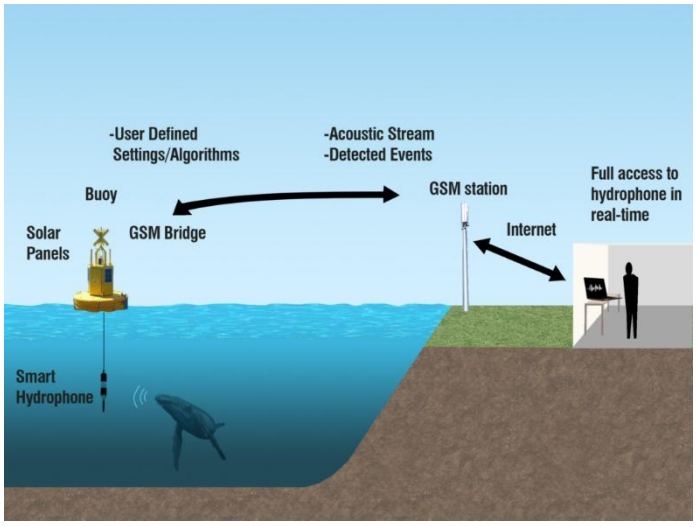
PAM Smart Buoy

A Passive Acoustic Monitoring (PAM) Buoy offers real-time acoustic monitoring with a smart hydrophone, environmental data buoy and global system for mobile (GSM) communications bridge. When deployed in the ocean, the PAM Smart Buoy captures sounds from the surrounding environment and facilitates real-time acoustic data transmission.



Ocean Sonics' icListen Kayak new architecture is compact, energy efficient and scalable. This Smart Hydrophone has a wide dynamic range for high quality data & long term stability. This all-in-one instrument processes data while streaming HD acoustic data in real time. It is configured to keep all raw data or keep only data of specific frequency set by the user.

Key Features of Ocean Sonics icListen Kayak Hydrophone

- Passive Acoustic Monitoring (PAM)

- Bandwidth 10 Hz to 200 kHz
- 24-bit Resolution
- Very High Sensitivity
- Ultra Low Noise Sensing Element
- Extra Low Power, 0.2W
- Scalable – can be used in arrays of up to 100 hydrophones

Assessment Criteria	Comment
Availability	Unknown. No response received from vendor enquiry. Vendor based in Cyprus, so potentially an issue.
Prior deployment histories and reported effectiveness.	As above, no response received.
Practicality of implementation	This system utilises GSM data telemetry, so not practical outside GSM coverage areas.
Safety & environmental concerns	None
Cost versus benefit	Unknown cost of equipment of shipping.

Unmanned Vessel PAM

Autonaut USV

The AutoNaut is an uncrewed surface vessel (USV) propelled forward by the motion of the waves. Patented Wave Foil Technology enables long-term mission duration. Powered entirely by renewable energy and with no requirement for offshore personnel the AutoNaut significantly reduces costs and safety risks at sea. Solar energy powers an extensive range of sensors and equipment for 24/7 operation.

- Uncrewed operation: no offshore personnel at risk
- Powered by renewable energy: no fuel costs, no emissions
- Mission duration of several months
- Station keeping within 25 metres
- Storm-proven robustness
- Simple deployment/recovery from vessel or slipway
- Flexible payload and sensor capacity
- Data transfer

SENSORS

Seiche analogue array

The Seiche analogue array incorporates two hydrophone sensors and a depth gauge. It is 30m in length and has been designed for minimal flow noise and simple deployment.

Seiche digital thin line array

This high-sensitivity acoustic array is fully configurable in real-time. Eight digital hydrophone sensors are incorporated within the 25metre array.

Additional sensors

Additional sensors can also be incorporated for supplementary meteorological and oceanographic data as well as visual imaging.

Assessment Criteria	Comment
Availability	Unknown
Prior deployment histories and reported effectiveness.	Unknown
Practicality of implementation	Unknown

Safety & environmental concerns	None
Cost versus benefit	Unknown

OceanObserver on the Slocum Autonomous Underwater Glider

JASCO Applied Sciences has teamed with Teledyne Webb Research to integrate JASCO's OceanObserver™ intelligent acoustic monitoring system into the Slocum underwater glider. The buoyancy driven Slocum glider gathers data as it rises and dives in the water to propel itself forward. The Ocean- Observer system onboard records the underwater sounds while running automated cetacean detectors that flag possible marine mammal calls or other events of interest. The glider surfaces at specified intervals to send the flagged events to shore, where analysts can review and confirm the detections. All data are recorded on 6 TB of removable SD memory cards for full analysis upon retrieval.

Customized Detections and Processing

JASCO's experienced bioacousticians tailor the detection algorithms to the species and call types of your choice. Concurrent detections are associated to provide con-textual information for onshore analysts. During times of high glider self noise, the processing algorithms can be disabled to minimize false alarms, reducing personnel workload and maximizing satellite bandwidth use.

Intelligent Communications

The processed events are prioritized so that important events, like detections of species at risk, are sent first, making best use of the communication window. The event information is then distributed by email. The durations of the event time windows vary, and events are aggregated as ensembles, to maximize the contextual information available to analysts.

Detailed Detection Contours

The acoustic data, and even spectrogram images, are too large to be sent by satellite. So the Observer converts the detection spectrograms into frequency contours that are small enough to be relayed via satellite. Superior to pitch tracks, the contours give a richer representation of the data for easier, more accurate species detection and identification.

Customized Onboard Processing

- Marine mammal call detectors for baleen whales, toothed whales, and pinnipeds
- Various call types, including moans, whistles, and clicks
- Seismic pulse detection and quantification
- Ambient sound level calculations

Communication

- Telemetry via Iridium (RUDICS) satellite
- Detection information distributed via email to end users

Technical Specifications

Acoustics
Sample rate: 8–512 ksps
Resolution: 24 bits
Hydrophone: Customizable options from various manufacturers.
Sensitivities and frequencies tailored to your needs.

Physical
Mass: 55–70 kg 122–155 lbs
Length: 1.5 m 59.1 in
Hull diameter: 220 mm 8.7 in
Maximum depth: 1000 m
Horizontal speed: 0.35 m/s (0.68 knots) average
Up to 0.5 m/s (1 knots) with full drive

Assessment Criteria	Comment
Availability	Slocum Gliders are in use worldwide for various applications and availability is not expected to be an issue.
Prior deployment histories and reported effectiveness.	Has been used for whale detections previously. Unknown for use during a seismic survey.
Practicality of implementation	System can be deployed from the survey or a support vessel by one or two persons.
Safety & environmental concerns	None
Cost versus benefit	Unknown cost of implementation.

Camera-Based Systems

Seiche Smart Visual Detection System (SVDS)

The SVDS camera system consists of: High-Definition Video (HDV) and Long-Wave Infrared (LWIR) & thermal imaging camera pair, with on-board processing and storage. Each unit is housed robustly for maritime use. Various configuration options are available to ensure optimal visual coverage and ranges up to 360 degrees.

The new generation camera system builds on decades of experience of visual and underwater acoustic maritime monitoring combined with technologies originally found in self-driving vehicles. The cameras are more robust, compact, and lighter, making them easier to ship, and install, thereby reducing operational costs. Boasting lower power consumption and 1000x more powerful computing than the previous generation systems, the new cameras are capable of real-time on-board automated detection. For improved data security our cameras have built-in encrypted SSD storage to allow continuous data capture even during network interruption or observer workstation down time. The improved pan and tilt system allows for user configurable automatic scanning of an area up to 360 degrees.

General

- Modular customisable configurations
- Optional mounting systems
- Portable system deployed in hard case
- Fully marinised waterproof housing IP68 (pending certification)
- Hydrophobic glass
- Operating Temperature Range: -30°C to 70°C (pending certification)
- Shock: 1,500 g @ 0.4 msec (pending certification)
- Operating Voltage 19-30 VDC / supply voltage AC 110-240V
- Power consumption: Low power mode 20W Nominal 35W, Max Peak 135W
- On board GPU image processing 32GB on system storage
- On board Dual 4TB storage, main and encryption backup
- Networked removable storage up to 100TB
- Wi-Fi & satellite connectivity available on request
- GigE connectivity

- External triggers available 3.3V, 5V, 12V, serial optional protocol upon request
- Optional Workstations
- Built in 48 Channel GPS
- IMU orientation +/- 0.1°
- 360-visual scan with PTU

Software

- Mysticetus software compatibility
- Fast logging
- Auto detection (customised training dependant)
- Radar map visualisation with built in antenna for target location
- Automatic ranging – accurate target range estimation

RGB Camera: Standard RGB camera

(Optional upgrades):

- Sensor: 1/2.3 CMOS SONY IMX392
- Resolution: 2.4MP
- Array Size: 1920x1080
- Pixel Size: 3.45µm x 3.45µm
- Dynamic Range: 48dB
- Shutter Type: Global Shutter

Thermal camera:

- Thermal sensitivity: <40mK
- Pixel Pitch: 12 µm
- Full Frame Rate: 60 Hz
- Array size: 640 x 512
- f-number: 1.0
- Continuous Electronic Zoom: 1X to 8X zoom
- Spectral Range: Long-wave Infrared; 7.5 µm – 13.5 µm
- Scene Dynamic Range: to 140 °C (high) to 500 °C (low)

Assessment Criteria	Comment
Availability	TBA

Prior deployment histories and reported effectiveness.	TBA
Practicality of implementation	The only limitation could be the ability to mount the camera in a position of unobstructed 360 degree visibility due to ship or USV masts.
Safety & environmental concerns	None
Cost versus benefit	TBA

WhalePOD

Introduction

WhalePOD is a bespoke thermal and colour camera system integrated with artificial intelligence, designed for automatic detections, ranging, and an intuitive software interface tailored for marine mammal detection and compliance reporting. What sets WhalePOD apart from other visual detection systems is our distinct camera platform design and approach. As we developed WhalePOD's camera platform to be deployed on vessels, our emphasis has been on achieving both long-range and high-speed panoramic coverage, day and night.24/7 automated detection of whale surfacing at sea.

Last month, we concluded a shore field trial of WhalePOD during the northern migration at North Stradbroke Island. The preliminary results are outstanding. To illustrate, during a night shift on 11 July, between 1 am and 4 am, I observed 40 whale surfacing events using our thermal camera, at distances ranging from 2 km to 4 km. In daylight, whale blows were visible from well over 10 km away. The system's ability to comprehensively cover an area without compromising detail was crucial in capturing these brief surfacing events. (*pers comms - Aqeel Akbar, Founder & Director, Thaum*)

Description

WhalePOD is an AI-centric product co-designed with regulators, industry, and researchers.

WhalePOD seeks to define a new gold-standard for ESG monitoring. We are aligning business outcomes with responsible stewardship and sustainability.

Feasibility Study: Awarded AUD $100k grant from NOPSEMA and AAD via BRII Priority Sectors, January 2020

ON Accelerate 7: WhalePOD completes Australia's premier deep-tech accelerator run by CSIRO, Feb-May 2023

Thaum, a startup team from the ANU Research School of Physics deep-tech incubator Momentum, is commercialising WhalePOD – a technology to enable a new age of industrialisation where environmental conservation and scientific contribution is an outcome of business, not a burden.

WhalePOD's disruptive vision capabilities help offshore industries implement harm mitigation strategies to protect marine mammals.

The core platform technology is a high-performance, panoramic, thermal and colour camera that uses artificial intelligence for 24/7, all-weather, and long-range detection of objects of interest in harsh marine environments.

Assessment Criteria	Comment
Availability	Thaum has indicated likely commercial availability in early 2024
Prior deployment histories and reported effectiveness.	Currently under testing for commercial deployment
Practicality of implementation	Unknown due to early stages of commercialisation
Safety & environmental concerns	None
Cost versus benefit	Unknown but unlikely to be cost prohibitive for the potential benefits of system deployment.

Aerial Drones

DJI Matrice 30T (thermal)

The new DJI Matrice 30 Series is DJI Enterprise's flagship drone that fits in a backpack. It integrates multiple high-performance sensors into one single camera payload, controlled with an ingenious redesigned remote control and runs on upgraded Pilot 2 software, which significantly improves the flight experience.

The M30 model offers much more power, endurance and capability for rugged professional uses, while its size makes it ideal for easy transportation and fast setup.

The DJI Matrice 30 series enterprise drone is a weather-proof, relatively portable UAV that offers a 48 MP stabilized camera with up to 200x hybrid zoom, thermal imaging camera, laser rangefinder, and a low-light optimized FPV camera. It comes with a new rugged DJI RC Plus controller. On top of that, an optional DJI Dock is able to automatically operate up to 7km away and charge the drone quickly when needed.

The M30 series comes in two versions, the M30 and the M30T. (Both versions are using a fixed payload system) The only difference is that the M30T also includes a thermal imaging camera. The use cases for this drone range from equipment inspection to seek-and-rescue types of missions.

The M30 model integrates a 48 megapixel 1/2" CMOS sensor zoom camera with 5×~16× optical and 200× digital zoom, a 12-megapixel wide-angle camera, 8k photo 4K/30 fps video resolution, and a laser rangefinder that can give the precise coordinates of objects up to 1,200 meters away.

Despite having integrated payloads, the Matrice 30 Series will continue to support PSDK integration for third-party payload development, including spotlights, loudspeakers, gas detectors, parachutes, and more.

It's clear DJI wants to revolutionize drone operations by extending flight time and use, regardless of the environment. When equipped with two TB30 intelligent batteries the new Matrice 30 Series drones offers up to 41 minutes of flight time. The self-heating feature of the TB30 batteries helps the M30 stay functional in extremely cold environments.

As part of the M30 Series kit, DJI launched the BS30 intelligent battery station, which can charge 4 pairs of the TB30, at three different levels: standard, storage, and ready to fly. Each level maintains differing charge capacities:

- **Standard:** Charges batteries to 90% in 30 minutes.
- **Storage:** Maintains batteries at 50% for a longer lifespan and overall health.
- **Ready to Fly:** Maintains full charge for immediate hot-swap during operation.

Key Features:

Wide Camera

- Equivalent Focal Length: 24 mm, DFOV: 84°
- 12 MP 1/2" CMOS Sensor
- Video Resolution: 4K/30fps
- Zoom Camera
- 48 MP 1/2" CMOS Sensor
- 5×-16× Optical Zoom
- 200× Max. Hybrid Zoom
- Photo Resolution: 8K
- Video Resolution: 4K/30fps

Thermal Imaging Camera

- Equivalent Focal Length: 40 mm
- Resolution: 640×512
- Frame Rate: 30fps
- Measurement Accuracy: ±2°C or ±2%
-
- Laser Rangefinder
- Range: 3 m - 1200 m
- Accuracy: ±(0.2m+D×0.15%)

Powerful Flight Performance

- A balance of power and portability delivers higher operational efficiency. Max Flight Time: 41-min
- Wind Resistance: 15 m/s
- Service Ceiling: 7000 m
- Max Speed: 23 m/s

Environmental Adaptability

- With IP55 protection, the M30 can easily handle adverse weather and temperatures ranging from -20° C～50° C.

FLAGSHIP PERFORMANCE

HYBRID VISUAL, THERMAL, LRF PAYLOAD CAMERA

Assessment Criteria	Comment
Availability	Available from several Australian vendors or direct from DJI
Prior deployment histories and reported effectiveness.	No available data on use for whale sighting missions but demonstration video footage of night search and rescue of people in the ocean would suggest whales would also be sighted using the thermal image camera when at the sea surface.
Practicality of implementation	Should be easily implemented with flights based to and from the survey vessel helideck. Need to check the potential for registering moving platform automated Return To Base (RTB) in the event of communications failure.
Safety & environmental concerns	None identified
Cost versus benefit	Relatively inexpensive drone purchase price at ~AUD18K. Cost of an additional contract drone pilot, if required, including bunk space & meals, may prove more costly and logistically restrictive.

Autel EVO II Dual 640T Enterprise

The Autel Robotics EVO 2 Dual 640T V3 is one of the most compact and advanced thermal drones on the market. Featuring a 640x512 radiometric thermal sensor and 50MP RGB lens with 16x digital zoom - it is easy to observe distant targets in amazing detail. The system uses a new image processing algorithm making thermal imaging details clearer and more discernible than competition with the similar resolution and hardware. With a 38-minute flight time and 9.3-mile transmission range - the EVO 2 Dual 640T V3 is a powerful tool professionals can use to get the job done right!

Thermal Camera

The thermal camera is equipped with a 13mm focal length lens and the ability to record at 640 x 512 resolution at 30 Hz. In dangerous situations, you can keep the drone back as you use 16x digital zoom with 4x lossless zoom to find what you're looking for. The V3 thermal image is designed to better display discernible differences and detail. Keep reading to view the array of thermal modes and features the EVO II Dual 640T offers, in addition to its thermal detection, recognition, and identification ranges:

- Central temperature measurement: View real-time temperatures in the center of the remote's display.
- Spot temperature measurement: Tap the remote's display and view an object's temperature in real time.
- Regional temperature measurement: A dynamic view of average, minimum, and maximum temperatures.
- Ten thermal color palettes: White Hot, Cold and Hot, Rainbow, Enhanced Rainbow, Ironbow, Lava, Arctic, Searing, Gradation, and Heat Detection.

- Picture-in-picture display mode: View visual and thermal imaging at the same time.
- Temperature alarm: This will monitor a set temperature in real time and set off an alarm if reached.
- Isotherm: Set a temperature range and the system will detect any object in view that's within that range.
- Image enhancement: Real-time adjustment of the thermal image brightness, contrast, and details; the system will highlight any object within the target temperature.
- Infrared thermal analysis tool: The IRPC tool quickly imports images, edits and analyzes temperature measurements, and generates detailed reports for sharing and collaboration.
- Detection range: Detects a person up to 0.34 miles away, an SUV from up to 1.03 miles away, and a truck from up to 1.8 miles away.
- Recognition range: Recognize if an object is a person from up to 443' away, an SUV from 0.26 miles away, and a truck from up to 0.45 miles away.
- Identification: Identify a person from up to 223' away, an SUV from up to 682' away, and a truck from up to 0.22 miles away.

Visual Camera

Inspections and rescues are not the only things you can do with your EVO II Dual 640T. The 50MP visual camera is capable of capturing stunning professional footage at 4K HDR resolution. With its 0.8" RYYB CMOS sensor instead of a traditional RGB sensor, the larger surface area delivers a high level of detail in high-contrast lighting conditions. Dynamic tracking shots are possible with the quick focusing of the PDAF+CDAF system, and low-light scenes will be clearer thanks to the moonlight algorithm 2.0's increased noise suppression.

Smart Controller V3 with SkyLink 2.0

Utilizing SkyLink 2.0, the Smart Controller V3's built-in 7.9" display can receive HD video transmission in flight from up to 9.32 miles away (or QHD quality from up to 0.62 miles away). Reception is engineered to be stable and interference-free, thanks to triple-band (900 MHz, 2.4 GHz, and 5.8 GHz) frequency hopping. Thanks to the display's 2000 cd/m² brightness, you can easily view the drone's footage, even in direct sunlight. You're not restricted to flying on sunny days, though. The Smart Controller V3 can withstand -4 to 104°F temperatures and is IP43-rated for all-weather performance.

360-Degree Obstacle Avoidance

While in flight, an array of 19 sensors, including 12 visual sensors, the main camera, ultrasound IMUs, and more, can build a 3D map of the drone's surroundings and plan a clear path to its destination in real time.

Additional Features

- Foldable design
- Can deploy and take off in under a minute
- Up to 38 minutes of flight time
- Up to 39 mph of maximum wind resistance
- Maximum flight speed up to 45 mph

- Maximum payload up to 2 lb
- Can be flown even if the firmware and app are not fully updated
- Without built-in fly zones, nothing prevents you from taking off when needed
- The EVO II Dual 640T is not under the United States ITAR (International Traffic in Arms Regulations)
- Compatible with optional Live Deck 2 for broadcasting live mission intel

Assessment Criteria	Comment
Availability	Available from at least one Australian vendor or from Autel based in Honk Kong or Shenzen.
Prior deployment histories and reported effectiveness.	No available data on use for whale sighting missions but demonstration video footage of night search and rescue of people in the ocean would suggest whales would also be sighted using the thermal image camera when at the sea surface.
Practicality of implementation	Should be easily implemented with flights based to and from the survey vessel helideck. Need to check the potential for registering moving platform automated Return To Base (RTB) in the event of communications failure.
Safety & environmental concerns	None identified
Cost versus benefit	At ~ AUD$10K the Autel 640T is less costly than the DJI M30T but lacks some of the DJI technology, like laser ranging and 200X image zoom. Cost of an additional contract drone pilot, if required, including bunk space & meals, may prove more costly and logistically restrictive.

1 Environmental Performance Tables

1.1 Management of the Activity (All Aspects)

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
The activity will have constraints and limitations in place such that all environmental aspects are not created for more than 90 days.	Operational logs and activity reports confirm that all activities were completed within a 90-day period, with records verifying that the activity was conducted within the activity limitations. Audits and inspections conducted throughout the activity show measures in place to manage impacts and risks performed as expected and deviations were corrected within procedural timeframes.
The activity is managed to ensure environmental impacts and risks remain within temporary, reversible, small-scale, and low-intensity impacts.	
The effectiveness of impact and risk management measures is continuously monitored and adapted as necessary to maintain compliance with the implementation strategy.	
The activity is conducted in a way that prevents unmitigated financial loss to affected persons and ensures social and cultural values are protected.	
The community and relevant persons are informed about the operational details of the activity and relevant persons objections and claims are promptly assessed.	Consultation records confirm that operational details were shared with the community and relevant persons, with documented assessments and responses for any objections and claims received within specified timeframes.
Social, cultural, and economic features are protected, sustaining their value for people and communities.	Behavioural observation reports, audits, verified incident reports, monitoring records and independent evaluations confirm no disruption to critical life-cycle behaviours of identified species, supported by documented mitigation measures. Compensation for verified income losses, such as reduced catch volume or displacement, is validated via claims assessments, economic desktop study, fish stock data, and spatial access mapping.
The activity is conducted such that environmental impacts and risks remain within the range assessed as medium or lower, with mitigation measures in place and functioning as intended.	All mitigation measures identified are implemented and function as intended, with no incidents indicating that residual impact exceeds the “medium” level assessed in the risk register.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
CGG Technical Operations Manager	Maintains oversight of the activity and implementation of EPOs and EPSs within the EP through daily reports.	Operational logs, daily HSE checklists, and meeting records confirm that the CGG Technical Operations Manager maintained oversight of vessel performance per the Sail Line Plan, conducted daily HSE checks, and attended daily operational meetings and toolbox talks,
	Ensure that seismic acquisition practices during the survey reflect the planning and alignment outcomes of the ‘Acquire	

Control Measures	Environmental Performance Standards	Measurement Criteria
	Seismic on Paper' exercise, including any corrective actions identified during the simulation.	with environmental matters documented and tracked for compliance.
	Verifies that the project vessels are performing as per the agreed contract and executing the seismic in accordance with the agreed (and varied) Sail Line Plan.	
	Continually monitor vessel HSE performance to ensure that the EP commitments are implemented.	
Quality Control and Reporting Representative	Ensure contracted vessels operate within the Sail Line Plan boundaries and sequences throughout acquisition.	GPS tracking data and activity logs confirm vessel movements complied with Sail Line Plan boundaries and sequences, with deviations identified, justified, and rectified in accordance with the operational procedure.
Environment Officer	Environmental incidents are documented, assessed, and responded to within required timeframes, with corrective actions implemented to prevent recurrence and minimise environmental harm in accordance with the Implementation Strategy.	Incident logs confirm all environmental incidents were recorded within 24 hours, with associated assessment outcomes and records of corrective actions implemented to minimise or prevent environmental harm.
	Continually monitor daily reports, weekly audit results, and incident reports, for ongoing compliance of the activity with the environmental performance outcomes and standards in this document.	
	Immediately initiate an inspection and/or corrective action upon identification of a non-compliance with any environmental performance outcome or standard.	
	Assessment of merit of an objection or claim is completed within 48 hours and any environmental protection requirements are implemented as soon as practical.	
Consultation Management System	Ensure relevant persons are provided with timely, accessible information that enables meaningful consideration of the activity	Communication logs, email records, and copies of notifications sent.
	All relevant person-related information, engagement plans, consultation activities, and complaints/feedback are accurately and completely documented and recorded.	Audit reports demonstrating the completeness and accuracy of documentation and records.
	Maintain comprehensive and up-to-date documentation of all processes, procedures, and records.	An audit shows compliance with documentation requirements and timely updates.

Control Measures	Environmental Performance Standards	Measurement Criteria
Environment Management System	Ensure all employees receive an activity specific induction on the environmental performance required for the activity and their environmental responsibilities.	Training records indicating that of employees and contractors have completed required induction.
	Establish clear communication channels for reporting environmental performance and incidents.	Daily and monthly reports demonstrate timely and accurate dissemination of information.
	Emergency response procedures are tested and shown to be capable of containing and mitigating potential environmental impacts in accordance with OPEP/OSMP requirements.	Pre-survey deployment exercises confirm that response resources can be deployed within response timeframes specified in the OPEP, with records showing containment of a simulated release scenario within acceptable limits.
	Conduct weekly audits to assess the effectiveness of the environmental performance outcomes and standards, the activity limitations, the implementation strategy and identify areas for improvement.	Audit reports showing completion of scheduled audits and implementation of corrective actions.
	Perform annual management reviews to evaluate the environmental performance outcomes and standards and make necessary improvements.	Meeting minutes and action plans from management reviews demonstrating continuous improvement.
	Ensure that suppliers and contractors comply with the organization's HSE requirements.	Supplier audits and compliance reports showing adherence to EMS standards.
Sound Source Verification Buoy Location Procedure	Anchored sound source verification buoys will only be deployed in locations where no mapped features of ecological significance (e.g. sensitive benthic habitats or protected seabed features) are present, as determined by available spatial data prior to deployment.	A record of spatial screening (e.g. GIS layer overlay or pre-deployment checklist) is maintained and available for audit.
	All components of the SSV buoys, including anchors, clump weights, chains, and associated equipment, will be fully recovered following deployment. No equipment will be intentionally left on the seabed.	Deployment and recovery logs document the quantity and type of equipment retrieved.

1.2 Accidental Release of Materials or Waste Overboard

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
No loss of materials or wastes overboard.	Operational logs, waste management records, and environmental audits confirm secure containment of all materials and wastes, with no recorded incidents or observations of overboard loss throughout the activity.
No death or injury to fauna, including listed threatened or migratory species, from the activity.	Verified incident reports, monitoring records, and environmental audits confirm zero observed or reported instances of fauna injury or mortality directly linked to the activity, with specific attention to listed threatened or migratory species.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
Streamer Recovery Units	The streamers will have recovery units fitted to prevent benthic disturbance in the event of loss.	Inspection and equipment logs confirm that recovery units are securely fitted to all streamers, with documentation showing pre-deployment checks and maintenance records for functionality.
	Streamer tail buoys will be of a design that does not represent an entrapment risk to turtles or turtle guards will be used.	Design specifications and inspection records verify that tail buoys are either designed to avoid turtle entrapment or fitted with turtle guards, confirmed through pre-deployment inspections.
Consultation Management System	If a loss of equipment poses a risk to other marine users, they will be notified via VHF Channel 16 and the event will be reported to AMSA, within 2 hrs.	Communication logs and incident reports verify that VHF Channel 16 was used to notify marine users of equipment loss, with timestamped records of notification to AMSA within the specified 2-hour window.
Garbage Management System	All containers for waste that has the potential to be blown overboard will have covers.	Inspection records confirm that all waste containers are equipped with secure covers to prevent overboard loss, documented in pre-survey audits and verified by ongoing inspections.
	All waste gathered during the survey is transferred to shore for disposal and this is recorded in the Garbage Management Book.	Waste transfer records and entries in the Garbage Management Book confirm that all collected waste was disposed of onshore, with records detailing each transfer and disposal event.
Support Vessel	When safe, assist in the recovery of lost equipment or unintentional garbage discharges.	Support vessel logs and incident response records document all recovery actions for lost equipment or garbage, with details of timing, location, and conditions confirming safe recovery practices.

1.3 Collisions with Marine Fauna

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
No death or injury to fauna, including listed threatened or migratory species, from the activity.	Verified incident reports, monitoring records, and environmental audits confirm zero observed or reported instances of fauna injury or mortality directly linked to the activity, with specific attention to listed threatened or migratory species.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
Turtle Guards	Tail buoys designed so they do not represent an entrapment risk to turtles or turtle guards will be used.	Design specifications and inspection records confirm that tail buoys meet entrapment risk mitigation standards or are fitted with turtle guards, with photographic verification from pre-deployment checks to ensure compliance.
Marine Fauna Observers	Two MFO's will always be resident on the survey vessel and will maintain a watch during daylight hours.	POB logs and daily records confirm that two MFOs were continuously present on both the survey and spotter vessels during daylight hours, maintaining active watch and providing immediate notifications of any fauna observations to the Survey Environment Advisor and Officer of the Watch, as required by monitoring protocols.
	Two MFO's will always be resident on the spotter vessel and will maintain a watch during daylight hours (except during port calls, crew transfers, and bunkering activities).	
	Provide immediate notification of an observation to the Survey Environment Advisor and the Officer of the Watch.	
Operational Procedure	All vessels as part of the Regia MSS will comply with of EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with Cetaceans to reduce the risk of collision with marine fauna during the activity.	MFO records will confirm that vessels adhered to EPBC Regulations (Part 8)

1.4 Introduction of Marine Pest Species

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
No introduction of a known or potential invasive marine species.	Ballast water management records, biofouling inspection logs, and environmental audits confirm adherence to marine pest prevention protocols, with no observed introduction or establishment of invasive marine species in the area, validated through post-activity desktop assessments.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
IMS Risk Assessment Procedure	Vessels/immersible equipment must be assessed as 'low risk' prior to mobilisation to the operational area by a qualified IMS inspector.	Inspection records confirm that all vessels and immersible equipment received a 'low risk' rating from a qualified IMS inspector before mobilization, with assessments documented and verified by audit reports.
	If any project vessels, including the seismic vessel and spill response vessels, have an overseas 'last port of call,' a Pre-Arrival Report must confirm that the vessel meets ballast and quarantine requirements.	Pre-Arrival Reports document compliance with ballast and quarantine standards for vessels arriving from overseas ports, with supporting inspection records confirming adherence to invasive species protocols.
Anti-Fouling System	The vessel's fuel consumption should not be increasing overtime more than 5% above the baseline established after last hull inspection.	Fuel consumption logs confirm that usage remains within 5% of baseline levels set post-inspection, with any increases promptly reviewed to ensure anti-fouling system efficacy.
	The interval between hull cleanings should be at least twelve months, as recorded in the maintenance logs. Any deviation from this schedule will be investigated to assess the anti-fouling system's performance.	Maintenance logs verify that hull cleaning occurs on a minimum 12-month schedule, with documented investigations into any deviations, including assessment of the anti-fouling system's condition.

1.5 Accidental Release of Fuel

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
No accidental release of fuel to the marine environment.	Incident logs and environmental audits confirm no recorded fuel releases into the marine environment during the activity, with secure fuel management practices documented throughout operations.
Maintain arrangements to respond to an unplanned release of fuel in accordance with the OPEP.	Response resources, mobilisation logs, exercise records, personnel competencies, and incident reports demonstrate that spill response arrangements remained in place and were capable of being activated and executed in accordance with the OPEP for the duration of the activity.
Maintain arrangements to monitor the effects of a release of fuel to the marine environment in accordance with the OSMP.	Monitoring equipment, deployment logs, sampling results, and reporting records demonstrate that environmental monitoring arrangements were maintained and capable of being implemented in accordance with the OSMP for the duration of the activity.
Respond to and clean-up any accidental release of fuel until termination criteria are met.	Clean-up efforts continue until no visible surface sheen remains, hydrocarbon concentrations in water and sediment meet regulatory thresholds, and an incident report confirming termination criteria are met is submitted.
Monitor any accidental release of fuel until termination criteria are met.	Monitoring continues until no visible surface sheen remains, hydrocarbon concentrations in water meet defined thresholds, and an incident report confirming termination criteria are met is submitted.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
Consultation Management System	Pre-start notifications and ongoing communications will be made over Channel 16 to ensure collision avoidance.	Communication logs and radio transmission records on Channel 16 confirm that pre-start notifications and ongoing updates were consistently broadcast at designated intervals, with records demonstrating alignment with collision avoidance protocols as outlined in the Consultation Management System.
CGG Marine Assurance System	Ensures vessels have a documented Preventative Maintenance System (PMS) that provides a status on the maintenance of equipment as per the manufacturer's specification for maintenance procedures for navigation equipment.	Maintenance records and PMS documentation confirm that navigation and bunkering equipment have been maintained per manufacturer specifications, verified by periodic audits and pre-survey inspections.

Control Measures	Environmental Performance Standards	Measurement Criteria
	Pre-survey inspection confirms: Navigation and bunkering equipment maintenance is up to date. Each vessel has an up-to-date SOPEP in place. Vessel materials or equipment that have the potential for spill overboard are within contained/bunded areas. Vessel contractor has an HSE management plan, and that plan will be approved by CGG prior to survey commencement.	Inspection and audit reports confirm that all vessels pass pre-survey checks, including current SOPEP documentation, maintenance status, bunding of spill-prone equipment, and CGG-approved HSE management plans.
Vessel Bunkering Procedure	Pre-bunkering inspection confirms: Dry break couplings and bunkering hoses are in serviceable condition and certified for use. Tank inventories are taken prior to, during, and after transfer.	Inspection logs confirm dry break couplings and bunkering hoses are certified and operational; inventory records document volumes before, during, and after bunkering to verify containment integrity.
	No one fuel tank inventory will exceed 250 m^3.	
	Only commence bunkering operations in sea states less than 5m and wind speeds less than 35 knots.	Bunkering operation logs, including sea state and wind speed data, confirm adherence to environmental limits, with operations conducted only within safe parameters.
Support Vessel	Support vessel to communicate future vessel movements with other marine users.	Communication logs show documented notifications of vessel movements to nearby marine users, with confirmation of receipt where applicable to facilitate collision avoidance.
	Support vessels will accompany the seismic vessel during surveying operations to patrol and maintain a clear zone ahead of the vessel.	Patrol records and vessel positioning data confirm that support vessels maintained a clear zone ahead of the seismic vessel throughout surveying, as documented in patrol logs and GPS tracking.
CGG Technical Operations Manager	CGG will notify any incidents in accordance with the procedures in the OPEP and OSMP.	Incident logs and notification records confirm that all incidents were reported per OPEP and OSMP protocols, with time-stamped evidence of compliance.
	CGG will execute a comprehensive monitoring and evaluation strategy aimed at assessing the environmental fate and ecological consequences of any potential spill incident in strict accordance with the OPEP and OSMP.	Monitoring reports and evaluation summaries document environmental fate assessments and ecological impact analysis for any spill incident, consistent with OPEP and OSMP strategies.

Control Measures	Environmental Performance Standards	Measurement Criteria
	CGG will establish an oiled wildlife response strategy in collaboration with the relevant State government to safeguard listed and migratory species in the event of an oil spill, ensuring prompt and effective protection measures are in place.	Response planning documents and collaborative agreements with State authorities confirm a standby oiled wildlife response strategy, with records of readiness measures and personnel training to protect listed and migratory species effectively.

1.6 Planned Discharges and Atmospheric Emissions

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
Planned discharges and atmospheric emissions comply with maritime law.	Discharge and emissions logs, along with compliance audits, confirm that all planned discharges and atmospheric emissions meet maritime law standards, with documented evidence of adherence to permitted levels and discharge protocols.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
CGG Marine Assurance System	Pre-survey audits of the contracted vessels show compliance with MARPOL, COLREGS, and Marine Orders 21, 30, 31, 59, 70, 71, 72, 91, 95, 96,97, and 98.	Pre-survey audit reports confirm that all contracted vessels comply with MARPOL, COLREGS, and specified Marine Orders, with documented evidence of inspections and compliance for each standard.
	Ensure that bilge discharges from all vessels remain below 15 ppm during all discharge events.	Oil content meters and discharge logs confirm bilge water discharges did not exceed 15 ppm, with real-time alarms triggered and reviewed for any anomalies, as recorded in the Oil Record Book.

1.7 Physical Presence

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
The activity is scheduled and located to avoid exclusion of commercial fishing from known, high-effort fishing areas for more than 90 consecutive days, with no resulting adverse effects on fish stock status.	Documented evidence of compliance with marine traffic management protocols, including the absence of reported or observed incidents of collision with other marine users, verified through regular logbook entries, GPS tracking records, and radar monitoring data.
As a result of the activity limitations and the adoption of the Otway Adjustment Protocol, no commercial marine user will be worse off because of the activity.	Reasonable claims assessments confirm compensation has been paid for any evidence-based decline in income (e.g. catch volume or displacement) attributable to the activity, validated through pre- and post-activity economic desktop study, fish stock data, and spatial access mapping.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
Consultation Management System (CMS)	Marine users are informed in a timely manner such that conflicts or incidents with the survey vessels are avoided, as verified by absence of marine user complaints or navigation incidents.	Communication logs confirm that marine users were identified and informed in compliance with maritime law, with documentation showing consistent outreach to stakeholders.
	The forward plan for the survey is communicated to fishers through the agreed on-water communications plan.	Notification records verify that the survey plan was communicated to fishers as per the agreed communications plan, with evidence of timing and content of messages shown in full text copies of the correspondence.
	The status of the claims process and how to make a claim for compensation are clearly communicated to all commercial fishers in the region before the survey starts.	Documentation of notifications, emails, and/or meetings confirms that all commercial fishers were informed of the claims process and compensation procedures prior to the survey.
Otway Adjustment Protocol (OAP)	Appropriately documented claims will be assessed, in accordance with the processes outlined in the OAP, and completed within 30 days of receipt of the required data.	Documentation of notifications, emails, and/ claims confirm that all commercial fishers commercially worse off because of the survey have made claims. Confidentiality agreements and payment receipts were appropriate.
	A claim can be lodged up to 180 days after the completion of the activity.	
	Adjustment can be claimed for up to 30 days after the completion of each activity.	

