ENVIRONMENT PLAN

GIPPSLAND BASIN DECOMMISSIONING CAMPAIGN #1 EXECUTION

Esso Australia Resources Pty Ltd

DC1-EM-OFS-RPREG-0001

Esso Australia Resources Pty Ltd acknowledges Aboriginal and Torres Strait Islander people as the Traditional Custodians of the land and acknowledges and pays respect to their Elders, past and present. Esso Australia Resources Pty Ltd is committed to safe and inclusive workplaces, policies and services for people of LGBTIQ+ communities and their families.

REVISION HISTORY

Rev	Document status	Date	Prepared by
0	IFA - Issued for Approval	4/04/2025	Katie Martin
1	IFA - Issued for Approval	16/09/2025	Katie Martin
2	IFA - Issued for Approval	13/01/2026	Katie Martin
3	IFA - Issued for Approval	10/04/2026	Katie Martin

OIMS MANUAL – DOCUMENT CONTROL DETAILS

Document number:	DC1-EM-OFS-RPREG-0001
Revision:	3
Document status:	Updated in response to Regulator
Date of issue:	10/04/2026
Document administrator:	Environment and Regulatory Advisor
OIMS document category:	Special Controls Mandatory
MPI classification:	None
Retention period:	IND, MIN ACT+10+LC (Indefinite, Retain while current + 10 years, then obtain Law Clearance prior to disposal)
Master storage location:	Document Management System - Aconex

ENDORSEMENT AND APPROVAL

Endorsed/approved by Esso Australia Pty Ltd, for and on behalf of Esso Australia Resources Pty Ltd.

Hena Kalam Australia Major Projects SSHE Manager

DocuSigned by: HENA KALAM 10BFC812BDD3493... April 8, 2026

ENDORSED Signature Date

Hussain Ali Asset Manager - Offshore Decommissioning

DocuSigned by: C7450AC1C79343A... April 8, 2026

ENDORSED Signature Date

Kent Alexander Removals Manager - Decommissioning

Signed by: 5558A13C56B045A... April 8, 2026

Signed for and on behalf of: Signature Date

Richard Perry Decommissioning Project Manager

APPROVED

DOCUMENT REVIEW AND UPDATE

The Document Administrator is responsible for maintaining and controlling changes to this document in accordance with the Document Management Manual.

In the course of using this document, users may identify opportunities to improve its content. They are requested to suggest these to the Document Administrator.

This document should be reviewed for accuracy and currency on a five yearly basis commencing from the original formal issue date. Major revisions to this manual are to comply with the OIMS System Manual/Process Management of Change procedures.

TABLE OF CONTENTS

1 Introduction 28
1.1 Bass Strait decommissioning overview 28
1.2 Scope of this Environment Plan 29
1.3 Compliance with Section 572 of the OPGGS Act 33
1.4 Life cycle of a facility 39
1.5 Titleholder details 44
1.6 Legislative requirements and industry guidance 45
1.7 Environment Plan Summary 65
2 Description of the activity 67
2.1 Activity summary 67
2.2 Location 68
2.3 Timing of the activities 71
2.4 Property description 71
2.5 Facility status prior to removal 104
2.6 Support operations 106
2.7 Removal preparations 115
2.8 Removal operations 118
2.9 BMB navigation aid installation 123
2.10 Sediment displacement/seabed disturbance 123
2.11 Prevention of dropped objects 125
2.12 Planned discharges 126
2.13 Marine growth 134
2.14 Optional scopes 134
2.15 Waverider buoy installation 135
2.16 As left seabed surveys 135
2.17 Facility status following Campaign #1 activities 135
2.18 Ongoing management of partially removed facilities 143
3 Description of the environment 147
3.1 Operational Area 147
3.2 Environment That May Be Affected 147
3.3 Values and sensitivities 149
4 Relevant persons consultation 191
4.1 Consultation requirements 192
4.2 Esso's consultation methodology 194
4.3 Methodology as applied to the scope of this Environment Plan 208
4.4 Relevant persons feedback 224

4.5 Ongoing consultation 224
4.6 Reporting 226
5 Environmental impact and risk assessment methodology 227
5.1 Overview 227
5.2 Definitions 227
5.3 Identification and characterisation of environmental aspects 228
5.4 Environmental impact assessment 230
5.5 Environmental risk assessment 235
5.6 Demonstration of As Low As Reasonably Practicable 237
5.7 Demonstration of acceptable level 239
6 Environmental impact assessment 242
6.1 Physical presence – Seabed displacement 243
6.2 Physical presence – Interference with other marine users 255
6.3 Planned discharge – Sewage and food waste 268
6.4 Planned discharge – Cooling waters and reverse osmosis system 273
6.5 Planned discharge – Bilge water/deck drainage (vessel discharges) 277
6.6 Planned discharge – Grout 281
6.7 Planned discharges – Umbilicals 288
6.8 Planned discharges – Pipeline and risers fluids 295
6.9 Planned discharges –ODSPs and CDSPs 303
6.10 Planned discharges – Jacket structure internal fluids 311
6.11 Planned discharges – Solids 317
6.12 Planned discharge – Marine growth 326
6.13 Sound emissions 340
6.14 Light emissions 401
6.15 Emissions to air 431
6.16 Waste generation and management 438
7 Environmental risk assessment 450
7.1 Physical interaction – Other users of the sea 450
7.2 Physical interaction – Marine fauna and seabirds 459
7.3 Translocation of native species 470
7.4 Introduction or spread of Invasive Marine Species 482
7.5 Accidental release – Dropped objects 519
7.6 Accidental release – Solid waste 530
7.7 Accidental release – Accidental release of hazardous or non-hazardous substances 536
7.8 Accidental release – Loss of containment refined oils (marine gas oil) 546
8 Implementation strategy 605
8.1 ExxonMobil's framework 605

8.2 OIMS System 1: Leading, Managing and Driving Performance 609
8.3 OIMS System 2: Identifying, Assessing, Mitigating and Accepting Risk 615
8.4 OIMS System 3: Quality Assurance and Pre-Start Up Review 616
8.5 OIMS System 3: Project Management and Execution 616
8.6 OIMS System 3: Design and Construction Practices and Standards 616
8.7 OIMS System 4: Information Needed for Construction, Operation, and Maintenance 616
8.8 OIMS System 5: Selecting, Engaging and Enabling People 617
8.9 OIMS System 5: SSHE Behaviours and Human Performance 622
8.10 OIMS System 6: Management of Work and Equipment 622
8.11 OIMS System 6: Regulatory Compliance and Sustainability Management 622
8.12 OIMS System 6: Critical Safeguard Management 627
8.13 OIMS System 7: Managing Changes 628
8.14 OIMS System 8: Selecting and Engaging with Third Party Providers 628
8.15 OIMS System 9: Learning from Project Activities and Incidents 630
8.16 OIMS System 10: Emergency Preparedness and Response 637
8.17 OIMS System 10: Managing Community Risk 638
8.18 OIMS System 11: Assessing and Driving Effectiveness 639

1 Introduction

Esso Australia Resources Pty Ltd (Esso) is the operator of joint ventures for the exploration, development and production of oil and gas from Bass Strait, Victoria. The offshore Bass Strait production network is comprised of 425 wells, 19 offshore platforms and six subsea facilities that are inter-connected by over 800km of pipelines. Esso has been producing oil and gas in Bass Strait since 1969 and in this time has supplied over 50% of Australia's crude oil and liquids and over 40% of all of Eastern Australia's natural gas, hence contributing significantly to the national economy and supporting growth in industry and employment. Although the Bass Strait production network has been producing energy for more than 50 years, it remains today the largest single source of gas supply to the Australian east coast domestic market and has the potential to continue supplying one third of southeast Australia's domestic gas demand through to the end of this decade.

After delivering energy to Australia for over 50 years, many of the Bass Strait fields are now reaching the end of their productive life. Esso is well underway in the planning and preparation to remove non-producing platforms during the first Bass Strait decommissioning campaign (Campaign #1). An extensive program of work is currently underway to prepare the facilities for removal, including the plug and abandonment (P&A) of wells that have ceased production and the care, preservation and preparation of topsides and jackets for removal. Production of gas and production fluids from Bass Strait also continues via the interconnected system of platforms and pipelines.

Campaign #1 activities include the removal of the topsides of up to 13 offshore platforms (from 10 steel piled jackets (SPJs) and one concrete gravity structure (CGS), the removal of the upper jacket sections of those 10 SPJs and the full removal of two monotowers). Removal of the facilities will be completed by a heavy lift vessel (HLV), supported by one or more construction support vessels (CSVs). The HLV or CSVs will transport the removed topsides and jacket sections to a sheltered location closer to shore within the Operational Area (OA), located in Commonwealth waters, where the removed topsides and jacket sections will be transferred onto a barge or a heavy transport vessel (HTV). Other smaller vessels, tugs and helicopters will provide support during the removal activities. These activities are defined as the 'petroleum activity' and form the scope of this Environment Plan (EP). A detailed description of the activities within the scope of this EP is provided in Section 2.

The SPJ topsides and removed jacket sections will be transported from the OA via barges or HTVs through existing Corner Inlet shipping channels to an Onshore Reception Centre (ORC) located within Barry Beach Marine Terminal for safe dismantling. Segregated materials will be sent offsite for recycling and disposal. These activities will occur outside of Commonwealth waters/onshore, are not within the scope of this EP and are addressed with the respective Regulators for those locations.

At the completion of the Campaign #1 activities, the lower sections that are more than 55m below Mean Sea Level (MSL) of some of the SPJs will remain in place. Esso will address these remaining lower sections and other remaining infrastructure (pipelines etc.) as part of future decommissioning submissions (refer to Section 1.3).

This EP has been prepared to meet the requirements of the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) (OPGGS Act) and OPGGS (Environment) Regulations 2023 (Cth) (Environment Regulations) as administered by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

1.1 Bass Strait decommissioning overview

The Esso-operated Bass Strait infrastructure consists of 425 wells, 19 platforms, six subsea facilities and more than 800 kilometres of subsea pipeline. Thirteen of these platforms are no longer producing oil and gas. Esso's priority in progressively decommissioning these assets is to eliminate or reduce the highest impacts and risks arising from these non-producing assets, being well P&A (managed via a separate, accepted Well Operations Management Plan) followed by removal of platform topsides and SPJs (this Campaign #1 EP). The extent of detailed planning and technical, execution and environmental studies required to safely execute decommissioning of this nature and scale is significant and there has been no comparable decommissioning programs undertaken in Australia to date. Esso also continues to operate the remaining producing offshore platforms and subsea facilities, which are expected to continue production until well into the 2030s.

An assessment was completed during early planning of the decommissioning requirements for offshore infrastructure. The assessment concluded that grouping infrastructure into three common types would enable a review of shared characteristics, environmental impacts, and removal techniques required. The infrastructure groups are:

- platforms with SPJ substructures and steel monotowers
- pipelines, umbilicals and associated subsea infrastructure
- CGSs.

NOPSEMA's Information Paper *Planning for proactive decommissioning* (NOPSEMA, 2025a) notes that decommissioning timelines *"will be based upon sound decommissioning planning outcomes"* and that considerations that will inform decommissioning timelines include among others *"adjusting of timelines to enable phased or campaign based decommissioning"*.

Decommissioning activities may take several different forms including full or partial removal, subject to various factors including but not limited to the nature and scale of the equipment and achieving an acceptable safety and environmental outcome, subject to permissioning.

The decommissioning approach for Bass Strait facilities is for removal via decommissioning 'campaigns', as the required specialist equipment such as HLVs are not readily available in the Asia Pacific region and will be mobilised by contractors for discrete seasonal periods based on global demand. Campaign #1 is the first decommissioning campaign planned for the Esso-operated Bass Strait facilities. Campaign #1 comprises the removal of topsides from up to 10 SPJs and full or partial removal of those jackets, complete removal of two monotowers and the topsides from one of the CGSs (Bream B (BMB)), as described in Section 1.2.

Planning for the decommissioning of pipelines, umbilicals and associated subsea infrastructure outside of the scope of this EP is well underway, with a structured decision-making process being used to identify and evaluate pipeline decommissioning options. Stakeholder and regulator engagement is being undertaken to identify and discuss potential options, along with technical and environmental studies to assess the impacts, risks and benefits of potential options. Subject to completion of these technical and environmental studies, an EP outlining the proposed decommissioning approach for pipelines, umbilicals and associated subsea infrastructure is expected to be submitted to NOPSEMA in 2026/2028. A separate EP outlining the decommissioning approach for selected non-producing shallow buried umbilicals, flexible pipeline and pipeline flexible jumpers is also being developed for submission to NOPSEMA in 2026.

There are two CGSs in Bass Strait – BMB and West Tuna (WTN). WTN is still producing and is expected to produce gas until after 2030. WTN is also the host facility for the Kipper subsea development which is expected to produce gas well into the 2030s. The topsides (including the production facilities, day quarters and module support frame) of BMB will be removed as part of Campaign #1 under this EP. The concrete substructure of BMB will remain on the seabed until such time as the WTN CGS has ceased production and is ready for decommissioning. Significant technical work, field investigation of the structures and field trials are required to confirm a technically feasible method of decommissioning the concrete sub-structures. No similar sized concrete gravity-based structures have been fully or partially removed to date worldwide, due to substantive technical and execution feasibility issues and risks.

Esso continues to provide updates to stakeholders and regulators on planning and progress of decommissioning in Bass Strait. This is achieved via:

- regular meetings held with NOPSEMA to review progress against the requirements of General Direction 817
- issue of an Annual Decommissioning Report, which is provided to NOPSEMA and published on the Esso website each year
- periodic stakeholder forums.

1.2 Scope of this Environment Plan

This EP has been prepared to meet the requirements of the OPGGS Act and Environment Regulations as administered by NOPSEMA to demonstrate that the activities undertaken under this EP meet the acceptance criteria contained in Regulation 34 of the Environment Regulations.

The activities in the scope of this EP are part of the Bass Strait decommissioning program. General Direction 817 also requires Esso to *"complete all preparatory decommissioning activities and commence the topside dismantling*

campaign as soon as reasonably practicable, and no later than 30 September 2027, for removal of all structures, property and equipment no longer in use associated with facilities listed in Schedule 3[1] of the Direction".

The activities set out in this EP will directly support Esso to meet its obligation under Direction 2(a) of General Direction 817 to:

- complete all preparatory activities to enable the scope of activities in this EP to occur (removals preparation using a CSV)
- commence the topside dismantling by 30 September 2027 of facilities listed in Schedule 3[1] with the arrival of the CSV in 2026 and the *Pioneering Spirit* HLV in 2027
- commence the removal of all structures, property and equipment no longer in use associated with the facilities set out in Schedule 3 of General Direction 817.

While the EP scope was developed to support compliance with General Direction 817, the scope of the activities provided for in this EP also includes the provision to remove additional property beyond what is required in General Direction 817, namely the removal of the topsides and upper jacket sections of the WKF, CBA and HLA platforms, as per Section 1.2 of this EP.

Further, this EP scope was developed to support progressive and prioritised decommissioning and reflects an optimised consideration of the available execution work window. The scope and methodology described reflects the preliminary engineering and approach proposed by the appointed works execution contractor (Allseas Marine Contractors Australia Pty Ltd (Allseas)).

A detailed description of the petroleum activity is provided in Section 2, while the spatial boundary of the activities – the OA - is described in Section 2.2.1. The activities not provided for by this EP or covered by separate permissioning documents are described in Table 1-1 and Section 1.3.1.

This EP considers direct and indirect impacts from activities conducted in Commonwealth waters (including off-title areas) within the OA as described in Section 2.2.1. Campaign #1 activities conducted outside of the OA will be subject to applicable approvals under Victorian and Commonwealth environment laws, and are not within the scope of this EP. Where required, Esso will submit referrals under the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) (EPBC Act) to the Department of Climate Change, Energy, the Environment and Water (DCCEEW) in relation to activities outside of the scope of this EP including:

- the first stage of the referrals will assess environmental impacts and risks associated with the establishment of the ORC
- the second stage of the referrals will assess environmental impacts and risks associated with the transportation of removed property through State waters and offloading and set down at Barry Beach Marine Terminal
- the third stage of the referrals will assess environmental impacts and risks associated with the processing and disposal of wastes once offloaded on shore.

The Barry Beach Marine Terminal has an existing site operating licence that allows the receival of priority wastes as part of Esso's ongoing operations. Any licence amendments will be referred to the Victorian Environment Protection Authority. Most of the materials in both the topsides and jackets is steel and current estimates anticipate that the majority (>95%) of the total mass of materials processed will be able to be recycled. Remaining materials that cannot be recycled will be disposed of at appropriately licenced facilities. All materials handling, transport and disposal will be managed in accordance with relevant legislation.

An overview of what is included in this EP scope, and what is not included in this EP scope, is shown in Table 1-1. The petroleum and pipeline titles relevant to this EP are listed in Section 2.2.1.

[1] The facilities listed in Schedule 3 of General Direction 817 are WTA, MKA, FTA, KFA, KFB, FLA, BMA, BMB, DPA and PCA.

Table 1-1 Scope of activities in this EP

Activities included in this EP scope	Activities not included in this EP scope and where addressed
Removal preparation activities which are undertaken by Allseas with a CSV such as the *Fortitude* or similar vessel, including: • topsides preparation works • separation of the topsides and the jacket (final air gapping) • grouting of lift points • jacket preparation works - including final surveys, localised seabed displacement, marine growth removal, soil plug removal, removal/pinning of appurtenances, flooded member drilling, pile pinning, cutting • removal of well conductor stubs where these remain above the seabed after P&A activities and jackets are to be removed to as close as practicable to the seabed • removal of well conductors should these be obstructive to removal activities and not achieved prior to Campaign #1 during P&A activities.	Inspection, maintenance and repair (IMR) of the facilities until the removal activities included in the scope of this EP commence: • included in the *Bass Strait Environment Plan (AUGO-EV-EMM-012)*. Facility preparation activities undertaken as part of the Cessation of Production (CoP) stage of the facility lifecycle (refer to Section 1.4), either from the facility, or a Multi Purpose Support Vessel (MPSV) in the case of unstaffed facilities: • included in the *Bass Strait Environment Plan (AUGO-EV-EMM-012)*. Well P&A activities: • platform-based P&A included in *Bass Strait Environment Plan (AUGO-EV-EMM-012)* • Jack-Up Rig or Mobile Offshore Drilling Unit (MODU) based P&A campaigns are subject to separate EP submission(s).
Severing of pipeline risers, umbilicals and flexibles (including plugging of pipelines and removal of sections of risers where applicable) in preparation for jacket removal.	Decommissioning of Bass Strait pipelines, umbilicals, flexibles and associated property: • included in future decommissioning EPs, to be submitted in line with pipeline/umbilical decommissioning timelines.
Removal of the Perch (PCA) and Dolphin (DPA) monotowers.	
Removal of the topsides and jacket of the Whiting (WTA) and Bream A (BMA) facilities to as close as practicable to the seabed. This may be below, or just above the seabed as described in Section 1.3.1.3.	Decommissioning of the WTA and BMA deep set piles and any jacket section that remains above the seabed, in the event that below seabed removal is not achieved in Campaign #1: • decommissioning of this property to be addressed in future EP/s which would reflect decommissioning approach (including any agreed alternative arrangement for this property).
One of two removal options for the Fortescue (FTA) facility, depending on the outcome of detailed removal engineering: • removal of the topsides and the jacket to as close as practicable to	Decommissioning of the FTA deep set piles and any jacket section which remains above the seabed, in the event that below seabed removal is not achieved in Campaign #1: • decommissioning of this property to be addressed in future EP/s which would reflect decommissioning approach (including any

Activities included in this EP scope	Activities not included in this EP scope and where addressed
the seabed. This may be below, or just above the seabed, or • removal of the topsides and the jacket to a depth of at least 55m below MSL.	agreed alternative arrangement for this property).
Removal of the topsides and upper jacket sections of up to six SPJs in deeper water - Kingfish A (KFA), Kingfish B (KFB), West Kingfish (WKF), Cobia (CBA), Mackerel (MKA), and Flounder (FLA) and optional Halibut (HLA) to a depth of at least 55m below MSL. The HLA option is contingent on the plan for HLA to be retained in use to transport fluids generated by well P&As and flushing activities on the remaining producing platforms from offshore to Longford utilising the HLA600/650 pipeline. In the event this option is not executed as part of this EP, the decommissioning of the HLA facility will be included in a future decommissioning EP.	Decommissioning of the lower jacket sections of the KFA, KFB, WKF, CBA, MKA, FLA and HLA SPJs (deep set piles and lower section if topsides and upper jacket sections removed as part of Campaign #1): • decommissioning of this property to be addressed in future EP/s which would reflect decommissioning approach (including any agreed/accepted alternative arrangement for this property). • this EP (Section 1.3.1.4) makes a commitment for removal of the lower jacket sections to commence in 2032 to ensure compliance with Section 572(3) and (7) as part of future decommissioning activities.
Ongoing management of partially removed facilities following the completion of Campaign #1 activities, until such time as the Bass Strait Non-Producing Environment Plan is accepted. This plan is expected to be submitted for assessment in March 2026.	Ongoing management of partially removed facilities following removal of the topsides will transition to the Bass Strait Non-Producing Environment Plan once accepted.
Removal of the topsides, including the module support frame, of the BMB platform that sits on a concrete substructure. Installation of a navigation aid onto the concrete substructure. Ongoing management of the BMB concrete substructure following removal of the BMB topsides, until such time as the Bass Strait Non-Producing Environment Plan is accepted. This plan is expected to be submitted for assessment in March 2026.	Decommissioning of the BMB concrete substructure: • included in a future decommissioning EP. Ongoing management of the BMB concrete substructure following removal of the topsides will transition to the Bass Strait Non-Producing Environment Plan once accepted.
Transport of removed property to a location closer to Corner Inlet and transfer of the property from a CSV or the HLV to a barge or HTV. Transport of removed property on barges or a HTV to Barry Beach Marine Terminal (where such transport occurs in Commonwealth waters). Typical marine vessel activities where these activities occur within the activity OA - for activities such as bunkering, provisioning,	Movement of Campaign #1 vessels outside of the OA as defined in Section 3.1. These vessels are deemed to be operating under the *Commonwealth Navigation Act 2012* (Cth) and not performing a petroleum activity. Transport of the property to Barry Beach Marine Terminal (where such transport occurs in State waters), load in at the ORC and dismantling and recycling/disposal of the components onshore. These activities will not occur within Commonwealth waters - hence will be conducted in accordance with State and Commonwealth legislation applicable to onshore and State waters activities.

Activities included in this EP scope	Activities not included in this EP scope and where addressed
equipment, waste, cargo transfer, crew changes, operational standby.	
Post removals surveys: • As left survey.	Post removals environmental monitoring. Activities required to undertake environmental monitoring are included in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). This applies to environmental monitoring pre and post removal of infrastructure. Post removals environmental monitoring will continue to be undertaken in accordance with the Bass Strait Non-Producing Environment Plan once submitted and accepted. Details of proposed arrangements and other information to support an application for surrender pursuant to Section 269 of the OPGGS Act (in accordance with Section 270 of the OPGGS Act). Any future surrender applications will be the subject of a future EP and will address the requirements of Section 270 of the OPGGS Act, including any agreed alternative arrangements for this property.

This EP will end once the following are complete:

- the activities as described in Section 2 of this EP (excluding options that are not selected); and
- acceptance of the Bass Strait Non-Producing Environment Plan, which will include the ongoing management of the facilities that are partially removed as part of Campaign #1. This plan is expected to be submitted for assessment in approximately March 2026; and
- submission and NOPSEMA acceptance of the notifications as required under Regulation 54(2) (end of activity) and Regulation 46(a) (end of EP) of the OPGGS (Environment) Regulations.

1.3 Compliance with Section 572 of the OPGGS Act

Section 572 of the OPGGS Act imposes obligations on a titleholder regarding maintenance and removal of property:

"Maintenance of property

(2) A titleholder must maintain in good condition and repair all structures that are, and all equipment and other property that is:

(a) in the title area; and

(b) used in connection with the operations authorised by the permit, lease, licence or authority.

Removal of property

(3) A titleholder must remove from the title area all structures that are, and all equipment and other property that is, neither used nor to be used in connection with the operations:

(a) in which the titleholder is or will be engaged; and

(b) that are authorised by the permit, lease, licence or authority

Section has effect subject to other provisions etc.:

(7) This section has effect subject to:

(a) any other provision of this Act; and

(b) the regulations; and

(c) a direction given by NOPSEMA or the responsible Commonwealth Minister under:

(i) Chapter 3; or

(ii) this Chapter; and

(d) any other law."

The obligations in Section 572(3) of the OPGGS Act are expressly subject to the provisions of Section 572(7) which would include Section 270 of the OPGGS Act. Section 270 provides a framework for titleholders to make an application to surrender their titles and includes the requirement at Section 270(3)(c) that the Joint Authority may consent to the surrender sought by the application only if the registered holder of the permit, lease or licence has (among other things):

"(i) to the satisfaction of NOPSEMA, removed or caused to be removed from the surrender area (defined by subsection (7)) all property brought into the surrender area by any person engaged or concerned in the operations authorised by the permit, lease or licence; or

(ii) made arrangements that are satisfactory to NOPSEMA in relation to that property."

Section 572(7) in conjunction with Section 270, provide scope for in situ decommissioning and other arrangements to be made where it can be demonstrated that the risks and impacts are As Low As Reasonably Practicable (ALARP) and acceptable as well as comply with all other Acts and Regulations. Consequently, the 'full removal' of all structures, equipment and other property on title is not required to comply with Section 572(3) or the acceptance criteria in Regulation 34 of the Environment Regulations.

This EP does not seek to permission an 'end state' or a satisfactory arrangement for the property, structures or equipment to remain on title following the completion of the activities, and these future arrangements are both outside the bounds of the activities in this EP and consequently the acceptance criteria. Refer to Section 1.3.1.4 for indicative key milestones for future decommissioning campaign(s) relevant to the lower jacket sections.

The future removal of property, structures and equipment remaining after Campaign #1 will be the subject of future permissioning documents and such activities are outside the scope of this EP. Ongoing IMR activities will occur until such time as the Bass Strait Non-Producing Environment Plan is accepted. This will ensure that Esso's obligations under Section 572(2) will be complied with so as to not preclude future removal.

1.3.1 Removal of property

This Section of the EP provides the reasoning for the exclusion of removal of particular lower jacket sections from the scope of this EP, as described in Table 1-1. Section 1.3.1.4 provides indicative key milestones for future decommissioning campaign(s) relevant to these lower jacket sections. These milestones are outside the scope of this EP.

A risk-based approach to progressive decommissioning has been applied which addresses both environmental and safety aspects.

For any petroleum activity, including jacket removal, the Environment Regulations require that Esso carries out such activities in a manner by which the environmental impacts and risks will be reduced to ALARP and will be of an acceptable level.

NOPSEMA's Information Paper *Planning for proactive decommissioning* (NOPSEMA, 2025a) states that, notwithstanding decommissioning targets included in the Information Paper,

"....actual timelines will be based upon sound decommissioning planning outcomes. Considerations that will inform decommissioning timelines (both accelerated and deferred) include:

- *risk assessments and actions required to reduce risks to as low as reasonably practicable and acceptable.*
- *effective maintenance and preservation of property to ensure structural integrity until it is decommissioned.*
- *outcomes of technical studies that support alternative timelines.*
- *adjusting of timelines to enable phased or campaign based decommissioning".*

In line with NOSPEMA's Information Paper, Esso's overall planning for decommissioning Bass Strait property prioritises property with higher potential environmental impacts and risks**.** Property with higher potential

environmental impacts and risks are targeted in Campaign #1 and that scope is included in this EP. Property to be decommissioned in order of risk prioritisation is as follows:

- non-producing wells, both platform-based and subsea (plugged and abandoned outside the scope of this EP)
- platform topsides preparation and removal (included in this EP)
- SPJ upper sections that are situated between MSL and 55m below MSL (included in this EP)
- other remaining infrastructure including SPJ bases more than 55m below MSL, pipelines, umbilicals, flexibles and CGSs (decommissioned outside the scope of this EP in future campaigns).

Safety Regulations require Esso's overall planning for decommissioning Bass Strait property to also consider the most suitable and appropriate vessels, methods, practices and procedures to minimise the risks to the health and safety of persons, while at the same time complying with the environmental obligations.

1.3.1.1 Non-producing wells

Non-producing wells are the first priority for decommissioning both to minimise risk and, in the case of wells on platforms, P&A is a major pre-cursor to the decommissioning of topsides equipment. As per Table 1-1, P&A of platform-based wells is included in the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) while Jack-Up Rig or MODU based P&A campaigns are subject to separate EP submission(s).

All wells will be plugged and abandoned on each Campaign #1 facility prior to removal activities under this EP commencing at the facility in accordance with the requirements of Direction 2(b) of General Direction 817. Conductors will be removed in accordance with the relevant Well Operations Management Plan through the point of severance and the platform safety case and the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) for conductor pulling. If this is not achieved and in order to ensure removals activities can commence, any remaining obstructive conductors or conductor stubs will be removed as part of the activities in this EP (refer to Section 2.14.2 and 2.14.3).

1.3.1.2 Platform topsides

During the historical production phase, platform topsides contained a range of hazardous inventories including petroleum, methanol, diesel, non-hydrocarbon chemicals, lube oils and refrigerants, fire-fighting foam and hydraulic oil. After completion of the P&A of platform non-producing wells, the platform topside inventories can be flushed, isolated and air-gapped where necessary. As per Table 1-1, these preparation activities are included in the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). Once topsides preparation is complete for the Campaign #1 platforms, removal, transport and backloading to barges or HTVs in Commonwealth waters is included in this EP.

1.3.1.3 Jacket removal

In balancing the environmental and safety risks of jacket removal together with the requirements of Direction 2(a) of General Direction 817 and decommissioning of Bass Strait property overall, Esso has considered (i) the capability of jacket removal equipment; (ii) uncertainties about how the jackets were piled into the seabed decades ago; (iii) information on the anticipated degradation rates of the jacket components and (iv) uncertainties that may arise during the execution of activities in the field. These considerations are further detailed below:

(i) The removal vessel *Pioneering Spirit* HLV is one of the largest offshore construction vessels in the world, designed for offshore heavy lift and is the foundation for the work scopes proposed in this EP. The size and capacity of the *Pioneering Spirit* HLV allows minimal lifts which contribute to minimising workforce and environmental exposure hours through reducing field execution duration. Factors considered in establishing the current and future campaign based approach to decommissioning are described in Section 1.3.1.4.

(ii) For the larger jackets with more piles (KFA, KFB, MKA, WKF, FLA, CBA), Esso has concluded that internal cutting of an individual pile, if feasible, would significantly reduce seabed disturbance for that pile (see Section 6.2.3). For all SPJs, there is uncertainty about the internal condition of the piles that fix each jacket to the seabed. This means that, until the piles are open for visual inspection, Esso cannot be assured that internal cutting can be reliably executed.

Based on visual surveys able to be completed on the 176 piles that are associated with Campaign #1 facilities, 59 are assumed to have either soil plugs or other internal obstructions which may be able to be removed to allow internal cutting. Each of these 59 piles requires developing a method of intervention for

the type of obstruction, to determine if internal cutting is feasible for that pile. Obstructions may include items such as installation aids from original construction of the platform, hard marine growth that has developed over time or sand/shells/ballast material that may be embedded making internal cutting without prior intervention not possible.

To sufficiently understand the uncertainties for each pile and determine whether internal cutting is feasible, the safest and lowest environmental impact option is to remove the upper sections of the jackets and enable detailed inspection of each of the piles. The internal inspections and subsequent development of tooling to attempt to remove the potential obstructions can only be completed once the upper sections of the jackets have been removed, hence enabling access to each leg and pile. Inspections and development of tooling will take some time to complete after the upper sections have been removed to ensure the maximum number of internal cuts are able to be executed. This will minimize the requirement to relocate sediment from around the piles and legs to enable an external cut below seabed, should internal cutting be infeasible. The inspection program, which will be executed following the completion of Campaign #1 activities will allow planning of the safest methodology for the removal of the lower jacket sections and ensure environmental impacts are reduced to ALARP and acceptable levels.

For the jackets in shallower water depths (either less than 55m depth or just over), the objective is to complete full removal down to just below seabed in Campaign #1 (if internal cutting is feasible) or as close to seabed as practicable through external cutting. This is possible due to the small number of jackets in this category (WTA and BMA and potentially FTA) which enables the investigation and resolution of the above issues to be accommodated within the Campaign #1 HLV availability window. Note that PCA and DPA are gravity-based platforms, are not fixed to the seabed by piles and can be fully removed in Campaign #1.

(iii) Extremely slow corrosion rates (open water corrosion rate of 0.1mm per year) (Kent Plc, 2022) are predicted on the lower jacket sections based on the material degradation study (refer to Section 2.18.1 for further information), as a result of the location of the jacket sections in water depths greater than 55m below sea level with the associated reduced oxygen levels required for corrosion to take place. Hence there is no risk to the integrity of the lower jacket sections while inspections, contracting, engineering and regulatory permissioning (including dredging permits under the Sea Dumping Act 1981, expected to be required for lower jacket section removal) is completed for their future removal. Each of the removal methods described below will be available to remove the structures within the timeframes proposed in Section 1.3.1.4, plus contingency. The jacket structures are very heavy walled tubular members, ranging from a 40mm thick steel leg, through to a 55mm composite profile (steel jacket leg, grout, steel pile/s). Considering the actual wall thickness of jacket structures, and the expected corrosion rate, it is calculated that leaving the jackets in place without ICCP for 10 years may result in a 2.5% wall loss. Given the expected structural strength required to undertake removal as per the removal approaches outlined below, and the small potential wall loss expected, each removal approach would be feasible and each would progress through a selection process to be considered for execution. Hence Esso confirms that potential approaches for the removal of the lower jacket sections down to seabed will remain feasible given the expected integrity of the lower jacket sections, as removal and lifting methods can be adapted to consider the individual structure.

(iv) The remaining structures on the seabed after Campaign #1 are expected to range in height above the seabed from approximately 15m to 40m. In the event jackets in shallower water depths (WTA, BMA and potentially FTA) cannot be removed to below the seabed, the lower sections of these jackets may remain on the seabed with a maximum height of 3m. Each jacket will continue to be secured to the seabed by deep foundation piles, ensuring they are fixed in their current position. The cuts to the upper sections of the jackets during Campaign #1 (included in this EP) have been selected based on engineering and concept reviews to ensure the safe execution of heavy lifts. The lower jacket section remaining on the seabed will be surveyed as part of the as-left survey (refer to Section 2.16) to confirm the exact heights of all legs and braces of the remaining lower jacket section to enable planning for the scope of the detailed internal inspection program. A key consideration for future removal of the lower jacket sections will be determining the presence of obstructions such as grout plugs in the legs and piles of the lower jacket sections and whether these can be safely removed. The presence of grout plugs or other obstructions will influence the execution of internal or external cutting methodologies as well as inform the preferred removal method, as the presence of grout plugs may have a significant impact on the weights of the

structures to be lifted. These lower sections retain structural integrity and will be able to be removed in a future campaign through a number of potential methods (as detailed below). Following the upper section removal and internal pile/leg inspections, engineering assessments will be completed including considerations of the heights of the lower jacket sections in selection of the final preferred removal approach. A number of potential removal approaches for the lower jackets sections are available and are outlined below;

a. Large section removal

   This approach would involve less cutting of the lower jacket structures prior to removal and would result in approximately 2-8 lifts of larger sections of each of the remaining lower jacket sections. This approach has the advantage of less cutting and lifts however it would require additional support vessels to enable the larger sections to be backloaded for transport to shore and recycling. This approach would require very detailed mapping of grout locations within the jacket structure to ensure robust lift detailed design for offshore removal and transit to shore. It would also require utilization of a larger vessel with a larger crane which is not currently readily available in the Australian market.

b. Smaller section removal

   This approach requires more cuts of the lower jacket sections prior to removal and would result in approximately 9-16 lifts to remove each lower jacket section. With this approach, sections are small enough to be backloaded to a smaller supply vessel, hence avoiding the need to mobilise alternative larger vessels for transport to shore. This approach also reduces some potential risks associated with lifting larger sections (as described above) due to the reduced weights for each lift, hence reducing loads on the crane vessel and jacket sections.

c. Piece small removal

   This approach requires a greater number of cuts than either of the two previous methods and would result in over 16 lifts to remove each lower jacket section. This approach results in the ability to use smaller vessels with smaller cranes that are more readily available in the Australian market. It also reduces the requirement to have exact details of grout locations due to smaller, lighter sections being removed. Small sections could be stored on the removal vessel which may then be able to transport these directly onshore, hence negating the need for support vessels.

For each of these approaches, other specific considerations will be assessed by the removal execution contractors. Vessel operators may use a range of cutting and lifting tools, including internal lifting tools inserted into the vertical members, or slings rigged by ROV underwater. These cannot be confirmed until access is provided with the removal of the upper jacket sections.

Selection of the preferred method for removal will be informed by the inspections post upper jackets sections being removed as well as market availability of vessels and equipment capable of executing the various options. All approaches have been used previously for jacket removal globally and are proven safe execution approaches. Each method has environmental advantages and disadvantages, which will be considered as part of the selection process. It is possible that each of the remaining lower jacket sections may be removed slightly differently, depending on what is deemed the safest and most efficient method for the specific structure. The selection of the preferred method is not impacted by the Campaign 1 activities included in this EP, and once a preferred method (or methods) is selected this will be the subject of a subsequent lower jacket removal execution EP. All of these removal approaches are standard in the global decommissioning industry and no removal options will be precluded or become disproportionally challenging due to any of the activities planned for cutting jackets as part of the Campaign 1 scope included in this EP.

1.3.1.4 Future decommissioning plans

Planning for the future decommissioning approach for lower jacket sections after Campaign #1 execution is underway, consistent with the risk-based approach described above. For a decommissioning scope the size of the Gippsland Basin, the optimal approach is to aggregate facilities into campaigns for decommissioning execution. The factors considered by Esso when developing a campaign based decommissioning approach include:

- campaigns enable learnings and skill development that can be adopted for each subsequent campaign, hence resulting in the safest approach to the execution of large repeat offshore scopes
- the environmental impact of each campaign compounds due to the need to repeat scope each time a project moves into execution phase. Campaigns enable the number of HLV and support vessel spread mobilisations to be minimised, thereby reducing overall fuel consumption and resultant greenhouse gas (GHG) and other air emissions. Other impacts related to decommissioning activities such as the potential disturbance of marine life through light and noise are also minimised by aggregating removal of facilities into campaigns
- the interconnectedness of facilities and varying CoP timing throughout the Gippsland Basin makes it important to ensure that the disconnection of non-producing facilities for decommissioning is carefully planned with limited impact to operating facilities, hence ensuring reliable gas supply to Victoria
- the approach attracts contractors with world class expertise, vessels and experience to mobilise to execute work in the safest and most efficient manner, hence also ensuring environmental impacts are minimised
- the remote geographical location and sea conditions of the Gippsland Basin also limits the availability of vessels with suitable size and capability to undertake a work program of this scale. Without a significant scope of work, it is not commercially viable for the optimal vessels to come to Bass Strait from the Northern Hemisphere as they need to forego other work in nearby locations in order to mobilise to Australia
- a campaign based approach minimises cost due to the efficiency associated with combining assets to be decommissioned into a scope of work requiring one vessel spread mobilisation.

The following key milestones are indicative for future decommissioning campaign(s) relevant to the lower jacket sections and making any satisfactory arrangements and/or separate regulatory approvals.

- During 2028/2029:
    - complete a post topside removal survey of the remaining piles and structures that are only accessible once upper sections of the jackets have been removed.
    - finalise concept select for the removal of the lower sections of the jackets
- During 2029/2030:
    - Commence contracting for lower jacket section removal
    - assuming minimal obstructions are identified in the piles or minimal intervention is required to clear obstructions, commence contracting (invitation to tender) for lower jacket section removal
    - if piles with obstructions have been identified, assess requirement for dredging permits with DCCEEW, and if necessary, apply for a permit to enable external cutting of piles below the seafloor
    - determine the approach to cut each jacket pile either internally or externally and develop a plan for lifting options for each jacket base
    - prepare and submit an execution EP for removal of lower sections of the jackets.
- During 2030:
    - award contract and undertake detailed engineering and execution planning with selected contractor
    - complete the majority of Campaign #1 dismantling to allow space at Barry Beach Marine Terminal for lower jacket sections.
- During 2031:
    - detailed engineering/lift design followed by procurement of suitable support vessels/barges, grillage, sea fastening, rigging, spreader bars etc.

    - receive execution EP acceptance (for removal of lower jacket sections).
- During 2032:
    - commence the activities to remove the lower jacket sections (unless an alternate 'end state' arrangement has been agreed with or accepted by NOPSEMA).

The key milestones outlined are contingent on a number of factors, including:

- successful execution of the Campaign #1 activities within the scope of this EP, noting as per Section 1.2 that activities not able to be completed within the Campaign #1 operational timeframe will be undertaken in future campaigns
- progressing the onshore dismantling of the removed Campaign #1 facilities to ensure the ORC has capacity to receive the lower jacket sections
- encountering obstructions in the piles which may necessitate additional regulatory permits and assessments (e.g. dredging permits required under the *Sea Dumping Act 1981*)
- the availability of suitable vessel(s) to mobilise to Bass Strait in the proposed suitable conditions execution window
- delays in execution EP (for the removal of the lower jacket sections) assessment and acceptance.

As discussed in Section 2.18, the integrity of each jacket structure has been maintained since installation via the use of a cathodic protection system which has been regularly monitored. Although this system will no longer be in operation following the conclusion of the Campaign #1 activities, given the typical steel wall thicknesses, and combination of the grouted annulus of sleeves and piles, the timeline for steel degradation of the SPJs to be of any significance is approximately 50 - 100 years (Kent Plc, 2022). This is well beyond the timeframes for removal outlined above and in compliance with Section 572(2) of the OPGGS Act.

Separate EPs will be utilised to facilitate future decommissioning activities not specifically included in the Campaign #1 scope.

1.3.2 Maintenance and repair of property

1.3.2.1 Prior to Campaign #1 removal activities

Maintenance and repair of structures, and all equipment and other property that are associated with the facilities to which this Campaign #1 EP applies are activities described in the accepted *Bass Strait Environment Plan (AUGO-EV-EMM-012)*.

1.3.2.2 After execution of Campaign #1 removal activities

Consistent with NOPSEMA's Information Paper *Planning for proactive decommissioning* (NOPSEMA, 2025a)

> *"...Property that is no longer in use or in a state of suspension must be preserved, inspected, and maintained in good condition and repair in accordance with Section 572(2) of the OPGGS Act to enable decommissioning in the future".*

Ongoing management, including any required IMR of the infrastructure associated with Campaign #1 facilities which remain in place following the removal activities is described in Section 2.18. These activities will be undertaken within the scope of this EP until such time as the Bass Strait Non-Producing Environment Plan is accepted. The Bass Strait Non-Producing Environment Plan is expected to be submitted for assessment in March 2026.

1.4 Life cycle of a facility

A titleholder may determine what is involved in a particular stage of a petroleum activity and provide adequately for those activities in an EP. As defined in *When to submit a proposed revision of an Environment Plan* (NOPSEMA, 2024a), a new stage of activity is defined as a change to the spatial or temporal limits of the petroleum activity described in the accepted EP.

The life cycle stages of the Gippsland Basin facilities are shown in Figure 1-1 and Table 1-2.

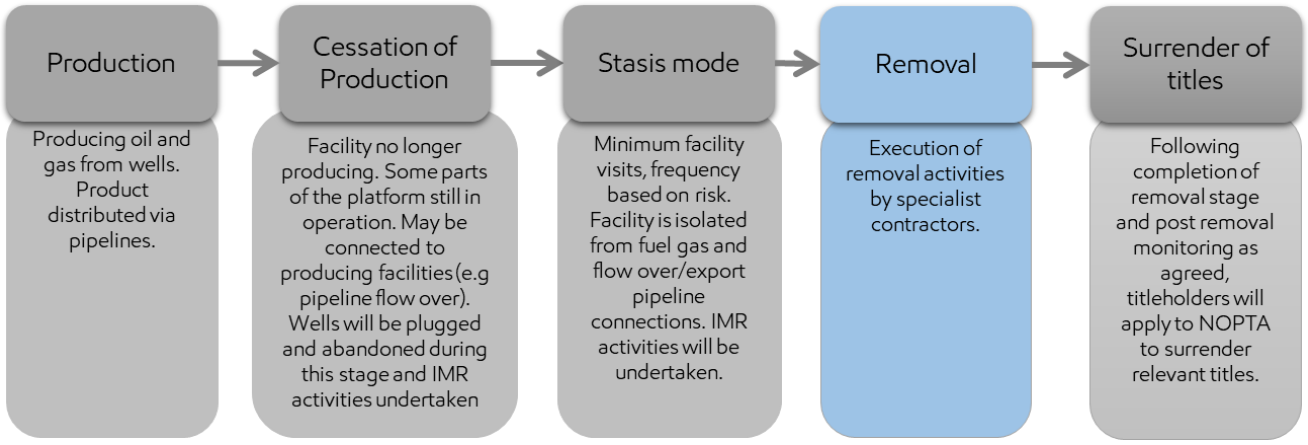

Figure 1-1 Life cycle stages of the Bass Strait facilities

The Campaign #1 facilities included in this EP are currently either in the CoP or Stasis mode life cycle stage. Activities carried out by crews that are based on facilities during the Production, CoP and Stasis mode stages, which include P&A of wells and preparation of the facilities for removal are outside the scope of this EP. The activities for these stages are included in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) and separate well P&A activity EPs as required.

The activities within the scope of this EP are part of the Removal stage of the facility life cycle. These activities are described in Section 2.

Following the execution of all decommissioning activities and the undertaking of any required post-decommissioning monitoring as agreed with NOPSEMA, the titleholders will apply to the National Offshore Petroleum Titles Administrator to surrender the relevant petroleum titles in accordance with Section 270 of the OPGGS Act.

Section 572(3) of the OPGGS Act, requires titleholders to remove from the title area all structures, equipment and other property that are neither used nor to be used in connection with the operations, but this provision is subject to Section 572(7) and Section 270(3)(c).

The surrender of title may also include a titleholder entering into a satisfactory arrangement with NOPSEMA for any remaining property within the licence area in accordance with Section 270(3)(c) of the OPGGS Act. Section 270 sets out the criteria for the Joint Authority to determine whether to give consent to the surrender of a title. The activities described in this EP, consisting of removal of property from the title areas listed in Section 2.2 is a key step toward compliance with Section 270(3)(c) of the OPGGS Act, however the Surrender of Titles stage is not within the scope of this EP and will be included in a future EP(s).

In order to obtain consent to surrender a title, Section 270(3)(e) and (f) of the OPGGS Act require that the registered holder of the permit, lease or licence has, to the satisfaction of NOPSEMA, made good any damage to the seabed or subsoil in the surrender area caused by any person engaged in the operations authorised by the permit, lease or licence and provided for the conservation and protection of the natural resources in the surrender area. As this EP is not the final EP for the facilities listed in Table 1-1 and as the Surrender of Titles stage of the facility life cycle is not within the scope of this EP, details of how the titleholders will address these Surrender of Titles requirements will be included in a future EP(s) and/or as part of a separate application to surrender under Section 270 of the OPGGS Act. The assessment of Section 270 compliance is also outside the scope of the acceptance criteria for in Regulation 34 of the Environment Regulations for the acceptance of an EP.

Table 1-2 Bass Strait facility lifecycle

Stage	Definition	Activities within the scope of this EP
Production	Facility is producing oil and/or gas which is distributed via pipelines. In some instances during this stage, production may temporarily be ceased while future development plans are being evaluated. A facility will move to the CoP stage when production has ceased and there is no intention of returning to production in the future.	No
CoP	Key change from prior stage – CoP stage commences when a facility is no longer producing oil and/or gas and all wells are shut-in. There are a number of activities within the CoP stage: • Care and Preservation activities pre well P&A: - systems are being maintained and/or preserved where they are required for future P&A and decommissioning activities and/or to facilitate upstream asset ongoing production - wells continue to be monitored as per the Wells Integrity Management System and risk assessments undertaken as required prior to P&A. Wells may be plugged and secured using a wireline rig to preserve wellbore integrity for the period prior to P&A. Once platforms are temporarily de-staffed, periodic platform visits are conducted as required to complete operations and maintenance tasks (e.g. Wells Integrity Management System testing, well operations, restart equipment that has shut down, top up lube oils, launch/receive pigs, re-establish communications) to facilitate upstream platform operations and/or maintain equipment for future decommissioning activities. Platform visits may be conducted as day trips, or by re-staffing the facility for a period of time (could be weeks/months). • Well P&A and well conductor removal: - wells will be P&A'd during the CoP stage. Timing of P&A is dependent on the risk profile of each well - well conductors will be removed either post-P&A OR as part of the SPJ Removal stage - some systems on the platform are still in operation with temporary or permanent connections (e.g. power, air, safety systems, fuel systems, pig launcher/receivers, cathodic protection, etc.). • Care and Preservation post-well P&A (as applicable): - platforms will continue to be staffed to complete operations and maintenance tasks in order to facilitate decommissioning activities such as well P&A campaigns. Various platforms may be periodically de-staffed for short periods (weeks to months) depending on operational resourcing.	No

Stage	Definition	Activities within the scope of this EP
	During these times, platform visits will be conducted as short trips as required to complete various tasks (e.g. restart power generation, top up lube oils, launch/receive pipeline pigs, re-establish telemetry). • Facility preparation for removal: - activities are being undertaken to prepare the platform for removal in parallel with IMR to preserve the facility for the Stasis Mode stage - facilities will be progressively isolated from fuel gas and flow-over/export pipeline connections and cathodic protection turned off. The overall duration of CoP is dependent on current and potential future use requirements of the facility. Due to the high level of interconnectedness of the Bass Strait facilities, some platforms continue to be used to facilitate pipeline 'flow over' from other facilities to facilitate the preparation of other facilities for decommissioning such as the flushing of pipelines and umbilicals, and removal of topsides hydrocarbons. At completion of Care and Preservation, the facility will have completed well P&A and facility preparation activities and can be put into Stasis Mode.	
Stasis Mode	Key change from prior stage: • activities to prepare facility for a period of minimal activity are complete • facilities are isolated from fuel gas and flow-over/export pipeline connections • facilities are considered to be 'not in use, nor to be used' in connection with the operations (per Section 572 of the OPGGS Act) when Stasis Mode stage is reached The duration for which a platform will remain in the Stasis Mode stage is dependent on the current and future use requirements (i.e. to facilitate preparation for removal of other facilities) of the facility and the timing of decommissioning campaigns.	No
	Ongoing management of partially removed infrastructure following the completion of Campaign #1 removal activities, as described in Section 2.18, until such time as the Bass Strait Non-Producing Environment Plan is accepted.	Yes
Removal	Removal preparation activities undertaken by the *Fortitude* CSV (or similar vessel/s). Removal decommissioning activities with scopes defined in decommissioning EPs.	Yes.

Stage	Definition	Activities within the scope of this EP
	Removal activities will be undertaken by specialised third-party contractors with the appropriate vessels, equipment and expertise to undertake this work.	
Surrender of Titles	Post decommissioning environmental monitoring. Following the completion of decommissioning and post-decommissioning monitoring, as agreed with NOPSEMA, the titleholders will apply to the National Offshore Petroleum Titles Administrator to surrender the relevant petroleum titles.	No

1.5 Titleholder details

Esso, a wholly owned subsidiary of ExxonMobil Australia Pty Ltd, is the operator for the Gippsland Basin Joint Venture (Esso and Woodside Energy (Bass Strait) Pty Ltd). Esso receives services, including personnel, from its wholly owned subsidiary, Esso Australia Pty Ltd, which is also a wholly owned subsidiary of ExxonMobil Australia Pty Ltd.

Petroleum Production Licences applicable to this EP are:

- VIC/L02
- VIC/L05
- VIC/L07
- VIC/L11
- VIC/L13
- VIC/L14
- VIC/L15
- VIC/L17.

As pipelines remaining on the seabed will be plugged or capped following cutting activities to enable the removal of the facilities (refer to Section 2.7.7), the following Pipeline Licences are also applicable to this EP:

- VIC/PL5
- VIC/PL6
- VIC/PL7
- VIC/PL8
- VIC/PL11
- VIC/PL14
- VIC/PL15
- VIC/PL16
- VIC/PL17
- VIC/PL18
- VIC/PL20
- VIC/PL21
- VIC/PL24
- VIC/PL25
- VIC/PL26
- VIC/PL29
- VIC/PL32

The titleholder details for this EP are as follows:

Esso Australia Resources Pty Ltd (ACN 091 829 819)
Level 9, 664 Collins Street, Docklands VIC 3008

The nominated liaison person for this activity is:

Hena Kalam, Australia Major Projects SSHE Manager
Esso Australia Pty Ltd for and on behalf of Esso
Level 9, 664 Collins Street, Docklands VIC 3008
Telephone: (03) 9261 0000
Email: eapl.regulatory@exxonmobil.com

NOPSEMA will be notified of a change in titleholder, a change in the nominated liaison person or a change in the contact details for either the titleholder or the nominated liaison in accordance with Regulation 23(3) of the Environment Regulations.

1.6 Legislative requirements and industry guidance

The principal offshore legislation for petroleum activities beyond 3nm to the outer extent of the Australian Exclusive Economic Zone at 200nm is the OPGGS Act.

1.6.1 Relevant legislation

In accordance with Regulation 21(4), relevant Commonwealth legislation as it applies to the operation of facilities and petroleum pipelines and projects is provided in Table 1-3.

No part of the activity is located within Victorian, New South Wales, or Tasmanian State waters (between the low water mark and the 3nm limit) and as such, no environmental approvals for the activity are required from the Victorian or other State governments. The State legislation would be relevant in the unlikely case of a large hydrocarbon release, as the Environment That May Be Affected (EMBA) intersects State waters, therefore legislation relevant to marine pollution in Victoria, is detailed in Table 1-4. Legislation relevant to marine pollution in New South Wales, is detailed in Table 1-5. Legislation relevant to marine pollution in Tasmania, is detailed in Table 1-6.

Table 1-3 Applicable Commonwealth legislation

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
OPGGS Act and Environment Regulations	The OPGGS Act addresses all licensing, health, safety, environmental and royalty issues for offshore petroleum exploration and recovery operations extending beyond the 3nm limit. The Environment Regulations ensures that petroleum activities are carried out in a manner; consistent with the principles of ecologically sustainable development (ESD) set out in Section 3A of the EPBC Act; and by which the environmental impacts and risks of the activity will be reduced to ALARP and will be of an acceptable level. Obligations in relation to the removal of property brought onto a title are provided in OPGGS Act Section 572(3) and (7). Obligations in relation to surrender of petroleum titles following the completion of decommissioning activities are provided in OPGGS Act Section 270. Esso acknowledges the requirements of Section 270, however Section 270 matters are not part of the scope of this EP and will be the subject of a future decommissioning EP.	The OPGGS Act applies to the activity assessed under this EP. The removal of structures, equipment and other property that is no longer used, by the undertaking of the activities described in Section 1.3 of this EP, is in compliance with Section 572(3) and (7) of the OPGGS Act. The removal of structures, equipment and property no longer in use by the undertaking of the activities described in Section 1.2 of this EP is also in compliance with Section 270 of the OPGGS Act, which requires removal of property (or other arrangements as agreed with NOPSEMA) to be undertaken prior to applying to surrender petroleum titles.	N/A	NOPSEMA
EPBC Act	The EPBC Act focuses on Matters of National Environmental Significance (MNES), streamlines the Commonwealth environmental assessment and approval process and provides an integrated system for biodiversity conservation and management of protected areas. MNES include but are not limited to world heritage properties; Convention on Wetlands of International Importance especially as Waterfowl Habitat 1971 (Ramsar) wetlands; listed threatened species and communities; migratory	EPBC Act Protected Matters Search Tool (PMST) utilised to identify relevant data. Approved conservation advice and management plans, including statutory recovery plans for threatened species listed under Part 3 of the EPBC Act, relating to listed species or threatened	1992 Convention on Biological Diversity & Agenda 21. Convention on International Trade in Endangered Species of Wildlife and Flora 1973.	DCCEEW For petroleum activities in Commonwealth waters, NOPSEMA

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
	species under international agreements; nuclear actions and the Commonwealth marine environment. On 28 February 2014, NOPSEMA became the sole designated assessor of petroleum and GHG activities in Commonwealth waters in accordance with the Minister for the Environment's endorsement of NOPSEMA's environmental authorisation process under Section 146 of the EPBC Act.	ecological communities (TECs) have been identified and considered where appropriate. Relevant MNES and recovery plans are covered in Appendix A.	Convention on Wetlands of International Importance especially as Waterfowl Habitat 1971 (Ramsar). Japan/Australia Migratory Bird Agreement 1974. China/Australia Migratory Bird Agreement 1986. Republic of Korea-Australia Migratory Bird Agreement 2006. International Convention on Whaling 1946. Convention on the Conservation of Migratory Species of Wild Animals 1979 (Bonn Convention). Convention Concerning the Protection of the World Cultural and Natural Heritage 1972.	