Control Measures	Environmental Performance Standards	Measurement Criteria
	Successful claims will receive compensation within 30 days of the Outcome Notification being executed.	
Streamer tail buoys	Each streamer will be fitted with a tail buoy to mark the end of the streamers so that they can be detected by other vessels.	Pre-deployment photographs confirm that tail buoys were fitted to all streamers prior to deployment, with audit records verifying visibility compliance.
Quality Control and Reporting Representative	Always monitor the location and planned activities of the contracted vessels in accordance with the Sail Line Plan.	GPS tracking data and activity logs confirm continuous monitoring of vessel locations and adherence to the Sail Line Plan, with records documenting compliance.
CGG Technical Operations Manager	Reasonable, evidence-based claims are promptly assessed and paid in accordance with the Otway Adjustment Protocol.	Claims assessment records show that compensation claims were reviewed and paid promptly, with supporting evidence based on the Otway Adjustment Protocol.
Fisheries Liaison Officer (FLO)	Individual located in the region to be able to meet fishers in person to discuss the operational outlook and support fishers with claims under the Otway Adjustment Protocol.	Meeting logs and consultation records verify that the FLO was present in the region, with documented interactions with fishers to discuss the survey outlook and claims process.
CGG Marine Assurance System	Navigation and communication equipment is part of the maintenance system and is functioning continually throughout the survey.	Maintenance records and inspection logs confirm that navigation and communication equipment was operational and maintained throughout the survey, with downtime incidents documented.
Support Vessel	Throughout the seismic survey, at least one support vessel will be in constant attendance to communicate with other marine users.	Support vessel logs confirm continuous presence and communication with marine users during the seismic survey, with documented records of interactions.

1.8 Underwater Sound

Environmental Performance		
Receptor	**Environmental Performance Outcomes**	**Measurement Criteria**
Plankton, Zooplankton and Krill	**As a result of complying with the sound source volume and activity limitations, sound emissions will not disrupt the ecological integrity of plankton communities.**	Operational logs and sound source tracking data confirm continuous movement during full-power operation, validated by GPS coordinates and real-time monitoring records showing no stationary positioning.
	As a result of complying with the sound source volume and activity limitations, no impacts to plankton communities beyond 740 metres from the sound source.	
Fish & Invertebrates	No change in the assessed stock status of commercial and aquaculture species during and following the activity.	Analysis of VFA or AFMA annual Stock Assessment Reports indicating no statistically significant change in biomass within the area of activity, validated by pre- and post-activity comparisons of biomass data over multiple years to account for natural variability.
	Fish will not be exposed to cumulative sound levels exceeding 186 dB SEL $_{cum24hr}$ for more than 24 hrs.	Operational logs and sound source tracking data confirm continuous movement during full-power operation, validated by GPS coordinates and real-time monitoring records showing no stationary positioning.
Birds, Marine Mammals & Reptiles	No death or injury to fauna, including listed threatened or migratory species, from the activity.	Verified incident reports, monitoring records, and environmental audits confirm zero observed or reported instances of fauna injury or mortality directly linked to the activity, with specific attention to listed threatened or migratory species.
Cetaceans	As a result of shutting down or relocating the sound source when whales enter shutdown zones, no physical injury or sustained interference with marine mammal life-cycle behaviours occurs during the activity.	Verified observation logs, real-time visual and acoustic monitoring records, and incident reports confirm adherence to sound source shutdown protocols when cetaceans (including low-frequency cetaceans, BWs, and SRWs, including cow-calf pairs) are observed within specified distances and durations from the sound source, with documentation showing compliance for each proximity and residency condition.
	As a result of complying with the activity limitations and environmental performance standards in place to protect threatened whales, environmental impacts and risks associated with the activity are managed in a manner that is demonstrably consistent with ecologically sustainable development principles.	
	As a result of shutting down or relocating the sound source when a blue whale is observed within 5 km, blue whales will not be behaviourally disturbed within this range, leading to the protection of important foraging areas and avoidance of displacement.	

Environmental Performance		
Receptor	**Environmental Performance Outcomes**	**Measurement Criteria**
	As a result of implementation of the suite of mitigation measures, SRW are not exposed to sound levels that result in auditory impairment or displacement from BIAs or HCTS.	
	As a result of shutting down the sound source when: - any pinniped or dolphin is observed within 500 metres, - any whale is detected within 2 km of the sound source, and - any low frequency cetacean observed within 9 km of the sound source Cetaceans will not be exposed to sound levels associated with auditory injury.	
	As a result of the implementation of real-time monitoring and activity limitations, SRW are not exposed to sound levels that cause substantial behavioural disturbance within or adjacent to BIAs or HCTS.	
	As a result of implementing shutdown or relocation procedures if a blue whale is detected within the 5 km ensonified area. blue whales will not be exposed to physical injury from sound exposure.	
	As a result of implementing shutdown or relocation procedures when a SRW enters the 13 km ensonified area.	
	Underwater sound emissions from the Regia MSS are empirically measured and validated through the sound source verification procedure to ensure they remain within levels that do not cause injury or unacceptable disturbance to Southern Right Whale.	
	As a result of the implementing the suite of mitigation measures, marine mammals will not experience auditory injury or sustained behavioural disturbance affecting survival, reproduction, or population distribution.	
Divers, Swimmer, and Surfers	Received sound levels at coastal areas accessible by coastal users will not exceed the human health safety criterion relating to amenity value.	Operational records and discharge logs confirm that sound levels at the source did not exceed the modelled parameters established to meet human health and safety criteria for coastal amenity value, with compliance documented through sound source output monitoring during activity.

Environmental Performance		
Receptor	**Environmental Performance Outcomes**	**Measurement Criteria**
Identified Cultural, Social and Economic Features	Social, cultural, and economic features are protected, sustaining their value for people and communities.	Behavioural observation reports, audits, verified incident reports, monitoring records and independent evaluations confirm no disruption to critical life-cycle behaviours of identified species, supported by documented mitigation measures. Compensation for verified income losses, such as reduced catch volume or displacement, is validated via claims assessments, economic desktop study, fish stock data, and spatial access mapping.

Control Measures	Environmental Performance Standards	Measurement Criteria
Survey Environment Advisor	Maintain communication with the Environment Officer, the Officer of the Watch, the Marine Fauna Observers, and PAM Operators, and the Coastal Whale Monitoring Teams (WMT) to implement shut down procedures as per the Fauna Management Plan.	Communication and detection logs confirm that the Survey Environment Advisor maintained continuous coordination with all observers/detectors with timely detection information provided to the Environment Officer and documented adherence to shutdown procedures as outlined in the Fauna Management Plan.
	Provide detection information to the Environment Officer.	
Environmental Officer	Convene the Whale Expert Panel to seek guidance on the detection circumstances and procedural responses to detections.	Records of meeting logs, communication reports, and shift documentation confirm that the Environmental Officer maintained 24/7 support, convened the Whale Expert Panel as needed, and promptly communicated all whale detections from external sources to the Survey Environment Advisor, ensuring timely procedural responses to detections as per established protocols.
	Communication of whale detections from other sources to the Survey Environment Advisor throughout the duration of the activity.	
	Maintain a 24/7 onshore presence to support the procedural responses to detections.	
	Issue tasks to marine fauna detectors and maintain a record of all taskings.	
	Review and approved the daily assignments of the Whale Monitoring Teams for the Coastal SRW Monitoring Plan.	
	Coordinate completion of the Sound Source Verification Procedure (Appendix G6) and ensure functionality of SSV buoys prior to survey commencement.	
Marine Fauna Observers	Two MFO's will always be resident on the survey vessel and will maintain a watch during daylight hours.	POB logs and daily records confirm that two MFO's were continuously present on both the survey and spotter vessels during daylight hours,

Control Measures	Environmental Performance Standards	Measurement Criteria
	Two MFO's will always be resident on the spotter vessel and will maintain a watch during daylight hours.	maintaining active watch and providing immediate notifications of any fauna observations to the Survey Environment Advisor and Officer of the Watch, as required by monitoring protocols.
	Fauna detections result in timely implementation of required mitigation responses in accordance with the Fauna Management Plan, including shutdowns or relocation if thresholds are exceeded.	
Passive Acoustic Monitoring Operators	One PAM Operator will always be resident on the survey vessel and will maintain a watch during nighttime hours.	POB logs confirm that a PAM Operator was continuously present on the survey vessel during nighttime hours, conducting active acoustic monitoring and providing immediate notifications of any detections to the Survey Environment Advisor and Officer of the Watch in accordance with procedural requirements.
	Fauna detections result in timely implementation of required mitigation responses in accordance with the Fauna Management Plan, including shutdowns or relocation if thresholds are exceeded.	
Relief PAM/MFO Observer	One additional MFO and PAM Operator will always be resident on the survey vessel to provide relief as needed.	Detection records verify immediate reporting of any acoustic detections to the Survey Environment Advisor and Officer of the Watch, with timestamps confirming prompt communication.
Whale Expert Panel	The whale expert panel will comprise at least four people with an expert in each of the following areas: Southern Right Whales Blue Whales Fauna Detections CGG Seismic Operations In addition, a First Nations knowledge holder participation can be facilitated through the Sea Country Protection Plan (Event ID EVT352).	Pre-survey meeting minutes confirm panel attendance and approval of the Fauna Management Plan, including recommendations for implementation resources.
	Recommendations from the Whale Expert Panel are incorporated into the activity's operational and mitigation plans to ensure cetaceans interactions remain of an acceptable level.	Meeting logs verify that the Whale Expert Panel convened as requested by the Environmental Officer and every two weeks, with minutes documenting any recommendations made.
	The whale expert panel will meet on request of the Environment Officer and at least fortnightly during the activity.	

Control Measures	Environmental Performance Standards	Measurement Criteria
Spotter Vessel	The spotter vessel will position itself at the most likely point of interaction with Southern Right Whales or Blue Whales, as directed by the Environment Officer, based on the recommendations of the Whale Expert Panel.	Positioning logs and communication records confirm that the spotter vessel was strategically placed at locations based on the standards, or as improved by written recommendations from the Whale Expert Panel.
	BW Mode: The spotter vessel will maintain position 20 km to the west of the survey vessel.	
	SRW Mode: The spotter vessel will travel parallel to the seismic vessel, 20km away and on the northerly side, while the seismic vessel is acquiring lines 31-67.	
	The spotter vessel will have PAM and position itself to maximise the probability of detecting low-frequency cetaceans at distances well beyond defined behavioural-effect thresholds (shutdown distances), enabling timely implementation of required mitigation responses.	PAM records, vessel-tracking data, and spotter logs verify PAM operation and positioning that enabled early detection of low-frequency cetaceans beyond shutdown distances, with detections communicated and responses implemented as required.
Spotter Vessel Procedures	BW and SRW Scouting Mode: The spotter vessel conducts pre-start and pre-turn scouting 10 km ahead of the survey vessel	Tasking records, daily reports, and vessel tracking data show the movement, mode, and observations of the spotter vessel and demonstrates that routes were adjusted in response to fauna sightings or environmental changes.
	SRW Sentry Mode: The spotter vessel will travel parallel to the seismic vessel, 20km away and on the northerly shoreside of the seismic vessel, while it is acquiring lines 31-67	
	Blue Whale Sentry Mode: The spotter vessel maintains a position 20 km to the west of the survey vessel	
Sound Source Verification (SSV) Buoys	Three SSV buoys must be deployed 4–6 weeks before seismic acquisition, subject to safe weather conditions, at locations proximate to Cape Nelson, Logan's Beach, and Cape Otway and be functional throughout the survey.	Deployment records and AHS notification confirm that the SSV buoys were installed. GPS records show the location and daily function tests confirm operability.
	If one SSV buoy becomes non-functional, remaining buoy data streams and drift-recording deployments will be used to maintain near real time verification of ambient and seismic sound levels until the buoy is restored.	Deployment records and AHS notification confirm that the SSV buoys were installed. GPS records show the location and daily function tests confirm operability. Daily reports show alternative measures deployed if buoys non-functional.
	If two or more SSV buoys become non-functional, contingency drift-recording and available fixed loggers will be deployed and prioritised to maintain sufficient spatial coverage for real-time sound-field verification until systems are restored.	

Control Measures	Environmental Performance Standards	Measurement Criteria
	Each SSV buoy must be fitted with a multi-channel broadband hydrophone capable of detecting ambient underwater sound and with communication systems capable of near real-time relay of pre-programmed exceedances.	Equipment specifications show hydrophone and communication capability. Data received shows time, date, and sound levels recorded.
	Each SSV buoy must record continuous broadband (10 Hz–25 kHz) ambient sound with complete 1-second RMS data streams suitable for generating valid 3-minute L75, L90 and L95 distributions ≥95% of the time, verified through automated integrity checks and post-download analysis.	Sound spectrograms from each buoy show compliance with data requirements for each buoy.
	All three SSV buoys must be cross-calibrated (both moored and unmoored) to establish each buoy's baseline ambient signature and quantify mooring-related noise.	Audio files of calibration tests show results and any adjustments made for calibration.
SSV Procedure (Appendix G6)	The IMOS Passive Acoustic Observatory dataset (2009–2017) must be downloaded, filtered to September–November, and analysed to produce a statistically valid mid-shelf ambient baseline distribution prior to SSV deployment.	Analysis report shows: (i) full download of the 2009–2017 IMOS dataset. (ii) extraction of all September–November acoustic data across all available years. (iii) generation of percentile distributions (L5, L25, L50, L75, L90, L95)
	At least six months of nearshore ambient sound recordings from multiple loggers in the SRW Reproduction BIA must be successfully collected, downloaded, and analysed to produce percentile distributions (L5–L95) suitable for validating baseline calculations.	Deployment logs and analysis outputs shows: (i) ≥8 months of continuous recordings from all nearshore loggers within the BIA (ii) successful download of all logger files with verified time synchronisation (iii) production of broadband percentile distributions (L5–L95) consistent with the methodology used for the IMOS mid-shelf baseline.
	All SSV buoys and bottom-mounted hydrophones will be deployed, positioned, and calibrated in accordance with the procedure to ensure accurate, comparable and reliable recording of ambient and survey-related underwater sound.	Deployment records, calibration logs, baseline ambient datasets, drift-measurement results at prescribed distances, and verified acoustic data packages (including metadata, diagnostics, and positional information) demonstrate that all monitoring equipment was correctly deployed and calibrated, that a minimum four-week ambient baseline

Control Measures	Environmental Performance Standards	Measurement Criteria
	Ambient sound levels will be continuously recorded at all designated sites for at least four weeks prior to acquisition to establish a robust, location-specific baseline for subsequent comparison.	was collected, that seismic sound levels were measured at 5–20 km during acquisition, and that all acoustic data were quality-checked, backed up, and transmitted in accordance with the procedure.
	During seismic acquisition, sound levels at 5 km, 10 km, 15 km and (if required) 20 km will be measured through drift deployments to provide real-time verification of the horizontal extent of the seismic sound field.	
	All acoustic datasets, metadata, logger diagnostics, and positional information will be verified, backed up, and transmitted in accordance with the procedure to ensure data quality and traceability.	
Pre-survey and aerial surveillance procedures	SRW: Monitor SRW presence/absence in the reproduction BIA from 1 May until 31 October in accordance with the Whale Coastal Monitoring Programme (Appendix G5).	Aerial survey logs confirm flights were conducted with sufficient coverage to detect presence of Southern Right Whales or Blue Whales within the monitoring zone. Flight results were used to inform the decision to commence or delay the activity.
	Data from all relevant published sources and social-media platforms is actively gathered, verified, and reviewed to support early prediction of Blue Whale migration speed and progression, enabling determination of the earliest likely arrival date in the Otway region and timely activation of 'Blue Whale Mode'.	Weekly records demonstrate that published reports and social-media sources were reviewed, with any Blue Whale sightings or migration indicators documented and assessed to update arrival predictions and inform startup of 'blue whale mode'.
	The seismic source will only be discharged in the Pygmy Blue Whale foraging BIA off Otway when the presence and distribution of Pygmy Blue Whales and other foraging whales have been assessed by CGG and confirmed to be compatible with the activity proceeding without causing unacceptable disturbance.	Whale monitoring data (visual and acoustic) confirm that the distribution and behaviour of Pygmy Blue Whales and other foraging whales were assessed prior to discharge of the seismic source, and that the activity was authorised to proceed only where the risk of disturbance was determined to be acceptable based on current detections and environmental conditions.
	Conduct daily weather-determined aerial surveillance from Cape Nelson starting two weeks after the first blue whale sighting at Augusta (WA) until the arrival of blue whales in the region is confirmed.	Aerial surveillance logs, flight reports, and meteorological records confirm that daily weather-permitting flights were conducted from Cape Nelson.
Pre-Start Up Procedure	Monitoring (visual and acoustic) must always be carried out, starting 24 hours prior to any start-up of the sound source during the day.	Detection logs confirm that monitoring for cetaceans began 24 hours prior to each planned sound source start-up, with continuous records indicating any sightings and procedural adherence.

Control Measures	Environmental Performance Standards	Measurement Criteria
	Soft start can only commence if there have been: • No confirmed detections of a SRW in the preceding 24 hours from any detection platform (including shore based MFOS): • No detections of a BW within 5km of the sound source. • No detections of any whale within 2 km in the preceding 60 minutes. ○ No detections of dolphins, pinnipeds, or turtles within 500m (except for bow riding dolphins). No start-up of the sound source if there have been three (3) or more shutdowns for any whale (including BWs) in the preceding 24 hr period.	Observation logs and procedural records verify that the soft start was initiated only after meeting all pre-start detection criteria, with documented checks showing compliance with SDZ and recent shutdown requirements.
Start-up Procedures	Soft start of the survey can only commence when there have been no confirmed detections of any BW from all the platforms for a period of one hour. Prior to start up, SEA to check with WMT's and the spotter vessel that no detection of SRW has occurred within the last 24 hours. When the sound source is first turned on soft starts will be undertaken by gradually ramping up the seismic source over a 30-minute period. When the sound source is in low power mode soft start will be undertaken by increasing the seismic source to full power mode (targeting 30 minutes duration subject to operational requirements).	Operational logs confirm that the soft start was conducted with pre-start observations and by gradually increasing the seismic source output over a 30-minute timeframe, with ramp-up intervals documented to ensure compliance. Log records verify that, following operation in low power mode, a soft start procedure was followed to increase the seismic source output to full power, with the procedure documented to meet compliance requirements.

Control Measures	Environmental Performance Standards	Measurement Criteria
	The SRW restart protocol: • 90 minutes prior to acquisition: the spotter vessel will start a pre-clearance detection survey of the line; the spotter vessel will be 20kmahead of the seismic vessel. • 60 minutes prior to acquisition: the MFO's and PAM operators on the vessel will start a pre-clearance detection survey • 30 minutes prior to acquisition : the soft start can commence, and the spotter vessel can resume its position, 20km away and on the northerly side, while it is acquiring lines 31-67.	
	Blue whale restart protocol: • 90 minutes prior to acquisition: spotter vessel starts pre-survey clearance observations at start of line 10km ahead of the survey vessel. • 60 minutes prior to acquisition start PAM and MFOs will start a pre-clearance detection survey • 30 minutes prior to acquisition commence soft-start, spotter vessel transitions to sentry mode (20 km due West of the survey vessel).	
Start-up delay procedures (if sighting)	If flocks of foraging birds are detected within 500 m of the sound source during the soft start procedure, the acoustic source will be shut down and will not be ramped up until all pre-acquisition criteria have been met again. [Paragraph added in response to Matter B15].	Observation logs and procedural records confirm that the acoustic source was set to low power mode upon detection of foraging bird flocks within 500 m, with subsequent ramp-up only occurring after all pre-acquisition criteria were met.
	If any whale is detected in relevant shut down zones (SDZs) during soft start procedures, the acoustic source will be shut down, and another soft start cannot commence until all pre-acquisition criteria have been met again.	Detection and shutdown records confirm that the acoustic source was promptly shut down upon whale detection within relevant SDZs, with records verifying that a new soft start was initiated only after meeting all pre-acquisition criteria.
Operating Procedure	The seismic vessel is not permitted to operate at speeds of more than 6 knots (speed over ground) during acquisition to reduce the risk of vessel collision to whales.	Acquisition vessel speed logs confirm compliance with the 5-knot speed limit during acquisition, with records verifying continuous adherence to speed restrictions.

Control Measures	Environmental Performance Standards	Measurement Criteria
	If a whale approaches within 300m of any vessel, the vessel must: – Reduce speed and maintain at least 300 m from the whale (subject to navigation and vessel safety). – Position vessel to not impede the path of the whale (subject to navigation and vessel safety). – Avoid sudden changes in speed or direction. – Communicate the sighting to the SEA and other vessels.	Daily reports and communication logs document vessel speed reduction, positioning, and communication with the SEA and other vessels upon whale sightings within 300 m, confirming adherence to procedural responses.
	If a dolphin, pinniped, or turtle approaches within 150m of any vessel, the vessel must: Reduce speed and maintain at least 150 m from the dolphin, pinniped or turtle. Position vessel to not impede the path of the dolphin, pinniped or turtle. Avoid sudden changes in speed or direction. Communicate the sighting to the SEA and other vessels.	Daily reports and communication logs verify that vessels reduced speed, maintained a 150 m distance, and followed proper positioning and communication procedures when a dolphin, pinniped, or turtle was observed within proximity.
Shutdown procedures	Shutdown the sound source if medium-large flocks of foraging birds are observed within 500 m of the source. Start-up procedures can commence when the seismic source is > 500 m from flocks of foraging birds.[1]	Observation logs, incident reports, and operational records confirm that the sound source was promptly shut down when required by procedural conditions within specified distances, with documentation showing compliance for each shutdown event.
	Shutdown the sound source if any pinniped, dolphin, or turtle is detected within 500 m of the source (except for bow riding dolphins).	
	Shutdown the sound source if any whale is observed within 2000 m of the sound source.[2]	

[1] This measure has been adopted to protect foraging penguins and other diving birds following consultation.

[2] Based on previous seismic surveys, CGG has chosen to only implement a shutdown zone and not a low power zone to provide another level of protection to all whale species. This is based on the low power zone for whales as detailed in the EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales (Policy Statement 2.1).

Control Measures	Environmental Performance Standards	Measurement Criteria
	If there is an "unidentified baleen whale" within 5 km of the seismic source, this will trigger a shutdown for one hour, or until daylight if at night.	
	Shutdown the sound source upon confirmed detection of any BW within 5km for one hour.	
	Shutdown the sound source if a Southern Right Whale is detected at any time, from any platform, until 24 hours of no detections have occurred.	
	If there are exceedances (as defined in the procedure) of impulsive noise over 120 dB, detected by any SSV buoy the sound source will be shut down. In October, if there have been 14 consecutive days without a SRW detection, the shutdown trigger for repeated impulsive-noise exceedances increases to 140 dB SPL.	
Night-time and low visibility procedures	Start-up may be commenced as per the Soft-Start Procedure if there have not been 3 or more whale instigated shut-down situations during the preceding 24-hour period.	Daily reports confirm that sound source start-up was conducted per the Soft-Start Procedure, with adherence to additional requirements for night-time or low visibility conditions.
	Operations may proceed if there have not been 3 or more whale instigated shut-down situations during the preceding 24-hour period.	
	If there is a SRW detection at night the sound source will be shut down until daylight.	
	If there is a confirmed blue whale PAM detection within 5 km at night the sound source will be shut down until daylight.	
Helicopter Operation Procedure	Helicopters will not fly lower than 1650 ft when within 500 m horizontal distance of a cetacean, except when landing or taking off and will not approach a cetacean from head on.	Flight logs and operational records confirm that helicopter operations aligned with procedural requirements to minimize disturbance to marine fauna.
End-of-Survey Procedures	Shutdown and do not recommence the survey 90 days after the survey started.	Daily reports confirm the start date of the survey (i.e first day of acquisition) and MFO daily reports show records of observations that confirm if the end-of-survey criteria have been met.

Control Measures	Environmental Performance Standards	Measurement Criteria
Drones for coastal aerial surveillance	Each drone must be capable of detecting and visually identifying a Southern Right Whale at a minimum slant range of 25 km using the H30T telephoto camera under clear atmospheric conditions.	Documented pre-season and mid-season validation tests showing the H30T camera can resolve a 10–18 m whale body at ≥12 pixels across at 25 km slant range and that line-of-sight remains unobstructed out to the geometric horizon at ≤120 m AGL. Manufacturer specifications and test reports confirming stable imaging performance within the defined operational wind envelope. Archival of all SRW detection imagery with embedded time, date, and GPS metadata, as verified through periodic QA checks of flight logs and image EXIF data.
	The drone's camera system must provide a minimum of 12 pixels across the critical dimension of a whale at any distance where a detection is claimed, consistent with Johnson/NATO identification criteria.	
	The drone must maintain sufficient gimbal and sensor stability to collect usable detection imagery (optical or thermal) in all operational wind conditions up to the Sub-Optimal threshold of 20 kt sustained winds and 25 kt gusts.	
	All imagery used to verify SRW presence must include time-stamped and geolocatable metadata automatically embedded by the drone's onboard systems.	
Coastal Whale Monitoring Teams (WMT)	For the duration of the SRW season, at least one WMT (1 x MFO and 1 x drone pilot) will perform daily coastal monitoring of the region between Cape Bridgewater and Cape Otway according to the applicable weather-dependent deployment plan.	Daily records verify that coastal monitoring between Cape Bridgewater and Cape Otway was completed by a WMT (1 MFO and 1 drone pilot) in line with the applicable weather-dependent deployment plan.
	When the survey commences until 31 October, at least three (3) WMT's will perform daily monitoring in accordance with Appendix G5 – SRW Coastal Monitoring Programme Implementation Plan.	
	Each WMTs must complete full daily coverage of their assigned coastal zones according to the applicable weather-dependent deployment plan,	
SRW Reproduction BIA - Coastal Detection Shutdown and Restart Procedures	All confirmed SRW detections must be communicated to the SEA immediately, with shutdown initiated within five minutes when the survey is acquiring.	SRW detection log confirms presence in the reproduction BIA. Comparison between acquisition log confirms full power at time of detection. Shutdown log confirms the sound source was shut down in response.
	All unconfirmed SRW detections must be referred to the Whale Expert Panel within two hours, with WMT deployment to verify the sighting within 12 hours where conditions allow.	

Control Measures	Environmental Performance Standards	Measurement Criteria
	Only restart the survey in accordance with the start-up procedures after 24 hours of no detections of SRW from any platform.	
	Conduct aerial surveillance flights with drones at least once per week off Cape Nelson to confirm arrival of blue whales into the region.	
Consultation Management System	Consult with local commercial divers and dive schools to raise awareness for and institute a Diving SIMOPS Plan.	Consultation records show best endeavours to provide the opportunity for local divers to participate in the scoping and implementation of the Diving SIMOPS Plan.
Citizen Science Observations	Maintain open communications with the Arthur Rylah Institute to share information about SRW detections and monitoring.	Consultation records show CGG's efforts to share information on SRW presence and behaviours in the reproductive BIA.
Satellite Detection Technology	Before the survey commences, undertake trials of satellite detection technology for detecting the presence and movements of SRW in the reproductive BIA.	A report of the trial will be made with recommendations for CGG to consider how the detection technology might complement the existing detection methods.

1.9 Light Emissions

Environmental Performance	
Environmental Performance Outcomes	**Measurement Criteria**
Biologically important behaviours within a BIA or outside a BIA can continue while the activity is being undertaken.	Behavioural observation records, remote monitoring, or third-party assessments confirm no statistically significant reduction or alteration in the frequency, duration, or success of biologically important behaviours within or outside the Biologically Important Area (BIA), with documentation showing comparisons to baseline behaviour data.
Light emissions will be reduced to minimum levels for safe operations and navigation in accordance with the Vessel Management Plan	Operational lighting logs and environmental audits confirm adherence to the Vessel Lighting Management Plan, with records showing that lighting intensity and directional use were minimized to the lowest safe levels during the activity.
Light emissions are managed to avoid displacing turtles or disrupting nesting, foraging, or migratory behaviours within or near biologically important areas.	Behavioural observation reports, environmental audits, and independent assessments indicate no observable impact on critical life-cycle behaviours, validated by pre- and post-activity comparisons and supported by records of mitigation measures implemented during activity.

Control Measures	**Environmental Performance Standards**	**Measurement Criteria**
CGG Marine Assurance System	Ensure that all vessel lighting complies with the Vessel Lighting Management Plan to minimize light emissions to levels required for safe operations and navigation.	Operational lighting logs and environmental audits confirm that lighting intensity and direction align with the Vessel Lighting Management Plan.
Survey Environment Advisor	Monitor and advise on vessel light emission practices to ensure compliance with the Vessel Lighting Management Plan.	Daily reports verify that light emissions are managed according to the Vessel Lighting Management Plan, with documented adjustments made as necessary.

2 Document Control

Version	Date of Revision	Author/Reviewer	Summary of Changes
0.0	29 March 2023	MS	Template created.
0.1	9 April 2023	MS	Community Liaison Program added.
0.2	5 May 2023	MS	Project vessels, IMS risk assessment procedure, marine assurance system, and bunkering procedure added.
0.3	7 May 2023	MS	Sail line procedure added. Reframed all measurement criteria to be more detailed.
0.4	28 August 2023	MS	Marine mammal adaptive management plan, and marine mammal observers added.
0.5	14 September 2023	MS	Acquire seismic on paper, and OPEP/OSMP added. Added column to EPSs to show whether the standard was adopted because of the consultations.
0.6	24 September 2023	MS	Moved into Regia MSS document template. Cultural heritage protection program, and Adjustment protocol added. Modified throughout to include all requirements from impact and risk assessments.
0.7	2 October 2023	PR/LT	CGG Review.
1	20 December	MS	Updated following CGG review and consultations with relevant persons.
2	15 May 2024	MS	Updates following public comment and the adoption of additonal environmental performance standards for spotter vessel, an additional MFO/PAM Operator.
3	28 October 2024	MS/CT/AH	Updated following NOPSEMA assessment.
4	16 April 2025	MS	Updated following NOPSEMA OMR 1 Letter
5	9 December	CT/RH/EO/MS	Updated following NOPSEMA OMR 2 letter and consequentail changes between submissions.

Annex 1: Public Comment

The following consultation feedback was received since the beginning of the public comment period starting 25 January 2024. As this feedback relates to a control measure, the Fauna Management Plan (FMP), details of how this feedback has been incorporated into the FMP are stated in this parent document, in Table G1-1 below.

Table G1-1 - Public comment input

Matter	Matter ID	Changes made arising from public comment
Matter: Impacts on fin and sei whales	M36	EP Appendix G2 (Fauna Management Plan) has been updated to include species exhibiting biologically important behaviours, being Fin and Sei Whales.
Matter: MFOs/MMO's do not have a 360-degree view, the use of one MFO/MMO is inadequate.	M45	CGG has considered these claims and has determined that additional MFO coverage is appropriate to further mitigate the potential for whales to go undetected within the 3 km observation zone. Consequently, CGG has has updated EP Appendix G2 (Fauna Management Plan), EP Appendix F3 (Acceptability Assessment) and EP Appendix G1 (Environmental Outcomes) to include an additional MFO/ PAM operator will be present on the vessel to support fatigue management. In addition to the two MFOs on the seismic vessel, two dedicated, trained and experienced MFOs will be onboard a dedicated spotter vessel at all times. In addition, officers of the watch on the attending support vessels will be trained to identify whales during daylight hours to support the visual detection of marine mammals.
Matter: Limitations of MFOs/MMOs when detecting marine mammals	M43	CGG has considered these claims and has updated EP Appendix G2 (Fauna Management Plan), G1 (Environmental Performance) and F3 (Acceptability Assessment) to include an additional MFO/ PAM operator to ensure fatigue management is appropriately addressed with allowance for 24/7 coverage.
Matter: The use of two PAM operators is inadequate.	M49	
Matter: Impacts on whales and whale songlines	FN05	CGG has considered these claims and the identified potential impacts and their measures concerning First Nations cultural values regarding whales has been added to Appendix G2, Fauna Management Plan, Annex 2.
Matter: Impacts to dive-based fisheries	F17	CGG has considered this claim and, based on the updated secondary sound modelling, has updated EP Appendix E8 (Impact Assessment – Underwater Sound: Surfers, Divers and Swimmers), Appendix A2 (Description of the Activity) and M#01: Activity limitation, to reflect that the sound source will not be discharged at full power from areas which result in an exceedance of the safety criterion for recreational divers, surfers and swimmers along the coastline. CGG has also made updates to modelling in Appendices (E1, E2, E3, E4, E5, E6, E7, F1 F3, G1 and G2.).
Matter: Mitigating sound exposure impacts to seabirds	B15	Clarification has been provided in EP Appendix E5 (Impact Assessment – Underwater Sound: Birds) and EP Appendix G2 that the acoustic source will be reduced to the low power setting if flocks of foraging birds are observed by the Marine Fauna Observer within 500 m of the source. Full power can commence when the seismic source is > 500 m from any flocks of foraging birds.

Annex 2: Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table G1-2. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table G1-2 - Objections and Claims raised from consultation

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4374	Claims that the Regia survey conflicts with the SRW National Recovery Plan, which stipulates that actions within or near southern right whale BIAs and HCTS must not prevent the whales from utilizing the area or cause auditory impairment. Additionally, the plan requires that such actions minimize the risk of behavioral disturbance.	Event ID 6529 - CGG has outlined several commitments to ensure compliance: • The proposed activity will occur before SRWs arrive or after they depart, with pre-survey monitoring in place to reasonably detect SRWs migrating to or from the reproductive BIA, and pre-start conditions if SRW'd are detected. • The Regia MSS EP includes extensive detection measures, covering multiple methods to detect SRWs within a 15 km radius, exceeding the requirements in the SRW National Recovery Plan's Policy Statement 2.1. • CGG will shut down the sound source if a SRW remains resident in the 15 km ensonified area for more than 12 hours or if a SRW cow and calf pair is observed within 10 km of the sound source. • SRWs within the reproductive BIA will not be exposed to underwater noise levels exceeding thresholds for permanent threshold shift (PTS), temporary threshold shift (TTS), or behavioral response thresholds. Further details on the control measures are available in Appendix G1 of the Regia MSS EP.	6410
4395	The project is adjacent to Warrnambool's Logans Beach Whale Nursery for Southern Right Whales and upstream of the Bonney Upwelling Key Ecological Feature, which could be affected.	The titleholder acknowledges this and has spent two years preparing a comprehensive Environmental Plan (EP). This process included ongoing consultations with communities and individuals, summarizing the EP into webinars, information sheets, and holding in-person meetings. The team recognizes the Otway region's marine environment as both spectacular and dynamic and believes environmental assessments must be thorough and detailed to respect its importance. Impacts are assessed in the Environmental Plan (EP) and can be found in Appendix E7 and F3. Measures to minimise adverse impacts to whales and ensures the Regia MSS does not prevent SRW and BW utilising their BIAs include: No discharge of the sound source in January, February, March (when the upwelling is in its peak month), the sound source will only be discharged in the Pygmy Blue Whale foraging BIA	6432

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		when low numbers of Pygmy Blue Whales and other foraging whales are in the BIA off Otway, and no discharge of the sound source within 15 km of the Southern Right Whale Reproduction BIA or Habitat Critical to Survival (HCTS) while Southern Right Whales are present in the BIA and HCTS. The full list of measures is included in Appendix E7 Section 9 and G1. The claim that some krill larvae from the proposed Regia MSS area may reach upwelling regions is acknowledged, but there is no evidence to support the idea that this area is a key source for krill in the Bonney Upwelling system. Krill larvae from across the broader region could also end up in the upwelling area. No cause-and-effect pathways have been identified that show the Regia MSS area as uniquely important for krill supply in the region. (Event ID 6815)	
4405	Objects to the assertion that ± 50% interannual variation in upwelling extent, mostly climate-driven, has not constrained whale population recovery.	Whales have evolved to handle significant fluctuations in their food source, with some years yielding more biomass and others less. The Regia EP provides references to support this argument. Upon closer examination of Wiedenmann et al. (2011), which the stakeholder cites, it becomes clear that while whales can adapt to decreases in krill abundance in a particular area, the net effect on their population vital rates is negligible. Wiedenmann et al. (2011) also suggest that blue whales may adjust their foraging behaviors in response to changes in local environmental conditions, mitigating the impacts of declines in krill abundance. They note that blue whales exploit different feeding areas based on large-scale prey abundance and can concentrate in productive areas when prey is scarce, such as during El Nino years (Benson et al. 2002, Bailey et al. 2010). Furthermore, Wiedenmann et al. (2011) propose that blue whales are better equipped to cope with environmental changes than species with more restricted foraging areas, thanks to their adaptive foraging behaviors and ability to travel long distances in a foraging season. (Event ID 6815)	6432
4454	Claims uncertainty due to reliance on fixed buoy, as this method is proposed as the sole strategy beyond visual and towed PAM detection ranges, means risks to threatened species have not been reduced to as low as reasonably practicable, and that CGG's environmental management system is not effectively implemented.	The EP acknowledges the limitation regarding guaranteed triangulation with the fixed buoy acoustic detection system. However, the system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions. This combination of measures supports the	EVT132

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	Stakeholder argues that the system's effectiveness is undermined because triangulation of detections is not guaranteed and the testing protocol requires only a single successful unit test before deploying an array.	implementation of the defined shutdown zones and activity limitations, thereby managing risks to ALARP and achieving acceptable environmental outcomes for species like BW and SRW. To note, an incorrect reference was used by the stakeholder.	
4455	The objection argues that the Environmental Plan's reliance on "near real time" data transmission between Acoustic Detection Monitoring operators and seismic operators is flawed because the term is undefined, with no limits on latency or provisions for equipment and communication failures in offshore conditions. The objection states that given the speed of whale movement and the immediacy of sound exposure, the lack of clear parameters renders the measure unreliable. Without evidence that the system can function effectively, the objection maintains that the control cannot be shown to reduce impacts to ALARP, and the ambiguity means the plan fails to meet regulatory requirements for appropriate, measurable environmental performance standards.	In Appendix G1 the EP describes standards for the control measures, including: One ADM Operator to always listen for LF cetacean calls for the duration of the survey and immediately communicate positive detections of LF cetaceans to the Environmental Officer. Further information on the towed and tethered ADM is contained in Appendix C7. This has not been made publicly available due to being commercial in confidence. In addition, the system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions. This combination of measures supports the implementation of the defined shutdown zones and activity limitations, thereby managing risks to ALARP and achieving acceptable environmental outcomes for species like BW and SRW. To note, an inncorrect reference was used by the stakeholder.	EVT132
4456	The objection contends that CGG's proposed tethered buoy Passive Acoustic Monitoring (PAM) system is an unproven and unreliable primary mitigation measure for detecting marine mammals beyond the range of visual observation and towed PAM. It highlights contradictions within Appendix F5, which claims such systems have been used in seismic surveys while also stating their application in this context is "unknown." Published research shows only limited use in very different settings, such as large-scale Arctic noise monitoring arrays, rather than real-time whale detection. The objection concludes that relying on this experimental technology as a primary safeguard does not meet the regulatory requirement to reduce environmental impacts to ALARP, given the absence of evidence demonstrating its effectiveness in comparable operational environments like the Otway Basin.	Regarding the alleged contradiction in F5: The EP describes both the potential and general use of PAM systems deployed near the survey area (which can include buoys) during seismic surveys for real-time monitoring, and then a detailed, vendor-specific assessment of the actual documented history of particular tethered buoy PAM products. As stated in the EP, the PAM system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions. The tethered buoy is also undergoing real-world testing, prior to any activity. This combination of measures supports the implementation of the defined shutdown zones and activity limitations, thereby managing risks to ALARP and achieving acceptable environmental outcomes for species like BW and SRW.	EVT132

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4457	The objection references NOPSEMA's 2019 inspection report for the Otway Basin 2DMC Marine Seismic Survey, which concluded that published scientific evidence does not support passive acoustic monitoring (PAM) as an effective method for detecting Whales, including foraging Blue Whale and lactating females with calves, when the system is towed directly behind an active seismic or support vessel, stating that CGG has not addressed known limitations and therefore is inconsistent with the precautionary principle without providing peer-reviewed evidence that addresses the limitations previously identified.	The 2019 comments from NOPSEMA are related to a different proposal, with an alternative towed PAM system. The Sercel Quietsea PAM system has been accepted and used during Australian seismic surveys. In addition, as stated in the EP, the PAM system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions.	EVT132
4499	GMTOAC notes that the April 2025 EP allows CGG a 90-day continuous window to complete the survey, with a maximum of 60 days of active seismic acquisition. GMTOAC claims that this limited timeframe will not allow CGG to meaningfully implement ongoing review and improvement measures intended to reduce harm to Karntubul.	Appendix G1 outlines that the Environment Officer is responsible for recording, assessing, and addressing environmental incidents within required timeframes, implementing corrective actions, and ensuring continuous compliance through daily reports, weekly audits, and incident reviews. Non-compliance triggers immediate inspection and corrective action, and objections or claims are assessed within 48 hours, with any necessary protections implemented promptly. This framework also illustrates how the proposed CVA project (Event ID EVT337), including the Sea Country Protection Plan, could involve Gunditjmara and supports CGG's position that the CVA should extend before, during, and after the activity.	EVT352
4503	GMTOAC claims inconsistencies and contradictions within CGG's April 2025 EP, particularly regarding the enforceable activity limitations intended to reduce risks to Southern Right Whales and Blue Whales. GMTOAC notes that NOPSEMA previously identified this issue in 2024, stating that duplication and inconsistencies left "no single source of truth" for assessing the EP. GMTOAC believes this fundamental flaw remains unresolved in the April 2025 version, undermining the reliability and enforceability of CGG's proposed control measures. GMTOAC provided the following examples: • Although the EP states that Appendix A2 contains the "final" list of enforceable activity limitations, it later states that Appendix G1 is "controlling" and overrides other lists. GMTOAC notes that many measures appear in one appendix but not the other, and others contain conflicting descriptions.	CGG rejects claims of inconsistency between Appendices A2, G1 and G2, however the stakeholder may have misunderstood the distinction between activity limitations and control measures. Appendix A2 sets enforceable activity limits, measures that restrict operations to avoid or reduce impacts—while Appendix G1 details the control measures, performance standards, and procedures used to implement those limits in line with NOPSEMA's definition of controls. A2 and G1 serve different but complementary purposes, with A2 defining mandatory constraints and G1 outlining the operational steps required to meet them, together ensuring SRWs are protected from behavioural disturbance. G1 and G2 are also complementary rather than conflicting: G2 defines roles and responsibilities, while G1 outlines the controls and measurement criteria used to verify them. CGG maintains that the Environmental Officer and Survey	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	For example, Appendix A2 and Appendix G1 both outline conditions for discharging the sound source in the Southern Right Whale reproduction BIA, but the conditions differ in scope and detail. GMTOAC warns that such internal discrepancies create confusion for vessel crews and contractors and could jeopardise the species the measures are intended to protect. • GMTOAC highlights conflicting and unclear role descriptions across appendices, particularly for key positions such as the Survey Environment Advisor and Environmental Officer. Responsibilities differ between Appendix G1 and G2, creating uncertainty about who is accountable for shutdowns, communication, monitoring, aerial surveys, technology trials, and 24/7 oversight. GMTOAC notes that the EP does not clarify whether multiple staff will be appointed to fulfil these demanding roles. • Several measures appear in one appendix but not another. For instance, Appendix G2 requires pre-survey aerial surveys, but this requirement is absent from the controlling Appendix G1. Similarly, Appendix G1 includes commitments to trial drone and satellite detection technologies, but these are not included in the Fauna Management Plan, leaving unclear whether they are required or how their effectiveness will be assessed. • GMTOAC claims that these inconsistencies make it difficult, if not impossible, for operators to understand or correctly implement the required measures, with potential serious consequences for Nyamat Mirring, its ecosystems, and culturally significant species such as Southern Right Whales and Pygmy Blue Whales. They also express concern that CGG's qualitative measures, such as determining whether disturbance is "acceptable", lack objective criteria and fail to involve the Whale Expert Panel or reference Recovery Plan standards.	Environment Advisor roles are clearly aligned across both appendices, collectively providing continuous oversight, shutdown authority, monitoring coordination, and expert engagement. CGG also notes that activity-level commitments, such as drone and satellite detection trials, rightly sit in G1, while position-specific duties like aerial surveys sit in G2. It states that the EP is intentionally structured so A2, G1 and G2 each fulfil distinct functions within an integrated management system, providing operators with clear instructions, objective decision-making criteria, and independent oversight from the Expert Panel. CGG concludes that this framework ensures transparent, robust management and effective protection of Southern Right Whales and Pygmy Blue Whales.

1 Introduction

The purpose of this Fauna Management Plan (**FMP**) is to provide details about how the Regia Marine Seismic Survey (Regia MSS) will be carried out in a manner by which the environmental impacts from underwater sound and the risk of a collision to fauna will be reduced to as low as reasonably practicable (**ALARP**) and will be of an acceptable level.

This FMP is a control measure to manage impacts to fauna from the following environmental aspects associated with the Regia MSS:

- Vessel collisions with fauna
- Underwater sound emissions

This FMP will ensure that the Environmental Performance Outcomes (**EPO**s) from the Regia MSS Environment Plan (**EP**) relevant to fauna will be achieved.

1.1 Pre-Start Up Procedure

The following criteria must be met for commencing soft starts.

- Monitoring must be carried out, starting 24 hours prior to any start-up of the sound source during the day.
- A Soft start can only commence if there have been:
  - No detections of any whale within 2 km in the preceding 60 minutes.[1]
  - No detections of dolphins, pinnipeds, or turtles within 500m (except for bow riding dolphins).

CGG acknowledges that there are less methods available for marine mammal detection during hours of darkness and low visibility. The precautionary design of the pre-acquisition criteria has addressed the inability to acquire visual observations by MFOs during these times by integrating observations and detections over a longer period for SRW and BW.

1.2 Important Foundational Information

Several informative statements have been made in the development of this FMP as detailed below, to assist users in interpretation and implementation of the FMP. If any aspect of this FMP is unclear, users should consider these statements in determining what action, if any, to take.

1) At all times and without exception, the safety of personnel, other marine users and vessel management takes priority over the requirements described in this FMP.

2) Vessel Masters, CGG Site Representative, Party Chief and Survey Environment Adviser (**SEA**) will work together to minimise impacts to fauna in the context of safety requirements.

3) Conservatism has been built into how the Activity Action Zone (**AAZ**) and Shut Down Zone (**SDZ**) distances have been determined to address management of underwater sound emission risks taking account of detection accuracy, weather conditions, uncertainty in the impact assessment, and whale behaviour.

4) Acoustic modelling was undertaken for several different survey line locations, and several different underwater sound effect criteria were used to interrogate model outputs. The SDZ distances are based on the furthest distance to the underwater sound effect criteria from the acoustic modelling utilising revised survey layouts for the Regia MSS and species-specific behavioural characteristics (Vallarta & Eickmeier 2025).

[1] This precautionary design addressed the inability to visually observe whales by extending the visual observation window in the daytime to beyond typical dive times (~30 min) of deep diving species such as blue whales. The design of pre-acquisition criteria has also been expanded to address concerns and insights raised through consultation.

5) Policy Statement 2.1 details if the likelihood of encountering whales is low, the chance of a seismic survey having a significant impact on a whale species should be minimal, provided that the proponent and the operator of the seismic survey adopt the measures outlined in Part A: Standard Management Procedures.

While every attempt has been made to limit ambiguity in the FMP, if there is a lack of clarity, or residual uncertainty, about the instructions in this FMP users are required to take actions in a manner that manages impacts to fauna, are precautionary, and will ensure impacts and risks are within the defined acceptable levels specified in the Regia MSS EP.

2 Implementation

2.1 Roles and Responsibilities

Figure G2-1 shows the Regia MSS organisation structure relevant to the FMP with responsibilities for each role detailed in Table G2-1.

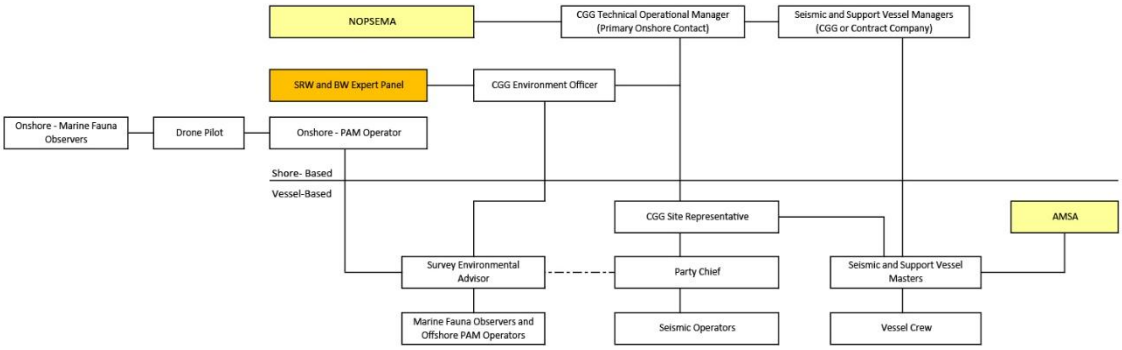

Figure G2-1: Regia MSS Organisation Structure Relevant to the FMP

Table G2-1 details the roles and responsibilities for the implementation of the FMP and details the records and reporting requirements.

Table G2-1 - Roles and Responsibilities for the FMP

Role	Responsibility
CGG Technical Operations Manager	Provide sufficient resources to implement the FMP.
CGG Environment Officer	Coordinate the SRW and BW Expert Panel and provide updates daily when SRW and BW detections and associated shutdowns occur.
	Develop the FMP Implementation Plan with input from SRW and BW Expert Panel, CGG Site Representative, SEA, Party Chief, MFOs, and PAM Operators.
	Collection and review of new relevant research, if any, will be completed within one month of the commencement of the Regia MSS. A risk assessment and management of change process will be instigated if outcomes of relevant research suggest that there has been a significant change to the context of the Regia MSS that may lead to an update to the FMP.
	Coordinate and document the review of effectiveness and compliance with the FMP.
	A review of the effectiveness and compliance with the FMP will be undertaken within one week of commencement of the Regia MSS and thereafter every four weeks while the Regia MSS is being undertaken.
	Ensure the Regia MSS induction provides an overview of the FMP.
	Review the FMP Daily Report to ensure detection and actions meet the requirements of the FMP.
	Provide support to the Survey Environment Adviser as required.
SRW and BW Expert Panel	Provide advice on the FMP Implementation Plan prior to commencement of the survey such that any recommendations can be adopted, as appropriate.

Role	Responsibility
	In considering the FMP Implementation Plan prior to commencement of the survey, the SRW and BW Expert panel will: Provide advice to optimise flight path and observer effort for detection of BW and SRW during aerial survey(s) to be instigated prior to commencement of the Regia MSS. Advise when aerial surveys are to be instigated during survey acquisition. Consider daily reports and monitoring of SRW and BW detections and associated shutdowns, if they occur, and recommend further management actions, as required. The panel will also help confirm the species of any 'unidentified whale' detections during the survey.
	Provide advice to CGG in relation to actions to take in connection with SRW and BW detections and associated shutdowns.
CGG Site Representative	Accountable for implementation of this plan.
	Provide records of FMP training and activity-specific environmental induction to SEA.
Survey Environment Adviser	Coordinate MFO, PAM and SSV observations/detections and provide advice to the Party Chief of required actions.
	Provide advice to the Party Chief and Vessel Masters (or delegate) on the requirements of the FMP.
	Develop daily FMP Report of MFO, PAM and SSV observations/detections and actions taken.
	Liaise with CGG Environment Officer to determine when aerial surveys are triggered and SRW and BW Expert Panel input required.
Party Chief	Maintain open communication with SEA.
	Communicate the status of the seismic activities (i.e. deployment, testing, soft start, shutdowns) to the SEA.
	Decide whether actions within the FMP can safely be implemented and act accordingly.
	Document reasons for not following the FMP Plan, if required.
	Provide input into the review of effectiveness and compliance with the FMP.
Drone Pilot in Command	Operate and manage all shore-based drone surveillance flights to detect, verify, and report Southern Right Whale presence in accordance with approved monitoring and safety protocols.
Vessel Masters	Maintain open communication with SEA.
	Decide whether actions within the FMP can safely be implemented and act accordingly.
	Document reasons for not following the FMP, if required.
	Provide input into the review of effectiveness and compliance with the FMP.
	Provide records of FMP training and activity-specific environmental induction for vessel crew to SEA.
Marine Fauna Observers (MFOs) **PAM Operators (Onshore and Offshore)**	Provide input into the development of the FMP Implementation Plan.
	Undertake observations/detections and immediately report whale and other fauna (MFO only) observations/detections to the SEA.
	Provide input into the review of effectiveness and compliance with the FMP.
	Submit daily reports to the SEA.
	Monitor data from SSV Buoys
Seismic Operators and Vessel Crew	Undertake Regia MSS induction that provides an overview of the FMP.
	Communicate whale sighting to SEA immediately, supported by relevant information where available (e.g. latitude and longitude, time of sighting, no. of whales).

2.2 Records and Reporting Requirements

Records and Reporting Requirement	Responsible	Description
Pre-Regia MSS FMP implementation review	CGG Environment Officer	Documentation and records of evidence of outcomes of engagement with the SRW and BW Expert Panel. Documentation and records of evidence to show that the FMP implementation requirements are in place prior to the commencement of the Regia MSS.
Regia MSS Induction records	CGG Site Representative Vessel Masters	Regia MSS induction records.
MFO and PAM operator qualifications	CGG Environment Officer	Resumes Training certificates
Communication of the FMP Plan to those who have responsibilities to implement the plan.	CGG Environment Officer	Signed record that roles responsible for implementation and actions in this plan have read and understand.
Daily observation/ detection report.	MFO PAM Operator	Report detailing marine fauna observations and whale detections taken as per the FMP, and reasons actions not taken.
Daily FMP Report	SEA	Report detailing marine fauna observations and whale detections and actions taken as per the FMP, and reasons actions not taken.
Review of effectiveness and compliance with the FMP	CGG Environment Officer	Documentation of efforts for collection and review of new relevant research. Documentation of risk assessment performed, and management of change process instigated, if any new research outcomes suggest that there has been a significant change to the context of the Regia MSS. Documentation of daily reports to the SRW and BW Expert Panel of SRW or BW observations and detections and associated shutdowns, if they occur. Documentation and any actions from the review of effectiveness and compliance with the FMP.
End of Survey Report	SEA	Report detailing marine fauna observations and whale detections, actions taken as per the FMP, and reasons actions not taken.
Compliance and Sighting Reports	SEA	Sightings and observations from all detection methods used as well as survey information are to be recorded within the DCCEEW Cetacean Sightings Application (CSA). Upon completion of the survey the information entered into the CSA is to be exported as a text file and provided to the CGG Environment Officer.
	CGG Environment Officer	Submit CSA text file to sightingsdata@aad.gov.au within two months of survey completion.

2.3 Detection and Observations Methods

Details of the detection and observation methods can be found in Section 9.3 of Appendix E7. In short, detections can occur from any of the following sources:

1. Seismic vessel
    a. Marine Fauna Observers
    b. PAM Detectors
    c. Officers of the Watch (verified by MFO/PAM Detector)
2. Aerial Drone Surveillance
3. Coastal Observers
4. Spotter vessel
    a. Marine Fauna Observers
    b. PAM Detectors
5. Other marine users
    a. Third parties with on-water activities (passing ships, petroleum titleholders, fishers)
    b. Offshore wind proponents with ADM technologies
6. State agencies/research institutions
    a. Arthur Rylah Institute – Citizen Science Program
    b. DEECA – Research programs
    c. Blue Whale Study
7. Local citizen science platforms

These multiple approaches provide extensive coverage for whale detections out to the required ranges.

3 Protection Procedures – At Sea

In the context of the Regia MSS, it is acknowledged that there are inherent challenges in detecting whales. Given the range of species, behaviours, and habitats, it requires a multifaceted approach.

These procedures apply to all marine mammals, however specific measures relating to sound and BWs and SRWs are discussed in Section 4 and Section 5.

Unless otherwise stated, all low frequency cetacean detections are assumed to be either a SRW or BW until confirmed otherwise, and the below procedures applied accordingly.

3.1 Start Up Procedures

A soft start will be implemented in the following circumstances:

1. When the sound source is turned on initially once all pre-start up criteria have been met.

   This type of soft start gradually increases the seismic source over a 30-minute period. It is anticipated that during this period mobile species including dolphins, seals, and turtles will move away from the sound source before it is at full power, providing them a level of protection. Once the source passes, animals will be free to move back into the habitat that they departed from.

2. When the sound source is in low power mode due to the presence of medium to large flocks[2] of foraging birds[3] within 500 m of the sound source.

3. When the sound source is in low power mode during line turns or otherwise transiting the Operational Area.

3.2 Start Up Delay Procedures

- If medium to large flocks of foraging birds is detected within 500 m of the sound source during the soft start procedure, the acoustic source will be set to low power mode and will not be ramped up until all pre-acquisition criteria have been met again. [Paragraph added in response to Matter B15].
- If any whale is detected in relevant SDZs during soft start procedures, the acoustic source will be shut down, and another soft start cannot commence until all pre-acquisition criteria have again been met.

3.3 Operating Procedures

- No vessel is permitted to operate at speeds of more than 6 knots during normal acquisition operations, to reduce the risk of vessel collision to whales.
- If a whale approaches within 300m of any vessel, the vessel must:
  - Reduce speed and maintain at least 300 m from the whale.
  - Position vessel to not impede the path of the whale.
  - Avoid sudden changes in speed or direction.
  - Communicate the sighting to the SEA and other vessels.
- If a dolphin, pinniped, or turtle approaches within 150m of any vessel, the vessel must:
  - Reduce speed and maintain at least 150 m from the dolphin, pinniped or turtle.
  - Position vessel to not impede the path of the dolphin, pinniped or turtle.

[2] There is no set number of birds that constitutes a flock. For the purposes of mitigating impacts/risks to all foraging birds, a small flock is considered a group of less than 20 birds, a medium flock a group of 20 to 100 birds and a large flock a group of over 100 birds. Mitigations should consider medium to large flocks of birds to minimise potential for negative impacts to occur. These impacts could include alterations to resting regime, alterations to foraging success, collision, alterations to group cohesion.

[3] Foraging, as it relates to birds, includes bird species participating in feeding behaviours such as plunging and diving.

- Avoid sudden changes in speed or direction.
- Communicate the sighting to the SEA and other vessels.

Figure G2-2 details the observation and detection distances for each observation and detection method. This approach ensures that information on the presence of whales and other species can be obtained at relevant distances. Figure G2-2 also illustrates deployment of aerial surveys that may provide additional information on the movement of SRW into and out of reproduction BIA and BW into and out of the Otway Region.

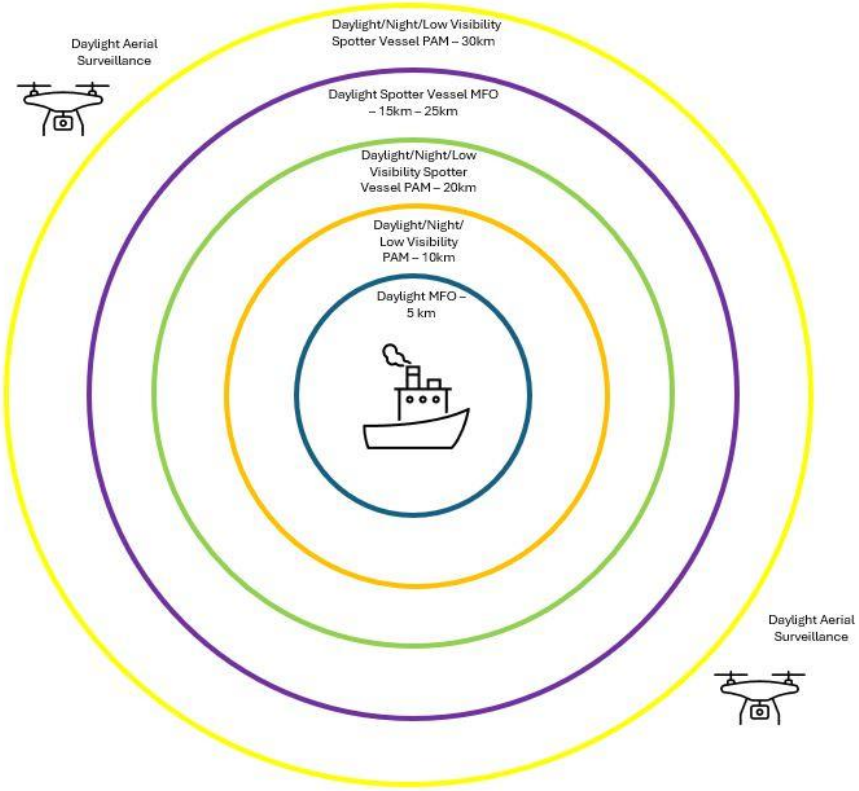

Figure G2-2 - Observation and Detection Zones

3.4 Shut Down Procedure

Once the seismic source is at full power, shut down of the sound source must occur if:

- Medium to large flocks of foraging birds are observed by the Marine Fauna Observer within 500 m of the source. Start-up procedures can commence when the seismic source is > 500 m from medium to large flocks of foraging birds.[4]
- Any pinniped, dolphin, or turtle is detected within 500 m of the source (except for bow riding dolphins).[5]

[1] Based on modelled PTS SEL24 distance for LF-cetaceans.

[4] This measure has been adopted to protect foraging penguins and other diving birds following consultation.

[5] Based on previous seismic surveys, CGG has chosen to only implement a shutdown zone and not a low power zone to provide another level of protection to all whale species. This is based on the low power zone for whales as detailed in the EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales (Policy Statement 2.1).

- Any whale[6] is detected within 2 km of the sound source.
- Any LF cetacean is detected within 9 km of the sound source[1]

3.5 Night-time and Low-Vis Procedures

At night-time or at other times of low visibility, the following measures apply for start-up and operations:

- **Start-up** may commence as per the Soft-Start Procedure if there have not been 3 or more whale instigated shut-down situations during the preceding 24-hour period.
- **Operations** may proceed if there have not been 3 or more whale instigated shut-down situations during the preceding 24-hour period.

3.6 Helicopter Operation Procedure

Helicopters will not fly lower than 1650 ft when within 500 m horizontal distance of a cetacean except when landing or taking off and will not approach a cetacean from head on.

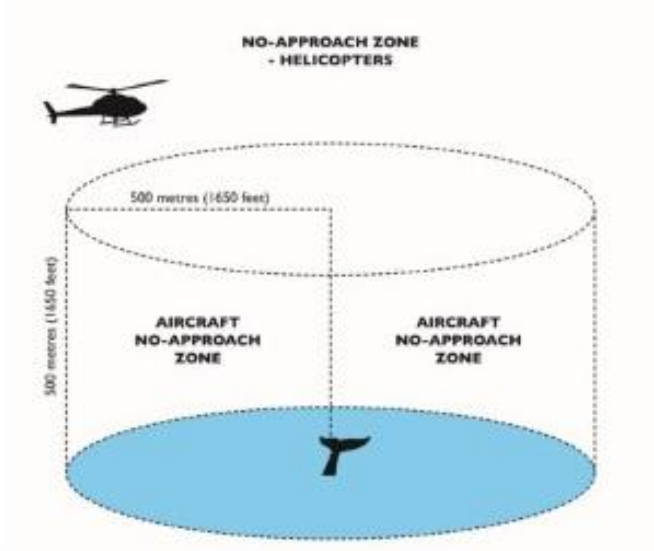

Figure G2-3 – Cetacean Approach Distances for Helicopters

3.7 End-of-Survey Procedure

The survey must stop if any of the following criteria are met:

- The activity started 90 days prior.

[6] As per Policy Statement 2.1 'Whales' includes baleen whales and larger toothed whales, such as, sperm whales, killer whales, false killer whales, pilot whales and beaked whales.

4 Protection Procedures – SRW Reproduction BIA

Pre-survey Procedures – Onshore MFOs and Drone Pilots in Command (PICs)

- Recruit, train, and brief all MFOs and PICs in SRW identification, behaviour recognition (especially mother–calf pairs), and use of optical equipment.
- Confirm observation sites along the coastline, ensuring safe access, unobstructed views, and coverage of key vantage points (e.g., Logan's Beach Whale Nursery, The Crags, Portland headlands).
- Calibrate and test equipment: binoculars, rangefinders, cameras, tablets/logbooks, and GPS units.
- Develop daily observation schedule and flight plans to ensure consistent coverage during daylight hours.
- Conduct trial observation days under different weather conditions to test protocols, and sighting forms.
- Establish clear reporting protocols for relaying sightings to the Survey Environment Adviser, including format, frequency, and escalation triggers.
- Establish contact with regional stakeholders, including DELWP, local whale groups, and other for data-sharing.
- Prepare guidance materials for field staff, including identification aids, behavioural cues, and reporting templates.

4.1 September Procedures – Onshore MFOs, PIC, and Onshore PAM Operators

- Conduct daily land-based observations and drone flights across designated coastal points.
- Communicate with and notify the Survey Environment Adviser immediately of any SRW sightings within the BIA as this will instigate a shutdown of the sound source.
- If an individual SRW or a SRW calf-cow pair is detected, record all sighting data, including:
  - Time, date, and location.
  - Group composition (e.g., mother and calf, lone adult).
  - Estimated distance from shore.
  - Behavioural state.
  - Environmental conditions (sea state, visibility).
- Note any observational limitations due to weather or sea state in daily logs.
- Track movement patterns to assess use of the BIA.
- Submit daily summary reports to the Survey Environment Adviser including full sighting and flight logs and absence confirmations.
- Participate in scheduled coordination briefings with marine fauna observers on the survey and spotter vessel to align detection data and mitigation responses.
- Ambient sound data from the SSV buoys will be monitored for any exceedances of impulsive noise over the 120 dB threshold.[7]

4.2 October Procedures – Onshore MFOs, PICs, and Onshore PAM Operators

SRWs have not been observed in the monitoring zone in October in any of the last 6 years however we recognise that does not mean SRW may not utilise the reproduction BIA in October and as such further observations to confirm presence/absence are required. However, the nature of the observer effort changes to reflect what the data indicates.

[7] The definition of exceedances can be found in Appendix G6.

The daily procedures in October are:

- Continue daily observation effort and drone surveillance with sufficient intensity to confirm presence or absence.
- Report any SRW sighting immediately to the Survey Environment Adviser, as this will instigate a shutdown of the sound source.
- If a SRW or SRW calf-cow pair is detected, record all sighting data, including:
  - Time, date, and location.
  - Group composition (e.g., mother and calf, lone adult).
  - Estimated distance from shore.
  - Behavioural state.
  - Environmental conditions (sea state, visibility).
- Use sighting trends from September to identify date thresholds for likely BIA departure.
- Continue daily logs, including 'no sightings' confirmations, environmental conditions, and any relevant incidental observations.
- Ambient sound data from the SSV buoys will be monitored for any exceedances of impulsive noise over the 120 dB threshold. In October, if there have been 14 consecutive days without a confirmed SRW detection, the shutdown trigger for repeated impulsive-noise exceedances increases to 140 dB SPL.
- Compile end-of-season summary report detailing observations, timing of departure, and any recommendations for future surveys.

4.3 SRW Spotter Vessel Procedure

This procedure governs the spotter vessel movements for monitoring SRWs and will be implemented from 16 September to 31 October. There are two modes for spotting:

Scouting Mode

The spotter vessel conducts reconnaissance 10[8] km ahead of the survey vessel before commencement of the survey and each line turn.

The spotter vessel is deployed at least 120 minutes before the survey vessel commences a new survey line.

The spotter vessel moves systematically up to 10[9] km ahead of the survey vessel and patrols areas adjacent to the Active Source Area along the expected line of travel of the survey vessel.

SRW Sentry Mode

The spotter vessel maintains a position adjacent to the SRW BIA to maximise SRW detection capabilities. This allows for proactive implementation of mitigation measures to minimise potential impacts to SRW when they are utilising the reproduction BIA. The spotter vessel will travel parallel to the seismic vessel, 20km away and on the shoreside of the seismic vessel, while it is acquiring lines 31-67 (Figure G2-4).

[8] The 10km separation distance while in Scouting Mode allows the spotter vessel to clear the first 20km (10km range of PAM on both seismic and spotter vessel) of the survey line, thus reducing the chance that a whale re-enters the previously cleared mitigation zone during the transition.
[9] The 20 km separation distance is informed by the performance of the PAM systems installed on both the seismic and spotter vessels, each capable of detecting whales at ranges of ~10 km. By positioning the spotter vessel 20 km away from the seismic vessel, CGG maximises combined detection coverage and enhances the likelihood of detecting Southern Right Whales.

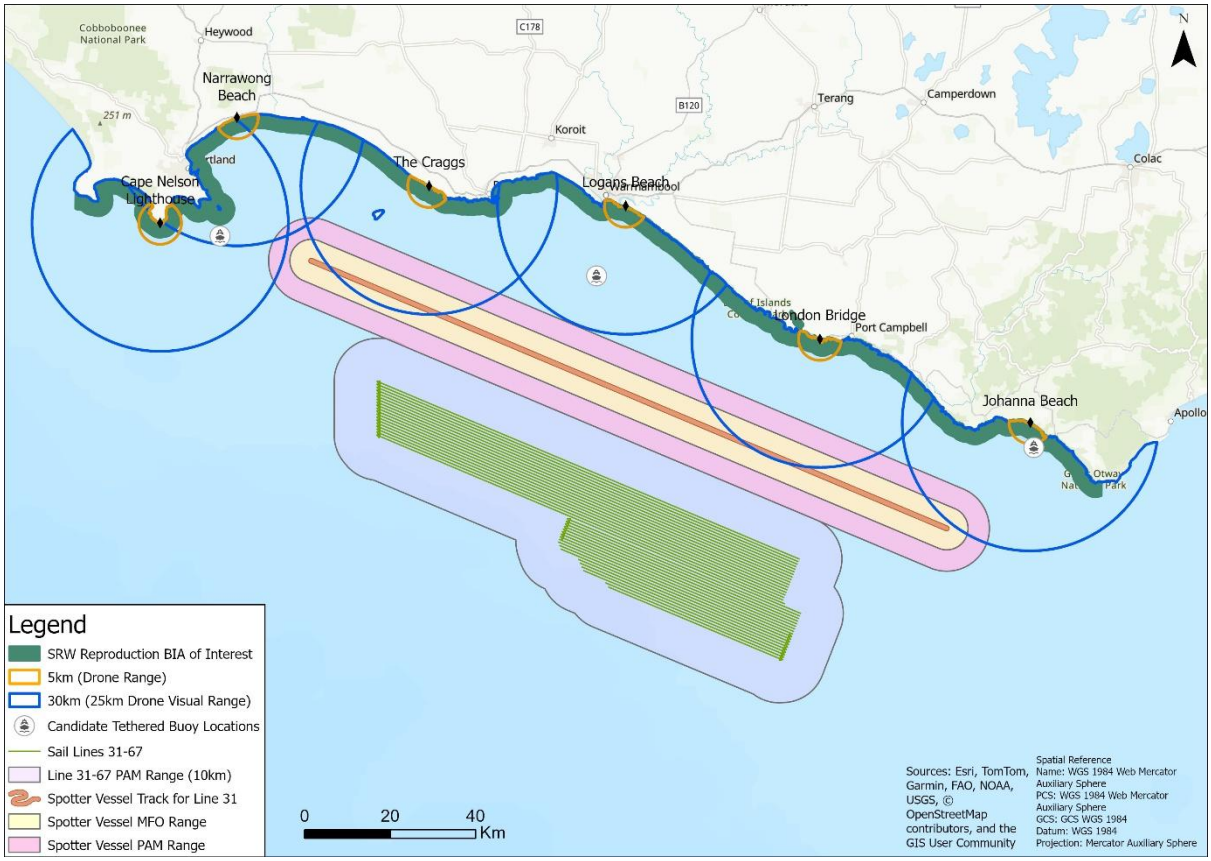

Figure G2-4 – Detection Capability for SRWs in September and October

4.4 Night-time and Low-Vis Procedures

If there is a confirmed SRW detection at night, the sound source will be shut down until daylight.

4.5 Detection Shutdown and Restart Procedures

This procedure applies from 16 September to 31 of October.

- Shutdown the sound source for 24 hours if:

  There is any confirmed[10] detection of a SRW (visual or acoustic from any detection platform) within the SRW Shutdown Area (See Figure G2-5); or
  There are any exceedances of impulsive noise over 120 dB SPL detected from the SSV buoys, and the survey is acquiring at full power in September. In October, if there have been 14 consecutive days without a confirmed SRW detection, the shutdown trigger for repeated impulsive-noise exceedances increases to 140 dB SPL.

10 A "confirmed detection" is a detection from any platform or program verified by a qualified MFO, an expert scientist in the field, or from photographic evidence that has been time and date stamped.