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
Australian Maritime Safety Authority Act 1990 (Cth)	The main objectives of this Act are to promote maritime safety and to protect the marine environment from pollution from ships and other environmental damage caused by shipping. The Act also establishes the Australian Maritime Safety Authority (AMSA) and a national search and rescue service.	Oil spill preparedness and response plans for dealing with a potential worst-case scenario spill is described in Section 7.7.5 including consultation and coordination of activities with AMSA.	International Convention on Oil Pollution Preparedness, Response and Co-operation) 1990.	AMSA
National Environment Protection Council Act 1994 (Cth) and *National Environment Protection Measures (Implementation) Act 1998* (Cth)	National Environment Protection Council develops (in conjunction with other State authorities) through the Intergovernmental Agreement on the Environment, consistent environmental standards to be adopted between States. These requirements take the form of National Environment Pollution Measures such as National Pollutant Inventory.	Reporting of emissions required by the National Pollutant Inventory is conducted annually for all Esso operated activities.	N/A	National Environment Protection Council
National Greenhouse and Energy Reporting Act 2007 (Cth)	Provides for the reporting and dissemination of information related to GHG emissions, GHG projects, energy production and energy consumption.	Annual submission covering Esso's Gippsland activities provided to Clean Energy Regulator.	United Nations Framework Convention on Climate Change,1992, and the Kyoto Protocol, 1997.	Clean Energy Regulator
Protection of the Sea (Prevention of Pollution from Ships) Act 1983 (Cth)	Regulates ship-related operational activities and invokes certain requirements of International Convention for the Prevention of Pollution from Ships, 1973 as modified by the Protocol 1978 (MARPOL) relating to discharge of noxious liquid substances, sewage, garbage, air pollution etc.	Activities described in this plan are controlled to prevent actions that would contravene this Act. Relevant control measures and the implementation strategy is described in this EP.	MARPOL, including the incorporation of the amendments that have been adopted, including the 2022 maritime Legislation Amendment Bill.	AMSA

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
Biosecurity Act 2015 (Cth) and associated regulations including Biosecurity Amendment (Biofouling Management) Regulations 2021 (Cth)	The Act is about managing diseases and pests that may cause harm to human, animal or plant health or the environment. It empowers authorities to monitor, authorise, respond to and control biosecurity risks for the movement of goods, vessels and people to prevent the introduction, establishment or spread of diseases or pests affecting human beings, animals, or plants. The Biosecurity Amendment (Biofouling Management) Regulations 2021 (Cth) entered into force on 15 June 2022 and requires that vessel operators provide information on biofouling management practices prior to arriving in Australia.	The risk of introduction of Invasive Marine Species (IMS) is considered and managed for all vessels covered under this activity as described in this EP.	International Convention for the Control and Management of Ships' Ballast Water and Sediments 2004. United Nations Convention on the Law of the Sea 1982. Convention on Biological Diversity 1992.	Department of Agriculture, Fisheries and Forestry
Navigation Act 2012 (Cth)	Regulates ship-related activities and invokes certain requirements of MARPOL convention relating to equipment and construction of ships.	Vessels operating within the permit areas comply with the requirements of the Act, covering maritime safety and marine pollution prevention. Specifically in relation to environment protection, activities relating to control of discharges are discussed in this EP, including perfluorooctane sulfonate (PFOS).	MARPOL (certain sections). Convention on the International Regulations for Preventing Collisions at Sea 1972 (COLREGs).	AMSA
Coastal Waters (State Powers) Act 1980 (Cth)	This Act transferred constitutional power over coastal waters, and title to seabed minerals within territorial limits, from the Commonwealth to the States.	Consultation, reporting and other matters impacting coastal waters are addressed with State authorities as described in this EP.	N/A	Geoscience Australia (Maritime Boundaries Advice Unit)

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
Protection of the Sea (Harmful Anti-fouling Systems) Act 2006 (Cth)	Regulates the use of harmful anti-fouling systems employed on vessels and their effects on the marine environment.	The risk of introduction of IMS is considered and managed for all vessels covered under this activity as described in this EP. This includes consideration of appropriate antifouling systems.	International Convention on the Control of Harmful Anti-fouling Systems on Ships 2001.	AMSA
Native Title Act 1993 (Cth)	Allows for recognition of Native Title through a claims and mediation process and sets up regimes for obtaining interests in lands or waters where native title may exist.	Native Title within the Bass Strait operations Described Area is identified and recognised in Section 1.6.5.	N/A	Attorney-General's Department
Underwater Cultural Heritage Act 2018 (Cth)	Provides for the protection of Australia's shipwrecks and has broadened protection to sunken aircraft and other types of underwater cultural heritage including Australia's Aboriginal and Torres Strait Islander underwater cultural heritage in Commonwealth waters. Projects that damage or interfere with a historic shipwreck or relic in Australian waters or with a submerged aircraft or associated artefacts in Commonwealth waters require a permit.	Shipwrecks, relics, submerged aircrafts or associated artifacts within the OA are identified in Table 3-2 of this EP. There are no Protected Zones within the OA. Shipwrecks, relics, submerged aircrafts or associated artifacts and protected areas within the EMBA are identified in Appendix A.	N/A	DCCEEW
Civil Aviation Act 1988 (Cth) and associated regulations including Civil Aviation Safety Regulations 1998 (Cth)	The Act sets up a Civil Aviation Safety Authority (CASA) with functions to regulate the safety of civil aviation, including the carrying of dangerous goods, airworthiness standards for aviation, maintenance; general operational and flight rules; and aerial application operations.	Rotary wing aircraft servicing the Gippsland facilities operate under the requirements of CASA. This contributes to safe operation and transport of goods thereby reducing risk of incidents which could have environmental impacts as described in this EP.	Chicago Convention 1944.	CASA

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
Radiocommunications Act 1992 (Cth)	The Act provides for the management of the radiofrequency spectrum to ensure accurate provision of the spectrum for use by agencies involved in the defence or national security of Australia, law enforcement or the provision of emergency services; and for use by the public or community services.	Radio-communications systems on vessels and aircrafts operate within frequency ranges permitted under the Act. Clear communication channels are required to enable effective controls preventing or limiting potential impacts from incidents (e.g. collision, emergency response) as defined in this EP.	N/A	Australian Communications and Media Authority
Hazardous Waste (Regulation of Exports and Imports) Act 1989 (Cth)	This Act regulates the export, import and transit of hazardous waste to ensure that hazardous waste is dealt with appropriately so that human health and the environment, both within and outside Australia, are protected from the harmful effects of waste.	Hazardous waste generated during the activity will be transported within Australia. As the activity does not involve the export, import or international transit of hazardous waste, permit requirements under this Act do not apply. Management measures applicable to hazardous wastes are presented in Sections 6 and 7 of this EP.	The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal, 1989.	DCCEEW
Aboriginal and Torres Strait Islander Heritage Protection Act 1984 (Cth)	This Act provides a framework to protect areas and objects of cultural significance to Aboriginal and Torres Strait Islander peoples. It supports preservation of cultural heritage by ensuring significant sites or objects are safeguarded during activities in Commonwealth waters.	While no culturally significant areas of objects have been identified within the OA, this Act ensures appropriate measures are in place should culturally significant Aboriginal or Torres Strait Islander heritage (such as objects or remains) be discovered during decommissioning activities.	N/A	DCCEEW

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
Australian Radiation Protection and Nuclear Safety Act 1998 (Cth)	This Act establishes the framework for radiation protection and nuclear safety across Australia. It governs the management, handling, storage, and use of radioactive materials, including radioactive waste, ensuring compliance with safety standards to protect the health of workers, the public and public and the environment.	The Act ensures that any naturally occurring radioactive materials present on offshore facilities are identified and managed to minimise potential environmental impacts. This includes compliance with radiation safety standards to prevent contamination of the marine environment.	Joint Convention on the Safety of Spent Fuel Management and on the Safety of Radioactive Waste Management.	DCCEEW
Industrial Chemicals Environmental Management (Register) Act 2021 (Cth)	Effective from 1 July 2025, the Australian Government has listed PFOS, perfluorooctanoic acid (PFOA), perfluorohexane sulfonate (PFHxS) and related substances on the Industrial Chemicals Environmental Management Register (Schedule 7) and has set standards in relation to prohibiting their import, export, manufacture, use and disposal. These chemicals are typically found in fire-fighting foams.	None of the Campaign #1 facilities will contain PFOS, PFOA, PFHxS and related substances at the time of removal. All Campaign #1 vessels will comply with the relevant obligations under the Industrial Chemicals Environmental Management Standard. While the generation of prohibited substances is not anticipated, any unplanned occurrence will be managed in accordance with the contractor waste management plans.	Industrial Chemicals Environmental (Register) Instrument 22.	DCCEEW
Recycling and Waste Reduction Act 2020 (Cth)	This Act supports action to regulate the export of certain waste materials from Australia. In particular, the Recycling and Waste Reduction (Mandatory Product Stewardship – Mercury-added Products) Rules 2021 made under the Act give effect to	For this activity, the Act applies to trace quantities of mercury that may be contained within grout.	Minamata Convention on Mercury	DCCEEW

Legislation	Description	Relevance to activity	International Convention enacted	Administering authority
	Australia's obligations under Article 4(5) of the Minamata Convention.			

Table 1-4 Key Victorian legislation

Legislation	Description	Relevance to activity	Administering authority
Environment Protection Act 2017 (Vic) and Environment Protection Regulations 2021 (Vic)	This Act is the key Victorian legislation regulating emissions to the environment within Victoria (relevant for waste transfer and disposal, National Pollutant Inventory reporting). The Regulations support the objectives of the legislation: to prevent or minimise risks of harm to human health or the environment from pollution or waste. The objectives of the Regulations are to further the purposes of, and give effect to, the Act.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act and Regulations may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Victorian Environment Protection Authority
Environment Effects Act 1987 (Vic)	This Act is the Victorian legislation that provides a framework for the environment impact assessment of projects that may have a significant event on the environment.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Victorian Department of Transport and Planning
Pollution of Waters by Oil and Noxious Substances Act 1986 (Vic)	This Act is the Victorian State legislation giving effect to the requirements of MARPOL within State waters.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Victorian Environment Protection Authority

Legislation	Description	Relevance to activity	Administering authority
Emergency Management Act 1986 and 2013 (Vic)	This Act ensures that the components of emergency management (prevention, response and recovery) are organised to facilitate planning, preparedness, operational coordination and community participation.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Department of Justice and Community Safety Police and Emergency Management Victoria
Port Management Act 1995 (Vic)	The Act sets out the establishment, management and operation of commercial trading and local ports in Victoria and the economic regulation of certain port services. The Act also sets out the functions of harbour masters. Under this Act all managers of local and commercial ports must prepare a Safety Management Plan and an Environmental Management Plan (EMP). Gippsland Ports is appointed under the Port Management (Local Ports) Regulations 2015 (Vic) to regulate ports and waterways in Gippsland, including application of the *Marine Safety Act 2010* (Vic) and other relevant legislation for port activities.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Ports Victoria
Marine Safety Act 2010 (Vic)	This Act provides for safe marine operations in Victoria.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Safe Transport Victoria

Legislation	Description	Relevance to activity	Administering authority
Heritage Act 2017 (Vic)	This Act is the Victorian State legislation which protects the heritage values of shipwrecks and relics within State waters.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Heritage Victoria.
National Parks Act 1975 (Vic)	This Act provides for the protection, use and management of Victoria's national and other parks.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Department of Energy, Environment and Climate Action (DEECA)
Radiation Act 2005 (Vic)	This Act provides for licencing for use and management of radioactive sources and conducting radiation practice (including radiation testing).	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Victorian Department of Health
Catchment and Land Protection Act 1994 (Vic)	This Act sets up a framework for the integrated management and protection of catchments.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	DEECA
Marine and Coastal Act 2018 (Vic)	This Act provides for co-ordinated strategic planning and management for Victorian coast, the preparation and implementation of management plans for coastal Crown land and a co-ordinated	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event	DEECA

Legislation	Description	Relevance to activity	Administering authority
	approach to approvals for use and development of coastal Crown land.	of a large hydrocarbon release where the EMBA intersects Victorian State waters.	
Land Titles Validation Act 1994 (Vic)	This Act validates past acts, provides for compensation rights for the holders of native title which has been affected by past acts, and confirms certain existing rights. The Act also confirms ownership by the Crown of natural resources, the right to regulate water flows and existing fishing rights under State law; and public access to waterways, beds and banks of waterways, coastal waters, beaches and public areas.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	Department of Transport and Planning
Dangerous Goods Act 1985 (Vic) and Dangerous Goods (Storage and Handling) Regulations 2012 (Vic)	This Act, Regulations and the *Code of practice for the storage and handling of dangerous goods* (WorkSafe Victoria, 2013) promotes the safety of persons and property in relation to the manufacture, storage, transfer, transport, sale, purchase and use of dangerous goods and the import of explosives and other dangerous goods.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act and Regulations may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	WorkSafe Victoria
Flora and Fauna Guarantee Act 1988 (Vic) And Flora and Fauna Guarantee Regulations 2020 (Vic)	This Act and Regulations cover the conservation and management of Victoria's native flora and fauna and provides a framework for the protection of threatened species and ecological communities, listing at-risk species, developing action statements and designating critical habitats.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act and Regulations may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	DEECA
Wildlife Act 1975 (Vic) and Wildlife (Marine Mammal) Regulations 2024 (Vic)	This Act and Regulations aim to promote the protection and conservation of wildlife, prevent wildlife from becoming extinct and regulate activities related to wildlife. The Wildlife (Marine Mammal) Regulations 2024 (Vic) prescribe	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act and Regulations may be relevant under certain circumstances, such as in the event of a large hydrocarbon	DEECA

Legislation	Description	Relevance to activity	Administering authority
	minimum distances to whales and seals/seal colonies, restrictions on feeding/touching and restriction of noise within a caution zone of a marine mammal (dolphins (150m), whales (300m) and seals (50m).	release where the EMBA intersects Victorian State waters.	
Offshore Petroleum and Greenhouse Gas Storage Act 2010 (Vic) and Offshore Petroleum and Greenhouse Gas Storage Regulations 2021 (Vic)	This Act and Regulations apply to petroleum operations effectively within 3nm of the Victorian coast and address licensing, health, safety, environmental and royalty issues for offshore petroleum exploration and development operations. Waters greater than 3nm offshore from the coast are Commonwealth waters and are covered by Commonwealth legislation (i.e. OPGGS Act). The Commonwealth and Victorian legislation are, by agreement, very similar with regard to petroleum.	While no part of the activity within the scope of this EP is located within Victorian State waters, the Act and Regulations may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Victorian State waters.	DEECA

Table 1-5 Key New South Wales legislation

Legislation	Description	Relevance to activity	Administering authority
Protection of the Environment Operations Act 1997 (NSW)	This is the main piece of New South Wales environmental legislation covering water, land, air and noise pollution and waste management.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects New South Wales State waters.	New South Wales Environment Protection Authority
Marine Pollution Act 2012 (NSW)	This Act is the New South Wales State legislation giving effect to the requirements of MARPOL within State waters.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under certain circumstances, such as in the event of	Transport for New South Wales

Legislation	Description	Relevance to activity	Administering authority
		a large hydrocarbon release where the EMBA intersects New South Wales State waters.	
Ports and Maritime Administration Act 1995 No.13 (NSW)	This Act provides for the provision of marine safety services and emergency environment protection services for dealing with pollution incidents in State waters.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects New South Wales State waters.	Transport for New South Wales
Heritage Act 1977 No.136 (NSW)	This Act provides for the identification, registration and interim protection of items of State heritage significance (including shipwrecks within State waters) in New South Wales.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects New South Wales State waters.	Heritage Council of New South Wales
National Parks and Wildlife Act 1974 No.80 (NSW)	This Act provides for the care, control and management of all national parks, historic sites, nature reserves, conservation reserves, Aboriginal areas and game reserves, and the protection and care of native flora and fauna, and Aboriginal places and objects.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects New South Wales State waters.	New South Wales Office of Environment and Heritage.
Wilderness Act 1987 No.196 (NSW)	This Act affords declared wilderness the most secure level of protection, requiring it to be managed in a way that will maintain its wilderness values and pristine condition by limiting activities likely to damage flora, fauna and cultural heritage.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects New South Wales State waters.	New South Wales Department of Planning and Environment.
Marine Parks Act 1997 No.64 (NSW)	This Act provides for the protection and management of marine areas.	While no part of the activity within the scope of this EP is located within New South Wales State waters, the Act may be relevant under	New South Wales Marine Parks Authority.

Legislation	Description	Relevance to activity	Administering authority
		certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects New South Wales State waters.	

Table 1-6 Key Tasmanian legislation

Legislation	Coverage	Relevance to activity	Administering authority
Environmental Management and Pollution Control Act 1994 (Tas)	This is the primary environment protection and pollution control legislation in Tasmania.	While no part of the activity within the scope of this EP is located within Tasmanian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Tasmanian State waters.	Environment Protection Authority Tasmania
Pollution of Waters by Oil and Noxious Substances Act 1987 (Tas)	This Act is the Tasmanian State legislation giving effect to the requirements of MARPOL within State waters.	While no part of the activity within the scope of this EP is located within Tasmanian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Tasmanian State waters.	Environment Protection Authority Tasmania
Emergency Management Act 2006 (Tas)	This Act establishes the Tasmanian emergency management framework which operates at state, regional and municipal levels.	While no part of the activity within the scope of this EP is located within Tasmanian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Tasmanian State waters.	Department of Police, Fire and Emergency Management
Marine and Safety Authority Act 1997 (Tas)	This Act establishes Marine and Safety Tasmania as the authority responsible for the safe operation of vessels in Tasmanian State waters and managing its marine facilities.	While no part of the activity within the scope of this EP is located within Tasmanian State waters, the Act may be relevant under certain circumstances, such as in the event of a large	Marine and Safety Tasmania

Legislation	Coverage	Relevance to activity	Administering authority
		hydrocarbon release where the EMBA intersects Tasmanian State waters.	
Historic Cultural Heritage Act 1995 (Tas)	This Act provides for the identification, assessment, protection and conservation of places having historic cultural heritage significance (including shipwrecks within State waters) in Tasmania.	While no part of the activity within the scope of this EP is located within Tasmanian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Tasmanian State waters.	Tasmanian Heritage Council and Historic Heritage Section of Parks and Wildlife Service Tasmania (shipwrecks).
National Parks and Reserves Management Act 2002 (Tas)	This Act provides for the management of national parks and other reserved land.	While no part of the activity within the scope of this EP is located within Tasmanian State waters, the Act may be relevant under certain circumstances, such as in the event of a large hydrocarbon release where the EMBA intersects Tasmanian State waters.	Parks and Wildlife Service Tasmania

1.6.2 Decommissioning guidance documents

1.6.2.1 Offshore petroleum decommissioning guideline

The *Guideline: Offshore petroleum decommissioning* (DISER, 2022) sets out the Australian Decommissioning Regulatory Framework, with the aim of assisting titleholders with planning and approval for decommissioning activities and understanding the expectations of the relevant decision makers.

1.6.2.2 Removal of oil and gas property and sea dumping of infrastructure in Commonwealth waters: draft guidance

Australian Government guidance for removal of oil and gas property and sea dumping of infrastructure in Commonwealth waters (DISR, 2024) outlines the types of property and infrastructure to be removed and consideration of those that may be permitted to remain in limited circumstances. It addresses considerations for titleholders and operators, clarifies how Australia's offshore decommissioning and sea dumping frameworks connect.

1.6.2.3 NOPSEMA decommissioning policy and guidance

NOPSEMA has issued specific guidance to assist industry in meeting OPGGS Act obligations in relation to decommissioning. The following policies and guidance have informed this EP:

- *Section 572 Maintenance and Removal of Property* (NOPSEMA, 2025b)
- *Decommissioning Compliance Strategy [2024 to 2029]* (NOPSEMA, 2023)
- *NOPSEMA decommissioning compliance plan* (NOPSEMA, 2021a)
- *Complying with your decommissioning obligations* (NOPSEMA, 2021b)
- *Planning for proactive decommissioning* (NOPSEMA, 2025a)
- *Section 270 Consent to surrender title* (NOPSEMA, 2025c)
- *Consultation in the course of preparing an environment plan* (NOPSEMA, 2024b)
- *Environment Plan Content Requirement* guidance note (NOPSEMA, 2025d)
- *Notification, Reporting and Recording Requirements for Incidents* guidance note (NOPSEMA, 2025e).

1.6.2.4 Industry guidance

NOPSEMA's *Environment Plan Content Requirement* guidance note (NOPSEMA, 2025d) highlights instances of industry guidance that an operator should be aware of including but not limited to:

- ISO 14031:2000 *Environmental management – Environmental Performance Evaluation – Guidelines*
- ISO 14001:2015 *Environmental management systems - Requirements with guidance for use*
- guidance published by the International Petroleum Industry Environmental Conservation Association (IPIECA) for oil spill risks.

1.6.3 General Direction 817

General Direction 817 made under Section 574 of the OPGGS Act, was issued to Esso and BHP (now Woodside Energy (Bass Strait) Pty Ltd) on 20 May 2021. A detailed implementation plan was subsequently submitted to NOPSEMA in August 2021, outlining Esso's approach to ensuring compliance with this General Direction, which relates to decommissioning. Regular meetings are held between Esso and NOPSEMA to measure progress against this implementation plan.

An Annual Decommissioning Report detailing progress with implementing the requirements of General Direction 817 is also submitted to NOPSEMA in December each year and published on the Esso website. This report should be referred to for current details on progress against General Direction 817 requirements.

The requirements of General Direction 817 and how they relate to this EP have been summarised in Table 1-7.

Table 1-7 General Direction 817 requirements

Direction	Action required	Relevance to this EP
1a, b and c	Commission, and submit to NOPSEMA, an independent review of the engineering and project management approach to decommissioning activities	N/A – review completed and submitted to NOPSEMA on 16 November 2021 and was accepted

Direction	Action required	Relevance to this EP
	to identify opportunities and propose measures to reduce the timeframe for commencing and completing all decommissioning activities. Implement reasonable and practicable measures based on this review.	by NOPSEMA on 8 December 2021.
2a	Complete all preparatory decommissioning activities and commence the topside dismantling campaign as soon as reasonably practicable, and no later than 30 September 2027, for removal of all structures, property and equipment no longer in use associated with facilities listed in Schedule 3[2] of the Direction.	Activities to prepare for removal (using a CSV) and to commence the topside dismantling of the facilities listed in Schedule 3 of the Direction are included within the scope of this EP (noting not all preparatory decommissioning activities for the activities contemplated under this EP are within the scope of this EP).
2b	To plug or close, to the satisfaction of NOPSEMA, all wells associated with the titles listed in Schedule 3, as soon as reasonably practicable and no later than 30 September 2027.	N/A. Well P&A activities utilising platform-based rigs is addressed in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). Well P&A activity utilising Jack-Up Rigs or MODUs are subject to activity specific EP submissions.
3a and b	Conduct, and submit to NOPSEMA, an integrity assessment of the PCA and DPA facilities to demonstrate that their full removal will not be precluded.	N/A Integrity assessment was submitted to NOPSEMA on 16 August 2021 and was accepted on 28 September 2021.
3c and d	Conduct, and submit to NOPSEMA, integrity assessments of all equipment structures and property that are in a non-producing state, to demonstrate that full removal of structures, property and equipment will not be precluded.	N/A Integrity assessments were submitted to NOPSEMA on 31 January 2022 and were accepted by NOPSEMA on 10 March 2022.
4	Undertake IMR activities on all property and wells associated with facilities listed in Schedule 3 of the Direction to ensure: • property continues to perform its intended function • approved decommissioning end states are not precluded	N/A IMR activities for facilities listed in Schedule 3 are described in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).

[2] The facilities listed in Schedule 3 of General Direction 817 are WTA, MKA, FTA, KFA, KFB, FLA, BMA, BMB, DPA and PCA.

Direction	Action required	Relevance to this EP
	occupational health and safety, structural integrity and environmental risks continue to be reduced to ALARP.	IMR continues on property as needed so as not to preclude full removal.
5	Submit a decommissioning progress report to NOPSEMA on an annual basis no later than 31 December each year outlining progress with implementing General Direction 817 requirements. Report to be published on the Esso website.	N/A As per the obligation under General Direction 817, Esso submits and gains acceptance from NOPSEMA of an Annual Decommissioning Report and publishes these on the Esso website each year.

1.6.4 Federal Court decisions

On 21 September 2022, the Federal Court of Australia (FCA) ruled in FCA 1121 (Tipakalippa v National Offshore Petroleum Safety and Environmental Management Authority (No 2), 2022) to set aside NOPSEMAs decision to accept an EP (the Santos Barossa Development Drilling and Completions EP) on the basis NOPSEMA could not be reasonably satisfied that the EP met the criteria specified in the Environment Regulations. This ruling specifically related to the undertaking of relevant person consultation, as required by Regulation 25 of the Environment Regulations. A subsequent appeal to this decision, FCAFC 193 (Santos NA Barossa Pty Ltd v Tipakalippa, 2022), was dismissed by the FCA on the 2 December 2022. From this date, the appeal decision represents the law regarding requirements for consultation in accordance with the Environment Regulations. Following the FCA decisions, NOPSEMA has developed *Consultation in the course of preparing an environment plan* (NOPSEMA, 2024b) as a guideline for industry. This guideline and the appeal decision have informed the preparation of this EP.

On 28 September 2023, the FCA ruled in FCA 1158 (Cooper v National Offshore Petroleum Safety and Environmental Management Authority (No 2), 2023) to set aside NOPSEMAs decision to accept an EP (subject to conditions) on the basis NOPSEMA did not have statutory power to make the decision to accept the EP subject to conditions in circumstances where it was not reasonably satisfied that the consultation required by Regulation 11A(g) of the Environment Regulations had been carried out. NOPSEMA published an announcement on its website acknowledging the decision of the FCA and advising that they are reviewing the reasons for the decision to ensure future regulatory actions are in accordance with the decision.

1.6.5 Native Title

The landmark judgements in High Court of Australia (HCA) 23 (Mabo v Queensland (No 2) 175 CLR 1, 1992) was the first time Indigenous people's assertions of inherited rights to land were recognised by Australian law. The judgements of the HCA overturned the legal fiction of terra nullius (land belonging to no one), and acknowledged that Indigenous people had, and still have, laws and cultural practices, relating to land ownership, management and resource use that survived the process of British colonisation. This recognition of Indigenous 'Native Title' was then formally embraced in statutory law through the *Native Title Act 1993* (Cth).

On 22 October 2010, the FCA recognised that the Gunaikurnai people hold native title over much of Gippsland.

On the same day, the State entered into an agreement with the Gunaikurnai people under the *Traditional Owner Settlement Act 2010* (Vic). The agreement between the State and the Gunaikurnai people was the first to be made under the *Traditional Owner Settlement Act 2010* (Vic).

The agreement area extends from West Gippsland, near Warragul, east to the Snowy River and north to the Great Dividing Range. It also extends 200m offshore. The determination of native title under the *Native Title Act 1993* (Cth) covers the same area. Both the agreement and the native title determination only affect Crown land within this area.

As part of the agreement, the Gunaikurnai people will be able to undertake traditional activities such as hunting, fishing and gathering for traditional, non-commercial, domestic or communal purposes. This will involve recreational fishing and game hunting without a licence, as long as the Gunaikurnai people comply with relevant laws and regulations (including any catch limits).

Native Title also provides the Gunaikurnai people with the right to negotiate with anyone seeking to carry out activities that might affect their rights. These rights do not impact access for existing users of the area, such as recreational fishers and hunters. The agreement does not provide the Gunaikurnai people with any commercial hunting, fishing or forestry rights.

However, in HCA 33 (Leo Akiba on behalf of the Torres Strait Regional Seas Claim Group v Commonwealth of Australia, 2013), the HCA said that the Native Title claim group had the right 'to take for any purpose resources in the native title areas'. This meant that the Native Title holders could continue to sell and trade fish as they had done under their traditional laws. It was the first time that native title rights were found to include commercial rights.

As a prescribed body corporate under the Native Title (Prescribed Body Corporate) Regulations 1999 (Cth), the Gunaikurnai Land and Waters Aboriginal Corporation (GLaWAC) is empowered to make native title decisions and negotiate agreements on behalf of the Gunaikurnai Native Title holders. GLaWAC must undertake a process of consultation and consent with Native Title holders as part of that agreement-making process.

The Gunaikurnai people lodged a Native Title determination application in the FCA on 9 December 2014 under the *Native Title Act 1993* (Cth). The application included the land and waters west of the Gunaikurnai determination area to the Tarwin West River, including Wilsons Promontory and Cape Liptrap. The Gunaikurnai name for this area, Yiruk, means rocky place. In September 2019, the Gunaikurnai withdrew the claim.

Esso acknowledges that, despite the claim withdrawal, the Gunaikurnai people hold strong connections to Yiruk with a long history of association with and caring for country, and they will continue to assert their rights and interests over this area.

As part of the Gunaikurnai people's native title, the following national parks and reserves are classified as Aboriginal title and subject to joint management between the State and the Gunaikurnai Traditional Owner Land Management Board:

- The Knob Reserve, Stratford
- Tarra Bulga National Park
- Mitchell River National Parks
- Lakes National Park
- Gippsland Lakes Coastal Park
- New Guinea Cave (within Snowy River National Park)
- Lake Tyers Catchment Area
- Buchan Caves Reserve
- Gippsland Lakes Reserve at Raymond Island
- Corringle Foreshore Reserve
- Nooramunga Marine and Coastal Park
- Avon Wilderness Park
- Baw Baw National Park
- Alpine National Park (on Gunaikurnai Country).

1.6.6 Sea Country

In April 2021, the Sea Country Indigenous Protected Areas (IPAs) Program was established by the Australian Government to strengthen the conservation and protection of Australia's unique marine and coastal environments, while creating employment and economic opportunities for Indigenous Australians. Under the program, grant funding will be provided to Indigenous organisations to expand existing IPAs and create new IPAs. The Government will also support delivery of the program, including the development of a Sea Country IPAs monitoring and evaluation system and the holding of a conference of Indigenous land and sea managers so they can share knowledge and experiences.

On 7 May 2022, 10 successful Sea Country IPAs consultation projects were announced, including the Nanjet to Mallacoota Sea Country IPAs managed by GLaWAC.

The Nanjet to Mallacoota Sea Country IPAs is in the coastal areas (land and sea) of the Gippsland region in Victoria from Nanjet, east of Wilsons Promontory to Mallacoota, on the Victoria/New South Wales border. The area comprises numerous marine and coastal parks and includes the Ramsar-listed Gippsland Lakes and Raymond Island.

A Nanjet to Mallacoota Sea Country IPAs Management Plan is being developed to support First Nations people to identify cultural and natural values, including the condition and any threats to these values, and plan for the conservation and management of these values.

GLaWAC is partnering with Monash University and the Arthur Rylah Institute to undertake specific research into culturally significant areas and species that occur along the coast.

While the plan is being developed, Esso has anticipated the values and sensitivities regarding Sea Country to potentially include:

- geographical features
- places with cultural and/or spiritual significance
- flora and fauna species that have a cultural and/or spiritual significance
- cultural harvesting and use of flora and fauna.

Esso has expressed an interest to participate in the Nanjet to Mallacoota Sea Country IPAs consultation project and understands that once the First Nations peoples' consultation phase has completed, commercial participants will be approached.

1.6.7 Underwater Cultural Heritage

Guidance has been issued by DCCEEW (DCCEEW, 2024f) in relation to the application of the *Underwater Cultural Heritage Act 2018 (Cmth) (the UCH Guidance)*. The *Underwater Cultural Heritage Act 2018 (Cmth)* provides blanket protection to all archaeological remains of vessels and aircraft (including Aboriginal and Torres Strait Islander traditional watercraft) that have been wholly or partially submerged in Australian waters for 75 years or longer, including their immediate environment and associated articles, regardless of whether or not their existence or precise location is known. Other types of underwater cultural heritage (UCH), including First Nations (Aboriginal and Torres Strait Islander) archaeological UCH associated with dry-land habitation on the submerged Pleistocene landscapes on the Australian continental shelf and archaeological remains of shipwrecks or aircraft younger than 75 years, can be declared by the Minister as protected under the *Underwater Cultural Heritage Act 2018 (Cmth)* upon discovery, and subject to significance assessment (DCCEEW, 2024f). First Nations UCH constitutes archaeological and/or environmental traces of human existence (habitation and/or activities), which can be discovered on the seabed surface (on exposed ancient land surfaces), or within stratified sediment deposits (accumulated on subsequently buried ancient land surfaces) within the submerged paleolandscape of the present-day Australian continental shelf (DCCEEW, 2024f).

The UCH Guidance states that all actions involving seabed contact, and most actions taken in proximity to the seabed, have the potential to cause adverse impact to UCH. Hence the following obligations of the UCH Act have been addressed in this EP:

- No adverse impact to UCH without a permit – refer to Section 6.1.3.7 and 7.5.3.3.
- Notify the discovery of all suspected UCH within 21 days of discovery – refer to Table 8-7
- Adhere to requirements of Protected Zones and obtain a permit to enter a Protected Zone should entry into a Protected Zone be required – there are no Protected Zones in the OA for this EP (refer to Section 3.3). There are three Protected Zones (submerged shipwrecks) within the EMBA (refer to Section A.1.5.2 of Appendix A).

1.7 Environment Plan Summary

This EP has been structured in accordance with the Environment Regulations, Regulations 35(6) and 35(7) as outlined in Table 1-8.

Table 1-8 Environment Plan summary

Summary Requirement	Section of EP
The location of the activity	Section 2.2
A description of the receiving environment	Section 3 and Appendix A

Summary Requirement	Section of EP
A description of the activity	Section 2
Description of the environmental impacts and risks	Sections 6 and 7
The control measures for the activity	Sections 6,7 and Appendix K
The arrangement for ongoing monitoring of the titleholder's environmental performance	Section 8.11
Response arrangements in the Oil Pollution Emergency Plan (OPEP)	Attachment 2
Consultation already undertaken and plans for ongoing consultation	Section 4
Details on the titleholder's nominated liaison person for the activity	Section 1.5

2 Description of the activity

2.1 Activity summary

The activities described in this EP are part of the broader Bass Strait decommissioning program, the priority of which is to progressively eliminate or reduce impacts and risks from the highest hazard aspects of non-producing assets, being well P&A (managed via a separate, accepted Well Operations Management Plan) and removal of platform topsides and jackets on non-producing platforms (this Campaign #1 EP). This Section specifically describes the petroleum activity to be performed as part of Campaign #1 and assessed for acceptance under the Environment Regulations. Activities included in the scope of this EP are summarised below, however, as detailed engineering is being performed at the time of writing this EP, specific methods of removal, final cut depths and details around how the structures will be removed is yet to be finalised and is subject to change. Fundamental plans such as mobilising of the *Pioneering Spirit* vessel to complete the majority of the removal scope for example will not change and forms the basis for this EP. Ensuring adequate flexibility during detailed planning and execution is a critical element required for safe and efficient execution of major projects such as the Campaign #1. Proposed changes to activities, assets, equipment, processes or procedures that have the potential to impact on the environment or interface with an environmental receptor will be assessed via the management of change (MOC) process outlined in Section 8.13 (OIMS System 7: Managing Changes) or Section 8.5 (OIMS System 3: Project Management and Execution. If the process identifies a significant new impact or risk, or a significant increase in an existing environmental impact or risk, then a revision of the EP (including additional relevant person consultation as required) will be required.

Activities included within the scope of this EP are:

- removal preparation at the Campaign #1 facilities
- the removal of the PCA and DPA monotowers and gravity base foundations to seabed
- the removal of WTA and BMA topsides and SPJs, as close as practicable to seabed to a maximum of 3m above seabed with deep foundation piles to remain
- the removal of topsides and upper jacket sections at MKA, WKF, FLA, CBA, KFA and KFB, to a depth of at least 55m below MSL:
    - at KFA and KFB, removal of struts will extend to the lower junction connection at the seabed template at least 55m below MSL.
- the FTA facility has two options for removal:
    - FTA Option 1: Removal as close as practicable to seabed to a maximum of 3m above seabed, with deep foundation piles to remain
    - FTA Option 2: Removal to a depth of at least 55m below MSL.
- the removal of the BMB topsides and module support frame only. The BMB concrete substructure will remain in place and a navigation aid will be installed on the substructure
- the option to remove HLA topsides, upper jacket section to a minimum of 55m below MSL and strut to the lower junction connection at the seabed template at least 55m below MSL. The option to remove HLA is contingent on a number of operational and logistics conditions including continued use as an alternate flow path for gas supply to Longford Plant which will need to be met within the required Campaign #1 timeframes. If the option is not exercised in Campaign #1, HLA will continue to be in use and decommissioned as part of Campaign #2
- the option to remove well conductors should this not be achieved during P&A prior to Campaign #1
- post removal as left survey
- topsides and jacket transport, backloading to barges or HTVs, sea fastening and initial transport of structures to the border of Victorian State waters.
- ongoing IMR of the infrastructure relating to the facilities partially removed in Campaign #1, until such time as the Bass Strait Non-Producing Environment Plan is accepted.

Allseas have been awarded the provision of engineering, preparation and removal services for the Gippsland Decommissioning Campaign #1 project. To complete Campaign #1 activities, a HLV and CSVs will be utilised. Other vessels may include barges, tugs, HTVs, platform supply vessels (PSVs) and support and survey vessels. See Section 2.6.1 for vessel details and Section 2.3 for timing of activities.

2.2 Location

Esso's operations are located in Bass Strait, off Victoria's Gippsland coast in Australia, as shown in Figure 2-1. The area lies entirely within the South-east Marine Region.

The facilities to be removed as part of Campaign #1 activities are located in water depths ranging from 38m (DPA) to 93m (MKA and FLA) and their distance from the coast ranges from 21km (DPA) to 77km (KFB). Refer to Table 2-1. The removal of facilities within the scope of the Campaign #1 activities will take place in Production Licences VIC/L02, VIC/L05, VIC/L07, VIC/L11, VIC/L13, VIC/L14, VIC/L15 and VIC/L17, as shown in Figure 2-1. Relevant pipelines licences upon which activities will take place (i.e. plugging and capping once sections have been removed) are listed in Section 1.5.

2.2.1 Operational Area

The OA, as shown in Figure 2-2, is the area within which all activities described within this EP will occur. The OA encompasses Commonwealth waters both on title and off title, and includes:

- a removal activity area around each facility to be removed (13 in total). The removal activity areas incorporate the existing 500m Petroleum Safety Zone (PSZ) around the facility and an additional 500m vessel exclusion zone radius to allow for safety (creating a 1000m radius). The additional area needed reflects the overall size of the *Pioneering Spirit* HLV. The additional exclusion zone will be communicated as needed through Notices to Mariners
- within the removal activity areas, any Campaign #1 vessel may operate but the predominant vessels will be the HLV, CSVs and possibly a PSV, and any vessel required to execute IMR activities of partially removed facilities following the completion of Campaign #1
- the OA includes the transport/transit route that the HLV and other vessels will operate in when transiting between facilities and transporting the removed topsides and sections of jackets from the removal activity areas to a suitable location for transfer onto a HTV or barge
- the transfer activity will occur within the OA and is considered part of the petroleum activities included in this EP:
    - the location of transfers will vary within the OA based on the HLV operator's assessment of weather and sea state and other operational and safety factors as described in Section 2.8.2
    - once the transfer is complete, the HTV or barge will travel to the Barry Beach Marine Terminal where the topsides and jackets will be unloaded for onshore dismantling and offsite recycling.
- for transfer activities, a 500m vessel exclusion zone is required for the *Pioneering Spirit* HLV to ensure safety. Works exclusion zones will be communicated as needed through Notices to Mariners. The 500m vessel exclusion zone is not needed whilst vessels are transiting, point to point, through the OA with the exception of the transit of the barge or HTV from the *Pioneering Spirit* or CSV towards Barry Beach with a load onboard.

All activities involving the transit of the HTV or barge once outside the boundary of the OA and subsequent onshore processing activity are outside the scope of this EP. The activities at Barry Beach Marine Terminal and State waters will be managed under relevant Commonwealth and State legislation and contractor environmental and safety management processes and plans.

The OA as shaded in Figure 2-2 excludes all Victorian State waters including those waters surrounding island groups.

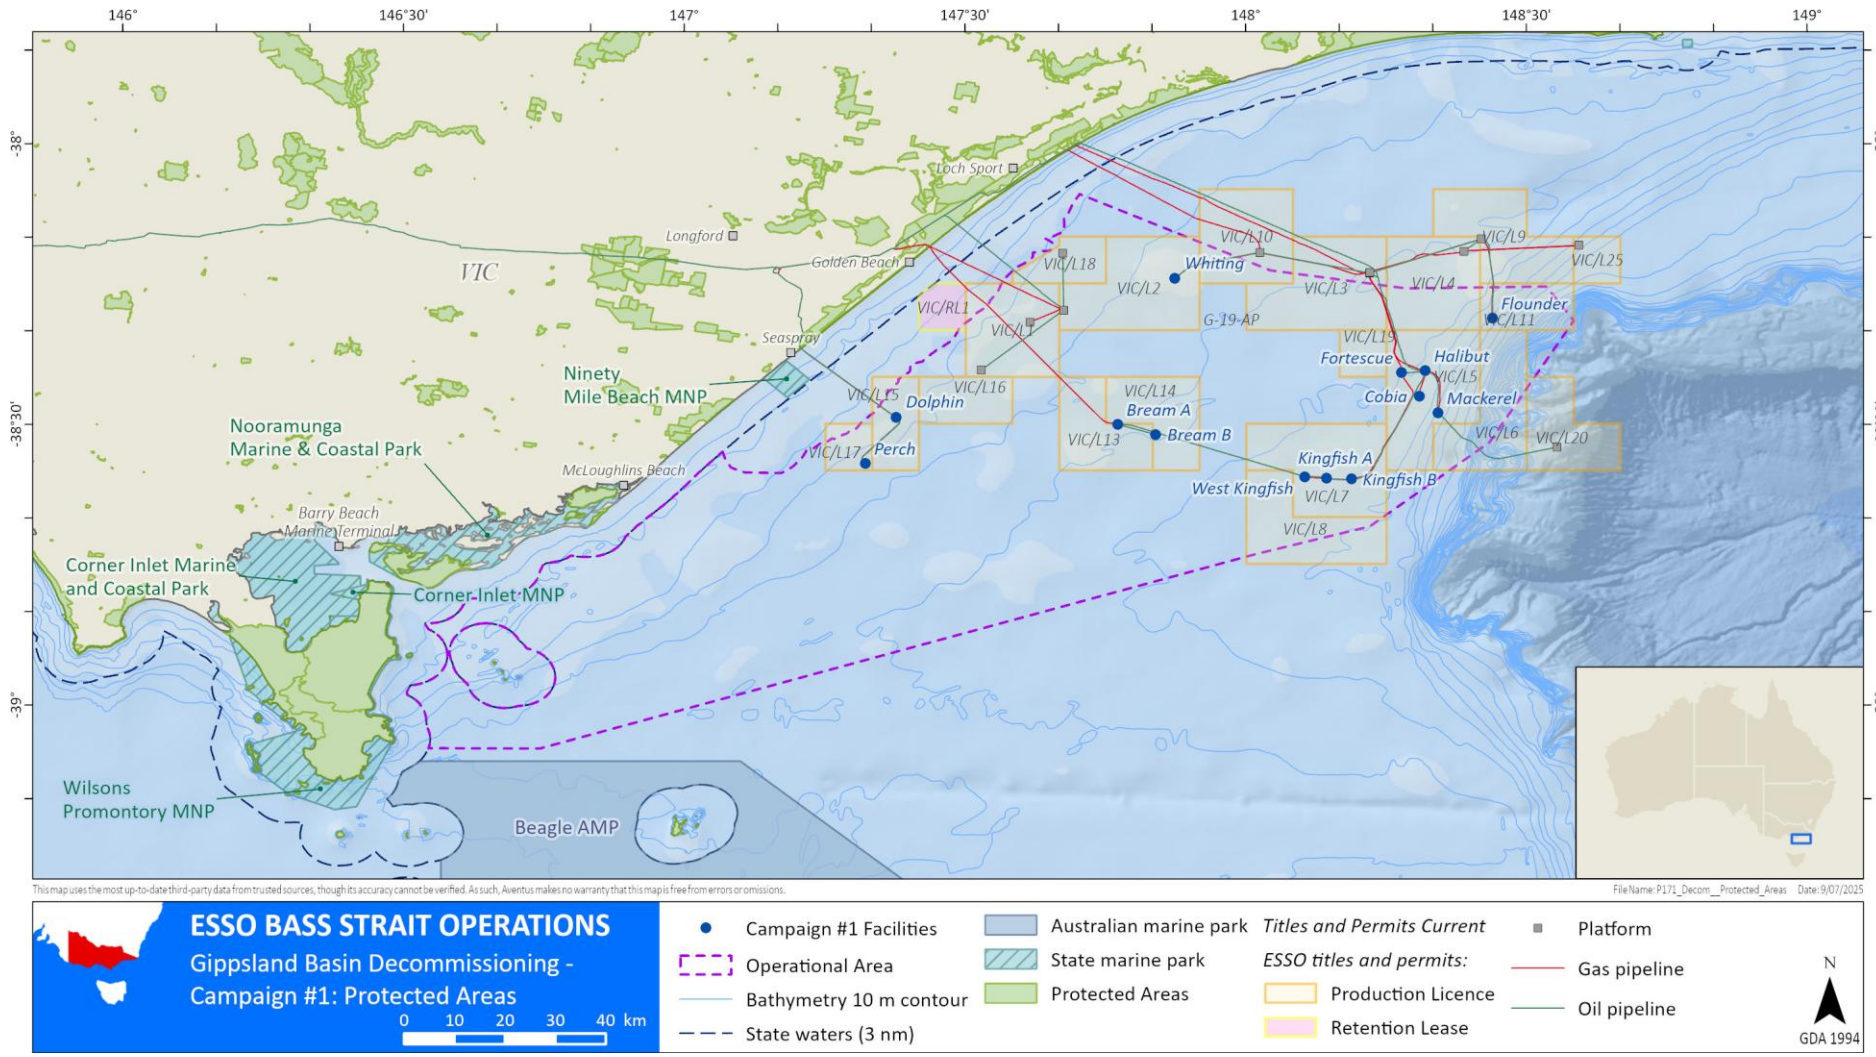

Figure 2-1 Activity location

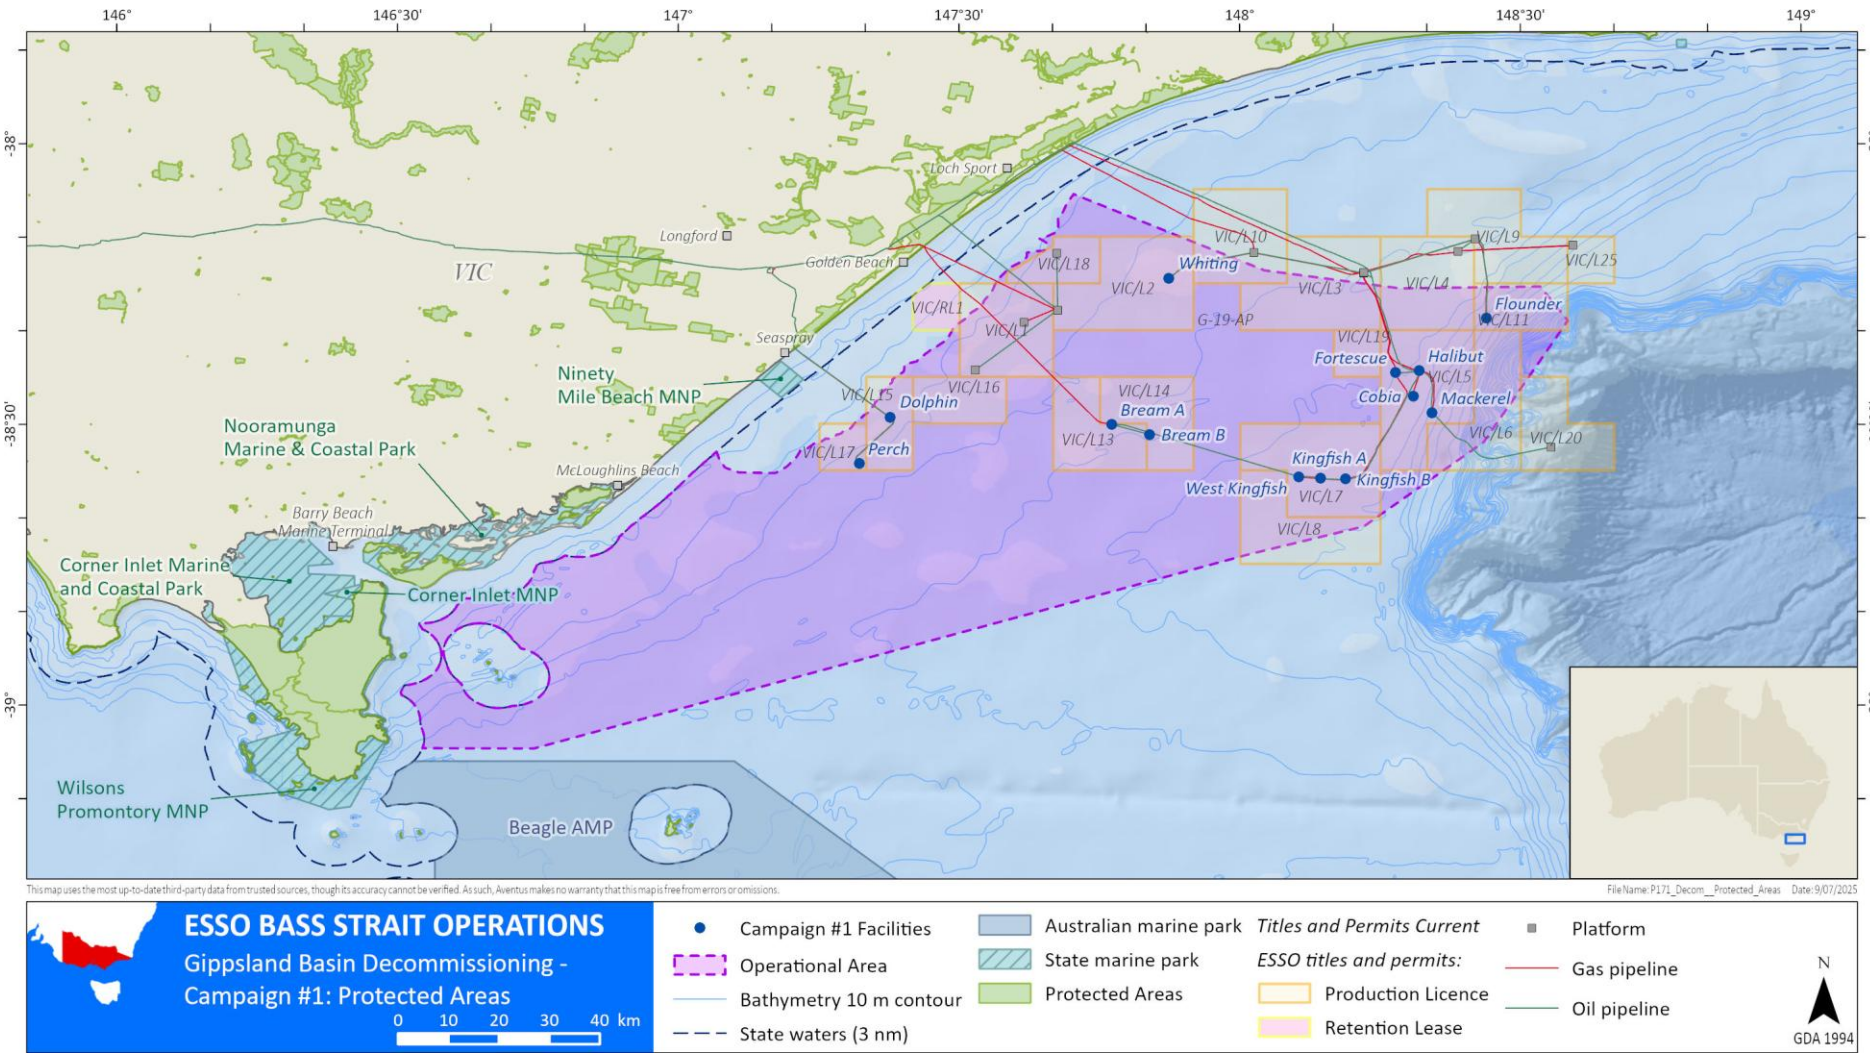

Figure 2-2 Campaign #1 OA

2.3 Timing of the activities

The activities under this EP are expected to commence in the third quarter 2026 and conclude by the first quarter 2028 following the completion of the as left survey. There will be a number of mobilisations required to complete Campaign #1:

- removal preparations are planned to commence in the third quarter 2026 with the mobilisation of a primary CSV (the *Fortitude* or similar vessel) and other support vessels as required
- removal preparation vessels will demobilise around the end of first quarter 2027 and re-mobilise second or third quarter 2027 to continue the removal preparations
- facilities removal is planned to commence third quarter 2027 and will utilise all vessels per Section 2.6.1
- all vessels are expected to demobilise by the end of the first quarter 2028.

These timings are indicative only. Mobilisation and demobilisation dates are dependent on alignment with the overarching Bass Strait decommissioning program.

This EP may span up to five years as the commencement and duration of activities under this EP may differ in execution to that outlined due to factors such as key vessel scheduling commitments and other required approvals.

Additionally, logistical challenges (such as weather or discovery of unexpected jacket conditions that may arise in the field) may prevent the entirety of the scope as listed in Section 2.1 from being completed within the Campaign #1 timeframe, which is based on the availability of the HLV and a suitable weather season to allow removals to be undertaken safely and efficiently. If any logistical challenges indicate that some scope items may not be achievable by the HLV within the availability timeframe, priority will be given to the topside removals consistent with the objective of eliminating or reducing the highest impacts and risks arising from these non-producing assets. Scoped removals not able to be safely completed in the allotted vessel execution window will be completed as part of the subsequent planned future campaign to remove the lower jacket sections not removed in Campaign #1 (refer to Section 1.3.1). This will be covered by a future EP submission.

The ongoing IMR of any facilities partially removed as per the scope listed in Section 2.1 will be undertaken as part of this EP, until such time as the Bass Strait Non-Producing Environment Plan is accepted (expected to be submitted in March 2026). Refer to Section 2.18.

2.4 Property description

2.4.1 Property within the scope of this Environment Plan

Property within the scope of this EP includes 10 SPJ facilities, two monotower facilities and one CGS facility. For Campaign #1, different decommissioning outcomes apply to each facility, as presented in Section 2.1 of the EP.

Descriptions in this Section are based on general and typical characteristics of facilities prior to preparations and removal. Section 2.5 details the state and condition of the facilities at handover to the HLV contractor Allseas for commencement of removal preparations and removal activities as described in this EP.

Table 2-1 Facility details - Location, Production Licence, asset generation, depth and distance from the coast (GDA94)

Facility name	Code	Facility type	Year of installation	Facility generation)[3]	Production Licence No.	Distance from the coast (km)	Water depth (m)	Latitude	Longitude
Kingfish A	KFA	SPJ	1969 Strut 1989	1st generation	VIC/L07	77	77	38° 35' 46"S	148° 08' 40"E
Kingfish B	KFB	SPJ	1969 Strut 1989	1st generation	VIC/L07	77	78	38° 35' 49"S	148° 11' 17"E
Mackerel	MKA	SPJ	1976	2nd generation	VIC/L05	73	93	38° 28' 45"S	148° 20' 33"E
West Kingfish	WKF	SPJ	1981	2nd generation	VIC/L07	72	76	38° 35' 35"S	148° 06' 20"E
Flounder	FLA	SPJ	1983	2nd generation	VIC/L11	58	93	38° 18' 40"S	148° 26' 22"E
Fortescue	FTA	SPJ	1982	2nd generation	VIC/L05	64	69	38° 24' 26"S	148° 16' 41"E
Whiting	WTA	SPJ	1989	3rd generation	VIC/L02	34	54	38° 19′ 05"S	147° 36′ 57″E
Dolphin	DPA	Monopod	1989	3rd generation	VIC/L15	21	38	38° 29' 14"S	147° 22' 39"E
Perch	PCA	Monopod	1989	3rd generation	VIC/L17	24	42	38° 34' 09"S	147° 19' 21"E
Bream B	BMB	CGS	1996	3rd generation	VIC/L14	51	61	38° 31' 06"S	147° 50' 21"E

[3] The differences of generation number relate to the year(s) facilities were installed. Facility generations relate to this EP as the method to prepare and remove differ in each facility generation. Second generation facilities were designed within a similar timeframe and have similar layouts. This is not the case for first or third generation facilities.

Facility name	Code	Facility type	Year of installation	Facility generation)[3]	Production Licence No.	Distance from the coast (km)	Water depth (m)	Latitude	Longitude
Halibut	HLA	SPJ	1968 Strut 1989	1st generation	VIC/L05	64	73	38° 24' 15" S	148° 19' 12"E
Cobia	CBA	SPJ	1982	2nd generation	VIC/L05	69	78	38° 26' 58" S	148° 18' 33"E
Bream A	BMA	SPJ	1987	2nd generation	VIC/L13	46	59	38° 29' 59" S	147° 46' 20"E

2.4.1.1 Steel pile jacket platforms

SPJ facilities have a tubular steel base structure (or jacket) which is fastened to the seafloor by piles. Figure 2-3 depicts a typical SPJ from the seabed to below the topsides and includes a depiction of different pile types. The jackets support the topsides which include the production facilities, living quarters (if present) for personnel working on the platform and a helicopter landing pad. A supporting strut is also in place on some SPJs (KFA, KFB and HLA) to provide additional support.

Each platform consists of the following elements:

- conductors, connecting the wellheads to the seabed
- pipeline risers connecting the platform to pipelines
- processing equipment/production facilities which include:
    - gas separators/scrubbers, oil separators, test separators, slug catcher/receivers
    - open and closed drain systems, including skimmer vessels and open and closed drain piles
    - potable water systems
    - produced water processing facilities, including hydro-cyclones and/or dissolved gas flotation units
    - diesel/methanol/glycol storage and injection systems
    - liquified petroleum gas/condensate reinjection facilities
    - instrument air systems.
- living quarters, including:
    - control room, radio room, offices
    - ablutions, laundry and galley
    - macerators for disposal of food scraps and sewage treatment.
- helideck
- safety features including evacuation capsules
- variable number of decks, including sea deck and cellar deck
- laydown area and one or more cranes
- pumps, compressors and electricity generators
- maintenance workshop(s)
- flare/vent boom and scrubbers.

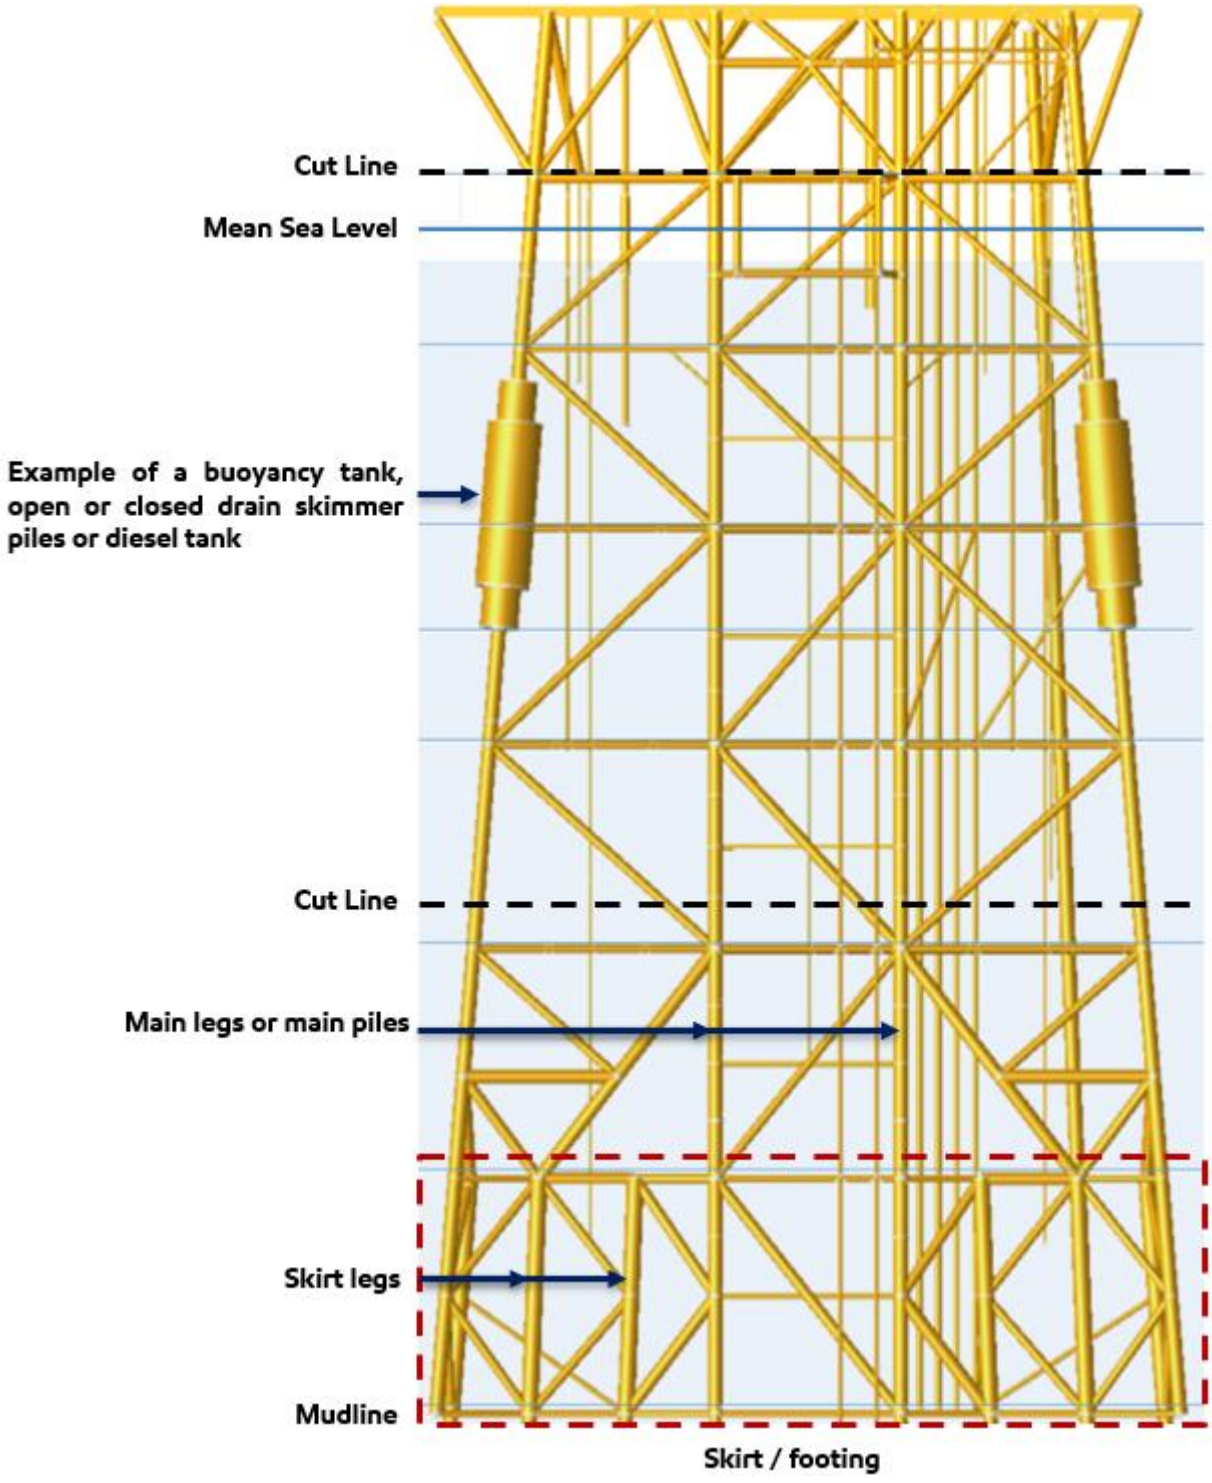

Figure 2-3 Example figure of a typical SPJ with indicative cut lines and other features

2.4.1.2 Monotower platforms

Monotowers, PCA and DPA, are fixed installations consisting of a steel gravity based monotower with three cement iron ore ballast pods supporting minimal, un-staffed topside production facilities. Key equipment on the facility includes the leg access deck, the wellhead deck, the mezzanine deck and the helideck. An overview of the PCA and DPA facility design is shown in Figure 2-4.

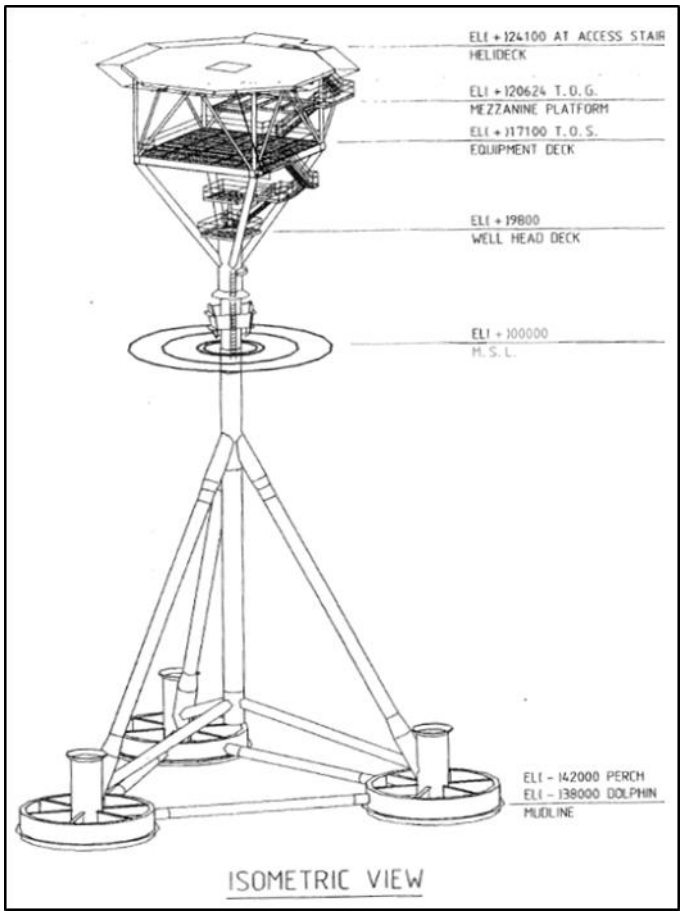

Figure 2-4 PCA and DPA platform configuration represented by one image as the facilities are similar (Esso, 1988)

2.4.1.3 Concrete gravity base structure – BMB

BMB is a fixed installation consisting of a single leg CGS. It holds a module support frame, which supports a single production module containing minimal production facilities and day-only accommodation. The facility is comprised of deck levels, including the sea deck, subcellar deck, cellar deck, mezzanine deck and main deck. An overview of the BMB CGS platform's topside design is shown in Figure 2-5.

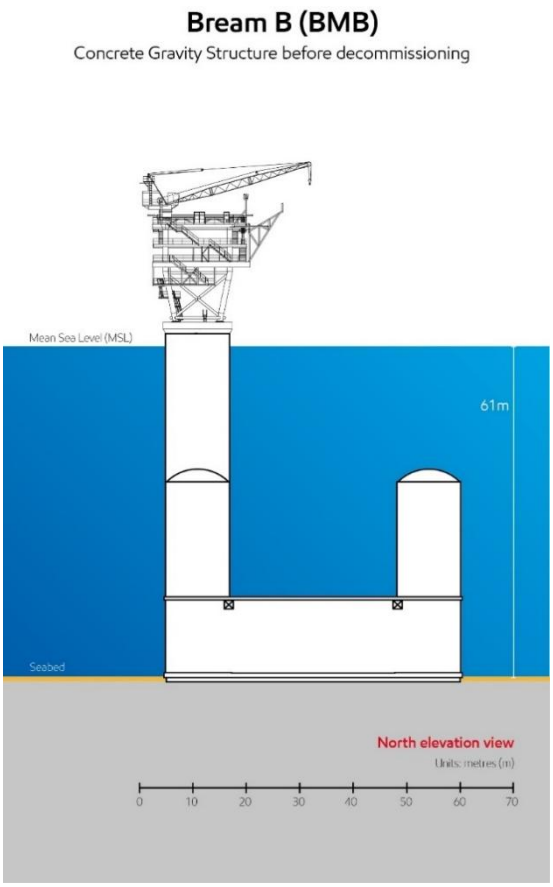

Figure 2-5 BMB depiction indicating the extent of the CGS

2.4.1.4 Description of facilities

The following section includes facility details, images of the topsides of each facility when operational and a depiction of facilities relative to overall scale, both prior to Campaign #1 and as expected following the completion of Campaign #1. Weight estimates are based off weight to below the mudline at approximately -1m as installed, it does not account for marine growth. A summary of the facility status following Campaign #1 and weight estimates for the remaining lower jacket sections and the BMB concrete substructure are provided in Section 2.17. Reference to P&A of each facility is based off the time of submission of this EP, first quarter 2025.

2.4.1.4.1 HALIBUT

HLA specifications are provided in Table 2-2. Figure 2-6 provides a photograph of the facility topsides while Figure 2-7 provides a depiction of the facility, both prior to Campaign #1 and as expected following completion of Campaign #1.

Figure 2-6 HLA – SPJ (twin), strut and topside

2.5 Facility status prior to removal

Prior to their removal per the scope of this EP, a range of facility preparation activities will have been undertaken, including but not limited to: P&A of wells, flushing of topsides equipment and pipelines, air gapping, demolition, destruction and installation of lifting points. These activities will be performed under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). The remaining operational systems on the facilities at the commencement of the activities within the scope of this EP will include navigation lights, cathodic protection and associated systems.

Prior to removal, the main hydrocarbon systems on the facilities will be free of bulk hydrocarbons, methanol and diesel. Flushing, purging, draining and/or isolation will have been completed to sufficiently manage hydrocarbons, hydrogen sulphide (H_2S) and pyrophoric risks to allow pipework and equipment to be safely transported. Table 2-15 indicates the status of systems on the BMA, BMB, CBA, FLA, FTA, KFA, KFB, MKA, WKF, PCA, DPA and WTA facilities prior to their full or partial removal.

Table 2-15 Status of facilities prior to removal

System description	Status
Petroleum processing Oil production header, surface flowlines, primary separation, crude transfer to export, gas production header, gas re-injection, gas compression, gas lift, vent relief system and flare, produced water, gas blowdown system, fuel gas.	Systems bulk de-inventoried and left isolated to prevent spills during topsides lifting. Targeted cleaning of selected piping as required for air gapping and subsequent topsides removal.
Methanol	Methanol piping bulk de-inventoried and where feasible a nitrogen (N_2) blanket applied. Piping isolated to prevent spills during topsides removal.
Diesel	Diesel piping bulk de-inventoried and where feasible an N_2 blanket applied. System isolated to prevent spills during topsides removal. There will be no temporary diesel generators on the facilities. Facility crane minimal inventory contained.
Non-hydrocarbon chemical injection systems	Bulk de-inventory with systems isolated to prevent spills during topsides removal.
Sealed lube oil and refrigerant	Sealed and de-pressured.
Tubing containing chemicals or hydrocarbon liquids	Drained and de-pressured, isolated or capped to prevent spills during topsides removal.
Foam system	De-inventoried by specialist contractor and isolated to prevent spills during topsides removal. None of the foam systems will contain PFOS, PFOA, PFHxS and related substances at the time of removal
Utility systems Service water, hydraulic system, utility (service) air, instrument air, lubrication system, waste oil recovery, potable water, hot water	Drained, de-pressured and isolated to prevent spills during topsides removal.
Fire-fighting systems	Drained and de-pressured, piping and tubing (that previously contained seawater or air) isolated.
Sewage treatment	Flushed and drained by specialist contractor and isolated to prevent spills during topsides removal.
Open drain skimmer piles (ODSPs) and closed drain skimmer piles (CDSPs)	De-inventoried and cleaned of hydrocarbons to the extent achievable against specified oil in water (OIW) targets and left open to atmosphere.
Jacket leg storage tanks (JLSTs)	JLSTs can contain either diesel, glycol, methanol or potable water. Diesel JLSTs cleaned to a specified OIW target. The methanol and glycol tanks will be diluted and drained, while the potable water tank will just require draining. All tanks will be left open to the atmosphere.

HLA presents unique structural and logistics challenges and as such the removal methodology is still being finalised. HLA cleaning targets will need to cover a range of removal options that may be executed in Campaign

#1 (single lift through the *Pioneering Spirit*) or a future subsequent campaign (which may involve an alternate removal method). Preparation scope will be defined at an appropriate date once the removal methodology and timing is confirmed.

Facility status will be documented and communicated to Allseas and other contractors as applicable via the Digital Decommissioning Management Tool. Such documentation may include: details of fluids remaining at the facilities and within pipelines; estimated volumes after facility and pipeline preparation activities are completed; air-gapping/demolition records; lifting aid installation records; hazardous materials register and de-energisation records. If and where applicable, information on make-safe measures and controls implemented to prevent spills from minor volumes of residual fluids that may be left within the platforms after facilities preparation activities are completed.

2.6 Support operations

2.6.1 Vessels

As required, vessels can operate on a 24-hours, seven days a week basis. For the removals of topsides, jackets and struts and other components, it is anticipated there will be approximately 26 barge or HTV transits between the transfer location and the ORC accompanied by support tugs over approximately five months, however this number may vary as detailed execution planning progresses

2.6.1.1 *Pioneering Spirit* heavy lift vessel

The *Pioneering Spirit* HLV is one of the world's largest construction vessels (Figure 2-33) which has not been used in the Bass Strait before. It will be used for the removals campaign mobilising around the end of third quarter 2027 and demobilise around the end of the first quarter 2028. It is designed for the single lift installation and removal of large offshore platforms, as well as the installation of subsea pipelines (Table 2-16). The *Pioneering Spirit* HLV can lift and transport entire platform topsides weighing up to 48,000t using the topsides lift system (TLS), which is comprised of 16 lifting beams mounted on its split bow.

The main aft deck area is reserved for the jacket lift system (JLS), another heavy lift system, which can remove and install jackets up to 20,000t in a single lift from the stern. A 5000t tub-mounted crane on the aft main deck, port side, can be used for smaller lifts, such as modules, piles, derrick towers, flares, and bridges. There is also a 600t crane port and starboard side. The *Pioneering Spirit* HLV is classified as a Dynamic Positioning (DP) (DP3) class vessel and may have up to two work class Remotely Operated Vehicles (ROVs) for Campaign #1 facility removal activities.

Table 2-16 lists the vessel characteristics of the *Pioneering Spirit* HLV.

Figure 2-33 Illustration of the *Pioneering Spirit* with a platform transferred to the TLS on the split bow and jacket structure on the JLS at the stern of the vessel

Table 2-16 *Pioneering Spirit* vessel characteristics

Vessel name	***Pioneering Spirit***	
Operator	Allseas	
Design	Platform installation/decommissioning and pipelay	
Built	South Korea (2011–2014)	
Class	+100A1 heavy lift and heavy cargo ship, upper deck aft of frame 43 strengthened for load of 15t/m^2, helicopter landing area, LA, *IWS, LI, EP (B, G, N, O, P, S), ice class 1C FS, LMC, DP (AAA), PSMR* with following descriptive note: pipe laying vessel shipright (BWMP (S+F)), split bow forward of frame 99	
Flag/registry	Malta, Port of Valletta	
Gross tonnage	403,342t	
Principal vessel dimensions	Length overall	477m
	Length hull	382m
	Breadth, moulded	123.75m
	Depth to main deck	30m
	Slot length	122m
	Slot width	59m
	Transit draught	11.50m
	Operating draught (minimum and maximum)	10.00 – 27.00m
	Maximum speed	14kn
	Total installed power	95,000kW
	Engines	8 x 11,200kW diesel generator sets
	Thrusters	12 x 6050kW electric driven non-retractable, fixed pitch, variable speed azimuth type
	Accommodation	571 persons
TLS	The TLS is mounted on the vessel's split bow hull, Figure 2-33, Figure 2-34 and Figure 2-35. The TLS comprises 16 lifting beams, eight on starboard side and eight on portside, and can be used in multiple set-ups. Beams can operate to lift individually or in pairs – a forklift unit. The number of forklift units involved in removal or installation operations varies per heavy lift project. Forklift units are fitted with removable connection tools on their lifting levers to exert their part of	

Vessel name	*Pioneering Spirit*
	the total lifting force onto the topsides. Connection tools are activity-specific structures and can be clamps, horseshoes, yokes or fit-for-purpose designs. A single lifting beam can also be fitted with a connection tool, depending on the heavy lift activity. TLS in general, and each lifting beam in particular, is designed and certified for the specific purpose of lifting and lowering of topsides, and not for any other (marine) application. Each beam is equipped with three main operating drives: X, Y and Z. The X- and Y-drive have active motion compensation. The Z-drive has active motion compensation and passive motion compensation. During TLS operations at sea, the vessel will be subjected to motion, position and angle changes due to heave, draught and tide variations, currents, wind and waves. To react to these changes, *Pioneering Spirit* is equipped with a position reference (and feedback) system, which detects these changes and sends signals to the active motion compensation and passive motion compensation control systems.
JLS	The JLS is designed for jacket installation and removal operations, executed in a single lift, Figure 2-33 and Figure 2-36. The JLS is located at the stern of *Pioneering Spirit* and consists of two beams, which can rotate on hinges (hang-off frames, integrated parts of the hang-off and upend system) on the vessel's stern by means of derrick hoist systems, compound pulley systems with multi-layer winches, located inside dedicated winch rooms. The JLS beams are connected at the top by the JLS connection beam. Each JLS beam is designed with permanent ballast weight aft of the hinge and will additionally have the capability to take in ballast water in the tail section. In addition, each beam is outfitted with an 8000t (17,630kips) upend system (part of the hang-off and upend system), which is a push-pull system with hydraulic cylinders. As a result, the derrick hoist systems will always be under tension during upending and will therefore control the rotation of the beams. With the beams in horizontal position, the ballast water can be pumped to inboard compartments to ensure that the combined centre of gravity of jacket and JLS will be located inboard and that no uplift of the JLS beams will occur during transportation. The top surface of the JLS beams will allow skidding of the jacket either on its launch runners or through support grillages positioned underneath the main hoist blocks. Jackets will be loaded or offloaded on the JLS beams by aligning the JLS beams with the tracks on a barge, refer to Section 2.8.2. The main hoist system can be used to pull the jacket onto the JLS beams.
5000t crane	The *Pioneering Spirit* also has a 5000t special purpose crane, located at the stern portside of the vessel to supports operations and is designed to install and remove modules, structures and jackets.
Fuel type and volumes	*Pioneering Spirit* will utilise marine gas oil (MGO) to power the vessel during decommissioning operations. The volume of fuel the vessel will require for Campaign #1 operations will be defined during the planning stages of the project. Refer to Section 7.7.5 for details on MGO volumes established for environmental risk assessment purposes.

Vessel name	*Pioneering Spirit*
	Heavy fuel oil (HFO) will not be used during Campaign #1 but there may be residual volumes of HFO remaining from previous operations. The maximum volume of residual HFO in a single tank is estimated to be up to approximately 80m^3.
Vessel ballast control system	The draught, trim and heel of *Pioneering Spirit* can be adjusted by filling and emptying the ballast water tanks. *Pioneering Spirit* is equipped with 87 ballast water tanks and four quick drop ballast water tanks, occupying a total volume of almost 750,000m^3.

Figure 2-34 Typical depiction of the *Pioneering Spirit* approaching a platform to execute a topside lift using the TLS

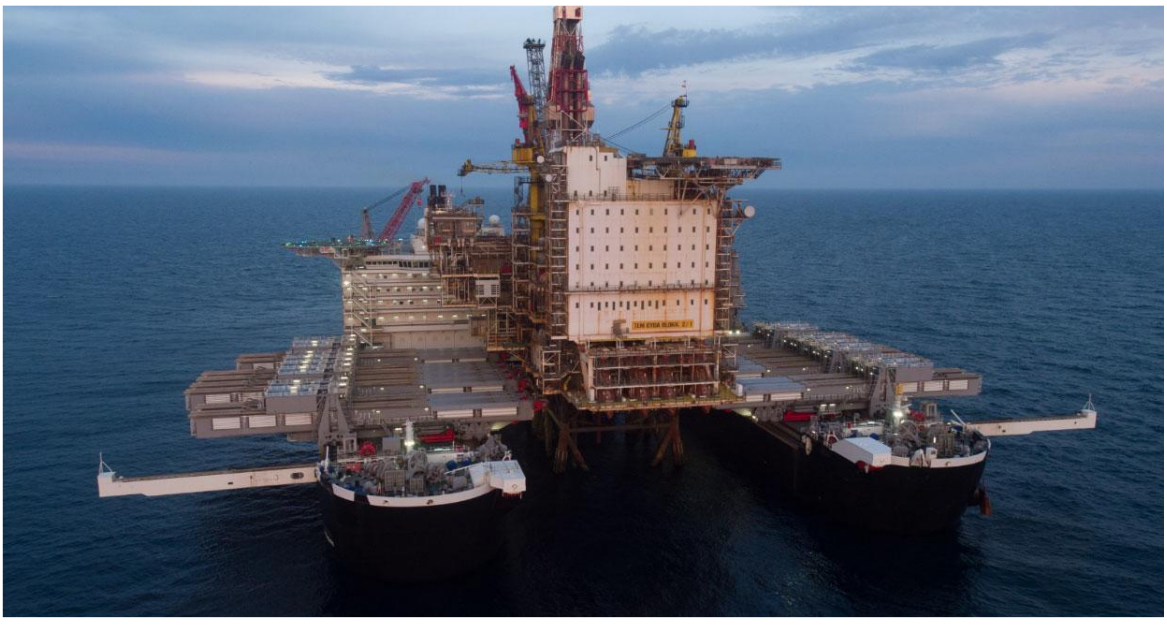

Figure 2-35 Typical view of the *Pioneering Spirit* highlighting the split bow and lifting beams

Figure 2-36 Typical depiction of jacket lift and jacket transport with *Pioneering Spirit's* JLS on the vessels stern showing the two beams on hinges, the hang-off and upend system, compound pulley systems and the connection atop the JLSs

2.6.1.2 *Fortitude* construction support vessel

A primary CSV will be required to support execution. For the purpose of this EP, the *Fortitude* is nominated as a representative example of the vessel that will be used. The *Fortitude* is a multipurpose CSV equipped with a full DP3 system, see Figure 2-37, for image of the *Fortitude*. The *Fortitude* or similar vessel will be used in both the removals preparation work and facility removal, see Section 2.3 for timing.

Table 2-17 lists the vessel characteristics of the *Fortitude*.

Figure 2-37 Allseas vessel the *Fortitude*

Table 2-17 *Fortitude* vessel characteristics

Vessel name	***Fortitude***	
Operator	Allseas	
Design	Multipurpose offshore construction vessel	
Class	LR 100A1 offshore supply vessel, fire-fighting ship type 2 (7200m^3/hour), helideck, *IWS, WDL+, ECO(TOC), Ice class 1C FS at a draught of 9.8m (max/min draughts: Fwd: 9.98/6.74m; aft 9.83/6.75m); power required 4959kW, power installed 10,050kW LMC, UMS, DP(AAA), shipright SRtP	
Flag/registry	Valetta, Malta	
Built	South Korea, 2018	
Gross tonnage	23,520t	
Principal vessel dimensions	Length overall	151m

	Transit draught	8m
	Operating draught	10m
	Maximum draught	13.62m
	Maximum speed	13.9kn
	Vessel speed, economical	10.5kn
	Total installed power	22,380kW

Vessel name	*Fortitude*	
	Thrusters	Main azimuth thrusters (stern): 3 x 3350kW (peak) Schottel SRP 4040 LSU non-retractable azimuth thrusters with fixed-pitch propellers
	Bow thrusters	2 x 3350kW Wärtsilä retractable azimuth thrusters, 2 x 2500kW Wärtsilä tunnel thrusters
	Stern thrusters	3 x 3350kW Schottel azimuth thrusters
	Accommodation	250 persons
Fuel type and total capacity	MGO: 2654m^3	
Ballast	8494m^3	

2.6.1.3 Second construction support vessel

For Campaign #1, the HLV will be mobilised, supported by the *Fortitude* or similar and a second CSV. The second CSV will be utilised across the OA. Indicative vessel specifications of the second CSV are per Table 2-18.

Table 2-18 Typical specifications of the second CSV

Specification	Details
Length overall	110m
Breadth	25m
Gross tonnage	10,181MT
Dynamic positioning (DP) system	DP2
Fuel type and total capacity	Fuel type MGO 2416m^3

2.6.1.4 Other vessels

The Campaign #1 marine spread will also include a combination of vessels that may include tugs, cargo barges, heavy transportation vessels, support vessels, PSV, crew transfer vessels and other vessel types. These may operate out of Barry Beach Marine Terminal and other ports as necessary. All vessels will primarily operate on DP when in the PSZ.

All vessels supporting Campaign #1 or the ongoing management of partially removed facilities will be specified and operated in accordance with International and Australian regulatory requirements. All vessels will be subject to Esso review and approval and will be certified as being in compliance with international maritime legislative requirements by a Classification Society registered with International Association of Classification Societies (IACS) or by the AMSA.

Vessel support activities will be required for removal preparations and during the facilities removal works. Vessel activities may include but not limited to:

- Bunkering
- crew change
- supply provisions including food, bulk chemicals, and fuels, and other cargo/materials and removal of waste to shore

- grouting
- deployment of ROVs or other subsea equipment
- crane operations
- surveys and other subsea activities
- monitoring the PSZ around a facility/removal vessels
- oil spill response if required.

2.6.1.5 Barges

There may be approximately five cargo barges to transport the topsides, jackets and other structures such as struts and piles or other items to the ORC. Preparations to make the barge suitable to receive the topsides/jacket will either take place prior to arrival to the OA, or in sheltered waters. Where barges are used, facilities will be transferred from the HLV to a barge within the OA, refer to Figure 2-2. The barges will then be towed to the ORC for offloading. Barges may have onboard generators, fuel storage, ballast water systems and other systems to support operations as needed. The indicative barge specifications are detailed in Table 2-19.

Table 2-19 Typical barge specification

Specification	Design (approximate)
Length overall	124m
Breadth	37m
Deadweight tonnage	20,000t
Fuel capacity (for onboard equipment)	40m^3

2.6.1.6 Tugs

There may be up to six tugs utilised in support and towing operations. Typical specification of tugs planned to be utilised for Campaign #1 is per Table 2-20. During transport operations of items removed from the OA to the ORC, approximately three tugs will be utilised per barge.

Table 2-20 Typical tug specification

Specification	Design (approximate)
Length overall	75m
Breadth	17m
Gross tonnage	2952MT
Fuel type and capacity	1300m^3 MGO or MDO

2.6.1.7 Heavy transport vessels

There may be up to four HTVs to transport the topsides, jackets and other structures to the ORC. Where HTVs are used, facilities will be transferred from the HLV to a HTV at a sheltered weather location within the OA, refer to Figure 2-2. The HTV will then sail to the ORC for offloading. For the purpose of this EP, the *Bigroll Busan* is nominated as a representative example of the vessel that will be used. The indicative HTV specifications are detailed in Table 2-21.

Figure 2-38 Typical HTV the *Bigroll Busan*

Table 2-21 Typical HTV specification (*Bigroll Busan*)

Specification	Design (approximate)
Length overall	166m
Breadth	40m
Deadweight	19,398MT
Fuel type and capacity	2033m^3 MGO or MDO

2.6.2 Remotely Operated Vehicles

During Campaign #1, ROVs such as work class, observation class or mini-ROVs will be utilised for various activities. These may be deployed from the HLV, *Fortitude* or similar vessel, or a second CSV. The ROVs will be fitted with various specialised tools and may work on the seabed, close to structures and in the water column at any depth. Activities that ROVs may conduct or assist with include but are not limited to:

- surveys and inspections
- subsea cutting and removal
- sediment displacement
- removal of debris to surface or temporary placement on the seafloor which may include the use of a subsea basket
- temporary placement of equipment, infrastructure on the seafloor and its retrieval
- marine growth removal
- drilling vent/drain holes in jacket structures such as storage legs and flooded members
- visual inspection (and potential sampling) inside the jacket leg skirt piles
- air lifting inside jacket legs
- installation of caps/plugs on pipes
- installation of caps/plugs on flexibles and umbilicals

- flooded member detection
- conductor cutting
- temporarily support structures such as sleeves or clamps

2.7 Removal preparations

Removal preparations conducted by Allseas will prepare the topsides and jackets for lifting. These activities will commence with the first mobilisation of the *Fortitude* or similar CSV vessel and continue during facilities removal.

2.7.1 Topsides removal preparation

The topsides removal preparation works that will be undertaken by Allseas under this EP include, but are not necessarily limited to:

- main and cellar (above) deck equipment demolition/removal
- establishment of utilities such as lighting, air compressors and diesel generators
- grouting of the lift points that were installed as part of facilities preparation
- installation of other lift points as required
- residual air-gapping, partial removal, or complete removal of pipelines, risers, umbilicals, J-tubes, skimmer piles, caissons or other appurtenances or supports
- removal as required of jacket leg piles
- topsides-jacket separation (final air gapping)
- strut – jacket separation (KFA, KFB, HLA)
- laying of struts on the seabed for temporary storage
- brace cutting, lifting and transportation preparation such as removal of objects that may become dropped objects upon lifting and transportation or securing of loose items and sea fastening.

2.7.2 Grouting

For the generation 1 facilities (KFA and KFB), preparation for lifting points will have been installed under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). To complete these lifting points, grout will be injected by Allseas from the CSV.

2.7.3 Topside – Jacket separation

Cut locations to separate the topsides from the jacket or monopods will be at approximately 5m above MSL. Legs will be cut using either oxyacetylene torch, diamond wire cutting machine (DWCM), abrasive water jetting cutting tool or gouging. All cuts will be engineered to ensure the stability of the facility. Cutting may occur more than a year in advance of removal, but in all cases the residual structural stability will be assessed prior to cutting, to ensure risks are managed. Figure 2-39 provides an example of cut locations on a typical jacket.

Figure 2-39 Example of cut locations on a typical jacket

2.7.4 Helicopters

Helicopter support will be provided from Allseas preferred location(s) to support the activities as follows:

- personnel transfers between shore and vessels for crew changes
- freight helicopter support
- emergency response, including medevac, and search and rescue.

Helicopter operations are performed in accordance with CASA regulations. Helicopter type, suitability, and performance criteria are contractually controlled, aligned with ExxonMobil minimum requirements, as are minimum flight and engineering crew qualifications and experience levels. Routine helicopter operations will occur during the daytime with the exception of emergency response which may occur at any time as needed.

2.7.5 Jacket preparation

Jacket preparations may be undertaken during removal preparations and/or coincide with facilities removal works. Temporary navigation lights will be installed on SPJ structures after topsides removal, prior to Allseas moving out of the PSZ. Temporary work platforms may be installed on the jackets, to facilitate the preparation and installation of the jacket lift points, refer to Figure 2-40.

Figure 2-40 Example of a temporary work platform installed on a typical jacket

Other activities that may occur prior to jacket removal include:

- debris survey and removal or relocation (temporary storage) as appropriate to enable jacket removal (refer to Section 2.10.5)
- lift points preparation and installation
- removal of items stuck within skirt piles (refer to Section 2.12.2)
- removal of titanium-iron oxide mineral sand (refer to Section 2.12.7)
- soil plug removal
- small areas of marine growth removal
- jacket cuts (refer to Section 2.7.5.1)
- removal of conductors in full or conductor stubs (refer to Sections 2.14.2 and 2.14.3)
- removal of subsea appurtenances, such as items attached to pipelines
- cutting and removal of jacket components such as bracing
- subsea cutting and plugging or removal of pipeline risers, umbilicals and flexibles (refer to Section 2.10.2)
- drilling of vent/drain holes in structures or equipment such as jacket storage legs and flooded structural members
- other tasks required to assist jacket removal operations.

2.7.5.1 Jacket cutting

For cuts to the jacket legs, main piles and skirt piles (see Figure 2-3 that depicts the difference in pile types), the preferred cutting method will be considered on a case by case basis based on assessment of a number of factors such as access/obstructions and likelihood of cut success. Internal cutting is preferred for cuts at or below seafloor to minimise sediment displacement however, as in all cases, the method selection will be based on the pile specific assessment. Internal cutting will be undertaken by either high pressure water jetting or abrasive water jet cutting.

For cutting smaller diameter jacket members, braces, appurtenances as well as the risers, j-tubes and umbilicals, a shear cutting tool or DWCM may be used.

To enable the jacket to be lifted, all structural members need to be cut. The cutting of the jacket members can be divided in two indicative phases, to enable a safe and efficient approach:

- Green cuts – Will be made between one and 18 months prior to jacket lifting
- Red cuts – the final cuts before lifting - hence will only be made once a suitable weather window has been found for the jacket lift.

As described in Section 2.1, the jackets located in deeper water (MKA, WKF, FLA, CBA, KFA, KFB and HLA as an option) will be cut at a depth of at least 55m below MSL. Jackets located in shallower water (WTA, BMA) will be cut as close as practicable to the seabed, which may be below the seabed, or just above (up to a maximum of 3m above as found seabed). FTA will either be cut to at least 55m below MSL, or as close as practicable to the seabed. The final cut heights are subject to detailed engineering being completed.

For those jackets that will be cut as close as practicable to the seabed - WTA, BMA and FTA (Option 2), Figure 2-41 provides an overview of the decision criteria followed to inform the final cut height for these jackets, depending on conditions encountered during execution.

In the event it is determined that the alternate cut plan MOC to cut above seabed listed in the final step of this decision criteria cannot practically and safely be completed during the Campaign #1 execution window, the jackets(s) will remain in place and removal will be completed as part of the future campaign to remove the lower sections of the jackets partially removed in Campaign #1 (refer to Section 1.3.1.3).

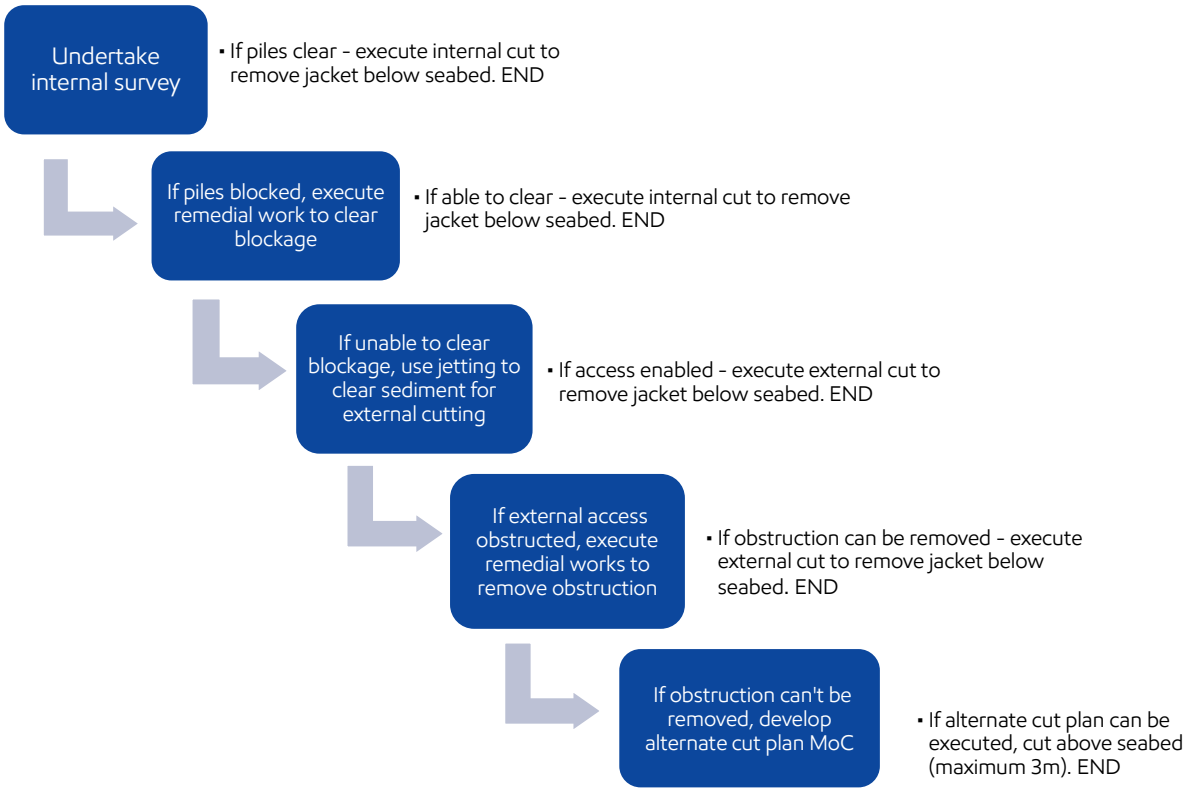

Figure 2-41 Decision criteria for jacket cutting - WTA, BMA and FTA (Option 2)

2.7.6 Removal of seabed obstructions

In the event obstructions such as rock, grout or debris are encountered during cutting of the jackets at the seabed (if external cutting is required at BMA, WTA and FTA) or cutting of pipelines, these will need to be removed or relocated to allow cutting to continue. If sediment displacement techniques (as discussed in Section 2.10.3) are

not successful, subsea tools such as a chain cutter, bucket or ripper may be required to move the obstructions away from the cut location. These subsea tools would be required on a contingency basis only and only in the event other methods, such as rigging and pulling or loading with a weight onto the obstruction to allow it to be moved, are unsuccessful. Some examples of the potential subsea tools which may be used in this contingency situation are provided in Figure 2-42.

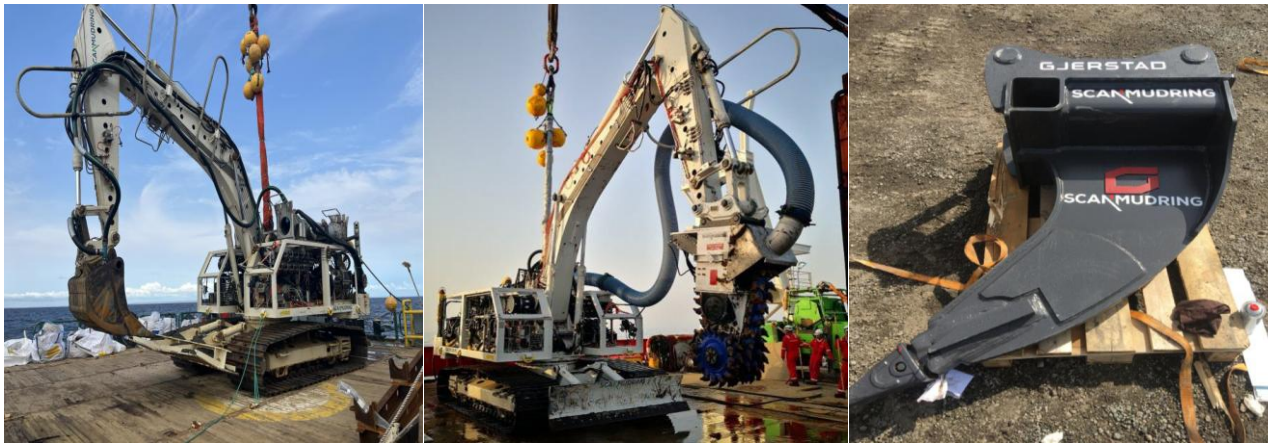

Figure 2-42 Potential subsea tools to remove obstructions to jacket/pipeline cutting (from top left, excavator bucket, chain cutter and ripper)

2.7.7 Pipelines, risers/j-tubes, umbilicals and flexibles

All pipelines, risers, flexible flowlines and umbilicals shall be cut approximately 5m horizontally away from the base of the jackets by Allseas and if required the cut sections removed individually if not safe to remove with the jacket. Cut sections may be stored temporarily on the seabed prior to removal as part of Campaign #1. A plug or cap will be inserted into the remaining pipeline ends resting on the seafloor. Umbilicals and flexibles may also be plugged or capped after being cut.

In the case of the BMB CGS, the riser, clamps and stubs will be removed by cutting close to the scour protection at the subsea end. The pipeline end will be plugged or capped. The j-tube, umbilical and clamps will be cut close to the top of the CGS caisson (base) and clamps and stubs removed.

Pipeline licence variation applications are being made by Esso following consultation with the National Offshore Petroleum Titles Administrator to facilitate the cutting of pipelines in preparation for topsides and jacket removal. These applications will be in place prior to the Campaign #1 activities and will vary the relevant pipeline licences to reflect the condition of the pipeline following cutting of the pipelines (i.e. amendments to the pipeline licence commencement or termination points). The pipeline sections that will be cut and removed as part of Campaign #1, following the finalisation of the pipeline licence variation will no longer form part of the pipeline licence and hence will be considered to be part of the facility covered by the production licence. As above, a plug or cap will be placed on or within the ends of the licenced pipeline sections that will remain on the seabed following the cutting and removal activity.

2.8 Removal operations

2.8.1 Lifting

After completing removal preparations, the HLV will be used to remove topsides, jackets and struts and other items as required. The HLV will perform numerous lifts during Campaign #1 and is likely to combine several lifts on the vessel before transporting structures to a sheltered location for transfer. The TLS or 5000t crane will be used to conduct topsides lifts (refer to Section 2.6.1.1 for details on the TLS) in different lifting configurations as required.

The HLV will remove jackets and struts, utilising the JLS or 5000t crane, (refer to Section 2.6.1.1 for details on the JLS and 5000t crane). The *Fortitude* or similar vessel may also conduct topside lifts during Campaign #1.

2.8.2 Transport and transfer operations

Given the size and draft of the *Pioneering Spirit* HLV, it is unable to enter Corner Inlet to deliver the platforms directly to the ORC. Hence the removed topsides and jacket sections will be transported from the removal locations to a sheltered location within the OA where they will be transferred to a barge or HTV for transit to the ORC. Structures removed by the *Fortitude* or similar CSV will also be transferred to barges, HTVs or supply boats at a transfer location for onward transit to the ORC. The HLV is expected to be at a sheltered water location (the 'transfer location') on approximately 21 separate occasions undertaking transfer operations over the duration of Campaign #1 activities, however this number may vary as detailed execution planning progresses.

Transporting topside and jacket loads from the offshore area onshore is logistically complex with many factors influencing the flow of activities and timing of works. Offshore decommissioning operations present some risk due to the nature of the environment, size of the infrastructure being moved and unknown factors which can cause complications and extensive measures are taken to ensure the safety of personnel and protection of the environment. Transportation of the structures and transfer operations will not commence unless there is a clear weather window identified that is within the defined limits for transfer operations to be undertaken safely.

The location at which transfers will take place within the OA may be different for each transfer operation and may only be selected during transit from the removal locations, subject to the discretion of the HLV Vessel Master. Identification of the chosen location will be communicated to other users of the sea via standard marine notification channels for example Notice to Mariners, and communication with local port authorities such as Gippsland Ports. The decision criteria to be followed when selecting the transfer location within the OA is discussed in Section 2.8.4.

Topsides will be set down on the barge or HTV. Ballasting of vessels/barges will be executed prior to approaching the HLV to ensure optimal stability while carrying the structures. Adjustments to ballasting will be made if required to ensure safe transit of all structures. Figure 2-43 is an example of a barge transfer within the slot of the HLV.

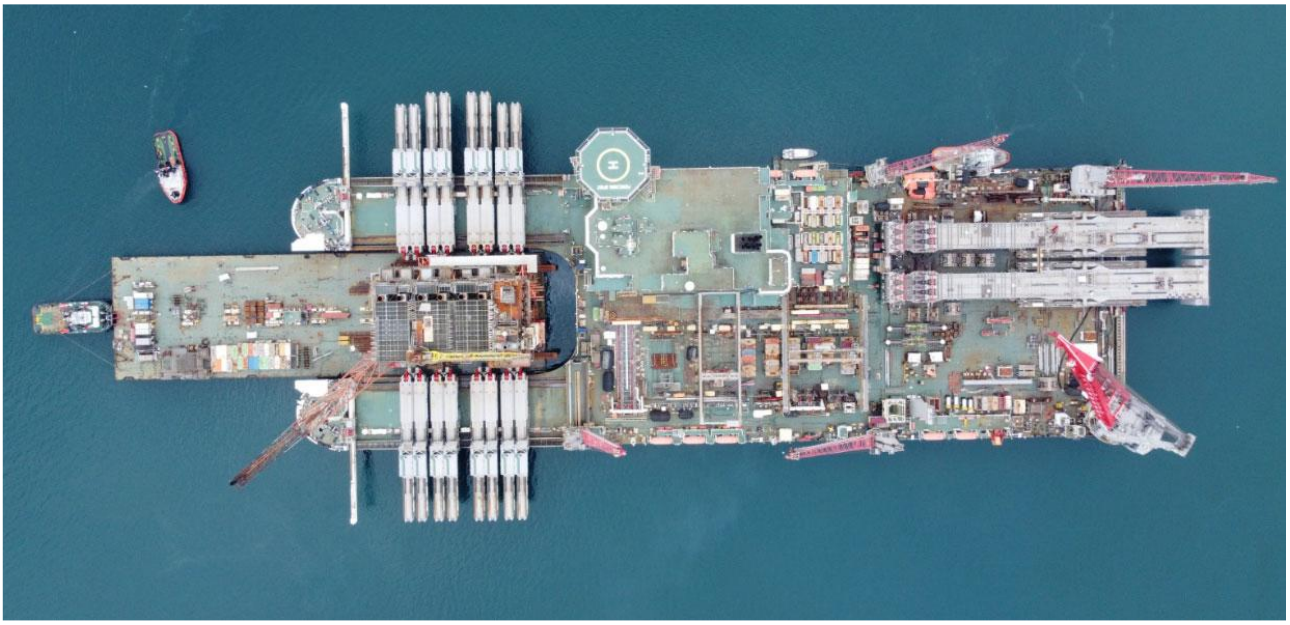

Figure 2-43 Example of a topsides transfer from TLS to cargo barge

For jacket transfers where the jacket has been lifted using the JLS, transfer to the barge or HTV will be from the stern of the HLV. Figure 2-44 shows an example of a jacket being set down on a barge at the stern of the HLV. Figure 2-45 shows an example of a jacket loaded onto a HTV.

For structures where the 5000t crane has been used for lifting, transfer to the barge or HTV, will be alongside the HLV.

Figure 2-44 Example of a jacket set down on a barge at the stern of the HLV utilising the JLS

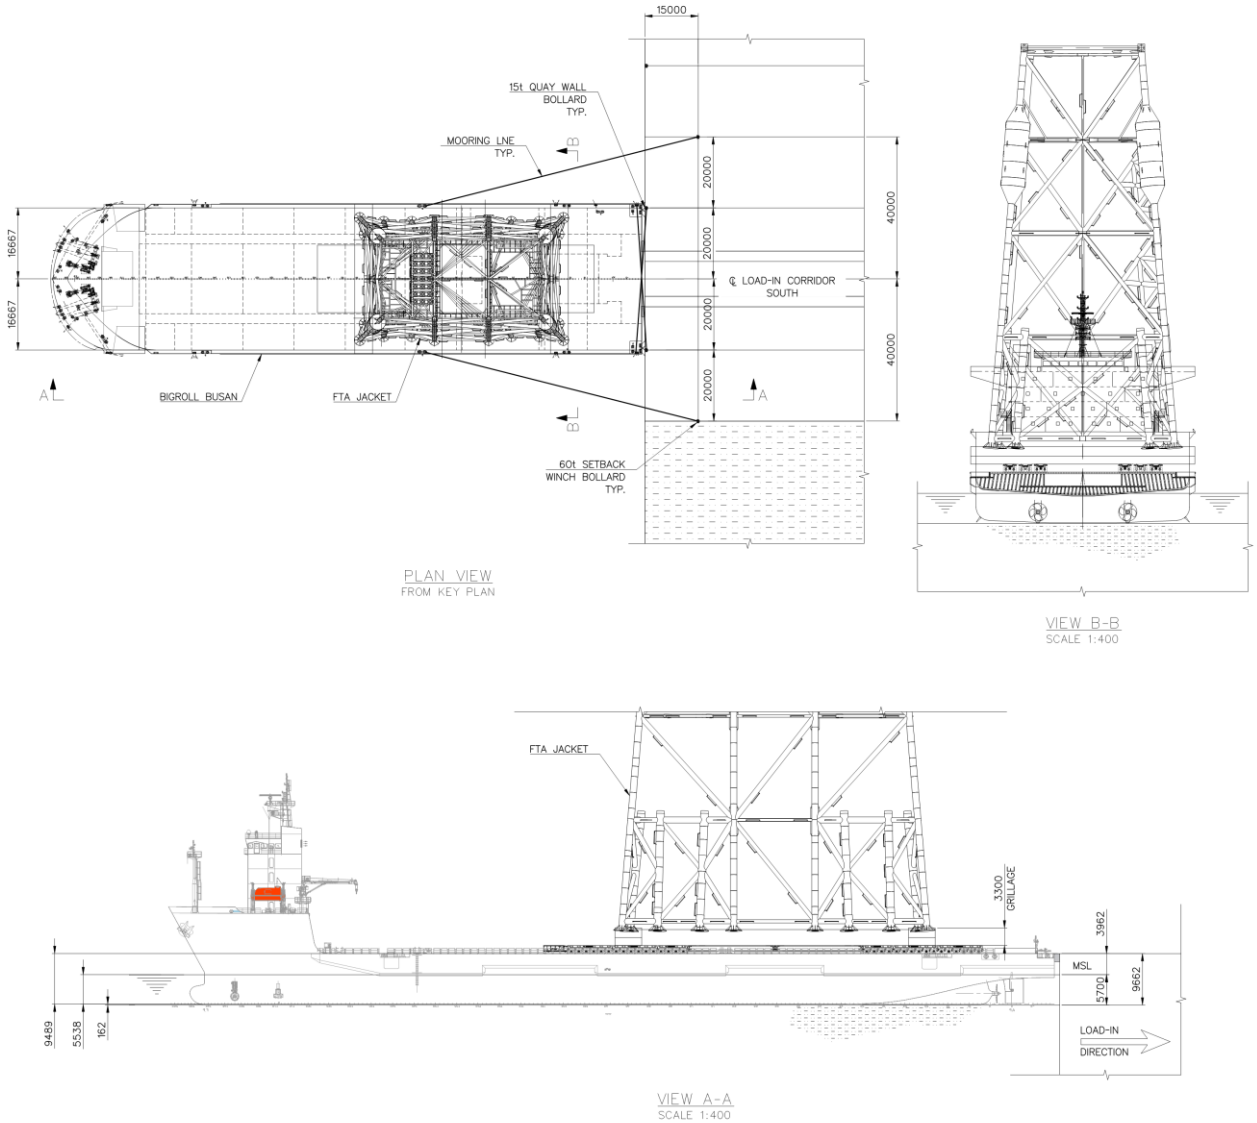

Figure 2-45 Example of a jacket loaded onto a HTV

Sea fastening will be used to secure the removed structures to prevent shift or loss during transit. There are anticipated to be approximately 26 transits between the transfer location and the ORC with HTVs/barges, however this number may vary as detailed execution planning progresses.

2.8.3 HLV mode change

As part of the HLV operations during Campaign #1, equipment on the HLV will need to be rearranged to change the topside lift system operating mode. Mode change activities consist mainly of alteration of lift points on the TLS for topside removal. HLV mode change activities may require the assistance of the *Fortitude* or similar vessel, a barge, tugs and/or a support CSV at a sheltered location.

2.8.4 Decision criteria - Transfer operations and HLV mode change operation

The selection of the location for each transfer within the OA, and for the one-off HLV mode change operation, will be based on the following decision criteria:

1. Water depth – The HLV requires a minimum water depth of 18 - 25m to safely operate – hence transfer operations and HLV mode change will not occur in water depths less than 18m.
2. Clear transfer and mode change area – The HLV will identify a clear area of at least a 500m radius so that the vessel can weathervane to the most favourable heading/weather condition. The clear transfer and mode change area will not contain:

- known shipwrecks protected under the *Underwater Cultural Heritage Act 2018* (Cth)
- underwater infrastructure (cables, pipelines, wellheads etc.) - which are marked on navigational charts
- additional Notices to Mariners which identify that other activities are occurring in the area.

3. Weather direction and sea state (wave height and period) – A location where predetermined weather and motion criteria can be met to ensure safe operations.
4. Proximity to the load in quay – A location that limits the weather exposed transport duration for HTV/barges to transfer to the Barry Beach Marine Terminal quayside to ensure safe transit during a continuous live lifting operation.

Figure 2-46 illustrates the areas in the OA, within which transfers and the mode change operation will occur.

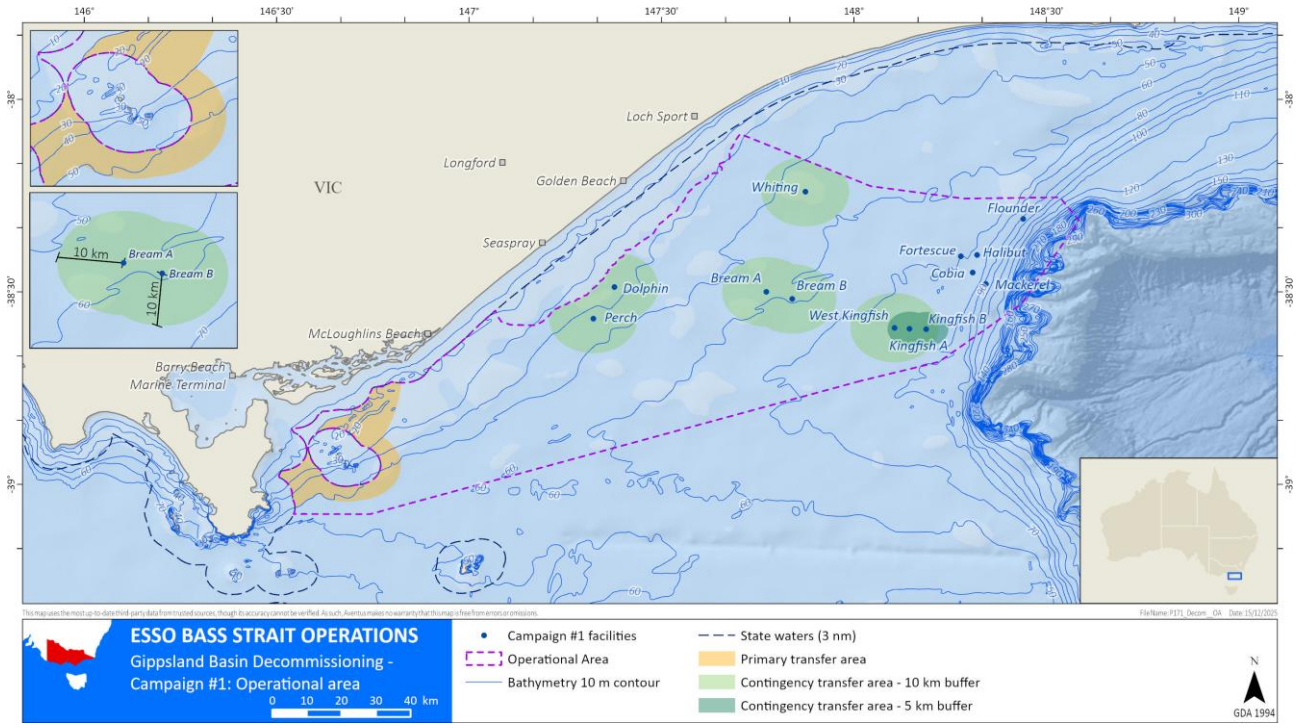

Figure 2-46 Primary and contingency transfer areas

2.8.5 Vessel safety-critical operations

Due to the nature of the decommissioning activities, where vessels will be used to lift and transport topsides and jackets, transfer the structures to a barge or HTV, transit to Barry Beach Marine Terminal and finally offload each structure via self-propelled modular transporters and set them down on their designated supports. Given each step of this process is weather constrained with limited safe stop intervals throughout each lift sequence, each removal lift is considered to be a vessel safety-critical operation. This means that, from the commencement of each lift sequence through to set down onshore, the lift is considered 'live' and expediting the sequence as efficiently as possible is critical to minimise the safety risk associated with weather changes.

For the purposes of Campaign #1 operations, vessel safety-critical operations are defined to commence once the HLV enters the 500m safety zone around each platform. The safety-critical operation will continue through transit with the load on the vessel through to backloading to the designated HTV/barge at the selected transfer location. Once the transfer is complete and the barge/HTV commences transit to Barry Beach Marine Terminal, the HTV remains part of the safety-critical operation until the HTV/barge is 500m away from the HLV after which the safety-critical operation remains only with the HTV/barge transit. The operations continue through to mooring at Barry Beach Marine Terminal, offloading the structure via self-propelled modular transporters and ends when the structure is safely set down in the final location at the ORC.

Throughout the safety-critical operation for each lift, as defined above, in order to minimise safety risk, the priority will be to ensure efficient operations to minimise exposure to weather. In addition, all vessels supporting the primary vessel/barge carrying the structures (such as support tugs etc.) will also be included in the safety-critical operations definition when they come within 500m of the primary vessel/barge carrying a structure.

2.9 BMB navigation aid installation

Following removal of the BMB topsides and the module support frame, a navigation aid will be installed on the concrete substructure, consistent with existing maritime requirements and recent discussions with AMSA.

The navigation aid will include two marine lanterns (for redundancy), both of which will be designed to have sufficient life for the time period between installation and the point at which decommissioning of the concrete substructure is carried out.

2.10 Sediment displacement/seabed disturbance

2.10.1 Monopod removal

In the removal of PCA and DPA there may be a requirement to displace some seabed sediments to remove the monopods. If required, this will be achieved via a water jetting method in a localised manner around the perimeter of each base to expose the underside or skirt. The material at the bottom of the monopods will need to be displaced by approximately 500mm below the current seafloor to expose approximately 100mm below the bottom of the skirt. Table 2-22 is a conservative estimate of the total cubic metres of seabed that may need to be displaced. During lifting, there will be suction between the seabed and the bottom of each monopod. This will also cause disturbance of sediment, also listed in Table 2-22.

Table 2-22 PCA and DPA sediment displacement estimates during water jetting and lifting

Facility	Estimated sediment volume (m^3)
DPA	Perimeter water jetting = 17m^3 total Suction/disturbance from lifting = 83m^3 total
PCA	Perimeter water jetting = 17m^3 total Suction/disturbance from lifting = 83m^3 total

2.10.2 Pipeline and riser cutting and removals

Other activities that may displace the seabed are subsea cutting and removal of primary and secondary pipelines and associated appurtenances such as sleds and bracing, risers and umbilicals as described in Section 2.7.7. Once cut, pipelines will have a plug installed as soon as practical to the end of the pipeline.

There may also be a need to displace seabed sediments to move any potential debris embedded in the seabed that may impede the cutting or lifting of pipelines. Estimates of sediment displacement vary based on the diameter of the pipeline or riser and condition of the local seabed (built up or not). The sediment displacement estimates presented in Table 2-23 are considered conservative because not all pipelines may be cut on the seabed. Table 2-23 is calculated based on cutting pipelines and risers at approximately 5m from the base of the jacket, where sediment displacement is more likely to be required. The estimated total displacement is less than 300m^3.

Table 2-23 Sediment displacement estimate per facility from pipeline cutting

Platform	Displacement estimates (m^3)	Platform	Displacement estimates (m^3)
PCA	5	WKF	27
DPA	5	KFA	27
WTA	5	KFB	47
BMB	Nil	CBA	5
FTA	3	MKA	11

Platform	Displacement estimates (m³)	Platform	Displacement estimates (m³)
FLA	5	HLA	57
BMA	47	**Total**	**244**

2.10.3 Jacket pile cutting

Where piles are not able to be cut internally, they will need to be cut externally, which may require sediment to be displaced for tooling access. Internal cutting is preferred to minimise sediment displacement however the cutting method will be considered on a case-by-case basis as described in Section 2.7.5.

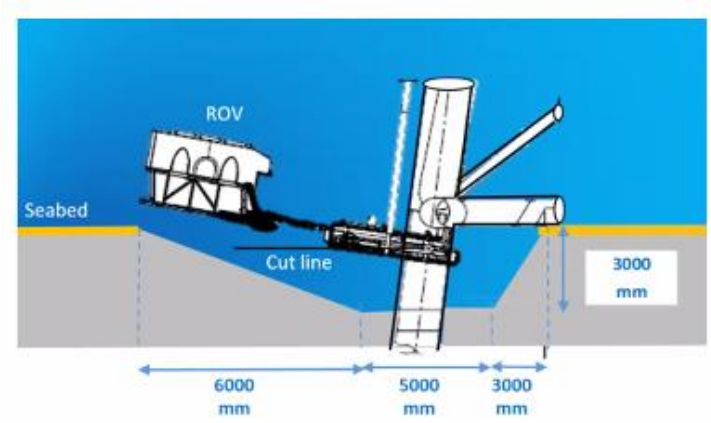

Figure 2-47 Indicative depiction of an external subsea cut below the seabed

Facilities such as FTA, BMA and WTA may be removed as close as practicable to the seabed, which may require external cutting. A conservative estimate for sediment displacement for external cutting of piles on these facilities is provided in Table 2-24. This estimate may reduce based on visual internal inspections of piles that will be conducted during the planning of removal operations at each facility. It may also increase by similar ratios if any other structures are decided to be cut as close as practicable to the seabed and internal cutting is not a practical solution.

There may also be a need to displace seabed sediments to move any potential debris embedded in the seabed that may impede the cutting or lifting of jackets.

Table 2-24 Pile cutting sediment displacement estimates for FTA, BMA and WTA

Facilities	Total	FTA	BMA	WTA
Number of piles	20	10	6	4
Estimated maximum sediment displacement (m³)	4760	2380	1428	952

2.10.4 Anchoring

There will be no planned anchoring of vessels within the OA. Vessels will only anchor if this is unavoidable in circumstances that are unplanned such as emergencies or when environmental conditions require. There is no plan to anchor barges or HTVs at the transfer location and during transfers, these will be tied/moored to the HLV to prevent excessive movement during transfer operations.

2.10.5 Temporary storage

Temporary subsea storage, or wet parking, may be required for items of removed infrastructure during Campaign #1. Temporary subsea storage will most often be planned in advance, however depending on operational requirements and circumstances, may be executed as an unplanned change and the activity managed through the temporary subsea storage register. Temporary subsea storage will occur within the PSZ of the facility and all items

temporarily stored on the seabed will be survey marked and recovered prior to completion of Campaign #1 activities, at a time that is suitable within the planned removal activities.

Examples of items that may be temporarily stored on the seabed include, but are not limited to, sections of supporting struts (present on KFA, KFB and HLA) which may be cut earlier in Campaign #1 by the CSV and temporarily stored on the seabed until lifted and removed by the HLV prior to the completion of Campaign #1 activities. Other items may include subsea equipment and flowlines and other jacket appurtenances. These items may be placed directly on the seabed or in a basket to aid recovery. The locations and description of items that require temporary storage will be recorded in the Campaign #1 temporary storage register. An ROV survey will be undertaken prior to items being placed on the seabed to ensure items are not placed on existing subsea infrastructure in the area.

The seabed disturbance footprint from temporarily stored items will depend on the size of the item, with the largest item being the struts present at KFA, KFB and HLA. The timeframe for temporary storage may be a number of months. The maximum seabed disturbance footprint associated with the placement of a strut on the seabed is 1800m^2, with the footprint of any other items placed considerably less than this.

In the unlikely event that smaller items of equipment listed in the Campaign #1 temporary storage register cannot be recovered within the Campaign #1 timeframe, these will remain in place and will be added to the Esso Subsea Material Register. Removal of these items will occur as soon as practicable as part of the broader Esso decommissioning program of work. This work will be completed in accordance with the process for ongoing removal of property within the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).

2.11 Prevention of dropped objects

2.11.1 Preparation of structures

The prevention of dropped objects from structures during lifting, transport and transfer operations will largely occur during facility preparation activities, carried out under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) which includes securing, removing and strengthening items as required to ensure topsides are made safe for removal and transport and any items that may become loose or sway are removed or securely fastened.

Dropped object prevention will also continue during removals preparations by the HLV contractor (refer to Section 2.7), with ROV surveys and inspections undertaken to identify any items that may become dropped objects during removal and transport. If potential dropped objects are identified, these will be risk assessed and may be:

- removed to the surface
- temporarily placed on the seabed (refer to Section 2.10.5)
- secured via subsea rigging or other support structures installed to hold items in place during lifting, transport and transfer activities.

2.11.2 Lift planning

A lift plan will be developed and in place prior to the lifting of each topside or jacket commencing. The lift plan details how the lifting operations should be undertaken, the equipment and accessories to be used, how the equipment and lifting accessories will be rigged up and the control measures in place to manage the risks (including dropped objects). The lift plan will be risk assessed as part of a HAZID assessment process. All lifts will be planned by a competent person. The competent person managing the lift operation will have adequate theoretical knowledge and practical experience of planning and executing lift operations.

Lifting and transfer of removed structures from the HLV or CSV to a barge is a vessel safety-critical operation (refer to Section 2.8.5). Prior to lifting operations (including transfer to a HTV or barge), weather conditions will be checked against the lift specific weather and vessel motion criteria and the decision to undertake (or delay) the lift will be made. If conditions are assessed as within the defined criteria, the structure will then be lifted per the lift plan. The location for the transfer operations will be selected per the decision criteria presented in Section 2.8.4.

2.11.3 Sea fastening

Sea fastening will be undertaken during facility and removal preparations to ensure the structure can be lifted safely, and also to secure the removed structures onto the CSV or HLV once lifted and also to the barges or HTV once transferred, to prevent shift or loss during transit. The most frequently used methods for sea fastening, securing and lashing are:

- welded sea fastening
- chains and wires
- heavy duty cargo straps.

The size, shape, condition and weight of the structure to be transported, the transport vessel type (HLV, CSV, HTV or barge) together with the expected weather and sea state environment within the OA will affect the selection of the most appropriate sea fastening method, which will be evaluated for each structure during detailed removal planning. Sea fastening requirements are determined in consultation with a Marine Warranty Surveyor to ensure they are fit for purpose in relation to the transport duration, design conditions and risk.

2.11.4 Execution planning

Detailed execution planning is underway to optimise the offshore execution sequence for the removal of all structures. This will ensure the facilities are removed in the least number of large structural sections. The use of the chosen HLV (Allseas *Pioneering Spirit*) minimises the number of lifts and transfers needing to be undertaken further minimising risk of dropped objects.

2.11.5 Recovery of dropped objects

In the unlikely event an object is dropped, all attempts will be made to recover the object during Campaign #1, hence any potential impacts would be temporary in nature. The location and particulars of all dropped objects would be documented on the Campaign #1 temporary storage register. If it is not safe and practicable to recover any dropped objects during the Campaign #1 timeframe, the details of these items will be recorded on the Esso Subsea Material Register, for removal as part of the ongoing property removal activities within the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).