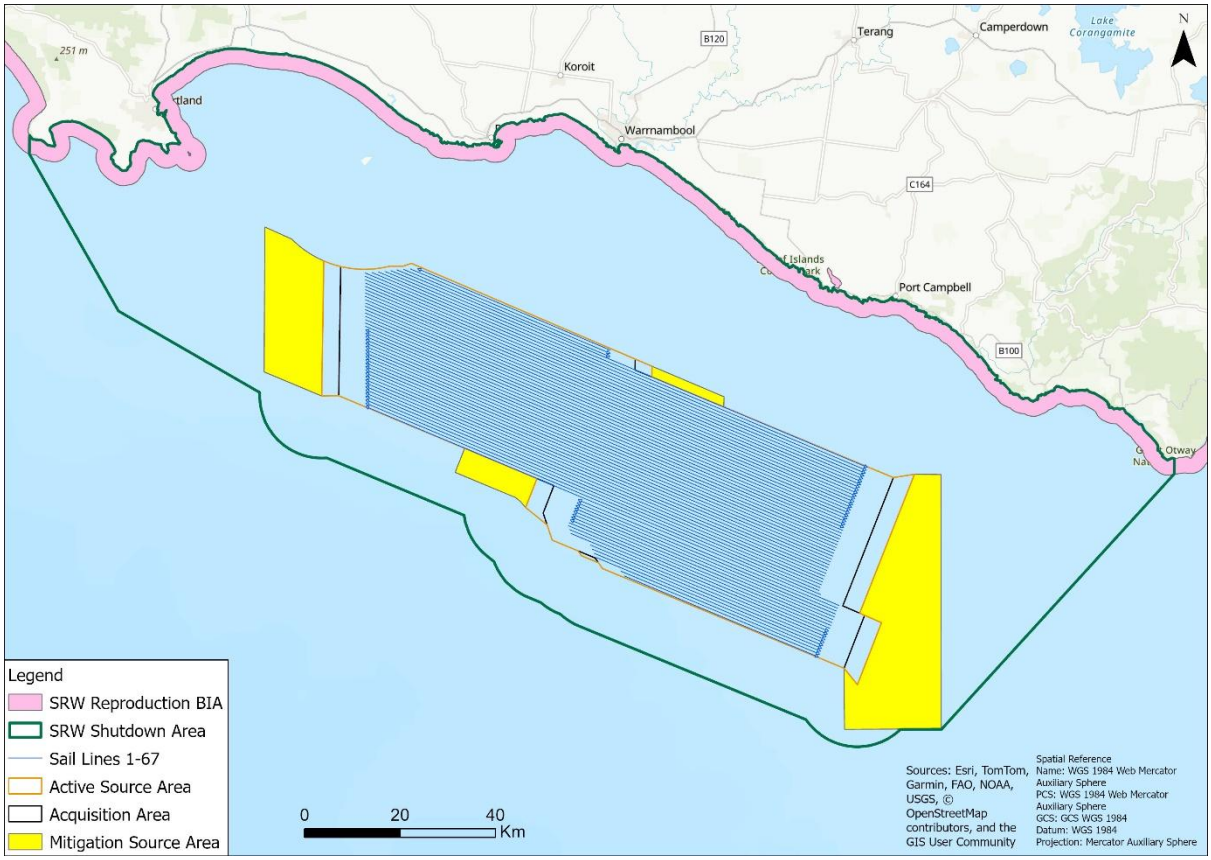

Figure G2-5 - SRW Shutdown Area

The restart protocol can only be initiated if:

- There have been no confirmed detections of any SRW from all the platforms for a period of 24 hours; and/or
- The seismic vessel has relocated; and/or
- There are no exceedances of impulsive noise above the 120 dB ultra conservative threshold from monitoring the SSV buoys during the soft start. The restart protocol will include the following procedures:

The SRW restart protocol:

- T-90 minutes: the spotter vessel will start a pre-clearance detection survey of the line; the spotter vessel will be 20 km ahead of the seismic vessel.
- T-60 minutes: the MFO's and PAM operators on the vessel will start a pre-clearance detection survey
- T-30 minutes: the soft start can commence, and the spotter vessel can resume its position, 20km away and on the northerly side, while it is acquiring lines 31-67.

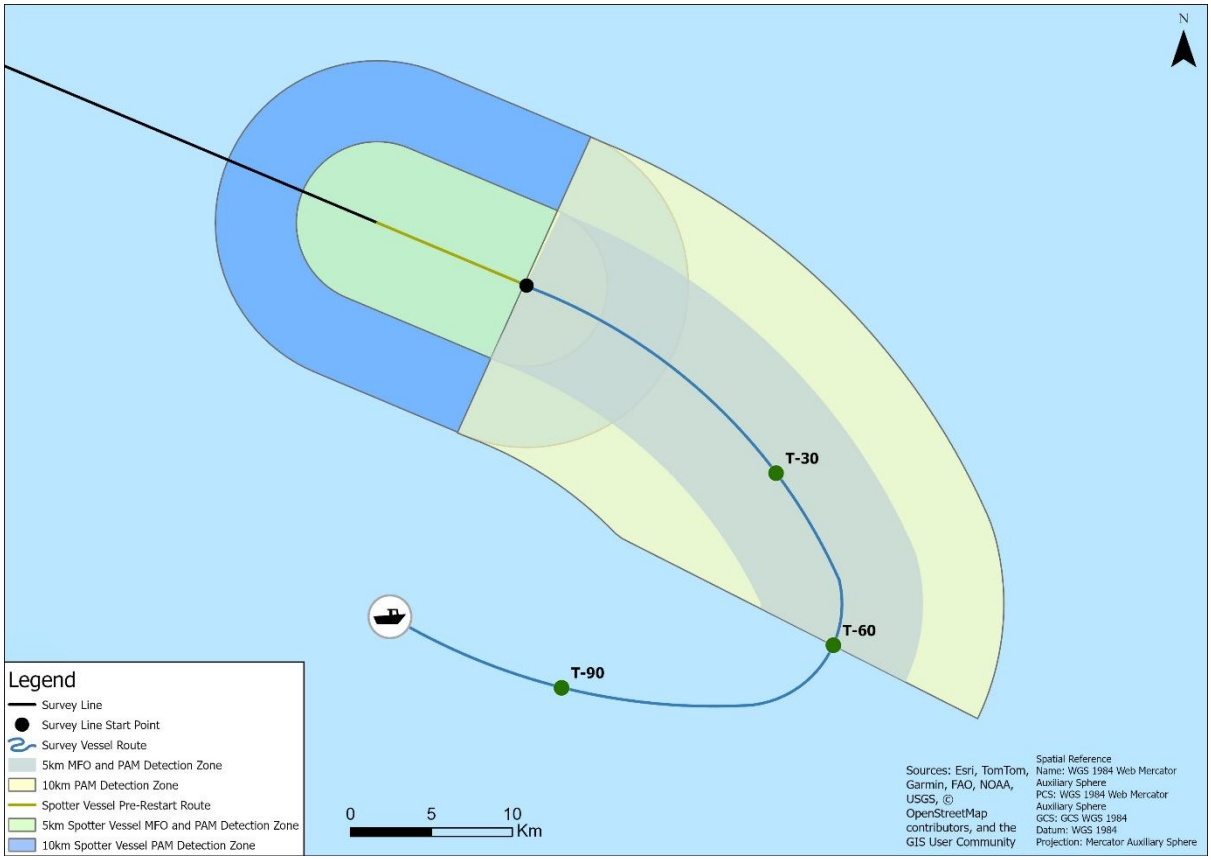

Figure G2-6: Restart procedure for SRW in September and October.

5 Protection Procedures – BW Foraging BIA

5.1 Pre-BW Season Drone and Coastal Monitoring (End of October)

One drone aerial surveillance flight will be conducted from Cape Nelson to try and detect any early arrivals of BWs into the Foraging BIA. Cape Nelson has been chosen as sighting databases indicate BWs pass by Cape Nelson when moving into the BIA.

5.2 1st November –31st December Detection Procedures

BW abundance data indicates initial feeding occurs in South Australian waters and move eastwards throughout the summer months. The BW detection measures have been designed with this in mind and to maximise all possible chances of BW detections.

Detection procedures for BWs include:

- Positioning the spotter vessel on Blue Whale Sentry Mode where the vessel will maintain a position 20 km[11] to the west of the survey vessel (see Figure G2-7 below)
- PAM and MFOs on board both the spotter and survey vessels.

5.3 BW Spotter Vessel Procedure

This procedure governs the spotter vessel movements for monitoring BWs and will be implemented from 1 November to 31 December. There are two modes for spotting:

Scouting Mode

The spotter vessel conducts reconnaissance 10 km[12] ahead of the survey vessel before commencement of the survey and each line turn. The spotter vessel is deployed at least 120 minutes before the survey vessel commences a new survey line.

The spotter vessel moves systematically up to 10km ahead of the survey vessel and patrols areas adjacent to the Active Source Area along the expected line of travel of the survey vessel.

Blue Whale Sentry Mode

The spotter vessel maintains position 20 km[11] to the west of the survey acquisition area because blue whale abundance data shows an initial tendency for foraging to occur in South Australian waters and move eastward throughout the summer months. Therefore, it is more likely that the survey will encounter blue whales on its western flank, and if the spotter vessel is in either mode, it would be positioned on the eastern side of the survey and is less likely to encounter blue whales (Figure G2-7).

[11] The 20 km separation distance while in Sentry Mode is informed by the performance of the PAM systems installed on both the seismic and spotter vessels, each capable of detecting whales at ranges of ~10 km. By positioning the spotter vessel 20 km away from the seismic vessel, CGG maximises combined detection coverage and enhances the likelihood of detecting Blue Whales.

[12] The 10 km separation distance while in Scouting Mode allows the spotter vessel to clear the first 20km (10km range of PAM on both seismic and spotter vessel) of the survey line, thus reducing the chance that a whale re-enters the previously cleared mitigation zone during the transition.

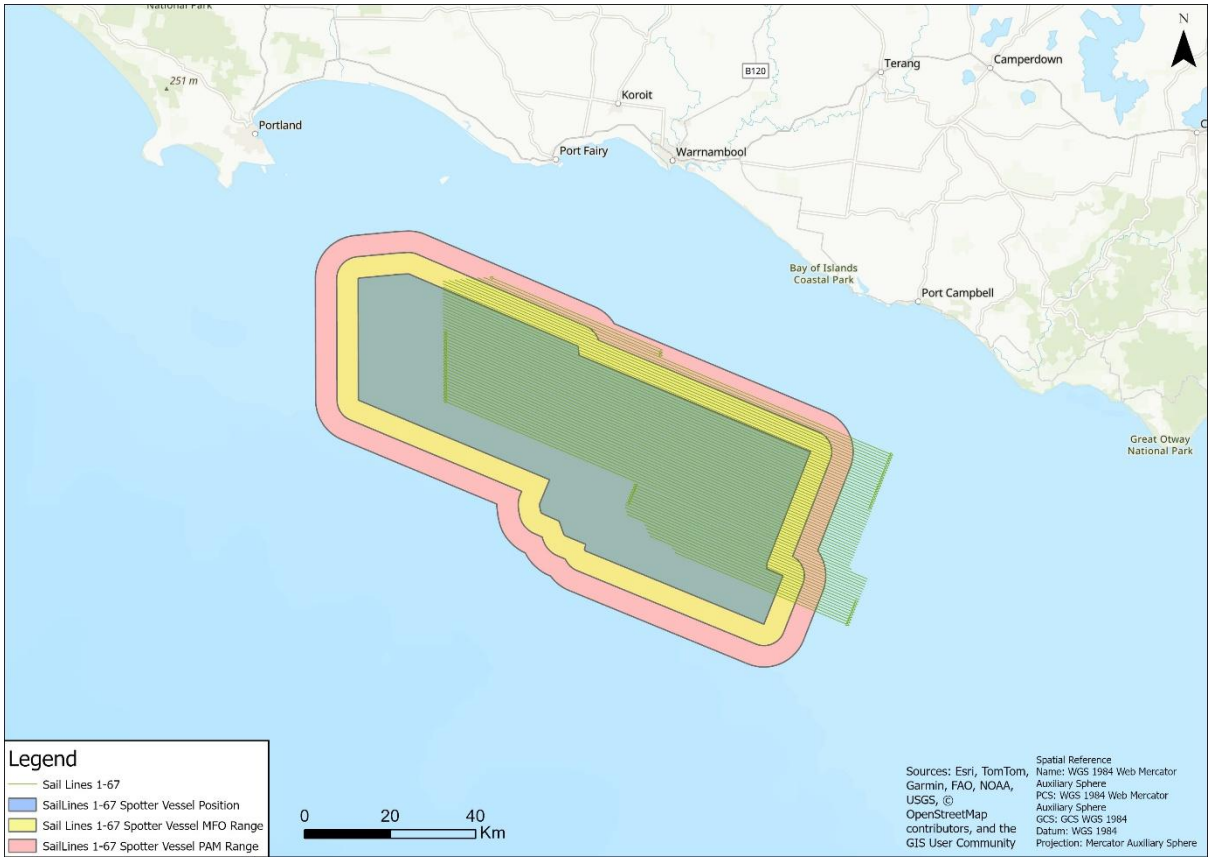

Figure G2-7 – Detection Capability for BWs in November and December

5.4 Night-time and Low-Vis Procedures

If there is a confirmed blue whale PAM detection within 5 km at night, the sound source will be shut down until daylight.

5.5 Shutdown and Restart Procedures

Once the seismic source is at full power, the sound source will be shut down for one hour [13] if:

- A Blue Whale is detected within 5 km (the TTS SEL distance) of the sound source.
- A Blue Whale is detected within 5 km (160 dB behavioural SPL distance) of the sound source.

If there is a PAM detection at night, the sound source will be shut down until daylight.

If there is an "unidentified baleen whale" within 5 km of the seismic source, this will trigger a shutdown for one hour, or until daylight if at night. Attempts will be made to identify the baleen whale, and if the individual is confirmed not to be a BW, restart procedures can commence immediately, provided all other restart measures have also been met.

The restart protocol can only be initiated if:

- there have been no confirmed detections of any BW from all the platforms for a period of one hour.

The BW restart protocol will include the following procedures:

- T-90 minutes: The spotter vessel will be 10km ahead of the seismic vessel.

[13] One hour is based on Policy Statement 2.1 which states shut down may last 30 minutes, CGG has adopted a more conservative approach extending the 30-minute shutdown to 1 hour.

- T-60 minutes: the MFO's and PAM operators on the vessel will start a pre-clearance detection survey
- T-30 minutes: the soft start can commence, and the spotter vessel transitions to sentry mode (20km due West of the survey vessel) (see Figure G2-8 below)

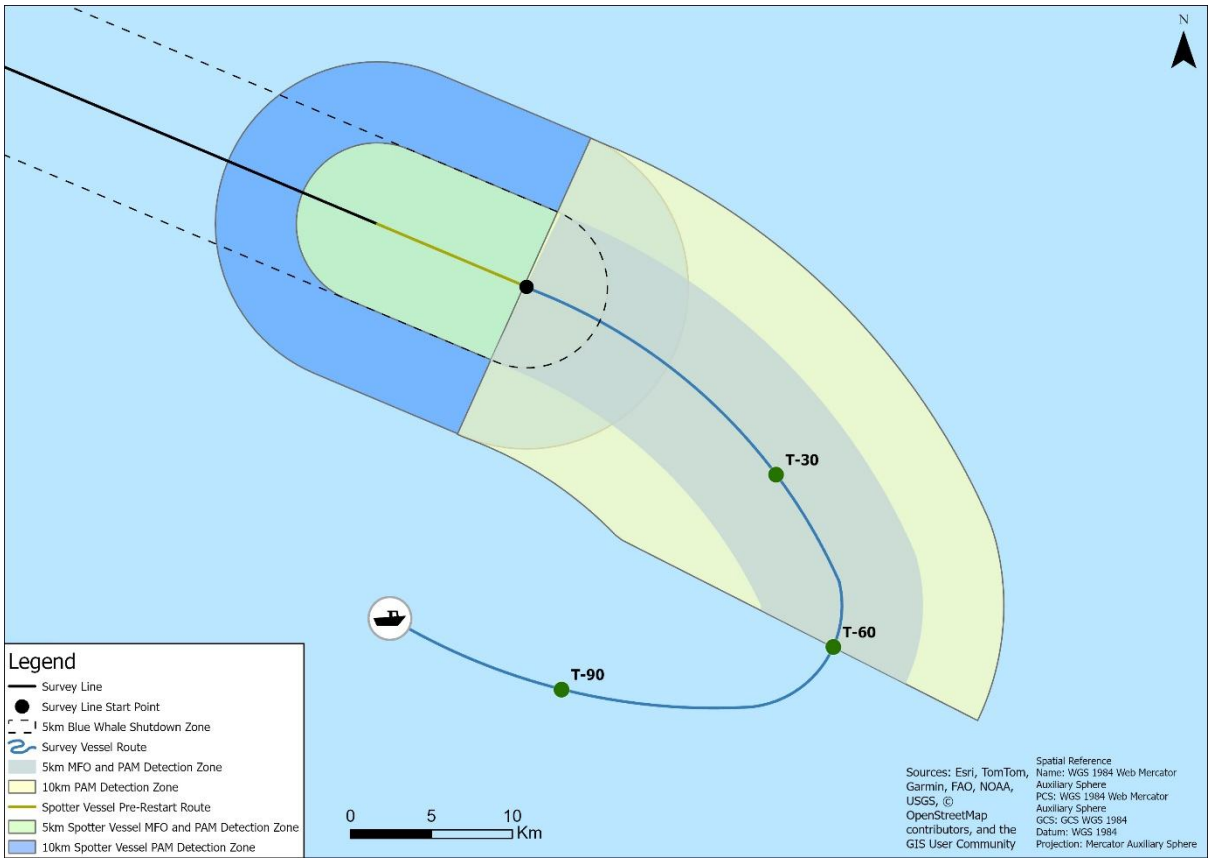

Figure G2-8: Restart procedure for BW in November and December.

6 Document Control

Version	Date of Revision	Author/Reviewer	Summary of Changes
0.0	2 November 2023	MS	Document created.
0.1	19 Novmber 2023	SJ	Updates to include all fauna, not just marine mammals.
0.2	2 January 2024	SJ	Updated following completion of assessments.
1	5 January 2024	MS	Accepted all tracked changes and formatted for public comment.
1.1	10 May 2024	CT/KC	Rework of document to ensure alignment with outcomes of the consultation process, public comment, and the updated environmental assessments.
2	14 May 2024	MS	Review and update ready for resubmission.
3	28 October 2024	MS/CT	Updated following NOPSEMA assessment.
4	12 April 2025	MS/CT	Updated following NOPSEMA, review and update of E7 & F3, and inclusion of protection procedures for the SRW reproduction BIA.
5	10 December 2025	CT/RH/EO/AH/MS	Updated following NOPSEMA OMR #2 and consequential changes.

7 Glossary of Acronyms and Terms

Acronym or Term	Description
Acoustic detection	Detection of whales via in water systems such as: • Passive acoustic monitoring (PAM) • Acoustic detection monitoring (ADM) on gliders or fixed buoys
ADM	Acoustic Detection Monitoring
ALARP	As Low As Reasonably Practicable
AAZ	Activity Action Zone
BW	All blue whale sub-species, pygmy blue whales, and Antarctic blue whale.
Cetaceans	Whales and dolphins.
Detection	Detection is used to mean detection of whales which may occur via MFO observation or via acoustic detection methods.
EP	Environment Plan
EPO	Environmental Performance Outcome
FMP	Fauna Management Plan
MFO	Marine Fauna Observer
PAM	Passive Acoustic Monitoring
PIC	Pilot in Command
Policy Statement 2.1	EPBC Act Policy Statement 2.1 – Interaction between offshore seismic exploration and whales
PTS	Permanent Threshold Shift
Regia MSS	Regia Marine Seismic Survey
SDZ	Shut Down Zone where the seismic source will be shut down.
SEA	Survey Environment Adviser
SRW	Southern Right Whale
Soft start	Gradually bringing on each acoustic source over a 30 min period.
SSV Buoy	Sound Source Verification Buoy
TTS	Temporary Threshold Shift

Annex 1: Blue Whale Diving Summary

Diving behaviour of blue whales associated with feeding at depth was observed by Gill and Morrice (2003) in the Otway region, who note that blue whales dived steeply, submerging for 1 – 4 minutes, then returned to the surface. Tagging of a pygmy blue whale at the Perth Canyon identified 1677 dives over the tag duration (7.6 days) (Owen et al. 2016). The duration of dives was:

- Feeding - mean of 7.6 minutes, maximum of 17.5 minutes.
- Migratory – mean of 5.2 minutes, maximum of 26.7 minutes.
- Exploratory – mean of 8.6 minutes, maximum of 22.05 minutes.

Tagging of 13 pygmy blue whales (five of which had tags that monitored dive depth and duration) in the Bonney upwelling identified (Möller et al. 2020):

- Whales predominantly carried out area-restricted search (presumably foraging) with generally shallow and short dives. However, dives were generally deeper at night compared to during the day.
- Whales performed mostly square shaped dives that were shallow in depth and short in duration.
- Dives recorded to a maximum of 492 m (mean = 59.5 m ± 94.3), and for a maximum duration of 112 minutes (mean = 6.1 minutes ± 5.2).

Although the maximum recorded dive time was 112 minutes, the mean dive time of 6.1 minutes ± 5.2 provides confidence that the typical dive time is less than 30 minutes (Möller et al. 2020). Tagging of eight blue whales off California (Irvine et al. 2019) identified that dive durations were as long as 30.7 minutes, and no feeding lunges were recorded during dives > 20 minutes in duration.

Annex 2: Objections and Claims Raised from Consultation

During the consultation process relevant persons were invited to raise objections and claims about the adverse effects of the activity. An assessment of merit of each objection or claim has been made by CGG which can be found in the consultation report using the Feedback ID number shown in Table G2-2. If an objection or claim had merit and was relevant to this assessment it has been included in the table below.

Table G2-2 - Objections and Claims raised from consultation

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
4016	Pygmy blue whales migrate out of the area from April to June and return in November to December, remaining in the Portland detection area until mid-June each year (McCauley et al. 2018). The timing of the proposed seismic survey overlaps with the migration periods of these endangered whales. Mitigation measure M#01 states that seismic operations will only occur in the pygmy blue whale foraging Biologically Important Area (BIA) when "low numbers of PBWs and other foraging whales are present," specifically during April, May, and June or September, October, and November. AMCS argues that this contradicts findings from McCauley et al. (2018) and Moller et al. (2020), which indicate that pygmy blue whale presence primarily occurs from January to April, with potential activity as early as October and lasting until June. Data from tagged whales in 2015 showed use of continental shelf areas from January to July. AMCS requests that CGG provide clear and comprehensive information on how the proposed activities will minimize interactions with and harm to migrating whales during their presence in the area.	CGG will adopt a monitoring program (see Appendix G2) to be able to detect baleen whales. One of the aims of the monitoring program will be to detect either the departure or arrival of blue whales and southern right whales into their respective biologically important areas (depending on the seasonal window). As per Policy Statement 2.1, there will be a threshold set to provide clarity about when the survey can or cannot start to acquire data and when it would need to stop. The monitoring program and threshold criteria will be structured to reflect the interannual variation of PBW presence in their foraging area. This measure will ensure there the activity is consistent with the respective management plans for these whales.	5040
4048	Concern about sustained noise impact on cetaceans in the area.	CGG has conducted a thorough impact assessment relating to underwater sound and marine mammals, with mitigation measures and management adopted as a result of both this assessment (which includes relevant marine mammal species) (Appendix E7) and a further assessment (which includes two key whale species: Blue Whale and SRW) (Appendix F3). A	1835

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		comprehensive fauna management plan was also established as part of this EP development (Appendix G2).	
4050	Concern about the destruction of smaller sealife and the wounding of larger marine animals due to seismic blasting.	Regia EP has conducted thorough assessments of the literature for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures are outlined in the EP.	1669
4053	Concern about the impact on marine creatures due to noise pollution from seismic surveys.	The titleholder acknowledged the feedback, noting that potential impacts from underwater sound to relevent receptors, including plankton, fish, invertebrates, birds, turtles, and marine mammals, are assessed in the Environmental Plan (EP) and can be found in Appendices E2, E3, E4, E5, E6, and E7. Measures to minimise adverse impacts on biological receptors are outlined in the EP also, and can be found in Appendix G2.	3237
4055	Concern about the impact on shearwater birds and their breeding ground at Griffith Island.	Titleholder has conducted a thorough assessment of the literature, with potential impacts to birds assessed in the Environmental Plan (EP) (Appendix E5). Measures to minimise potential adverse impacts birds are also outlined in the EP (Appendix G2).	2908
4058	Concern about the mass destruction the blasting will cause to local sea animals, particularly mentioning the Southern Right Whales that migrate to Warrnambool every year to give birth.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of Southern Right Whales, within the area of operation. A fauna management plan, along with a suite of measures are also in place to reduce any impacts to as low as practicable.	886
4063	Concern for various birds and little penguins and the effects of sound and light.	Impacts from underwater sound and artificial light on birds, including little penguins, are assessed in the Environmental Plan (EP) and can be found in Appendices E5 and E9. Further assessment of little penguins was also undetook by CGG to demonstrate that environmental impacts and risks arising from the activity will be of an acceptable level. Measures to minimise	1783

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		adverse impacts on birds in the region are also outlined in the EP.	
4096	Concerns about the environmental impact of seismic testing on marine life and the clash between business interests and environmental protection.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals, in relation to underwater sound and artifical light as aspects of the activity. Other marine users have also been considered in another impact assessment that considers physical presence as an aspect of the activity.The Regia MSS is required to define acceptable levels of impact and risk, and work below those levels. Acceptable levels of impact are established based on relevant up-to-date technical and scientific studies, government advice, and are considerate of the information gathered through the consultation process. This information is used to make predictions of the levels of impact we expect to occur and compares those to the previously defined acceptable levels and is presented in the Environment Plan. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures are outlined in the EP.	2766
4106	Feedback raises concern for the welfare of whales that come to calve in local waters, emphasising the need to consider the impact of proposed activities on these vulnerable marine animals.	We will not survey while SRW mothers and calves are in the area. Oil and gas has successfully co-existed with wildlife in this area for 25 years and we are doing everything we can do protect the wildlife and natural beauty of the area (Event ID 1781).	1781
4118	Impact on marine animals, which are the livelihood of the community.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures have been outlined in the EP.	2274
4133	Mass destruction of marine populations through the blasting process.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures have been outlined in the EP.	2274
4135	Mention of being heavily impacted by the whales in the tourism industry.	Title holder has undertaken a thorough analysis and assessment of all relevant literature related to Marine Mammals to inform its decisions. The MSS will not	1244

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		impact the population stability of marine mammals within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable.	
4140	No mention of ceasing activities when whales are present in the area.	CGG has conducted a thorough impact assessment relating to underwater sound and marine mammals, with mitigation measures and management adopted as a result of both this assessment (which includes relevant marine mammal species) (Appendix E7) and a further assessment (which includes two key whale species: Blue Whale and SRW) (Appendix F3). A comprehensive fauna management plan was also established as part of this EP development (Appendix G2).	1835
4146	Opposes seismic testing, claiming it will have catastrophic effects on marine life due to high-decibel blasting sounds. States activities can harm various marine species and may cause whales to beach themselves from the pain, making them unacceptable in a whale sanctuary area.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to as low as practicable. Regia EP has found seismic impacts to cetaceans can be mitigated and managed through appropriate timing of the survey and a comprehensive fauna management plan	537
4206	Stakeholder raised concerns about the number of planned overflights stating that 12 was insufficient	CGG has revised it's commitment to only 1 aerial surveillance flight as a minimum, there may be up to 10 but the need will be established by the Whale Expert Panel.	3783
4231	The feedback expresses concern that the project might disrupt blue whale migration, movements, and natural behavior due to potential interference in their habitat.	The effects of underwater sound have been extensively assessed based on the latest scientific literature. CGG has committed to a variety of protective measures for blue whales and an extensive detection area. These measures have been assessed in Appendix E7, F3 and G2.	2081
4265	The seismic process is going to affect local marine life, ecosystems, and the climate in the community.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any taxa within the area of operation. Mitigation plans are also in place to reduce any impacts to defined acceptable levels and as low as reasonably practicable.	1259
4270	The stakeholder asserts seismic surveying has been proven to be harmful and disruptive to marine life of many species.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the	3343

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
		region and relevent mitigation measures have been outlined in the EP.	
4306	The stakeholder was concerned about potential negative impacts of gas exploration and development on Country, the marine and coastal environment, the local economy, Traditional Owners, and local communities.	The titleholder acknowledged the feedback, noting that all relevant impacts are assessed in the Environmental Plan (EP) and can be found in Appendices E1-E9. Measures to minimise adverse impacts on functions, interests and activities on relevant receptors are also adopted and can be found in Appendix G1.	3152
4309	The stakeholder was concerned about the impact on marine life sensibilities and populations.	Regia EP has conducted thorough impact assessments for all relevent receptors including plankton, fish, invertebrates, birds, turtles, and marine mammals. The Regia MSS will not impact the population stability of any taxa within the area of operation. Measures to minimise adverse impacts on relevant biological receptors in the region and relevent mitigation measures have been outlined in the EP.	2273
4351	There is a request for information concerning detection technologies utilised for monitoring blue whales.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. CGG has committed to several detection methods including aerial surveys, MFO's, PAM systems,and a fixed buoy detection system. CGG will also establish a whale expert panel to help infoprm decision making during the survey. This information is inlcuded in the EP E7, G1 and G2.	2007
4353	Concerns about the impact of oil and gas exploration on the marine environment, particularly in regards to seismic testing and its harmful impacts on whales.	Titleholder responded that a detailed assessment has been completed of all available relevant scientific literature to inform the management and mitigation of MSS and their interaction with whales. Spatial and temporal zoning in conjunction with mitigation measures will ensure that interactions will minimise disturbances to whales.	612
4354	Uncertainty about the full extent of damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831
4356	Concerns about the harm and damage to the marine ecosystem.	Titleholder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the marine environment within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2831

	fishing industry, local economy and environment.	stability of commercial fish species and sensitive species within the area of operation. The MSS will also not impact the local economy. Mitigation plans are in place to reduce any impacts to as low as practicable.	
4358	The stakeholder was concerned about the impacts on flora and fauna being damaged and killed away from the coastline.	Title holder has undertaken a thorough analysis and assessment of all relevant literature to inform its decisions. The MSS will not impact the population stability of any flora or fauna within the area of operation. Mitigation plans are in place to reduce any impacts to as low as practicable.	2821
4454	Claims uncertainty due to reliance on fixed buoy, as this method is proposed as the sole strategy beyond visual and towed PAM detection ranges, means risks to threatened species have not been reduced to as low as reasonably practicable, and that CGG's environmental management system is not effectively implemented. Stakeholder argues that the system's effectiveness is undermined because triangulation of detections is not guaranteed and the testing protocol requires only a single successful unit test before deploying an array.	The EP acknowledges the limitation regarding guaranteed triangulation with the fixed buoy acoustic detection system. However, the system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions. This combination of measures supports the implementation of the defined shutdown zones and activity limitations, thereby managing risks to ALARP and achieving acceptable environmental outcomes for species like BW and SRW. To note, an incorrect reference was used by the stakeholder.	EVT132
4455	The objection argues that the Environmental Plan's reliance on "near real time" data transmission between Acoustic Detection Monitoring operators and seismic operators is flawed because the term is undefined, with no limits on latency or provisions for equipment and communication failures in offshore conditions. The objection states that given the speed of whale movement and the immediacy of sound exposure, the lack of clear parameters renders the measure unreliable. Without evidence that the system can function effectively, the objection maintains that the control cannot be shown to reduce impacts to ALARP, and the ambiguity means the plan fails to meet regulatory requirements for appropriate, measurable	In Appendix G1 the EP describes standards for the control measures, including: One ADM Operator to always listen for LF cetacean calls for the duration of the survey and immediately communicate positive detections of LF cetaceans to the Environmental Officer. Further information on the towed and tethered ADM is contained in Appendix C7. This has not been made publicly available due to being commercial in confidence. In addition, the system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions. This combination of measures supports the implementation of the defined shutdown zones and activity limitations, thereby managing risks to ALARP and achieving acceptable environmental outcomes for species like BW and SRW. To note, an inncorrect reference was used by the stakeholder.	EVT132

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	environmental performance standards.		
4456	The objection contends that CGG's proposed tethered buoy Passive Acoustic Monitoring (PAM) system is an unproven and unreliable primary mitigation measure for detecting marine mammals beyond the range of visual observation and towed PAM. It highlights contradictions within Appendix F5, which claims such systems have been used in seismic surveys while also stating their application in this context is "unknown." Published research shows only limited use in very different settings, such as large-scale Arctic noise monitoring arrays, rather than real-time whale detection. The objection concludes that relying on this experimental technology as a primary safeguard does not meet the regulatory requirement to reduce environmental impacts to ALARP, given the absence of evidence demonstrating its effectiveness in comparable operational environments like the Otway Basin.	Regarding the alleged contradiction in F5: The EP describes both the potential and general use of PAM systems deployed near the survey area (which can include buoys) during seismic surveys for real-time monitoring, and then a detailed, vendor-specific assessment of the actual documented history of particular tethered buoy PAM products. As stated in the EP, the PAM system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions. The tethered buoy is also undergoing real-world testing, prior to any activity. This combination of measures supports the implementation of the defined shutdown zones and activity limitations, thereby managing risks to ALARP and achieving acceptable environmental outcomes for species like BW and SRW.	EVT132
4457	The objection references NOPSEMA's 2019 inspection report for the Otway Basin 2DMC Marine Seismic Survey, which concluded that published scientific evidence does not support passive acoustic monitoring (PAM) as an effective method for detecting Whales, including foraging Blue Whale and lactating females with calves, when the system is towed directly behind an active seismic or support vessel, stating that CGG has not addressed known limitations and therefore is inconsistent with the precautionary principle without providing peer-reviewed evidence that addresses the limitations previously identified.	The 2019 comments from NOPSEMA are related to a different proposal, with an alternative towed PAM system. The Sercel Quietsea PAM system has been accepted and used during Australian seismic surveys. In addition, as stated in the EP, the PAM system is one part of a multi-faceted detection and mitigation strategy that also includes towed PAM, visual observers, aerial surveys, and spatial/temporal activity restrictions.	EVT132
4458	Objects to the procedures concerning 'flocks of forgaing birds' not providing	Appendix G2 has been updated to footnote definition of flock and forgaing as follows: There is no set number of birds that constitutes a	EVT132

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	criteria for what constitutes a flock.	flock. For the purposes of mitigating impacts/risks to all foraging birds, a small flock is considered a group of less than 20 birds, a medium flock a group of 20 to 100 birds and a large flock a group of over 100 birds. Mitigations should consider medium to large flocks of birds to minimise potential for negative impacts to occur. These impacts could include alterations to resting regime, alterations to foraging success, collision, alterations to group cohesion. Foraging, as it relates to birds, includes bird species participating in feeding behaviours such as plunging and diving.	
4459	Objects to the commitment in the Fauna Management Plan (FMP) to adhere to the EPBC regulations regarding vessel speed and direction changes, due to the assertion that this is beyond the capability of a seismic vessel.	As stated in the EP, if a whale approaches within 300m of any vessel, the vessel must: • Reduce speed and maintain at least 300 m from the whale • Position vessel to not impede the path of the whale • Avoid sudden changes in speed or direction • Communicate the sighting These are all within the ability of the vessel.	EVT132
4503	GMTOAC claims inconsistencies and contradictions within CGG's April 2025 EP, particularly regarding the enforceable activity limitations intended to reduce risks to Southern Right Whales and Blue Whales. GMTOAC notes that NOPSEMA previously identified this issue in 2024, stating that duplication and inconsistencies left "no single source of truth" for assessing the EP. GMTOAC believes this fundamental flaw remains unresolved in the April 2025 version, undermining the reliability and enforceability of CGG's proposed control measures. GMTOAC provided the following examples: • Although the EP states that Appendix A2 contains the "final" list of enforceable activity limitations, it later states that Appendix G1 is "controlling" and overrides other lists. GMTOAC notes that many	CGG rejects claims of inconsistency between Appendices A2, G1 and G2, however the stakeholder may have misunderstood the distinction between activity limitations and control measures. Appendix A2 sets enforceable activity limits, measures that restrict operations to avoid or reduce impacts—while Appendix G1 details the control measures, performance standards, and procedures used to implement those limits in line with NOPSEMA's definition of controls. A2 and G1 serve different but complementary purposes, with A2 defining mandatory constraints and G1 outlining the operational steps required to meet them, together ensuring SRWs are protected from behavioural disturbance. G1 and G2 are also complementary rather than conflicting: G2 defines roles and responsibilities, while G1 outlines the controls and measurement criteria used to verify them. CGG maintains that the Environmental Officer and Survey Environment Advisor roles are clearly aligned across both appendices, collectively providing continuous oversight, shutdown authority,	EVT352

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	measures appear in one appendix but not the other, and others contain conflicting descriptions. For example, Appendix A2 and Appendix G1 both outline conditions for discharging the sound source in the Southern Right Whale reproduction BIA, but the conditions differ in scope and detail. GMTOAC warns that such internal discrepancies create confusion for vessel crews and contractors and could jeopardise the species the measures are intended to protect. • GMTOAC highlights conflicting and unclear role descriptions across appendices, particularly for key positions such as the Survey Environment Advisor and Environmental Officer. Responsibilities differ between Appendix G1 and G2, creating uncertainty about who is accountable for shutdowns, communication, monitoring, aerial surveys, technology trials, and 24/7 oversight. GMTOAC notes that the EP does not clarify whether multiple staff will be appointed to fulfil these demanding roles. • Several measures appear in one appendix but not another. For instance, Appendix G2 requires pre-survey aerial surveys, but this requirement is absent from the controlling Appendix G1. Similarly, Appendix G1 includes commitments to trial drone and satellite detection technologies, but these are not included in the Fauna Management Plan, leaving unclear whether they are required or how their effectiveness will be assessed. • GMTOAC claims that these inconsistencies make it difficult, if not impossible, for operators to understand or correctly implement the required measures, with potential serious consequences for Nyamat Mirring, its ecosystems, and culturally	monitoring coordination, and expert engagement. CGG also notes that activity-level commitments, such as drone and satellite detection trials, rightly sit in G1, while position-specific duties like aerial surveys sit in G2. It states that the EP is intentionally structured so A2, G1 and G2 each fulfil distinct functions within an integrated management system, providing operators with clear instructions, objective decision-making criteria, and independent oversight from the Expert Panel. CGG concludes that this framework ensures transparent, robust management and effective protection of Southern Right Whales and Pygmy Blue Whales.	

Feedback ID	Objection or Claim Summary	Titleholder Response	Event ID
	significant species such as Southern Right Whales and Pygmy Blue Whales. They also express concern that CGG's qualitative measures, such as determining whether disturbance is "acceptable", lack objective criteria and fail to involve the Whale Expert Panel or reference Recovery Plan standards.

First Response Actions

In the event of a hydrocarbon release, first call the AMSA Rescue Co-ordination Centre Australia (JRCC Australia) via:

Phone: 02 6230 6811, 1800 641 792 (24 hours)
Fax: 02 6230 6868
Telex: 62349
AFTN: YSARYCYX

The following information should be provided wherever possible:

- ☐ Name and contact details.
- ☐ Where and when the spill occurred.
- ☐ A description of the pollutant.
- ☐ The size of the area where the oil is visible.
- ☐ The source of the spill including vessel registration numbers if known.
- ☐ Any photographs of the incident.

Victoria
If the spill is in, or is likely to move into Victorian State waters, the spill must be reported using the contact details below. If the spill occurs outside port jurisdictions, relevant port authorities will be notified as defined in the relevant State response plan. In the case of a Level 1 release within or close to State waters Portland Port will be the Control Agency. Contact the Port of Portland via:

Reporting (24-hour) Port of Portland +61 3 5525 2450.

For a Level 2 or 3 spill, or where a spill originates in Commonwealth waters and is likely to enter State waters (and where AMSA hand over Control Agency role), DJSIR will be the Control Agency.

Contact DJSIR via: DJSIR State Duty Officer on 0428 863 564.

In the event of a spill in one of the Victorian ports to be used by the Regia MSS seismic vessels, the relevant Port Authority must be notified immediately.

Tasmania
If the spill is in, or is likely to move into Tasmanian State waters, the spill must be reported using the contact details below.

In the case of any spill within State waters the Environment Protection Authority Tasmania is the Control Agency. TasPorts is the control agency for oil spills within Port waters.

For a Level 2 or 3 spill, or where a spill originates in Commonwealth waters and is likely to enter State waters (and where AMSA hand over Control Agency role), the Tasmanian Environment Protection Authority (EPA) is the Control Agency.

Ship's masters, owners, charterers, and agents must provide notification in accordance with statutory requirements (under Marine-related Incidents (MARPOL Implementation) Act 2020).

Telephone: Control Officer (SOPCA): +61 (0)3 6165 4599 or 1800 005 171 (within Tasmania only)
Radio: TasPorts Vessel Traffic Services

VHF radio channel 16/14/12, Call sign “relevant port name VTS" (e.g. Grassy VTS)

Email: incidentresponse@epa.tas.gov.au
EPA: Pollution Incidents: 1800 005 171
General enquiries: +61 3 6165 4599 enquiries@epa.tas.gov.au

The name, IMO number and radio call sign of the vessel must be provided, along with a written report commencing with the code letters “POLREP”. The report must include key basic information, including location, nature and scale of the spill, and contact details. A detailed written report may

also be required. Notify the relevant party when injured/oiled wildlife is confirmed or could potentially occur.

1 Introduction

Welcome to the Regia MSS Oil Pollution Emergency Plan (OPEP). The Regia MSS OPEP serves as a blueprint for responding effectively to potential oil and chemical spill emergencies that may arise during our operations at sea.

The development of an Oil Pollution Emergency Plan (OPEP) is required by Section 14(8) of the OPGGS(E) Regulations. This OPEP for the Regia MSS comprises relevant components of the CGG seismic vessel or contractor's Shipboard Oil Pollution Emergency Plan (SOPEP) and the National Plan for Maritime Environmental Emergencies (NATPLAN) (AMSA 2014).

2 Purpose of the Document

The primary purpose of the Regia MSS OPEP is to establish a clear and systematic framework for preventing, managing, and mitigating oil pollution incidents on the vessels deployed during the Regia MSS. By outlining specific procedures and responsibilities, this document can be followed to ensure that our crews address environmental emergencies swiftly and efficiently.

3 OPEP Objectives

The Regia MSS OPEP strives to achieve the following objectives:

Environmental Protection: Our commitment to safeguarding the marine environment is paramount. This document is designed to prevent and minimize the impact of oil and chemical spills on aquatic ecosystems, marine life, and coastal regions.

Compliance: The Regia MSS OPEP is developed in accordance with the Offshore Petroleum and Greenhouse Gas (Environment) Regulations. It is also designed to be consistent with the Australian national system for oil spill preparedness and response.

Safety: The safety of our crew members and the vessels themselves is of paramount importance. This plan outlines measures to protect our personnel while responding to pollution emergencies and prevent accidents that could lead to such incidents.

Reputation Management: Recognizing that environmental responsibility is a core value of CGG, this OPEP reinforces our commitment to stakeholders, partners, and the broader community. Effective pollution response measures help safeguard our reputation as a responsible and conscientious maritime operator.

4 Scope of the OPEP

The Regia MSS OPEP applies to all vessels and operations under the jurisdiction of the Australian Maritime Safety Authority (AMSA). The scope of this document encompasses:

Response Protocols: Clear and decisive steps to be followed in the event of a pollution incident, including containment, clean-up, and notification procedures.

Personnel Responsibilities: Allocation of roles and responsibilities to crew members, ensuring a coordinated and effective response to emergencies.

Documentation and Reporting: Requirements for maintaining records, reporting incidents, and cooperating with relevant authorities and organizations.

This document does not include the testing arrangements for this OPEP which can be found in the Regia MSS Implementation Strategy and are not part of this document.

The Regia MSS OPEP is a dynamic and evolving document, subject to periodic reviews and updates to reflect changes in technology, regulations, and best practices. It is our collective responsibility to implement and uphold the principles outlined in this plan, ensuring the continued success of our operations while preserving the integrity of our oceans and marine ecosystems.

This document is not a Shipboard Oil Pollution Emergency Plan (SOPEP). The SOPEP is part of the response arrangements for the Regia MSS as it is a critical document and preparedness measure required for vessels operating at sea. Each SOPEP is designed to outline the procedures and responsibilities that the crew of a vessel must follow in the event of an oil spill to minimize environmental damage and respond effectively to such emergencies. SOPEPs are a mandatory requirement under the International Maritime Organization's (IMO) International Convention for the Prevention of Pollution from Ships (MARPOL).

5 The National System for Preparedness and Response

NATPLAN is the framework that integrates Commonwealth and State Government(s) response, facilitating an effective response to marine pollution incidents via Australian Emergency Management Arrangements. AMSA manages NATPLAN and is the control agency for vessel spills in Commonwealth waters. As such, AMSA works with State Governments, emergency services and relevant industries (shipping, oil and gas, exploration, and chemical industries) to maximise Australia's response capability.

NATPLAN applies to all spills from vessels in Commonwealth waters. The SOPEP recognises the divisions of responsibility to provide effective response to marine pollution incidents, as defined under NATPLAN. The SOPEP is the principal response document that will be implemented in the event of a marine oil spill, which provides specifics and provision for guiding management response to mitigate oil spills from vessels.

NATPLAN applies to Commonwealth waters seaward of the boundary of State Waters (3 NM offshore) and integrates with State response plans. NATPLAN identifies several of the roles that are fulfilled by State agencies as defined in the relevant State contingency plan.

5.1 Jurisdictional Authority (JA)

A JA is a statutory responsibility required to ensure that an adequate spill response plan has been prepared. In the event of a spill, the JA also ensures that a satisfactory response can be implemented by the Control Agency. In Commonwealth waters, the JA for petroleum activities is NOPSEMA, and AMSA for vessel spills.

5.2 Control Agency (CA)

The CA is responsible for operational control and response to an oil spill in the marine environment. The Commonwealth waters CA for the Regia MSS is AMSA. AMSA may request that State CAs assume the lead CA role, even where the spill has occurred in Commonwealth waters (but where there is a likelihood that spill hydrocarbons may impact State resources/shorelines).

National Plan response equipment and resources are managed and controlled by AMSA's Marine Environment Protection (MEP) Division, and include:

- Maritime Emergency Response Commander (MERCOM)
- Oil spill response equipment managed via the Marine Oil Spill Equipment System (MOSES)
- Oil Spill Response Atlas (OSRA) which identified sensitive receptors (e.g. marine and shoreline ecosystems and biological resources)
- Oil Spill Trajectory Modelling (OSTM).

In addition, the Australian Marine Oil Spill Centre (AMOSC) is an oil spill response organization funded by industry membership fees that can be contracted as an oil spill response agent.

5.3 State Waters

If a hydrocarbon release occurs in state waters (or if it is likely to move into State waters), the following relevant state oil spill contingency plans will apply:

The Victoria state plan is the State Maritime Emergencies (non-search and rescue) Plan (Emergency Management Victoria 2016). The State Jurisdictional Authority (JA) and Control Agency (CA) is the Department of Economic Development, Jobs, Transport and Resources (DEDJTR).

The Tasmania state plan is the Tasmanian Marine Oil Spill Contingency Plan (TASPLAN) (EPA Tasmania January 2022). The State JA is the Environmental Protection Authority Tasmania, and the State CA is the Tasmanian Environment Protection Authority (EPA).

The deployment of state resources in Commonwealth waters will be requested and coordinated by AMSA.

5.4 Roles and Responsibilities

AMSA is the Control Agency and hence responsible for managing response to all oil spills in Commonwealth waters under NATPLAN. Both MARPOL 73/78 and the vessel's SOPEP require the vessel master to report to the nearest State whenever there is an incident involving actual or probably discharge. The vessel SOPEP is implemented to initiate clean up resources and control discharges.

The following roles will also provide key support:

Prior to commencement of the survey **the Survey Vessel Master will ensure that all relevant personnel have undergone relevant inductions and are familiar with the SOPEP** (and oil spill response arrangements therein) and are appropriately trained to undertake their responsibilities under the SOPEP.

The Seismic Survey Vessel Master will be responsible for notifications and reporting all spills to the sea to the AMSA JRCC, via a POLREP form included in the vessel SOPEP. Further reports will be sent at regular intervals to inform AMSA, NOPSEMA, CGG, survey contractors, State Control Agencies).

The Survey Vessel Master will continue to provide situation reports (SITREPs) throughout the response activity, at the direction of AMSA. AMSA will maintain the response until relevant termination criteria are achieved.

The Survey Vessel Master will make the area safe (protect human life) and to make reasonable efforts to stop the leak to prevent further spillage, for example by transferring fuel to another tank.

The Survey Vessel Master will be responsible for ensuring that the spill containment and recovery kits are serviced and in-date (where relevant), and appropriately always stocked.

The CGG Client Site Representative on board the vessel is responsible for reporting directly to CGG. The CGG Technical Operations Manager (shore-based) is then responsible for notifying NOPSEMA of any spills in Commonwealth waters.

AMSA will appoint the MERCOM, who is supported by statutory powers under the Protection of the Sea (Powers of Intervention) Act 1981. The responsibilities of the MERCOM include the management of emergency intervention issues during a response to maritime casualty incidents where there is a real (or even potential) risk of significant pollution.

6 Assessment Of Spill Scenarios

The level of hydrocarbon release is used to identify the level of resources required to respond to the spill. This approach allows scaling of response in line with the evolving nature and scale of the incident. Incident classification (Levels 1 to 3) are defined in NATPLAN as follows:

Level 1 incidents with a release of 0 to 10 m³, and where sensitive species or habitats are not at risk. These incidents are generally resolved through a First Strike response (i.e., local, or initial resources only).

Level 2 incidents with a release of 10 to 1000 m³ may require deployment of jurisdictional resources supplementary to the initial response due to the more complex size/duration/resource management/risks involved. A Level 1 release may be escalated to a Level 2 where sensitive environmental/socio-economic receptors may be at risk.

Level 3 incidents with a release of greater than 1,000 m³ may require national and international resources, and where the incident controller must delegate all management functions and focus on strategic leadership and response coordination. A Level 2 release may

be escalated to a Level 3 where sensitive environmental/socio- economic receptors may be at risk.

The following spill scenarios have been identified for the Regia MSS:

Level 1 (<10 m^3): The complete loss of hydrocarbons from a transfer hose during refuelling operations.

Level 2 (>10 m^3 of Marine Diesel Oil (MDO)): The complete loss of inventory from the largest fuel tank of an example wide-tow capable survey vessel resulting from collision or grounding. Note that should a release of this volume pose a significant risk to key sensitive receptors, then escalation to Level 3 may be triggered.

7 Environment That May Be Affected (EMBA)

The Environment That May Be Affected (EMBA) is the sea surface area, water column, seabed and any relevant shorelines that could be impacted by oil spilled from a petroleum activity. The EMBA for a Level 1 bunkering incident is expected to be limited to the immediate vicinity of the release point due to rapid spreading, evaporation, and dilution of the spilled MDO and the actions taken under the vessel SOPEP.

The EMBA for a Level 2 spill is based on the outcomes of extensive SIMAPs modelling for various scenarios ranging from 200m^3 to 373m^3 (Appendix B11).

7.1 Protection priorities within the EMBA

The NATPLAN protection priority hierarchy has been used to define protection priorities and response objectives within the EMBA:

PRIORITY 1: protection of human health and safety remove marine users and any potential casualties from areas considered to be a safety hazard.

PRIORITY 2: protection of habitat and cultural resources.

PRIORITY 3: protection of rare and/or endangered fauna prevention of oil exposure to threatened fauna that are or may be present in (or near) the operational area.

PRIORITY 4: protection of commercial resources prevent exposure to commercial fisheries in (or near) the operational area.

8 Spill Response Preparedness

8.1 Oil Spill Resources

Typical oil spill resources expected to be carried onboard the survey vessel are listed in the vessel's SOPEP. The vessel will carry spill containment and recovery kits with sufficient absorbent booms and materials to contain small to medium-scale deck spills. Minor spills will be managed through good housekeeping practices and the use of absorbent materials. Deck spills will not be discharged into the ocean. Spill clean-up materials will be retained on board the survey vessel and stored in covered containers for subsequent disposal at an appropriate onshore facility.

8.2 Proposed Spill Response Strategies

Spill response strategies for the credible scenarios identified (<125 L and 268 m3 MDO) are presented in Table G3-1. In the unlikely event of a spill, the potential use of each spill response strategy would be assessed for feasibility with the recommended responses subject to a Net Environmental Benefit Analysis (NEBA) or Spill Impact Mitigation Assessment (SIMA) by the CA (e.g., AMSA in Commonwealth waters). Any rejected response strategy may be adopted if directed by the CA.

Table G3-1 - Assessment of Spill Response Strategies.

Response Strategy	Assessment	Recommendation	Termination Criteria
Monitor and evaluate	Vessel observation is the easiest and most available option available in all spills. Information gathering for spills is critical for situational awareness and supporting a coordinated spill response. Visual operations of surface hydrocarbons are limited to daylight. Understanding of entrained or dissolved hydrocarbons distribution is limited to spot-point water column sampling using suitable equipment (e.g., fluorometer).	Adopt	No visible surface sheen, slick, or floating oil remains in the affected area, as confirmed by systematic visual surveys over multiple tidal cycles.
Mechanical dispersion	Undamaged vessels in the area can be used to breakup surface slicks if safe to do so. This strategy may be effective in sheltered/near shore areas and is unlikely to be effective in open ocean conditions where wind and wave energy will naturally disperse the slick.	Reject	Not required.
Containment and recovery	The wind and wave conditions are likely to breakup any surface slicks and limit the operational window of this strategy to port or nearshore areas. The relative thickness and spreading of MDO renders this strategy ineffective.	Reject	Not required.
Shoreline protections and shoreline clean-up	The spreading and relative thickness of MDO slicks on shorelines would mostly be below the 10 g/m^2 impact threshold. This along with the exposed and high energy shorelines of the Otway coast make this strategy ineffective.	Reject	Not required.
Chemical dispersion	Due to the spreading and relative thickness of MDO slicks on water, chemical dispersants would not be used as they are unlikely to be effective on an MDO spill (CSIRO 2016). This along with the exposed and high energy shorelines of the Otway coast make this strategy ineffective.	Reject	Not required.

8.3 Oil Spill Response Run-sheet

Given the location of the proposed Regia MSS, the preferred strategy for MDO spills will be to allow small spills to disperse and evaporate naturally, and to monitor and evaluate the position and trajectory of any surface slicks. This passive response and reliance on natural processes greatly reduces the potential for impacts associated with spill response activities.

For Level 1 fuel spills in Commonwealth waters, initial actions will be undertaken by the survey vessel in accordance with the vessel SOPEP (See Page 1), with subsequent actions determined in consultation with AMSA (under NATPLAN). In such situations, the Survey Vessel Master (or delegate) will monitor the spill and notify AMSA of the situation status. AMSA will monitor and continue to assess this level of spill.

For Level 2 spills, AMSA is the responsible CA for oil spills from vessels within the Commonwealth jurisdiction and will respond in accordance with its Marine Pollution Response Plan, as approved by the AMSA Executive. Upon notification of an incident, AMSA will assume control of the incident (AMSA 2014). CGG and the vessel contractors will support the response as required.

After ensuring the safety of the crew and fire prevention (and notifying AMSA), the Survey Vessel Master will implement the SOPEP and consider relevant actions (e.g., tank lightering) to reduce the oil volume released to the environment. AMSA will determine the appropriate response strategies depending upon the protection priorities at risk within the EMBA.

AMSA will determine the potential need for oil spill trajectory modelling (OSTM) and possible sea/aerial surveillance to confirm/inform trajectory predictions, depending on the location, prevailing weather conditions, available vessel responses and volume released.

Recognising that there is potential for impacts associated with spill response activities, these risks would be assessed as part of any NEBA/SIMA coordinated by AMSA, to which CGG would contribute if requested by AMSA.

The NEBA/SIMA process requires several data and information inputs to allow a robust and transparent assessment. AMSA will require CGG to provide this information in a timely manner. Information requirements will likely include:

- The oil spill risk assessment in the accepted EP.
- Vessel observations obtained immediately prior to and following the spill.
- On water capability information to support spill response.
- Any available baseline data.

Where hydrocarbons from the spill are likely to cross from Commonwealth to State waters, AMSA will undertake the NEBA/SIMA in conjunction with representatives from the relevant State CAs.

8.3.1 Oiled Wildlife Response

If AMSA identify that an oiled wildlife response is required in Commonwealth waters, this will be based on the Oiled Wildlife Response Plan (AMSA 2017). Responses in State waters will be implemented by or under the direction of State CAs and align with current State oiled wildlife response plans. The accumulation of hydrocarbons on shorelines is considered unlikely based on the credible scenarios; however, to allow for an adaptable response, consideration will be given to migratory shorebird feeding and roosting sites/nesting colonies and any seal colonies in and adjacent to the EMBA (e.g., on the northern coast of King Island). In addition, species protected under Part 3 of the EPBC Act will be given particular attention, with consideration of information provided in relevant plans, guidelines, and policies (e.g., NOPSEMA 2016a).

8.3.2 Communication with Other Marine Users

Commercial and recreational fishers and other users that operate in the area would be advised of any spill and associated response activities within 2 hours of the incident, and every 24 hours for the duration of the incident. This would minimise the potential for interaction with their activities or unnecessary risks to personnel or property.

Subsequent actions will be determined in consultation with the Control Agency and regulatory authorities (AMSA and NOPSEMA) under NATPLAN, with regards to the low potential for impacts posed by the spill. AMSA has indicated that it does not require titleholders to directly consult on OPEPs for seismic surveys or those addressing the operations of offshore supply vessels (AMSA 2014). Such operations are already covered by existing NATPLAN arrangements.

Any reportable fuel or oil spills will be reported using CGG's Event Reporting Management Procedure (GRP_HSE_GEI_17E).

8.3.3 Communication with other relevant interested persons or organisations

There is no specific commitment for CGG to communicate the details of the spill to relevant persons consulted in the preparation of the EP, or to other relevant interested persons or organisations as part of ongoing consultation. This position is justified because the Control Agency under the National Plan would be responsible for such communication. CGG will issue updates to relevant persons if requested to do so by the Control Agency and prior approval of the content.

9 Operational And Scientific Monitoring Plan (OSMP)

The specific operational and scientific monitoring program undertaken following an oil spill would be developed based on the following information:

- location of the spill
- nature and scale of the spill, and likely evolution
- types of values and assets within the EMBA
- potential for impact upon sensitive resources
- review of available baseline data.

An assessment of gaps in available baseline data and potential/requirements for post-spill/pre-exposure baseline data collection will be considerations in the monitoring design. AMSA will direct and lead any monitoring requirements in the event of an oil spill, supported by CGG.

All monitoring personnel will be suitably experienced and qualified for their role. A pre-mobilisation assessment of experience and certifications will be used to allocate specific roles to personnel. Multiple personnel will be allocated to monitoring roles to allow for shift rotations (where multiple shifts per day are required) or survey rotations (where staff are rotated from the field as part of effective fatigue management planning). The availability of personnel with in-date certificates (e.g., offshore medical, TBOSIET and MSIC) will then identify which personnel will support immediate mobilisation or comprise the second rotation.

9.1 Operational Monitoring

In the event of a hydrocarbon release, CGG would implement Operational (Type I) Monitoring in consultation with AMSA, and where appropriate, relevant State agencies. This monitoring will be implemented to;

- determine the extent and character of a spill.
- track the movement and trajectory of surface MDO slicks.
- identify areas/ resources potentially affected by surface slicks.
- determine sea conditions/ other constraints.
- identify the efficacy and potential impacts of spill response strategies and tactics (to inform any remediation activities and any subsequent NEBA assessments).

Oil Spill Trajectory Modelling (OSTM), used in conjunction with water quality monitoring, will help determine the potential extent and direction of travel of the plume of entrained MDO, and to determine the risk of hydrocarbon toxicity impacts to sensitive receptor locations.

This monitoring will be instigated by AMSA and will enable CGG to provide the necessary information to AMSA, to assist in planning appropriate response actions under NATPLAN. Specific monitoring and data collection would include aspects of the following, as agreed with AMSA:

- immediate monitoring (approximately 0 to 6 hours):
- estimate of sea state
- estimates of wind direction and speed
- characteristics of the surface MDO slicks (thickness and areal extent)
- GIS mapping
- OSTM triggered for a Level 2 spill or greater.

Modelling, if triggered, will be used in conjunction with other field observation/monitoring data to identify the likely direction, spread and potential speed of the slick. This will be used as a guide to support the planning for other operational monitoring scopes (e.g., water quality, sampling and fluorometry). This information will allow initial identification sites for sampling, which may also provide information on the subsurface distribution of hydrocarbons via vertical profiling of the water column (should sufficiently levels of hydrocarbons remain to be detectable).

Water column profiling data will be used to identify the sites and depths at which water samples will then be taken for laboratory analysis. Water sampling for hydrocarbons should be undertaken using suitable equipment by personnel trained in the relevant procedures. “Improvised” approaches will not be used as the samples obtained may result in inaccurate results or a failure or a delay in confirming the credible source of the spill (as described in NOPSEMA 2017c).

The following operational monitoring techniques must be mobilised once immediate response actions have concluded:

- aerial surveillance for Level 2+ spills (if aircraft available offshore).
- GPS tracking using satellite drifter buoys (if available).
- measuring concentrations of entrained hydrocarbons through the water column (e.g., from water samples or using fluorometers calibrated to an appropriate hydrocarbon type).
- stochastic modelling predictions for Level 2+ spills (requires up to two weeks to receive results).

Field-based operational monitoring will be restricted to daylight hours only when surface slicks will be visible from either vessels or via aerial surveillance. Where available and practicable, remote sensing (e.g., using satellite-mounted optical imagery and Synthetic Aperture Radar (SAR)) may be used to provide situational awareness of the spatial distribution of the surface slick(s) during daylight, at night, or during overcast days.

The information gathered from this monitoring will be passed on to AMSA is it becomes available and via ongoing SITREP reports. Where GPS tracking using satellite drifter buoys, real-time spill modelling, aerial surveillance, water quality sampling and/or visual slick estimation is required, CGG can engage RPS under existing contractual arrangements to provide urgent specialist response services.

Should there be the need to implement field response activities using external parties, a response logistics plan would be developed and initiated immediately on notification of the spill. The plan would detail logistics, equipment personnel and detailed OSMP plans. CGG will implement, assist with, or contribute to (including funding if required) any other operational or scientific monitoring as directed by AMSA.

9.2 Scientific Monitoring

Scientific (Type II) Monitoring would be triggered and implemented if there is a reasonable expectation that there may be adverse impacts to marine biota or habitats in the area. The scientific monitoring likely to be implemented includes the programs listed in the sections below. The key receptors for which scientific monitoring studies would be considered are:

- benthic sediments (particularly soft sediments able to retain hydrocarbons, infauna)
- subtidal marine benthos (filter-feeders, macroalgae)
- seabird populations (foraging individuals)
- non-avian marine wildlife (cetaceans, marine reptiles, and fish).
- intertidal sediments and habitats.
- fisheries and aquaculture operations.

9.2.1 Scientific Monitoring Program 1

SMP1 is about monitoring for hydrocarbons in benthic sediments. The aims of SMP1 are to understand the characteristics, persistence, and fate of hydrocarbons in sediments to provide data for the assessment of potential impacts on seabed sediments and to understand the effect of hydrocarbon concentrations on infaunal macrobiota.

The objectives of SMP1 are to:

- Quantify hydrocarbon concentrations at locations within the EMBA.
- Quantify change in sediment hydrocarbon concentrations at sampling locations over time (considering seasonal and inter-annual change).
- Provide sediment hydrocarbon data to support determination of potential cause-effect relationships between spill hydrocarbons and changes in benthic communities.
- Identify potential areas of benthic impact based on sediment hydrocarbon concentrations and impacts to benthic macroinfaunal assemblages.

SMP1 will start in the event of a Level 2 or 3 spill and where modelling and/or operational monitoring (e.g., water quality) indicates likely exposure to benthic sediments.

SMP1 will end when sediment contamination results showed recovery to a point where hydrocarbon concentrations are no longer demonstrated to be a primary driver of infauna assemblage composition.

9.2.2 Scientific Monitoring Program 2

SMP2 is about monitoring and surveys of shoreline and intertidal benthos to determine impacts of oil spill and recovery. The aim of SMP2 is to determine and monitor the impact of the spill, dispersants or response activities and potential subsequent recovery for intertidal benthos at both individual (species) and community (habitat) levels.

- The objectives of SMP2 are to:
- Monitor the spill and spill management operations on intertidal marine coastal habitats (like tidal seagrass, tidal mud flats, mangroves, intertidal saltmarsh, and saltpans).
- Monitoring associated organisms (like fishes, crustaceans, arboreal mangrove biota, microphytobenthos, macroalgae, mangrove/saltmarsh plants, seagrass)
- Establish necessary responses.
- Quantify the biological and ecological effects of the spill and response activities.

SMP2 will start in the event of a Level 2 or 3 spill and if modelling predicts possible shoreline/intertidal contact or there are any reports of shoreline/intertidal contact.

SMP2 will end when all reasonable and practical measures have been taken to assess the impact of the spill on intertidal benthos and affected intertidal benthos has returned to baseline (or reference site) conditions or oil pollution impacts on critical intertidal benthos species and taxa are no longer identifiable.

9.2.3 Scientific Monitoring Program 3

SMP3 is about monitoring of subtidal marine benthos to determine impacts of oil spill and recovery. It aims to enable assessment of impacts and potential for subsequent recovery of benthic marine habitats (soft and hard substrate habitats) and associated macro-epibenthic organisms (e.g., macroalgae, seagrass, sponges and other filter feeders, motile invertebrates, and associated fishes) in response to a spill event and associated response activities. It also aims to document recovery of affected biota and habitats.

The objectives of SMP3 are to:

- characterise and quantify habitat composition and coverage/abundance of macro-epibenthic organisms and site-associated demersal fish.
- allow comparison with historical (baseline) data and seasonal/interannual surveys.
- define recovery in macro-benthic and demersal populations and recovery/change in habitat type.

SMP3 will start in the event of a Level 2 or 3 spill and where modelling and/or operational monitoring (e.g., water quality) indicates likely exposure to benthic habitats or if there are any reports of subtidal contact.

SMP 3 will end when reasonable and practicable scientifically robust measures have been taken to assess the effects or impact of the spill on benthic habitats / communities and oil pollution effects / impacts on benthos are no longer detectable, or impacts shown to be within accepted protection limits (to be defined in Sampling and Analysis Plan) and when a trend towards post-impact recovery or alternate developmental trajectory has been demonstrated (in comparison with control/reference sites) at sites that were exposed to elevated concentrations of hydrocarbons.

9.2.4 Scientific Monitoring Program 4

SMP4 is about undertaking wildlife surveys to determine impact of oil spill on seabird and shorebird populations and recovery. It aims to assess any short-term or longer-term environmental effects on seabird and shorebird populations within the study area that may have resulted from the oil spill (i.e., damage extent and recovery). It also aims to document recovery of affected biota and habitats.

The objectives of SMP4 are to:

- Quantify foraging seabird and shorebird populations.
- Quantify foraging, nesting or breeding shorebird populations.
- Quantify records of oiled birds and bird mortalities.
- Allow comparison of changes in populations over time (seasonal and inter-annual).

SMP4 will start in the event of a Level 2 or 3 spill and where post-spill observations indicate possible contact with foraging seabird populations and/or any reports of oiled or dead seabirds and/or shoreline oil indicates possible contact with shoreline bird habitats or populations.

SMP4 will end when the extent of damage and rate of recovery of key seabird/shorebird behaviour and breeding activities has been quantified using scientifically robust methods and the affected environment or natural resource has returned to baseline conditions (taking into account natural variability) in terms of breeding population (for seabirds) or counts (for shorebirds), with regard to reference sites and/or baseline data and oil pollution effects/impacts on critical species and taxa are no longer detectable.

9.2.5 Scientific Monitoring Program 5

SMP5 is a desktop study and survey about occurrences of oiled/mortalities of non-avian marine wildlife to determine impacts of oil spill and recovery. SMP5 aims to assess any short-term or longer-term environmental effects on non-avian marine wildlife that may have resulted from the oil spill (i.e., damage extent and recovery). It also aims to document recovery of affected biota and habitats.

The objectives of SMP5 are to:

- quantify records of sightings of dead or oiled marine wildlife.
- allow seasonal or inter-annual comparison of records of dead or oiled wildlife.

SMP5 will start in the event of a Level 2 or 3 spill and where modelling indicates possible contact with populations and/or any reports of oiled or dead non-avian marine wildlife.

SMP5 will end when reasonable and practical measures have been taken to assess the effects or impact of the spill on non-avian marine wildlife and restoration or resumption of key biological processes (e.g., abundance, distribution, breeding) necessary to ensure post-impact recovery have been identified and oil pollution impacts on non-avian marine wildlife are no longer detectable.

9.2.6 Scientific Monitoring Program 6

SMP6 is about monitoring of intertidal receptors to determine impacts of spill hydrocarbons and recovery. SMP6 aims to understand the behaviour, persistence, and fate of hydrocarbons in intertidal sediments, and enable assessment of potential impacts and recovery to intertidal habitats. It also aims to identify the potential implications of changes in intertidal communities to other biota (e.g. shorebirds).

The objectives of SMP6 are to:

- Quantify hydrocarbon concentrations at locations within the EMBA.
- Characterise and quantify habitat composition and coverage/abundance of epibenthic and infaunal organisms.
- Quantify change at sampling locations over time (considering seasonal and inter-annual change).
- Define recovery/change in habitat type and epibenthic and infaunal organisms.
- Provide sediment hydrocarbon data to support determination of potential cause-effect relationships between spill hydrocarbons and changes in benthic communities.

SMP6 will start in the event of a Level 2 or 3 spill and where modelling or operational monitoring indicates likely exposure to intertidal habitats.

SMP6 will end when the results of the monitoring tasks achieved the objectives and appropriate, meaningful, and defensible scientific monitoring results have been achieved and sediment contamination results have shown recovery to a point where hydrocarbon concentrations are no longer demonstrated to be a primary driver of habitat composition.

9.2.7 Scientific Monitoring Program 7

SMP7 is about impacts to fisheries and aquaculture. SMP7 aims to understand the potential short and long-term impacts and recovery of fisheries (should they be closed), and aquaculture facility/operation that have been exposed to spill hydrocarbons.

The objectives of SMP7 are to:

- quantify hydrocarbons in tissue of organisms targeted by fisheries or aquaculture.

- determine potential effects on population size/structure.
- identify potential impacts to organism health.
- determine potential risks to human health.

SMP7 will start in the event of a Level 2 or 3 spill and where fisheries have been closed in response to a hydrocarbon spill and/or where modelling or operational monitoring indicates likely exposure to aquaculture operations or key brood stock collection locations.

SMP7 will end when the results of the monitoring tasks achieved the objectives and appropriate, meaningful, and defensible scientific monitoring results have been achieved and sediment contamination results have shown recovery to a point where risks to human health are understood and data on population structure have shown that recovery is possible through retention of sexually mature adults and demonstrated recruitment of juveniles.

9.3 Initiation Of Scientific Monitoring

CGG will implement scientific monitoring in the event of a Level 2 spill (or greater), in accordance with initiation criteria described in Table G3-2. A detailed OSMP Implementation Plan based on commonly used, scientifically robust and easily accessible methods would be developed to ensure an efficient and technically defensible response. This approach builds time efficiencies into development of the OSMP as existing RPS documentation (e.g., Health and Safety Plans) can be adapted to meet the requirements of the OSMP. Potential suppliers of available survey equipment would be identified as a priority, with a preference for those with existing contracts.

Relevant permit applications (e.g., for sediment/biota sampling) will be identified and submitted as soon as reasonably practicable. This approach does not work from the base assumption that permit requirements will be waived by relevant authorities to minimise potential delays in mobilisation and permit approval should permit requirements not be waived.

The OSMP Implementation Plan will detail the equipment required for each study, travel and freight arrangements, notifications, vessel support, HSE planning, and the sampling and analysis plan. Within 12 hours of RPS being notified, a teleconference will be held between the CGG, AMSA, the nominated scientific personnel, and the Vessel Master to finalise the requirements for implementation. Scientific teams can be on site within 48 to 72 hours of the implementation plan and budget being approved (and where permits are not required or have been approved). It is recognised that MDO is only likely to remain measurable on the water surface for a few days, and that realistically a response team would not be on site until it had dispersed.

Given the extremely low probability of a catastrophic spill and MDO subsequently contacting sensitive biota, and the rapid weathering and likely dispersal of spill hydrocarbons before a response team could be mobilised, CGG considers the costs associated with pre-emptive development of the Implementation Plan and full assembly and preparation of the response team to be grossly disproportionate to the benefit of a more rapid response.

The area of potential impact to be targeted in the scientific monitoring plan would be based on observations of the slick trajectory, water quality data collected during the operational phase, and available modelling. Due to the nature of the spill, potential for spread/dispersion, constrained spatial area of the EMBA, and likely field team mobilisation period, it is considered that post-spill pre-impact baseline data collection will likely not be feasible (but will remain a consideration for planning purposes).

Scientific monitoring would focus on determining potential short and long-term environmental impacts of the spill and response actions, and subsequent recovery). Scientific monitoring may continue for some time following the termination of the operational monitoring response (NOPSEMA 2016c).

9.4 Scientific Monitoring Team

In the event of the requirement to undertake scientific monitoring, CGG would engage a specialist subcontractor such as RPS to rapidly finalise response plans and to deploy the required resources to undertake the monitoring activities. Primary scientific monitoring studies could include some, or all, of the elements described in Table G3-2 depending on the size, timing, and location of the spill.

An adaptable scientific monitoring response must allow for the potential for operational monitoring or situational awareness obtained during a spill to indicate exposure to additional sensitive receptor types, depending on the nature and scale of the actual release. Where such an occurrence is identified, additional optional SMPs may be implemented, following agreement with AMSA.

9.5 Study Template

For each SMP described above, a detailed study template would be developed following implementation. This is summarised in Table G3-2.

Table G3-2 - Scientific Monitoring Studies Template

Study Heading	Description
Monitoring objective and rationale	Details the monitoring objectives for the study to focus sampling design.
Natural resource description and/or importance	Provides background information relevant to the context of the study; distribution, temporal patterns, life-stages present, critical habitats, and processes.
Activation trigger for monitoring tasks	Criteria to initiate the scientific monitoring study, based on likely exposure to harmful concentrations (acute and/or chronic)
Potential sensitivity to spilled MDO at exposure levels	General context of possible impacts associated with the spill, exposure pathways and effects concentrations. Range of measurable responses.
Spatial awareness	Outcomes of operational monitoring that support survey design
Monitoring methods / sampling and analysis plan	
Overview of the monitoring method	Provides a scientific and practical context for the monitoring methods to be used. Includes consideration of statistical methods and sampling effort required to achieve the monitoring objectives.
Details of the survey design, methods, standards and techniques to be utilised	Provides the information required to collect samples in a defined geographic area (based on operational monitoring data) as part of a robust scientific study program. Includes relevant specifications, standards, and requirements of the study.
Permits	Details any permit requirements and/or exemptions.
Data collection, analysis, and reporting requirements	Provides details on the necessary data requirements including baseline information, analytical parameters and detection limits, and metadata. Details the deliverables from the study.
Personnel resourcing requirements, qualifications, and skills	Provides minimum skill/experience, qualifications/certifications, and resourcing requirements to deliver the study safely and robustly. Considers shifts and survey rotations for effective fatigue management. Includes contingency resource planning.
Field equipment, survey platforms and logistics	Details equipment and logistics requirements to fulfil the study requirements.
Recommended procedures for data collection, sampling, storage, transport, and analysis	Provides the necessary sampling and analytical techniques, and standards to ensure data quality and ensure consistency throughout the study (including Chain of Custody (CoC) forms).

Study Heading	Description
Risk assessment, occupational health, and safety considerations	Describes the risks and mitigation controls associated with undertaking the study.
Data management, QA/QC, transmittal, and archiving	Provides QA / QC requirements for all data obtained as part of the study.
Supporting documents, standards, and references	Identifies the relevant guidelines and high-level references required to implement the study.
Reporting requirements	Provides description of reporting of the scientific outcomes of the survey(s), including identification and qualification/quantification of potential impacts and subsequent recovery. Each survey report identifies the need for any further scientific monitoring based on the survey outcomes.
Termination criteria	
Criteria for the terminating the monitoring activity	Completion criteria to be met to demonstrate that study objectives have been achieved to terminate the study.

1 Protocol Overview

1.1 Purpose

This protocol establishes a baseline environmental standard to underpin petroleum activity adjustment for displacement, loss of catch, and fishing gear loss or damage, between petroleum titleholders and commercial marine operators, including fishers.