In the extremely unlikely event of the loss of a larger structure, recovery may not be possible within Campaign #1 due to safety considerations, operational constraints, the availability of suitable equipment and the need for detailed planning and engineering to develop a safe and feasible recovery plan. A plan would be developed to include a timeframe for removal as soon as practicable. If the dropped structure was outside the existing facility locations (500m PSZ), appropriate measures would be taken to ensure the temporary presence of the structure is known to other users of the sea.

2.12 Planned discharges

All facilities will be free of bulk hydrocarbons from the main hydrocarbon systems; hydrocarbon processing, methanol and diesel systems, see Section 2.5, however there will be residual release of liquid and solid discharges.

Planned discharges will occur from:

- lifting the ODSPs and CDSPs
- removal of contents of the skirt piles by the use of an air lift tool
- small volumes of grout overflow during grouting of lift points at KFA and KFB
- small areas of marine growth removal during preparation activities (refer to Section 2.13)
- the cutting and removal of umbilicals
- the cutting and removal of pipelines and risers
- release of solids from cutting equipment and activities
- flooded member discharge
- JLSTs draining.

2.12.1 ODSPs and CDSPs

Prior to commencement of decommissioning activities that are part of the scope of this EP, Esso will conduct facility preparation works that includes de-inventory and cleaning of ODSPs and CDSPs. These facility preparation activities are covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) scope, however, description of this activity is relevant for this decommissioning Campaign #1 EP as residual fluids from the de-inventory and cleaning of ODSPs and CDSPs that may remain within these systems will be discharged to the sea during HLV lifting operations. Therefore, understanding of the planned discharges of residual fluids from ODSPs and CDSPs that may occur during Campaign #1 operations has informed the impact assessment presented in Section 6.9.

Facilities with ODSPs and CDSPs are KFA, KFB, FTA, FLA, WKF, CBA, MKA, WTA, BMA. De-inventory and cleaning works to be completed in these systems prior to the commencement of activities on each platform that are part of the scope of this EP include:

- de-inventory of pile residue oil
- high-pressure water jetting of pile walls and internal pipes
- purging of Generation 2 CDSPs (FTA, MKA, FLA, BMA, CBA, HLA, WKF) to dislodge entrapped hydrocarbons underneath internal structures and bring them to the surface for containment and disposal
- pump-out of internal fluids generated during the cleaning process, using a floating submersible pump
- removed oily fluids generated during the de-inventory and cleaning process may be directed to the platform pipeline to be managed onshore at the Longford Plant.

The de-inventory and cleaning process to be implemented aims at reduction in the concentration of hydrocarbons in water to the maximum extent practicable. Residual fluids that are expected to remain within these structures after this process has been completed will be discharged to the marine environment during lifting operations as part of the scope of works in this EP. Cleanliness targets are defined based on current best knowledge of the residual fluid characteristics. Consideration is also given to the specific characteristics of each system, as pile design has a significant influence on the cleanliness level that can be practicably achieved. For CDSPs and ODSPs, the following apply:

  - target cleanliness for all ODSPs and Generation 1 CDSPs (KFA/KFB) is 30ppm or diminishing returns[4]. A maximum volume lost has been calculated on the conservative assumption that 30ppm is uniform throughout the operating volume of the pile with an estimated total volume of residual oily fluids to be discharged of less than 1L per pile

- target cleanliness for Generation 2 CDSPs (FTA, MKA, FLA, BMA, CBA, HLA, WKF) is 250ppm or diminishing returns:
  - 250ppm has been selected as a conservative target, acknowledging the increased complexity of the internal configuration of the Generation 2 closed piles
  - a maximum volume lost has been calculated on the conservative assumption that 250ppm is uniform throughout the operating volume of the pile, with an estimated total volume of residual oily fluids to be discharged of approximately 50L per pile.
- ODSP and CDSP's will be left open to atmosphere and will free drain upon lifting.

Both the ODSPs and CDSPs have subsea windows where seawater can exit via displacement when hydrocarbons enter and where seawater can enter when hydrocarbons are pumped out. Although there is seawater exchange when operational, it is expected that water within the ODSPs and CDSPs will have become anoxic over time and have the potential for some rust deposits. Upon lifting there may be turbid, discoloured water discharged as well as the predicted residual hydrocarbon content.

As part of removals preparation activities, the status of structures post cleaning will be documented in a hazardous materials register for each facility which will be included in the Digital Decommissioning Management Tool. This register will be used to support verification of records of facility preparation activities.

2.12.2 Airlifting

In preparing the jacket leg skirt piles for internal cutting, an airlift tool will be used where necessary to remove obstructions and enable internal cutting. The air-lift tool has been designed to allow for the removal of subsea sediment from within a subsea structure using high pressure air. Compressed air is pumped subsea within the tool,

[4] For the purposes of this Section, diminishing returns is defined as when oil in water measurements taken during ODSPs and CDSPs de-inventory/cleaning process are within a nominated content band of measured OIW content. For the Generation 2 CDSPs, this correlates to five readings within a one hour period being within a 30ppm band as analysed by portable field instruments, or onshore laboratory where direct field measurement is not possible. For all other piles, this correlates to five consecutive hourly readings being within a 10ppm band as analysed by portable field instruments, or onshore laboratory where direct field measurement is not possible.

creating a venturi which allows for the sediment to flow up through the airlift tool and be deposited outside the pile. The airlift tool will be deployed via the aid of the vessel crane.

Inside the skirt piles is predominantly marine growth with some debris obstructions and potential for minimal sand and grout. The airlift tool will displace internal materials to the surrounding environment and deep within the piles as particulates settle. Harder materials may be displaced via a different high pressure water jetting tool in which case most of the materials will be captured within the pile. Larger obstructions may be retrieved via a fishing tool or will be pushed down within the pile below the cut height with a clump weight or similar.

It is likely airlifting will be required on FTA and BMA. There may also be a need to use the airlift tool on any other facility as required.

2.12.3 Grouting of lift points

For the KFA and KFB facilities, to enable the lifting of the topsides, prefabricated lifting points will be installed at designated locations around the nominated jacket legs. This activity will be undertaken as part of facilities preparation activities and is not part of the scope of this EP.

The final activity for installation of the lifting points is the injection of grout, which will be undertaken by Allseas as part of the CSV removals preparation campaign commencing in the third quarter 2026 and is within the scope of this EP. Injection of grout will be via grout inlets, with the grout spread and ancillary equipment set up on the CSV or the topsides for the grouting operations. Grout will be mixed and pumped into clamps sequentially by closing and opening the corresponding valves to the clamps on the manifold. Once overflow on top of the clamp is seen, grout lines will be closed off by closing the valves on the manifold.

On top of the clamp, there is a grout retaining ring (refer to Figure 2-48), which acts as a bund to contain the volume of grout that is left in the hose after the valves on the manifold are closed. This mitigates excess grout being discharged to the marine environment. It is estimated that less than 1t of grout will be discharged per lifting point at KFA and KFB. This estimated amount accounts for any minor overfill of the lifting point assembly as well as necessary draining and purging of installation equipment between lift point locations to prevent curing and fouling of the installation equipment. The cleaning and maintenance of the grouting equipment whilst at sea is critical to ensure no quality issues with subsequent installations.

Once filled with grout, the lifting points will be left to cure. Prior to lifting with the HLV, the grouted lifting points will be tested.

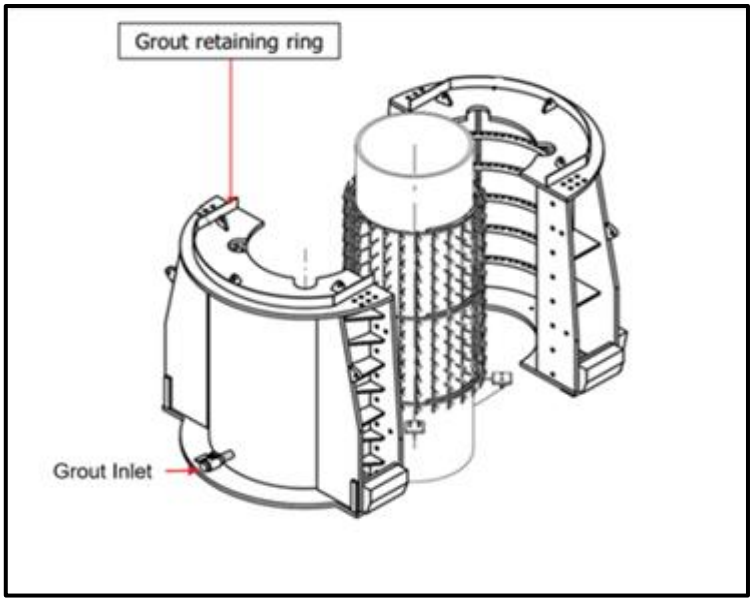

Figure 2-48 Depiction of the lifting point assembly

2.12.4 Umbilical cutting

Umbilicals will be cut on the topsides during the facility preparation phase under the *Bass Strait Environment Plan (AUGO-EV-EMM-012)*. Subsea umbilicals will be cut approximately 5m from the structures and the cut sections will be removed. The umbilicals may contain hydraulic fluids, corrosion inhibitor and pour point depressant.

Flushing of umbilicals during facility preparation activities under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) aims to displace and remove any bulk quantities of fluids inside the umbilicals. After this process is completed, there will be residual fluids remaining in these systems, some of which will be released during subsea cutting and removing a section of the umbilicals as part of the Campaign #1 removal activities covered within this EP.

Indicative volumes of residual fluids remaining in umbilicals that are part of the scope of the Campaign #1 EP are:

- KFA, KFB, WKF: approximately 40L each
- BMA: approximately 100L
- MKA: approximately 215L.

2.12.5 Pipelines and riser residual fluids

Flushing activities of pipelines and risers will be conducted under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) scope, prior to commencement of the removal activities. However, a description of this activity is relevant for this EP as residual fluids that remain inside these systems, after facility preparation works are completed, will be discharged to the sea during removal operations. Therefore, understanding of the planned discharges of residual fluids from pipelines and risers that may occur during Campaign #1 activities has informed the impact assessment presented in Section 6.8.

Before Campaign #1 activities, that are part of the scope of this EP commence, pipelines and risers connecting to platforms, that will be decommissioned as described in this EP, will be flushed. Fluids generated during this process are received onshore at the Longford Plant and are managed through Longford Plant's existing wastewater management practices.

After flushing of the pipelines and risers is completed, they will be filled with seawater treated with inhibitor to prevent corrosion and biofouling of these systems. It is expected that small concentrations of oily residues will remain in the pipelines and risers, with an estimated OIW content of <30ppm (refer to Table 2-25). In addition, these systems will be isolated to prevent ingress of contaminants post-flushing, to retain the cleanliness state achieved from the facility preparation activities until removal operations under the scope of this EP commence.

When cutting of pipelines is performed as part of the Campaign #1 EP scope, they will have a plug installed as soon as practical to the end of the pipeline but expected to be within seven days of the cut. Plugs will be an environmental cap on the end of the line that can withstand a nominal pressure and have a design life of approximately 10 years. In retrieving pipelines and risers to surface, there will be a release of residual pipeline and riser fluids. Table 2-25 presents an estimate of the volumes of residual fluids that may remain inside the pipelines after the flushing process is complete, and that is expected to be released to the marine environment during cutting and lifting operations. These volumes assume an OIW content target of <30ppm and a nominal cut location 5m horizontally outboard from jacket or pipeline connector. However, where not all prerequisite assessment criteria can be met due to specific constraints or practicability to confirm the <30ppm target, or where a diminishing return[5] assessment cannot be made, an alternate mode of cleanliness acceptance will consider the absolute hydrocarbon volume remaining in the pipeline. To achieve this, at least three OIW measurements will be made immediately prior to the conclusion of flushing operations to form the baseline of a structured risk screen or risk assessment including:

- calculated hydrocarbon volume left in the pipeline
- consequence of loss of this volume to sea at different times and events, considering:
    - oily water loss from topside riser cutting works for air gapping
    - oily water loss from subsea riser cutting works. (amount lost from riser and jacket removal, and amount lost from pipeline side prior to capping)
    - oily water loss from potential pipeline end states

[5] For the purposes of this Section, diminishing returns is defined as where OIW measurements taken during pipeline flushing show a slowing trend in reduction of measured OIW content. For pipelines this correlates to four readings within a one hour period being within a 10ppm band as analysed by portable field instruments, or onshore laboratory where direct field measurement is not possible.

- consideration of pipeline location relative to shore and potential area that may be affected.
- any mitigative actions available to further reduce OIW level.

Table 2-25 Pipeline and riser fluid release volumes

Facility	Pipeline	Section volume (m^3)	Oil @ 30ppm (L)	Inhibitor @ 2000ppm (L)

TOTAL		**163**	**5.5**	**326**

2.12.6 Jacket leg storage tanks

De-inventory and cleaning activities to prepare JLSTs for removal will be conducted on each applicable facility under the *Bass Strait Environment Plan (AUGO-EV-EMM-012)* scope, prior to commencement of facilities removal operations by the HLV. However, description of this activity is relevant for this Campaign #1 EP as residual fluids that remain in the JLSTs after the de-inventory and cleaning activities are completed will be discharged to the marine environment during HLV lifting operations. Therefore, understanding of the planned discharges of residual fluids from JLSTs that may occur during Campaign #1 activities will help inform the impact assessment.

Platforms where JLSTs are present include FTA, FLA, BMA, WKF, CBA and MKA. These tanks were used to contain diesel, glycol, methanol or potable water. A description of the type of product stored in JLSTs for each platform is shown in Table 2-26.

Table 2-26 JLST location and product stored

Facility	Product stored in the JLST			
	Diesel	Glycol	Methanol	Potable water
FTA	✓	X	X	✓
FLA	X	✓	X	✓
BMA	✓	X	X	✓
WKF	✓	X	X	✓
CBA	✓	X	X	✓
MKA	X	X	✓	✓

JLSTs used for storage of diesel, glycol and methanol will be de-inventoried in preparation for decommissioning activities and left open to the atmosphere via a dedicated vent line. Fluids removed during the cleaning process of the diesel and methanol JLSTs will be sent to the platform pipeline and then directed onshore to the Longford Plant. For the glycol JLST, residual fluids generated during the cleaning process will be stored in portable tanks and then transported onshore for management according to relevant waste management regulations. Fluids inside the tanks will be pumped out using a submersible pump, as far as practicable, however it is expected that a residual volume of fluids will remain at the bottom of the tanks.

The cleaning process for JLSTs that contained diesel, methanol or glycol consists of an initial de-inventory of fluids, followed by dilution using seawater, and then additional de-inventory of fluids generated during this process. For JLSTs used to store potable water, they will be drained and de-inventoried to as far as practicable using existing platform pumps, however no cleaning of these specific JLSTs is required prior to drainage.

In addition, after the topsides have been removed, JLSTs will be left open at the top, approximately 5m above MSL. This generates exposure of these structures to large waves that may result in ingress of seawater prior to the removal of the jacket at which the JLST is attached.

JLSTs have a sealed bottom which prevents drainage. Residual fluids, potable water or seawater that may remain inside these tanks after the de-inventory process is completed, must be allowed to drain/free flow from the tanks to the sea to avoid unintended added structural loads in the jacket during lifting operations. As a result, holes will be drilled at the bottom of the tanks to allow for this free flow of water and residual fluids from the tanks into the sea. Based on dilution calculations from the de-inventory process that will take place prior to removal operations, a conservative volume of residuals fluids of concern within the tanks is estimated to be <2L per tank for diesel (based on an estimated concentration of <30ppm), <10L for methanol, and <25L for glycol. For JLSTs used to store potable water, they will be drained and de-inventoried to as far as practicable using existing platform pumps, however there is no presence of potential contaminants of concern in these specific tanks.

As part of removals preparation activities, the status of structures post drain and de-inventory will be documented in a hazardous materials register for each facility. This register will be used to support verification of records of facility preparation activities.

2.12.7 Solids during cutting and lifting of jackets

There is steel shot and titanium-iron oxide mineral sand mix in several piles at KFA and KFB which has historically been used as structural ballast material. Prior to jacket cutting, the ballast material may need to be removed to allow the abrasive waterjet cutting tool to fit inside the pile. The method to remove the steel shot and titanium-iron oxide mineral sand mix is likely to be via the airlift tool or a suitable alternative. Given the proximity of this material mixed within the pile, it will not be possible to capture the steel shot and titanium-iron oxide mineral sand mix, and it will discharge to sea and dispersed, and will not be able to be recovered. Where external cutting is required, steel shot and titanium-iron oxide mineral sand mix will be released upon lifting where this material extends above the cut height. Indicative volumes are per Table 2-27.

During cutting operations metal particles will also be released to sea. Garnet will be used for high pressure water jetting. Indicative volumes of swarf and garnet are indicated in Table 2-27.

Table 2-27 Estimated mass of materials release to the environment as a result of removing facilities

Facility	Steel cuts m^3	Grout cuts m^3	Steel shot and titanium-iron oxide mineral sand mix (MT)*	Garnet m^3
KFA	0.03	0	48	0.9
KFB	0.03	0	27	0.9
MKA	0.03	0	0	0.5
WKF	0.02	0	0	0.5
FLA	0.03	0	0	0.5
FTA	0.04	0.09	0	1.9
HLA	0.04	0	0	1.9
WTA	0.01	0.01	0	0.5
CBA	0.02	0	0	0.5
BMA	0.02	0.07	0	1.9
Totals	0.27	0.17	75	10

*Aggregate composition assumed to be 50wt.% titanium-iron oxide mineral sand, 50wt.% steel shot for the purpose of weight calculations.

2.12.8 Discharge from other jacket structures

Selected structural members, such as legs and braces will have been intentionally flooded with seawater when the jackets where originally set down on the seabed. These members will free drain upon lifting out of the water. Prior to removal, some of these structures will require drilling of drain and vent holes to ensure the entrapped water drains relatively quickly, to limit additional weight of entrapped seawater during lift. Creating drain and vent holes will be assessed on a case-by-case basis. The water within the members is likely to have become anoxic over time. Upon lifting there may be discoloured water discharged.

2.13 Marine growth

Narrow bands of marine growth will be removed in the following instances as required to facilitate the safe and efficient removal of subsea materials:

- where subsea cutting or drilling will be performed
- in areas around the cutting elevation of both jacket legs, pipe work and appurtenances to allow installation of cutting tool
- at locations where subsea rigging may be attached
- at the location of the jacket that will make contact with the support saddles on the JLS beams during the lift
- in locations where detailed inspection is required or locations which require additional attention after the visual inspections
- in other locations that may be determined as required based on other potential impacts and risks relating to dropped marine growth during transportation of structures.

The removal of marine growth will be conducted by an ROV utilising an ROV-held flexiclean tool or marine growth removal tool via high pressure water jetting or other methods that may be identified.

2.14 Optional scopes

2.14.1 HLA removal of topsides and upper jacket sections

The scope of Campaign #1 may also include the removal of the HLA topsides and upper jacket sections (to at least 55m below MSL) which is not a facility included in the General Direction 817 compliance activities. This option is contingent on the plan for HLA to be retained in use to transport fluids generated by well P&As and flushing activities on the remaining producing platforms from offshore to Longford utilising the HLA600/650 pipeline. In the event this option is not executed as a part of this EP, the decommissioning of the HLA facility will be included in a future decommissioning EP.

2.14.2 Conductor removal

There may be a need to remove conductors as a part of Allseas removal activities to enable lifting of the topsides and jackets where this has not already been completed. Prior to the removal of topsides, obstructive conductors that were not able to be removed during the wells' P&A activity (covered in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) or a separate EP for Jack-Up Rig or MODU P&A activities) will be cut and removed, either as a single piece or as smaller pieces depending on final rigging and transportation planning.

During removal of the conductors, some external marine growth on the conductors is likely to be scraped off as each conductor passes through its individual guide on the conductor guide frame. A machine may also be positioned above the upper conductor guide frame, to clean out some of the external marine growth from the conductor as each is removed from its position, allowing easier handling during removal.

The conductor sections above sea deck may be lifted out and stored on the platform or pinned to the topside structure to be lifted with the topside. The water within the conductors is likely to have become anoxic over time. Upon lifting there may be discoloured water discharged.

2.14.3 Conductor stub removal

Similarly to conductor removal, there may be a need to remove conductor stubs as a part of Allseas removal activities to enable lifting of the topsides and jackets where this has not already been done as part of P&A activities covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012), a separate EP for Jack-Up Rig or MODU based P&A activities and the Well Operations Management Plan. To cut the conductor stubs an ROV with DWCM will be used to cut close to the conductor guide and be lifted to the surface.

2.14.4 Fortescue removal depth

The scope of Campaign #1 includes two options for the depth of removal of FTA. Option 1 is removal of the topsides and the jacket to as close as practicable to the seabed. This may be below, or just above the seabed, or Option 2 which is removal of the topsides and the jacket to a depth of at least 55m below MSL.

In both cases the depth of removal considers the need to ensure the jacket is removed to a depth safe for navigation. Option 1 allows for further structural engineering considerations for the safety and stability of the jacket lift and transport based on a number of factors including the position of bracing relative to the final cut positions. Further engineering is required before a final decision on the viability of each option can be fully assessed.

2.15 Waverider buoy installation

A temporary waverider buoy may be installed within the OA to provide field measurement of wave height and wave direction in real time. The purpose of a waverider buoy is to provide the Campaign #1 Project Management team with data to prepare for the removal works and also provide guidance to weather windows for removal activities. The optimal location(s) are yet to be determined but may be in any locations within the OA. A typical waverider buoy arrangement includes a buoy which floats on the ocean surface and a tether from the buoy to a clump weight which would be sitting on the seabed.

2.16 As left seabed surveys

An as left visual inspection of each Campaign #1 removal location will be undertaken by Allseas following the completion of removal activities. The purpose of the as left survey is to:

- confirm infrastructure has been removed as planned and in accordance with this EP
- document the general condition of any infrastructure remaining in place following removal activities (i.e. height above the seabed)
- verify that all pipelines and flexibles have been cut and plugged/capped as required
- verify that removal has taken place of any objects that may have been accidentally dropped during the removal activities or those documented in the Campaign #1 temporary storage register.

If the as left survey indicates that any infrastructure has not been removed as planned and in accordance with this EP, remediation plans will be developed by Allseas to rectify any differences as soon as practicable.

The as left survey will be undertaken by a suitable vessel utilising a variety of equipment such as seabed scanning, mapping, video and audio overlay using cameras mounted on an ROV.

The as left survey is expected to encompass a 50m perimeter around the removal locations. The as left survey will be undertaken as soon as practical after the removal of the facilities, with contingency to complete within the 12 months of completion of removals activities. An 'as removed' report will be generated following completion of the survey.

2.17 Facility status following Campaign #1 activities

As outlined in Section 1.2, following the completion of the Campaign #1 activities, PCA and DPA will be fully removed, while for all other facilities partial removal is anticipated, with lower jacket sections and the BMB concrete substructure remaining on the seabed. Decommissioning of the remaining lower jacket sections and BMB concrete substructure will be addressed in a future campaign covered by a separate EP submission, as described in Section 1.3.1.

A summary of the infrastructure and materials that will remain following Campaign #1 has been provided in Table 2-28. A detailed material weight breakdown (estimate) is provided in Table 2-29.

Environmental impacts and risks associated with the infrastructure and materials that will remain following Campaign #1 have been assessed in Section 6 and Section 7 of this EP where these may occur within the timeframe of this EP. These include:

- Physical presence – Interference to other marine users (Section 6.2)
- Physical interaction – Other users of the sea (Section 7.1).

The topsides and upper sections of the SPJs which may contain (or are coated with) contaminants such as splash zone coatings and integrated jacket leg tanks that have previously been used for hydrocarbon storage will all be removed as part of the activities within the scope of this EP. Hence the material that will remain following Campaign #1 is predominantly carbon steel and grout (in the annulus between the jacket), titanium-iron oxide

mineral sand contained within some piles and any remaining sacrificial anodes (which will continue to protect the jacket structure from corrosion until they are depleted).

Given the very slow degradation timeframe of the infrastructure that will remain following Campaign #1 (refer to Section 2.18), no impacts to the environment as a result of material degradation are anticipated within the timeframe of this EP. These impacts will be assessed in a future EP which would reflect the decommissioning approach for this infrastructure (including evaluation of any alternative arrangements).

Figures depicting the remaining lower jacket sections and BMB concrete substructure following Campaign #1 are included in Section 2.4.

Table 2-28 Infrastructure and material to remain post Campaign #1

Facility	Production Licence No.	Infrastructure to remain on title following Campaign #1	Material to remain on title following Campaign #1	Maximum height of remaining infrastructure to remain above seabed following Campaign #1 (m)
PCA	VIC/L17	• Debris (refer to Esso Subsea Material Register).	Potential for some grout to remain.	N/A
DPA	VIC/L15	• Debris (refer to Esso Subsea Material Register).	Potential for some grout to remain.	N/A
WTA	VIC/L02	• SPJ footings with a maximum height of 3m above seabed. • 4 piles extending to a maximum of 85m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms.	3
KFA	VIC/L07	• Lower section of SPJ. • Strut footings. • 20 piles extending to a maximum penetration of 156m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, titanium-iron oxide mineral sand and steel shot aggregate, rubber diaphragms, potential timber.	22
KFB	VIC/L07	• Lower section of SPJ. • Strut footings. • 20 piles extending to a maximum of 156m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, titanium-iron oxide mineral sand and steel shot aggregate, rubber diaphragms, potential timber.	23
MKA	VIC/L05	• Lower section of SPJ. • 16 piles extending to a maximum penetration of 102m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms, potential timber, remnant aluminium anodes.	38

Facility	Production Licence No.	Infrastructure to remain on title following Campaign #1	Material to remain on title following Campaign #1	Maximum height of remaining infrastructure to remain above seabed following Campaign #1 (m)
WKF	VIC/L07	• Lower section of SPJ. • 16 piles extending to a maximum of 103m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms, potential timber, remnant aluminium anodes.	21
FLA	VIC/L11	• Lower section of SPJ. • 16 piles extending to a maximum of 122m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms, potential timber, remnant aluminium anodes.	38
FTA	VIC/L05	Option 1: • SPJ footings with a maximum height of 3m above seabed. • 16 piles extending to a maximum penetration of 102m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms.	3
		Option 2: • Lower section of SPJ. • 16 piles extending to a maximum penetration of 102m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms, potential timber, remnant aluminium anodes.	14
HLA	VIC/L05	• Lower section of SPJ. • Strut footings. • 40 piles extending to a maximum penetration of 145m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, titanium-iron oxide mineral sand and steel shot aggregate, rubber diaphragms, potential timber.	18

Facility	Production Licence No.	Infrastructure to remain on title following Campaign #1	Material to remain on title following Campaign #1	Maximum height of remaining infrastructure to remain above seabed following Campaign #1 (m)
CBA	VIC/L05	• Lower section of SPJ. • 16 piles extending to a maximum penetration of 102m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms, potential timber, remnant aluminium anodes.	23
BMA	VIC/L13	• SPJ footings. • 12 piles extending to a maximum of 107m below the seabed. • Debris (refer to Esso Subsea Material Register).	Steel, grout, rubber diaphragms.	3
BMB	VIC/L14	• Concrete substructure, with navigation aid in place. • Perimeter rock berm. • Debris (refer to Esso Subsea Material Register).	Reinforced concrete, steel, wooden formwork, polystyrene, UPVC, GRP, HDPE, polyethylene, electrical components, aluminium alloy anodes, locally sourced rock	67

Table 2-29 Material weight breakdown for remaining SPJ's following Campaign #1 (estimates)

Facility	Total mass to remain (MT)	Mass to remain above seabed (MT)					Mass to remain below seabed (MT)			
	All materials	Steel	Grout	Anode	Steel shot and titanium-iron oxide mineral sand mix	Rubber with nylon fibre reinforcement	Steel	Grout	Steel shot and titanium-iron oxide mineral sand mix	Rubber with nylon fibre reinforcement

WTA	963	202	13	13	0	0.2	335	400	0	0.1

1 Estimates include SPJ, struts, strut footings (where relevant) and well conductors (above seabed, applicable for MKA and FTA only). Weight does not include marine growth present on the SPJ.

2 'Total mass to remain' includes above seabed and below seabed estimates following Campaign #1 activities.

3 Grout estimates for 'remain below seabed' are based on as-built pile arrangements drawings. Grout estimates do not include any additional grout flow not documented on the as-built drawings.

4 For anodes on FTA, CBA, MKA, WKF, FLA, BMA - maximum remaining anode material has been assumed at 25% from installation.

5 For anodes on WTA. Assume 90% of anode material remaining.

6 HLA, KFA, KFB - no sacrificial anodes.

7 MT = metric tonnes.

Table 2-30 Material weight breakdown for remaining BMB CGS following Campaign #1 (estimate)

Material	Mass to remain above seabed (MT)	Mass to remain below seabed (MT)	Total (MT)
Concrete	28,058	-	28,058
Reinforcing steel	4848	-	4848
Steel tendons	454	-	454
Ballast (ore-crete)	10,535	-	10,535
Wooden formwork	37	-	37
Anodes (aluminium alloy)	27	-	27
Steel*	262	-	262
Electrical components*	14	-	14
GRP (glass reinforced polyester)*	5.5	-	5.5
HDPE (High Density Polyethylene)*	3.3	-	3.3
UPVC (unplasticised polyvinyl chloride)*	0.7	-	0.7
Polystyrene	0.7	-	0.7
PE (polyethylene)	0.8	-	0.8

Material	Mass to remain above seabed (MT)	Mass to remain below seabed (MT)	Total (MT)
Rock berm	13,099	-	13,099
Steel skirts	-	93	93
Grout	-	1214	1214
All materials (total)	57,345	1307	58,652

*The majority of these materials/components are associated with the water ballast system, air vent system, grouting system and water evacuation system.

2.18 Ongoing management of partially removed facilities

Section 2.17 provides information on the expected 'as left' status of facilities following the Campaign #1 activities. As described in Section 1.2, management of the partially removed facilities that will remain until future removal (unless a satisfactory arrangement is agreed for the facility) is included within the scope of this EP, until such time as the Bass Strait Non-Producing Environment Plan is accepted. The acceptance of a satisfactory arrangement or 'end state' outcome for these facilities is not an activity within the scope of this EP.

Section 572(2) of the OPGGS Act requires a titleholder to maintain property in the title area in good condition and repair. NOPSEMA's policy on *Section 572 Maintenance and removal of property* (NOPSEMA, 2025b) states that property etc.:

> *"must be maintained in good condition and repair at all times. This includes, but is not limited to, ensuring that all elements of the property etc. continue to be regularly inspected, monitored, maintained and repaired where necessary so that it can be removed in a safe and environmentally responsible manner unless other satisfactory arrangements have been accepted by NOPSEMA under 572(7)."*

This Section outlines the proposed management of the partially removed facilities to ensure their future removal in accordance with the timeframes proposed in Section 1.3.1.4 is not precluded. Pipelines and umbilicals that have been cut to enable the facilities to be removed in Campaign #1 will continue to be managed per the IMR requirements detailed in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).

The Facility Integrity Management System (FIMS) is used to manage the IMR of facilities regardless of producing or non-producing status. For the partially removed facilities which will remain in place following Campaign #1, the focus of IMR activity is structural integrity, navigation lights and cathodic protection systems where these are applicable.

The structural integrity objectives for the partially removed facilities are:

- the facility remains sufficiently robust to withstand anticipated environmental loads such as wind, wave and seismic loads until removal
- the facility remains in a condition that enables its removal in accordance with the proposed timeframes provided in Section 1.3.1.4 (unless a satisfactory arrangement is agreed for the facility).

IMR for partially removed facilities will continue to be managed in accordance with FIMS equipment strategies. . Planned maintenance activities are not undertaken, however surveillance activities are completed, including underwater inspections as required.

2.18.1 Partially removed steel piled jackets

Each jacket structure, post installation, has maintained integrity through the use of an active ICCP system, which by means of regular monitoring, confirmed the ICCP remained sufficiently active. Following completion of Campaign #1 removal activities there will be no actively maintained cathodic protection of the steel piled jacket sections that remain on the seabed. A material degradation study to investigate the anticipated rate of degradation of the key SPJ constituents (steel and anodes) in the marine environment was commissioned by Esso in 2021/2022. The methodology and results of this study are discussed in the following sections to provide information on the anticipated degradation process and timelines once the cathodic protection is no longer active.

2.18.1.1 Material degradation study

The material degradation study used available information to establish degradation rates for the SPJ structural components and included the scenario of the lower jackets remaining on the seabed, cut at a depth of 55m below MSL. As part of the study, degradation of the remaining lower jacket sections and anodes was investigated with likely long term corrosion rates and the time to significant local wall thickness loss defined. The output of the material degradation component of the study was then used as input into an environmental impact assessment of long term degradation of the steel and anode constituents. The material degradation component of the study is discussed further in this section.

The Campaign #1 jackets were classified into three groups following a review of data such as structural drawings, structural analysis and inspection reports. The grouping criteria included platform generation (when the platform was installed), water depth and framing/pile arrangements. Representative SPJs from each group were then chosen to be assessed in detail and the results applied to the other SPJs in the group on the basis that differences

between the jackets were unlikely to affect the overall degradation timeline. Table 2-31 summarises the groupings, with the SPJs chosen to be studied in detail highlighted in **bold**. WTA is not discussed further in this section - as per the scope of this EP, this facility will be removed to as close as practicable to the seabed.

Table 2-31 SPJ groupings for material degradation study (Kent Plc, 2022)

Classification	Name	Installed	Water Depth (m)	Structure Type	Corrosion Protection System	Strut installed?
1st Generation	**HLA**	**1968**	**73**	**8 leg SPJ with skirt piles (twin jacket)**	Impressed current cathodic protection	Yes
	KFA	1969	77	8 leg SPJ with skirt piles		
	KFB	1969	78			
2nd Generation	MKA	1976	93	8 leg SPJ with skirt piles	Sacrificial anode cathodic protection with impressed current cathodic protection retrofit	No
	FLA	1983	93			
	WKF	1981	76			
	CBA	**1982**	**78**			
	FTA	1982	69			
	BMA	1987	59			
Post 2nd Generation	**WTA**	**1989**	**54**	4 leg SPJ	Sacrificial anode cathodic protection	No

Once the topsides and upper jacket sections are removed, the overall corrosion (degradation) of the lower jacket sections is predicted to occur in 4 phases (Kent Plc, 2022).

- Phase 1: Demise of Cathodic Protection

MKA, WKF, CBA, FLA, FTA and BMA were all installed with sacrificial anode cathodic protection (SACP) systems before a subsequent retrofit with an ICCP system. Residual anodes associated with the initial SACP systems are expected to be in place on the jacket structures. Once the ICCP systems are disconnected, these residual anodes will reactivate until they are fully consumed. Once these anodes are fully consumed, the jacket steel will commence its degradation process. Cut ends of the jacket structure that will be exposed to seawater for the first time may receive some initial protection from the residual anodes.

- Phase 2: Depolarisation

Once cathodic protection has ceased completely, which will either occur once the residual anodes are consumed (for those jackets with remaining sacrificial anodes) or immediately following the removal of the ICCP system on those jackets with no sacrificial anodes present, a period of depolarisation will occur where the surface potential of the jackets returns to 'free corrosion' potential.

- Phase 3: Coating/surface deposit loss

Scale deposits on the jackets, which formed due to the elevated pH of the jacket surfaces during the time cathodic protection was active, will dissolve.

- Phase 4: Free corrosion

Once the residual protection has depleted and surface deposits have dissolved, the steel jacket will begin to corrode, with the long term corrosion rate dependant on a number of factors which have been taken into account in the degradation study, such as exposure to seawater (i.e. internal surfaces are less exposed), dissolved oxygen, and biological influences (marine growth).

Technical references utilised in the *Gippsland Decommissioning Project Campaign 1, SPJ – Rate of Degradation Study* (Kent Plc, 2022) to establish corrosion rates for the varying structural components included:

- *Corrosion in Seawater* (Dexter, 2006)
- *Corrosion of metals and alloys in the deep ocean* (Reinhart, F M, 1976)
- *Materials Selection* (NORSOK, 2014)
- *Long term degradation of offshore structures and pipelines: decommissioned and left in-situ* (OGUK, 2013).

A number of long-term corrosion mechanisms were considered to determine applicable corrosion rates for the various structural components. Of all the mechanisms, direct exposure to open seawater produced the highest potential rate of corrosion of the steel at 0.1mm per year with a potential for local pitting at a rate of 0.2mm per year (Kent Plc, 2022). A further literature review of factors impacting steel corrosion in seawater concluded that the rate of 0.1mm per year represents the higher end of the range of expected corrosion values at similar field conditions and average water temperatures (approximately 12°C) (Mutch Associates, Windward Environmental, EcoTox, and Barr Engineering, 2023).

The corrosion rates were used to establish the time to wall perforation and loss of overall structural integrity. Reported structural integrity anomalies such as weld defects, member thickness loss and/or physical damage were considered in the assessment. While these anomalies may accelerate local areas of failure, they were not deemed to be extensive or significant enough to change the outcome of the overall degradation timeline. The detailed assessment of the CBA and HLA SPJs for the removal to at least 55m below MSL scenario identified that:

- The hydrodynamic, or environmental load (using 100 year storm conditions, combined wave and current loading) is insignificant, hence was not considered in the development of degradation timelines for the jackets remaining on the seabed;
- the first significant degradation (the potential initial failure of the smallest jacket components) is predicted to occur within the range of 50 - 100 years for HLA and 60 - 120 years for CBA following the removal of cathodic protection.

Based on the outcome of the degradation assessment, there will be no significant degradation in the interim period following the completion of Campaign #1 and the removal of these sections to the seabed in accordance with the timeframes proposed in Section 1.3.1.4 will not be precluded. Hence no scheduled maintenance and repair is planned for the lower sections of the jackets during this period. Surveillance of the lower jacket sections (including underwater inspections) will continue to be undertaken in accordance with the FIMS equipment strategy.

Movement of the lower jacket sections away from their decommissioned locations (which will be marked on navigational charts to ensure other users of the sea are aware of their ongoing presence) is not considered credible due to the design of the structures to withstand extreme weather and current conditions (deep piles extending up to 156m below the seabed secure the structures).

Targeted inspections/surveys will be undertaken of these lower sections when planning removal execution. As detailed in Section 1.3.1.4, these are expected to commence from 2030. These inspections will provide validation of the assumptions made regarding the degradation of the partially removed facilities and allow determination of the safest and most environmentally responsible removal methodology.

As described in Section 1.3.1.3, the full removal of the lower jacket sections is not precluded regardless of the integrity of the structure, as the removal methodology can be adapted to remove the lower sections in smaller pieces to ensure compliance with Sections 572(2) and (3).

2.18.2 BMB concrete substructure

As depicted in Figure 2-32 the BMB concrete substructure will also remain in place following removal of the topsides and module support frame during Campaign #1.

An independent assessment completed in 2022 (Olsen, 2022) determined that the estimated remaining life of the BMB concrete substructure is in excess of 120 years, provided that the cathodic protection system continues to

operate as designed. The cathodic protection system for the substructure currently relies on a large number of sacrificial anodes, which were installed during the construction of the substructure in Port Kembla (New South Wales). An assessment completed in 2024 (Corrosion Control Engineering, 2024) has confirmed that the remaining anode material (on the anodes) external to the drill shaft is adequate to fully protect the external surface of the structure for in excess of another 10 years. However, the anodes internal to the drill shaft have been more significantly depleted and therefore additional anodes will be installed (prior to removal of the topsides) in order to extend the life of this portion of the cathodic protection system for an additional 10 years. As part of this retrofit work, a cathodic protection remote monitoring system (operated via satellite signal) will also be installed, so that the continued operation of the cathodic protection system within the drill shaft can be monitored on an ongoing basis, without the need for any personnel to physically board the facility once the topsides are removed.

Based on the long period of time determined by the independent assessment before any structural degradation occurs, during the interim period between the completion of Campaign #1 and the implementation of the final end state for the substructure, the IMR that will be undertaken is expected to be routine general visual inspections of the concrete substructure, at an interval to be defined in the revised equipment strategy that will be developed following removal of the topsides. Risk based inspections/surveillance will continue to be managed via the electronic maintenance management system, International Production Enterprise System (or IPES).

The navigation aid (including a redundant second marine lantern) that will be installed on the concrete substructure (following removal of the topsides) as described in Section 2.9, will also be designed to have at least a 10-year design life and will have remote condition monitoring and operation via satellite signal. The BMB navigational aid configuration and type has been discussed and agreed with AMSA.

3 Description of the environment

To set the environmental context required to assess impacts and risks associated with the petroleum activities described in this EP, two areas have been identified:

- **Operational Area (OA)** – the area within which the activities addressed by this EP will be undertaken.
- **Environment that May Be Affected (EMBA)** – Determined by oil spill modelling and is the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, as a result of 100 individual hydrocarbon spill simulations for various scenarios. Then, these results are combined to identify the largest envelope in which a single spill is predicted to occur. This worst-case assessment of a potential spill scenario covers the largest offshore area, extending beyond potential areas that may be affected by other aspects such as noise, and light emissions during Campaign #1 activities.

3.1 Operational Area

As described in Section 2.2.1 and shown in Figure 2-2, the OA for this EP is an area encompassing:

- the PSZ around the facilities that are part of the Decommissioning – Campaign #1 scope, including WTA, PCA, DPA, BMB, FTA, MKA, FLA, BMA, KFA, KFB, WKF, CBA and HLA
- the area within which the HLV and CSVs will operate when transporting the removed topsides and sections of jackets from the PSZs to a sheltered weather location closer to the Corner Inlet shipping channel so that removed topsides and sections of jackets can be transferred from the HLV or CSV to receiving barges or HTV.

The OA is situated entirely within Commonwealth waters. Transport of structures to an onshore reception centre following transfer to a barge or a HTV is not considered a petroleum activity for the purpose of this EP.

3.2 Environment That May Be Affected

The EMBA for Campaign #1 activities has been defined using the outcomes from the spill modelling exercises as described in Section 7.8. Results from these spill modelling reports determined the total area that could be exposed to hydrocarbons, including trace concentrations of oil in the water column, as a result of worst-case spills from decommissioning activities within the OA. This EMBA is used for planning purposes to ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the EP.

Using the results of the oil spill modelling report (RPS, 2024), the boundary of the EMBA is defined as:

The combined extent of oil exposure to the sea surface (≥1g/m^2), accumulated on shorelines (≥10g/m^2), entrained in the water column (≥10ppb) and dissolved in the water column (≥10ppb) as a result of a release of 1665m^3 of MGO (over 12 hours) from the *Pioneering Spirit* and from a release of 280m^3 of MGO (over 6 hours) from a support vessel during transfer operations, for an unplanned release event within the OA using annualised metocean conditions Following best practice, thresholds selected for identification of the EMBA are the low thresholds or low exposure values. The low thresholds may not be ecologically significant, however, they provide a conservative predictive approach to inform the outer boundary for potential contact or presence of oil and allow for an adequate risk assessment and emergency preparedness and response planning. It is important to note that the EMBA defined for Campaign #1 represents the outcome from the overlap of hundreds of different spill modelling outcomes (stochastic modelling). As such, the area potentially affected by a single spill event will be significantly smaller than the area defined as the EMBA for Campaign #1 activities.

The description of the EMBA is provided in Appendix A. Further information on the hydrocarbon thresholds, or exposure levels used to define the EMBA are shown in Table 3-1.

Table 3-1 Thresholds used to define the EMBA (NOPSEMA, 2019a)

Exposure level	Threshold	Description
Surface – Low exposure	1g/m^2	Approximates the range of socioeconomic effects and establishes the planning area for scientific monitoring.
Shoreline – Low exposure	10g/m^2	Predicts potential for some socioeconomic impact.

Exposure level	Threshold	Description
In-water (dissolved) – Low exposure	10ppb (instantaneous)	Establishes the planning area which may be considered for scientific monitoring based on the potential for exceedance of water quality triggers.
In-water (entrained) – Low exposure	10ppb (instantaneous)	Establishes the planning area which may be considered for scientific monitoring based on the potential for exceedance of water quality triggers.

3.3 Values and sensitivities

The values, sensitivities and receptors found within the OA are described in Table 3-2. The values, sensitivities and receptors found within the EMBA are described in Appendix A.

EPBC Act listed species identified for the OA and EMBA are provided in Appendix B. EPBC Act PMST Reports for the OA and EMBA are presented in Appendix C and Appendix D respectively.

Any receptor listed within the PMST report (Appendix D) that was either outside the extent of the EMBA or a terrestrial feature has not been described within this EP.

Table 3-2 Values and sensitivities within the OA

Value/sensitivity	Receptor	Description
Protected matter		
World Heritage	-	World Heritage Listed Properties are sites that represent the best examples of the world's cultural and heritage values, of which Australia has 20 properties (DCCEEW, 2024a). In Australia, these properties are protected under Chapter 5, Part 15 of the EPBC Act. There are no World Heritage Properties within or adjacent to the OA. The closest World Heritage Property is the Royal Exhibition Building and Carlton Gardens which is located approximately 180km northwest of the OA. There are no World Heritage-listed places intersected by the EMBA, as described Section A.1.1.1 of Appendix A.
National Heritage	-	The National Heritage List is Australia's list of natural, historic, and Indigenous places of outstanding significance to the nation (DCCEEW, 2024b). These places are protected under Chapter 5, Part 15 of the EPBC Act. There are no National Heritage-listed places within or adjacent to the OA. The closest National Heritage Place is the Australian Alps National Parks and Reserves (onshore), which is located approximately 95km north the of OA. There are no National Heritage-listed places intersected by the EMBA, as described in Section A.1.1.2 of Appendix A.
Wetlands of International Importance (Ramsar wetlands)	-	Australia has 67 Ramsar wetlands that cover more than 8.3 million hectares (DCCEEW, 2022a). Ramsar wetlands are those that are representative, rare, or unique wetlands, or are important for conserving biological diversity, and are included on the List of Wetlands of International Importance developed under the Ramsar Convention. These wetlands are protected under Chapter 5, Part 15 of the EPBC Act. There are no Ramsar wetlands within the OA. The closest Ramsar wetland is Corner Inlet, which is located approximately 5.8km north of the OA. Ramsar wetlands intersected by the EMBA are described in Section A.1.1.4 of Appendix A.

Value/sensitivity	Receptor	Description	
NIWs		NIWs are considered significant for a variety of reasons, including their importance for maintaining ecological and hydrological roles in wetland systems, providing important habitat for animals at a vulnerable or particular stage in their life cycle, supporting 1% or more of the national population of any native plant or animal taxa or for its outstanding historical or cultural significance (DCCEEW, 2021a). There are no NIWs within the OA. The closest NIW is Corner Inlet, which is located 5.8km north of the OA. NIWs intersected by the EMBA are described in Section A.1.1.5 of Appendix A.	
Listed threatened species and listed migratory species (listed in Appendix B, described in Appendix A)	Fauna	Threatened species (Appendix B)	
		Total threatened species Critically endangered Endangered Vulnerable Conservation dependent	44 2 10 26 6
		Listed migratory species	
		Total migratory species Fish – Bony (Appendix B Table B-1) Fish – Cartilaginous (Appendix B Table B-2) Birds (Appendix B Table B-3) Mammals – Cetaceans - (Appendix B Table B-4) Mammals – Pinnipeds (Appendix B Table B-5) Mammals – Sirenia (N/A) Mammals – Reptiles (turtles) (Appendix B Table B-6)	45 - 6 25 11 - - 3
Biologically Important Areas (BIAs)	Marine fauna	BIAs are areas where a protected species display biologically important behaviours such as breeding, foraging, resting and migration. These areas serve to highlight parts of a marine region that are particularly important for the conservation of protected species (DCCEEW, 2021b). The following 14 BIAs are within the OA. The BIAs within the EMBA are outlined in Appendix A.	
		Species	BIA type
		Birds (Appendix B Table B-3)	

Value/sensitivity	Receptor	Description	
		Antipodean albatross (Figure 3-3)	Foraging
		Black-browed albatross (Figure 3-1)	Foraging
		Buller's albatross (Figure 3-1)	Foraging
		Campbell albatross (Figure 3-1)	Foraging
		Common diving-petrel (Figure 3-2)	Foraging
		Indian yellow-nosed albatross (Figure 3-1)	Foraging
		Short-tailed shearwater (Figure 3-2)	Foraging
		Shy albatross (Figure 3-2)	Foraging likely
		Wandering albatross (Figure 3-2)	Foraging
		White-faced storm-petrel (Figure 3-3)	Foraging
		Sharks (Appendix B Table B-2)	
		White shark (Figure 3-6)	Reproduction and foraging
		Whales (Appendix B Table B-4)	
		Pygmy Blue Whale (*Balaenoptera musculus brevicauda*) (PBW) (Figure 3-4)	Foraging
		Southern Right Whale (*Eubalaena australis*) (SRW) (Figure 3-5)	Reproduction and migration
Listed TECs	-	An ecological community is a naturally occurring group of native plants, animals and other organisms that are interacting in a unique habitat. TECs are a MNES under the EPBC Act. TECs provide wildlife corridors and/or habitat refuges for many plant and animal species, and listing a TEC provides a form of landscape or systems-level conservation (including threatened species) (DCCEEW, 2022b). There are no TECs within the OA. TECs intersected by the EMBA are described in Section A.1.1.6 of Appendix A.	
Australian Marine Parks (AMPs)	-	AMPs are areas established to help conserve the marine environment. AMPs have natural, cultural, heritage and socio-economic values. These values are defined as: • natural values - habitats, species and ecological communities, and the processes that support their connectivity, productivity and function • cultural values—living and cultural heritage recognising Indigenous beliefs, practices and	

Value/sensitivity	Receptor	Description
		obligations for Country, places of cultural significance and cultural heritage sites • heritage values—non-Indigenous heritage that has aesthetic, historic, scientific or social significance • socioeconomic values—the benefits for people, businesses and/or the economy (Australian Marine Parks Science Atlas, 2024). There are no AMPs within the OA. The closest AMP is Beagle AMP which is located approximately 2.5km south of the OA. AMPs intersected by the EMBA are described in Section A.1.1.7 of Appendix A.
KEFs	Upwelling East of Eden (Figure 3-7)	KEFs are components of the marine ecosystem that are considered to be important for biodiversity or ecosystem function and integrity of a Commonwealth marine area (DCCEEW, 2021b). The Upwelling East of Eden is present along the eastern Victorian and southern New South Wales. Dynamic swirls of the East Australian Current cause episodic productivity events when they interact with the continental shelf and headlands. The episodic mixing and nutrient enrichment events drive phytoplankton blooms that are the basis of productive food chains including zooplankton, copepods, krill, and small pelagic fish. Therefore, the key value of the KEF is its high productivity and aggregations of marine life (DoE, 2015a). The upwelling contributes to regionally high primary productivity which supports fisheries and biodiversity, including top order predators, marine mammals, and seabirds. This area is one of two feeding areas for blue whales and humpback whales, that are known to arrive when significant krill aggregations form. The area is also important for seals, other cetaceans, sharks, and seabirds (DoE, 2015a). KEFs intersected by the EMBA are described in Section A.1.1.8 of Appendix A.
	Shelf rocky reefs (and hard substrates)	Rocky reefs and hard grounds are located in all areas of the South-east Marine Region continental shelf, including Bass Strait, from the sub tidal shore to the continental shelf break, which generally occurs in 50m to 150-220m water depth (DoE, 2015a) Rocky reefs and hard substrate provide attachment sites for macroalgae and sessile invertebrates, increasing the structural diversity of shelf ecosystems, as well as providing habitat and shelter for fish. This is important for aggregations of biodiversity and enhanced productivity (DoE, 2015a). There is no mapping or graphic representation on the exact locations where this KEF has been confirmed to be present based on information available from the South-east marine regional profile (DoE, 2015a) and the South-east Marine

Value/sensitivity	Receptor	Description
		Parks Network Management (Director of National Parks, 2025). Historical ROV surveys of platforms (from Esso ROV inspection data from 2010, 2013 and 2014) have not detected variances in abundance of biota on the seabed surrounding the platforms that are within the scope of this EP, which may be indicative of hard substrates occurring. The South-east reef is mapped to exist in the VIC/L5 area and thought to possess some low-relief limestone reef features (Bax & Williams, 2001). The reef is situated in approximately 70 metres water depth, with the nearest SPJs to this feature being FTA, CBA and HLA (McLean, et al., 2022). Figure 3-7 shows known locations of hard substrate and rocky reefs in the OA that are considered to meet the definition of this KEF - based on information available from government agencies, literature, and ROV data from Esso operations in the Bass Strait.
Other protected areas		
Social/cultural/ conservation	National parks and reserves	There are no national parks or reserves within the OA. The closest protected area is Wilsons Promontory National Park, which is located approximately 6km west of the OA. National parks and reserves intersected by the EMBA are listed in Section A.1.1.9 of Appendix A.
Commonwealth Heritage Listed places	-	Commonwealth Heritage Listed places are Indigenous, historic, and natural heritage places owned or controlled by the Australian Government. These include places connected to defence, maritime safety, communications, customs, and other government activities that also reflect Australia's development as a nation (DCCEEW, 2021c). There are no Commonwealth Heritage Listed places within the OA or EMBA (identified Commonwealth heritage places were identified as terrestrial features or outside of the EMBA).
Underwater Cultural Heritage	Historic shipwrecks, sunken aircraft and First Nations UCH. (Figure 3-8)	Historic shipwrecks and sunken aircraft, including associated artefacts that have been in Australian waters more than 75 years, are subject to automatic protection under the UCH Act (DCCEEW, 2024f). In addition, some protected UCH may have a declared protection zone that limits access and is regulated via a permitting regime (DCCEEW, 2024f). The *SS Glenelg* shipwreck and its protection zone are located just outside the OA (see Figure 3-8). There are no other protection zones or declared protected maritime UCH sites within the OA. Protection zones intersected by the EMBA are identified in Section A.1.5.2 of Appendix A.

Value/sensitivity	Receptor	Description
		Historic shipwrecks are located all along the Australian coastline, with numerous shipwrecks located within the Gippsland region. The following shipwrecks are within the OA (refer to Figure 3-8): • City of Hobart (1877) • Dunkeld (1870) • Favourite (1852) • Rembrandt (1861) • Struan (1856) • *Talark* (n.d).
Environmental values – Other		
Physical environment	Climate and meteorology	Climate statistics from 1991-2020 at East Sale (Victoria) (the closest weather station to the OA) has average monthly minimum temperatures ranging from 3.6°C – 13.6°C and average monthly maximum temperatures ranging from 14.2°C - 26.1°C with January hosting the hottest temperatures and July the coolest. Rainfall ranges from 33.4mm in May (lowest) to 62.2mm in November (highest) (BOM, 2025). Wind speeds for East Sale between 1991 - 2010 range from 11.1 - 16.3km/hour in the morning and 17.1 - 24.2km/hour in the afternoon, with maximum gusts reaching 152 km/hour. Bass Strait is located on the northern edge of the westerly wind belt known as the Roaring Forties. Occasionally, intense meso-scale low-pressure systems occur in the region, bringing very strong winds, heavy rain and high seas. These events are unpredictable in occurrence, intensity and behaviour, but are most common between September and February (McInnes & Hubbert, 2003).
	Oceanography	Wind driven currents in Gippsland Basin can be caused by the direct influence of weather systems passing over Bass Strait (wind and pressure driven currents) and the indirect effects of weather systems passing over the Great Australian Bight (Global Environmental Modelling System, 2005). The eastern parts of the region are strongly influenced by the East Australian Current that flows southward adjacent to the east coast of New South Wales, Victoria and Tasmania, carrying warm equatorial waters and forming eddies which in turn cause upwellings. At the shelf break east of Bass Strait, nutrient-rich waters rise to the surface in winter as part of the processes of the Bass Strait Water Cascade creating an area of high productivity. Further offshore currents are driven by the Sub-Antarctic Water movement, coming from the south, and the Bass

Value/sensitivity	Receptor	Description
		Strait Water movement from the west (Tomczak, 1985) (Gibbs, Arnott, Longmore, & Marchant, 1991).
	Bathymetry (Figure 3-9)	The seabed bathymetry across the OA is highly variable, ranging mostly from 20 - 70m water depth. It is noted that water depths to the northeastern corner of the OA, towards the continental slope that leads to the Bass Canyon, range between 70 - 300m.
	Benthic habitat	The Gippsland Basin is composed of a series of massive sediment flats, interspersed with small patches of reef, bedrock, and consolidated sediment. The sandy plains are only occasionally broken by low ribbons of reef; however, these reefs do not support the large brown seaweeds characteristic of many Victorian reefs, but instead are inhabited by resilient red seaweeds and encrusting animals that can survive the sandy environment, with poor light and low energy conditions away from shallow waters (*Bass Strait Environment Plan* (AUGO-EV-EMM-012)). Benthic fauna present on the soft sediment can be broadly divided into two groupings (Parry, Campbell, & Hobday, 1990): • epibenthos which includes sessile species such as sponges and bryozoans, hydroids, ascidians, poriferans and mobile fauna including hermit crabs, sea stars and octopus • infauna which includes a diverse range of species such as amphipods, shrimps, bivalves, tubeworms, small crustaceans, nematodes, nemerteans, seapens, polychaetes and molluscs.
Economic environment	Commercial fishing (See Appendix A, Section A.1.6 for description of fisheries)	Commonwealth fisheries overlapped by the OA: • Bass Strait Central Scallop Zone Fishery (BSCZSF) - 2.00% overlap with the OA (see Figure 3-10) • Eastern Tuna and Billfish Fishery (ETBF) – 0.25% overlap with the OA (see Figure 3-11) • Small Pelagic Fishery (SPF) – 0.28% overlap with the OA (see Figure 3-12) • Southern and Eastern Scalefish and Shark Fishery (SESSF) - 0.28% overlap with the OA (see Figure 3-13). Section A.1.6.2 of Appendix A details the subsectors of the fishery that have jurisdiction to fish in the OA and EMBA • SESSF Commonwealth Trawl Sector (CTS) Otter-board - 0.74% overlap with the OA (Figure 3-14) • SESSF CTS and Scalefish Hook Sector (SHS) – 0.37% with the OA (Figure 3-15) • SESSF Commonwealth Shark Gillnet and Shark Hook Sectors (SGSHS) Shark Hook - 0.62% overlap with the OA (Figure 3-16)

Value/sensitivity	Receptor	Description
		• SESSF SGSHS Shark Gillnet - 0.62% overlap with the OA (Figure 3-17) • SESSF CTS Danish-seine – 0.74% overlap with OA (Figure 3-18) • Southern Bluefin Tuna Fishery (SBTF) – 0.12% overlap with the OA (see Figure 3-19) • Southern Squid Jig Fishery (SSJF) - 0.34% overlap with the OA (see Figure 3-20 State fisheries – Victoria overlapped by the OA: • Abalone Fishery – 8.21% overlap with the OA (see Figure 3-21) • Rock Lobster Fishery and Giant Crab Fishery – 8.15% overlap with the OA (Figure 3-22) • Pipi Fishery – 10.84% overlap with the OA (see Figure 3-23) • Wrasse Fishery – 5.73% overlap with the OA (see Figure 3-24) • Sea Urchin Fishery – 9.83% overlap with the OA (see Figure 3-25) • Scallop Fishery – 5.73% overlap with the OA (see Figure 3-26) • Octopus Fishery – 8.03% overlap with the OA (see Figure 3-27). State fisheries – Tasmania overlapped by the OA: • Lobster, Giant Crab, Scallop Fishery – 0.02% overlap with the OA (see Figure 3-28).
	Oil and gas	Other than the Esso permit areas in the Gippsland Basin there are 14 other permit areas held by other operators: • Cooper Energy (VIC/L32, VIC/RL13, VIC/RL14, VIC/RL15, VIC/RL16, VIC/P72, VIC/P75, VIC/P80) • SGH Energy (VIC/L29) • Carnarvon Hibiscus (VIC/RL17) • Emperor Energy/Shelf Oil Pty Ltd (VIC/P47) • Liberty Petroleum (VIC/P77, VIC/P78) • 3D Energi Limited (VIC/P74).
	Shipping (Figure 3-30)	The southeast coast of Australia has high shipping activity. This traffic includes international and coastal cargo trade, and passenger and ferry services.
	Defence	The Australian Defence Force conducts a range of training, research activities, and preparatory operations in Australian waters. These activities may include transit of naval vessels, training exercises, shipbuilding and repairs, hydrographic survey, surveillance and enforcement, demolition, use of explosives, use of radar, sonar, sonobuoys, flares, sensors and other equipment, and search and rescue. There are no known defence activities within the OA.

Value/sensitivity	Receptor	Description
		During relevant person consultation for this EP, the Department of Defence advised there were areas identified as potentially containing unexploded ordnances which may fall within the OA. These two areas are located between Port Albert and Lakes Entrance (see Figure 3-31).
	Tourism	In East Gippsland, primary tourist locations are the Gippsland Lakes (the largest inland waterway in Australia), Lakes Entrance, Marlo, Cape Conran, and Mallacoota. The area is renowned for its nature-based tourism (e.g. Croajingolong National Park), recreational fishing and water sports (lake and beaches). In South Gippsland, the primary tourist location is Wilsons Promontory Marine National Park, which is Victoria's largest marine protected area at 15,604ha. Situated at the southern tip of Wilsons Promontory, the park includes the Promontory itself and thirteen offshore islands. As one of Victorias largest and oldest national parks, Wilsons Promontory is renowned for its natural beauty and diverse ecosystems, making it a prominent destination for outdoor adventure and nature-based experiences. The South Coast Region includes all the towns from Wollongong to the Victorian border.
	Renewable energy (Figure 3-29)	The OA is located within Australia's first offshore area declared available for renewable energy projects (OEI-01-2022 Part 1). The OA overlaps with the following licence areas: • Blue Mackerel North - FL-001 • Star of the South – FL-006 • Greater Eastern - FL-010 • Navigator North – FL-011 • Aurora Green – FL-012.
Cultural	Native Title determinations and claims	A 'determination of Native Title' is a decision on whether native title exists in relation to a particular area of land or waters. An 'approved determination of native title' is a determination of native title made by the FCA, the HCA, or a recognised State/Territory body within its jurisdictional limits (Australian Government, 2024). Native Title claims are claimants whose applications (for a determination) have been accepted for registration. A claim application is made by a native title claim group that claims they hold native title rights and interests in an area of land and/or water, according to their traditional laws and customs (Australian Government, 2024); (National Native Title Tribunal, 2025). There are no Native Title determinations or claims within the OA. Native Title determinations or claims intersected by the EMBA are described in Section A.1.5 of Appendix A.
	Sea Country	Gunaikurnai is the name of the Indigenous group who have inhabited the Gippsland region for at least 18,000 years

Value/sensitivity	Receptor	Description
		(Ramahyuck, 2023). The GLaWAC (GLaWAC, 2025a) describe their Country as: *"The land, the rivers and the ocean, the people, and the stories, the past and the future. All of it is connected. All of it is important to us. Country heals us and connects us to our ancestors, our culture and our history".* Country can be broadly categorised (although interconnected) into Land and Sea Country. Sea Country, also known as Saltwater Country, is of particular importance for this activity, as the OA may exist within known areas of Sea Country. Smyth and Isherwood (2016) describe Sea Country as all estuaries, beaches, bays, and marine areas collectively, within a traditional estate. Sea Country contains evidence of the ancient mystical events by which all geographic features, animals, plants, and people were created. The sea, like the land, is integral to the identity of Indigenous groups. Connection to Sea Country is accompanied by a complexity of cultural rights and responsibilities. Formal recognition of Sea Country rights lags considerably compared to land rights; this could be for a range of reasons including conflicting perspectives and opinions on traditional custodianship of land and how far it extends (Smyth & Isherwood, 2016). There has been recent momentum regarding Sea Country in Australia, which can be seen in the Australian Government's $11.6 million commitment to the Sea Country IPAs program. The program seeks to increase the area of sea in IPAs to strengthen the conservation and protection of Australia's marine and coastal environments, while creating employment and economic opportunities for Indigenous Australians (DCCEEW, 2024c). The GLaWAC has commenced steps to establish the Sea Country IPAs and is currently conducting Sea Country Assessments (GLaWAC, 2024), undertaking information gathering and is actively seeking engagement with Traditional Owners on how the IPAs should be managed (GLaWAC, 2025b). The proposed Sea Country IPAs area is located within the coastal waters of the Gippsland region, comprising of numerous marine and coastal parks and includes the Ramsar listed Gippsland Lakes and Raymond Island, a highly significant cultural site (DCCEEW, 2024d) (both sites are outside of the OA). First Nations people would have lived on lands that are now submerged under the water as a result of rising seas in the last ice age. Hence the potential presence of cultural features along the ancient shoreline in waters less than 120m is recognised. Feedback received from the Kurnai People during consultation for this EP is that Sea Country is central to Kurnai identity, law, and ceremony — including waters, seabed, marine ecosystems, and ancestral sites.

Value/sensitivity	Receptor	Description
Social environment	Recreational fishing, boating, diving and leisure activities	Most recreational fishing occurs in nearshore coastal waters (shore or inshore vessels), and within bays and estuaries. Offshore fishing (>5km from the coast) only accounts for approximately 4% of recreational fishing activity in Australia; charter fishing vessels are likely to account for the majority of this offshore fishing activity. There is one marked dive site in the OA, the *Duke of Wellington* wreck, which is located approximately 26km from Port Albert and 46km to the east of Wilsons Promontory. There is moderate to high recreational use along most of the Victorian coast, mostly amongst the Nooramunga islands (near Corner Inlet), on the Gippsland Lakes, along Ninety Mile Beach, at Cape Conran Coastal Park and Croajingolong National Park and off the coast of Mallacoota, comprising both boat-based fishing and beach-based surf fishing. All these areas are outside the OA. Common recreational fish species (coastal area) include tiger flathead, bream, snapper, Australian salmon, and lobster.

4 Relevant persons consultation

Esso has undertaken consultation in the course of preparing this EP in accordance with Regulation 25 of the Environment Regulations.

The judgements of the FCA (Tipakalippa v National Offshore Petroleum Safety and Environmental Management Authority (No 2), 2022) and Appeal (Santos NA Barossa Pty Ltd v Tipakalippa, 2022) represents the law regarding requirements for consultation in accordance with the Environment Regulations.

Following the Appeal and the FCA decision on 28 September 2023 (Cooper v National Offshore Petroleum Safety and Environmental Management Authority (No 2), 2023), Esso revised its methodology (refer to Section 4.2) to better reflect the intent of the judgements.

This Section provides the outcomes of consultation conducted up to and including information received by early August 2025. During the consultation process, which commenced in December 2023, feedback and requests for further information received have been summarised in Appendix E-2 and incorporated throughout this EP, where relevant.

Over the past 50 years of operations in Bass Strait, Esso has established relationships with relevant persons identified in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) and activity-specific EP submissions, as well as the broader public and other interested parties.

Esso recognises and respects the important contribution of relevant persons, including First Nations people, throughout offshore petroleum activities. Esso is committed to ensuring that relevant persons are identified and given sufficient information and reasonable time for consultation to allow them to make an informed assessment of the possible consequences of a proposed petroleum or GHG activity on them.

The consultation process outlined in this EP allows Esso to ascertain, understand and address all the environmental impacts and risks that might arise from its proposed activity. The consultation process also allows Esso to receive information that the Company might not otherwise receive, and to use this information to enhance understanding of the environment, people, communities, heritage values, and social and cultural features that may be affected by the proposed activities and to inform decision-making.

For the purposes of this EP, Esso defines 'consultation' as a process of communication that leads to a decision where the views of relevant persons have been taken into account. Whereas 'engagement' aims to build long term relationships by exchanging information. While Esso is required by legislation to consult with relevant persons, Esso is also committed to engaging with relevant persons and continuing to further develop relationships already established.

Esso will consider and adopt appropriate measures, in response to the matters raised by relevant persons, in the management of environmental impacts and risks as part of the EP development process.

This Section describes Esso's approach to consultation and engagement, and the steps taken to develop and maintain consistent, constructive and effective relationships with relevant persons associated with this EP.

More specifically, this Section outlines in detail:

- Section 4.1 Consultation requirements – Outlines the applicable consultation and engagement standards and legislative requirements, including Esso's definition of relevant persons
- Section 4.2 Esso's consultation methodology – Describes Esso's methodology used to identify and consult with relevant persons for any EP
- Section 4.3 Methodology as applied to the scope of this EP – Details how Esso has applied the methodology (as described in Section 4.2) for this specific EP and the activities it proposes. This includes:
    - the relevant persons identified under the scope of this EP and the verification process applied
    - communication and consultation methods used to ensure sufficient information is provided in relation to the scope of this EP
    - how the consultation process is planned and tailored as appropriate to the nature and scope of this EP
    - a description of consultations undertaken to-date
    - a summary of how feedback received to-date has been considered, addressed and communicated.

4.1 Consultation requirements

Esso is committed to undertaking all consultation and engagement activities in accordance with applicable Australian legislation and ExxonMobil standards.

4.1.1 Legislative requirements

For each EP, Esso undertakes consultation in accordance with legislative requirements, including case law. As such, Esso's consultation processes are designed to meet obligations specified in Section 280 and Section 460 of the OPGGS Act and in the context of the objects of Regulation 4 of the Environment Regulations.

Consultation-specific requirements are covered in several of the Environment Regulations, as discussed in the following Sections.

4.1.1.1 Regulation 25

Esso categorises relevant persons into five categories aligned to Regulation 25(1)(a)-(e), as shown in Table 4-1.

For the purpose of the consultation, the titleholder must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person.

Per Regulation 25(2), Esso defines 'sufficient information' to include:

- sharing information that is tailored to a relevant persons' needs
- detailing the proposed activity and any impacts and risks that may be relevant to them
- describing the control measures proposed to manage the potential impacts to them.

Esso considers the functions, interests or activities of relevant persons and the impacts and risks that affect them when determining information requirements and acknowledges that information may need to be provided in an iterative manner.

Following guidance provided in *Consultation in the course of preparing an environment plan* (NOPSEMA, 2024b), Esso acknowledges that:

> *"The phrase 'functions, interests or activities' in Regulation 25(1)(d) should be broadly construed as this approach best promotes the objects of the Regulations, including that offshore petroleum and greenhouse gas activities are carried out in a manner consistent with the principles of ESD14.*
>
> *Functions: Refers to 'a power or duty to do something'.*
>
> *Activities: To be read broadly and is broader than the definition of 'activity' in Regulation 5 of the Environment Regulations and is likely directed to what the relevant person is already doing.*
>
> *Interests: To be construed as conforming with the accepted concept of 'interest' in other areas of public administrative law. Includes 'any interest possessed by an individual whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation'."*

In accordance with Regulation 25(3), Esso determines a reasonable period for consultation in relation to this EP, as discussed in Table 4-1.

In accordance with Regulation 25(4), Esso will inform each relevant person that they may request that particular information they provide in the consultation not be published. Esso is committed to honouring this request and will not publish information subject to such a request.

4.1.1.2 Regulation 26

In accordance with Regulation 26(8), sensitive information relating to relevant persons and the full text of any response by a relevant person to consultation under Regulation 25 in the course of preparation of the EP, will only be included in the 'sensitive information part' and not anywhere else in the EP. The 'sensitive information part' is removed prior to publication in accordance with Regulation 28(1).

4.1.1.3 Regulation 34

In accordance with Regulation 34(g), this Section is intended to demonstrate how Esso has carried out the consultations required by Division 3. In developing this EP, Esso has also considered the guidance provided in

Environment Plan Assessment (NOPSEMA, 2024c), *Environment Plan decision making* (NOPSEMA, 2024d) and *Environment plan content requirement* (NOPSEMA, 2025d).

4.1.1.4 Regulation 22

In accordance with Regulation 22(15), Esso ensures appropriate consultation is conducted with relevant departments, authorities and ministers through their identification as relevant persons under Regulation 25(1)(a), (b) and (c). Refer to Section 4.2.4.1.

Other persons or organisations with functions, interests or activities are identified as relevant persons under Regulation 25(1)(d). Refer to Section 4.2.4.2.

In addition, Esso may categorise any other person or organisation as a relevant person under Regulation 25(1)(e). Refer to Section 4.2.4.3.

Esso also conducts broad-based information sharing engagements as outlined in Section 4.3.6.

4.1.1.5 Regulation 24

In accordance with Regulation 24(b), Esso provides a report on all consultations undertaken with any relevant person in accordance with Regulation 25 (see Appendix E). The report contains:

- a summary of each response made by a relevant person
- an assessment of the merits of any objection or claim about the adverse impact of each activity to which the EP relates
- a statement of the titleholder's response, or proposed response, if any, to each objection or claim
- a copy of the full text of any response by a relevant person.

4.1.1.6 Case law

The judgements from the Decision (Tipakalippa v National Offshore Petroleum Safety and Environmental Management Authority (No 2), 2022) and Appeal (Santos NA Barossa Pty Ltd v Tipakalippa, 2022) are considered law and constitute the legal requirements of consulting with relevant persons.

This Section is intended to demonstrate how Esso has consulted, in a way that complies with the judgements made in the Decision and the Appeal.

In the Appeal (Paragraphs 96 and 104), FCA has noted that there is no shortage of guidance in decisions on consultation processes under *the Native Title Act 1993* (Cth), which is illustrative of how a seemingly rigid statutory obligation to consult persons holding a communal interest may operate in a workable manner. The *Native Title Act 1993* (Cth) authorities require reasonable notice to group members, but not exhaustive communications with each and every person.

Esso also implements the guidance outlined in *Consultation in the course of preparing an environment plan* (NOPSEMA, 2024b), which was revised to incorporate the judgements.

4.1.2 ExxonMobil standards

In accordance with ExxonMobil Operations Integrity Management System (OIMS) System 10: Managing Community Risk, Esso has developed a consultation and engagement methodology that enables Esso to:

- ensure every effort is made to identify relevant persons
- undertake a verification process to ensure all representatives of relevant persons are a true representation/advocate of the views of their constituents and can be relied upon to faithfully communicate the results of engagements back to their constituents
- ensure relevant persons, especially those who are directly impacted, are consulted on matters that may affect them
- ensure that consultation is genuine and provides a meaningful two-way dialogue to develop and maintain consistent and constructive relationships with relevant persons to further understand potential environmental, social and economic impacts
- pursue engagement with relevant persons using a level of effort commensurate with the nature and scale of the activity
- keep relevant persons informed with respect to their specific functions, interests or activities

- encourage relevant persons to assess the information provided to them and respond to Esso with any feedback including questions, issues, concerns, suggestions, objections and/or claims
- maintain confidence of relevant persons in Esso and its activities through ongoing open, informative, inclusive and timely communications, wherever possible.

Implementation of the consultation methodology provides a mechanism by which Esso can:

- meet regulatory obligations and align with industry best practice consultation and engagement methods
- review and update the consultation methodology to reflect any changes to applicable laws, best practices or standards
- provide meaningful information in a format and language that is readily understood and tailored to the needs of relevant persons and groups
- provide information within an adequate timeframe to inform decision-making
- ensure consultations are based on open communication that is transparent, collaborative, inclusive and are conducted with integrity to foster respect and trust
- disseminate information in formats, methods and locations that make it easy for relevant persons to access
- respect local traditions and the relevant person's preferred ways of doing things
- establish two-way dialogue that gives all relevant persons the opportunity to exchange views and information, to listen, and to have their feedback heard and addressed
- seek inclusiveness in representation of views, including minority and special interest groups
- develop clear mechanisms for receiving, documenting, and responding to feedback
- incorporate feedback from relevant persons into the program design and provide clear and transparent reporting back to relevant persons in a reasonable timeframe.

Esso acknowledges the Traditional Custodians of Country, and the land and sea upon which our operations are located. We recognise the Traditional Custodians continuing connection to land, sea, culture and community, and pay our respects to Elders past and present. Esso understands that First Nations people see no distinction between the land and the sea, considering it all as a part of their Country. This understanding aligns with the regulatory guidance (NOPSEMA, 2024b), which states:

> *"...a connection of traditional owners with sea country may constitute an interest for the purposes of regulation 25(1)(d)".*

Esso continues to identify and attempt consultations with environmental non-government organisations (eNGOs) and other environmental protection and advocacy groups.

4.2 Esso's consultation methodology

This Section provides a detailed methodology for identifying and consulting with relevant persons, which has been followed in preparing this EP.

It covers the process for identifying relevant persons applicable to an offshore activity that requires a new EP or a revision to an EP under the Environment Regulations, including:

- the process for classification of relevant persons based on their functions, interests or activities
- preparation of appropriate consultation materials and forms of consultation for each relevant person identified
- the process of consultation including assessment of information and responses received.

For specific information on how this process was undertaken in relation to this EP, refer to Section 4.3.

4.2.1 Definition

To ensure a consistent approach to identifying and consulting with relevant persons in relation to offshore EPs, the definitions included in Table 4-1 have been used as the basis for this methodology.

Table 4-1 Definitions

Term	Definition
Activities	In relation to Regulation 25(1)(d), activities are considered to be what other persons or organisations are already doing.
Area To Be Avoided (ATBA)	The boundary which commences at the most easterly intersection of the coastline of the State of Victoria at mean low water by the parallel of latitude 38°14′54.50″ S and then runs southeasterly along the geodesic to the point of latitude 38°34′54.49″ S, longitude 147°44′04.61″ E and then along the coastline of the State of Victoria at mean low water to the point of commencement.
Claims	Evidence provided that suggests there are potential adverse impacts from the petroleum or GHG activities to which the EP relates.
Consultation	Targeted and tailored information provided to enable effective consultation on a specific planned activity within a defined timeframe.
Consultation period	Esso defines the consultation period during the development of an EP as being 30 days, subject to the nature and scale of the proposed activity.
EMBA	Oil spill modelling is used to determine the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, as a result of any spill and is used for planning purposes to ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the EP.
Engagement	Ongoing relationship building or general engagement not related to a specific activity or defined timeframe.
Environment	The Environment Regulations defines this as: (a) ecosystems and their constituent parts, including people and communities; and (b) natural and physical resources; and (c) the qualities and characteristics of locations, places and areas; and (d) the heritage value of places; and includes (e) the social, economic and cultural features of the matters mentioned in paragraphs (a), (b), (c) and (d).
Functions	In relation to Regulation 25(1)(d), functions refer to a power or duty to do something.
Geographical consultation boundary	The geographical areas (OA, ATBA and EMBA) used as the basis for identifying relevant persons.
Interests	In relation to Regulation 25(1)(d), interests represent a connection to the values described in the EP. Any interest possessed by an individual, whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation. An interest does not extend to general public interest in an activity.
Objection	A reason or argument that asserts that there are potential adverse impacts arising from the petroleum or GHG activities to which the EP relates.

Term	Definition
OA	The area within which all activities described within this EP will occur. The OA encompasses Commonwealth waters both on title and off title.
Petroleum/GHG activity	A planned offshore petroleum or GHG activity for which an EP is required. This also includes activities undertaken in the event of an emergency condition such as oil spill response.
Reasonable period	A reasonable time for relevant persons to identify the effect of a proposed activity on their functions, interests or activities and make a response detailing their objections or claims. Esso defines a reasonable period for a relevant person to review and provide an initial response (i.e. the consultation period) as being 30 days, subject to the nature and scale of the proposed activity. Where engagement with relevant persons is ongoing after this period, Esso will continue to engage with these persons until Esso believes that it has provided sufficient evidence/justification to close the consultation (i.e. they have been provided sufficient information and reasonable time).
Relevant person	Can be a person, organisation, department or agency that falls within one of the classifications defined by Regulation 25(1) of the Environment Regulations.
Stakeholder	Stakeholder is a general use term and includes any person, group or organisation with an interest or concern in something. It includes those that may be affected in an immaterial or negligible way. Esso uses this terminology in general terms when describing those persons/organisations not deemed to be relevant persons, for example a stakeholder database containing a broad and diverse range of relevant and non-relevant persons for multiple activities.
Unplanned activity/event	Accidental release for example loss of containment (LOC) of refined oils (collision) or LOC of reservoir hydrocarbons Covered by the OPEP.

4.2.1.1 Petroleum activity (planned activity)

The Environment Regulations require that consultation be undertaken to ensure that persons who may be affected by a petroleum activity are given the opportunity to inform the titleholder how they may be affected and to allow the titleholder to assess and address any objections or claims about that activity in the preparation of environment submissions.

Regulation 5 of the Environment Regulations defines a petroleum activity as

> *"any operations or works in an offshore area carried out for the purpose of:*
>
> *(a) exercising a right conferred on a petroleum titleholder under the Act by a petroleum title, or*
>
> *(b) discharging an obligation imposed on a petroleum titleholder by the Act or a legislative instrument under the Act."*

When identifying relevant persons, Esso considers which stakeholders perform a function in relation to – or have a function, interest or activity that may be affected by – the planned activity.

Therefore, in determining who is a relevant person for consultation, Esso sought to identify and consult with persons whose functions, interests or activities could be affected by the activities described in detail in Section 2 of this EP.

4.2.1.2 Unplanned event/activity (emergency conditions)

Relevant persons who may perform a function in Esso's planning for, or management of an unplanned activity, and whose information is integral to the development of emergency management plans, are engaged during the development of this EP and the OPEP.

Persons whose functions, interests or activities are within the EMBA for the unplanned activity are provided with broad, high-level information such as activity information bulletins and information regarding EMBA and oil spill modelling.

If requested, consultation may include face-to-face engagements, phone calls, community meetings, specialist group meetings, community information sessions. If no response is received no further consultation is required.

4.2.1.3 Geographical boundaries

Esso uses the following geographical boundaries to define EP consultation:

- OA: As described in Section 2.1
- Bass Strait ATBA: As described in Schedule 2 of the OPGGS Act
- EMBA: As described in Section 3.2.

4.2.2 Esso's approach to consultation

Esso's approach to consultation with relevant persons involves steps undertaken across four consultation Levels, as shown in Figure 4-1.

If Esso identifies a group of relevant persons that may be potentially affected, but is unable to confirm individual contact details as these are not ascertainable through normal mechanisms (e.g. website, associated government agencies, organisations or groups who hold these details or who can advise who these individuals are), the opportunity exists for such persons to contact Esso via the publicly accessible Esso Consultation Hub, consultation email or phone. Newspaper advertisements are also used to highlight activities so that individuals or groups can self-identify to Esso.

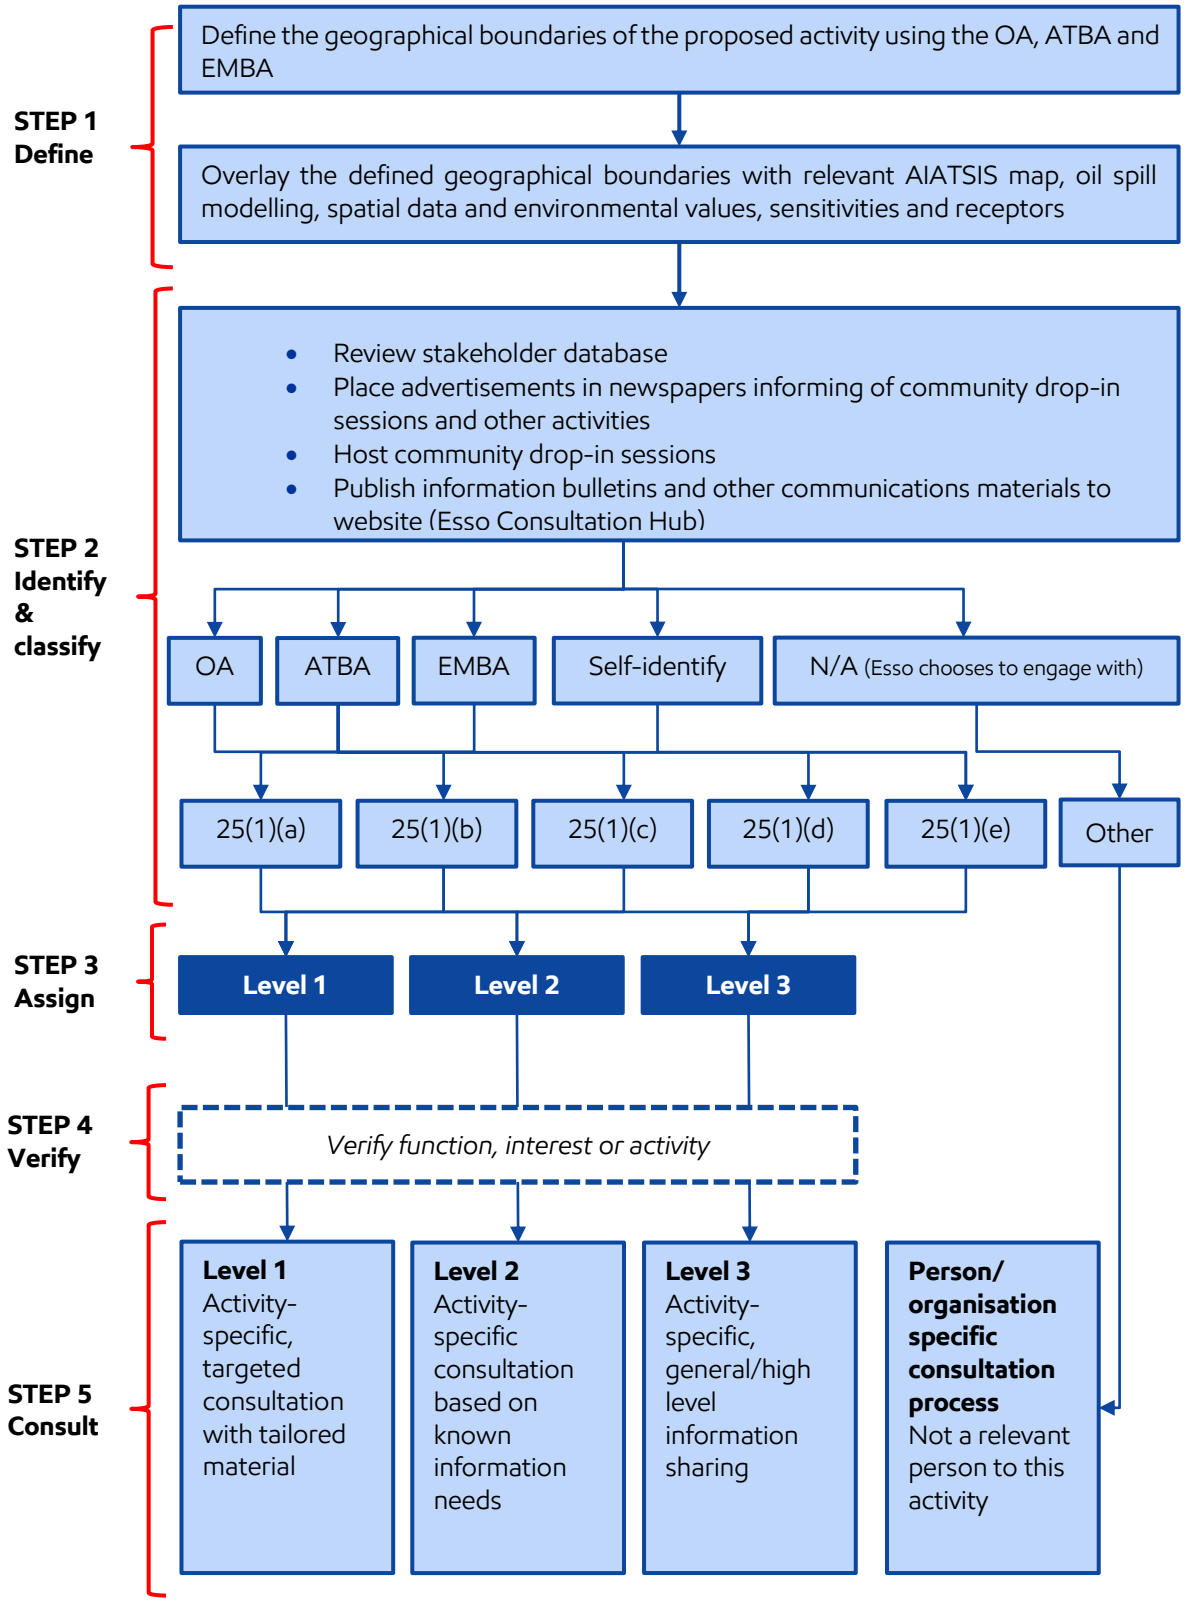

Figure 4-1 Esso's approach to consultation

4.2.3 Step 1 – Define

When preparing for consultation for each new petroleum activity, Esso first identifies the geographic boundaries of the EP. These geographic boundaries are the:

- OA
- ATBA
- EMBA.

Each of the defined geographical boundaries are then overlayed with relevant Australian Institute of Aboriginal and Torres Strait Islander Studies (AIATSIS) map, oil spill modelling, spatial data and environmental values, sensitivities and receptors.

Esso must also outline the EP specifications for:

- activity description, which is compared to previous consultations undertaken for other Esso activities and/or facilities
- scope of the EP, taking into consideration factors such as planned and unplanned impacts to environmental factors including air and water emissions, culturally sensitive areas, Sea Country and marine environments; and potential socioeconomic impacts including job creation throughout the supply chain
- environmental values and sensitivities of the proposed activity, including cultural heritage (world, national and local), Sea Country, wetlands of international significance (Ramsar), listed threatened species and listed migratory species, listed TECs and Commonwealth marine areas
- timing of the proposed activity, including any seasonal changes.

After considering these specifications, Esso then identifies the anticipated key functions, interests and activities of relevant persons.

4.2.4 Step 2 – Identify and classify

Esso acknowledges that factors such as the nature of the activity, the environment in which the activity is being undertaken and the possible impacts and risks of the activity should be taken into account when determining whether the activity may be relevant to authorities, or determining who has functions, interests or activities that may be affected (NOPSEMA, 2024b).

The approach to consultation involves using the defined OA, ATBA and EMBA to identify relevant persons by geographical boundary. They are then classified in accordance with the regulatory definitions in Regulation 25(1)(a)-(e) which includes five relevant persons classifications as follows:

- Regulation 25(1)(a) – Each Commonwealth, State or Northern Territory agency or authority to which the activities to be carried out under the EP may be relevant. For Esso's operations in Bass Strait, this includes any Commonwealth department or agency that has responsibility for managing or protecting the marine environment from pollution. It may also include those with responsibilities for environmental and fisheries management, defence and communications, maritime/navigational safety, marine parks, and native title
- Regulation 25(1)(b) – The Department or the responsible State Minister, if the plan relates to activities in the offshore area or a State
- Regulation 25(1)(c) – The Department of the responsible Northern Territory Minister – if the plan relates to activities in the Principal Northern Territory offshore area. This is not applicable for Esso Bass Strait activities
- Regulation 25(1)(d) – A person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP. A connection of traditional owners with sea country may constitute an interest for the purposes of Regulation 25(1)(d) classification. For Esso's operations in Bass Strait this includes First Nations groups, non-government organisations, worker unions and fishing groups. It may also include community groups and individuals
- Regulation 25(1)(e) – Any other person or organisation that the Esso considers relevant.
- Specific processes for the identification of relevant persons are outlined in the following Sections.

4.2.4.1 Methodology for identification of Regulation 25(1)(a)-(c) relevant persons

Regulation 25(1)(a)-(b) requires the identification of relevant persons in Commonwealth or State government departments or agencies who may have responsibilities either related to or impacted by the activities to be carried out under the EP.

Regulation 25(1)(c) requires Esso to identify the department of the responsible State Minister.

Esso has a history of extensive and ongoing consultation for offshore activities in the Bass Strait spanning more than 50 years, meaning that most, if not all, Regulation 25(1)(a)-(c) relevant persons are known to Esso.

The first step in identification is to review Esso's existing stakeholder database. This review involves comparing the 'activity description' to previous Esso activities and/or facilities to identify past consultations of a similar nature. This is then used to filter Esso's stakeholder database, providing a list of relevant persons for all past activities of a similar nature.

If Commonwealth or State departments, agencies or ministers change, Esso leverages existing relationships to ensure consistency of consultation.

4.2.4.2 Methodology for identification of Regulation 25(1)(d) relevant persons

Identification of relevant persons consistent with Regulation 25(1)(d) requires their functions, interests or activities to be understood and applied broadly taking into account how potential risks and impacts of the EP activity may affect them. This is achieved via several methods as outlined in the following Sections.

4.2.4.2.1 REVIEW OF RELEVANT PERSONS PREVIOUSLY IDENTIFIED FOR OTHER ACTIVITIES

Given Esso's extensive history of consultation in the area, identification of relevant persons starts with a review of Esso's existing relevant persons database to generate a list of any persons, groups, and organisations with functions, interests or activities matching those defined for the EP.

4.2.4.2.2 ACTIVELY SEEK OUT NEW RELEVANT PERSONS

To ensure the broad capture of ascertainable persons and organisations who may have their functions, interests or activities affected by the activity (Santos NA Barossa Pty Ltd v Tipakalippa, 2022), Esso seeks to identify any new relevant persons through:

- using local knowledge of existing relationships to identify marine users and interest groups active in the area (e.g. Indigenous groups, commercial fisheries, recreational fishers, other energy producers, local business, etc.)
- providing a link to the Esso Consultation Hub and Esso Consultation Questionnaire with existing relevant persons and asking them to share it with anyone who may be interested in Esso's activities
- seeking the advice of First Nations groups such as land councils and prescribed body corporates in relation to who and how other First Nations groups or individuals should be consulted as relevant persons whose interests may be affected by the activities
- searches of internet sources, including search engines, websites, social media platforms etc.
- members of the Company's local workforce providing suggestions of other potentially impacted relevant persons
- identified relevant persons providing recommendations of other potentially impacted relevant persons, through direct engagement and/or the Esso Consultation Questionnaire
- guidance from the Regulator, other government agency/department, industry associations or bodies about other potentially relevant persons
- advertisements in newspapers and other relevant news sources (e.g. Koori Mail, local papers)
- hosting community information sessions where members of the public can attend and review materials relevant to Esso's activities and ask questions of staff
- a review of legislation applicable to petroleum and marine activities
- active participation in industry bodies and collaborations, for example Australian Energy Producers (formerly APPEA), Centre for Decommissioning Australia, National Energy Resources Australia, and the National Decommissioning Research Initiative
- leveraging existing relationships with relevant Commonwealth and State departments and agencies to identify other relevant stakeholders
- reviewing the relevant persons identified for other oil and gas EPs in the area

- conducting a search of the National Electronic Approvals Tracking System to access publicly available information concerning offshore electricity infrastructure licences under the *Offshore Electricity Infrastructure Act 2021* (Cth).

Relevant persons identified through these means are added to the list generated by the review of the relevant persons database (per Section 4.2.4.1).

4.2.4.2.3 SELF-IDENTIFICATION THROUGH BROAD-BASED INFORMATION SHARING

As part of the Company's own commitments to consultation and engagement, Esso regularly conducts broad-based information sharing designed to reach both relevant persons identified for any EP and a broad range of other interested parties. This broad-based information sharing allows Esso to create awareness of its activities and encourages potentially relevant persons to make themselves known to the Company (NOPSEMA, 2024b). Any persons or organisations who self-identify are added to the list generated by the ongoing review of the relevant persons database (per Section 4.2.4.1).

4.2.4.2.4 SPECIFIC IDENTIFICATION PROCESSES FOR CERTAIN GROUPS

COMMONWEALTH AGENCIES WITH RESPONSIBILITIES IN THE MARINE AREA

When developing or revising an EP in accordance with the Environment Regulations, Esso must consult with relevant Australian Government agencies with responsibilities in the Commonwealth marine area. Esso has reviewed NOPSEMA's guidelines on *Consultation with Commonwealth agencies with responsibilities in the marine area* (NOPSEMA, 2024e) and applied the guidance to the identification process for relevant persons within Australian Government agencies.

In accordance with the guidance, Esso recognises that while agencies may provide comments or advice on control measures that should be considered by titleholders to manage the potential impacts and risks of a petroleum activity. it is NOPSEMA's role to determine whether proposed control measures are appropriate to the nature and scale of the proposed petroleum activity.

FIRST NATIONS PEOPLES

Esso's consultation approach is consistent with Regulation 25, incorporating guidance provided by the Appeal ruling (Santos NA Barossa Pty Ltd v Tipakalippa, 2022). The consultation methodology includes sufficient time for each stage of the consultation process, including identification of First Nations groups as well individuals within the community, information sharing, receipt of feedback and assessment of merit.

Identification commences with a review of the relevant person database (as described in Section 4.2.4.1). Additional potentially relevant First Nations peoples are identified using the AIATSIS map of Indigenous Australia, overlaid with the geographical information of the OA, ATBA and EMBA, followed by an assessment of whether there will be any impacts from Esso's planned activities affecting the functions, interests or activities. Government resources such as State Government spatial data sets are also utilised to identify potentially relevant Aboriginal Land Councils, Registered Aboriginal Parties and Registered Aboriginal Community Organisations.

The Commonwealth Heritage List (DCCEEW, 2021c) is a list of Indigenous, historic and natural heritage places owned or controlled by the Australian Government which have a significant heritage value to the nation have been reviewed as described in Appendix A.

The Nanjet to Mallacoota Sea Country IPA consultation project, which extends from Corner Inlet to the Victoria/New South Wales border has also been reviewed as described in Appendix A.

Esso reviewed the *Gunaikurnai Whole-of-Country Plan* (GLaWAC, 2015) and the *Position Statement: Offshore Renewable Energy Infrastructure Area* (GLaWAC, 2022) with particular regard to Sea Country mapping.

Currently, there is no Sea Country mapping in Esso's ATBA available. Esso will continue consulting with GLaWAC as a Level 1 relevant person to allow opportunity to discuss Sea Country in the development of future EPs.

Representatives from the Kurnai Aboriginal Corporation self-identified as relevant persons when attending a community information session in Leongatha on 24 October 2024. Esso will continue to consult with the Kurnai Aboriginal Corporation on Esso's broader decommissioning activities in Bass Strait.

LOCAL COUNCILS

Identification commences with a review of the stakeholder database (as described in Section 4.2.4.1). Additional potentially relevant local government/councils are identified using government resources such as State Government spatial data overlaid with the geographical information of the OA, ATBA and EMBA.

COMMERCIAL FISHING

Esso has a long-standing relationship with Bass Strait commercial fishing operators' representative bodies and their members. Esso meets with South East Trawl Fishing Industry Association (SETFIA), Lakes Entrance Fishermen Limited (LEFL) and Seafood Industry Victoria (SIV) on a quarterly basis to discuss all upcoming and current offshore activities including any potential risks and how/if an activity may impact their members.

Where it is identified that an activity may affect their members, various strategies can be implemented including:

- distribution of SMS text message updates to the eastern fishing fleet advising of vessel movements, activities being performed outside the PSZ, coordinates of survey work, etc. Messages may be sent as often as daily during an activity, if appropriate
- updating Esso chartered vessel plotters to show where commercial fishing equipment is to avoid that area
- commercial fishers may choose to relocate their equipment for the duration of the activity.
- Esso also attends representative board meetings and any members meetings to consult directly with members on any proposed activities as requested.

While fishing is prohibited in any PSZ, reminders about PSZs are provided to all local fishing groups annually.

OFFSHORE WIND INDUSTRY

In December 2022, the Minister for Climate Change and Energy declared the offshore Gippsland area in Victoria (Commonwealth area only) as suitable for offshore electricity infrastructure. This declaration does not grant exclusive rights to use the area. In July 2024, the Australian Government granted 12 feasibility licences for offshore wind projects off Gippsland's coast in Victoria (DEECA, 2024). As of December 2025, Gippsland Dawn Project (Bluefloat), Kent Offshore Wind Project (RWE) and Gippsland Skies (AGL) feasibility licenses have been withdrawn, resulting in 9 feasibility licences remaining for offshore wind in Gippsland.

Esso began consultation in July 2024 to establish if these offshore wind licence holders' feasibility stage functions, interests or activities have the potential to be affected by the activities outlined in this EP and may be relevant persons.

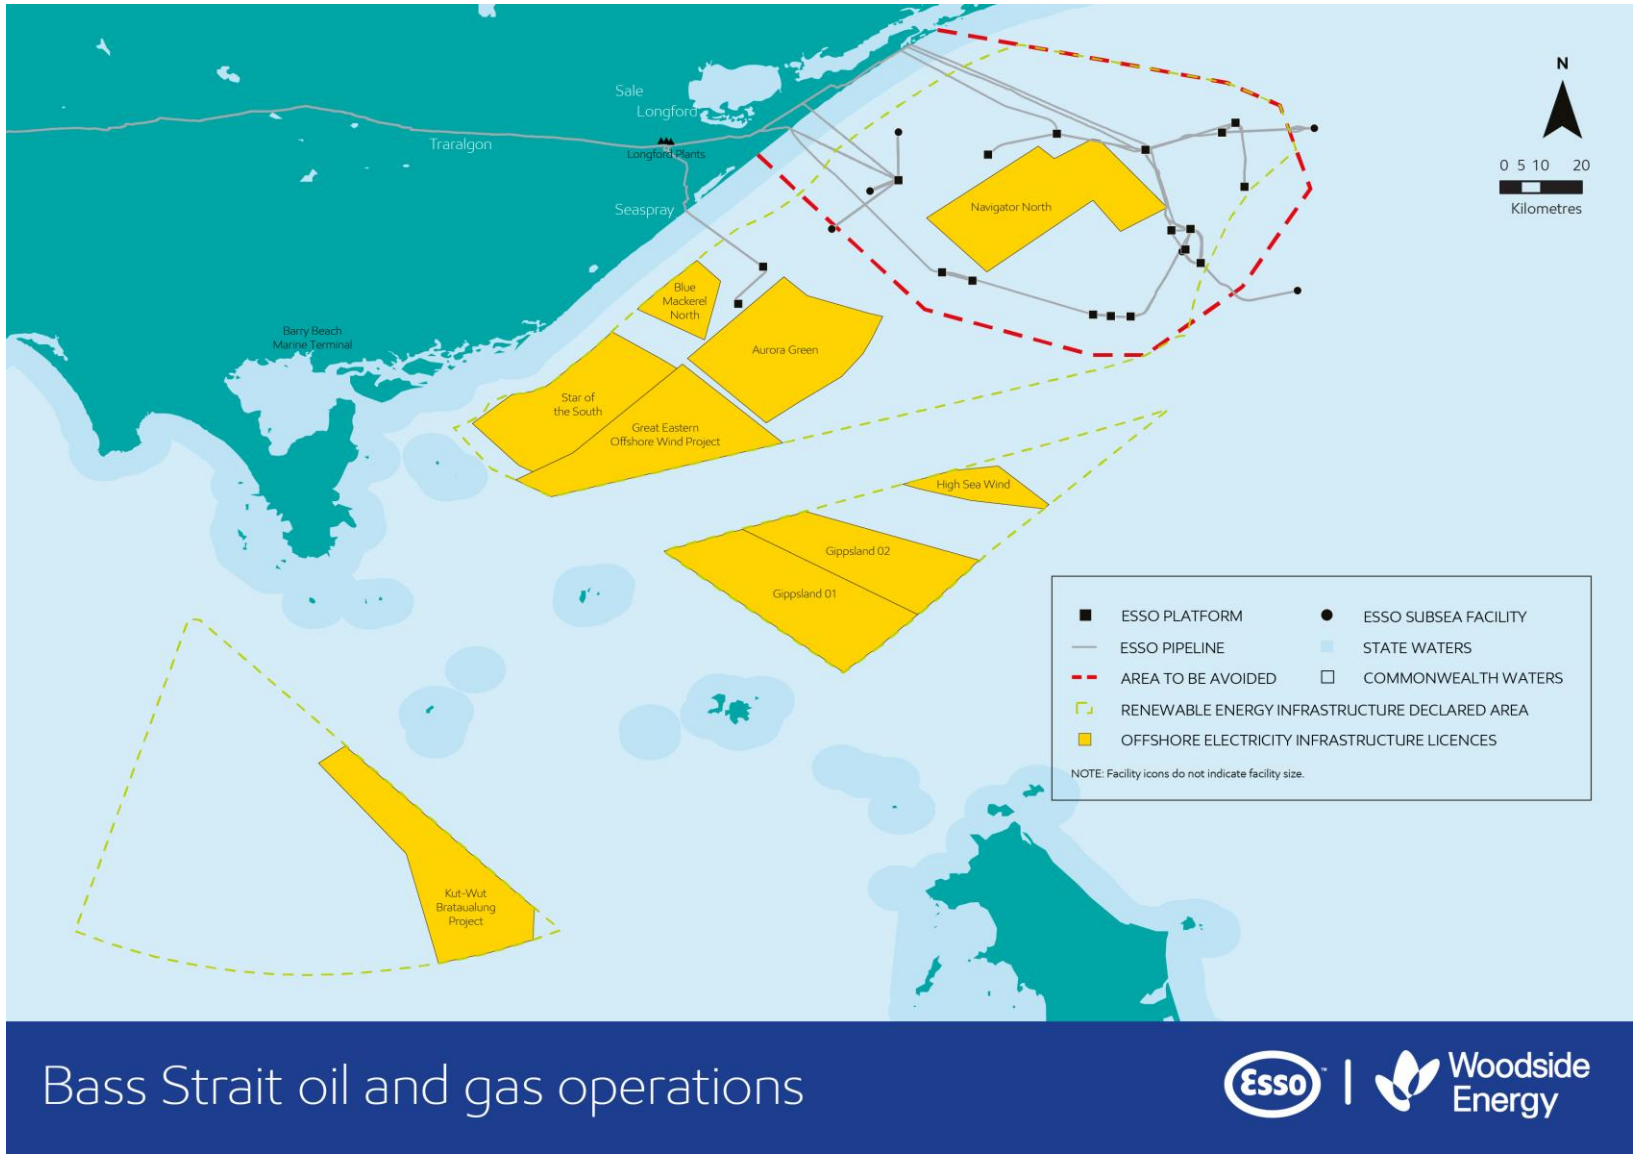

Figure 4-2 Victoria's offshore wind zone

4.2.4.3 Methodology for identification of Regulation 25(1)(e) relevant persons

Where Esso chooses to consult with persons that would not be considered a relevant person in accordance with Regulation 25(1)(a)-(d), the provisions of Regulation 25(1)(e) allow for Esso to nominate these persons/organisations, at their discretion.

4.2.4.4 Persons or organisations who self-identify

As part of the Company's own commitments to consultation and engagement, Esso regularly conducts broad-based information sharing designed to reach both relevant persons identified for any EP and a broad range of other interested parties. This broad-based information sharing allows Esso to create awareness of its activities and encourages potentially relevant persons to make themselves known to the Company (NOPSEMA, 2024b). Any persons or organisations who self-identify are added to the list generated by the ongoing review of the stakeholder database (as described in Section 4.2.4.1).

Esso will undertake advertising and publish information on a proposed activity to help identify any other relevant persons that may not have been identified by the process.

Esso will place advertisements in newspapers informing people of community information sessions and directing them to the Esso Consultation Hub to seek out anyone else who may be relevant based on the defined geographical area of the activity.

Where a person, organisation, department or agency identifies themselves to Esso via these campaigns, Esso will apply the methodology as defined in Figure 4-1 to assess if the person, organisation, department or agency is a relevant person, for the purposes of the EP and assign the relevant consultation Level.

The advertisements will also act as a means for sharing information to identified relevant persons and providing an ongoing mechanism for feedback.

4.2.4.5 Persons or organisations Esso chooses to contact

Over the past 50 years of operations in Bass Strait, Esso has established relationships with relevant persons identified in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) and activity-specific EP submissions, as well as the broader public and other interested parties.

Esso recognises and respects the important contribution of stakeholders and is committed to maintaining and developing further these important relationships.

In addition to consulting with relevant persons under Regulation 25(1), there may be persons or organisations that Esso chooses to contact in relation to a proposed activity. For example, these are persons or organisations:

- that are 'not relevant' pursuant to Regulation 25(1), but that Esso has chosen to contact potentially for additional guidance, for example to update contact information or obtain the correct contacts
- that are 'not relevant' pursuant to Regulation 25(1), but that Esso has contacted as a result of consultation requirements changing or updated guidance from the Regulator
- where it is unclear what their functions, interests and activities are, or whether they may be affected. In this circumstance, engagement is required to inform relevance under Esso's consultation methodology
- Esso wishes to maintain and continue to develop a relationship with.

4.2.5 Step 3 – Assign

Once each relevant person has been identified and classified as per Regulation 25(1)(a)-(e), the consultation Level is assigned during workshop(s) held with Esso consultation advisors and relevant subject matter experts. The more complex the activity, the more discussions are needed to ensure all matters are considered appropriately.

In assigning a consultation Level, the following considerations are taken into account:

- the location of the activity (OA, ATBA or EMBA) and whether or not their functions, interests and activities are impacted by the planned or unplanned activity
- if any impact, the degree of that impact, for example – level of EMBA overlap with a known fishery
- the functions, interests and activities of the person(s) or organisation
- persons or organisations known to Esso and previously recorded in the stakeholder database
- relevant persons/organisation's known preferred methods of communication and any specific information needs

- Esso's relationship with the relevant person/organisation, for example when did Esso last engage with them? On what topic? What is their level of interest? Is Esso currently consulting with them on other activities?
- the environmental values and sensitivities and whether or not the persons functions, interests and activities are impacted by the activity; if any impact, the degree of that impact
- if the relevant person/organisation can provide any information that will assist the design or management of the planned activities
- the duration of the activity.

The output of the workshop is recorded in a register of all relevant persons related to the activity including the justifications and reasons for the assigned consultation Level, this information is then provided in the relevant EP.

Esso notes that throughout the consultation process the assigned Level of consultation may be adjusted based on feedback received from the relevant persons, for example a relevant person may request more or less information and may therefore move to a higher or lower Level of consultation.

4.2.6 Step 4 – Verify

For Regulation 25(1)(a)-(c) relevant persons, the verification process confirms the details of the department/agency are correct. This involves checking for departmental restructures, name changes, staff/contact person changes, contact information changes etc.

For Regulation 25(1)(d)-(e) relevant persons, verification aims to ensure that:

- the functions, interests and activities used to evaluate and categorise the person or organisation as a relevant person are confirmed
- identified representatives are a true representation/advocate of the views of their constituents and can be relied upon to faithfully communicate the results of engagements back to their constituents
- relevant persons have been provided with the Esso Consultation Questionnaire to confirm they are willing to participate in the consultation process.

Verification processes for Regulation 25(1)(d)-(e) relevant persons are further detailed in the following Sections.

4.2.6.1 Verifying functions, interests and activities

In order to verify functions, interests and activities, Regulation 25(1)(d)-(e) relevant persons (or their verified representative) will be provided with:

- an information bulletin (or similar) providing sufficient information on the activity proposed in the EP
- Esso Consultation Questionnaire to verify functions, interests and activities.

The information bulletin aims to ensure all relevant persons are provided with sufficient information at the outset of the consultation process so they can make informed decisions about their participation or otherwise. This information bulletin will be in the form of a brochure or link to a specific webpage.

One aim of the Esso Consultation Questionnaire is to verify the functions, interests and activities of each relevant person. This is achieved through providing a tailored list of functions, interests and activities (relevant to the EP) so that the relevant person can select one or more items. Esso updates the relevant persons database and may re-evaluate the person's/group's status as a relevant person.

In some cases, relevant persons have developed guidance detailing their own functions, interests or activities and how and when they wish to be consulted on activities (NOPSEMA, 2024b), which will be considered throughout the process. This includes, for example:

- *Consultation with Commonwealth agencies with responsibilities in the marine area* (NOPSEMA, 2024e)
- *Interim Engaging with First Nations People and Communities on Assessments and Approvals Under the Environment Protection and Biodiversity Conservation Act 1999* (DCCEEW, 2023a)..

If the functions, interests or activities of a person(s) have not been advised directly to Esso via the above methods, an assessment is made based on available information relating to the person(s) or organisation(s), as per NOPSEMA function, interests and activities definitions.

4.2.6.2 Verifying true representation

The Esso Consultation Questionnaire is also used to determine the group participation of individual relevant persons. This information is used to develop a list of group members that Esso can engage with directly to seek verification that the right group representatives have been identified. This ground-truthing of views of the designated representatives is essential to confirm they will provide a comprehensive and accurate representation. The Questionnaire also allows for individual relevant persons to choose whether they want to be consulted with directly or if their preference is for Esso to consult with the group representative on their behalf.

4.2.6.3 Confirming participation

Provision is made in the Questionnaire to allow for a relevant person to 'opt out' of the consultation process. Esso will respect the wishes of the relevant person should they choose to 'opt out'.

Where the Esso Consultation Questionnaire has not been completed and returned, this will not be considered 'opting out' and Esso representatives will seek to make further contact with the relevant person to obtain a response, as appropriate.

Relevant persons can also notify Esso via the Consultation email to opt in or out of communications on specific activities.

It is recognised that in any community consultation there will inevitably be persons who cannot participate for various reasons, however the absence of their participation would not invalidate the process provided reasonable efforts are made to identify the relevant persons and to consult with them (NOPSEMA, 2024b).

4.2.7 Step 5 – Consult

Esso seeks to consult with relevant persons so that each relevant person has sufficient information to understand the activity and to help them make an informed assessment of possible consequences associated with the EP activities pursuant to their own functions, interests or activities. Esso acknowledges that what constitutes sufficient information as part of a consultation process may differ depending on the relevant person(s) (NOPSEMA, 2024b). As such, Esso seeks to consult in a way that is appropriate for each relevant person and adapted to the nature of the relevant persons to be consulted.

To achieve this, Esso consults with relevant persons in accordance with their assigned consultation Level. The consultation methods for each Level are outlined in Sections 4.2.7.1 to 4.2.7.3.

Each consultation has the overarching goals of:

- further strengthening foundation relationships with existing relevant persons
- developing relationships with new relevant persons
- facilitating genuine two-way dialogue between Esso and relevant persons
- building upon preceding consultations (where applicable) to further a relevant person's understanding of the activity.

Throughout the consultation process, relevant persons are invited to correspond with Esso if they have concerns or require clarifications. Follow-up verbal discussions occur where required or if requested.

Esso also provides avenues for relevant persons to contact Esso outside of formal engagement activities if they have any questions or concerns. If needed, Esso will provide support or assistance to relevant persons in relation to understanding the technical data.

All relevant persons are given the opportunity to nominate how they would like to be consulted. As appropriate, direct engagement with relevant persons, for example First Nations groups, will include co-design of their consultation methodology. This may require consultation over an extended period of time.

Relevant persons are not obligated to respond to a titleholder's requests to participate in the consultation process. In cases where no response has been received from a relevant person, and where sufficient information and reasonable period has been afforded to the relevant person, Esso will consider consultation closed for the purposes of the preparation of the EP.

The assigned consultation Levels and associated rationale for each relevant person are included in the relevant EP.

4.2.7.1 Consultation Level 1

Relevant persons assigned with consultation Level 1 will be provided with targeted and tailored activity-specific information to enable an effective consultation process. This can include meetings, presentations, workshops, forums, phone calls and specific information such as mapping. Consultation Level 1 is the highest level of engagement with relevant persons and may require consultation over an extended period of time.

Consultation Level 1 is applied to relevant persons whose functions, interests or activities are located in the OA of the planned activity. Esso may also determine this level of consultation appropriate if it is demonstrated that a stakeholder's functions, interests or activities are impacted by the proposed activity and are not within a geographical boundary.

Relevant persons will be provided with sufficient information (in a variety of formats, i.e. written, face-to-face, telephone etc.) and a reasonable period (30 days, but can be more according to the activity complexity) to respond. If no response is received, Esso will make a second attempt to contact the relevant person.

4.2.7.2 Consultation Level 2

Relevant persons assigned with consultation Level 2 will be provided with specific information based on known information needs (e.g. published industry guidance notes or proformas outlining what information a relevant person wishes to receive).

This may include meetings, presentations, workshops, forums, phone calls and specific information such as mapping. This may require consultation over an extended period of time.

Consultation Level 2 is applied to relevant persons whose functions, interests or activities are located in the ATBA of the planned activity. Esso may also determine this level of consultation appropriate if it is demonstrated that a stakeholder's functions, interests or activities are impacted by the proposed activity and are not within a geographical boundary.

Relevant persons will be provided with sufficient information (in a variety of formats, i.e. written, face-to-face, telephone etc.) and a reasonable period (30 days, but can be more according to the activity complexity) to respond.

4.2.7.3 Consultation Level 3

Relevant persons assigned with consultation Level 3 will be provided with activity-specific information but at a broader, level. This can include: activity-specific information bulletins including the impacts, risks and the mitigative controls in place, information regarding EMBA and oil spill modelling, and/or links to the Esso Consultation Hub and Esso Consultation Questionnaire.

If requested, consultation can include face-to-face engagements, phone calls, community meetings, specialist group meetings or community information sessions.

Consultation Level 3 is applied to relevant persons whose functions, interests or activities are located in the EMBA and may be affected by unplanned activities associated with the planned activity or if the relevant person has indicated that this is the level of consultation they prefer.

Relevant persons will be provided with sufficient information (in a variety of formats, i.e. written, face-to-face, telephone etc.) and a reasonable period to respond (30 days but can be more according to the activity complexity). If no response is received, no further consultation will be undertaken but Esso will continue to provide broader, high level information.

4.2.8 Relevant persons responses

Esso makes ongoing efforts to obtain responses through consultation. Esso is committed to considering all input and/or responses received from relevant persons in the development of EPs. Relevant person responses may be received in various ways.

Esso accepts responses and engages in consultation in order to understand the responses. Esso clearly identifies and addresses each matter raised by relevant persons, and if applicable to the activity to which the EP relates:

- demonstrates that the risk or impact in question has been reduced to ALARP and will be of an acceptable level

- provides a statement that addresses each element of the objection or claim made by a relevant person and where control measures are implemented to resolve objections and claims, will clearly communicate this to the relevant person
- provides copies of all written responses provided by a relevant person to NOPSEMA.

Responses received from relevant persons, throughout the development of an EP and its subsequent revisions, is considered and addressed as appropriate. A summary of responses, objection and/or claim, as well as Esso's assessment of the merits of feedback, objections and/or claim, and Esso's response, are provided in the EP.

4.2.9 Ongoing engagement

Esso recognises the importance of ongoing engagement with stakeholders as it is an opportunity to review and update Esso's current relevant persons functions, interests and activities, and as a forum for enquiry, objections or claims to be raised during an EPs activity.

In the case that a response is received following the submission of this EP, the response will be considered for any implications to the proposed activity and clearly communicated to the relevant person.

4.2.10 Consultation reporting

Esso maintains a Gippsland-wide stakeholder database. Communications, including meetings, calls, distribution of communications materials, emails etc. with relevant persons are logged in the database, detailing any feedback received, including questions, issues, concerns, suggestions, objections and/or claims, and any actions/responses. Actions are tracked and responses are provided to relevant persons as required.

During all communications, Esso encourages relevant persons to provide feedback through:

- emailing the consultation@exxonmobil.com email address
- accessing the Esso Consultation Hub
- calling +61 3 9261 0000
- or writing to GPO Box 400 Melbourne VIC 3001.

A report on all consultations between the Company and any relevant person is included in the relevant EP.

4.3 Methodology as applied to the scope of this Environment Plan

This Section demonstrates how Esso applies its consultation methodology specifically to this EP and how the Company ensured the consultations were appropriate and adapted to the nature of the interests of the relevant persons.

During the course of consultation for this EP, which commenced in December 2023 and concluded in early August 2025, relevant persons provided feedback on various topics including both onshore and offshore activities. Feedback specific to the activities of this EP have been summarised in Appendix E-2 and incorporated throughout the EP, where relevant.

4.3.1 Step 1 - Define

For Campaign #1 activities, Esso has outlined the following specifications, which were the basis for determining the anticipated key functions, interests and activities of each relevant person's category and defining criteria to determine categorisation as a relevant person within the scope of this EP:

- Activity description: Refer to Section 2
- Scope: Refer to Section 1.1
- Timing: Refer to Section 2.2
- Values and sensitivities: Refer to Section 3.3
- Geographic location: For the purposes of consultation, the facility location used to determine relevant persons includes the OA, ATBA and EMBA as shown in Appendix A.

Campaign #1 activities include:

- removal preparation works at Campaign #1 facilities
- removal of the PCA and DPA monotowers and gravity base foundations to seabed
- removal of WTA and BMA topsides and SPJs, as close as practicable to seabed to a maximum of 3m above seabed with deep foundation piles to remain

- removal of topsides and upper jacket sections at MKA, WKF, FLA, CBA, KFA and KFB, to a depth of at least 55m below MSL
    - at KFA and KFB, removal of struts will extend to the lower junction connection at the seabed template at least 55m below MSL
- the FTA facility has two options for removal:
    - FTA Option 1: Removal as close as practicable to seafloor to a maximum of 3m above seafloor, with deep foundation piles to remain
    - FTA Option 2: Removal to a depth of at least 55m below MSL
- removal of the BMB topsides and module support frame only. The BMB concrete substructure will remain in place and a navigation aid will be installed
- the option to remove HLA topsides, upper jacket section to a minimum of 55m below MSL and strut to the lower junction connection at the seabed template. The option to remove HLA is contingent on a number of operational and logistics conditions including continued use as an alternate flow path for gas supply to Longford Plant which will need to be met within the required Campaign #1 timeframes. If the option is not exercised in Campaign #1, HLA will continue to be in use and decommissioned as part of Campaign #2
- the option to remove well conductors should this not be achieved during P&A prior to Campaign #1
- post removal as left survey
- topsides and jacket transport, backloading to barges or HTVs, sea fastening and initial transport of structures to the border of Victorian State waters
- Ongoing IMR of the infrastructure relating to the facilities partially removed in Campaign #1, until such time as the Bass Strait Non-Producing Environment Plan is accepted.

Therefore, in determining who is a relevant person for consultation, Esso sought to identify and consult with persons whose functions, interests or activities could be affected by the activities described in Section 2 of this EP.

4.3.2 Step 2 - Identify and classify

A complete list of all relevant persons that may be affected from either the planned activities or the unplanned activities, including the assessment of their relevance, their assigned relevant person category, their functions, interests and activities and subsequent consultation Level is provided in Appendix E-1.

4.3.2.1 Regulation 25(1)(a)-(c) relevant persons

To identify relevant persons in accordance with Regulation 25(1)(a)-(c), Esso used the methods as outlined in Table 4-2. The full list of Regulation 25(1)(a)-(c) relevant persons is shown in Appendix E-1.

Table 4-2 Regulation 25(1)(a)-(c) relevant persons identification methods

Method	Description
Relevant persons previously identified for other activities	
Review of Esso's existing relevant person database	Identify existing relevant persons based on Regulation 25(1)(a)-(c) and the: • activity description • scope • geographic location.
Actively seek out new relevant persons	
Regulation 25(1)(a)-(c)	Search for any Commonwealth or State departments, agencies or ministers related to any of the values and sensitivities listed in Section 3.3 and located in either the OA, ATBA or EMBA.