This protocol provides a practical, evidence-based process and reasonable monetary adjustment to licensed commercial fishers for displacement, loss of catch, and fishing gear loss or damage. Adjustment is available during a petroleum activity and will remain available for a specified period after the completion of a petroleum activity conducted under an Environment Plan (**EP**) that references, and is therefore subject to, this protocol.

This protocol also serves as the mechanism for other marine operators (e.g. fishing co-operatives, fishing charters, dive schools) to initiate discussions with titleholders on evidence-based monetary adjustment if they could potentially be impacted by petroleum activities.

1.2 Background

In 2018, National Energy Resources Australia (**NERA**) in consultation with an industry consortium, established the Collaborative Seismic Environment Plan (**CSEP**) Project, to seek approval from the National Offshore Petroleum Safety and Environmental Management Authority (**NOPSEMA**) for seismic survey activities in an area in Commonwealth waters off Western Australia and the Northern Territory from 2021 and beyond. The CSEP Project was aimed at achieving fundamental and long-term improvements to the way that seismic activities were planned with due consideration for commercial fishing activities.

As part of this project, an adjustment protocol (the NERA Protocol) was developed by the CSEP Project Steering Committee in consultation with State, Territory and Commonwealth commercial fishing license holders as well as relevant fishing associations, regulators, and petroleum industry associations.

In recent years the NERA Protocol has become a petroleum industry standard for all types of activities and has been used as the basis of this Otway Commercial Marine Operators Adjustment Protocol (Otway Adjustment Protocol (OAP)).

1.3 Commitment

Recognising the collaborative benefits the NERA Protocol has provided where it has been adopted, petroleum titleholders in the Otway offshore region (refer **Appendix 1**) commit to minimising impacts on commercial marine operators, including commercial fishing and the fish stocks that support the fishing industry primarily through avoidance of each others' activities.

However, petroleum titleholders recognise that their activities may, from time-to-time, take place in the same area and at the same time as commercial operations of others who have a history of using that area. Minimising interference with each other's rights and interests is also reflected in primary petroleum and fishing legislation[1].

[1] For relevant statutory information refer to section 280 Offshore Petroleum and Greenhouse Gas Storage Act 2006, section 124 Petroleum (Submerged Lands) Act 1982 (Vic), section 124 Petroleum (Submerged Lands) Act 1982 (Tas), and section 171 Fish Resources Management Act 1994.

Best endeavours will be made to avoid, minimise, and mitigate potential impacts on other marine operators, including the commercial fishing industry, before the adjustment processes contained in this protocol are applied.

1.4 Definitions

Activity – A petroleum activity or greenhouse gas storage activity and includes, where the context permits, a reference to a proposed activity or any stage of an activity.
Adjustment Area – An area extending 10 kilometres around the perimeter of a seismic survey Acquisition Area or a circular area of radius 4 kilometres around a drilling activity (refer Figure 1 for explanatory diagram).[2] [3]

Acquisition Area - The area of petroleum activity where seismic data is acquired (not a permitted Acquisition Area in an Environment Plan).

Active Source Area – An area including and around the Acquisition Area in which the seismic energy source (airgun array) can be active. This includes survey line run-ins and run-outs.

Affected person – for the purpose of this protocol, an affected person is a commercial fishing licencee, other commercial marine operator, company or business who would have either a) received the revenue from the landed catch or other activity that is the subject of a claim under this protocol, or b) can show they have incurred the cost of lost or damaged fishing gear, equipment or displacement.

Catch Per Unit of Effort (CPUE) – For the purposes of this protocol the catch will be defined in kilograms of landed catch and the unit of effort will be defined in hours (decimal hours where available) fished for trawl, hours fished or kilometres of line set or number of hooks per kilometre for line fishing, or number of pot lifts, resulting in the landed catch e.g. CPUE = kilograms per (trawl/line) hour or pot lift.

Claim Period – The period during and after a petroleum activity for which a claim for loss adjustment can be made, which is from the notified start date of an activity and no more than 30 days after the notified end date of an activity.

Commercial fisher – for the purpose of this protocol, a commercial fisher is the affected entity, person, licence holder, company or business who would have received the revenue from the landed catch that is the subject of a claim under this protocol, or who can show they have incurred the cost of lost or damaged fishing gear or displacement.

Displacement – the relocation of commercial fishing activity or other commercial marine operations from within the Adjustment Area to a Displacement Area as a result of a petroleum activity.

Displacement Area – an alternative fishing ground that is within 50 kilometres of the Adjustment Area.

Fishing gear – Fishing equipment deployed in the water by a vessel engaged in a commercial fishing activity.

[2] 10 kilometers is proposed as a reasonable distance around the Acquisition Area of a seismic survey and consistent with existing industry standards.

[3] Spatial parameters of an Adjustment Area for a 2D survey will require case-by- case specification due to the differing survey layout.

Historical fishing activity, block – A statistical fishing block (as defined here), or fishing event location (latitude/longitude) plotted within the 10 x 10 nm grid system, with fishing activity detailed in either a) Government catch and effort information or b) recorded in a statutory Catch and Disposal Record for at least two out of the previous five years, prior to a relevant petroleum activity conducted under this protocol.

Landed catch – The whole landed weight as detailed in Government catch and effort information provided for the purpose of this protocol, or as recorded in statutory Catch and Disposal Records.

Lodgement Period – The period during and after a petroleum activity within which a claim can be lodged, which is from the notified start date of an activity and no longer than 183 days after the notified end date of an activity.

Market price – The price received by a commercial fisher at the point of first landing, excluding any price margins for marketing, transport, sales commissions, value adding or packaging. In respect to a claim under this protocol, the market price should reflect the price at the time the loss of catch was incurred by the claimant.

Other commercial marine operator – means a commercial marine operator who identified they could potentially be impacted by the petroleum activity during relevant persons consultation in preparation of the relevant EP.

Petroleum activity – means operations or works in an offshore area undertaken for the purpose of exercising a right conferred on a titleholder under the OPGGSA by a petroleum title or discharging an obligation imposed on a petroleum titleholder by the OPGGSA.

Statistical fishing block – Government statistical grid/block numbering system used to record commercial fishing activity data and referred to in this protocol as a block.

Titleholder – The registered holder of the Access Authority, Special Prospecting Authority, Exploration Permit, Retention Lease or Petroleum Production Licence over which the petroleum activity will be acquired, as detailed in the EP for the petroleum activity subject to this protocol.

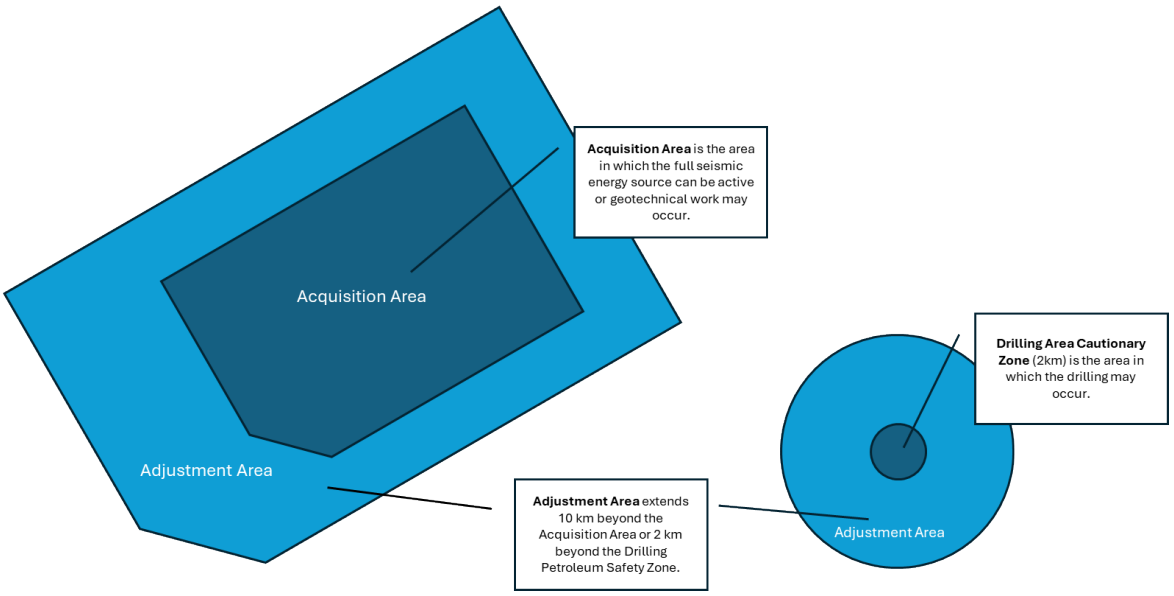

Figure 1 - Representation of defined terms for Acquisition Area and Adjustment Area

1.5 Scope

The OAP is intended to apply to commercial users of the marine environment who are directly affected by petroleum activities, where interference is unavoidable.

This protocol covers:

- A marine operator who is a commercial fisher (refer definition) who fishes as a normal part of their commercial fishing activity within an Adjustment Area (refer definition), during and/or for a specified period after a petroleum activity, conducted under an accepted EP that references and is therefore subject to this OAP. Adjustment is also available for fishing outside of an Adjustment Area in some circumstances, if agreed in advance with the titleholder.
- Other commercial marine operators who identified they could be potentially affected by the petroleum activity during relevant persons consultation, who utilise an area as a normal part of their commercial activity within an Adjustment Area (refer definition) during a petroleum activity conducted under an accepted EP that references and is therefore subject to this OAP.

This protocol applies to marine operators with one or more Victorian, Tasmanian, or Commonwealth fishing licences.

1.6 Consultation

This protocol has been founded by CGG and ConocoPhillips Australia and developed by Klarite Sustainable Ventures (**KSV**) building on the NERA CSEP Commercial Fishing Industry Adjustment Protocol. While preparing EPs for petroleum activities in the Otway, the founding titleholders consulted with fishers, fishing license holders, and fishing associations, which indicated a single method for compensation was desirable. Subsequently, on the request of the founders, KSV has undertaken preliminary consultation with some fishing industry associations and other commercial marine users identified during relevant persons consultation, as relevant persons, to provide input.

Each titleholder will continue to consult as per the requirements of the regulations with each relevant person. Consultation on this protocol may also be carried out by KSV on behalf of each titleholder proposing to adopt this protocol. All records of consultation will be treated as confidential in accordance with Section 25(4) of the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023.

Consultation on the OAP will include:

- Writing to all commercial fishers (Commonwealth and State) who may have rights within the Otway region providing an opportunity for input into the content and format of the protocol.
- Writing to other commercial marine operators who identified they could be potentially impacted by the petroleum activities during consultation in preparation of the Eps.
- Inviting fishing associations and commercial marine operators, including fishers to nominate appropriately qualified and experienced claims assessors for their industries/fisheries.

1.7 Operation of the protocol

Notification of the establishment of an Adjustment Area will be provided to relevant commercial fishing licence holders and other commercial marine operators in writing, no less than 28 days before a petroleum activity starts. Notification is to be provided in the form of a map plus digital files in easily readable formats such as KML, GPX or shapefiles.

Fishers (the fishing vessel/licence) must have established previous fishing history, at a minimum of two out of the previous five years, for all block(s) or fishing event(s) for which they wish to make a claim for loss of catch or displacement adjustment under this protocol.

To receive adjustment under this protocol, a commercial fisher must be able to show that they would have received the revenue from the landed catch that is the subject of a claim, incurred additional costs for displacement, or show that they have incurred the cost of lost or damaged fishing gear.

Adjustment under this protocol is dependent on a commercial fisher or commercial marine operator continuing to carry out their activities to the best of their ability and to mitigate and limit financial loss despite the occurrence of a petroleum activity. Titleholders using this Protocol reserve the right to refuse a claim if fishers interfere with a petroleum activity through deliberately operating in properly notified areas, noting that such interference may also be in breach of Section 603 of the Offshore Petroleum and Greenhouse Gas Storage Act 2006 (See Appendix 7).

Note that this protocol may be referred to in the EP developed by each titleholder to manage potential impacts to commercial fishing licence holders and other marine users, where identified during consultation, and will therefore be subject to inspection under NOPSEMA's environmental inspection program.

2 Commercial Adjustment Available Under This Protocol

2.1 Displacement

If a commercial fisher is unable to fish in their historical fishing area (refer definition) within an Adjustment Area during a petroleum activity and incurs costs over and above the normal running costs for a fishing trip while relocating to another historical fishing area, then additional costs associated with increased distance/transit time, fuel and crewing will be considered under this protocol for monetary adjustment. The Displacement Area is an alternative fishing ground within 50 kilometres of the Adjustment Area.

For fishers, displacement will be assessed based on a comparison of the running costs per day at sea against the previous yearly average. A commercial fisher who decides it is necessary to relocate to another fishing ground because of a petroleum activity subject to this protocol and wants to be considered for displacement adjustment must notify the titleholder of the petroleum activity, where possible, prior to undertaking the relocation. When making a claim, evidence must also be provided to substantiate fishing gear in use at the claim time.

Claimants undertaking commercial activities within their normal operating range during a petroleum activity may be eligible to make a claim where the fisher can evidence that the average distance travelled per fishing operation is greater compared to the historical pattern during the same calendar month(s) in the preceding 5 years. This includes the distance travelled between the fishers' home port and subsequent fishing locations. It is not necessary to have records for all years for that calendar month, but there must be at least one year for the corresponding calendar month.

For other commercial marine operators, displacement will be assessed on a case-by-case basis through prior agreement with a titleholder on the method of calculation. Timeframes related to displacement claims can be found in Appendix 6.

2.2 Loss-of-Catch Adjustment

Evidence-based loss-of-catch adjustment under this protocol relates to fish lawfully caught and retained by a fishing vessel under a Victorian, Tasmanian or Commonwealth fishing licence. The adjustment process applies to historical fishing activity over established fishing grounds, and not to speculative fishing activity.

The loss-of-catch adjustment process applies to commercial fishing activity conducted by a licensed fishing vessel within an Adjustment Area, and other fished areas within a given calendar month. For each month where adjustment is claimed, the licensed fishing vessel must conduct fishing within an Adjustment Area.

Loss-of-catch adjustment is available for the period of an activity and for six months after an activity is completed[4]. However, claims must fall within the thirty-day claim period after the activity. This adjustment process assumes that any loss-of-catch experienced will be demonstrated through a reduced CPUE for that fishing vessel (or license if subject to boat replacement) compared to previous years for the same eligible claim block/fishing event location by species by month.

Loss of catch assessments will be conducted using the petroleum activity period catch and effort

[4] Temporal parameters for a 2D survey will be considered on a case-by-case basis.

data per month plus the previous 10 years (by same block/fishing event location and month) where available.

Timeframes related to loss-of catch claims can be found in Appendix 6.

2.2.1 Method of Assessing Loss-of-Catch Adjustment

Treatment of catch-and-effort data to determine eligible fishing events to be included in the adjustment assessment process.

As detailed in this protocol, adjustment is available for fishing activity where it can be shown there is a minimum of two out of the prior five years where fishing activity has taken place in the same block or fishing event location that is the subject of a claim. This requirement applies to the Adjustment Area and for any other block/fishing event location/area for which adjustment is being claimed.

For State fisheries, catch-and-effort data are provided in a 10 x 10 nm statistical grid format, the same block by month will be checked for the five years preceding the activity year to ascertain the minimum requirement of a minimum of two years fishing activity within the previous five years. Where catch-and-effort data are provided in larger than 10 x 10nm statistical grid format, applicants may be asked for additional positional information for blocks that partially overlap the Adjustment Area, or are outside of the Adjustment Area, to assess the minimum fishing history requirement.

For Commonwealth fisheries, catch-and-effort data from AFMA are provided for the location of each fishing event identified with latitude and longitude coordinates. The existing Victorian grid system will be used to assess the minimum fishing history requirement. The start point of each fishing event will be plotted within the 10 nm grid system to aid the assessment of previous fishing history by allocating each event to a 10 nm block to determine fishing events eligible to be included in the adjustment assessment process. Note that assessors have the flexibility to make judgements that will enhance the statistical accuracy of an assessment and/or provide balanced practical assessment outcomes.

2.2.2 Calculating an average CPUE

Catch-and-effort history covering the prior 5 years is required to calculate an average CPUE value. Averaging across this period reduces the influence of yearly fluctuations in recruitment and environmental parameters.

CPUE will be defined in kilograms of landed catch and the unit of effort will be defined in hours (decimal hours where available) fished for trawl, hours fished, or kilometres of line set or number of hooks per kilometre for line fishing or number of trap lifts, resulting in the landed catch, for example CPUE = kilograms per trawl/line hour or trap lift. Average CPUE will be based on the mean catch-and-effort values of all eligible fishing events per claim month.

It is recognised that in some cases, 5 years of catch history data may not be available and where this occurs an assessor should determine an appropriate average CPUE based on the information available in the application and any other information that an assessor deems appropriate.

The use of 5 years prior catch history and the intention of this protocol is that assessments are conducted based on the available catch and effort information. However, an assessor may also consider significant catch trends within a fishery and/or management changes if they are thought to materially affect resulting catch rates or landed catch volumes.

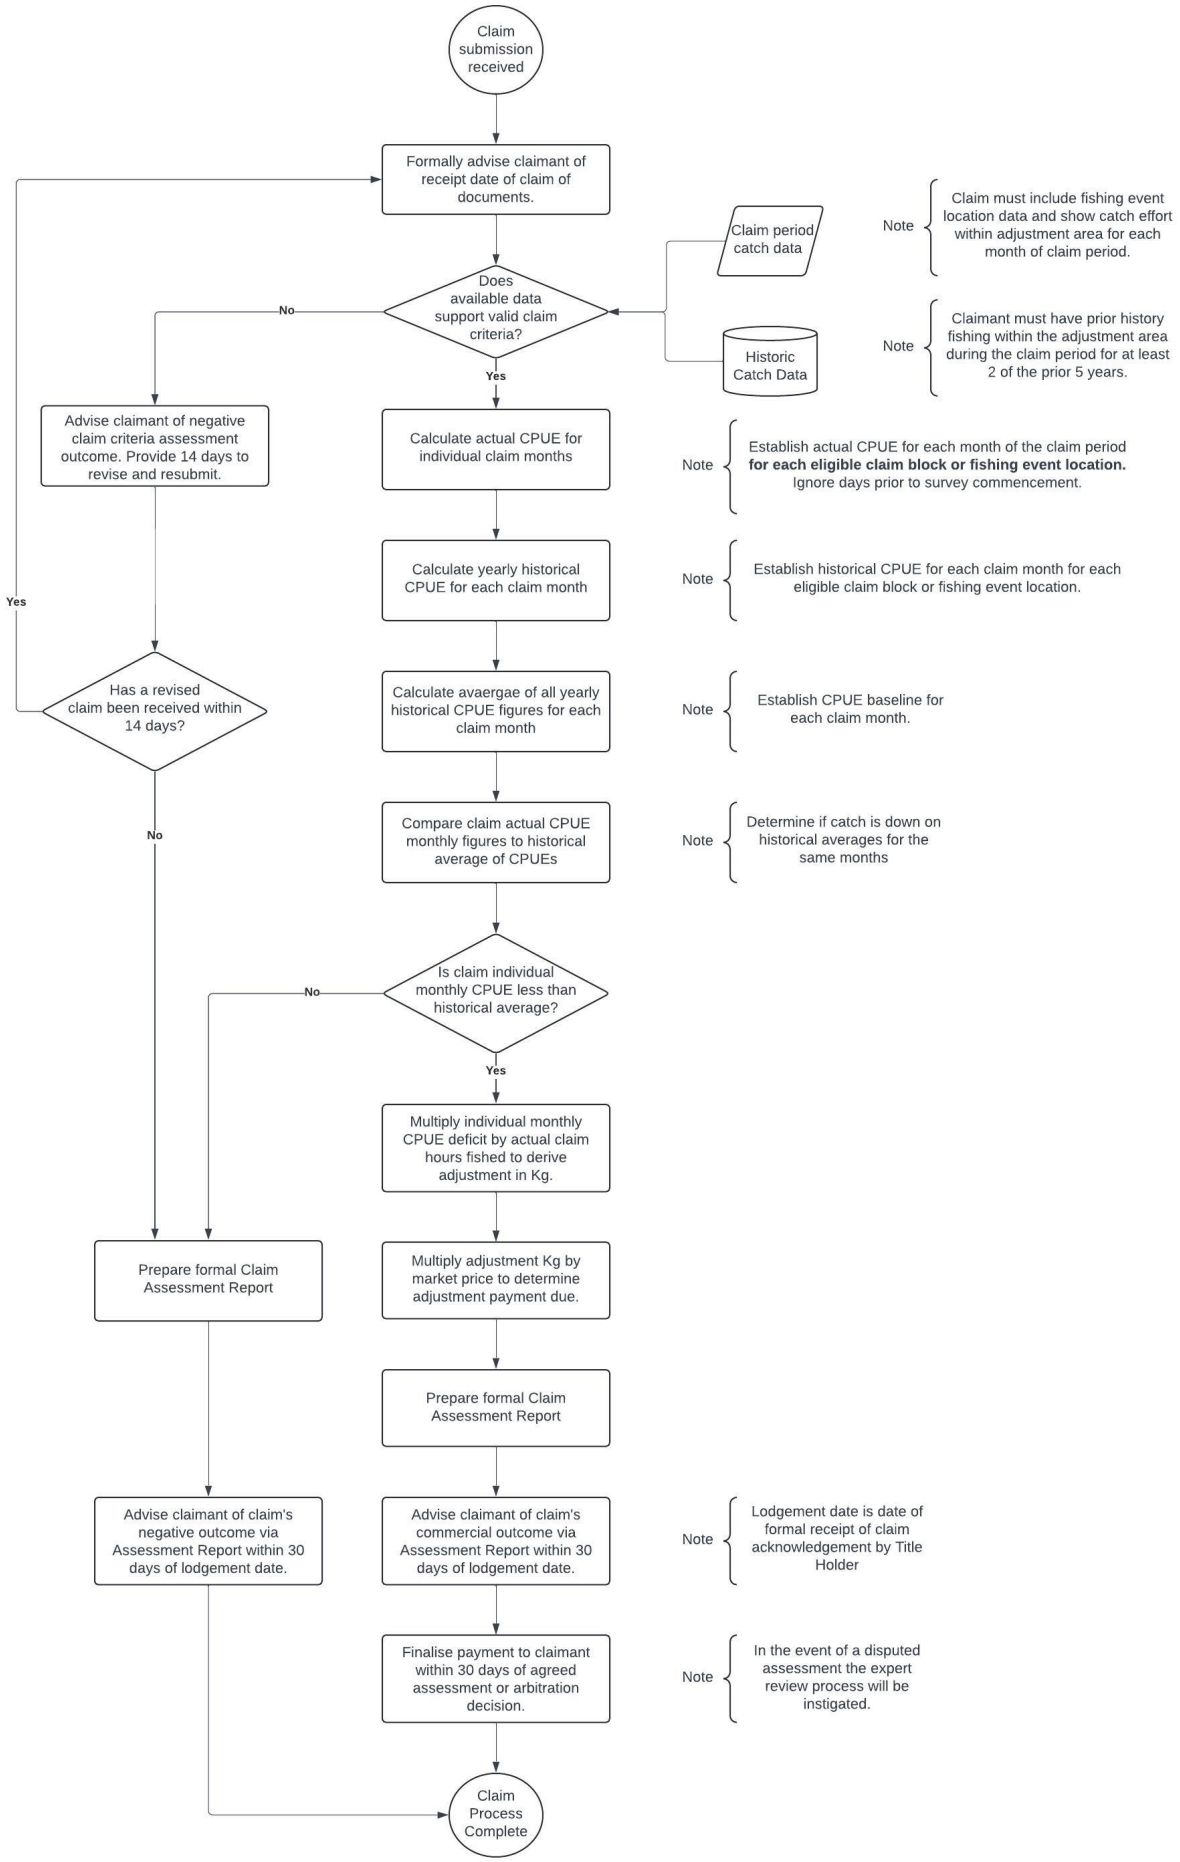
2.2.3 Loss-of-Catch Adjustment Assessment Method

1. Claim month must contain fishing activity within the Adjustment Area.
2. A claimant must have historical fishing activity (refer definition) for each block or fishing event location subject to a claim.
3. Average CPUE's are calculated for each calendar month for all eligible fishing events, using the previous 5 years of data. These averages are used as a baseline CPUE from which to assess claims.
4. The CPUE for the month/s and block/s being claimed for will then be compared to the baseline CPUE's calculated for the same block/fishing events and month/s, and where a shortfall is established, an adjustment will be calculated.
5. The established shortfall in CPUE will be multiplied by the unit of effort (number of pot lifts, trawl hours, kilometres of line set/number of hooks per kilometre,) fished for that claim month, and then the grouped species market price, to provide the amount of monetary adjustment due for that month.
6. Adjustment can be calculated for individual species or combined as appropriate.

2.2.4 Adjustment Method Loss of Catch Adjustment Calculation Example

Claim period April 2020	Species: Rock Lobster Pot Lifts: 400 Market price: $80/kg Total catch: 500 kgs.
Claimant has historical fishing activity within Adjustment Area prior to April 2020	Condition met
Claimant fished in Adjustment Area during April 2020	Condition met
April historical baseline CPUE	1.75kg/potlift
April 2020 CPUE	1.25kg/potlift
Shortfall in CPUE	0.50 kg/potlift
Shortfall multiplied by 400 pot lifts in April 2020	200kg
200 kgs multiplied by market price of $80 per kg	$1,600
Monetary adjustment due for reduced catch April 2020	$1,600
Administration Allowance for claim with supporting documents	$1,950
Total Remuneration for claim	$3,550

2.2.5 Loss of Catch Assessment Flow Chart



2.2.6 Exceptions to loss-of-catch assessment method information requirements.

Where a fisher is unable to provide 5 years prior catch-and-effort data due to Government confidentiality requirements or other reason, an assessment may still be conducted subject to the claim assessor being satisfied that an accurate assessment can still be conducted using the volume of data available.

If requested by the claimant, an assessment may be conducted using a fisher's own catch and effort data where a claim assessor forms the view that the data is consistent with Government data accuracy and formatting and that the data is suitable to conduct an accurate assessment.

The loss of catch adjustment process under this protocol does not cover circumstances where there may be discussions and/or agreement reached between a petroleum activity titleholder and a commercial fisher prior to an activity taking place, that it is not appropriate for fishing to occur within the area of a petroleum activity. Likewise, if a commercial fisher feels that they will be disadvantaged by a petroleum activity due to alternative suitable fishing grounds not being available to them during the petroleum activity, then they should engage with the titleholder ahead of an activity commencing.

A commercial fisher wishing to lodge a claim for adjustment should notify the titleholder of their intention to lodge a claim as soon as possible after the conclusion of operations of a petroleum activity.

2.3 Fishing gear loss or damage

A commercial fisher may lodge a claim in accordance with this protocol if they experience accidental loss or damage of deployed fishing gear where a fisher can demonstrate that the petroleum activity and/or the in-water equipment or supporting vessels subject to this protocol.

Through pre-activity notifications and communications, titleholders and commercial fishers should have an awareness of activity and fishing activities and make all reasonable efforts to avoid direct interaction and fishing gear loss or damage. It should be noted that petroleum activity vessels/rigs carrying out petroleum activities identify as 'vessel restricted in her ability to manoeuvre' under international marine navigation laws.

If fishing gear loss or damage occurs, the commercial fisher should immediately notify the titleholder.

When lodging a claim, the claimant should clearly document when, where and how the gear damage or loss occurred and where possible, the name and details of vessel(s) involved in the incident. A claim should include a quote (two where possible) with costs associated with repairing or replacing the lost or damaged fishing gear.

As a result of assessing the claim, by mutual agreement with the claimant, the titleholder may offer to cover the cost of repairing or replacing the damaged fishing gear or providing like-for-like replacement equipment.

Fishers making a claim for lost or damaged gear may also make a CPUE based claim for the lost catch associated with the lost or damaged gear.

In the event a claim for forgone catch has been submitted, the titleholder may (at their sole expense) enlist the services of an independent person or organisation to assess the claim. If agreement cannot be reached between the claimant and titleholder, then refer to the independent expert review provisions in the *How long will it take to deal with my claim and independent expert review process* section of this protocol.

A claim for fishing gear loss or damage must be lodged within 6 months of the conclusion of the activity.

3 Claim Information and Assessment Process

Titleholders conducting petroleum activities in accordance with an EP subject to this protocol will provide a centralised contact point and online portal to relevant commercial fishers/marine operators relating to lodging a claim or notification regarding displacement, loss of catch, or fishing gear loss or damage, as relevant. Contact information will also be provided to relevant fishing associations as the respective peak commercial fishing industry bodies.

All information provided in an application under this protocol must be kept confidential by the titleholder, an assessor or expert reviewer of a claim and any other person who has access to the information.

Provided a claimant can demonstrate the required previous fishing history within an Adjustment Area, if all the remaining information requirements set out in this protocol are not available to a claimant, then such claims will be considered on a case-by-case basis, in consultation with the nominated competent claim assessor. For example, if a commercial fisher, whose regular fishing grounds are within the Displacement Area, believes they are indirectly affected by another commercial fisher who has been displaced and has moved into the first fishers regular fishing grounds they may qualify as a claimant under the CPUE adjustment process detailed above.

An option for applicants lodging a claim is to authorise an assessor to access the relevant fishing catch and effort information directly with the appropriate Government Department. Alternatively, applicants may provide the required Government catch and effort information with their claim application.

Applicants will receive confirmation of a claim being lodged with the titleholder. If an assessor forms the view that the information lodged with a claim is not sufficient to conduct a meaningful assessment or support the application, then the claimant will be advised in writing and given 14 days to respond to the assessor. If no response is received within 14 days, then the assessment will be completed, and the claimant advised of the outcome.

Claims will be assessed by separate monthly fishing activity, with each month assessment outcome not influencing or impacting on any other month's assessment outcome. This protocol outlines the adjustment processes in a manner to provide consistent assessments over time. However, assessors have the flexibility to make judgements that will enhance the statistical accuracy of an assessment and/or provide balanced practical assessment outcomes.

For fully documented claims that meet the Adjustment Area historical fishing/usage activity requirement, whether successful or not, clerical costs relating to preparing, submitting, and engaging in the adjustment process under this protocol, up to a value of $2,000 per claim, will be reimbursed by the activity's titleholder as part of the claim process. A statement outlining time and resource costs to support an amount up to $2,000 should be included with a claim. Clerical costs that exceed $2,000 may also be included with a claim and reimbursed under this protocol if evidenced by documentation.

3.2 Who can lodge a claim and when?

A commercial fisher who is an affected person who has suffered displacement, a loss of catch, or gear loss or damage whilst operating in and around a petroleum activity Adjustment Area, subject to this protocol can lodge an adjustment claim.

Other commercial marine operators (refer definition), identified during relevant persons consultation during the preparation of the relevant EPs, who suffers displacement whilst operating in and around a petroleum activity Adjustment Area, subject to this protocol can lodge an adjustment claim.

A person so authorised may lodge a claim on behalf of a commercial fisher/marine operator. Claims may be lodged by a person, company, or association on behalf of more than one commercial fisher/marine operator, provided that the required individual usage/catch history is provided and there is evidence of the authority to lodge the claim on behalf of others.

Claims can be submitted up to 6 months after the conclusion of a relevant petroleum activity.

3.3 What information is needed to lodge a claim?

Claimants will need to be able to identify the relevant vessel and licence(s) that are involved in the claim, and to provide evidence of the entity that would have received the revenue that is the subject of a claim. For fishers, a key information requirement when lodging a loss of catch claim will be to either authorise access to the relevant Government catch and effort data or provide the catch and effort data with the application. For other commercial marine operators, the information needed for lodging a claim will have been agreed between the titleholder and the entity that would have received the revenue that is the subject of a claim.

Full details on the information required to be lodged with a claim are contained in the application forms at:

- Appendix 2 – Claim for Loss-of-catch, Displacement, Gear damage and C&E Permission
- Appendix 3 – Statutory declaration for making claim

Each claim should relate to only one petroleum activity and associated titleholder. If a claimant is not sure which titleholder is undertaking the activity the claim may be delayed whilst a claim assessor confirms the correct titleholder.

3.4 Who will assess the claims and what information will be in the report?

Subject to a claim being lodged, the titleholder of a petroleum activity (at their expense) in consultation with the claimant, will engage a suitably experienced/qualified independent person or organisation as the assessor of the claim.

The titleholder is to provide the assessor with a letter of instruction/project brief, which is to be provided to the claimant as part of the assessment report.

An assessment report prepared by an assessor should include the following information:

- a copy of the letter of instruction/project brief received by an assessor when engaged to carry out the independent assessment,
- confirmation (or otherwise) that the information provided in the claim is sufficient to conduct a meaningful assessment,
- a summary of the claim details (activity, applicant, vessel, month(s)),
- for a loss of catch claim, monthly CPUE assessments as outlined in this protocol including an estimation of any loss of catch (in kilograms) and its market price, and
- any other information, comments, or views relevant to the assessment that

the assessor may wish to include.

Upon receiving and considering the assessment report, the titleholder will provide a copy of the report to the claimant and offer to meet with the claimant to discuss/address the claim.

3.5 How long will it take to deal with a claim?

An appropriately documented claim (including relevant catch and effort information) should be assessed, and a report provided to the claimant within 30 days of the lodgement date of the claim. If an assessor is authorised to access catch and effort data, then the 30-day period begins upon receipt of the necessary catch-and-effort data. If an appropriately documented claim report cannot be made available to the claimant within 60 days of a claim being lodged or receipt of catch and effort information as appropriate, and no mutual agreement to extend the time period has been entered into, then the titleholder (at their expense) in consultation with the claimant, shall appoint a suitably experienced/qualified independent person or organisation to provide an expert review of the claim.

Included as part of the settlement of each claim, will be a binding agreement that summarises the claim outcomes and an agreement by the claimant that acceptance of the settlement negates any further claims for the same species and month(s) of that petroleum activity.

3.6 Independent expert review of a claim

If a claimant disagrees with a claim assessment outcome and cannot reach agreement with the titleholder, they may opt to go to an independent expert review (funded by the titleholder of the activity).

If a claim is subject to independent expert review, then as part of that process, both the claimant and the titleholder shall be given the opportunity to address the assessor to state their position, prior to an independent expert review decision being reached.

An independent expert reviewer must provide a view as to whether the claim assessment process has been conducted in line with the requirements of the protocol. The independent expert reviewer may also consider any additional information deemed appropriate by themselves, including information provided by either the claimant or the titleholder. An independent expert review decision is binding on the claimant and the titleholder and may differ from the initial assessment report. A timeline diagram setting out the relevant time frames under this protocol can be found at Appendix 4.

3.7 How long will it take to be paid adjustment?

Once a claimant and titleholder agree with a claim outcome, or an expert reviewer has issued a report, the titleholder will provide monetary adjustment to the claimant as soon as possible and within 30 days.

4 Protocol Review and Maintenance

This protocol will remain in force for the validity period of any accepted EP for any of the titleholders who become members of the OAP, anticipated to be a five-year term from date of acceptance by NOPSEMA. The protocol will be subject to review and update by KSV and the members at least once in each 12-month period. Changes will be considered in consultation with relevant fishing associations (and other stakeholders as appropriate) and subject to agreement by the titleholder members.

The forms in the Appendices will be made available for download through the OMICC Portal, or online forms may be used to submit a claim.

4.1 Revision History

Revision	Date	Notes
0.1	2 February 2024	Creation of document based on the NERA protocol and following consultation inputs from commercial fishing industry consultation in preparation of relevant EPs.
0.2	22 February 2024	Amendments to add other commercial marine operators and prepare for consultation with OMICC founders.
0.3	14 March 2024	Amendments following OMICC founder input and clarifications to scope. Preparation for first legal review by titleholders.
0.4	30 April 2024	Reviewed and updated for distribution and comment.
0.5	29 August 2024	Updated following consultation with commercial fishers.
0.6	18 March 2025	Updated following further consultation with commercial fishers and amendments following OMICC founder input.

Appendix 2: Consent and Confidentiality Form

CATCH & EFFORT and CATCH DISPOSAL RECORDS CONSENT
Records from this year and previous years are needed to support your claim. Please complete the following consent form for lodgement with the appropriate fisheries management agency.

I, (insert name) ……give permission to the Klarite Sustainable Ventures

nominee to have access to my (insert fishery) ……. catch and effort records at

(fisheries management agency) ……..

I affirm that the fishing cooperatives listed below (leave blank if not applicable):

(insert fishing cooperative) …… receive (insert percentage) ……% of my landed catch.

(insert fishing cooperative) …… receive (insert percentage) ……% of my landed catch.

(insert fishing cooperative) …… receive (insert percentage) ……% of my landed catch.

I, (insert name) …… do:

(a) Certify that the details and particulars in this application are true to the best of my knowledge, information, and belief; and

(b) Acknowledge that the making of a false statement is unlawful and open to prosecution.

Signed: …….. Date: ……..

Appendix 3: Displacement Application Form

Commercial Fishing Industry Adjustment Protocol - Application Form for Displacement Claim

Application Form - Commercial Marine Operator Adjustment Protocol - Displacement	
Activity Details	
Petroleum activity name	
Activity titleholder	
Claimant Details	
Name of person/company making claim	
Address	
Email	
Contact number	
I am the entity that would have received the revenue from the catch that is the subject of this claim. Please include evidence of above statement	Yes or No
Relevant authorisation holder details (if different from claimant)	
Name	
Address	
Email	
Contact number	
Authorisation/licence(s) name and number	
Claim details	
Evidence of the additional distance, fuel and crew costs incurred by the relocation of the fishing/other marine operation.	Attach receipts/evidence of costs for claim month. Include vessel track data, fuel receipts, transit time, distance travelled etc.
Evidence of previous year daily (at sea) average distance, fuel and crew costs	Attach receipts/evidence of costs for previous year.