4.3.2.2 Identification of Regulation 25(1)(d) relevant persons

To identify relevant persons in accordance with Regulation 25(1)(d), Esso used the methods as outlined in Table 4-3. The full list of Regulation 25(1)(d) relevant persons is shown in Appendix E-1.

Table 4-3 Regulation 25(1)(d) relevant persons identification methods

Method	Description
Relevant persons previously identified for other activities	
Review of Esso's existing relevant person database	Identify existing relevant persons based on Regulation 25(1)(d) and: • area of planned activities and geographic location of potentially affected areas from unplanned activities • reasonably ascertainable functions, interests or activities • provide information bulletins, Consultation Hub and Esso Consultation Questionnaire.
Actively seek out new relevant persons	
Local knowledge	Use local knowledge of existing relationships to identify marine users and interest groups active in the area.
Existing relevant persons	Ask existing relevant persons to share information bulletins, Esso Consultation Hub and Esso Consultation Questionnaire with anyone they consider may be interested.
Seek advice of First Nations groups	Advertised community information sessions in Indigenous media (e.g. *Koori Mail*). Maintained Esso Consultation Hub including information bulletin and Esso Consultation Questionnaire provided to all First Nations identified in the EMBA. Identified potentially relevant First Nations peoples are identified using the Australian Institute of Aboriginal and Torres Strait Islander Studies map of Indigenous Australia, overlaid with the geographical information of the OA (and EMBA if applicable). Utilised Government resources such as State Government spatial data sets to identify potentially relevant Aboriginal Land Councils, Registered Aboriginal Parties and Registered Aboriginal Community Organisations. Continued engagement with GLaWAC as the Registered Aboriginal Party, and other self-identified Indigenous relevant persons.
Community information sessions	Considered the attendees of community information sessions.
Recommendations	Considered recommendations received from relevant persons via responses provided in the Esso Consultation Questionnaire or through consultation with them.
Searches of internet sources	Google, social media platforms using the geographical boundaries of the EMBA. Search for any potentially relevant persons related to any of the values and sensitivities listed Section 3.3. Search using methodology in Section 4.2.4.1.

Method	Description
Advertisements in newspapers and other relevant news sources	Advertised in national, State, regional and local papers using the geographical boundaries of the EMBA including *Koori Mail*.
Review of legislation applicable to petroleum and marine activities	Following on from (Santos NA Barossa Pty Ltd v Tipakalippa, 2022) Esso conducted a further review of worker unions, eNGOs, First Nations groups and communities within the geographic boundary of the EMBA.
Offshore Wind Industry	Search of the National Electronic Approvals Tracking System to access publicly available information concerning offshore electricity infrastructure licences under the *Offshore Electricity Infrastructure Act 2021* (Cth).
Professional conferences	Attended/staffed booths at relevant industry conferences.
Self-identification	
Broad-based information sharing	Relevant persons self-identify in response to Esso's broad-based information sharing mechanisms, such as the Esso website, *Connection* magazine, advertisements etc.
Other means	Relevant persons self-identify.

4.3.2.3 Identification of Regulation 25(1)(e) relevant persons

To identify relevant persons in accordance with Regulation 25(1)(e), Esso has reviewed the existing stakeholder database to identify other persons or organisations that Esso considers to be relevant. These persons were added to the list of relevant persons and assigned an appropriate consultation Level. The full list of Regulation 25(1)(e) relevant persons is shown in Appendix E-1.

Esso has considered community members as relevant persons where the individual has:

- registered and attended a community information session on this activity, OR
- completed Esso Consultation Questionnaire and selected to be consulted of this activity, OR
- contacted Esso independently (email/phone) and nominated as relevant to this activity.

4.3.2.4 Persons or organisations Esso chooses to contact

As part of Esso's ongoing stakeholder relationship management activities, Esso may choose to contact other persons and organisations that did not meet the Regulation 25(1) categories. For the purposes of consultation, they may not be relevant persons.

The persons and organisations in this category may include those who:

- do not have a function, interest or activity that overlapped with either the OA, ATBA or the EMBA and were not going to be impacted by the activities outlined in this EP
- have an interest in Esso's other activities (e.g. onshore facilities in Longford or Hastings) and were notified as part of our ongoing communications with them
- have a broader industry interest and are included in our broader communications
- Esso approached to clarify what their functions, interests and activities are, or whether they may be affected.

4.3.3 Step 3 - Assign

In order to confirm the appropriate Regulation 25(1) category and assign the appropriate consultation Level to each identified relevant person, a number of consultation workshops were held with Esso consultation advisors and relevant subject matter experts.

Factors considered in the workshops, specific to the Campaign #1 activities, include:

- the various locations of the OA's
- the OAs are within the 500m PSZ
- the well sites are located within existing Commonwealth fisheries that may be used by commercial fishers
- the 500m PSZ will be communicated to the commercial fishing organisations
- there may be recreational fishing in the area but unlikely to be significant given the closeness of the Traffic Separation Scheme
- the duration of the work, estimated to be up to 13 days per platform, timing at each location will differ depending on the work scope
- there is no known Sea Country mapping currently available
- relevant government departments are known
- the functions, interests and activities of the relevant person(s) or organisations identified and their known preferred methods of communication
- Esso's relationship with the relevant person or organisation, for example when did Esso last engage with them? On what topic? What are their levels of interest? Is Esso currently consulting with them on other activities?
- the environmental values and sensitivities have been assessed in the impact and risk assessment as **Risk Category 3** or **Risk Category 4** per Section 5 and 6 of this EP
- if the relevant person/organisation can provide input to the design of the or management of the planned activities have been identified.

A complete list of all identified relevant persons, their assigned consultation Level and the justification for the consultation Level, as per the process outlined in Section 4.2.5 is provided in Appendix E-1.

4.3.4 Step 4 - Verify

A link to the Esso Consultation Questionnaire was emailed to every person in the stakeholder database to verify:

- which Esso activities they wish to be consulted on
- how they would prefer Esso to communicate with them
- which functions, interests or activities that may apply to them
- any group(s) they are represented by a member of, or participate in
- if they wish to be consulted through their representative.

Esso confirmed representation for the groups outlined in Table 4-4.

Table 4-4 Relevant person representatives

Relevant person	Representative for
SETFIA	Incorporated association representing commercial fishers in Commonwealth South East Trawl Sector; SHS; SGSHS; small pelagic fishery.
SIV	Representative peak body for the Victorian seafood industry, from professional fishers, through to wholesalers, processors, and retailers, predominately in State waters.
LEFL	Represents Lakes Entrance commercial fishing by providing a full-service unloading facility to the local fishing fleet. From here, fresh seafood is distributed to local shops.
GLaWAC	Registered Aboriginal Party that represents the Gunaikurnai people, the Traditional Owners of our Country, as determined by the Victorian Aboriginal Heritage Council under the *Aboriginal Heritage Act 2006* (Vic).
Game Fishing Association of Victoria (GFAV)	Governing body for Game Fishing in Victoria affiliated with the Game Fishing Association of Australia and the International Game Fishing Association.

4.3.5 Step 5 – Consult

Esso has been engaging with stakeholders to discuss decommissioning activities more broadly since 2020. For the activities specific to Campaign #1, consultations began in December 2023, using various methods, and continued until early August 2025.

4.3.5.1 Consultation timing

For the nature and scale of the activity described in this EP, Esso determined that 60 business days would provide a reasonable period for relevant persons to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of relevant persons.

All relevant persons were consulted for a minimum of 60 business days. Esso has met the requirement to provide a reasonable period for consultation.

4.3.5.2 Provision of sufficient materials

Esso developed four Campaign #1 specific information bulletins as outlined in Table 4-5 and presented in Appendix F to provide each relevant person with sufficient information, in accordance with Regulation 25(2), by providing an overview of the proposed activity including information on the activity description, scope, timing, location, risks, impacts, mitigation measures and EMBA information. The information bulletins were shared with stakeholders via email, face-to-face and were made available on the Esso Consultation Hub.

Table 4-5 Campaign #1 specific information bulletin issue dates

Information bulletin		Date	Details
Information Bulletin #1 (Appendix F-1)	Decommissioning Campaign #1 – Project Update (March 2024)	28 March 2024	Campaign #1 update, activity timing, activity location.
Information Bulletin #2 (Appendix F-2)	Decommissioning Campaign #1 – Environmental impacts and risks (June 2024)	1 July 2024	Potential impacts and risks, ORC.
Information Bulletin #3 (Appendix F-3)	Decommissioning Campaign #1 – Impacts and risks update (September 2024)	30 September 2024	Key impacts and risks following completion of the impacts and risks workshop.
Information Bulletin #4 (Appendix F-4)	Gippsland Basin Decommissioning – Onshore Reception Centre Campaign #1 ORC update (December 2024)	13 December 2024	Campaign #1 update, activity timing, activity location. Potential impacts and risks.

All information bulletins remain accessible via the Esso Consultation Hub.

In addition to the provision of information bulletins, Esso undertook the consultations shown in Table 4-6 with all relevant persons.

Table 4-6 Campaign #1-specific consultations undertaken with all relevant persons

Date	Summary of consultation
14 February 2024, 28 March 2024, 25 April 2024, 14 May 2024, 11 June 2024, 12 June 2024, 6 July 2024, 11 July 2024, 15 July 2024, 13 August 2024, 16 August 2024, 28 January 2025, 7 May 2025.	Email to stakeholders advising of several offshore activities proposed by Esso including links to proposed Campaign #1 activity information available via the Consultation hub.

Date	Summary of consultation
28 March 2024, 14 May 2024, 11 June 24, 12 June 2024, 6 July 2024, 9 July 2024.	Email to EMBA stakeholders advising of several offshore activities proposed by Esso including links to proposed Campaign #1 activity information available via the Consultation hub.
10 April 2024	Email to stakeholders to provide Esso Australia: 2023 Annual Decommissioning Report.
3 March 2025	Email to stakeholders to provide Esso Australia: 2024 Annual Decommissioning Report.

Esso acknowledges that what is considered 'sufficient information' may vary from relevant person to relevant person. As such, the information bulletins were accompanied with the Esso Consultation Questionnaire, which provides relevant persons with a mechanism to communicate what they consider 'sufficient information'.

4.3.5.3 Community information sessions

Esso has been undertaking community information sessions in Sale and Lakes Entrance since 2017 and continues to hold these on a quarterly basis providing community updates on all Esso activities.

Given the location of the proposed ORC and community feedback, Esso provided additional information sessions to include the Corner Inlet area on a monthly basis between August and November 2024. Attendance increased throughout 2024 with over 40 attendees at community information sessions held during September alone and increasing to 60 attendees during October community information sessions. A total of 20 people attended community information sessions held during November 2024. Esso continued quarterly community information sessions in 2025 across South Gippsland and East Gippsland, with a total of 84 attendees in February and 60 attendees in May. Esso will continue to hold community information sessions during second half of 2025.

Community members attending sessions have advised that they are satisfied with the frequency of sessions being held at Sale and Lakes Entrance.

Over the course of the consultation period for Campaign #1 activities, Esso provided a total of 31 community information sessions in the local area as summarised in Table 4-7.

Table 4-7 Consultation period community information sessions

Session	Date	Location	No. of attendees
1	29 February 2024	Lakes Entrance	5
2	29 May 2024	Sale	10
3	30 May 2024	Lakes Entrance	3
4	21 August 2024	Sale	2
5	22 August 2024	Lakes Entrance	3
6	27 August 2024	Welshpool	1
7	28 August 2024	Foster	9
8	29 August 2024	Golden Beach	3
9	25 September 2024	Welshpool	15

Session	Date	Location	No. of attendees
10	25 September 2024	Leongatha	5
11	26 September 2024	Foster	21
12	22 October 2024	Yarram	5
13	23 October 2024	Foster	45
14	24 October 2024	Leongatha	10
15	18 November 2024	Lakes Entrance	3
16	18 November 2024	Welshpool	4
17	19 November 2024	Foster	8
18	19 November 2024	Sale	4
19	20 November 2024	Leongatha	1
20	17 February 2025	Yanakie	13
21	18 February 2025	Foster	31
22	19 February 2025	Leongatha	7
23	24 February 2025	Lakes Entrance	8
24	25 February 2025	Yarram	15
25	26 February 2025	Sale	10
26	19 May 2025	Welshpool	4
27	20 May 2025	Foster	18
28	21 May 2025	Leongatha	13
29	26 May 2025	Yarram	7
30	27 May 2025	Lakes Entrance	14
31	28 May 2025	Sale	4

To ensure every effort was made to reach relevant persons, the community information sessions were advertised in various news outlets, including local and national, as shown in Table 4-8. Esso also provided details of community sessions via ExxonMobil Instagram, ExxonMobil website and *Connection* Magazine.

Copies of advertisements for each session are provided in Appendix G.

Table 4-8 Community information session advertisement news outlets

News outlet	East Gippsland			Central Gippsland		South Gippsland					State - Victoria	National	
	Bairnsdale Advertiser	Lakes Post	Snowy River Mail	Latrobe Valley Express	Gippsland Times and Maffra Spectator	South Gippsland Sentinel Times	South Gippsland Voices	Prom Coast News	Foster Community Online	The Bridge, Yarram	Herald Sun	Koori Mail	The Australian
February 2024	✓	✓	✓	N/A	✓	N/A	N/A	N/A	N/A	N/A	✓	✓	N/A
May 2024	✓	✓	✓	✓	✓	✓	N/A	N/A	N/A	N/A	✓	✓	✓
August 2024	✓	✓	✓	✓	✓	✓	✓	N/A	N/A	N/A	✓	✓	✓
September 2024	N/A	N/A	N/A	✓	✓	✓	✓	✓	✓	✓	✓	N/A	✓
October 2024	N/A	N/A	N/A	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
November 2024	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
February 2025	✓	✓	✓	✓	✓	✓	✓	✓	N/A	✓	✓	✓	✓
May 2025	✓	✓	✓	✓	✓	✓	✓	✓	N/A	✓	✓	✓	✓

Where appropriate, some advertisements were distributed to stakeholders via email mailing lists. This applies to the community sessions held in Golden Beach in August 2024.

Flyers for November 2024 community information sessions were displayed at the local venues as outlined in Table 4-9. Flyers were continued to be displayed at local venues for February 2025 and May 2025 community information sessions.

Table 4-9 Community information session flyers

Town	Location
Leongatha	• Laundromat • Information Centre • IGA Supermarket • Community House • Sports Power • Library • Mitre 10 • Nutrien Ag Solutions
Meeniyan	• Bowls Club • Bakery • Post Office • Service Station
Fish Creek	• Pharmacy/Post Office • Hardware Store
Foster	• Information Centre • Manna Gum Community House • Post Office • Laundromat • Hotel • Foodworks • Andos Café
Yarram	• Betta Electrical • Manners Department Store • Bargain Centre • BP Service Station
Woodside	• Service Station

In addition to the above activities, in March and April 2024, Esso staffed a booth and engaged with a wide variety of community members at the Sale Music Festival and Air Show in West Sale. Community members were provided with a Gippsland Basin Activities information bulletin including Campaign #1 EP information, which included links to the Esso Consultation Hub.

Qube, site operator of Barry Beach Marine Terminal, held the following community information sessions in Corner Inlet area to provide the local community with information relating to Barry Beach Marine Terminal activities:

- 6 May 2024 – Toora
- 6 May 2024 – Welshpool
- 7 May 2024 – Foster
- 30 May 2024 – Foster.

Members of Esso's Project Management team and Consultation team attended to provide information on Campaign #1 activities.

Esso also conducts regular meetings with organisations and/or agency representatives of Regulation 25(1)(a)-(c) relevant persons and with groups and/or group representatives identified under Regulation 25(1)(d). Details of these meetings are recorded in the relevant persons database and presented in the Consultation report (Summary) (refer to Appendix E-2).

4.3.5.4 Stakeholder forums

Esso held six Campaign #1-specific stakeholder forums across Lakes Entrance, Sale, Port Welshpool, Aspendale and online between May and August 2024, as shown in Table 4-10. Invitations were sent to stakeholders allowing them to register for their preferred session (Appendix E-2). Over 80 people from across a range of different backgrounds took the opportunity to learn more about what was being considered to decommission the Esso platforms and to hear from each other about the potential risks and impacts of options being considered and how these could be managed.

Table 4-10 Stakeholder forum summary

Forum	Stakeholders	Date	Location	No. of attendees
1	Commercial fishing	27 May 2024	Lakes Entrance	15
2	All stakeholders	4 June 2024	Sale	12
3	All stakeholders	5 June 2024	Online	21
4	Commercial fishing	19 June 2024	Port Welshpool	1
5	Recreational fishing	17 July 2024	Aspendale	20
6	All stakeholders	8 August 2024	Port Welshpool	15

The stakeholder forums aimed to help relevant persons make an informed assessment of the possible consequences of decommissioning activities on their functions, interests and activities and to advise Esso of any potential impacts or risks that may affect them. These forums also enabled stakeholders to participate in the identification of Campaign #1 impacts and risks and consider mitigations that may be required to address these risks.

The stakeholder forums were facilitated by Esso Australia's Major Projects Decommissioning Project Manager and supported by Esso's Consultation Team and Environment and Regulatory Team.

All forums included a presentation that covered:

- an overview of Esso's operations
- the facility lifecycle
- Esso's approach to decommissioning
- details of vessels involved in Campaign #1
- information on transfer locations
- recycling and disposal plans
- an outline of impacts and risks associated with Campaign #1
- an overview of the regulatory process.

Opportunities were provided during the forums for questions to be raised and responded to by stakeholders.

Discussion topics on Campaign #1 raised by participants were:

- opportunities to increase transferable skills and job capacity in the area
- clarification of removal campaign activity details, such as load in operations at Barry Beach Marine Terminal and vessel exclusion zones
- feedback on potential impacts and risks of removal Campaign #1 activities
- disturbance to established ecosystems on jackets, residual debris presenting a snag risk, displacement of seals and seabirds

- feedback on potential controls associated with these impacts and risks – provision of navigation aids, regular notifications
- benefits of leaving infrastructure in situ - retaining established marine ecosystems and providing recreational fishing opportunities
- potential impacts (positive and negative) on tourism and local businesses
- opportunities to share research associated with infrastructure removal and/or leaving in situ
- Corner Inlet seagrass monitoring opportunities.

Information gathered at the stakeholder forums, where applicable, informed the environmental impacts and risks assessment undertaken as part of preparing this EP (Sections 6 and 7).

A summary of the stakeholder forums from May to August was provided to stakeholders on 10 September 2024 (Appendix F-5) and Information Bulletin #3 (Appendix F-3), including the outcomes of the impacts and risks assessment, was provided to stakeholders on 30 September for feedback.

4.3.5.5 Consultation with Commonwealth agencies with responsibilities in the marine area

Esso engages with Commonwealth Government departments and agencies as required for project activities. Esso met with DCCEEW in July 2024 to provide an overview of Campaign #1 and the strategy for regulatory pathways. A second meeting was held in October 2024 to provide an update on the Campaign #1 strategy, followed by a meeting in November 2024. Esso met with DCCEEW Wetlands Branch in January 2026 to discuss Campaign #1 activities and potential indirect risks and impacts relevant to the Corner Inlet Ramsar Site. Esso undertakes ongoing quarterly meetings with NOPSEMA to provide updates on Campaign #1 progress.

Table 4-11 outlines the Commonwealth agencies with responsibilities in the marine area (NOPSEMA, 2024e) relevant to Campaign #1 activities as outlined in this EP. Consultations undertaken with each agency is included in Appendix E-2.

Esso will continue to meet with relevant Commonwealth Government departments and agencies in an ongoing manner and/or as required. Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

Table 4-11 Commonwealth agency relevance to Campaign #1 activities

Commonwealth agency		Relevant to this EP
DCCEEW	EPBC Act administration and the Australian Antarctic Division	Not relevant to these activities.
	Underwater cultural heritage	Relevant to these activities.
	Sea dumping	Not relevant to these activities.
Director of National Parks		Relevant to these activities.
Department of Agriculture, Fisheries and Forestry	Fisheries	Relevant to these activities.
	Biosecurity (vessels, aircraft and personnel)	Relevant to these activities.
	Biosecurity (marine pests)	Relevant to these activities.
Australian Fisheries Management Authority		Relevant to these activities.
AMSA		Relevant to these activities.
Department of Defence (including the AHO)		Relevant to these activities.

Commonwealth agency	Relevant to this EP
Department of Foreign Affairs and Trade	No relevant to these activities.

4.3.5.6 Consultation with First Nations people

Esso engages with First Nations people and representative organisations respectfully and effectively in meeting statutory obligations. Esso considers guidance developed by Australian Government agencies, including but not limited to the guidance provided in *Interim Engaging with First Nations People and Communities on Assessments and Approvals under the Environment Protection and Biodiversity Conservation Act 1999* (DCCEEW, 2023a).

4.3.5.6.1 GUNAIKURNAI LAND AND WATERS ABORIGINAL CORPORATION

As a Prescribed Body Corporate under the federal Native Title (Prescribed Body Corporate) Regulations 1999 (Cth), the GLaWAC is empowered to make native title decisions and negotiate agreements on behalf of the Gunaikurnai Native Title holders. GLaWAC must undertake a process of consultation and consent with Native Title holders as part of that agreement-making process. GLaWAC is the Registered Aboriginal Party under the *Aboriginal Heritage Act 2006* (Vic) recognising them as the primary guardians, keepers and knowledge holders of Aboriginal cultural heritage of country, including sea country, throughout much of Gippsland.

Esso commenced decommissioning consultation with GLaWAC more broadly in March 2022. Between March 2022 and August 2025 GLaWAC was provided with information via email and during an in-person meeting held in May 2023 at GLaWAC's office in Kalimna. Following this meeting, the Esso Consultation Hub and Esso Consultation Questionnaire, which provides activity-specific information to the public, was launched and communicated to GLaWAC in July 2023. GLaWAC provided a response to the Esso Consultation Questionnaire nominating to be consulted on decommissioning activities, including the ORC.

Monthly consultation meetings for Esso's proposed decommissioning activities commenced with GLaWAC in February 2024 and covered Campaign #1proposed scope. Post this meeting, an Esso Key Messages brochure was developed including ORC information and links to the Consultation Hub and provided by Esso in February 2024 as requested by GLaWAC for use during consultations with community members.

Esso followed-up and sought feedback to the initial February meeting via Campaign #1-specific consultation with GLaWAC in March, May, and June 2024, providing activity details (e.g. description, location, logistics, impacts and risks). In August 2024 GLaWAC attended an Esso site visit to the proposed South-East Australia Carbon Capture and Storage Project pipeline easement from Longford Plant to Valve Site 3 (Paradise Beach). The visit also included attendance at the Site 1B BMA350 and BTA350 shore crossing (Paradise Beach) that included discussions on pipeline decommissioning, as well as discussions on Campaign #1 decommissioning activities and the proposed ORC activities at Barry Beach Marine Terminal.

Engagement with GLaWAC is an ongoing exercise via monthly consultation meetings, emails and phone calls, and includes discussions on Esso's offshore and onshore proposed activities. The content of monthly meetings is agreed between Esso and GLaWAC attendees, and includes sharing of information related to:

- decommissioning – offshore and onshore activities
- production activities (including gas production, P&A of wells, and wastewater treatment).

The monthly meetings, as well as emails and site visits provide continuous and targeted opportunities for GLaWAC to be consulted on Campaign #1 and other activities. The Campaign #1 EP submission date was communicated to GLaWAC in April 2024.

As per Esso's methodology for Level 1 consultation, GLaWAC has also received Campaign #1 EP information bulletins via email in March, June, September and a follow-up in November 2024 as well as the ORC Stage 1 Early Works information bulletin in December 2024).

Additionally, GLaWAC was invited to participate in-person and online for Campaign #1 forums held in June 2024, as well as being offered private forums for both GLaWAC and/or Gunaikurnai community members (which have not been accepted to date).

In relation to Traditional Custodian relevant persons, Esso has discharged its duty under Regulation 25 and considers that consultation under Regulation 25 is complete. Discharge and completion is on the basis that during the ongoing provision of detailed information, GLaWAC has advised that information provided in relation to

Campaign #1 activities since consultation commenced in March 2024 is satisfactory in answering queries. Furthermore, at the time of submission of this EP, GLaWAC has not raised objection to proposed Campaign #1 activities.

General engagements (beyond Campaign #1 activities) with GLaWAC are ongoing and have included:

- Esso representatives attended the NOPSEMA facilitated National Summit on Consultation on Offshore Petroleum Activities with First Nations Peoples (Perth, 21-22 June 2023)
- the Australian Energy Producers facilitated National Sea Country Alliance Summit (Perth, 6-7 November 2023), which were also attended by GLaWAC representatives
- Esso requested information on Gunaikurnai Sea Country to further understand how offshore activities might impact on cultural heritage (November 2023). A meeting was conducted between Esso and GLaWAC (GLaWAC's Kalimna office) in December 2023 to further discuss GLaWAC's IPA application and to identify potential opportunities for Esso to share information that might support this application
- information sharing workshops were held in April (Esso's Sale office) and August 2024 (GLaWAC's Morwell office) to share Esso environmental and GIS information, including Campaign #1 underwater survey data, with GLaWAC to support the GLaWAC IPA application.

Esso considers these activities as valuable relationship building, as well as facilitating information sharing.

4.3.5.6.2 KURNAI ABORIGINAL CORPORATION

Under the *Native Title Act 1993* (Cth), the FCA determined the Gunai/Kurnai groups to be Native Title holders over much of Gippsland. The GLaWAC (on behalf of the Gunai group) signed an agreement with the State of Victoria in 2010 under the *Traditional Owner Settlement Act 2010* (Vic) to extinguish Native Title rights for land management including a number of State parks. GLaWAC is the Prescribed Body Corporate and the Registered Aboriginal Party that holds rights and interests which sometimes compromise the Native Title of the common law holders; the Kurnai group declined to sign the agreement to instead maintain their rights as the Native Title holders. Esso recognises the Kurnai Aboriginal Corporations status as Native Title holders and First Nations people and will continue to meet with the corporation at their request to consult on Esso's activities.

The Kurnai Aboriginal Corporation actively promotes respect for Kurnai history, lore, laws and culture. The Kurnai Aboriginal Corporation do not represent/are not represented by GLaWAC.

Elders from the Kurnai Aboriginal Corporation attended the community information session in Leongatha on 24 October 2024. In November 2024 the Kurnai Aboriginal Corporation contacted the Esso Consultation Team nominating to be consulted on Campaign #1 offshore and onshore activities.

Esso met with representatives from the Kurnai Aboriginal Corporation on 17 December 2024 in Morwell to discuss the Campaign #1 scope. The Kurnai Aboriginal Corporation representatives provided an overview of the corporation including members, goals and expectations for stakeholder consultation. Both parties agreed to meeting again in 2025 on an ad-hoc basis.

On 13 August 2025, the Kurnai Aboriginal Corporation provided a letter to Esso in which the Kurnai Aboriginal Corporation made various claims and requests of Esso A response was provided to the Kurnai Aboriginal Corporation on 5 December 2025 addressing their various claims and requests. Further correspondence was received from the Kurnai Aboriginal Corporation on 11 December 2025, agreeing to quarterly consultation meetings and providing response to Esso letter dated 5 December 2025.

Esso provided a response to Kurnai Aboriginal Corporation 12 January 2026 confirming Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.7 Consultation with local councils.

Esso maintains a strong relationship and frequent engagements with local councils in the Gippsland area, including Wellington Shire Council and South Gippsland Shire Council. During the consultation period for Campaign #1, Esso held meetings with South Gippsland Shire Council between February and August 2025 to discuss Campaign #1 activities, including the ORC.

Council members were also invited to community information sessions and stakeholder forums, with attendance from Wellington Shire, East Gippsland Shire, South Gippsland Shire and Mornington Peninsula Shire councils across various locations.

Esso considers it has discharged its obligations for consultation under Regulation 25having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.8 Consultation with commercial fishing

Esso started decommissioning consultation with the commercial fishing industry more broadly in January 2022. Esso has continued more detailed consultation between December 2023 to August 2025, providing activity overview (description, location, impacts and risks) and seeking feedback. Esso has continued to meet with SETFIA, LEFL and SIV via face-to-face and online meetings on a quarterly basis throughout the Campaign #1 consultation process, as well as targeted meetings to discuss issues, concerns or items as required. Esso also conducted Campaign #1 engagements specific to commercial fishers, as detailed in Section 4.3.5.4.

There are 23 fisheries permitted to work around Esso Australia's field; 14 are State managed, and nine are Commonwealth managed. Of those 23 fisheries, only 15 have recorded recent (10 year) fishing efforts around the ATBA.

SETFIA represents more than 80% of the SESSF CTS, a Commonwealth managed fishery activity in the vicinity of the OAs. SIV represents Victorian State fisheries, with Inshore Trawl Fishery and Eastern Zone Octopus Fishery active in the vicinity of the OAs. LEFL (also a member of SETFIA) represents approximately eight boat owners that may fish in the vicinity of the OAs. Southern Shark Industry Alliance supports the Southern Shark Fishery, Southern Shark Industry Alliance shares the same key contact as the SETFIA Executive Officer.

Esso attempted to consult directly with individual commercial fishermen but was unable to obtain contact information due to confidentiality. Therefore, all consultation was conducted through the representative bodies, SETFIA, SIV and LEFL, unless Esso was contacted by commercial fishermen independently. Consultation records with the commercial fishing Industry are provided in Appendix E-2.

The commercial fishing industry has provided feedback on Campaign #1 activities, refer to Appendix E-2. Esso has considered this feedback within the development of this EP.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.9 Consultation with recreational fishers

Esso has held ongoing meetings with GFAV, both face-to-face and online, including a presentation on Campaign #1 activities at the GFAV State Council Meeting on 17 July 2024 (details summarised in Appendix E-2).

Victorian Recreational Fishing Peak Body (VRfish) has been invited to meetings with GFAV and Esso directly contacted VRfish for a separate meeting. Esso continues to send VRfish updates on all activities.

Esso attends Gippsland Lakes Fishing Club meetings, as scheduled, to present to club members on Esso activities. Esso held a presentation on 6 March 2024 providing details on Campaign #1.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.10 Consultation with unions

Esso held meetings with the Australian Manufacturing Workers Union, Australian Workers Union, Electrical Trades Union, Maritime Union of Australia and the Construction, Forestry and Maritime Employees Union throughout the consultation period between December 2023 to August 2025. These meetings specifically focused on decommissioning plans and job opportunities, with the unions expressing interest in the broader decommissioning activities. This not only includes Campaign #1 but also the ORC and pipelines activity. Further meetings will be held and information shared with the unions as required.

Unions members were also invited to community information sessions and stakeholder forums, with attendance from Maritime Union of Australia, Victorian Trades Hall Council and the Australian Manufacturing Workers Union across various locations.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.11 Consultation with environmentally focused non-government organisations

In the course of consultation, Esso has identified multiple eNGO's, including Friends of the Earth, The Wilderness Society and Birdlife Australia who self-identified as relevant persons for Campaign #1. Esso has communicated information regarding Campaign #1 activities via email, phone, online and individualised in-person meetings and during community information sessions and stakeholder forums. Esso will continue to share updates on Campaign #1 activities with eNGO's. Feedback from all eNGO's will be considered within the development of regulatory submissions.

Esso has engaged other eNGOs to provide information on Esso's offshore activities as outlined in Appendix E-2. Feedback from eNGOs has been considered and incorporated into the EP, where applicable. Updates on Esso's activities will continue to be shared with eNGO's.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.12 Consultation with State Government departments/agencies

Esso engages with State Government departments and agencies as required for Campaign #1 activities. Relevant departments were invited to Campaign #1 stakeholder forums with attendance from: the Gippsland office of the Victorian Environment Protection Authority; the Gippsland office of the Department of Employment and Workplace Relations; the East Gippsland Catchment Management Authority; and Gippsland Water.

Esso also engages with departments relevant to emergency response (Quick Reference Guide) including the Victorian Environment Protection Authority and the Victorian Department of Transport and Planning. Esso has met with Parks Victoria specifically regarding Campaign #1 activities, with a presentation provided on 12 September 2024. Esso continues to meet with DEECA in an ongoing manner and/or as required.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.5.13 Offshore wind industry

Feasibility licences for the offshore wind industry in Bass Strait were granted in second quarter 2024 and third quarter 2024. Esso began consultation with the new licence holders during second quarter 2024 to establish if the functions, interests or activities of these offshore wind developers have the potential to be affected by the Campaign #1 activities and may be relevant persons. Esso held meetings throughout 2024 and 2025 with offshore wind developers within the Campaign #1 OA and ATBA. Esso continues to undertake meetings with offshore wind developers as required.

During these consultations, offshore wind developers have asked to be kept informed of Esso's timing for decommissioning to allow for project planning. Esso will continue to share details of offshore activities including timing and locations with wind industry proponents. Consultation with all licence holders is summarised in Appendix E-2.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.3.6 Broad-based information sharing

As part of Esso's commitment to engaging with relevant persons to build lasting long-term relationships, a range of broad-based information sharing mechanisms are used. Identified relevant persons can also choose to 'opt in' to distribution lists through the Esso Consultation Questionnaire.

Esso's broad-based information sharing mechanisms are outlined in Table 4-12.

Table 4-12 Broad-based information sharing mechanisms

Mechanism	Description
Periodic updates	Esso uses email distribution to provide updates about Esso's offshore operations and activities, reports or information bulletins to relevant persons as appropriate.

Mechanism	Description
Esso Consultation Hub	A Consultation Hub has been developed and shared with all relevant persons to provide access to information on all offshore activities and the opportunity to request further information and consultation preferences.
Esso Consultation Questionnaire	A Consultation Questionnaire has been developed and shared with all relevant persons to allow Esso to consult with relevant persons based on their preferences: • Which of the following Esso activities would you like to be consulted on? • How would you prefer Esso communicates with you? • Please select any functions, interests or activities that may apply to you • Please select any group(s) you are represented by a member of, or participate in • Do you wish to be consulted through your representative? • How did you hear about our activities?
Connection magazine	Esso's monthly newsletter, which is distributed via email and accessible on the Company website. The magazine provides relevant persons with regular updates on Esso's activities.
Esso website	Esso's website is an online portal that gives broader groups of relevant persons up-to-date information on various facets of our business and provides an opportunity for relevant persons to make enquiries about our offshore activities and projects. The website is updated periodically to reflect new information and activity progress.
Annual Decommissioning Report	Accessible from Esso's website, this Report provides technical, yet accessible, insight into Esso's decommissioning plans and yearly progress. The Report is emailed directly to all Relevant Persons and shared more broadly with other interested relevant persons.

4.4 Relevant persons feedback

Throughout the consultation process, all relevant persons had the opportunity to contact Esso's consultation team by emailing consultation@exxonmobil.com, completing the Esso Consultation Questionnaire, calling Esso's Head Office on +61 3 9261 0000 or writing to GPO Box 400 Melbourne VIC 3001.

Esso provides a summary of all responses, objections and/or claims, as well as Esso's assessment of the merits of these and Esso's response in Appendix E-2.

Feedback received from relevant persons, either through face-to-face, email or phone requests, or through responses provided in the Esso Consultation Questionnaire for the scope of this EP is summarised in Appendix E-2 and incorporated throughout this EP, where relevant.

Esso considers it has discharged its obligations for consultation under Regulation 25 having provided a reasonable period, sufficient information and opportunity for relevant persons to provide feedback, objections and/or claims.

4.5 Ongoing consultation

Following the submission of this EP, Esso will continue communicating with relevant persons to provide activity updates. Updates will include activities within the scope of this EP as well as broader Esso operations. Table 4-13 outlines the ongoing consultation plans for this EP.

Should feedback be received after the EP has been accepted, it will be assessed and, where appropriate, Esso will apply its OIMS System 7: Managing Changes (see Section 8.12).

Table 4-13 Ongoing consultation plan

Relevant person(s)	Planned ongoing consultation mechanism	Timing
All	Information-sharing materials regarding the outcome of this submission. Continuing to respond to specific feedback received via email, phone or meetings. Ensuring the Esso website is maintained and kept up to date. Continuing to develop and distribute regular newsletters and issues of Connection magazine.	As required
Regulation 25(1)(a)-(b)	Conducting regularly scheduled meetings with Commonwealth and State Government departments and agencies.	As scheduled
Commercial fishing representatives	Meetings to provide updates on all activities.	Quarterly
Offshore wind industry	Meetings to provide updates on all activities and discuss planning.	Quarterly/as required
Unions	Meetings to provide updates on all activities.	Quarterly
Recreational fishing representatives	Meetings to provide updates on all activities.	As scheduled
Relevant persons identified as marine users and relevant government departments and agencies	Notifications of commencement of activities as appropriate.	Two weeks prior to activity commencing
	Notifications of vessel activities via text message or email where appropriate.	During activity
NOPSEMA	GD 817 – Decommissioning update.	Quarterly
	Regulatory notification of start of activity.	Ten days prior to activity commencing
	Regulatory notification of cessation of activity.	Within 10 days of activity completion
Newly identified relevant persons	Periodic review of relevant persons to ensure new relevant persons are identified and consulted. If a new relevant person is identified, consultation will commence by providing an information bulletin containing details of the activity, including information on the potential environmental impacts and risks associated with the activities.	Six monthly

4.6 Reporting

In accordance with Regulation 24, Esso has included within this EP reports on all consultations under Regulation 25 undertaken with any relevant person identified in this EP.

A summary report on all activity-specific consultations undertaken up to the date of submission of this EP is included as Appendix E-2. The summary report is intended to be made public with this EP and does not contain any sensitive information.

Sensitive information relating to relevant persons and the full text of any response by a relevant person to consultation under Regulation 25 in the course of preparation of the EP, also referred to as the 'sensitive information part', is also provided to NOPSEMA as Attachment 1. However, in accordance with Regulation 28(1), the 'sensitive information part' is removed prior to publication.

5 Environmental impact and risk assessment methodology

5.1 Overview

Esso's decommissioning priority is to eliminate or reduce impacts and risks from the highest hazard aspects of non-producing assets, being well P&As (managed via a separate, accepted Well Operations Management Plan and not discussed further in this Campaign #1 EP) and removal of platform topsides, jackets and risers on non-operational platforms (this Campaign #1 EP). Both the well decommissioning and the platform decommissioning activities adopt the same environmental impact and risk assessment methodology.

Environmental impact assessment is concerned with activities that are reasonably certain to occur (such as planned discharges to the air or water), while environmental risk assessment is concerned with unplanned events that may possibly occur (such as hydrocarbon spills or loss of materials overboard).

Environmental impacts result from the proposed activity and will result in a change to the environment or a component of the environment, whether adverse or beneficial.

Environmental risks resulting from unplanned activities are those where a change to the environment or component of the environment may occur (i.e. there may be impacts if the event actually occurs). Risk is a combination of the impact or consequence of an event and the associated likelihood (probability) of the event occurring. For example, a hydrocarbon spill may occur if a support vessel's fuel tank is punctured by a collision during the activity. The risk of this event is determined by assessing the consequence or environmental impact (using factors such as the type and volume of fuel and the nature of the receiving environment) and the likelihood of this event happening (which may be determined qualitatively or quantitatively).

Impacts and risks associated with the proposed activity were identified in an environmental impacts and risk assessment workshop held in Melbourne in July and August 2024 with the required subject matter experts and in accordance with the *Sustainability Management: Environmental Aspects Guide* (ExxonMobil, 2024a). This ExxonMobil Guide is consistent with the approach outlined in:

- ISO 14001:2015 *Environmental management systems - Requirements with guidance for use*
- ISO 31000:2018 *Risk management - Guidelines*
- HB203:2024 *Environmental Risk Management – Principles and Processes*.

From the environmental impact and risk assessment workshop, an impacts and risk register is produced which details the outcomes from the assessments against each of the aspects against the environmental and socioeconomic dimensions outlined in Section 5.4.

5.2 Definitions

Table 5-1 describes terms relevant to the impacts and risk assessments completed.

Table 5-1 Definitions

Term	Definition
Activity	An activity refers to a component or task within a project which results in one or more environmental aspects.
Aspect	An environmental aspect is an element or characteristic of an activity, product, or service that interacts or can interact with the environment. Environmental aspects can cause environmental impacts.
Impact (HB203:2012)	Any change to the environment or a component of the environment, whether adverse or beneficial, wholly, or partly resulting from an organisation's environmental aspects.
Risk (HB203:2012)	The effect of uncertainty on objectives. The level of risk can be expressed in terms of a combination of the consequences and the likelihoods of those consequences occurring.

Term	Definition
Receptor	The term receptor refers to a feature of the natural and human surroundings that can potentially be impacted. This includes air, water, land, flora, and fauna including people.
Consequence	The consequence of an impact is the outcome of the event on affected receptors. Consequence can be positive or negative.
Likelihood	The likelihood is the chance (probability) of a risk occurring.

5.3 Identification and characterisation of environmental aspects

In order to undertake meaningful impact and risk assessment, a clear understanding of the context of the assessment is required, by defining the activity and the receiving environment, and understanding any requirements (legislative or other) which are relevant to either the activity or the environment.

All components of the activity have been identified and described in Section 2. After describing the activity, an assessment was carried out during the environmental impact and risk assessment workshop to identify environmental receptors and potential interactions between the activity and the receiving environment. The existing environment in the region is described in Section 3. The interactions, or environmental aspects associated with this activity have been identified as shown in Table 5-2.

Based upon an understanding of the environmental aspects, impacts and risks were defined and ecological and social receptors identified enabling a systematic evaluation to be undertaken. Feedback received during relevant person consultation (as detailed in Section 4) has been incorporated into the aspects, receptors, impacts and risks identification and evaluation.

Table 5-2 Activity and aspect matrix

Activity	Aspect																				
	Physical presence – Seabed displacement	Physical presence – Other marine Users	Sound emissions	Emissions to air	Light emissions	Planned discharge – Bilge water and deck drainage	Planned discharge – Sewage and food waste	Planned discharge – Cooling water and reverse osmosis systems	Planned discharge – Grout	Planned discharge – Umbilical and pipeline fluids	Planned discharge – Jacket structure internal fluids	Planned discharge - Solids	Planned discharge – Marine growth	Planned generation and management of waste	Physical interaction – Other marine users	Physical interaction – Marine fauna	Physical interaction – Translocation of native species	Physical interaction – Introduction of IMS	Accidental release – Dropped objects	Accidental release – Waste	Accidental release – LOC: Hazardous/non-hazardous substances	Accidental Release – LOC: Refined oils (collision)
Vessel operations		Yes	Yes	Yes	Yes	Yes	Yes	Yes						Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Topside cutting and removal					Yes				Yes					Yes					Yes	Yes	Yes	
Jacket cutting and removal	Yes		Yes		Yes					Yes	Yes	Yes	Yes	Yes			Yes		Yes	Yes	Yes	
ROV operations	Yes		Yes															Yes			Yes	
Helicopter operations			Yes	Yes																		

5.4 Environmental impact assessment

Environmental impacts, or consequences, are evaluated in terms of the degree of the effects and the sensitivity of the environment. Esso evaluates three effects dimensions (scale, duration, and intensity) (Table 5-3) and three environmental sensitivity dimensions (irreplaceability, vulnerability, and influence) (Table 5-4) (ExxonMobil, 2024a).

In addition to the environmental impact evaluation, Esso also evaluates the severity of impacts on socioeconomic receptors using the community impact severity interpretation outlined in Table 5-5 and Table 5-6.

The determination of impact severity involves evaluating each dimension as lower, moderate, or higher based on qualitative descriptions. Once each dimension is evaluated, results for effect and sensitivity are compared against interpretive criteria to define the overall environmental and public impact consequence level (Table 5-7). These determinations are made during the Environmental Impact Identification (ENVID) process, which is undertaken as part of the environmental impacts and risk assessment workshop.

Table 5-3 Evaluation of environmental effect dimensions

Effect dimension	Value	Description
Duration	Short-term (lower)	Hours to days; effects highly transitory.
	Medium-term (moderate)	Weeks to months. Trigger/cause is temporary; effects decline over time. For chemicals, consider persistence, breakdown product, and bioaccumulation potential in determining effects duration.
	Long-term (higher)	Years; effects are ongoing. For chemicals, consider persistence or bioaccumulation potential in determining effects duration.
Size/scale	Localised (lower)	Within or near an operational site, facility, etc.; affecting an area similar to or smaller than a typical operational site (for small and/or mobile sources); effects are physically contained/controlled; not a significant portion of any sensitive area.
	Moderate	Affecting an area significantly larger than a typical operational site, facility, etc.; a significant portion of a habitat, watershed or single ecological area; a significant portion of the range or occurrence of a population of a species.
	Widespread (higher)	Encompassing entire ecosystems, watersheds, or bioregions (landscape-scale); affecting most of the global range or occurrence of a species; having a noticeable impact on corporate-level environmental performance reporting.
Intensity	Minor (lower)	Minor changes to wildlife, habitat, water occurrence/drainage, or vegetation; low density. For chemical effects: low concentration or hazard* potential.
	Moderate	Moderate or partial changes to habitat, water occurrence/flow, ground cover, ground stability, vegetation or wildlife. For chemicals, moderate concentrations, bioaccumulation or hazard* potential; sub-lethal, non-reproductive direct or indirect effects on organisms.
	Significant (higher)	Notable changes to, fragmentation of, or elimination of habitat, water drainage/features, ground cover, ground stability, vegetation, and/or wildlife; for chemicals, high concentrations, bioaccumulation, or hazard*

Effect dimension	Value	Description
		potential. Significant direct or indirect survival and/or reproductive effects on organisms.

* Chemical hazard generically includes radioactivity, reactivity, toxicity, carcinogenicity, mutagenicity, pathogenicity, reproductive effects potential, etc.

Table 5-4 Evaluation of sensitivity dimensions

Sensitivity dimension	Value	Description (applies to species, ecosystem, and/or ecosystem features/functions/services, all at same scale as consequence)
Irreplaceability	Lower	Common, plentiful.
	Moderate	Less common or plentiful, but not rare or unique.
	Higher	Unique or rare.
Vulnerability	Lower	Healthy, resilient, unthreatened, undamaged, or no remaining natural elements (such as some industrial settings).
	Moderate	Moderately resilient, existing stress or damage not significantly impairing function. Sustainable demand on resources/services.
	Higher	Not resilient or capable of recovery, highly stressed, threatened and/or endangered, functions/ services failing (such as collapsing fishery).
Influence	Lower	Providing few or no services (supporting, regulating, provisioning, cultural).
	Moderate	Considered moderately important, providing a range of ecological, cultural, social, or commercial services for humans and biodiversity.
	Higher	Highly productive and/or biodiverse, critical for human well-being (such as subsistence), functions/services provide critical support for key human/biological communities (such as clean water), considered highly important by public.

Table 5-5 Evaluation of community effect dimensions

Effect dimension	Value	Description
Duration	Short-term (lower)	Hours to days; effects highly transitory
	Medium-term (moderate)	Weeks to months. Trigger/cause is temporary; effects decline over time.
	Long-term (higher)	Years; effects are ongoing, persistent.
Size/scale	Localised (lower)	Limited to the close surroundings of an operating site, facility, etc.; affecting an area similar to or smaller than a typical operational site (for small and/or mobile sources); effects are physically contained/controlled; affecting less than 100 people.

Effect dimension	Value	Description
	Moderate	Affecting an area significantly larger than a typical operating site, facility; affecting between 100-1000 people.
	Widespread (higher)	Affecting a large portion of the community of several communities; affecting more than 1000 people.
Intensity	Minor (lower)	Minor changes to local demographics; low level of immigration; no or small number of resettlements (less than approximately 10 households/businesses); no or minor changes to social status, education, livelihood/income and/or community safety and security; minor effects on availability/accessibility of local goods and services; minor changes to natural and/or cultural resources (water supply, fisheries, foraging/hunting grounds, erosion protection, recreational, spiritual or cultural heritage sites, etc.) no or minor changes to local customs, traditions and lifestyles.
	Moderate	Moderate changes to local demographics; moderate level of immigration; moderate number of resettlements (less than approximately 10 - 100 households/businesses); moderate changes to social status, education, livelihood/income and/or community safety and security not significantly affecting lifestyle; moderate effects on availability/accessibility of local goods and services; moderate changes to natural and/or cultural resources not significantly affecting functionality (water supply, fisheries, foraging/hunting grounds, erosion protection, recreational, spiritual or cultural heritage sites, etc.); moderate changes to local customs, traditions and lifestyles not significantly affecting cultural identity.
	Significant (higher)	Notable changes to local demographics; high level of immigration; high number of resettlements (greater than 100 households/businesses); significant changes to social status, education, livelihood/income and/or community safety and security notably affecting lifestyle; notable effects on availability/accessibility of local goods and services; notable changes to natural and/or cultural resources significantly affecting functionality (water supply, fisheries, foraging/hunting grounds, erosion protection, recreational, spiritual or cultural heritage sites, etc.); notable changes to local customs, traditions and lifestyles significantly affecting cultural identity.

Table 5-6 Evaluation of community sensitivity dimensions

Sensitivity dimension	Value	Interpretation (applies to communities or members of the community at the same scale as effect)
Irreplaceability	Lower	Average livelihood or income exceeds basic needs; diverse sources of livelihood/income (diverse commercial enterprises/jobs and/or diverse effective forms of agriculture/subsistence); essential goods and services readily available.
	Moderate	Average livelihood or income meet but do not significantly exceed basic needs; moderately diverse sources of livelihood/income (moderate diversity of commercial enterprises/jobs and/or of effective forms of agriculture/subsistence); essential goods and services moderately available (quantity/accessibility moderately limited).

Sensitivity dimension	Value	Interpretation (applies to communities or members of the community at the same scale as effect)
	Higher	Average livelihood or income barely meet or do not meet basic needs; Few or limited sources of livelihood/income (e.g. few if any commercial enterprises/jobs and/or few effective forms of agriculture/subsistence). Essential goods and services not or rarely available.
Vulnerability	Lower	No presence of marginalised or disadvantaged people, groups, or sub-groups (e.g. local Indigenous peoples); natural and/or cultural resources (water supply, fisheries, traditional hunting/foraging grounds, erosion barriers, cultural heritage/recreational areas, spiritual sites, etc.) are healthy, resilient and undamaged; local culture and heritage (cultural identity) well integrated into present lifestyle.
	Moderate	Presence of moderately marginalised or disadvantaged people, groups, or sub-groups (e.g. local Indigenous peoples); natural and/or cultural resources (water supply, fisheries, traditional hunting/foraging grounds, erosion barriers, cultural heritage/recreational areas, spiritual sites, etc.) show existing stressor damage not significantly impairing function; present lifestyle in moderate conflict with local culture and heritage (cultural identity).
	Higher	Presence of highly marginalised or disadvantaged or disadvantaged people, groups, or sub-groups (e.g. local Indigenous peoples); natural and/or cultural resources (water supply, fisheries, traditional agriculture/hunting/foraging grounds, erosion barriers, cultural heritage/recreational areas, spiritual sites, etc.) show existing stress or damage significantly impairing function (e.g. collapse of fisheries, eroded stormwater protection, etc.); present lifestyle in notable conflict with local culture and heritage (cultural identity at threat of dispersal).
Social structure	Lower	Homogeneous cultural identity; no pronounced social group structure or social groups are non-adverse/share common cultural identity; local hierarchy well established and stable; low crime rate; internal community conflicts addressed in a measured manner; social support and benefits (security, education, medical care, etc.) available and accessible via local offices/institutions or designated representatives, etc.
	Moderate	Moderately homogeneous cultural identity; various cultural identities (e.g. tribes/clans) are well integrated and mostly non-adverse; moderate crime rate; internal community unrests/conflicts result in isolated confrontations without significant impairment to community safety; social support and benefits (security, education, medical care, etc.) moderately available and accessible via local offices/ institutions or designated representatives, etc. and/or moderately effective (limited staffing, several hours travel time, moderate reliability, etc.).
	Higher	Highly inhomogeneous cultural identity; dominant cultural identities (e.g. tribes/clans) display significant confrontational tendencies; high crime rate; internal community unrests/conflicts significantly impair community safety; basic human rights for others not regarded; social support and benefits (security, education, medical care, etc.) mostly unavailable or inaccessible and/or mostly ineffective (multiple days travel time, low reliability, etc.).

During the ENVID, the environmental and community effects are considered together and assessed to give the worst-case inherent consequence rating (impact or risk without controls in place). Controls are then established and recorded for each of the identified impacts and risks in Sections 6 and 7. and the overall residual determination of the environmental and public impact consequence is recorded. The outcome of the assessment for each aspect is provided in the residual consequence assessment sub-section in Sections 6 and 7 and summarised in Table 6-1 and Table 7-1.

An impact or risk may have either an environmental consequence or a community (public impact) consequence, or both. If an impact or risk has both consequences, the higher of the two consequence levels is applied.

The controls adopted to reduce and manage the inherent consequence levels are listed for each impact and risk in Sections 6 and 7 and environmental performance objectives, standards and measurement criteria are identified. A summary is provided in Appendix K.

Socioeconomic (public impact) consequence (e.g. impact on commercial fisheries) is defined in four Consequence Levels, I-IV as per the *Risk Matrix Application Guide* (ExxonMobil, 2024b) by the scope of the disruption and the size of the population affected as shown in Table 5-7.

Table 5-7 Determination of environmental and public impact consequence

Consequence Level	Environmental impact	Public impact	Interpretative examples of environmental consequence dimension considerations
I	Potential widespread, long term, significant adverse effects	• Extended (greater than three months) national or international media coverage. • Large community disruption or evacuation (>1000 people). • Closure of major transportation route >24 hours.	Sensitivity of receptors are higher. Effects are longer term and widespread and/or of a higher intensity.
II	Potential localised, medium term, significant adverse effects	• National media coverage. • Medium community disruption or evacuation (100–1000 people). • Closure of major transportation <24 hours.	Sensitivity of receptors are moderate or higher. Effects are medium to long term and/or have a moderate to higher intensity.
III	Potential short term, minor adverse effects	• Public complaints; small community impact (<100 people). • Closure of secondary transportation route <24 hours. • Tier 1 Process Safety Event.	Sensitivity of receptors are lower to moderate. Effects are medium term and/or moderate intensity, or Sensitivity of receptors is lower, but effects are longer term/higher intensity, or Effects are localised, short term and/or low intensity, regardless of receptor sensitivity.

Consequence Level	Environmental impact	Public impact	Interpretative examples of environmental consequence dimension considerations
IV	Inconsequential or no adverse effects	• Public complaint. • Temporary closure of minor transportation route. • Minor inconvenience.	Sensitivity of receptors are lower. Effects are short term, localised and of low to moderate intensity.

5.5 Environmental risk assessment

5.5.1 Determination of consequence

When assessing the consequence of an unplanned event, the same methodology is used as for determining the consequence of a planned event (as described in Section 5.4).

5.5.2 Determination of likelihood

Once the most severe environmental consequence of an unplanned event is assessed, the probability of the unplanned event occurring is assessed. This is done by assessing the probability for each failure, event, or condition necessary to produce the impact.

In order to ensure that the highest possible risk is identified, scenarios with a lower severity consequence but higher probability and potentially a higher overall risk are also considered. The five categories of likelihood are as shown in Table 5-8.

Table 5-8 Likelihood Categories

Likelihood Category	Qualitative interpretation guidance	Quantitative interpretation guidance (probability of occurring per year of exposure)
A	Very likely Similar event has occurred once or more at site in the last 10 years. Has happened several times at site or many times in Company.	0.1 to 1
B	Somewhat likely Has happened once before at site or several times in Company.	0.01 to 0.1
C	Unlikely Has not happened before at site or has happened a few times in Company.	0.001 to 0.01
D	Very unlikely Have been isolated occurrences in Company or has happened several times in industry.	0.0001 to 0.001
E	Very highly unlikely Has happened once or not at all in Company. Has happened a few times or not at all in industry.	<0.0001

5.5.3 Determining significance of risk

The combination of consequence severity and likelihood of occurrence determines the level of risk. ExxonMobil's risk framework considers existing controls when determining risk. The overall risk category is given on the basis of the likelihood of the consequence occurring after application of the control measures. The effectiveness of control measures is considered when determining the likelihood of events with control measures in place, i.e. factors such as functionality, availability, reliability, survivability, independence and compatibility of control measures, are considered.

ExxonMobil classifies risk into four Risk Categories (refer to Figure 5-1). The significance of each risk category is as follows:

- **Risk Category 1:** A higher risk that should have specific controls established in the short term and be reduced as soon as possible.
- **Risk Category 2:** A medium risk that should be reduced unless it is not 'reasonably practicable' to do so. Reasonably practicable is:
    - the level of resource expenditure is not significantly disproportionate in relation to the resulting decrease of risk.
- **Risk Category 3:** A medium risk that should be reduced if 'lower cost' options exist to do so. Lower cost denotes follow-up work that can be completed without:
    - allocating extensive engineering, technical, and operations resources, or
    - the need for unit shutdowns or activities which may introduce other risks or use resources that may be more appropriately used to address higher risk category items.
- **Risk Category 4:** A lower risk that is expected to be effectively managed in base OIMS practices:
    - typically requires 'No Further Action'
    - risk control measures that are in place to manage the risk to **Risk Category 4** should be continued.

Figure 5-1 ExxonMobil risk matrix

5.6 Demonstration of As Low As Reasonably Practicable

Regulation 21(5)(c) of the Environment Regulations requires that the EP includes details of the control measures that will be used to reduce the impacts and risks of the activity to ALARP and an acceptable level. The ALARP aspect of this requirement is addressed in this Section: the acceptability aspect is addressed in Section 5.7.

Control measures are selected to reduce:

- for an impact - the consequence of a planned event occurring, and
- for a risk – the consequence and/or the likelihood of an unplanned event occurring.

Control measures that are required by legislation are adopted regardless of the evaluated impact or risk level.

5.6.1 Principle of As Low As Reasonably Practicable

In outlining its approach to assessing whether environmental impacts and risks of the activity will be reduced to ALARP, NOPSEMA's guideline *Environment Plan decision making* (NOPSEMA, 2024d) outlines that

> *"Reducing impacts and risks to ALARP is based on the concept of reasonable practicability; the weighing up of the magnitude of impact or risk reduction against the cost of that reduction. The 'cost' in this context means the sacrifice associated with implementing a control measure which includes an evaluation of the benefits versus the impost such as money, time and/or effort required to implement a particular control measure. The titleholder must adopt additional control measures or increase effectiveness of existing control measures if the cost of doing so is not grossly disproportionate to the environmental benefit gained."*

5.6.2 Application of As Low As Reasonably Practicable principle in practice

Esso has adapted a framework for risk-related decision making referenced in NOPSEMA's guidance note *ALARP* (NOPSEMA, 2022) for use in an environmental context. This framework helps to determine the assessment technique or techniques required to demonstrate that impacts and risks have been reduced to ALARP (Figure 5-2).

The framework considers three factors that influence the Decision Context:

- the type of activity
- the risk and uncertainty of the activity
- stakeholder influence in the activity.

And three assessment techniques that can be used depending on the Decision Context:

- good practice
- engineering risk assessment
- precautionary approach.