Application Form - Commercial Marine Operator Adjustment Protocol - Displacement
Include five years catch data preceding the year of the claim in the following form: • Vessel • Year • Month • Fishery • Fishing event location/blocks fished provided at the highest available block resolution. • Whole weight calculated based on the reported landed weight and listing any relevant conversion factor(s). For other commercial marine operators, include five years historical area usage data preceding the year of the claim in the following form: • Vessel • Year • Month • Location provided at the highest available resolution. Note 5 years of data is required for displacement purposes to show recent operational history has occurred within an Adjustment Area. If less than 5 years data available, then claim assessor should evaluate appropriate method of assessment.

Application Form - Commercial Marine Operators Adjustment Protocol – Fishing gear loss or damage	
Activity Details	
Activity name	
Activity titleholder	
Claimant Details	
Name of person/company making claim	
Address	
Email	
Contact number	
I am the entity that has incurred the costs of the lost or damaged fishing gear that is the subject of this claim. If claiming for loss of catch, I am the entity that would have received the revenue from the catch that is the subject of this claim. Please include evidence of above statements.	Yes or No and supporting information.
I wish to authorise direct access to my catch and effort history relevant to this application.	Yes/No (If yes then authorisation holder to sign here)
Relevant authorisation holder details (if different from claimant)	
Name	
Address	
Email	
Contact number	
Authorisation/licence(s) name and number	
Claim details	
Evidence of notification to the titleholder of the gear loss and/or damage incident.	
Information describing when, where, and how the gear damage and/or loss occurred.	
Where possible, the name and details of vessel(s) involved in the incident.	

A claim should include a quote (two where possible) with costs associated with repairing or replacing the lost or damaged fishing gear.	
Estimate of any proportionate loss of catch including market price, plus catch and effort information sufficient to calculate CPUE for claim month or same month in previous year.	
Please list the documents provided with your application	
1.	
2.	
3.	
4.	

Appendix 6: Adjustment Protocol Timeframes

The titleholder will provide 28-day notice of a future Adjustment Area including a map and coordinates.

The titleholder will provide notice of activity start and activity end through the OMICC portal and any other communications methods specified in the associated accepted Environment Plan.

The Claim Period:

1. A claim can be made from the starting date of the activity.
2. A claim can be made once per month for the whole month, or part thereof.
3. A claim can be made for evidence-based losses up to 30 days after the end date of the activity.

The Lodgement Period:

1. All claims must be lodged within 183 days (6 months) after the end of an activity.

Timeframes for processing a claim:

1. Claims to be finalised within 60 days of being lodged, or receipt of catch and effort information, unless mutual agreement reached between claimant and titleholder to extend time frame.
2. If agreement cannot be reached between the titleholder and claimant within the prescribed times above then the titleholder, in consultation with the claimant, must appoint an independent expert reviewer to decide the claim.
3. Subject to an independent expert review decision, the titleholder shall settle the claim in accordance with the decision within 60 days.

Appendix 7: Legislation Section 603

Offshore Petroleum and Greenhouse Gas Storage Act 2006
No. 14, 2006

Compilation No. 54
Compilation date: 18 October 2023
Includes amendments up to: Act No. 74, 2023
Registered: 21 October 2023

603 Interfering with offshore petroleum installations or operations

(1) A person commits an offence if:

(a) the person engages in conduct; and

(b) the person's conduct results in:

(i) damage to, or interference with, any structure or vessel that is in an offshore area and that is, or is to be, used in exploring for, recovering, processing, storing, preparing for transport, or transporting, petroleum; or

(ii) damage to, or interference with, any equipment on, or attached to, such a structure or vessel; or

(iii) interference with any operations or activities being carried out, or any works being executed, on, by means of, or in connection with, such a structure or vessel.

Penalty: Imprisonment for 10 years.

1 Introduction

This document describes a monitoring programme required because of the outcomes of an environmental impact assessment conducted by CGG for the Regia Marine Seismic Survey (**Regia MSS**). Context for this document can be found in the Regia MSS Environment Plan (**EP**) and users unfamiliar with the Regia MSS EP should read, in the following order:

- Impact Assessment – Underwater Sound: Marine Mammals (Appendix E7)
- Further Assessment – Southern Right Whales (Appendix F3, Section 3.1.1)
- Implementation Strategy (Appendix B3)
- Fauna Management Plan (Appendix G2)

Section 0 of this document presents the implementation plan for Southern Right Whales (**SRW**). This coastal monitoring program is designed to ensure the requirements of the National Recovery Plan for SRW are met and impacts from the activity are kept below an acceptable level.

Section 3 of this document presents the implementation plan for Blue Whales (Antarctic and Pygmy) (**BW**s). This pre-season coastal aerial surveillance plan is designed to detect BWs as they arrive at the Otway region ahead of their foraging season, with the aim to provide an early signal for scaling protection measures before their arrival near the survey.

2 Monitoring Framework – Southern Right Whale

Herein we outline the framework for a dedicated SRW monitoring program along the south-west Victorian coastline to monitor the presence and movements of SRW in the lead-up to and during the Regia MSS.

2.1 Monitoring Objective

The key objective of this program is to provide real-time visual assessment of SRW whale presence within the greater Otway offshore region encompassing waters exposed to elevated levels of sound from the Regia MSS.

The program forms part of a multiple lines-of-evidence approach to SRW detection that will work in parallel with in-water ambient sound monitoring, citizen science data, social media monitoring, and offshore detection methods (Passive Acoustic Monitoring (PAM) systems and vessel-based Marine Fauna Observers (MFO's)) to provide a continual scanning system for whale presence to inform management and mitigation decisions.

2.2 Coastal Activities within the Monitoring Framework

2.2.1 Detection Methods Selection

CGG has evaluated various visual (coastal and aerial) surveillance methods. A full evaluation of these methods is presented in Appendix F2. In short, Unmanned Aerial Vehicles (UAVs)[1], otherwise known as drones, allied with qualified Marine Fauna Observers (MFOs) have been selected as the preferred coastal detection method with the largest geographical coverage due to their lower cost, lower safety risk, higher uptime, and operational flexibility.

2.2.2 Coastal Monitoring Area

The primary study area is a strip extending 5 km from the shore and running continuously between Cape Bridgewater and Cape Otway. This strip encompasses the SRW Biologically Important Area (BIA) (extending 5 km from shore) and covers the portion of the Victorian coastline with possible sound exposure exceedances above ambient levels from the Regia MSS (Figure G5-1).

[1] The terms Remotely Piloted Aircraft System (RPAS), Drones, Unmanned Aerial Vehicle (UAV), and Remotely Piloted Aircraft (RPA) are used interchangeable across industries and refer to the same generalised technology. For this framework, these systems are collectively referred to as "drones."

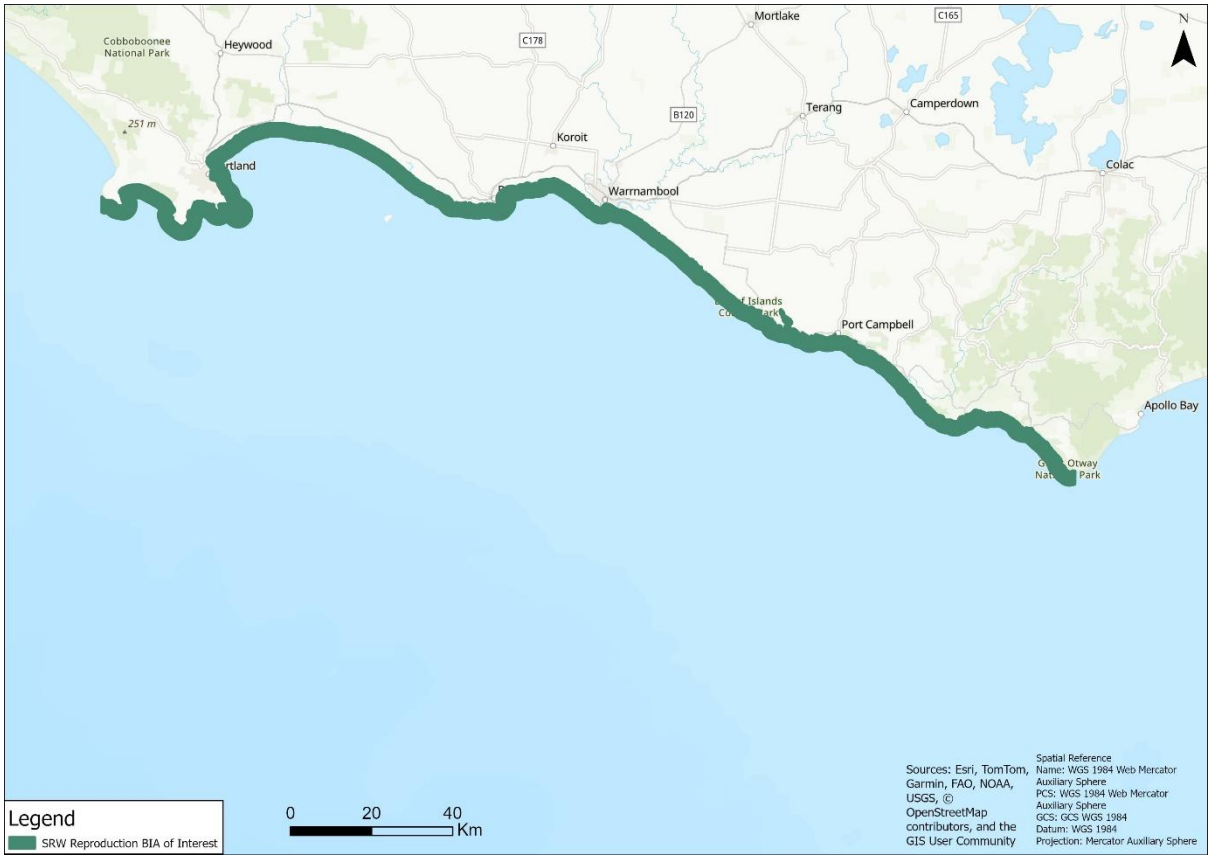

Figure G5-1 – Primary Study Area - SRW Reproduction BIA from Cape Bridgewater to Cape Otway

2.2.3 Resources

The monitoring will be undertaken with two "Whale Monitoring Teams" (WMTs) - each comprising one trained MFO and one Drone Pilot-in-Command (PIC) – who will be responsible for conducting flights west (Zone 1) and east (Zone 2) of Logans Beach respectively (See Figure 2 for flight area delineations). A third team will serve as a backup should extra observation capability be needed.

Using MFOs and drones together provides a more comprehensive approach to coastal marine fauna monitoring. WMT's will move between coastal vantage points each day. Drone PICs will operate their UAVs to extend effective observation ranges, enhance spatial coverage, increase detection probability, and allow for dynamic monitoring of whale movements. MFOs will conduct systematic visual watches and provide taxonomic identification through firsthand observations and through reviewing drone footage. Behavioural observations may also be recorded. Together, these coordinated efforts are expected to support near real-time mitigation enforcement and ensure continued compliance with all relevant regulatory (NOPSEMA and CASA) requirements.

This strategy provides a flexible and operationally efficient approach to whale monitoring, enabling rapid mobilisation across an array of coastal locations. This adaptability is particularly valuable given the variable and often unpredictable weather conditions characteristic of the Otway Coast, ensuring that monitoring efforts remain effective throughout the season.

2.2.4 Program Duration

The program will run for the entirety of the SRW season in Southern Australia which is nominally from May until November.

2.2.5 Program Tasking

Three operational plans have been developed, based around daily weather conditions:

1 Optimal Weather Deployment Plan
2 Sub-Optimal Weather Deployment Plan, and
3 No-Fly Plan

Analysis of long-term weather records for the area indicates there will be optimal conditions up to 15 % of the time, and sub-optimal conditions for up to 60 % of the time (See analysis of weather records in Appendix 2).

The Drone PIC holds ultimate authority and the responsibility for the planning and safe conduct of all flight operations lies with them. Therefore, the daily operational plan will be selected by the Drone PIC, and signed off by the Environment Officer, after assessing forecast weather conditions. While operational weather thresholds and procedural guidelines provide a framework for decision-making, the PICs assessment of real-time conditions always takes precedence. Factors such as visibility, wind strength, cloud ceiling, sea state, and crew readiness must all be evaluated on-site, and the PIC may modify, delay, or cancel a flight at any time if safety could be compromised.

All nominated flight locations identified in this document are publicly accessible areas that have been visually assessed as the most suitable sites for drone deployment based on current information. However, access to these sites may become temporarily restricted due to factors such as high visitor activity, local events, or other unforeseen circumstances. As such, the locations outlined should be considered indicative only. If a preferred site is inaccessible, a nearby alternative location offering comparable vantage and operational safety will be identified and utilised. Final deployment sites will be confirmed and adjusted as required on the day of operations, in accordance with access conditions and safety considerations.

2.3 Coastal Deployment Plans

2.3.1 Optimal Weather Deployment Plan

Optimal weather days represent conditions that are highly suitable for drone operations, characterised by low wind speeds, good visibility, and minimal precipitation. Under these conditions, drone endurance and stability are maximised, allowing for extended flight durations and broader spatial coverage. The weather conditions are expected to permit each WMT to operate efficiently across larger zones, enabling comprehensive monitoring with reduced operational overlap across the survey region.

This monitoring design has four central locations with two to the west and two to the east of Warrnambool (Figure G5-2), with the aim to provide visual coverage of up to 100% of the defined scope area each day during daylight hours. One WMT will monitor the eastern locations and another WMT will do the western locations. A summary of the meteorological parameters that will typically define this plan are presented in Table G5-1. These conditions are predicted to occur on approximately 10-15 % of days in September and October (Refer to Appendix 2 for analysis of climate data).

The primary monitoring sites (PMSs) were identified based on elevated vantage and visual arc, drone deployment feasibility, and accessibility. At each PMS, WMTs will undertake shore-based visual monitoring and at least one drone flight. Drone transects will be defined for each plan in the lead-up to the activity and will be designed to optimise battery efficiency and spatial coverage.

The primary monitoring sites to the west of Warrnambool have a visual range encompassing the Reproduction BIA offshore of Cape Bridgewater, Cape Nelson, Portland, The Craggs, Port Fairy, and Warrnambool. The PMSs within Zone 1 are:

(i) Cape Nelson Lighthouse
(ii) The Craggs.

The primary monitoring sites to the east of Warrnambool have a visual range encompassing the Reproduction BIA offshore of Warrnambool, Logan's Beach Whale Nursey, Mathiesons Road, the Gables, and Cape Otway Light Station. The PMSs within Zone 2 include

(i) Mathiesons Road
(ii) The Gables.

A third WMT will be stationed at a central base located at Logan's Beach, Warrnambool near the midpoint of the scope area between Cape Bridgewater and Cape Otway on days when this plan is active. This WMT will serve as a contingency resource, ready to be deployed at short notice in the event of an unforeseen situation, or if additional monitoring effort is required.

Table G5-1 - Optimal Deployment Plan – Meteorological Parameters

Parameter	Optimal Conditions Threshold	Description
Wind	≤ 10 kt sustained (gusts ≤ 15 kt)	Stable hover, no gimbal shake
Beaufort Sea State	≤ Bft 3 (wave height < 0.5 m)	Minimal whitecaps; stable horizon
Visibility	≥ 10 km	Full horizon clarity for long-range optical ID
Precipitation	Nil	Keep airframe and optics dry
Cloud ceiling	≥ 300 m	Ample vertical separation
Glare / Sun angle	Low or manageable	Smooth horizon contrast
Temperature	5–35 °C	Normal battery operating range

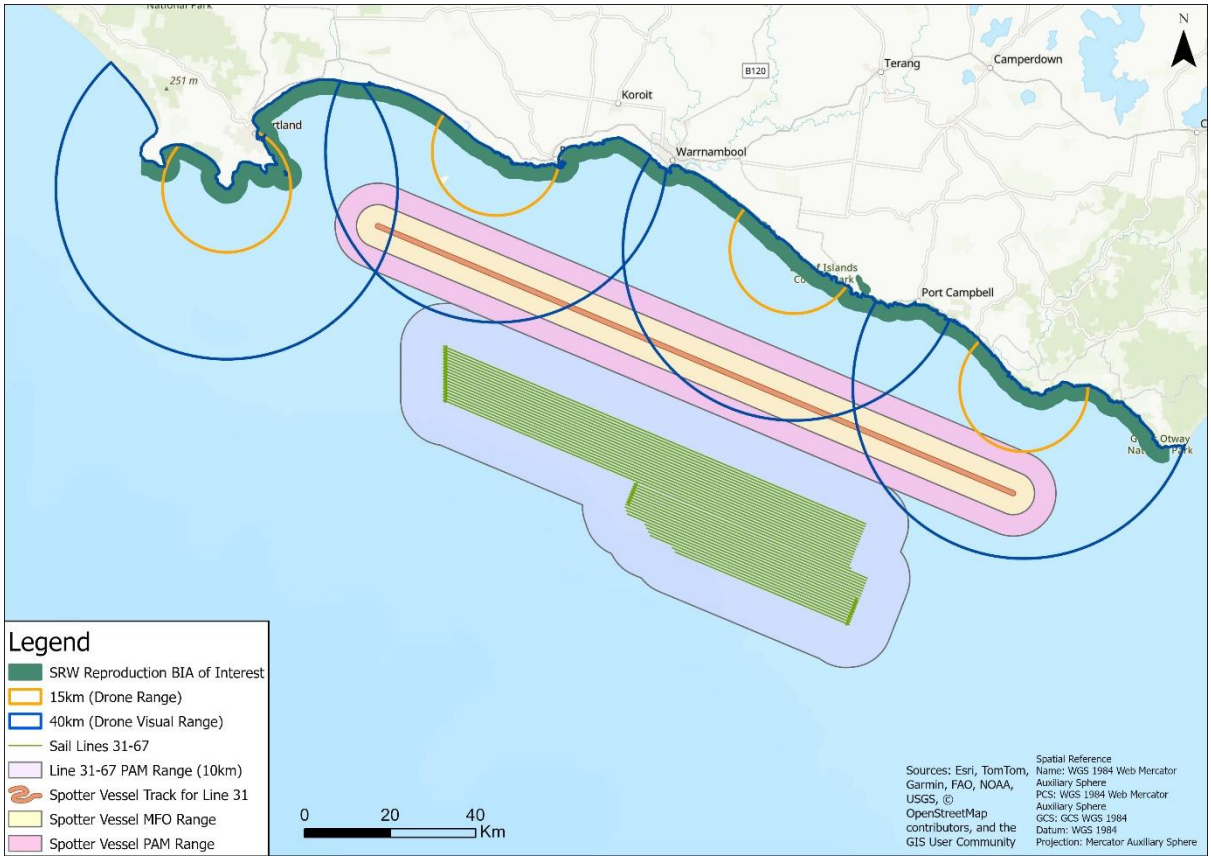

Figure G5-2 - Optimal Weather Deployment Plan Coverage – Figure also shows the Regia MSS survey lines for September & October (lines 31-67) and indicative location of the spotter vessel that has PAM and MFO capacity.

2.3.2 Sub-Optimal Weather Deployment Plan

Sub-optimal weather days are characterised by conditions that may not be ideal for drone operations but are still considered suitable for deployment. On these days, while drone flights are likely to remain feasible, operational efficiency and endurance may be affected. Stronger winds, increased cloud cover, or intermittent light rain can reduce visibility, shorten safe flight windows, and accelerate battery depletion, limiting the duration or range of individual flights.

To maintain effective monitoring coverage under these conditions, three WMTs will be deployed in accordance with the weather-dependent deployment plan. By reducing the spatial extent each team is responsible for, operational demands can be balanced against weather constraints, allowing teams to focus on shorter missions within safer operating limits. This adaptive approach permits monitoring even under less favourable meteorological conditions and remains consistent with the required performance standards.

Under this monitoring design, six primary monitoring sites will be utilised, with WMTs allocated across these sites each day to support broad visual coverage of the defined scope area during daylight hours (See Figure G5-3). Team distribution will remain flexible and may vary according to weather, access, and operational considerations, enabling the intent of achieving up to 100% daily coverage while adhering to all applicable SRW coastal monitoring requirements.

A summary of the meteorological parameters that will typically define this plan, are presented in Table G5-2 below. Long term averages suggest these conditions will prevail on approximately 55-60 % of days in September and October.

At each PMS, WMTs will undertake coastal visual monitoring effort combined with the aim of at least one drone flight at each PMS. Drone transects will be defined for each plan in the lead-up to the activity and will be designed with the intention to optimise battery efficiency and spatial coverage to search for SRWs.

The western third of the scope area, has a visual range encompassing the Reproduction BIA offshore of Cape Bridgewater Cape Nelson, and Portland. The central area encompasses The Craggs and Warrnambool while the eastern third encompasses London Bridge and Johanna Beach (Figure G5-3).

Table G5-2 - Sub-Optimal Deployment Plan – Meteorological Parameters

Parameter	Sub-Optimal Conditions Threshold	Description
Wind	11–21.5 kt sustained (gusts ≤ 23 kt)	Fly only ≤ 5 km; limit altitude 90 m
Beaufort	Bft 4–5 (0.5–2.0 m waves)	Whitecaps frequent; avoid long-range optical ID
Visibility	5–10 km	Thermal useful
Precipitation	Light intermittent drizzle only	Abort on sustained rain
Cloud ceiling	≥ 150 m	Maintain visual horizon
Glare / Sun angle	Moderate; sun on water	Adjust gimbal tilt ≥ 25°
Temperature	0–5 °C or 35–40 °C	Monitor battery performance

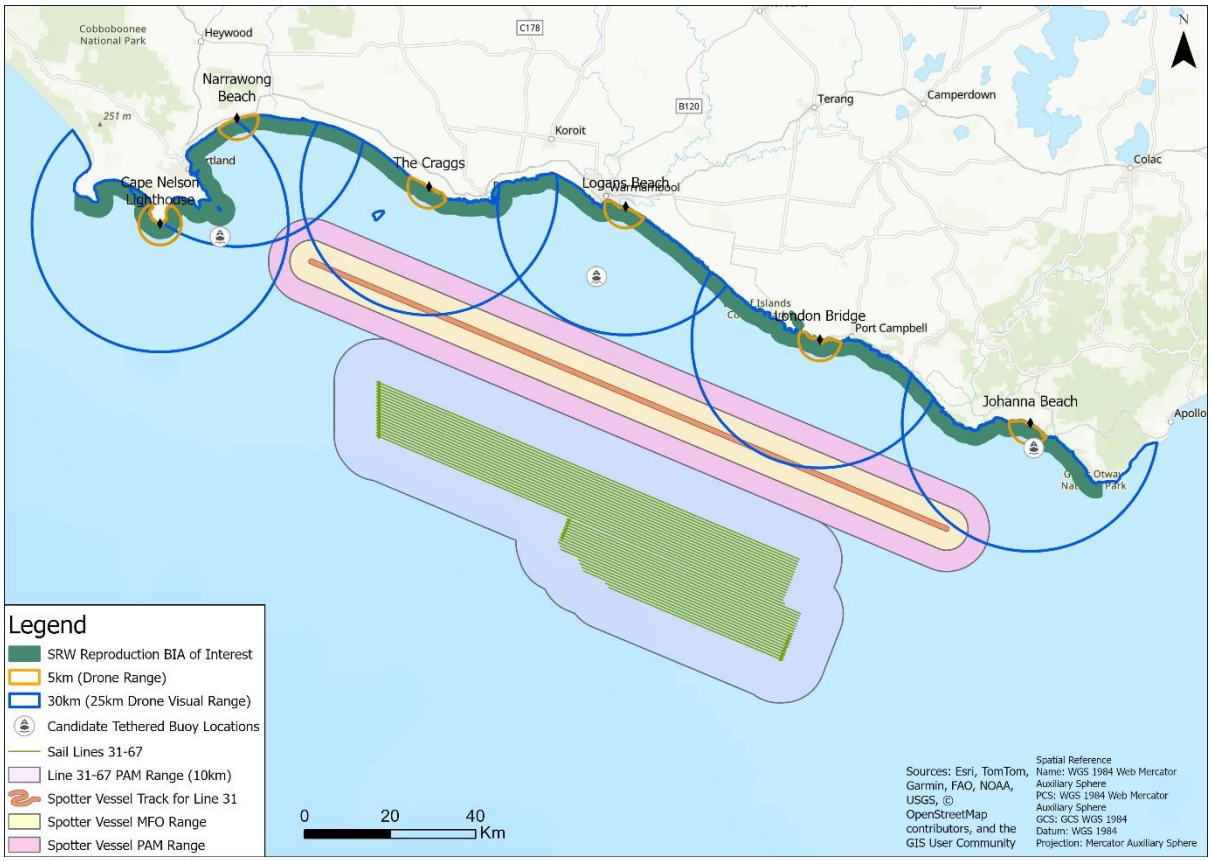

Figure G5-3 - Sub-Optimal Deployment Plan Coverage - Figure also shows the Regia MSS survey lines for September & October (lines 31-67) and indicative location of the spotter vessel that has PAM and MFO capacity.

2.3.3 No-Fly Plan

No-Fly weather days are characterised by adverse meteorological conditions that render drone operations unsafe or impractical. These conditions typically include high or gusting winds, heavy or persistent rainfall, low cloud cover, or reduced visibility, any of which can compromise flight stability, sensor performance, or personal safety. On these days, drone deployment will be suspended, and the focus of monitoring will shift entirely to shore-based visual observation.

Under this monitoring design, multiple PMSs are established along the coast wherever safe access can be gained, with the intent to provide broad visual coverage of the defined scope area during daylight hours. WMTs will be distributed across the broader region in a manner that supports this coverage objective (Figure G5-4).

A summary of the meteorological parameters that will typically define this plan is presented in Figure G5-4. These conditions are predicted to occur on approximately 25-30 % of days in September and October (see Appendix 2).

Under No-Fly conditions there will be no predefined PMSs due to the variable and unpredictable nature of adverse weather conditions. Instead, each WMT will identify and select the most suitable vantage points available on the day to maintain safe and effective visual coverage of their respective portion of the coast.

Given that heavy rain, strong winds, or rough coastal conditions may render certain locations unsafe or inaccessible, site selection on these days will remain highly adaptive. Teams will assess local

conditions in real time and make informed decisions regarding the safest and most practical observation points. In some cases, no coastal observations may be possible if weather or safety conditions prevent effective or safe deployment.

This approach is designed to maintain the maximum monitoring effort across the scope area that weather, and visibility allow. Even when drone deployment is not possible, WMTs will remain active and adaptive throughout the survey period.

Table G5-3 - No Fly Plan – Meteorological Parameters

Parameter	Threshold / Description
Wind	≥ 21.5 kt sustained or gusts > 23 kt
Beaufort Sea State	≥ Bft 6 (waves > 2 m, heavy whitecaps, spindrift)
Visibility	< 5 km or heavy haze / rain curtain
Precipitation	Rain, squalls, hail, or low cloud over site
Thunderstorms	Any convective activity within 10 NM
Temperature	< 0 °C or > 40 °C
Equipment / telemetry	GPS lock < 10 satellites, link instability, compass/IMU warning
Glare	Extreme surface reflection making horizon unreadable
Sea spray / salt fog	Persistent aerosol reducing visibility and risking corrosion

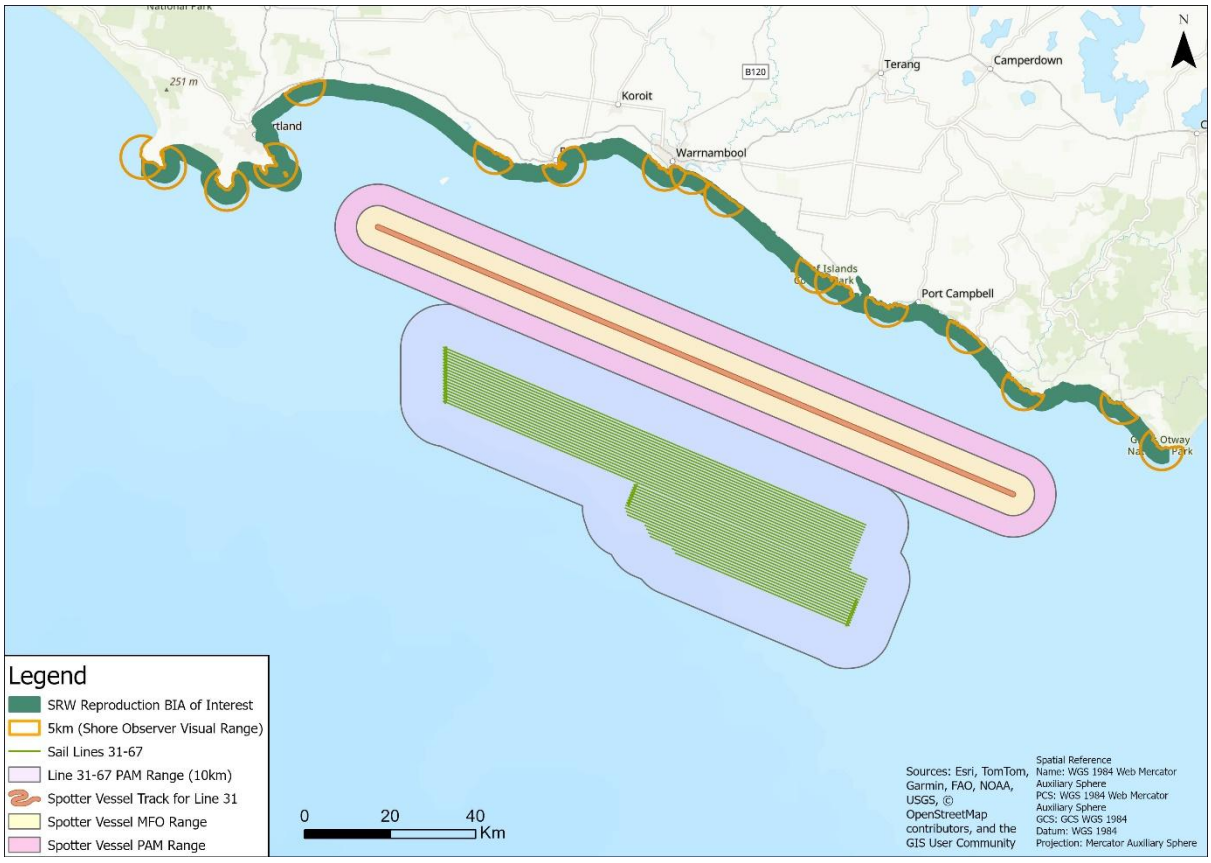

Figure G5-4 - No-Fly Plan Coverage - Figure also shows the Regia MSS survey lines for September & October (lines 31-67) and indicative location of the spotter vessel that has PAM and MFO capacity.

2.4 SRW Detection and Escalation Procedure

2.4.1.1 Confirmed Detection

A confirmed detection is a SRW sighting that has been verified by:

- a qualified MFO or an expert scientist in the field, and
- photographic/video evidence showing a visible time/date stamp and a geographically traceable location.

Only detections meeting this standard are treated as confirmed for shutdown and restart decisions. All confirmed and unconfirmed detections must be reported immediately to the Survey Environment Adviser (SEA) and the CGG Environment Officer.

2.4.2 SEA Decision Pathway

Upon receiving a detection, the SEA determines which pathway applies:

A. Confirmed Detection (from any platform)

1) If the survey is acquiring, the sound source must be shut down immediately.
2) The SEA records time and location and provides instructions to the Party Chief consistent with Appendix G2.
3) Restart may only occur after 24 hours with no confirmed detections from any platform.

B. Unconfirmed Detection

1) The SEA refers the sighting to the Whale Expert Panel (WEP) for advice within 2 hours of receiving the report.
2) The WEP provides advice on whether the sighting is likely to represent a SRW in or near the BIA.
3) If the WEP advises that the sighting is credible, the SEA must treat it as requiring precautionary action. If the survey is acquiring, the SEA will direct an immediate shutdown.
4) The SEA must also direct the nearest WMT to mobilise within 12 hours, where conditions allow, to investigate and attempt to verify the sighting.
5) If the WEP advises that the sighting is unlikely to be a SRW, the SEA may choose not to shut down but must still direct WMT verification.

This approach ensures potential SRW presence is taken seriously while maintaining evidence-based decision-making.

2.4.3 Daytime Procedure (Post-Confirmation)

If a WMT confirms a SRW inside the BIA after shutdown, the team will continue monitoring for as long as daylight and visibility allow or until visual contact is lost. The 24-hour restart clock begins from the last daylight confirmed observation of the SRW within the BIA.

2.4.4 Night-Time Procedure

If a WMT has confirmed SRW presence during daylight and daylight ends:

- Night-time monitoring is not feasible due to safety and visibility constraints.
- The WMT must return to the last confirmed location at first light.
- If the SRW is not observed, the 24-hour restart clock begins from the time absence is confirmed.

The survey remains shut down overnight.

2.4.5 External Sightings and Citizen Science Information

WMTs may use external information (citizen science programs, whale-watching platforms, or social-media reports) to support situational awareness and detection confirmation.

Only reports with verifiable photographic/video evidence (time/date-stamped, traceable location) may be treated as confirmed detections unless verified independently by a WMT or expert.

All other external reports are treated as unconfirmed detections and escalated through the SEA and WEP as per Section 2.2.2(B).

3 Monitoring Framework – Blue Whale

3.1 Purpose and Objectives

The proposed timing of the Regia MSS sits between the end of the SRW season and the beginning of the BW season. Managing the interaction of these two groups with the MSS requires a real-time understanding of their numbers in time and space. Shore or boat based visual surveillance is a traditional method for visual detection of whales, but the spatial coverage is limited due to vessel speeds and viewing height above water. Drones, however, now provide a relatively low-cost method for drastically increasing visual coverage at higher speeds and vantage points.

Drones will be used to detect BW as they arrive at the Otway region ahead of their foraging season, which typically occurs between November and March each year.

BW arrive in the Otway region following historical marine highways, which lead them down the West Coast, around the SW Cape and directly across the Great Australian Bight to feed on krill associated with the upwelling systems off the Otway coast. Because of this consistent west to east path, flights launched from Cape Nelson could improve early detectability through more extensive searching of offshore waters than is otherwise possible.

3.2 Site Rationale

Cape Nelson is one of the few vantage points along the southwest Victorian coast where BW can, at times, be observed from shore. Located west of the Operational Area, it is likely to be the first location through which BW pass as they arrive at the region. Its elevation above sea level and orientation toward the offshore feeding zone reduce curvature limitations, maximise sensor line-of-sight, and minimise transit time to areas of interest. The lighthouse precinct offers secure ground infrastructure suitable for controlled Beyond Visual Line of Sight (**BVLOS**) operations. Taken together, these characteristics make Cape Nelson the most suitable site for launching long-range surveillance intended to detect early BW presence.

3.3 Operational Context

Flights will focus on monitoring near-shore to mid-shelf sectors, up to approximately 40 km offshore of Cape Nelson, aligned with recent historical observations (Figure G5-5 and Figure G5-6) and expected prey distribution, using established altitudes, ranges, and sensor configurations appropriate to BVLOS over-water operations. Weather-responsive scheduling will be used to capitalise on short windows of suitable conditions. Outputs will include time-stamped georeferenced imagery and observation notes sufficient to confirm presence/absence, general distribution, and indicative movement, providing an early signal for subsequent survey scaling.

3.4 Summary

Pre-season aerial surveillance from Cape Nelson Lighthouse has the potential to provide a practical and strategically positioned means to confirm early blue whale arrival using an already trialled drone platform and procedures. The activity supports timely decision-making for the duration of the Regia MSS and offers a low-impact, cost-effective approach to initiating broader monitoring efforts once presence is confirmed.

Appendix 1 - Cape Nelson Lighthouse - September-October Operational Weather Analysis (1995 - 2025 Analysis)

4.1 Executive Summary

This report provides an analysis of a 30-year (1995–2025) climatological dataset that considers wind, rainfall, and associated environmental factors that have the potential to affect drone operations at Cape Nelson Lighthouse, Victoria. Cape Nelson was chosen as the sole analysis site because it is the most exposed headland on the regional coastline, directly influenced by the Southern Ocean.

Of the total feasible fly-time, optimal conditions are projected to occur based on historical averages, between 10 and 15 percent of the time, while sub-optimal but flyable conditions are anticipated for approximately 55 to 60 percent of the period.

Taken together, these results indicate that drone deployment is feasible for an estimated 70 to 75 percent of the September–October period, with the remaining 25 to 30 percent classified as no-fly conditions due to wind or rainfall exceeding operational thresholds.

The weather analysis conducted was used to develop threshold-based definitions for three categories of drone operations: Optimal, Sub-optimal, and No-Fly conditions. These definitions are presented below:

Condition Level	Wind Speed (km/h)	Rainfall (mm/day)	Environmental Description	Operational Guidance
Optimal	≤ 20	≤ 1	Calm to light winds and dry or near-dry conditions. Excellent visibility and platform stability.	Safe for full-scale drone operations. Ideal for mapping, whale observation, and precision video capture.
Sub-optimal	21–40	>1 to ≤10	Moderate winds or intermittent light rain. Some turbulence and minor visibility reduction expected.	Proceed with caution. Experienced pilots only. Reduce altitude, range, and payload weight. Monitor gusts.
No-fly	>40	>10	Strong winds or moderate to heavy rain associated with frontal systems. High turbulence and low visibility.	Suspend all drone operations. Unsafe for launch, flight, or recovery. Resume only when conditions improve.

4.2 Introduction

This report presents a climatological assessment of environmental conditions relevant to drone deployment at Cape Nelson Lighthouse, Victoria. Using 30 years of Bureau of Meteorology (BOM) data (1995–2025), the analysis evaluates wind speed, direction, and rainfall to determine operational feasibility for over-water drone surveys during the Austral spring months of September and October. This assessment draws on daily climate observations obtained from the Bureau of Meteorology's Climate Data Online database (Station ID: 090184) for the full 1995–2025 period.