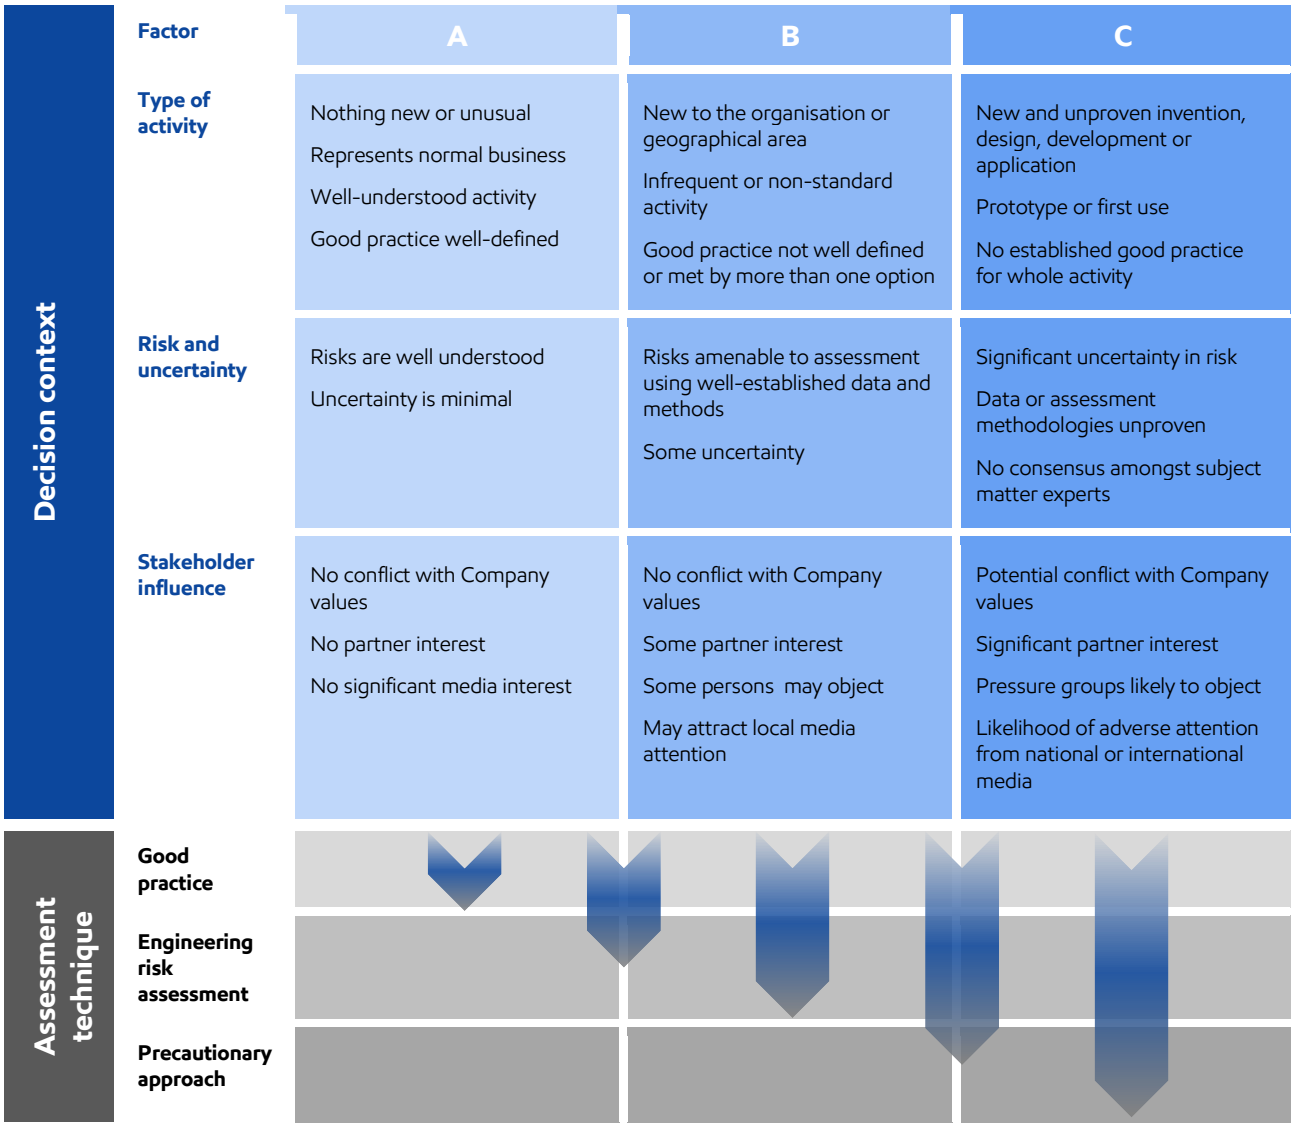

Figure 5-2 Risk-related decision support framework (NOPSEMA, 2022)

5.6.3 Decision Contexts

5.6.3.1 Decision Context A

Where the activity and associated potential impacts and/or risks are well understood, and there are no conflicts with Company values nor stakeholder interest. The environmental consequence for planned activities (impacts) and unplanned events (risks) is Level III or IV. The risk of unplanned events is either Category 2, 3 or 4.

5.6.3.2 Decision Context B

Where the activity is infrequent or non-standard; potential impacts and risks are amenable to assessment but with some uncertainty; and some stakeholder interest. The environmental consequence for planned activities (impacts) and unplanned events (risks) is Level II. The risk of unplanned events is either Category 2, 3 or 4.

5.6.3.3 Decision Context C

Where the activity has higher potential impact or uncertain risks or expected significant adverse stakeholder reaction. The environmental consequence for planned activities (impacts) and unplanned events (risks) is Level I. The risk of unplanned events is either Category 2 or 3.

The Decision Context for each aspect has been identified in Sections 6 and 7.

5.6.4 Good practice

Esso notes NOPSEMA's key principle regarding "*good practice*" (NOPSEMA, 2022):

> *"The term 'good practice' in NOPSEMA guidance documentation therefore is taken to refer to any well defined and established standard or codes of practice adopted by an industrial/occupational sector, including 'learnings' from incidents that may yet to be incorporated into standards. Good practice generally represents a preferred approach; however it is not the only approach that may be taken. While good practice informs, it neither constrains, nor substitutes for, the need for professional judgement. Good practice may change over time because of technical innovation, or because of increased knowledge and understanding."*

For this EP, Esso's sources of good practice include:

- requirements from Australian legislation and regulations
- relevant Australian policies
- relevant Australian Government guidance
- relevant industry standards and/or guidance
- relevant international conventions.

5.7 Demonstration of acceptable level

Regulation 21(5)(c) of the Environment Regulations requires that the EP includes details of the control measures that will be used to reduce the impacts and risks of the activity to ALARP and an acceptable level. The acceptability aspect of this requirement is addressed in this Section: the ALARP aspect is addressed in Section 5.6. The demonstration of acceptability is completed independently of the ALARP evaluation described above. However, as with the demonstration of ALARP, the demonstration of acceptability detailed below applies the decision-making principles described in Section 5.6.1, ensuring consistency with the precautionary principle when considering the acceptable levels of impact and risk caused by the activity.

5.7.1 Demonstrating acceptability

In assessing the acceptability of an impact or risk, Esso has considered the factors that influence NOPSEMA's decision regarding whether an EP has demonstrated that the environmental impacts and risks will be of an acceptable level (NOPSEMA, 2024d) to arrive at the criteria shown in Table 5-9.

Table 5-9 Demonstration of acceptability

Factors influencing decision making (NOPSEMA, 2024d)	How addressed
Acceptable levels are defined and based on reasonable internal and external context, legislative and industry standards. Acceptable levels of environmental impact and risk must be appropriate and relevant to the environment that may be affected by the project including activities that are part of the project.	Levels have been defined with reference to relevant corporate policies, legislative requirements and industry guidance (Section 1.6).
The predicted levels are compared to the acceptable levels to demonstrate that acceptable levels will be achievable.	Recorded in the assessment of each impact and risk.
The evaluation of an impact or risk is consistent with the principles of ESD set out in Section 3A of the EPBC Act: a) The integration principle - Decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations. b) The precautionary principle - If there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a	Recorded in the assessment of each impact and risk. In accordance with the OPGGS Act, Esso is required to demonstrate compliance with the financial assurance obligations under the OPGGS Act to NOPSEMA prior to acceptance of this EP. Hence consideration of the valuation principle of ESD is factored into the maintenance of Campaign #1 financial assurances to prove the titleholder's capacity to meet the costs, expenses

Factors influencing decision making (NOPSEMA, 2024d)	How addressed
reason for postponing measures to prevent environmental degradation. c) The intergenerational principle - The present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations. d) The biodiversity principle - The conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making. e) Improved valuation, pricing and incentive mechanisms should be promoted.	and potential liabilities associated with Campaign #1 activities. The financial assurance provision applies to the EP as a whole and as such no further consideration of the valuation principle (e) of ESD is included in Sections 6 and 7.
The activity will not result in unacceptable impacts to a migratory species or an area of important habitat for a migratory species.	Recorded in the assessment of each impact and risk.
The impacts and risks of the activity are not inconsistent with: • a recovery plan or threat abatement plan for a listed threatened species or ecological community • a management plan in operation for a Commonwealth reserve (e.g. an AMP) or if there is no management plan in operation, the Australian International Union for Conservation of Nature (IUCN) reserve management principles (Schedule 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 (Cth) (EPBC Regulations)) including a demonstration that an activity will not have unacceptable impacts on the values of an AMP, to the extent these are relevant to the activity and the nature of its impacts and risks • a management plan for a Commonwealth Heritage Place.	Listed threatened species that may be present within the OA are described in Appendix B and Appendix D applicable recovery plans or threat abatement plans were considered based on the identified species. Consideration was given to the following conservation management plans and advice: • *Conservation Management Plan for the Blue Whale 2015–2025* (Commonwealth of Australia, 2015) (CMPBW) • *Listing Advice Megaptera novaeangliae Humpback Whale* (TSSC, 2022) • *National Recovery Plan for the Southern Right Whale* (DCCEEW, 2024f) (NRPSRW) • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a) • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b) • *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017) • *Approved Conservation Advice for Dermochelys coriacea (Leatherback Turtle)* (DEWHA, 2008a). In regard to the *National Recovery Plan for the Littoral Rainforest and Coastal Vine Thickets of Eastern Australia Ecological Community* (Commonwealth of Australia, 2019), Esso has assessed that the impacts and risks of the activity are not inconsistent with this plan. In regard to Commonwealth reserves: • East Gippsland AMP • Beagle AMP

Factors influencing decision making (NOPSEMA, 2024d)	How addressed
	• Flinders AMP • Jervis AMP • Freycinet AMP. Modelling of a spill of MGO has demonstrated that the activity is not inconsistent with the Australian IUCN reserve management principles and will not have unacceptable impacts on these AMPs. See Appendix A Section A.1.1.7. Three Commonwealth Heritage sites identified are considered not relevant due to their lack of marine/coastal features. See Appendix A Section A.1.1.3.
The activity does not contravene: • a plan of management for a World Heritage place • a plan of management for a National Heritage place, or • a plan of management for a Ramsar wetland. If a relevant plan of management is not in place, then all reasonable steps have been taken to ensure that the activity is not inconsistent with the: • Australian World Heritage Management principles • National Heritage management principles • Australia Ramsar management principles • Commonwealth Heritage management principles.	Because there are no World Heritage Properties nor National Heritage Places within or adjacent to the OA, the activity does not contravene a plan of management for either of these. Esso has reviewed the *Gippsland Lakes Ramsar Site Management Plan 2024* (EGCMA, 2024) and has assessed that the activity does not contravene the plan of management for the Gippsland Lakes Ramsar site. In regards to the Corner Inlet Ramsar site, Esso has reviewed the *West Gippsland Regional Catchment Strategy 2021-2027* (WGCMA, 2025) and *Corner Inlet Marine National Park Management Plan* (Parks Victoria, 2005) and assesses that the activity is not inconsistent with the Australian Ramsar management principles (Schedule 6 of the EPBC Regulations).
Relevant policy documents, guidance, bioregional plans, wildlife conservation plans, management plans, gazettal instruments under the EPBC Act, conservation advices, marine bioregional plans and other information on the DCCEEW website including spatial data (e.g. National Conservation Values Atlas, replaced by Australian Marine Spatial Information System (AMSIS) (Geoscience Australia, 2025)) have been reviewed and incorporated into this EP as appropriate.	Esso has reviewed the following EPBC Act and associated Policy Statements and incorporated them in this EP as appropriate. See Appendix A.
Areas of uncertainty in predictions of impact and risk are identified, acknowledged and addressed.	Decision Context process described in Section 5.6.
The method for comparing predicted impacts and risks to acceptable levels of impacts and risks is systematic, applied thoroughly, defensible and reproducible.	Impacts and risks methodology as outlined in Section 5 of this EP.
Information provided during relevant person consultation is incorporated appropriately.	Recorded in the assessment of each impact and risk.

6 Environmental impact assessment

A discussion of the environmental impacts associated with the planned activities to be carried out under this EP, the assessed consequences and the control measures that will be implemented to reduce impacts to ALARP and acceptable levels, are presented in this Section. Potential environmental risks associated with unplanned events are covered in Section 7.

Alternative controls identified and considered to ensure impacts are ALARP and comply with the acceptability criteria are also covered. Environmental Performance Outcomes (EPOs), controls, Environmental Performance Standards (EPSs), and measurement criteria are provided for each aspect of the planned activities. A summary is provided in Appendix K.

The following definitions are used in this EP, as defined in Regulation 5 of the Environment Regulations:

- EPO – a measurable level of performance required for the management of environmental aspects of an activity to ensure that environmental impacts and risks will be of an acceptable level (i.e. a statement of the environmental objective)
- EPS – a statement of the performance required of a control measure
- Measurement criteria (not defined in the regulations) – defines the measure by which environmental performance used to determine whether the EPSs and EPOs have been met.

A summary of the impacts and risk assessment is provided in Table 6-1. Inherent consequence level does not take any mitigating controls into consideration, the residual consequence level reflects the post control consequence. Where consequences have been assessed for more than one receptor within an impact assessment, the highest consequence level assessed has been reflected in Table 6-1.

Table 6-1 Summary impact assessment

Section Identifier	Hazard	Inherent Consequence Level	Residual Consequence Level
6.1	Physical interaction – Seabed displacement	IV	IV
6.2	Physical presence – Interference to other marine users	III	IV
6.3	Planned discharges - Sewage and food waste	IV	IV

6.15	Emissions to air	IV	IV
6.16	Waste generation and management	IV	IV

6.1 Physical presence – Seabed displacement

6.1.1 Sources of seabed displacement

The Campaign# 1 removal activities that will result in localised seabed displacement or disturbance associated with the following activities are described in Section 2.10 and summarised as:

- clearing of seabed sediments and obstructions to allow access to cut pipelines and/or umbilicals that are connected to Campaign #1 facilities (DPA, PCA, WTA, BMA, FTA, FLA, WKF, KFA, KFB, CBA, MKA, and HLA)
- potential localised clearing of seabed sediments to allow external pile cutting and removal of debris that may impede external cutting of SPJs at FTA, WTA and BMA and potentially other platform locations in the event internal pile clearing and cutting techniques are not feasible
- potential localised clearing of seabed and the suction effect associated with the lifting of the DPA and PCA monotowers from the seafloor
- temporary storage on the seabed of items during the removal campaign
- installation and retrieval of a waverider buoy (refer to Section 2.15) if deployed
- ROV operations close to the seafloor (e.g. as part of surveys undertaken prior to placing items on the seabed and as part of the as left survey) potential localised clearing of seabed to allow ROV cutting and separation of pipelines/risers and umbilicals being removed with the SPJ.

There will be no planned anchoring of vessels within the OA. Vessels will only anchor if this is required in unplanned circumstances such as emergencies. Planned sediment displacement will only occur during removal operations at the facility locations. There will be no planned sediment displacement associated with transfer of the removed infrastructure at a transfer location.

6.1.2 Impacts of seabed displacement

The potential impacts of seabed disturbance on receptors are:

- direct mortality (as a result of direct impacts during seabed displacement)
- change in habitat (sediment deposition leading to smothering or burial)
- change in water quality (increased turbidity/suspended solids in the water column near the seabed)
- toxicity from mobilised contaminants in the seabed sediments (if present)
- change to tangible underwater cultural heritage values

6.1.3 Impact assessment

6.1.3.1 Sediment displacement modelling

Hydrodynamic modelling was completed for key sediment dispersion scenarios in order to assess potential sediment disturbance impacts. The study performed by Stantec Australia Pty Ltd (Stantec), estimated sediment displacement within Bass Strait using DELFT numerical modelling. The assessment included hydrodynamic modelling using DELFT3D-Flow which is a sophisticated tool used for simulating hydrodynamic conditions, including tidal patterns, in various coastal and ocean environments and DELFT-WAQ, the water quality and

ecology module. The combined use of DELFT3D-Flow and DELFT-WAQ enables detailed assessments of sediment transport under various scenarios (Stantec Australia, 2024a).

Table 6-2 summarises the scenarios modelled and outcomes. Based on the scenarios assessed, the largest potential impact associated with a single activity was identified as the seabed disturbance associated with the cutting of all FTA piles externally. Results of modelling undertaken by Stantec indicate that for all scenarios (including the worst-case in terms of radial dispersion and suspended sedimentation levels), the area of impact will be localised (i.e. within 50 – 100m of the facilities). Areas of influence may extend beyond this (up to 650m) but the concentrations of suspended sediments at these distances would be negligible in terms of impacts to marine biota and likely within levels of natural variability (Stantec Australia, 2024a).

Table 6-2 Sediment modelling outcomes

Scenario modelled	Facilities	Estimated volume displaced (m^3)	Modelling outcome
Seabed displacement generated during preparation of area required by ROV for external cutting of SPJ piles at or below seabed	WTA	950	The scenario assessed conservatively assumes sediment displacement would be needed for cutting of all piles at each facility. Of the three facilities, the largest sediment displacement modelled occurred at FTA which was 1.6 times larger than that at BMA and 2.5 times larger than that at WTA. Modelled FTA outcomes indicated a sand concentration of 100mg/L and above would only occur within 50m from the centre of the FTA facility. A concentration of 1mg/L is expected to extend up to 650m further to the east and 400m to the west. For fines, the maximum concentration of 5mg/L and above would only occur within about 10m from the centre of the facility. For deposition, it is expected that most of sediment particles would quickly settle near the centre of the platform. In this regard, modelling results show that the thickest sediment layer of 10cm and above is confined to within 30m from central FTA (Stantec Australia, 2024a).
	FTA	2380	
	BMA	1430	
Seabed displacement and disturbance generated during preparation activities and lifting of two monotowers	DPA and PCA	For each: Preparation = 17 Lifting = 83	For modelling it was assumed that water jetting would be used to prepare each monotower for lifting. Modelled outcomes indicated sand concentrations of 100mg/L would occur within 50m from the centre of the facility and 25m for fines during preparation activities. Both sand and fine particles are expected to be spread out in the southwest to the northeast directions. The accumulated sediment layer settled on the seabed near the facility is also very thin (only 1mm thick) because the total sediment displacement required for the preparation of area is small. The process of lifting the structures would lead to larger sediment disturbance. The concentration of sediment is anticipated to be highest in the immediate vicinity of the facility. Modelled results suggest that a sand concentration of 100mg/L will be confined to an area within 100m of the facility while fines are expected to have a more limited impact area of 20m For sediment deposition on the seabed, it is projected

Scenario modelled	Facilities	Estimated volume displaced (m^3)	Modelling outcome
			that most of the sediment will settle rapidly, particularly near the centre of the facility, potentially creating a sediment layer up to 1cm thick within a 20m radius (Stantec Australia, 2024a).
Seabed displacement generated during preparation of area required by ROV for external cutting of pipelines/ risers and umbilicals at seabed	DPA PCA, WTA, FLA, CBA,	Five each	Sediment displacement volumes vary across different facilities. For the purpose of modelling, HLA was modelled as a worst-case scenario as the external cutting of pipelines and risers will result in the largest volume of seabed displacement at this facility. Modelling of activities at HLA resulted in sand concentrations surpassing 100mg/L predominantly localised within a 50m radius surrounding the facility, indicating a significant deposition in this immediate area. Conversely, the area with elevated fines concentrations is considerably smaller, with the highest recorded concentration being approximately 10mg/L within a 20m radius (Stantec Australia, 2024a).
	FTA	Three	
	BMA, KFB	47 each	
	WKF, KFA	27 each	
	MKA	10	
	HLA	57	

6.1.3.2 Direct disturbance leading to mortality or habitat loss

The seafloor in the OA will be subject to localised physical disturbance at the Campaign #1 facility locations associated with cutting and removal of structures which will result in the loss of epifaunal and infaunal invertebrates occurring on structures and sediments within the immediate footprint of the activities. The activity which is expected to result in the highest volume of sediment displacement is water jetting required to displace sediment to allow external cutting. This activity is limited to the BMA, WTA and FTA removal locations (if external cutting of piles is required). Placement of items on the seabed for temporary storage would also lead to direct disturbance of the epifauna and infauna located within the footprint of the placed item. Soft bodied organisms such as polychaetes, crustaceans, soft corals and sponges are the most susceptible to mortality as a result of the direct disturbance during seabed displacement activities. These impacts will be very localised and short term, as the area of the seabed to be disturbed is limited to the immediate vicinity of each facility and any placement of items on the seabed for temporary storage will occur in close proximity to their original locations.

The disturbance footprint of temporary storage of items on the seabed is relatively small, with the largest item to be temporarily stored are the struts at KFA, KFB and HLA, which is expected to impact a maximum seabed area of 1800m^2.

Given the small disturbance footprint and localised scale of the impact, this has been assessed as:

- **Consequence Level IV**.

6.1.3.2.1 CUMULATIVE IMPACTS

While it is likely that cutting and removal activities at all facility locations will result in very localised direct losses of infauna and epifauna, given the infaunal and epifaunal assemblages associated with soft sediment habitats in the vicinity of the facilities are comparable and do not offer unique or ecologically important habitat in comparison to the broader soft sediment environment (Stantec Australia, 2024b), cumulative impacts across Campaign #1 facilities are not expected to impact the diversity and abundance of benthic fauna within Bass Strait.

6.1.3.3 Change in habitat – Burial and smothering (deposition)

An organism's ability to survive burial and smothering due to sedimentation will vary largely depending on the particle grain size, rate of sedimentation, depth of burial and the organism's physiology and adaptation to

smothering. This may vary among individual species of the same family. The predominant epifauna known to be associated with soft sediments around the facilities that are part of Campaign #1 activities include: sessile species such as sponges and bryozoans, hydroids, ascidians, poriferans and mobile fauna including hermit crabs, sea stars and octopus.

In terms of infauna, sediment analysis from the seabed around HLA, CBA, KFA, FLA, WTA, BMB, BTA and DPA in Esso's Bass Strait operations during Environmental Survey 1 (Summer) undertaken in the first quarter 2021, provides a profile of the infaunal species in the area around the facilities (AECOM, 2024). The results of this study showed that although infauna assemblages differed between sites, these differences were not pronounced. Similarly, the analysis of reference sites (away from the facilities) showed that infaunal assemblages did not differ markedly to those at facility sites. The analyses also indicated that *Corophiidae* were present as typifying species at all platforms and reference sites, with *Tanaidacea spp.* and *Ostrocoda spp*. being common at most sites. *Corophiidae, Tanaidacea spp*. and *Ostrocoda spp*. are all subcategories of small crustaceans. The abundance of these species throughout the sites probably contributed to the relatively limited variation in species assemblages across the whole range of the sites. Even FLA, the site most dissimilar to all the other sites, including reference sites, was still dominated by amphipod crustaceans (*Phoxocephalidae, Platyischnopidae, Lysianassidae, Corophiidae*, *Oedicerotidae)* like most of the other sites. Polychaete worm species were also noted as being present at the majority of facilities sampled.

Environmental Survey 1 (Summer), analysed the composition of seabed sediments present at CBA, FLA, HLA, KFA, WTA, BMB, DPA and BTA (not within the scope of this EP) and at reference sites. The composition of the seabed sediments around MKA, FTA, BMA, WKF, PCA and KFB were analysed as part of Environmental Survey 2 (Winter) in 2022. The areas surveyed showed a relatively uniform sediment grain size. In all locations the predominant sediment grain size was sand (0.063 - 2.0mm in diameter), with comparatively minor contributions (most often less than 10% but up to 16%) from clay- and silt-sized particles at all sites. On average, gravel-sized particles exceeded 15% at WTA (Hook S. E., 2021) and (AECOM, 2024). The size distribution did not change considerably across the Gippsland Basin area or appreciably with depth.

Some studies have been undertaken to investigate the ability of infaunal invertebrates to tolerate burial and sedimentation, although the results are highly variable depending on a number of physical factors (e.g. sediment composition, rate of smothering, duration of burial) as well as numerous physiological factors, behavioural traits and adaptations (Stantec Australia, 2024b). A study undertaken to investigate the burial survival of benthic fauna following the deposition of simulated dredged material at various depths (Bolam, 2011) found that sedimentary deposit feeders such as polychaete worms had less ability to survive sediment deposition and were unable to survive 6cm of overburden burial. More mobile species such as gastropods however exhibited relatively good vertical migration capability through sediments when buried and were able to cope well with 6cm of overburden and almost 50% vertically migrated through 16cm of overburden, primarily when the organic content of the sediments was low (Bolam, 2011).

Dispersion modelling undertaken by Stantec (Stantec Australia, 2024a), indicated that heavier particles are expected to settle within short distances from the facilities while finer particles will be temporarily suspended in the water column before settling onto the seafloor. A conservative approach was taken to assess impacts to infauna as a result of smothering, which considered the ability of infauna to evade a burial depth of up to 1cm, but not greater than 10cm. If this is considered, the scale of the impact around the facilities would not exceed 50m under any of the scenarios modelled (Stantec Australia, 2024a). Even a total loss of infauna in this localised area would not result in a significant impact to the overall diversity of abundance of infauna within the wider OA.

Recovery and recolonisation following direct physical disturbance, elevated suspended sediments and deposition, is likely to be relatively fast (e.g. in a matter of weeks or months) for surrounding soft sediment habitats. Whether the composition of the recolonised assemblage is similar to that of the pre-decommissioning conditions will depend on if there have been any permanent changes to physical conditions (e.g. hydrology and currents, particle size distribution and sediment quality) that may favour different or more opportunistic species (Stantec Australia, 2024b).

The area that will be disturbed, compared with the overall extent of this habitat in the region, is small and consequently, there will be no long term impact on the diversity and abundance of benthic fauna. The impact has been assessed as:

- **Consequence Level IV**.

6.1.3.3.1 CUMULATIVE IMPACTS

Cumulative smothering impacts as a result of seabed displacement may occur if facilities to be removed are in close proximity to each other and the sediment plumes overlap. Plume dispersion modelling undertaken by Stantec did not indicate the potential for overlap of any sediment plumes overlapping across facility locations (Stantec Australia, 2024b). There have been no concurrent activities (by Esso, other oil and gas operators or other marine project such as wind energy) identified within the OA and within the Campaign #1 execution timeframe that would result in significant sediment displacement. Operations undertaken by Esso and other oil and gas operators in the area are limited, with potential sporadic, short-term IMR activities that would take place at least several kilometres away from the nearest Campaign #1 facility. As a result, it is not expected Campaign #1 activities will overlap with activities that could result in cumulative impacts to infauna populations in the OA as a result of smothering or burial.

Future Bass Strait decommissioning activities such as the removal of lower jacket sections and the removal of pipelines associated with the Campaign #1 facilities (which are not covered in this EP) may result in sediment disturbance. The sediment disturbance associated with removing buried or partially buried pipelines, in particular, is likely to be extensive and hence smothering and burial impacts to infauna could be significant as a result of these activities.

Pipeline removal activities are expected to commence after the completion of Campaign #1 activities, with selected unburied pipelines and umbilicals to be removed in an initial campaign (subject to a separate EP submission). As outlined in Section 1.3.1.3, the removal of lower jacket sections is expected to commence in 2032. Given the recovery and recolonisation of sediment infauna from smothering and burial impacts is expected within weeks to months (Stantec Australia, 2024b) cumulative impacts to infauna as a result of the Campaign #1 activities are not expected.

6.1.3.4 Change in water quality

Turbidity may occur when seabed sediments are stirred up during the Campaign #1 facility removal activities, however this disturbance will settle quickly after the actions are completed. Increased turbidity can have impacts to infaunal communities such as suspension feeders and filter feeders by invertebrates via the clogging of respiratory and feeding appendages. Long term reduction of light penetration may also lead to mortality or sub lethal effects on light sensitive organisms such as corals or algae. Given the limited and localised nature of the dispersion plume, any mobile species such as fish or marine megafauna would be able to avoid the affected area and find similar unaffected habitat elsewhere.

The PBW has foraging habitat overlapping the OAs and the SRW migration BIA also overlaps the OAs. Research data detailing potential impacts from suspended solids to megafauna is scarce, however such megafauna is highly mobile, transitory, and able to avoid the plumes. The area of the turbidity plumes is regarded as a very small percentage of the foraging grounds of protected seabirds such as shearwaters, albatrosses, and petrels.

The impacts to sensitive receptors such as suspension/filter feeders, as a result of increased turbidity, will be based on the amount of sand and fines suspended in the water column and the extent of the dispersion plume caused by the removal activities. The conservative sediment dispersion modelling undertaken indicated that modelled levels of turbidity for both sand and fines exceeded the marine water quality objectives for the protection of aquatic ecosystems (0.5 – 10ntu/1.5 – 30mg/L) (ANZG, 2018), however these concentrations of suspended sediments would be limited to within a maximum 50m footprint of the facilities for sandy sediments and between 10 - 100m for fines (Stantec Australia, 2024a). It would be expected that filter feeders would be impacted within this radius, however other infaunal species that are dominant within the facility areas such as deposit feeders (polychaetes) and those which feed on dead or decaying material (detrivores) would be expected to be able to tolerate short periods of higher concentrations of suspended sediments in the water column.

Given the predicted limited and localised nature of the dispersion plume generated, as a result of the removal activities, impacts to sensitive receptors as a result of a change in water quality are expected to be of a short term nature, with inconsequential effects on sensitive receptors at a population level and hence have been assessed as:

- **Consequence Level IV**.

6.1.3.4.1 CUMULATIVE IMPACTS

Plume dispersion modelling undertaken by Stantec did not indicate the potential for overlap of any sediment plumes overlapping across facility locations (Stantec Australia, 2024b). Activities that result in sediment

displacement such as displacement of sediments to enable pipeline/umbilical cutting and external cutting of jacket piles will not be undertaken concurrently at any facility location and given that modelling predicted that displaced sediments would settle rapidly to the seafloor, cumulative impacts to water quality are not anticipated.

Future Bass Strait decommissioning activities such as the removal of lower jacket sections and the removal of pipelines associated with the Campaign #1 facilities (which are not covered in this EP) may result in sediment disturbance. The sediment disturbance associated with removing buried or partially buried pipelines in particular is likely to be extensive.

Cumulative water quality reduction is most likely to occur if there was simultaneous removal of the facilities and multiple pipelines (Erias/RSK, 2025). Pipeline removal activities are expected to commence after the completion of Campaign #1 activities, with selected unburied pipelines and umbilicals to be removed in an initial campaign (subject to a separate EP submission). As outlined in Section 1.3.1.3, the removal of lower jacket sections is expected to commence in 2032. Hence simultaneous removal activities will not occur. Given the residence time of any suspended solids in the water column is likely to short before settlement to the seabed occurs, cumulative impacts to infaunal communities or mobile species such as fish or marine megafauna as a result of the Campaign #1 activities would not be expected.

6.1.3.5 Toxicity from mobilised contaminants

The potential for effects of toxicity from the mobilisation of contaminants as a result of sediment disturbance within the water column will depend on the particular toxicant, its concentration, level of dilution and sensitivity of the biological receptors. Metals can be essential for organisms as trace elements, however at higher concentrations they can become toxic.

Sediment samples were collected around Campaign #1 SPJs WTA, KFA, CBA, HLA, DPA, BMB and FLA during Environmental Survey 1 (Summer). Sediment samples from MKA, FTA, BMA, WKF, PCA and KFB were collected during Environmental Survey 2 (Winter). The samples were analysed for metal and hydrocarbon concentrations at platform locations and at reference locations in Bass Strait. The screening levels against which analytical results from sediment samples were compared to are provided in Appendix J. The screening levels labelled as 'regulatory' are based on the Australian and New Zealand guidelines for fresh and marine water quality (ANZG, 2018) (or similar) guideline values and are for the protection of environmental health. The screening levels labelled as 'literature' are for bioaccumulation or community change endpoints identified through literature and defined during the design of the environmental survey (Hook S. E., 2021).

An overview of the results of the sediment sampling during these two surveys is provided below.

- More than 95% of sites sampled during the two surveys returned concentrations that were below the screening levels.
- There were no screening level exceedances at the CBA and WKF platforms.
- Although measured metals concentrations in samples collected from the areas around platforms were higher than those measured in reference sites, measured concentrations only occasionally exceeded the screening levels, with some exceptions, namely:
    - zinc concentrations at BMB (two samples out of 40 taken), KFA (one sample out of 40 taken) and MKA (one sample out of 40 taken), which exceeded the regulatory screening levels
    - lead results at KFA, KFB and HLA were below the screening levels (regulatory), with one sample (out of 40 samples taken) at KFA, one sample (out of 40 samples taken) at KFB and one sample (out of 40 samples taken) at HLA exceeding the literature screening levels
    - mercury results were below the screening (regulatory) levels, with one sample (out of 40 samples taken) at HLA exceeding the screening (literature) levels.
    - During Environmental Survey 1 (Summer) Naturally Occurring Radioactive Material (NORM) at FLA (one sample out of 33), KFB (one sample out of 28) and WTA (two samples out of 30) exceeded the screening level derived from the Australian Radiation Protection and Nuclear Safety Agency exemption limit of 1Bq g-1. Further samples and investigation of NORM levels in sediments was undertaken in Environmental Survey 2 (Winter) which concluded that all predicted dose rates, including background samples, were below the 10µGy/h screening level, hence it is not expected there would be a radiological risk to marine organisms from sediments within the areas sampled (ANSTO, 2023). Arsenic concentrations at FTA (one sample out of 13 taken) exceeded the screening (regulatory) level.

- Arsenic concentrations at PCA (12 out of 14 samples taken) and DPA (27 samples out of 31 taken) exceeded the screening (regulatory) level – see below for explanation.

Where concentrations above screening levels were noted for some analytes, they sometimes occurred within the same grab samples and were grouped around the same platforms, namely at BMB and HLA (Hook S. E., 2021).

The distribution of arsenic around the platforms and in reference sites did not follow the same patterns of the other metals. Arsenic concentrations exceeded the screening level concentration in the majority of sediment samples collected around the DPA and PCA platforms, as well as some of those from nearby reference sites (Hook S. E., 2021) and (AECOM, 2024). There is also no relationship between arsenic concentration and distance to platforms, which might be expected if the platforms (or activity at the platforms) were the source of the elevated concentrations (Hook S. E., 2021) and (AECOM, 2024). This, together with the elevated concentrations of arsenic at reference sites are factors which indicate that the elevated concentrations of arsenic around the DPA and PCA platforms are naturally occurring.

From Environmental Survey 1 (Summer), elevations in sediment polycyclic aromatic hydrocarbons (PAHs) concentration were found predominantly in the low molecular weight PAHs. In most instances, the PAHs were below detection at the platforms, and although measured concentrations of several PAHs exceed the lower, 'effects possible' screening levels, they did not exceed the 'effects probable' thresholds. Measurable concentrations of PAHs were most common for phenanthrene and naphthalene. Some of the samples at WTA and BMB that exceeded the lower screening levels did so for multiple PAHs and were grouped in the same area within 500m of the platform. Of the facilities sampled in Environmental Survey 1 (Summer), only WTA showed summed PAH levels exceeding the lower, 'effects possible' screening level (Hook S. E., 2021).

From Environmental Survey 2 (Winter) PAH was analysed for samples where total petroleum hydrocarbons were recorded above limits of reporting. From the platforms surveyed, PAHs were only recorded at BMA and WKF (WKF recorded PAHs in one sample only with no exceedances of screening levels). The trend in results were similar to those of Environmental Survey 1 (Summer). At BMA exceedances of the screening levels were seen in two samples for naphthalene and three samples of phenanthrene, all within 100m of the platform. Two of these samples recorded exceedances for both PAHs. One sample at BMA was the only sample with a summed value of the low molecular weight PAH exceeding the lower, 'effects possible' screening level. Elevations in sediment PAH concentration were found predominantly in the low molecular weight PAH. In most instances, the PAHs were below detection at the platforms, and although measured concentrations of several PAH exceed the lower, 'effects possible' screening levels, they did not exceed the 'effects probable' thresholds. Measurable concentrations of PAH were most common for phenanthrene and naphthalene.

Based on the sediment sampling undertaken in 2021 and 2022, while there were some instances where concentrations of metals or occasionally PAHs exceeded screening levels, over 95% of samples returned concentrations below screening levels, indicating that the overall level of contamination around the facilities is low. The largest volume of sediment which may be displaced during the removals activities (hence the scenario considered to be the worst-case in terms of contaminant mobilisation) is at BMA, WTA and FTA if external cutting of these facilities is required to enable removal at or below the seabed (refer to Table 6-2). Dispersion modelling undertaken for this scenario indicated that the modelled extent of high concentrations of fines for this scenario was predominantly within 10m of the centre of the facility (Stantec Australia, 2024a). The level of bioavailability of certain contaminants may be increased where finer sediments are mobilised due to a greater affinity and capacity of fine sediments to bind contaminants (Stantec Australia, 2024b). Hence the area of potential impact to marine fauna via the potential mobilisation of sediments will be very localised. While the jacket structures at WTA, BMA and FTA support a diverse range of marine species, encrusting biota will be lost in any case upon the removal of the jackets, while mobile species such as fish or marine megafauna would be able to avoid the affected area and find similar unaffected habitat elsewhere.

This combined with the low levels of contamination measured in the sediments around the facilities, indicates impacts to marine fauna as a result of toxicity from mobilised contaminants during removal activities is low and has been assessed as:

- **Consequence Level IV**.

6.1.3.6 Cumulative impacts

There have been no concurrent activities (by Esso, other oil and gas operators or other marine project such as wind energy) identified within the OA and within the Campaign #1 execution timeframe that would result in

significant seabed displacement and hence result in cumulative impacts to marine biota receptors as a result of the mobilisation of contaminants.

Future Bass Strait decommissioning execution activities such as the removal of lower jacket sections and the removal of pipelines associated with the Campaign #1 facilities (not within the scope of this EP) may also result in the redistribution of sediments and potentially contaminants in the OA. Contaminants that deposit on the seabed will either disperse over a large area via currents and water movement, thereby reducing concentrations and minimising cumulative effects, or will become incorporated into deeper sediments over time through bioturbation (Erias/RSK, 2025). It is noted that modelling by Stantec did not indicate the potential for overlap of any sediment plumes or sedimentation overlapping across platforms (Stantec Australia, 2024b).

6.1.3.7 Change to tangible underwater cultural heritage values

According to s15 of the *Underwater Cultural Heritage Act 2018*, underwater cultural heritage means:

(a) Any trace of human existence that:

a. has a cultural, historical, or archaeological character; and

b. is located underwater

Under the *Underwater Cultural Heritage Act 2018,* specific UCH are automatically protected, including the remains and associated articles of vessels and aircraft that have been in Commonwealth waters for at least 75 years. First Nations UCH in Commonwealth waters, associated with dry land habitation on the submerged landscapes of the Australian continental shelf, can be declared by the Minister as protected upon discovery and significance assessment (DCCEEW, 2024f).

No protected underwater cultural heritage zones or articles have been identified within the locations where sediment disturbance is planned to take place as part of Campaign #1 removal activities (Section 3.2). Therefore, no impacts to protected UCH (e.g. maritime, aviation or archaeological sites, including First Nations) are expected.

Given the locations of the sediment disturbance are in close proximity to selected facility locations and pipelines, where the sediment has been previously disturbed upon installation, it is not considered likely that unidentified archaeological artefacts may be discovered as a result of this activity. However parts of the OA are located within the boundary of land that may have been emergent during First Nations occupation (Extent Heritage and Wessex Archaeology, October 2024) and feedback during stakeholder consultation with First Nations groups indicated that '*offshore infrastructure removal risks damage to underwater heritage*'. As a result, to ensure this feedback is addressed, and the requirements of the *Underwater Cultural Heritage Act 2018* to notify the discovery of all suspected UCH and ensure actions do not result in an adverse impact to UCH, an Unexpected Finds Protocol will be developed and implemented for the Campaign #1 activities.

Given the small sediment disturbance footprint associated with the activity, sediment disturbance only being located within previously disturbed areas and the absence of protected UCH zones or articles, a change to underwater cultural heritage values as a result of planned seabed disturbance is not predicted to occur. As such, this has been assessed as:

- Consequence Level IV

6.1.4 Demonstration of As Low As Reasonably Practicable

Table 6-3 Decision Context and justification

Decision Context
Seabed disturbance from offshore activities is a common occurrence both nationally and internationally. The seabed displacement methods are well understood. Use of positive displacement methods in a controlled manner is an accepted industry practice. During consultation with relevant persons, no objections or claims regarding seabed disturbance were made. The environmental consequence for the impacts resulting from seabed displacement have been assessed as **Consequence Level IV**. Hence, Esso believes **Decision Context A** should apply.

Table 6-4 Good practice controls

Good practice	Adopted	Control	Rationale
Comply with UCH Act *and Torres Strait Islander Heritage Protection Act 1984* (Cth).	Adopted – IMP1–CM1	Unexpected finds of potential Underwater Cultural Heritage sites/features, including First Nations archaeological UCH are managed in accordance with an Unexpected Finds Protocol.	Provides guidance in the event that an unexpected UCH find is encountered. By implementing an Unexpected Finds Protocol, potential impacts to UCH objects and values will be minimised. This allows management and reporting of unexpected finds in accordance with legislative requirements (e.g. UCH Act) and the *Guidelines to assessing and managing impacts to Underwater Cultural Heritage in Australian waters* (DCCEEW, 2024f).

Table 6-5 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Control adopted
Do not undertake seabed displacement.	Environmental impacts as a result of seabed displacement will not occur.	This is not a feasible option. Access to infrastructure located below the seabed is required to undertake removal activities.	Not adopted
No temporary storage of items on the seabed.	Disturbance to the seabed as a result of the placement of items to be temporarily stored will not occur.	The ability to temporarily store items on the seabed enables a more efficient and expedient removal campaign, hence reducing environmental and socioeconomic impacts such as the displacement of other users.	Not adopted – cost is grossly disproportionate to the environmental benefit gained.
No planned anchoring of vessels.	Eliminates disturbance to the seabed as a result of anchoring.	Feasible.	Adopted – IMP1-CM2
Utilise internal cutting methods in preference to external cutting methods where jacket piles are to be cut below seabed.	Minimises the volume of seabed required to be displaced.	External pile cutting methods will only be used for pile cuts targeted below seabed if internal methods cannot be used due to blockages within the pile, or where a blockage is identified and there is uncertainty as to success of removing it.	Adopted – IMP1-CM3
Remove temporarily stored infrastructure prior to the end of the Campaign #1 activities.	Eliminates any potential ongoing	Partially feasible. All items temporarily placed on the seabed during removal activities are planned for	Partially adopted – IMP1-CM4

Control Measure	Benefit	Cost/feasibility	Control adopted
	impacts to the seabed.	retrieval prior to the end of Campaign #1 activities. However, in the event there are safety considerations, operational constraints or suitable equipment is not available, the removal of larger items which require a HLV will be prioritised and smaller items placed on the seabed may be recorded and tracked for removal as soon as practicable in accordance with the ongoing removal of property process in the *Bass Strait Environment Plan (AUGO-EV-EMM-012)*.	

6.1.5 *Demonstration of acceptability*

Table 6-6 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle - decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The precautionary principle has been applied and studies have been undertaken where knowledge gaps were identified (sediment dispersal modelling). This knowledge has been applied during the assessment of environmental impacts as a result of seabed displacement. The impact assessment undertaken for seabed displacement has concluded that impacts are assessed as **Consequence Level IV** (inconsequential or no adverse effects) hence it is not considered that seabed displacement as a result of Campaign #1 removal activities has the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the	✓	Not inconsistent. The impact assessment undertaken for seabed displacement has concluded that environmental impacts will be short term and localised in nature.

Factor	Demonstration criteria	Criteria met	Rationale
	environment is maintained or enhanced for the benefit of future generations.		Hence any impacts as a result of seabed displacement will not impact the health, diversity and productivity of the environment such that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The impact assessment undertaken has shown that the potential impact associated with seabed displacement is limited to a localised short term impact and has been assessed as **Consequence Level IV** (inconsequential or no adverse effects). There are no marine protected areas, KEFs, threatened benthic species or ecological communities, critical habitats, or BIAs relevant to the benthic environment within the areas which may be disturbed by seabed displacement. . Any impacts as a result of seabed displacement are not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The proposed activities align with the requirements of the OPGGS Act: • Section 280(2) – No interference with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the exercise of the rights conferred by titles granted • Section 572(3) – Requirement to remove from the relevant title areas structures and all equipment and other property that is neither used nor to be used in connection with the operations. Activities will be undertaken in compliance with the requirements of the *Underwater Cultural Heritage Act 2018.*
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "*comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist*".
	Meets ExxonMobil Environmental Standards.	✓	Although there is no specific standard related to offshore (i.e. seabed) land use, the controls proposed meet the requirements of the Upstream Standard on Land Use specifically to "*avoid use of land within environmentally or socioeconomically sensitive areas*" and "*site selection process considers impacts on the ecological and social environment*".

Factor	Demonstration criteria	Criteria met	Rationale
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner. Decommissioning contractor was selected in accordance with Esso's OIMS procurement processes.
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	No specific relevant person concerns have been raised concerning seabed displacement activities included in this EP. Feedback from First Nations relevant persons during consultation for the EP has been considered and addressed. Feedback from DCCEEW (Underwater Cultural Heritage) that activities have regard to the *Guidelines to assessing and managing impacts to Underwater Cultural Heritage in Australian waters* has been considered and the Guidance requirements have been addressed throughout the impact assessment.

6.1.6 EPOs, control measures, EPSs and measurement criteria

Table 6-7 EPOs, control measures, EPSs and measurement criteria – Seabed displacement

EPO	Control measure	EPS	Measurement criteria
IMP1-EPO1: No adverse impact to unexpected finds of Underwater Cultural Heritage without a permit .	IMP1-CM1: Unexpected finds of potential UCH sites/ features, including First Nations UCH, are managed in accordance with an Unexpected Finds Protocol.	IMP1-EPS1.1: In the event potential UCH is discovered, management of the find will be undertaken in accordance with an Unexpected Finds Protocol. This Protocol will meet the requirements of the *Guidelines to assessing and managing impacts to Underwater Cultural Heritage in Australian waters* (DCCEEW, 2024f).	IMP1-MC1.1.1: No non-compliance with the Unexpected Finds Protocol.

EPO	Control measure	EPS	Measurement criteria
IMP1-EPO2: Seabed displacement is limited to planned activities and defined removal locations.	IMP1-CM2: No planned anchoring of vessels.	IMP1-EPS2.1: No planned anchoring by vessels undertaking Campaign #1 activities within the OA. Any anchoring during Campaign #1 will be recorded as an environmental incident.	IMP1-MC2.1.1: Removal procedures confirm no planned anchoring by vessels. IMP1-MC2.1.2: Records confirm incident reporting requirements have been communicated to appropriate vessel crew via Campaign #1 inductions.
	IMP1-CM3: Utilise internal cutting methods in preference to external cutting methods where jacket piles are to be cut below seabed.	IMP1-EPS3.1: Internal cutting methods are used where possible in preference to external cutting methods where jacket piles are cut below seabed.	IMP1-MC3.1.1: Removal procedures for each facility which documents planned cutting location and methods. IMP1-MC3.1.2: As removed survey report will document final removal heights above seabed or each facility.
IMP1-EPO3: Temporarily stored equipment is removed as soon as reasonably practicable in accordance with the requirements of Section 572(3)	IMP1-CM4: Remove temporarily stored infrastructure prior to the end of the Campaign #1 activities, or document for future removal.	IMP1-EPS4.1: Temporarily stored equipment is removed prior to the end of Campaign #1. If any items are not removed during Campaign #1 these are documented for future removal.	IMP1-MC4.1.1: The Campaign #1 temporary storage register confirms temporarily stored items are recorded and removed. IMP1-MC4.1.2: Esso Subsea Material Register is updated following Campaign #1 for items that have not been removed.

6.1.7 Residual consequence assessment

With the above controls in place, the consequence of seabed displacement has been assessed as:

- **Consequence Level IV**.

6.2 Physical presence – Interference with other marine users

6.2.1 Sources of interference with other marine users

The movement of vessels within the OAs, and the physical presence of the HLV, CSVs, barges, HTVs, tugs and other support vessels has the potential to result in interference with the activities of other marine users such as commercial and recreational fishing vessels and merchant shipping vessels. Given the overall size of the OA, close interactions between these vessels are considered unlikely to occur. The presence of Campaign #1 vessels in the OA is expected to have minor impacts to commercial fishing.

The physical presence of the lower jacket sections remaining in place on the seabed (at least 55m below MSL) and the BMB concrete substructure has been considered in assessing interference with other marine users.

Note that this Section deals with displacement or interference in a socioeconomic sense. Collision risk (and potential resulting spill and other socioeconomic impacts) is addressed in Sections 7.1 and 7.7.5.

During facility removal and transfers to barge/HTV, a 500m exclusion zone will be in place around the HLV and any other transfer associated vessels. For facility removal activities with the HLV, a 500m exclusion zone will be in place in addition to the existing PSZ, hence other marine users will be excluded from an area of 1000m radius. This additional exclusion zone is required due to the length of the *Pioneering Spirit* HLV. Marine users will be requested to avoid Campaign #1 vessel exclusion zones during activities to ensure the safety of both Campaign #1 vessels and third-party vessels. No exclusion zone will be in place while the HLV and CSVs are in transit between the facility locations and the transfer location.

A temporary waverider buoy (or multiple at different locations) may be installed within the OA to provide real time field measurement of wave height and wave direction to support decommissioning activities. A typical waverider buoy arrangement includes a buoy which floats on the ocean surface and a tether from the buoy to a clump weight which would be sitting on the seabed. Marine users would be notified of the installation and location, and the buoy would be fitted with standard identifiers.

A clump weight on a taut wire may be deployed to provide localised confirmation of vessel depth. This weight would be deployed from the HLV within the OA and expected to sit on the seabed temporarily while measurements are completed.

Commercial fishing and other third-party vessels are currently excluded from the 500m PSZs around each facility. The PSZs have been in place since the installation of the facilities.

6.2.2 Impacts of interference with other marine users

The impacts of interference with other marine users are considered to be:

- changes to the function, interests or activities of other users through disruption to commercial, recreational or other marine industry activities.

Disruption to commercial activities may include:

- diversion from navigation path (displacement of shipping)
- exclusion from fishing grounds as a result of the presence of vessels and subsequent loss of catch
- obstacles to trawling (presence of infrastructure).

Disruption to recreational activities may include:

- exclusion from recreational fishing areas as a result of the presence of vessels
- diversion from navigation path (displacement of recreational boating activities)

Disruption to other marine industry may include

- interruption to activities due to the presence of vessels.

6.2.3 Impact assessment

6.2.3.1 Change to the function, interests or activities of other users – Shipping

A shipping exclusion zone - the ATBA - exists around the operating oil and gas facilities in the Gippsland Basin, where unauthorised vessels larger than 200 gross tonnes are excluded from entry. The ATBA is defined in Schedule 2 of the OPGGS Act and shown in Figure 6-1 (Australian Border Force, 2024). Two Traffic Separation Schemes have been implemented to enhance safety of navigation around the ATBA by separating shipping into one-direction lanes for vessels heading north eastwards and those heading south-westwards. One separation area is located south of Wilsons Promontory, and the other south of KFB. The locations of the two Traffic Separation Schemes are depicted in Figure 6-2.

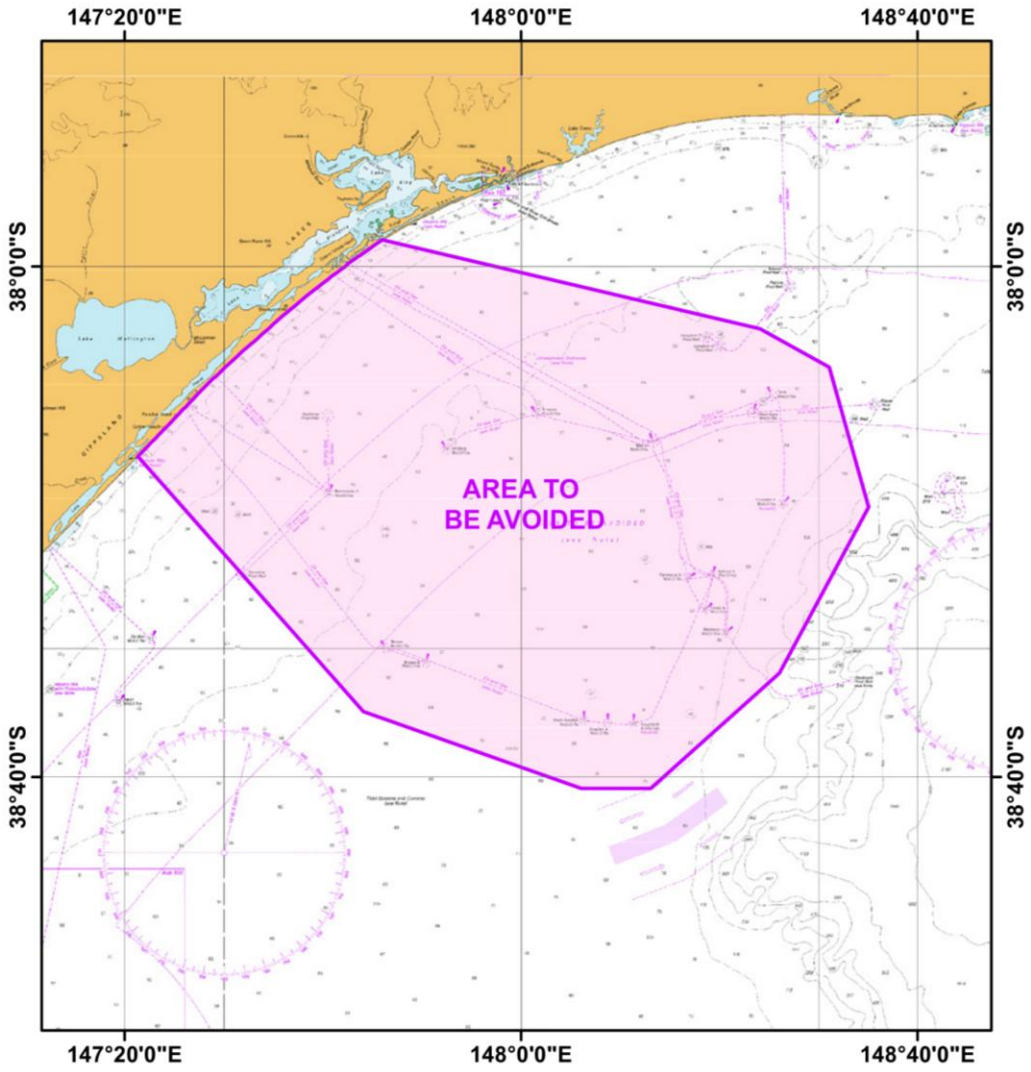

Figure 6-1 Shipping exclusion zone (ATBA) (AHO, 2024)

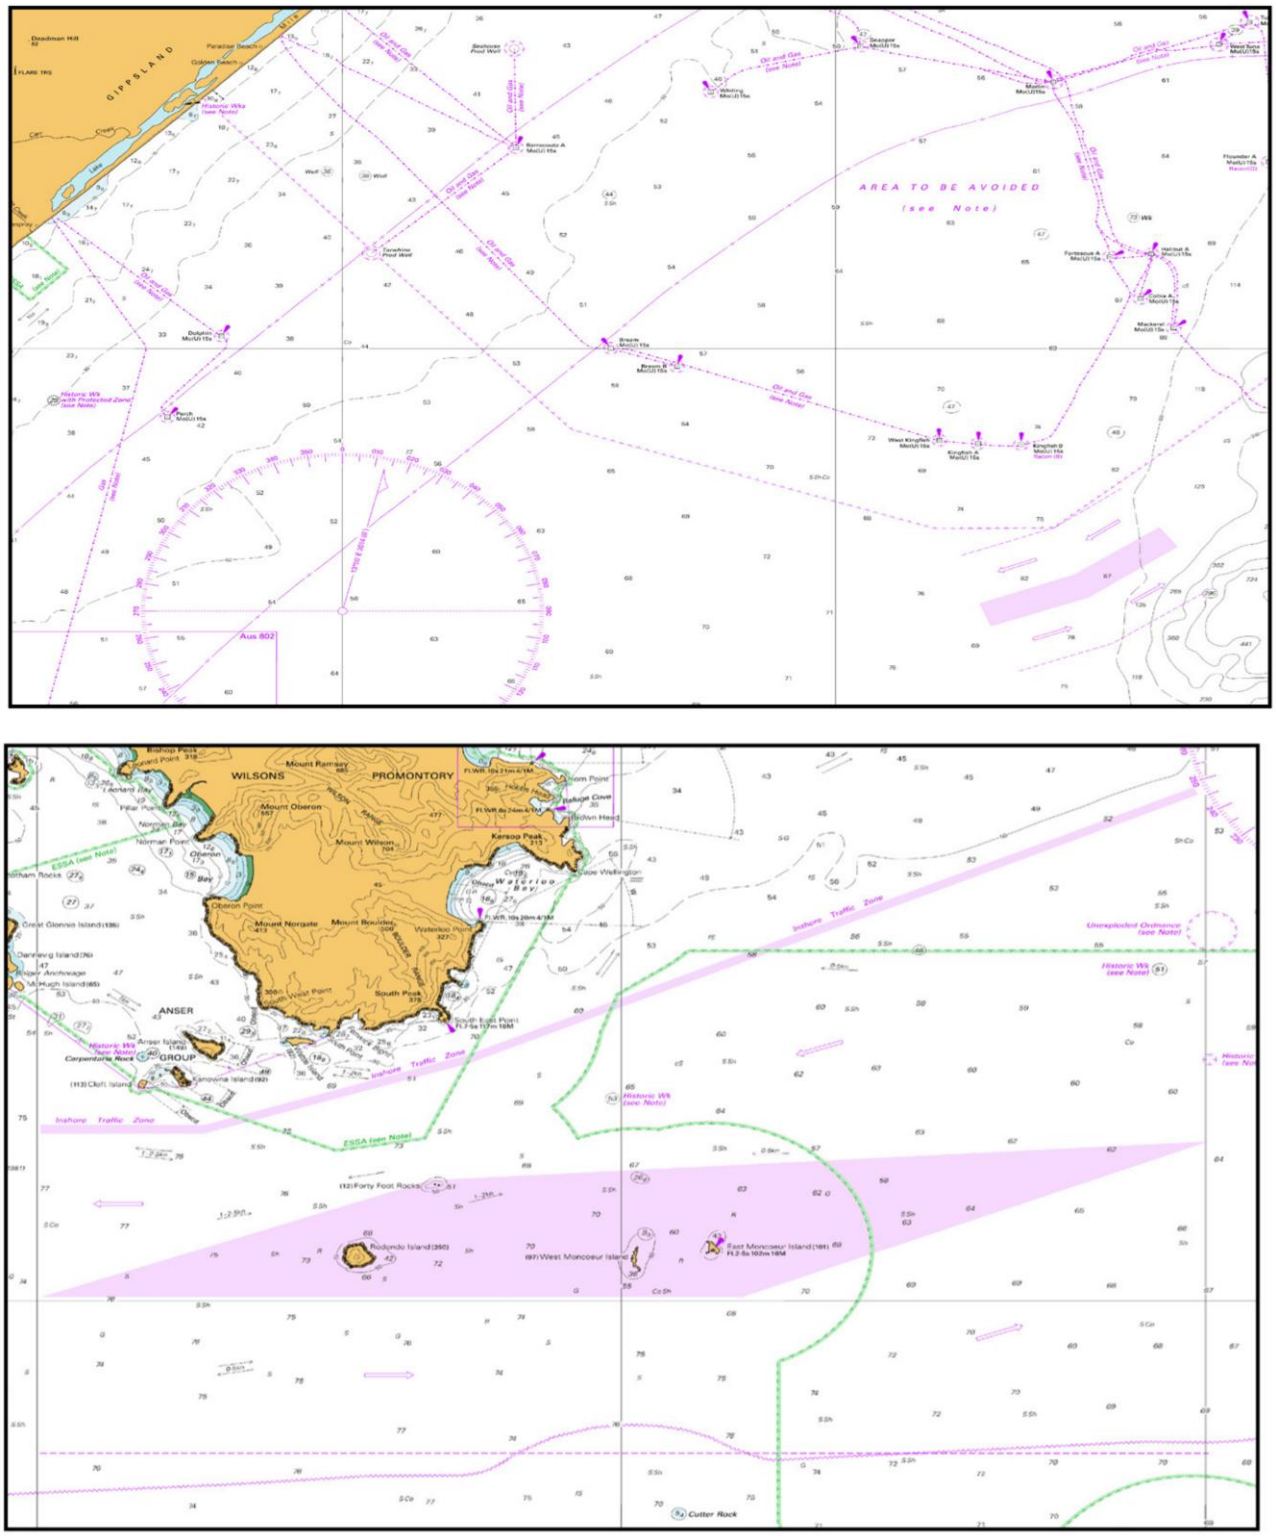

Figure 6-2 Traffic Separation Schemes (Bass Strait and south of Wilsons Promontory) (AHO, 2024)

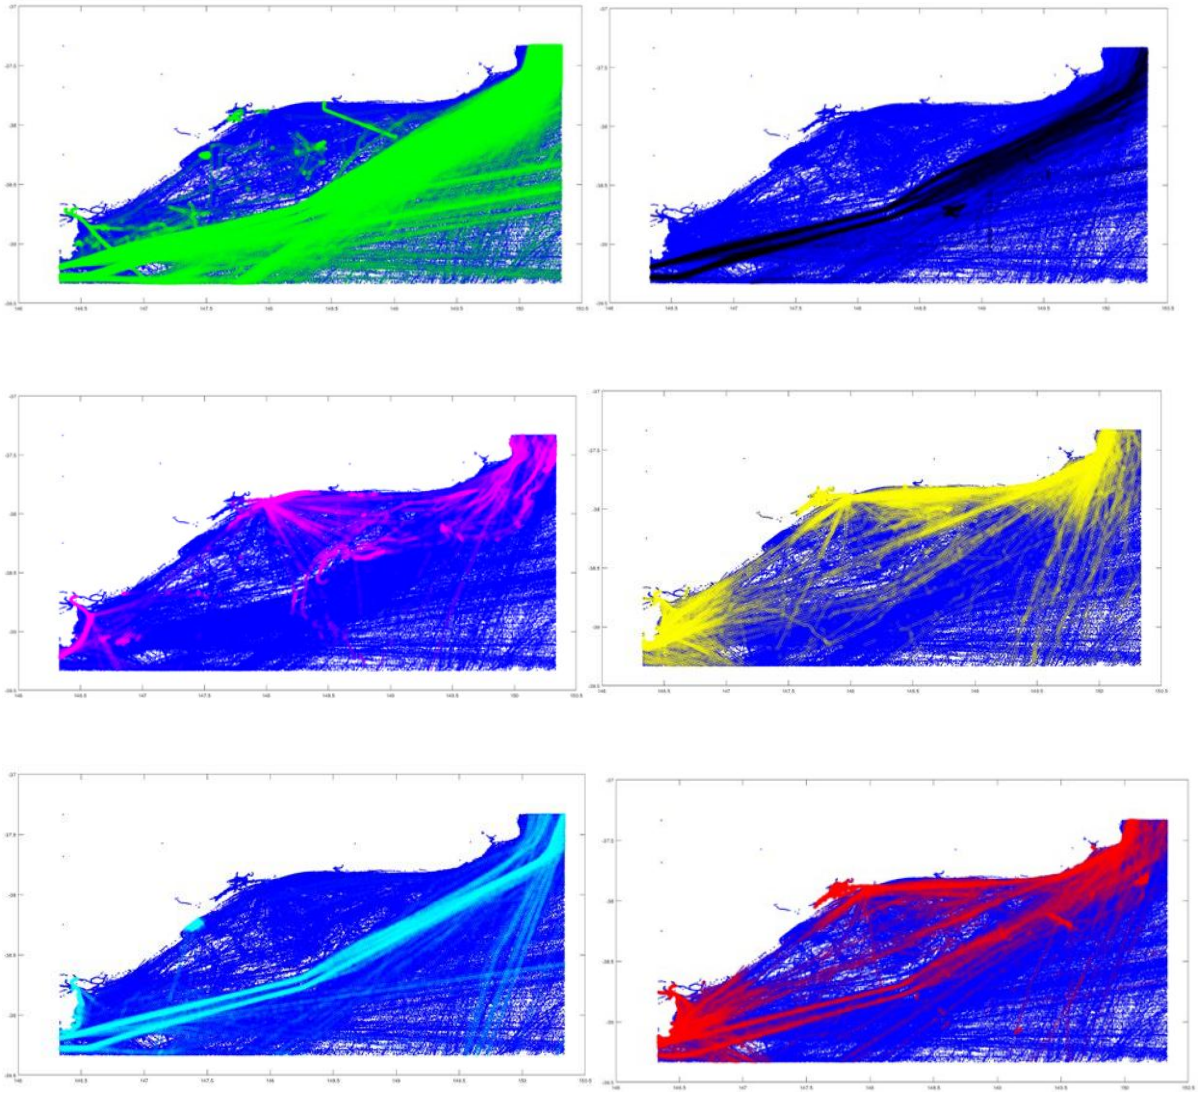

The PCA and DPA monotowers are not located within the ATBA and part of the transport route from the facilities to the transfer area will also occur outside the ATBA. However, given the proximity of these facilities and the transport route to the shore, and the presence of the two Traffic Separation Schemes to direct vessels around the ATBA, large commercial vessels are not expected to be transiting in the vicinity of PCA or DPA and within the transport route.