The findings provide a data-driven foundation for defining optimal, sub-optimal, and no-fly thresholds, enabling informed scheduling, risk management, and field safety planning for marine monitoring activities.

Overall, the results show Cape Nelson experiences drone-deployable conditions approximately 70% of the time, when wind and rainfall are within acceptable operational limits.

Fully optimal conditions are defined as wind speeds below 20 km/h and rainfall less than 1 mm per day - occur on average 10-15% of the time, primarily during calm morning windows associated with high-pressure systems. Sub-optimal conditions, where operations remain viable but require pilot discretion, represent on average 55-60% of the period, while no-fly conditions (winds >40 km/h or rainfall >10 mm) occur on average 30% of the time, generally aligned with frontal weather systems. This report combines these meteorological patterns to provide practical guidance for deployment planning, ensuring that operations can be conducted safely, efficiently, and with minimal disruption due to environmental constraints.

4.3 Site Selection Rationale – Cape Nelson Lighthouse

Cape Nelson Lighthouse was selected as the single reference location for this weather analysis because it represents the most exposed and meteorologically demanding site along the regional coastline. Positioned on a prominent headland facing the Southern Ocean, Cape Nelson experiences the full impact of prevailing westerly and south-westerly systems, including the strongest winds, highest rainfall totals, and most rapid weather changes. These conditions consistently exceed those recorded at more sheltered inland or coastal stations. As a result, using Cape Nelson as the baseline ensures that the operational thresholds and risk assessments presented in this report are based on worst-case environmental conditions. If drone deployment is feasible under Cape Nelson parameters, it is expected to remain safe and viable at any nearby site with more moderate exposure, providing a conservative and reliable foundation for regional flight planning.

4.4 Wind

Wind conditions at Cape Nelson Lighthouse were observed to be consistently strong throughout September and October, reflecting the region's exposure to prevailing westerlies from the Southern Ocean. Long-term BOM data show mean wind speeds of approximately 24 km/h at both 9 AM and 3 PM, with stronger afternoon winds being common, especially in October. Wind rose analysis confirms that winds exceeding 20 km/h occur over 80% of the time, while calm conditions (<10 km/h) are rare (<5%). The dominant wind directions are from the west to northwest, occasionally shifting southerly in the afternoon.

For drone operations, these conditions indicate that moderate to strong winds (20–40 km/h) should be expected during most daylight hours. Optimal flight windows are likely to occur during brief calm periods in the early morning, especially under wind speeds below 20 km/h, which represent only 15–20% of observations. Pilot discretion should remain critical due to the expected rapid onset of gusts exceeding 40 km/h.

Time / Month	<10 km/h	10–20 km/h	20–30 km/h	30–40 km/h	>40 km/h	Most Prevalent Wind Directions	Additional Information
9 AM Sep	~5 %	~10 %	~25 %	~40 %	~20 %	W, NW, N	Strong morning westerlies
3 PM Sep	~5 %	~10 %	~25 %	~40 %	~20 %	W, NW, S	Afternoon pattern mirrors morning but slightly more southerly winds
9 AM Oct	~5 %	~10 %	~30 %	~35 %	~20 %	W, NW, N	Persistent westerlies with slightly higher moderate winds
3 PM Oct	~5 %	~10 %	~25 %	~35 %	~25 %	W, NW, S	Strongest winds overall; higher incidence >40 km/h

4.5 Defined Operational Conditions – Wind

September

Condition Level	Wind Speed (km/h)	Approx. Frequency (% of time)	Operational Guidance	Key Points for Planning
Optimal	0–20	15%	Safe for full-scale drone operations. Ideal for long-range surveys, whale detection, or detailed mapping.	Calm morning windows before strengthening westerlies. Occurs mainly around sunrise to mid-morning.
Sub-optimal	21–40	65%	Suitable for experienced pilots only. Maintain shorter flight durations and reduced altitudes.	Moderate to strong westerlies dominate most of the day. Maintain visual line-of-sight over water.
No-fly	>40	20%	Suspend all drone operations. Winds and gusts exceed safe control limits.	Frequent strong westerly gusts; ensure all equipment secured. Pilot discretion required to resume.

October

Condition Level	Wind Speed (km/h)	Approx. Frequency (% of time)	Operational Guidance	Key Points for Planning
Optimal	0–20	15%	Proceed with operations during calm early-morning periods. Excellent visibility and platform stability.	Calm periods shorter than September; prioritise early flights.
Sub-optimal	21–40	63%	Continue operations with caution. Reduce flight range and duration. Maintain awareness of shifting wind direction.	Afternoon conditions stronger and more variable (W–S sector). Maintain buffer for gusts.
No-fly	>40	22%	Suspend operations. Turbulent airflow and high gusts exceed control tolerances.	October prone to stronger spring winds; monitor gust forecasts.

Combined Averages

Condition Level	Wind Speed (km/h)	Approx. Frequency (% of time)	Operational Guidance	Key Points for Planning
Optimal	0–20	15%	Fully suitable for over-water flights, high-resolution observation, and extended coverage.	Short, reliable windows—mostly in early morning under stable westerlies.
Sub-optimal	21–40	64%	Viable for limited operations under pilot discretion. Shorter flights and reduced payloads recommended.	Most common condition; use this band for regular flight planning.
No-fly	>40	21%	Ground all operations; unsafe for drone control or recovery over water.	Expect multiple high-wind days per week; plan standby or alternate tasks.

4.6 Rain

Rainfall during this period averages 18.7 days in September and 15.8 days in October, though most events are light (<10 mm).

	September	October
Mean number of days of rain >= 1 mm for years 1995 to 2025	12.8	9.1
Mean number of days of rain >= 10 mm for years 1995 to 2025	2.1	1.2

4.7 Defined Operational Conditions – Rainfall

September

Condition Level	Rainfall (mm/day)	Approx. Frequency (% of time)	Operational Guidance	Key Points for Planning
Optimal	≤ 1	~58%	Safe for full-scale drone operations. Light or no precipitation allows clear visibility and stable flight.	Most days are light or dry. September still experiences regular light rain but short-lived.
Sub-optimal	>1–10	~38%	Fly with caution. Reduced visibility and light moisture can affect sensors and optics. Limit flight duration.	Typical during frontal passages. Allow drying time for equipment after light showers.
No-fly	>10–25	~4%	Suspend all drone operations. Moderate to heavy rainfall creates unsafe conditions for takeoff, flight, and recovery.	Occasional heavier rain days; usually associated with passing cold fronts.

October

Condition Level	Rainfall (mm/day)	Approx. Frequency (% of time)	Operational Guidance	Key Points for Planning
Optimal	≤ 1	~70%	Fully suitable for flight operations. Minimal rainfall supports longer flight windows and safe equipment handling.	October is drier and more stable than September. Ideal for extended operations.
Sub-optimal	>1–10	~27%	Operate with caution during light showers. Maintain visual contact and assess water exposure on equipment.	Occasional light rain; often short-lived. Avoid over-water recovery during precipitation.
No-fly	>10–25	~3%	Ground all operations. Heavy rain severely limits visibility and can damage electronics.	Heavy rain days are rare; monitor forecasts to plan around them.

Combined Averages

Condition Level	Rainfall (mm/day)	Approx. Frequency (% of time)	Operational Guidance	Key Points for Planning
Optimal	≤ 1	~64%	Ideal for consistent flight scheduling with minimal precipitation interference.	Majority of operational days are dry or lightly damp; early-morning dew possible.
Sub-optimal	>1–10	~33%	Proceed cautiously; intermittent light rain may disrupt data capture.	Use water-resistant drones or delay until rainfall ceases.
No-fly	>10–25	~3%	Suspend all flights. Heavy rain significantly increases operational risk.	Rare but impactful; align operations around dry periods.

4.8 Wind-Rain Relationship at Cape Nelson

At Cape Nelson (and most exposed southern coastal sites in Victoria), windy days and rainy days are highly correlated because both are typically driven by passing low-pressure systems and cold fronts.

Key Points:

- Strong westerlies and heavy rain are part of the same synoptic event — frontal systems from the Southern Ocean.
- Calm, dry periods occur under high-pressure ridges between fronts.
- So, the same weather system that brings >40 km/h winds also produce most of the rainfall >10 mm.

4.9 Adjusted Interpretation of Deployment Opportunity

Given the correlation between wind and rain, the restrictions shouldn't be double counted. Instead, most "rain-restricted" days overlap with "wind-restricted" days.

Adjusted Combined Estimate (Factoring Overlap):

Condition	Combined (Wind + Rain)	Adjusted Occurrence	Operational Meaning
Optimal	Calm (<20 km/h) and Dry (≤1 mm)	**10-15%**	Excellent windows — clear, dry, and stable. Usually early morning under high pressure.
Sub-optimal	Moderate wind (20–40 km/h) and/or light showers (≤10 mm)	**55-60%**	Most common. Light drizzle or gusty periods, but often flyable. Pilot experience essential.
No-fly	High wind (>40 km/h) and/or moderate-heavy rain (>10 mm)	**25-30%**	Typically, the same frontal events. High turbulence, rain, and low visibility.

4.10 Summary

Analysis of long-term data from Cape Nelson Lighthouse (1995–2025) indicates that wind and rainfall restrictions are strongly interrelated. The site is highly exposed to Southern Ocean weather systems, where the passage of low-pressure troughs and cold fronts produces both elevated wind speeds and rainfall events. These systems typically generate westerly or north-westerly winds exceeding 40 km/h, coinciding with the majority of rainfall days (>1 mm). Consequently, days restricted by rainfall are usually the same days restricted by wind, rather than separate occurrences. In contrast, calm and dry periods occur under high-pressure ridges that follow frontal passage, resulting in stable, dry conditions with wind speeds typically below 20 km/h. These periods provide the most favourable conditions for drone deployment, offering clearer visibility, minimal turbulence, and reliable flight control.

When this overlap is accounted for, the combined analysis shows that approximately 70% of the September–October period is potentially usable for some level of drone operation. Within this window, 10-15% of days present fully optimal conditions - light winds (<20 km/h), dry weather (≤1 mm rainfall), and stable air - ideal for full-scale drone operations. The remaining 55-60% of the time falls into a sub-optimal but manageable category, characterised by moderate winds (20-40 km/h) or light showers. No-fly conditions (>40 km/h winds or >10 mm rainfall) are limited to approximately 25-30% of the time, typically concentrated around cold-front events.

Operational planning should therefore emphasise flexibility, with teams ready to mobilise rapidly during calm high-pressure intervals, which often persist for two to three consecutive days. Scheduling should avoid the days immediately surrounding frontal activity, when gusts and residual instability remain high despite clearing rainfall.

4.11 Full Operational Conditions Parameters

Optimal Conditions

Parameter	Optimal Conditions Threshold	Notes
Wind	≤ 10 kt (≤ 20 km/h) sustained, gusts ≤ 15 kt (28 km/h)	Stable hover and control; minimal gimbal movement.
Beaufort Sea State	≤ Bft 3 (wave height < 0.5 m)	Calm to slight seas; stable horizon reference for optical tracking.
Visibility	≥ 10 km	Full horizon clarity for long-range optical identification.
Precipitation	Nil	Dry airframe and optics; optimal camera performance.
Cloud Ceiling	≥ 300 m	Safe vertical separation and strong line-of-sight.
Glare / Sun Angle	Low or manageable	Good contrast for tracking and horizon definition.
Temperature	5–35 °C	Normal operational range for batteries and sensors.

Sub-Optimal Conditions

Parameter	Sub-Optimal Conditions Threshold	Notes
Wind	11–21.5 kt (21–40 km/h) sustained, gusts ≤ 23 kt (43 km/h)	Moderate turbulence; requires skilled pilot control.
Beaufort Sea State	Bft 4–5 (0.5–2.0 m waves)	Noticeable whitecaps; minor horizon instability.
Visibility	5–10 km	Haze or marine layer; maintain conservative range.
Precipitation	Light drizzle or 1-10 mm/day	Limit flight duration; monitor sensor moisture.
Cloud Ceiling	150–300 m	Lower clearance; operate at reduced altitude.
Glare / Sun Angle	Moderate glare	Use filters or adjust angle of approach.
Temperature	0–5 °C or 35–40 °C	Battery and sensor efficiency reduced; shorten flights.

No-Fly Conditions

Parameter	No-Fly Threshold	Notes
Wind	> 21.5 kt (> 40 km/h) sustained or gusts > 23 kt (> 43 km/h)	Unsafe for control; excessive drift and instability.
Beaufort Sea State	≥ Bft 6 (wave height > 2.0 m)	High seas; severe horizon instability and spray risk.
Visibility	< 5 km	Unsafe for navigation or VLOS/BVLOS flight.
Precipitation	> 10 mm/day (moderate to heavy rain)	Electronics and optics at risk; terminate flight.
Cloud Ceiling	< 150 m	Insufficient clearance for safe operation.
Glare / Sun Angle	Severe glare or low sun directly on horizon	Loss of horizon contrast; risk of sensor blinding.
Temperature	< 0 °C or > 40 °C	Exceeds manufacturer safety range; hardware failure likely.

4.12 Justification of Flight Environment Parameters

There are currently no legislated environmental parameters specific to Remotely Piloted Aircraft System (RPAS) operations in Australia beyond the overarching requirement under the Civil Aviation Safety Regulations (CASR) for operators to maintain safe control and operate within aircraft limitations. Accordingly, the environmental parameters defined in this report have been established using a combination of manufacturer specifications, aeronautical best practice, and empirical field experience obtained through extensive on-site observation and trial operations conducted by the project team at Cape Nelson during the current season, in preparation for next year's deployment.

The wind parameters are derived conservatively from the DJI Matrice 350 RTK / H30T system's manufacturer-rated maximum wind resistance of approximately 43 km/h (23 kt). Operating at or near this upper limit presents an unacceptable risk margin for coastal BVLOS operations, where mechanical turbulence, terrain-induced shear, and abrupt gusting are common. To ensure stable flight control, accurate telemetry, and reliable gimbal performance, the Sub-optimal category is limited to 40 km/h (21.5 kt) sustained wind, with any sustained or gust conditions above this level classified as No-Fly. This approach provides a buffer below the manufacturer limit, consistent with aviation risk-management principles that require operational ceilings below technical maxima.

Other environmental parameters, including Beaufort Sea State, visibility, cloud ceiling, precipitation, and temperature, have been benchmarked against CASA Beyond Visual Line of Sight (BVLOS) operational guidance under CASR Part 101 and associated Advisory Circulars, together with established industry best practice for over-water RPAS operations. These frameworks collectively require operators to define environmental limits that preserve safe control, telemetry integrity, and situational awareness equivalent to or better than Visual Line of Sight (VLOS) operations.

A minimum visibility of 5 km has therefore been adopted to ensure reliable sensor-based situational awareness and effective use of electro-optical and thermal payloads for target detection and tracking. The cloud-ceiling thresholds maintain adequate vertical separation from coastal terrain while preserving uninterrupted command-and-control links. Precipitation limits are based on payload manufacturer guidance and field observations demonstrating that even light moisture, glare, and refraction significantly reduce optical and thermal imaging performance and can impact electrical components.

Collectively, these parameters represent accurate, fair, and conservative operating envelopes for BVLOS marine drone operations at Cape Nelson and similar exposed coastal environments. They ensure flight safety, maintain data quality, and provide a transparent, defensible framework suitable for regulatory review and inclusion within the operator's Safety Management System and Operations Manual in the absence of formal legislative limits.

Appendix 2 – Technology Specifications – Drone and Camera

This section presents examples of proposed technology-types that may be used to support long-range aerial whale monitoring, including examples of commercially available drones and associated high-performance optical sensors/cameras for attachment to a drone, expected to be capable of meeting the operational requirements. While the exact makes and models have not yet been selected, the examples have been provided to demonstrate the general capabilities of systems currently available on the market. Sections 4.13 and 4.14 present indicative drone platforms and camera specifications (with links to publicly available technical data), while Section 4.15 illustrates how the proposed camera technology is technically capable of detecting and observing whales at distances of up to 25 km under suitable conditions.

4.13 Example of Drone Specifications -DJI Matrice 400

https://enterprise.dji.com/matrice-400/specs

4.14 Example of Camera Specifications - Zenmuse H30 Specs:

https://enterprise.dji.com/zenmuse-h30-series/specs

4.15 Demonstration that the H30T Tele Camera Can Visually Detect a Whale at 25 km

Demonstrate, on an optics-only basis (independent of radio link or endurance), that the Zenmuse H30T telephoto camera provides sufficient angular resolution to resolve a whale at a slant range of 25 km under clear atmospheric conditions and low sea state.

Basis and Parameters:

- Camera geometry: Zenmuse H30T tele module, horizontal field of view (HFOV) 15° with 8192 effective horizontal pixels.

  Per-pixel angular subtense $\alpha = \frac{15^\circ \times \pi/180}{8192} \approx 3.20 \times 10^{-5}$ rad/px.

- Target: Southern right whale; adult body length typically 14–18 m. To account for foreshortening, partial emergence, and non-broadsides presentation, adopt a conservative apparent dimension of 10 m.

- Range of interest: $R = 25{,}000$m.

- Identification criterion: Johnson/NATO electro-optical standards (50 % probability) require approximately 12–13 pixels across the critical dimension to achieve identification (recognition is ≈8 px; detection ≈2 px).

- Line-of-sight geometry: Operation at or below 120 m AGL (Above Ground Level).

Optical Resolving Power at 25 km

The target's angular extent at 25 km with a 10 m apparent dimension is

$$\theta = \frac{10}{25{,}000} = 4.0 \times 10^{-4} \text{ rad.}$$

Pixels across the target are:

$$N = \frac{\theta}{\alpha} = \frac{4.0 \times 10^{-4}}{3.20 \times 10^{-5}} \approx 12.5 \text{ px.}$$

Interpretation: Even under the conservative 10 m apparent size, the body spans ~12.5 px, which meets the Johnson identification threshold. Using the typical adult length (14-18 m) would yield ≈17.5–22.5 px at the same range, providing additional margin.

Line-of-Sight Constraint:

From 120 m AGL, the geometric horizon to sea surface is ~39 km (to the top of a 5 m blow ~47 km). A 25 km slant range is therefore well within the curvature-limited line of sight and does not constrain the optical result.

4.16 Conclusion

On an optics-only basis, the Zenmuse H30T tele camera provides ≥12 pixels across a conservatively modelled 10 m whale body at a slant range of 25 km, satisfying the Johnson identification criterion. Line-of-sight at ≤120 m AGL does not limit this range. Accordingly, a 25 km visual observation claim is conservative and technically supported by the camera's angular sampling.

Regia Marine Seismic Survey
Sound Source Verification Procedure

1 Purpose

This procedure describes the sound logging system which CGG has designed with the primary objectives being to:

a) obtain an empirical baseline of in-water ambient sound profiles.
b) to monitor sound profiles emanating from the Regia MSS.
c) Meet the EPO: Underwater sound emissions from the Regia MSS are empirically measured and validated through the sound source verification procedure to ensure they remain within levels that do not cause injury or unacceptable disturbance to Southern Right Whale.

The collection of on-location ambient sound data (which has historically been very sparse and not location specific) will enable further calibration and testing of existing acoustic model predictions. It will also allow for more informed impact analyses where sound masking is an important consideration.

It provides assurance that the EPO for sound source verification (SSV) can be met by ensuring that:

- Ambient sound levels are measured and recorded at representative sites.
- Hydrophone and mooring configurations function as designed.
- The Regia MSS sound source meets predicted received-level characteristics.

As these activities are within and/or near to the designated Biologically Important Area (BIA) for Southern Right Whales they are being conducted in accordance with Regulation 27 of the Marine and Coastal (Prescribed Consents) Regulations 2025 (Vic), with written approval obtained from the Director of Safe Transport Victoria.

2 Scope

Applies to all sound source verification (SSV) related activities within the Regia MSS Environmental Planning Area. All operations are governed by the CGG Marine Assurance System.

The sound monitoring program contains three primary components.

- Deployment:
    - Recording of ambient sound will be undertaken at 7 locations (see Figure G6-1) three of which will be via tethered PAMS and four of which will be via bottom mounted hydrophones (see Figure G6- 1 below).
- Sound Source Testing:
    - Multiple comparison tests will be made between logging units to ensure they are all listening and recording in a comparable way.
    - To better quantify the influence of noise from mooring systems in masking incoming sounds there will be multiple comparison tests between moored PAM units and free-floating PAM units to try and isolate the components of the ambient noise signal that are from movement of the mooring system.
- Data recoding:
    - Recording will start before the MSS and run throughout the survey period. Once the survey starts PAM data will be accessed multiple times daily to inform our monitoring of impulsive sound coming from the MSS.
    - To quantify and monitor the acoustic noise signal coming from the MSS there will be a regular sampling program undertaken throughout the survey period. This will involve obtaining recordings at a series of distances from the Regia MSS with the maximum distance defined by no seismic signal present. These distances will be set at increasing 5km increments out to 20km from the survey vessel, i.e. at 5km, 10km, 15km and 20km.

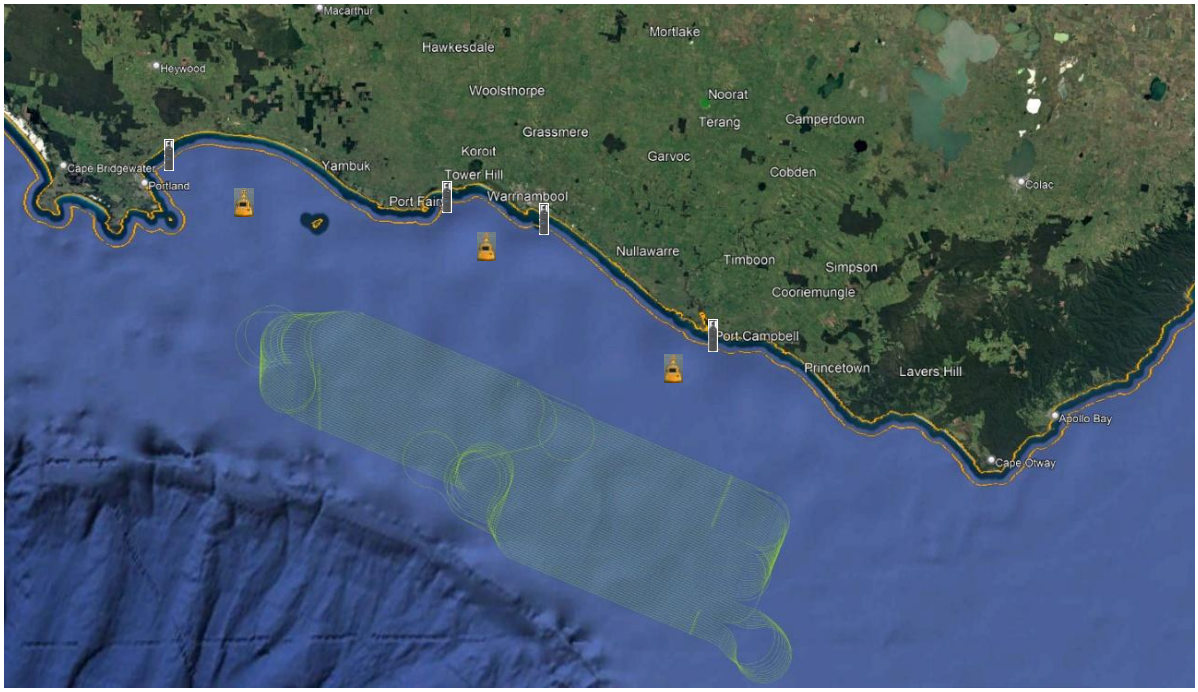

Figure G6- 1: Tentative locations of bottom mounted sound loggers (≤20m depth) and anchored PAM systems (40-50m depth).

3 Responsibilities

Roles and responsibilities for the Regia MSS apply and can be found in the Implementation Strategy (Appendix B3).

4 Equipment

Tethered SSV Buoys (©Sercel QuietSea)

- Three SSV buoys from Sercel with QuietSea technology, and real-time autonomous passive acoustic monitoring capability. These units have an integrated hydrophone, data logger, GPS, and telemetry (https://www.sercel.com/en/products/quietsea). Data will be retrieved at regular intervals through either a 4G connection or Satellite links.
- Buoys will be moored at pre-determined locations at Portland Bay (40-50 m depth), Logan's Beach (40-50 m depth), and Port Campbell (40-50 m depth). Precise GPS coordinates TBD (once actual deployment has occurred, but Figure G6-1 gives approximate locations).
- These systems will be deployed/recovered via a dedicated vessel with appropriate certified lifting gear, acoustic release systems, and mooring interface assemblies.

Bottom-Mounted SSV Loggers (© Ocean Instruments, SoundTrap)

- Four SoundTrap hydrophones from Ocean Instruments will be deployed at four locations (see Figure G6-1) where SRW mothers and calves are historically known to reside for extended periods. These loggers are for short term deployments of up to 3 months between battery changes.
- Data is recorded on 4 micro-SD cards and retrieved when the instrument is brought to the surface for battery renewal.
- The STD model (as opposed to High Frequency Model) used here has very low self-noise, ensuring clean recordings.
- A custom bracket has been developed which contains a clamping system. This enables the units to be retrieved by release of the clamping system, while the bracket remains attached to the bottom. Data is downloaded from the unit on the boat then the unit has its batteries replaced and is returned to the bracket and reclamped. Brackets will be permanently removed once sound logging is no longer needed.

5 Procedures

5.1 Deployment of loggers for ambient sound recording.

This section describes the sequence, controls, and responsibilities for deployment of the three tethered SSV buoys and the four bottom mounted hydrophones. These units will collect ambient sound measurements from the nearshore and midshelf regions which will be used for calculation of ambient baseline conditions prior to the Regia MSS acquisition phase. All units will continue collecting received sound measurements throughout the MSS acquisition period to help calibrate sound models. As the three SSV buoys have real-time access capability they will be used to monitor the far-field sound source from the MSS as it approaches the BIA.

5.1.1 Calibration of sound loggers

Prior to deployment all loggers will record data simultaneously with other recorders to ensure that sound measurements are comparable. This will be done by putting loggers close together while they simultaneously record for a minimum of 30 minutes.

5.1.2 Quantification of mooring-related self-noise (e.g. line strumming).

SSV buoys will produce their own sound signature through noise generated from the mooring, which will add confounding noise to the ambient sound recordings. Recording of ambient noise with a similar SSV buoy that is not moored will provide a means to calibrate the contribution that mooring noise makes to recordings. As an SSV is moored and starts recording a second SSV will be deployed, but not moored, to record from the same soundscape but at a distance far enough away to not have the signal contaminated by mooring noise. Recording will be for a minimum of 30 minutes. The mooring has also been designed to minimise noise effects as much as possible.

5.1.3 Ambient background sound recording.

The initial role of the sound logging system is to obtain ambient noise recordings when seismic is not being undertaken. This baseline information will be used to quantify the characteristics of the sound field adjacent and near to the SRW BIA. Such data is needed to enable masking effects to be incorporated into analysis of sound signatures emanating from the seismic survey. This data will also be augmented with a pre-existing dataset of ambient noise captured by the IMOS program from 2012-2017. This data was collected from loggers located approximately 20km off Portland in ~130-150m water.

The three surface moored SSVs will collect and transmit data for near real-time analysis during the MSS. They are effectively functioning as sentinels which stand between the MSS and the SRW BIA. If sound levels are detected above pre-determined thresholds and are determined to have come from a seismic source, then the SSV system will send a notification to this effect which will initiate responses as needed.

5.1.4 Logistical Details

Mobilisation and Transit

1. Load all buoys and mooring hardware at port. Candidate ports are Portland Port or Port Fairy.
2. Transit to Cape Nelson (Site 1) by ~ 1 August 2026.

Site 1 – Cape Nelson

3. Connect Buoy 1 to pre-installed mooring and commence ambient recording.

4. Deploy Buoy 2 for capturing sound field without mooring noise - should remain ~ 500 m distant to Buoy 1 (to ensure no mooring noise is being captured) and let drift past Buoy 1; record free-field ambient data for minimum 30 minutes.
5. Recover Buoy 2 and log all times, positions, and instrument diagnostics.
6. Transit to Site 2.

Site 2 – Logan's Beach

7. Connect Buoy 2 to pre-installed mooring and commence ambient recording.
8. Deploy Buoy 3 as per Site 1 instructions and allow to drift past Buoy 2; record free-field ambient data for minimum of 30 minutes.
9. Recover Buoy 3 and log all times, positions, and instrument diagnostics.
10. Transit to Site 3.

Site 3 – Cape Otway

11. Connect Buoy to pre-installed mooring and commence ambient recording.
12. Return to port once all deployments are verified.

Data Handling

Confirm recording integrity; back-up metadata; transmit summary to CGG Environment Advisor promptly.

5.2 Monitoring of the Seismic Sound Field

This section describes t the method and sequence for monitoring of the seismic sound field while the survey is acquiring.

The objective is to:

- Measure received sound levels at 5 km, 10 km, 15 km (and if necessary 20km) from the seismic source zone to obtain a real-time understanding of the sound envelope that is accompanying the acquisition process. This process will be repeated multiple times as the survey moves over different depths and habitat types. This real time measurement will provide an early warning system for potential sound violations into the SRW BIA as the spatial extensions of the sound envelope will be known in advance of approaching the closest point to the BIA.
- This data will also be used to check alignment of real data with modelled predictions for the Regia MSS source configuration.
- Demonstrate that operational control measures for sound source ramp-up and shutdown are effective and compliant with CGG's environmental performance outcomes (EPOs) for underwater sound.

5.2.1 Logistical Details

First recordings will commence within the first week of the seismic acquisition. Subsequent timing of recordings will be decided based on changing depth and bathymetry conditions. We anticipate at least 3 recordings will be undertaken across the duration of the MSS.

Deployment for Drift Recording

While the Seismic vessel follows pre-ordained transects the support vessel will travel to a position approximately 5 km, 10 km, 15 km (and 20km if needed) from the seismic vessel along a rhumb line running from the seismic vessel and meeting the coast at a perpendicular angle. At each nominal distance a sound logger will be deployed to record for at least 30 minutes. Once a recording is completed the support vessel will move to the next distance along the rhumb line and repeat. A

deployment will consist of a sound logger attached to a buoy and tether and free floating independent of the support vessel and far enough away to minimise support vessel noise being recorded (see Figure G6-2). Distance travelled will be noted and sound files verified before moving to a new location.

Figure G6-2: Schematic indicating how drift recording at staged distances from the seismic vessel will proceed.

5.3 Determination of sound breaches in the BIA

CGG will implement a precautionary and pro-active underwater sound monitoring program during the Regia MSS. This program draws directly on current best practice for characterising and managing underwater noise impacts (e.g., Marotte et al. 2022[1]).

The objectives are to ensure that:

- underwater sound levels remain within natural and/or acceptable levels as defined by ambient sound recordings from the area.

[1] Marotte et al (2022), provide a detailed description of relevant approaches to quantifying underwater noise impacts to North Atlantic Right Whales, which are clearly an appropriate proxy for Southern Right Whales. Conclusions are based on the collective response of 24 experts in fields relevant to such a topic e.g. underwater noise, impacts of noise on marine mammals, marine mammal hearing, policy and management etc. Moreover, seismic airguns were identified as a major acoustic stressor and hence there are detailed guidelines relevant to this type of disturbance.

- any statistically/biologically meaningful departures from natural and/or acceptable levels are detected promptly.
- The likely source of any such departures is promptly identified to determine if the signals can be directly attributed to the seismic survey; and
- Where the cause- effect pathway is identified as linked to the MSS, timely management actions are implemented to mediate any potential for disturbances.

To establish baseline distributions of ambient (natural) underwater sound levels, prior to acquisition, CGG will:

- Download and analyse data collected by the IMOS Passive Acoustic Observatories buoy array operating off Portland between 2009 and 2017. Sound data from the months September, October and November will be assessed from multiple years to establish a mid-shelf baseline dataset for the period appropriate to the MSS.
- Collect, download and analyse ~8 months of ambient sound data collected from multiple loggers deployed in the nearshore environment (~20m depth) within the SRW reproduction BIA. These data will establish a nearshore baseline dataset for the MSS.

5.3.1 Warning System Methodology

Ambient baseline data will be used to determine whether any unacceptable sound levels from the seismic survey reach the BIA. Having empirically derived ambient noise data for the area will enable masking effects to be incorporated into calculations which is a more realistic approach than only using received sounds. Warning parameters will be set based on violations of the ambient sound scape and its interaction with any masking effects (see Figure G6-3 for further details).

The MSS survey is scheduled to start from the 16 September 2026. At this time the moored SSV buoys will have been recording ambient sound conditions for at least 4 weeks which will provide the baseline spectral probability plot against which any seismic related incursions can be detected.

Active seismic will start approximately 70 km from the coast at the most southerly lines (refer to MAP-REG-EPM-040). Drift recording of the sound profile will be undertaken at this time and sound data captured at 5km, 10km, 15km and 20km (if needed) will be analysed to ascertain the extent of horizontal, seismic attenuation. This process will be repeated at least 3 times as the survey comes progressively closer to the coast and BIA boundary. This will serve as an early warning system - independent of the tethered PAMS – to indicate whether inappropriate levels of seismic sound may penetrate the BIA.

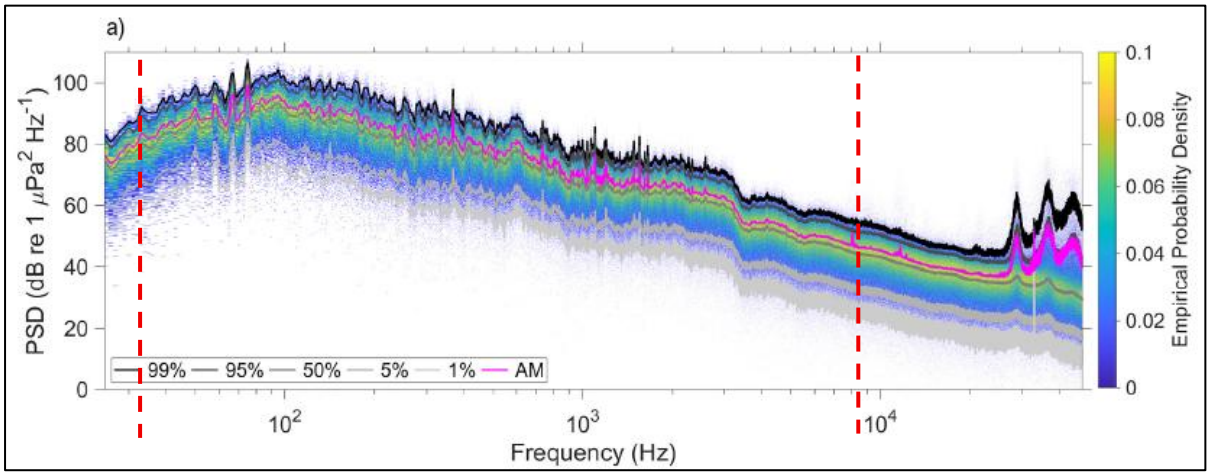

Figure G6-3: Example of a Spectral Probability Plot (SPP) with percentiles and the arithmetic mean (AM) represented.

This is from a 20-minute recording off Scotland in 2018 (van Geel et al 2022). These plots will be generated and updated multiple times each day from data uploaded from the moored PAMS. Warnings will be programmed into the PAM software to provide notice of any anomalous sound signals as defined by the running SPP. For the Regia MSS the calculations will be filtered to the frequency band between 7Hz and 36kHz (NOAA Technical Guidance 2024) – as indicated by the dashed red lines.

Having established the baseline ambient sound profile and then actively monitoring the seismic attenuation signal as the survey progresses, we then set the parameters on which an anomalous signal will be defined. We will be using sampling protocols as recommended by Marotte et al (2022)[2] and Southall et al (2023) for monitoring of behavioural changes and masking in baleen whales.

Specifically, a probability distribution of third-octave sound levels across the relevant weighted bands and established using a 0.1- second sound assessment window will be used. To capture short-term behavioural response thresholds for impulsive noise, the peak sound pressure level (PK) and the sound exposure level (SEL) from the individual impulses are calculated. The values will be averaged over a 3-min interval for checking against the set thresholds (Southall et al 2023). The target thresholds have been pre-determined with the lowest threshold set at an ultra-conservative 120 dB as calculated across the frequency band most applicable to hearing in LF cetaceans (see Figure G6-3).

If a significant breach is confirmed by the system, then the adaptive management protocols will be activated as described in Appendix G2- Fauna Management Plan.

6 Environmental and Safety Controls

- Comply with MARPOL Annex V – no discharge or disposal of materials overboard.
- Suspend activities if sea-state > 4 m or operating at night.
- If any whale is detected in relevant SDZs during soft start procedures, the acoustic source will be shut down, and another soft start cannot commence until all pre-acquisition criteria have been met again.
- Lost-gear notification to AMSA within 2 hours.
- Maintain 500 m separation between vessels during all manoeuvres.
- Adhere to CGG HSE-OMS stop-work authority and toolbox briefings before each phase.

7 Data Management and Reporting

- Verify logger clock synchronisation and sample rates.
- Store duplicate copies of datasets on encrypted drives and upload to Regia server as soon as possible.
- Submit SSV Validation Report summarising:
    - measured vs modelled received levels;
    - hydrophone calibration records; and
    - compliance statement against relevant EPOs (Underwater Sound, Section 1.8 of Appendix G1).

8 Deliverables

Deliverable	Responsible Party	Timing
Daily Operations Logs	Field Team Leader	During operations
Acoustic Datasets (5, 10, 15 km)	Acoustic Team	Within 48 hours of test
Ambient Baseline Data	Acoustic Team	Ongoing
SSV Validation Report	CGG Technical Ops Manager	45 business days after the conclusion of the survey.