An additional Traffic Separation Scheme has been established to the south of Wilsons Promontory to separate the opposing flows of traffic and to keep vessels clear of the island groups in the area (AHO, 2024). Given the presence

of this Traffic Separation Scheme and local geographic features, it is not expected that commercial shipping vessels will be transiting through or near sheltered waters closer to Wilsons Promontory where transfer operations may take place.

Further information on vessel movements in the area was obtained by a study undertaken in 2022 which assessed potential impacts to other users of the sea as a consequence of decommissioning (AMC Search, 2022a). Vessel tracks transiting within Bass Strait by the type or category of vessel were produced as part of this study and are provided in Figure 6-3. From the diagrams it can be seen that tankers, passenger ships and cargo vessels all keep clear of the ATBA and use the two Traffic Separation Schemes that are in place. Hence any disruption to commercial shipping as a result of the physical presence of the vessels undertaking removal, transport and transfer activities within the OA is unlikely to occur and the consequence has been assessed as:

- **Consequence Level IV**.

First row left – Cargo ships (green)

First row right – Tankers (black)

Second row left – Fishing (purple)

Second row right – Sail/Pleasure craft (yellow)

Third row left – Passenger (light blue)

Third row right – Type 0 (default /unknown) (red)

Figure 6-3 Ship tracks in Bass Strait by type for period 2015 - 2019

The partially removed facilities which will remain in place after Campaign #1 activities will continue to be located within the ATBA. The AMSA have noted during consultation that the Traffic Separation Scheme is likely to be maintained given other regional considerations for navigation safety. A risk assessment carried out by AMC Search

in 2022 also concluded that *"removal at 55m will not affect the passage of merchant vessels of current design characteristics"* (AMC Search, 2022b). The minimum 55m vessel clearance was assessed as adequate for clearance even under extreme weather events and for the largest vessels. Hence there is no change to the current situation and impact to shipping activities is not expected to occur as a result of the presence of these structures on the seabed for a period of time until removal. The consequence level has been assessed as:

- **Consequence Level IV**.

6.2.3.2 Change to the function, interests or activities of other users – Commercial fishing

A number of Commonwealth and State (Victoria) managed fishery areas overlap with the OA (refer to Table 3-2).

The physical presence of the removal activities will result in the exclusion of commercial fishing vessels from parts of the fisheries management area. Given commercial fishing vessels are already excluded from the 500m PSZ around the facilities to be removed, these exclusions are restricted to the transfer area while transfer activities are taking place and a slightly larger area (additional 500m) around each facility while the HLV is undertaking removal operations.

The presence of the HLV and the CSVs may also result in vessels needing to make minor deviations around these vessels while they are transiting through the area and transporting the removed infrastructure from the facility locations to the transfer area.

Esso have consulted with a broad range of stakeholders including fishing industry bodies representing both Commonwealth and State fisheries, individual fishing licence holders, recreational fishers and wind energy proponents (refer to Section 4). Fisheries (commercial and recreational) were interested in understanding the potential exclusions that would be in place during the removal activities and were provided information in this regard. It has been communicated that in addition to the existing PSZ, vessel specific exclusions will be required during lifting and transfer operations for the safety of all vessels and these requirements will be communicated in Notices to Mariners. No concerns were raised with this approach.

Commercial fishers raised whether compensation would be available to address any impacts to commercial fishers as a result of exclusion from any areas around the transfer locations during the activities. Esso is continuing to engage with commercial fishers on a regular basis and is considering the possibility of compensation for displacement around transfer areas.

Stakeholders were advised that at the completion of works, relevant authorities would be advised to allow navigation charts to be updated. A temporary navigation aid will be installed on the structures once topsides are removed if no vessel will remain in the PSZ. A navigation aid will be installed on the BMB concrete substructure.

The areas of exclusion during the removal and transfer activities are minor relative to the size of the fishery areas available. Any impacts will be short-term in nature given the short duration of the activities, expected to be approximately five months. Hence it is anticipated that any disruption to fishing operations from displacement from fishing grounds as a result of the removal activities will be minor and the consequence level has been assessed as:

- **Consequence Level III**.

6.2.3.3 Change to the function, interests or activities of other users – Recreational activities

Recreational vessels are already excluded from the 500m PSZ around the facilities to be removed, and a slightly larger area (additional 500m) will be in place around each facility while the HLV is undertaking removal operations. Exclusions will also apply to the transfer area while transfer activities are taking place.

The presence of the HLV and the CSVs may also result in vessels needing to make minor deviations around these vessels while they are transiting through the area and transporting the removed infrastructure from the facility locations to the transfer area.

The areas of exclusion during the removal and transfer activities are minor relative to the size of the surrounding areas available. Any impacts will be short term in nature given the short duration of the activities, expected to be approximately five months. Hence it is anticipated that any disruption to recreational activities from displacement as a result of the removal activities will be minor. The consequence level has been assessed as:

- **Consequence Level IV**.

As part of consultation, game fishers were interested in understanding the timing of any removal of the PSZs. It was noted that PSZs are authorised by NOPSEMA and the timing of any removal is not determined by Esso.

6.2.3.4 Change to the function, interests or activities of other users – Other marine industries

It is recognised that a number of existing and emerging marine industries have interests and operations within the OA. The Campaign #1 activities may result in other industries needing to make minor deviations in vessel operations or adjustments in activity planning based on their individual needs and activities.

The areas of exclusion during the removal and transfer activities are minor relative to the size of the surrounding areas available. Any impacts will be short-term in nature given the short duration of the activities, expected to be approximately five months. It is anticipated that any disruption to recreational activities from displacement as a result of the removal activities will be minor.

The consequence level has been assessed as:

- **Consequence Level IV**.

Esso have consulted with a range of existing and emerging marine industry stakeholders including but not limited to other oil and gas operators in the region, potential future wind energy operators with licence areas within the OA (refer to Section 4). Wind operators asked to be kept informed of decommissioning activities as part of general communications for information/interest.

6.2.3.5 Cumulative impacts

Removal activities will be conducted within the ATBA for Esso operations in the Bass Strait. Operations from other oil and gas operators in the area are limited, with potential sporadic, short term IMR activities that would take place several kilometres away from nearest Esso Bass Strait facility. As a result, it is not expected Campaign #1 activities will overlap with vessel operations from other operators that could result in cumulative levels of interference to other marine users.

Transfer activities will most likely occur outside the ATBA and within the OA closer to the Corner Inlet shipping channels, hence vessel traffic to service offshore areas may be present in this area. Transfer operations will be short in duration and due to detailed execution planning, the least number of transfer operations will be undertaken - the HLV is expected to be at a sheltered water location (the 'transfer location') on approximately 21 separate occasions undertaking transfer operations over the duration of the Campaign #1 activities.

It is not expected that Campaign #1 activities will overlap with vessel operations from other Esso projects within the Bass Strait that could result in cumulative levels of interference to other users of the sea.

From a wind energy projects perspective, the Australian Government has granted 12 feasibility licences for offshore wind projects in the Gippsland region. As of July 2025, Gippsland Dawn Project (Bluefloat) feasibility license has been withdrawn, resulting in 11 feasibility licences remaining for offshore wind in Gippsland (DEECA, 2024) . Six of these 11 projects overlap at some extent with the OA for Campaign #1. Offshore wind farm projects are currently in early stages of planning, with processes for environmental and other approvals currently under way. Currently there is high uncertainty on exact timing when early offshore works (geophysical surveys) and construction activities of wind farms will take place. However, based on communications held between Esso and wind farm operators, there is not forecast to be an overlap between the Campaign #1 activities and construction activity for potential wind farms. Refer to Section 6.13.3.8 for more detailed information on timing of activities based on consultation with potential wind farm operators. Based on this, it is not expected that Campaign #1 activities will overlap with vessel operations from wind farm operators that could result in cumulative interference to other users of the sea.

6.2.4 Demonstration of As Low As Reasonably Practicable

Table 6-8 Decision Context and justification

Decision Context
The impacts associated with marine user interference are well managed via legislative control measures. These controls are understood and well implemented by the industry.

Decision Context
Esso has been operating in this part of Bass Strait for 60 years, with other marine users well aware of Esso's facilities and operations. The environmental consequence for the impacts resulting from interference with other users of the sea have been assessed as **Consequence Level IV**. Concerns raised during relevant persons consultation have been considered/addressed. Hence, Esso believes **Decision Context A** should apply.

Table 6-9 Good practice controls

Good practice	Adopted	Control Measure	Rationale
Ensure other users of the sea are aware of exclusion zones and vessel operations prior to removal activities commencing.	Adopted – IMP2-CM3	Notify AHO prior to commencing removal activities.	Under the *Navigation Act 2012* (Cth), the AHO is responsible for maintaining and disseminating hydrographic and other nautical information and nautical publications including Notices to Mariners. Details of the PSZ and other vessel exclusion zones will be published in Notices to Mariners, thus enabling other marine users to plan their activities, and minimising disruption to exclusion zones.
	Adopted – IMP2-CM2	Notify AMSA Joint Rescue Coordination Centre prior to commencing removal activities.	Relevant details will be provided to the Joint Rescue Coordination Centre to enable AUSCOAST warnings to be disseminated.
Notify relevant persons with activities in the OA in advance of removal operations to ensure they can plan their activities to minimise interference.	Adopted – IMP2-CM5 and IMP2-CM6	Distribution of SMS text message updates to the eastern fishing fleet advising of vessel movements or activities being performed outside the PSZ. Provide updates to other marine users with activities in the OA as requested during consultation for this EP.	Prior notification and understanding of the Campaign #1 activities enables other users of the sea in and around the OA to plan their activities and avoid unexpected interference. The consultation undertaken during the preparation of this EP, as detailed in Section 4, has ensured that relevant persons with activities within the OA are identified, consulted with and provided with sufficient information to enable them to assess any potential impacts to their functions, interests or activities. If requested during consultation, relevant persons will continue to be kept updated on the removal activities (including commencement and completion of activities), in the manner and form agreed during consultation.
Notify AHO of changes to facilities following Campaign #1 to enable update of navigational charts.	Adopted – IMP2-CM7	Notify AHO of the location of infrastructure remaining following the completion of Campaign #1 so navigational charts	Ensures infrastructure continues to be marked on navigational charts so other marine users are aware of their presence.

Good practice	Adopted	Control Measure	Rationale
		can be updated if required.	

Table 6-10 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
No exclusion zone in place (or a reduction in the size of the exclusion zone) around Campaign #1 vessels during transfer operations.	Reduces the area of displacement of other users of the sea.	Not adopted – exclusion zone is required to ensure the safety of operations and minimise the risk to other users of the sea.	Not adopted
Temporary storage of removed items restricted to within the facility 500m PSZ.	Avoids additional interference to other users of the sea by the presence of items of the seabed outside existing exclusion areas.	Feasible and cost not disproportionate to benefit gained.	Adopted – IMP2-CM1
Undertake transfer operations in areas where there is low activity from other users of the sea.	Reduces interference to other users of the sea.	Not adopted – as detailed in Section 2.8.4, to ensure the safety of operations, transfer activities must be undertaken in areas where metocean and weather conditions are within specified limits.	Not adopted
Schedule the removal operations to avoid peak periods of activity for other users of the sea.	Reduces interference to other users of the sea.	Not adopted – no specific peak periods of activity have been identified. Removal activities must be undertaken in the period outlined in this EP in order to meet General Direction 817 requirements, suitable weather conditions for HLV and transfer activities and Campaign #1 vessel availability constraints.	Not adopted
Implement a rolling map to provide updated information on removal activities throughout Campaign #1.	Provides another method for commercial fishers to be aware of activities that may impact their activities.	SETFIA has proposed implementation of a rolling chart that can be used by commercial fishing bodies and fishers to better communicate shared marine space activities that affect fishing – including the Campaign #1 activities. This chart will be managed by SETFIA, with Esso (and other wind energy proponents/oil and gas operators) providing information to a dedicated contact prior to activities commencing to allow for the charts to be produced/updated.	Adopted – IMP2-CM6

6.2.5 Demonstration of acceptability

Table 6-11 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Long term and short term economic, environmental, social and equitable considerations have been incorporated into the assessment of impacts to other users of the sea as a result of the removal and transfer activities and the ongoing presence of partially removed facilities on the seabed. The removal campaign and the ongoing presence of the partially removed facilities on the seabed do not significantly impinge on the rights of other users of the sea (particularly commercial fishers) to access resources now and into the future.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The impacts of other marine users as a result of vessel activities and infrastructure on the seabed are well understood and have been managed throughout the decades of Esso operations in Bass Strait.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. Impacts to other marine users as a result of the physical presence of Campaign #1 vessels and partially removed infrastructure will be short term in nature and will not impact upon the environment such that future generations cannot meet their needs.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	Not relevant	This principle is not considered relevant to this aspect, as impacts relating to interference with other users of the sea are socioeconomic rather than environmental.

Factor	Demonstration criteria	Criteria met	Rationale
Legislative requirements	Legislative and other requirements have been identified and met.	✓	Legislation and other requirements considered as relevant include: OPGGS Act: • Section 280 requires that a person carrying on activities in an offshore area under the permit, lease, licence, authority or consent must carry on those activities in a manner that does not interfere with navigation or fishing (among others) to a greater extent necessary than for the exercise of the rights conferred by titles granted • Section 619 prohibits unauthorised vessels from entering a PSZ. The exclusion of vessels within the PSZ is considered an acceptable impact for safety reasons, in particular to avoid interaction between the subsea facilities and other marine users, a PSZ is required for Esso to exercise the rights conferred by the production title.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "*comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist*".
	Meets ExxonMobil Environmental Standards.	✓	The proposed controls meet the requirements of the *ExxonMobil Upstream Socioeconomic Management Standard* (ExxonMobil, 2021) specifically in relation to managing community relations.

Factor	Demonstration criteria	Criteria met	Rationale
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 10: Managing Community Risk objective to maintain public awareness and confidence in the Operations Integrity (OI) of operations and facilities.
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	Relevant persons concerns have been considered/addressed.

6.2.6 EPOs, control measures, EPSs and measurement criteria

Table 6-12 EPOs, control measures, EPSs and measurement criteria – Interference with other marine users

EPO	Control measure	EPS	Measurement criteria
IMP2-EPO1: Limit interference with other marine users to the extent necessary for the reasonable exercise of the right conferred by the titles granted.	IMP2-CM1: Temporary storage of removed items is restricted to within the facility 500m PSZ.	IMP2-EPS1.1: Temporary storage is undertaken within the 500m PSZ of a facility.	IMP2-MC1.1.1: The Campaign #1 temporary storage register confirms the locations of temporarily stored items are within the 500m PSZ of a facility.
IMP2-EPO2: Marine users are informed prior to the commencement of the Campaign #1 activities such that they can plan their activities and avoid unexpected interference.	IMP2-CM2: Notify AMSA Joint Rescue Coordination Centre prior to commencing removal activities.	IMP2-EPS2.1: AMSA Joint Rescue Coordination Centre (JRCC) notified before removal, and removal preparation, activities commence to enable AMSA to distribute an AUSCOAST warning.	IMP2-MC2.1.1: Records confirm that information to distribute an AUSCOAST warning was provided to the JRCC before removal operations commenced. IMP2-MC2.1.2: Issued AUSCOAST warning dated prior to, or on the date activities commenced.
	IMP2-CM3: Notify AHO prior to	IMP2-EPS3.1: AHO notified before removal, and	IMP2-MC3.1.1: Issued Notice to Mariners dated

EPO	Control measure	EPS	Measurement criteria
	commencing removal and removal preparation activities.	removal preparation, activities commence to allow generation of navigation warnings (including Notice to Mariners).	prior to, or on the date removal operations, or removal preparation activities commenced.
	IMP2-CM4: Provide updates to other marine users with activities in the OA, as requested.	IMP2-EPS4.1: Other marine users with activities in the OA are provided with updates on the removal activities and the removal preparation activities, if requested during consultation for this EP.	IMP2-MC4.1.1: Relevant person consultation records confirm that relevant persons were provided with updates in the manner and form as agreed during consultation.
	IMP2-CM5: Distribution of SMS text message updates to the eastern fishing fleet advising of vessel movements or activities being performed outside the PSZ.	IMP2-EPS5.1: Distribution of SMS text message updates to the eastern fishing fleet advising of vessel movements and Campaign #1 activities being performed outside the PSZ of facilities. Messages may be sent as often as daily during an activity, if appropriate.	IMP2-MC5.1.1: Records of SMS text message communications held by Esso, confirming when and to whom updates were sent.
	IMP2-CM6: Utilise a rolling map to provide updated information on removal activities throughout Campaign #1.	IMP2-EPS6.1: SETFIA notified prior to removal and removal preparation activities and provided with the required information to allow the rolling chart administered by SETFIA to be updated.	IMP2-MC6.1.1: Record of required information sent to the SETFIA Project Manager within the requested timeframes.
IMP2-EPO3: Marine users are aware of the ongoing presence of infrastructure following Campaign #1 activities.	IMP2-CM7: Notify AHO of the location of infrastructure remaining following the completion of Campaign #1 so navigational charts can be updated if required.	IMP2-EPS7.1: AHO notified of the location of infrastructure remaining following completion of Campaign #1, so these can continue to be marked on navigational charts.	IMP2-MC7.1.1: Records show that the AHO has been notified of the locations of infrastructure remaining following the completion of Campaign #1.

6.2.7 Residual consequence assessment

With the above controls in place, the consequence of interference with other users of the sea has been assessed as:

- **Consequence Level IV**.

6.3 Planned discharge – Sewage and food waste

6.3.1 Sources of sewage and food waste discharges

Vessels used in the oil and gas industry vary in size but often include accommodation facilities for crew and passengers. The crew will generate wastes, including food wastes (or putrescibles), and the use of ablution, medical facilities, laundry and galley that will result in the generation of sewage and grey water

The average volume of putrescible waste from each vessel depends on the number of POB and is estimated at 1 - 2kg/person/day (NERA, 2017). Assuming between 150 - 250 people working on the *Pioneering Spirit*, 55 people on each CSV and up to 100 people across the other Campaign #1 vessels (tugs, HTV etc.) this equates to an estimated range of 355 – 710kg of putrescible waste discharged daily.

Total volumes of sewage and grey water (from the use of ablution, laundry and galley facilities) typically generated at offshore facilities ranges between 0.04 and 0.45m^3/person/day (NERA, 2017). Assuming between 150 - 250 people working on the *Pioneering Spirit* and 55 people on each CSV and up to 100 people across the other Campaign #1 vessels (tugs, HTV etc.) this equates to an estimated range of 11 – 167m^3 of sewage and grey water discharged daily.

Discharges of sewage and food waste from vessels may occur at any location within the OA, provided the discharge standards of MARPOL are met which include (Australian Maritime Safety Authority, 2025):

- food waste comminuted or ground to a particle size of less than 25mm is permitted to be discharged while the vessel is enroute (unless the retention of food waste onboard presents an imminent health risk to people onboard), as far as practicable from the nearest land, but in any case, greater than or equal to 3nm from the nearest land. Note the boundary of the OA is equal to or greater than 3nm from the nearest land
- if food waste is not comminuted or ground, discharge is permitted while vessel is enroute, unless the retention of food waste onboard presents an imminent health risk to people onboard, as far as practicable from the nearest land, but in any case, greater than or equal to 12nm from the nearest land
- treated sewage effluent discharged through an approved sewage treatment plant certified by the administration to meet the operational requirements referred to in Regulation 9.1.1 of MARPOL Annex IV
- sewage which has been comminuted and disinfected using an approved treatment system in accordance with MARPOL Annex IV can be discharged as long as the discharge location is no less than 3nm from nearest land. Note the boundary of the OA is equal to or greater than 3nm from the nearest land
- sewage which is not comminuted or disinfected is permitted as long as the discharge location is no less than 12nm from nearest land.

6.3.2 Impacts of sewage and food waste discharges

Impacts of the discharge of sewage or food waste considered are:

- change in water quality (temporary and localised increase in nutrients and biological oxygen demand)
- change in fauna behaviour (changing predator/prey dynamics from increased scavenging behaviours).

6.3.2.1 Change in water quality.

The PBW and several protected seabirds such as shearwaters, albatrosses and petrels have foraging habitat overlapping the OA.

Sewage will be managed in accordance with Marine Order 96 (Marine pollution prevention — sewage) 2018 as appropriate to vessel class.

Nutrients in sewage, such as phosphorus and nitrogen, may contribute to eutrophication of receiving waters (although usually only calm, inland waters) causing algal blooms, which can degrade aquatic habitats by depleting oxygen levels, reducing light levels and producing certain toxins, some of which are harmful to marine life and humans. Given the tidal movements and currents in deep open waters, eutrophication of receiving waters will not occur.

Discharges will disperse and dilute rapidly, with concentrations of wastes significantly dropping with distance from the discharge point.

The receptors with the greatest potential to be impacted are those in the immediate vicinity of the discharge. Given that sewage discharges from vessels and facilities are at or near the surface, and are buoyant discharges, the receptors with the potential to be impacted are also those within or on surface waters, for example, plankton, fish, and other marine fauna.

Plankton forms the basis of all marine ecosystems, and plankton communities have a naturally patchy distribution in both space and time (ITOPF, 2011). They are known to have naturally high mortality rates (primarily through predation), however in favourable conditions (e.g. supply of nutrients), plankton populations can rapidly increase. Once the favourable conditions cease, plankton populations will collapse and/or return to previous conditions. Plankton populations have evolved to respond to these environmental perturbations by copious production within short generation times (ITOPF, 2011). However, any potential change in phytoplankton or zooplankton abundance and composition is expected to be localised, typically returning to background conditions within tens to a few hundred metres of the discharge location (Abdellatif, Ali, Khalil, & Nyonje, 1993) (Axelrad, et al., 1981) (Parnell, 2003).

As a result of the small quantities and rapid dilution and dispersion of the sewage and food waste from the vessels, impacts are not anticipated to environmental receptors along the food chain, namely, fish, reptiles, birds, and cetaceans beyond the immediate vicinity of the discharge in deep open waters.

Given the requirement under MARPOL for vessels to discharge food waste while enroute, or in transit, cumulative impacts to receptors as a result of the discharge of food waste is very unlikely, given Campaign #1 vessels and any other vessels present in the OA will not be transiting in close proximity to each other. During transfer or removal activities where there are multiple vessels in the area, planned discharges of food waste will not occur as the vessels will be stationary.

Also given that sewage is required to be discharged per MARPOL requirements, Section 6.3.1, cumulative impacts to receptors as a result of the discharge of sewage is very unlikely.

It is possible that protected marine fauna such as cetaceans and seals transiting the OA may come into contact with sewage and food waste discharges. However, given the localised extent of impacts from vessel discharges within the OA, impacts to marine fauna are not expected.

6.3.2.2 Change in fauna behaviour

The overboard discharge of macerated food wastes has the result of creating a localised and temporary food source for scavenging marine fauna or seabirds, whose numbers may temporarily increase as a result. This in turn can provide an increase in food source for predatory species. The rapid consumption of this food waste by scavenging fauna, and physical and microbial breakdown, ensures that the impacts of putrescible waste discharges are insignificant and temporary.

6.3.2.3 Cumulative impacts

The discharge of sewage and food waste per MARPOL requirements means that cumulative impacts to receptors as a result of the discharge of sewage or food waste is very unlikely.

6.3.3 Demonstration of As Low As Reasonably Practicable

Table 6-13 Decision Context and justification

Decision Context
Discharge of sewage, greywater, and food waste offshore (from vessels and other facilities) is a commonly practised activity. The potential impacts are well regulated via various treaties and legislation, both nationally and internationally, which specify industry best practice control measures. These are well understood and implemented by the industry. No objections or claims were raised by relevant persons with regard to the discharge of sewage and food waste. The environmental consequence for the impacts resulting from the discharge of sewage and food waste from vessels have been assessed as **Consequence Level IV**.

Decision Context
Hence, Esso believes **Decision Context A** should apply.

Table 6-14 Good practice controls

Good practice	Adopted	Control	Rationale
MARPOL Annex IV Regulations for the Prevention of Pollution by Sewage from Ships. MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships.	Adopted – IMP3-CM1	Compliance with MARPOL Annex IV and MARPOL Annex V and associated Marine Order 96 (Marine pollution prevention — sewage) 2018 and Marine Order 95 (Marine pollution prevention — garbage) 2018 (as appropriate to vessel class).	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the International Maritime Organization (IMO) across many critical areas including the International Convention for the Safety of Life at Sea, (SOLAS), the 1988 Protocol to the International Convention on Load Lines and MARPOL. A vessel built in accordance with the applicable Rules of an IACS member society may be assigned a class designation relevant to the IMO Rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex IV Regulations for the Prevention of Pollution by Sewage from Ships specifically requires vessels (as appropriate to class) to hold an International Sewage Pollution Prevention certificate which identifies the type of sewage management the vessel must comply with. MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships specifically requires that food waste is macerated or ground to particle size <25mm. Macerated food waste may be discharged no less than 3nm from shore and unmacerated food waste no less than 12nm (and not within the PSZ of fixed platforms) whilst enroute.

Table 6-15 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted

6.3.4 Demonstration of acceptability

Table 6-16 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated assessment of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV** impact thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment has concluded that environmental impacts will be short term and localised in nature. This is not considered to impact the health, diversity and productivity of the environment such that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The requirements of MARPOL Annexes IV and V have been adopted. The following legislative and other requirements are considered relevant as they apply to the implementation of MARPOL in Australia: • *Protection of the Sea (Prevention of Pollution from Ships) Act* 1983 (Cth) • *Navigation Act 2012* (Cth) – Chapter 4 (Prevention of Pollution) • Marine Order 96 (Marine pollution prevention — sewage) 2018

Factor	Demonstration criteria	Criteria met	Rationale
			• Marine Order 95 (Marine pollution prevention — garbage) 2018.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"*.
	Meets ExxonMobil Environmental Standards.	✓	The proposed controls meet the requirements of the ExxonMobil's Upstream Water Management Standards specifically *"to comply with regulatory requirements and legally binding arrangements related to waste management"* and *"meet specified discharge criteria"* including MARPOL requirements.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements, and • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/ addressed through the consultation process.	✓	No relevant person concerns have been raised concerning sewage and food waste discharges.

6.3.5 EPOs, control measures, EPSs and measurement criteria

Table 6-17 EPOs, control measures, EPSs and measurement criteria – Sewage and food waste

EPO	Control measure	EPS	Measurement criteria
IMP3-EPO1: Impacts as a result of sewage and food waste from vessels are limited to localised, temporary changes in water and habitat quality.	IMP3-CM1: Compliance with MARPOL Annex IV and MARPOL Annex V and associated Marine Order 96 (Marine pollution prevention — sewage) and Marine Order 95 (Marine pollution prevention —	IMP3-EPS1.1: Campaign #1 vessels are compliant with Marine Order 96 (Marine pollution prevention — sewage) requirements as appropriate to vessel class.	IMP3-MC1.1.1: Records demonstrate vessel maintains an International Sewage Pollution Prevention certificate. IMP3-MC1.1.2: Preventative

	garbage) (as appropriate to vessel class).		maintenance system records demonstrate sewage treatment plant is maintained as required.
		IMP3-EPS1.2: Campaign #1 vessels are compliant with Marine Order 95 (Marine pollution prevention — garbage) requirements as appropriate to vessel class.	IMP3-MC1.2.1: Vessel maintains a Garbage Record Book. IMP3-MC1.2.2: Garbage Management Plan current and implemented. IMP3-MC1.2.3: Preventative maintenance system records demonstrate macerator/s are maintained as required.

6.3.6 Residual consequence assessment

With the above controls in place, the consequence of the planned discharge of sewage and food waste has been assessed as:

- **Consequence Level IV**.

6.4 Planned discharge – Cooling waters and reverse osmosis system

6.4.1 Sources of cooling water and reverse osmosis discharges

The following activities have been identified as resulting in surface discharges:

- seawater cooling system
- reverse osmosis system.

These fluids are typical discharges associated with vessels – cooling water is discharged to the sea from the vessel and the reverse osmosis system discharges brine as the byproduct of the production of potable water.

A discharge of cooling water or potable water generation waste is continuous. Given the nature of these discharges, marine fauna most susceptible to toxic impacts are mainly limited to less mobile fish embryo, larvae, and other plankton. There is potential for short-term impacts to species that rely on plankton as a food source. Any impact to prey species would be temporary as the duration of exposure would be very limited, and fish larvae and other plankton are expected to rapidly recover as they are known to have high levels of natural mortality and a rapid replacement rate (UNEP, 1984).

Discharges of cooling water and brine will occur in any location within the OA.

6.4.2 Impacts of cooling water and reverse osmosis discharges

Impacts of the planned discharge of brines and cooling waters are:

- change in water quality (increased salinity in the water column)
- change in the local water temperature and potential biofouling chemicals.

6.4.2.1 Change in water quality

6.4.2.1.1 INCREASED SALINITY

Reverse osmosis systems create brine which is discharged to the sea as part of the process.

Brine water will descend through the water from the discharge point where it will be rapidly mixed with receiving waters and dispersed by ocean currents. As such, any potential impacts are expected to be limited to the source of the discharge where concentrations are highest. This is confirmed by studies that indicate effects from increased salinity on planktonic communities in areas of high mixing and dispersion are generally limited to the point of discharge only (Abdul Azis, et al., 2003).

The receptors with the potential to be exposed to an increase in salinity include pelagic fish species and plankton found in surface waters within the OA. Changes in salinity can affect the ecophysiology of marine organisms. Most marine species are able to tolerate short-term fluctuations in salinity in the order of 20 to 30% (Walker & McComb, 1990). However, larval stages, which are crucial transition periods for marine species, are known to be more susceptible to impacts of increased salinity (Neuparth, Costa, & Costa, 2002). Mobile pelagic species may be subjected to slightly elevated salinity levels (approximately 10-15% higher than seawater) for a very short period which they are expected to be able to tolerate.

It is anticipated that ecological receptors that have the potential to be exposed are those that use the surface waters for transit or foraging such as whales, turtles, fish, and plankton. The PBW has a foraging habitat BIA overlapping the OA and the SRW migration BIA also overlaps the OA, but they would be required to be very close to the vessel which is considered unlikely. Vessel Masters will implement cetacean interaction management actions consistent with the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a) and Part 8 Division 8.1 of the EPBC Regulations which, amongst other things, require that vessels not knowingly get closer than 100m to a whale.

6.4.2.1.2 INCREASED WATER TEMPERATURE

The water discharged will be at a greater temperature to the surrounding seawater. Like the brine discharge the temperature will rapidly decrease due to the high mixing and dispersion until equilibrium with the ocean temperature is achieved.

It is anticipated that ecological receptors that have the potential to be exposed are those that use the surface waters for transit or foraging such as whales, turtles, fish and plankton. The PBW has a foraging habitat BIA overlapping the OA and the SRW migration BIA also overlaps the OA, but they would be required to be very close to the vessel to be impacted by vessel discharges which is considered unlikely.

6.4.2.1.3 WATER QUALITY

Some heat exchange systems will have biofouling chemicals such as antifouling paints or have a system that doses with biofouling and anticorrosion chemicals. These will be in accordance with class requirements.

These are designed to provide protection for the system with the vessel and not to impact the environment.

6.4.2.2 Cumulative impacts

Vessels requiring cooling water and those that have a reverse osmosis system that discharges brine may discharge water continuously. Cumulative impacts to receptors as a result of the discharge of cooling water or brine are very unlikely, as Campaign #1 vessels and any other vessels present in the OA will not be transiting in close proximity to each other. Although there will be multiple vessels in the transfer area during transfer activities that may discharge cooling water or brine, once the vessels move away from an area, the high energy marine environment is expected to result in the change in water quality quickly dissipating, and ambient water quality will be quickly restored. Hence cumulative impacts to receptors during transfer activities are not anticipated.

6.4.3 Demonstration of As Low As Reasonably Practicable

Table 6-18 Decision Context and justification

Decision Context
The surface discharge of fluids from cooling and reverse osmosis systems is common both nationally and internationally. The release of brine and cooling waters are standard discharges associated with vessels and are not considered unusual in Commonwealth waters. The environmental consequence for the impacts resulting from the discharge of cooling and reverse osmosis systems from vessels have been assessed as **Consequence Level IV**.

Decision Context
No objections or claims were raised by relevant persons about the planned operational discharges from vessels. Hence, Esso believes **Decision Context A** should apply.

6.4.5 EPOs, control measures, EPSs and measurement criteria

Not applicable.

6.4.6 Residual consequence assessment

- **Consequence Level IV**.

6.5 Planned discharge – Bilge water/deck drainage (vessel discharges)

6.5.1 Sources of treated bilge water and deck drainage

Bilge water contains fluids from machinery spaces, internal drainage systems, sludge tanks and various other sources and is directed to a bilge water tank on a vessel. Bilge water shall be diverted to a holding tank either for onshore disposal at an appropriately licenced facility, or for discharge in accordance with MARPOL Annex 1 requirements. Discharge of machinery space bilges is permitted anywhere in the OA when the following conditions are met (Australian Maritime Safety Authority, 2025):

- the vessel is enroute and not stationary
- the oil content of the discharge is less than 15ppm
- the oil discharge monitoring and control system and oil filtering equipment is operating.

For vessels less than 400 gross tons, oil and oily mixtures must be retained onboard unless the vessel has in operation equipment of an approved design that ensures oil content is less than 15ppm, and the discharge is made enroute.

Deck drainage comprising seawater from waves/spray, rainwater and deck wash water, will be intermittent depending on weather conditions and frequency of deck washing and may contain minor quantities of substances such as oil and grease which may be present on the deck.

6.5.2 Impacts of treated bilge water and deck drainage discharge

Impacts of the discharge of treated bilge water and deck drainage considered are:

- change in water quality.

6.5.2.1 Change in water quality

A discharge of treated bilge or deck drainage is non-continuous and infrequent. Given the nature of bilge or deck washing discharges, marine fauna most susceptible to toxic impacts are mainly limited to less mobile fish embryo, larvae, and other plankton. There is potential for short term impacts to species that rely on plankton as a food source; however, any effects are expected to be temporary, given the limited exposure duration and the high natural mortality and rapid replacement rates of plankton. These discharges occur at or near the water surface and are expected to dilute and disperse quickly due to wave action and surface currents and volatile components will rapidly evaporate upon air exposure. Consequently, the change in water quality from these infrequent discharges is limited to a localised area and returns to ambient following completion of the discharge; therefore, any impacts are considered inconsequential.

6.5.2.2 Cumulative impacts

Given the requirement under MARPOL for vessels to discharge bilge while enroute, or in transit, cumulative impacts to receptors as a result of the discharge bilge or deck drainage is very unlikely, given Campaign #1 vessels and any other vessels present in the OA will not be transiting in close proximity to each other. During transfer or removal activities where there are multiple vessels in the area, planned discharges will not occur as the vessels will be stationary.

6.5.3 Demonstration of As Low As Reasonably Practicable

Table 6-22 Decision Context and justification

Decision Context
Discharge of treated bilge and deck drainage offshore (from vessels)) is a commonly practised activity. The potential impacts are well regulated via various treaties and legislation, both nationally and internationally, which specify industry best practice control measures. These are well understood and implemented by the industry. The environmental consequence for the impacts resulting from the discharge of bilge and deck drainage from vessels have been assessed as **Consequence Level IV**.

Decision Context
No objections or claims were raised by relevant persons with regard to the discharge of treated bilge water and deck drainage. Hence, Esso believes **Decision Context A** should apply.

Table 6-23 Good practice controls

Good practice	Adopted	Control	Rationale
MARPOL Annex I Regulations for the Prevention of Pollution by Oil. MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships.	Adopted – IMP5-CM1	Compliance with MARPOL Annex I and associated Marine Order 91 (Marine Pollution Prevention – Oil) as applicable to vessel class. MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships and associated Marine Order 95 (Marine Pollution Prevention – Garbage) as applicable to vessel class.	The vast majority of commercial ships are built to and surveyed for compliance with the standards laid down by classification societies. The role of vessel classification and classification societies has been recognised by the IMO across many critical areas including the SOLAS, the 1988 Protocol to the International Convention on Load Lines and MARPOL. A vessel built in accordance with the applicable Rules of an IACS member society may be assigned a class designation relevant to the IMO Rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require vessels (as appropriate to class) hold an International Oil Pollution Prevention Certificate, are equipped with an approved oil discharge monitoring and control system which ensures that the oil-in-water content of treated bilge water is <15ppm and maintain an Oil Record Book. MARPOL Annex V specifically require vessels (as appropriate to class) to utilise deck cleaning products which are not a "*harmful substance*" in accordance with criteria in Appendix to MARPOL Annex III nor contain a component that is carcinogenic, mutagenic or reprotoxic.

	Meets ExxonMobil Environmental Standards.	✓	The proposed controls meet the requirements of the Upstream Water Management Standard specifically *"to meet regulatory requirements and legally binding agreements".*
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 7: Managing Changes objective to evaluate change against an established set of criteria and establish endorsement/approval levels • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	No relevant person concerns have been raised concerning treated bilge water and deck drainage discharges.

6.5.5 EPOs, EPSs and measurement criteria

Table 6-26 EPOs, EPSs and measurement criteria – Discharge of bilge water/deck drainage from vessels

EPO	Control measure	EPS	Measurement criteria
IMP5-EPO1: Impacts as a result of the discharge of bilge water or deck drainage are limited to localised, temporary changes in water and habitat quality.	IMP5-CM1: Compliance with MARPOL Annex I and MARPOL Annex V and associated Marine Orders.	IMP5-EPS1.1: Campaign #1 vessels are compliant with Marine Order 91 (Marine Pollution Prevention – Oil) requirements as applicable to vessel class.	IMP5-MC1.1.1: Vessel maintains an International Oil Pollution Prevention Certificate. IMP5-MC1.1.2: Vessel is equipped with an approved oil discharge monitoring and control system which ensures that the oil-in-water content of treated bilge water is <15ppm. IMP5-MC1.1.3: Vessel maintains an Oil Record Book.
		IMP5-EPS1.2: Campaign #1 vessels are compliant with Marine Order 95 (Marine pollution prevention — garbage) requirements as appropriate to vessel class.	IMP5-MC1.2.1: Vessel maintains a garbage record book. IMP5-MC1.2.2: Garbage management plan current and implemented.

6.5.6 Residual consequence assessment

With the above controls in place, the residual potential consequence has been determined as:

- **Consequence Level IV**.

6.6 Planned discharge – Grout

6.6.1 Sources of grout discharge

The lifting of KFA and KFB requires Allseas to complete the installation of grouted lifting points by injecting grout into the lifting point assembly. The grouted lifting point assembly will have been installed as part of facilities preparation activities under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) as described in Section 2.12.3. The grouting operations will result in the planned discharges of small amounts of grout to the marine environment. The estimated volumes to be discharged to the environment is <1t of mixed grout per lifting point. There are a total of 12 lifting points, hence it is estimated that a maximum of 12t of grout could be discharged to sea across KFA and KFB.

Within the OA, the planned discharge of grout will only occur at the KFA and KFB facility locations.

6.6.2 Minamata Convention on mercury

The Minamata Convention on mercury is an international treaty that seeks to protect human health and the environment from emissions and releases of mercury and mercury compounds caused by humans. Australia ratified the Convention on 7 December 2021. Countries that have ratified the Convention are bound to put controls in place to manage the discharges, emissions and disposal or mercury and mercury compounds. In Australia, the Convention is regulated via the *Recycling and Waste Reduction Act 2020* (Cth). In particular, the Recycling and Waste Reduction (Mandatory Product Stewardship – Mercury-added Products) Rules 2021 made under the Act give effect to Australia's obligations under Article 4(5) of the Minamata Convention.

Mercury is a toxic heavy metal that can harm the immune system, brain, heart, kidney and lungs of humans and animals, and cause serious harm to ecosystems through bioaccumulation. The effects of mercury exposure can occur at very low concentrations.

Trace amounts of mercury can be present in some cement/grout products originating from the raw materials used in the manufacturing process. As part of the grout selection process, the contractor will ensure that the concentration in grout to be used will be at or below a mercury concentration of <1mg/kg (1ppm) as outlined in the American Petroleum Institute (API) standards.

6.6.3 Impacts of grout discharges

Impacts of the planned discharge of grout on marine fauna considered are:

- change in water quality (increased turbidity of the water column and potential toxicity)
- change in habitat.

6.6.3.1 Change in water quality.

6.6.3.1.1 INCREASED TURBIDITY IN THE WATER COLUMN

Grout discharges will disperse under action of waves and currents and eventually settle out of the water column; the initial discharge will generate a downwards plume, increasing the initial localised turbidity of receiving waters.

Modelling of the release of 18m^3 of cement/grout wash water (De Campos, Paiva, Rodrigues, Ferreira, & Junior, 2017) indicate an ultimate average deposition of 0.05mg/m^2 of material on the seabed; with particulate matter deposited within the three-day simulation period. Given the low concentration of the deposition of the material, it is therefore expected that the in-water suspended solids (i.e. turbidity) created by the discharge is not likely to be high for an extended period of time, or over a wide area.

Modelling of larger cement/grout discharges was undertaken by BP (BP, 2013), which is useful as a conservative comparison of the potential impacts from this activity. This modelling was undertaken for significantly larger discharges at surface, i.e. 480bbl/hour (equivalent to approximately 76m^3/hour) and intermittent surface discharge of cement (following flushing of lines and equipment) in shallower water depths. The BP modelling results provide a high level of conservatism and as such is considered appropriate to apply for this program. The modelling indicates that two hours after the start of discharge, plume concentrations are between 5-50mg/L with the horizontal and vertical extents of the plume approximately 150m and 10m respectively (BP, 2013). Four hours after the start of the discharge, the modelling indicates that the plume will have completely dispersed to concentrations of less than 5mg/L (BP, 2013).

The PBW has foraging habitat overlapping the OAs and the SRW migration BIA also overlaps the OAs. Research data detailing potential impacts from suspended solids to megafauna is scarce, however such megafauna is highly mobile, transitory, and able to avoid the plumes. The area of the turbidity plumes is regarded as a very small percentage of the foraging grounds of protected seabirds such as shearwaters, albatrosses, and petrels.

The environmental receptors with the potential for exposure and considered to be most sensitive to an increase in turbidity include pelagic fish species and plankton found in the area around the discharge locations.

Suspended sediments greater than 500mg/L are likely to produce a measurable impact upon larvae of most fish species (Jenkins & McKinnon, 2006). It is also indicated that levels of 100mg/L may affect the larvae of several marine invertebrate species and that fish eggs and larvae are more vulnerable to suspended sediments than older life stages.

Neither modelling (De Campos, Paiva, Rodrigues, Ferreira, & Junior, 2017) (BP, 2013) suggests that suspended solids concentrations from a discharge of the cement/grout will be at or near levels required to cause an effect on fish or invertebrate larvae.

6.6.3.1.2 POTENTIAL TOXICITY

The potential for toxicity is associated with chemicals that are added to the dry grout mix; grout itself is classed as Poses Little or No Risk. Toxicity associated with the discharge of grout is limited to the surface discharge of grout slurry or equipment washings (not surface discharge of dry materials). The environmental receptors with the potential to be exposed and most at risk from an increase in toxicity include pelagic fish species and plankton. Impacts to ambient water quality from planned discharge of cement will be highly localised and temporary, with

chemical toxicity impacts quickly ceasing following discharge. Any impacts will be inconsequential or have no adverse effect, and impacts to pelagic organisms (such as plankton, fish, marine fauna) are not expected.

Any grout additives will be assessed and approved for discharge in accordance with Esso's *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013). Table 6-27 provides examples of indicative additives that are used in industry. At the time of writing this EP, the engineering assessment is required to determine any additive use needs. The process uses the Offshore Chemical Notification Scheme (OCNS) ranking in conjunction with toxicity, biodegradation, and bioaccumulation data to determine potential impacts to the environment and acceptability of planned discharges. The process is described as part of the Implementation Strategy outlined in Section 8.

Table 6-27 Indicative grout additives

Function	OCNS ranking[1]	
	CHARM	Non-CHARM
Antifoaming agent	Silver	-
Antifoaming agent/foam breaker	Gold/substitution warning	-
Cement	-	E

Multi-temperature cement retarder	Gold/substitution warning	-
Retarder	-	E
Spacer additive	Gold/substitution warning	-
Spacer viscosifier	Gold/substitution warning	-

[1] The OCNS uses the Harmonised Mandatory Control Scheme developed through the Convention for the Protection of the Marine Environment of the North-East Atlantic (OSPAR Convention). This ranks chemical products according to Hazard Quotient, calculated using the Chemical Hazard and Risk Management (CHARM) model.

6.6.3.2 Change in habitat

Discharges of grout have the potential to smother or alter the benthic substrate, resulting in a change in sediment quality. As shown in sediment displacement modelling (refer to Section 6.1.3.1), the depth of accumulated sediments will be greatest close to the facility location where the heavier particles are deposited and will decrease with an increase in distance from the source point. The infaunal and epifaunal assemblages associated with soft sediment habitats in the vicinity of the facilities have been shown to be comparable and do not offer unique or ecologically important habitat in comparison to the broader soft sediment environment (Stantec Australia, 2024b). The area of soft sediment habitat that is potentially impacted is small compared with the amount of similar habitat available across the region. As a result, any impacts to sediment habitat as a result of the planned discharge of grout at the KFA and KFB locations are expected to be inconsequential or have no adverse effect.

6.6.3.3 Cumulative impacts

The planned discharge of grout to the marine environment will only occur at the KFA and KFB removal locations. At these locations, additional activities which may result in a change in water quality or change in habitat include:

- the planned release of titanium iron oxide mineral sand and steel shot ballast, which is present within some of the skirt piles and will be release upon cutting and lifting the jackets (refer to Section 6.11);
- the planned release of contents of the ODSPs and CDSPs during lifting of the jackets, which may contain residual levels of hydrocarbons (refer to Section 2.12.1)
- the planned release of residual fluids from pipelines following cutting and prior to capping, which may contain residual levels of hydrocarbons (refer to Section 2.12.5)
- sediment displacement as a result of clearing of seabed sediments to allow access to cutting of pipelines and/or umbilicals (refer to Section 2.10).

Given grout discharges will occur during removal preparation activities, approximately 12 months prior to the other activities listed above and impacts to water quality and sediment quality have been assessed as short term and highly localised, cumulative impacts to marine receptors within the area are not expected. Cumulative impacts as a result of planned discharges during the cutting and lifting of the jackets have been assessed in Section 6.9.2.3 and Section 6.11.3.4.

6.6.4 Demonstration of As Low As Reasonably Practicable

Table 6-28 Decision Context and justification

Decision Context
The impacts of inert discharges such as grout are well known. The practice of discharging grout to the marine environment is a well understood activity both nationally and internationally and good practice is well defined. Industry good practice control measures are considered sufficient to reduce the impacts and risks associated with this hazard to ALARP. The environmental consequence for the impacts resulting from the discharge of grout have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regard to the discharge of grout. Hence, Esso believes **Decision Context A** should apply.

Table 6-29 Good practice controls

Good practice	Adopted	Control	Rationale
Discharge of least environmentally hazardous chemical	Adopted – IMP6-CM1 and IMP6-CM2	All grout planned for discharge will be evaluated as acceptable in accordance with the *Environmental Chemical Discharge*	This risk control practice requires that new chemicals must be approved prior to discharge. This practice assesses chemicals that are planned to be discharged to the environment to ensure the lowest toxicity, most biodegradable and least accumulative chemicals are selected which meet the technical and safety requirements of the application.

Good practice	Adopted	Control	Rationale
		Assessment Process (AUGO-EV-PCE-013).	
		Grout will be selected to ensure a mercury concentration of <1mg/kg (1ppm) as outlined in the API standards.	Control is required to ensure consistency with the Minamata Convention requirements to protect human health and the environment from human-caused emissions and releases of mercury and mercury compounds.
No overboard discharge of bulk unused grout whether mixed or unmixed.	Adopted – IMP6-CM3	Grouting procedures will be in place which will include the requirement of no discharge of bulk grout to the environment (mixed or unmixed).	The grout jobs are conducted in accordance with the procedures and processes. It is a general industry standard that unused grout is not discharged offshore; this has also been applied to this program. There will be no planned discharge of bulk unused grout to the marine environment. Bulk unused grout, whether mixed or unmixed will be returned to shore for reuse or appropriate disposal.

Table 6-30 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Dust recovery system	Collects dust from vent lines of bulk storage silos/tanks and reduces the amount of cement emitted into the environment during pneumatic transport.	If space is available and fitting the equipment is feasible (e.g. cyclones mounted on a secondary receiving vessel), the cost of retrofitting this equipment, combined with the additional time required during transfer to unload the collected product and transfer it back to the primary storage vessel, and the potential for costly delays due to blockage of the vent lines is considered to outweigh the benefit gained.	Not adopted
Collection of excess grout applied to lifting points and grout slurry as a result of cleaning of equipment.	No discharge of excess grout slurry to the marine environment.	There is no technically feasible and safe method to collect the minor overfill of grout which will occur as a result of the lifting point assembly. The overfill is required to ensure the lifting points meet the design integrity requirements to ensure the safe lifting of the topsides. Flushing and cleaning of equipment and piping is essential to ensure the	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		grout does not cure within the grouting system and become unusable. Discharge of excess slurry (overfill or from flushing/cleaning of equipment and piping) to the marine environment will be minor and volumes limited to ALARP.	
Transfer of excess grout to other Esso operations.	No planned discharge to the marine environment.	Given the small quantities and activity specific technical specifications of the grout to be used, transfer and use of excess mixed grout to other Esso operations is not considered practicable.	Not adopted

6.6.5 Demonstration of acceptability

Table 6-31 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV** thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment has concluded that environmental impacts will be short term and localised in nature. This is not considered to impact the health, diversity and productivity of the environment such that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological	✓	Not inconsistent.

Factor	Demonstration criteria	Criteria met	Rationale
	integrity should be a fundamental consideration in decision making.		The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	Minamata Convention considered part of grout selection.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to the discharge of grout, but the controls proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	No relevant person concerns have been raised concerning offshore discharges.

6.6.6 EPOs, control measures, EPSs and measurement criteria

Table 6-32 EPOs, control measures, EPSs and measurement criteria – Discharge of grout

EPO	Control measure	EPS	Measurement criteria
IMP6-EPO1: Impacts from grout discharges are limited to	IMP6-CM1: All grout planned for discharge will be evaluated as acceptable.	IMP6-EPS1.1: All grout planned for discharge will be evaluated as acceptable in accordance	IMP6-MC1.1.1: Documentation in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013)

EPO	Control measure	EPS	Measurement criteria
localised, temporary changes in water and habitat quality.		with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	(refer to Section 8.11.2.1) confirms proposed grout and additives were evaluated as acceptable prior to discharge.
	IMP6-CM2: Grout will be selected to ensure a mercury concentration of <1mg/kg (1ppm) as outlined in the API standards.	IMP6-EPS2.1: Grout will not be discharged unless it has been confirmed as containing a mercury concentration of <1mg/kg.	IMP6-MC2.1.1: Documentation in accordance with the Environmental Chemical Discharge Assessment Process (AUGO-EV-PCE-013) (refer to Section 8.11.2.1) confirms proposed grout and additives were evaluated as acceptable prior to discharge.
	IMP6-CM3: Grouting procedures will be in place and include the requirement of no discharge of bulk grout to the environment (mixed or unmixed).	IMP6-EPS3.1: Contractor will develop and implement a grouting procedure for grouting operations. The procedure will include the requirement not to discharge bulk grout to the environment (mixed or unmixed).	IMP6-MC3.1.1: Grouting procedure developed. IMP6-MC3.1.2: Training records confirm procedure requirements and discharge limitations have been communicated to crew/subcontractors. IMP6-MC3.1.3: Grout pumping logs developed to track waste and unused grout returned onshore for appropriate management.

6.6.7 Residual consequence assessment

With the above controls in place, the residual potential consequence has been determined as:

- **Consequence Level IV**.

6.7 Planned discharges – Umbilicals

6.7.1 Sources of umbilical fluids

Flushing of umbilicals during facility preparation activities under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) aims to displace and remove any bulk quantities of fluids inside the umbilicals where practicable. After this process is completed, there will be fluids remaining in these systems that may include inhibited water (including residues), hydraulic fluid, corrosion inhibitor and pour point depressant, which may be released during subsea cutting and lifting of the umbilical section as part of the Campaign #1 removal operations covered under this EP. Inhibited water maintains the integrity of the umbilical until removal activities occur. Inhibited water is bore, sea or fresh water conditioned with a hydrotest corrosion inhibitor that is Chemical Hazard Assessment and Risk Management (CHARM) rated Gold or Silver through the Offshore Chemical Notification Scheme or assessed as acceptable for discharge under the Esso chemical discharge assessment process (*AUGO-EV-PCE-013*). Potential release of pour point depressant and corrosion inhibitor is applicable only to the umbilical at MKA; all remaining umbilicals to be removed as part of the scope of this EP would only have a potential release of hydraulic fluid. During flushing of the umbilical at MKA (as part of the preparation for decommissioning activities covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012)), it was found that the pour point depressant and the corrosion inhibitor were gummed up inside the line and have caused blockages. As a result, it is not expected that remnants of these two fluids will be discharged during the lifting of the umbilical section that will be removed. On the other hand, hydraulic fluid discharge is considered possible at all umbilicals within the scope of the Decommissioning – Campaign 1 EP. The amount of hydraulic fluid potentially remaining in each umbilical will vary based on the overall length of the umbilical and extent to which flushing was able to be achieved.

The location of sections of umbilicals to be removed as part of Campaign #1 activities, and indicative volumes of residual fluids (hydraulic fluid) that may be released from those sections during cutting and lifting operations is presented below:

- MKA - The estimated volume of total residual fluids that could be released from umbilicals at MKA during lifting operations is in the range of approximately 215L. This estimate accounts for the densities of fluids that will remain in the umbilical such as the pour point depressant and the corrosion inhibitor and the limited area of the cut end. The bulk of the fluid within this umbilical is hydraulic fluid. The options to flush the hydraulic fluid (Aqualink 325-F v2) from the umbilicals at MKA was reviewed and is not considered reasonably practicable due to technical complexities. This hydraulic fluid was previously assessed as acceptable for use and discharge into the marine environment as part of the production operations in the Bass Strait (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012)). This assessment followed the same *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) that is referred to in Section 8.11.2.1) of this EP. Corrosion inhibitor, pour point depressant and inhibited seawater is also present within this umbilical.

- BMA - It is estimated that a total volume of 100L of hydraulic fluid (Oceanic HW443R) could be released from the BMA umbilicals during cutting and lifting operations. This hydraulic fluid was previously assessed as acceptable for use and discharge into the marine environment as part of the production operations in the Bass Strait (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012)). This assessment followed the same *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) that is referred to in Section 8.11.2.1) of this EP.
- KFA, KFB, WKF - It is estimated that a total volume of 40L of hydraulic fluid (Oceanic HW540) could be released from each umbilical at these locations. This hydraulic fluid has been assessed as acceptable for use and discharge into the marine environment as per the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) that is referred to in Section 8.11.2.1) of this EP. During facility preparation activities, it may be possible that a percentage of the remaining residual fluids contained within the umbilicals could drain into the service caisson. As a result, the pathway for release of residual fluids from umbilicals at the time of cutting and lifting operations may also include these service caissons. However, total volumes of residual fluids from umbilicals, including the potential release from service caissons, that is expected at each facility remains unchanged and as described in this Section of the EP.
- CBA2 – the residual fluid in this umbilical is limited to inhibited seawater, with no hydraulic fluid expected to be present within this line. The potential release of inhibited seawater from the CBA2 umbilical is considered to have a negligible impact on the marine environment and is not discussed further.

6.7.2 Impacts of umbilical fluids discharge

6.7.2.1 Change in water quality and injury/mortality of fauna

The release of fluids from umbilicals will occur only at five facilities, and it will be a one-off event at each facility during cutting and lifting operations. Residual hydraulic fluid that is present in the umbilicals and that may be released is Aqualink 325-F for MKA, Oceanic HW443R for BMA, and Oceanic HW540 for KFA, KFB and WKF. These products have been assessed using the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) (refer to Section 8.11.2.1) and determined to be acceptable for use and discharge to the marine environment.

Severing the connection between the umbilical and the platforms is required to enable lifting operations of the facility and therefore the cutting operation cannot be eliminated. As a result, the following has been considered to minimise the potential impact from planned discharges from umbilicals:

- flushing umbilical cores where possible to minimise the concentration of chemicals (i.e. hydraulic fluid) present in the residual fluids that remain inside the umbilicals that will be discharged into the marine environment during cutting operations. These flushing activities are undertaken within the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012)
- any chemical used as part of the flushing of these systems must be gold or silver CHARM rated under the OCNS or must be assessed as acceptable for discharge under the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013). Refer to Section 8.11.2.1. The flushing of umbilicals is undertaken within the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012)

- the feasibility of plugging or capping the umbilicals to minimise discharge to the marine environment. Technical challenges must be considered, therefore this option is assessed on a case-by-case basis.

As a reference, the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) presents an analysis and assessment of produced formation water discharge from production operations. A description provided in the referenced EP indicates that during platform operations, wells bring water to the surface alongside the oil and gas, then the produced formation water is separated and treated to remove hydrocarbons prior to discharge. Separation of formation water from reservoir fluids is not completely effective and separated produced formation water often contains small amounts of naturally occurring substances (such as dispersed oil) and residual process chemicals. The *Bass Strait Environment Plan* (AUGO-EV-EMM-012) established a mixing zone of produced formation water for each platform, and extent of this zone ranged between 140-230m. It is noted that the release volume established for calculation of the mixing zones in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) ranged between 1000-12,000kL/day.

It is noted that the concentrations of potential chemicals expected to be present in the fluids that will be discharged from the umbilicals during cutting and lifting operations will be significantly less than that used in the assessment presented in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). This is due to the significant difference in the volumes expected to be discharged from the umbilicals, the type of residual fluid remaining inside the umbilicals, and the flushing program to be completed which provides for a reduced concentration of chemicals where possible. From this perspective, it is considered that potential impacts from planned releases from the umbilicals to the marine environment will not have a significant effect on water quality and marine fauna and have been assessed as:

- **Consequence Level IV**.

6.7.2.2 Cumulative impacts

Planned discharges from umbilicals will be limited to KFA, KFB, WKF, BMA and MKA platforms, and it will be a one-off discharge to the marine environment at each facility during the cutting and lifting of the umbilicals. At these locations, additional activities which may result in a change in water quality or that may directly or indirectly affect marine fauna are:

- for KFA and KFB, there is a planned release of titanium iron oxide mineral sand and steel shot ballast, which is present within some of the skirt piles and will be released upon cutting and lifting the jackets (refer to Section 2.12.7);
- for KFA and KFB, planned discharge of grout (refer to Section 2.12.3)
- the planned release of contents of the ODSPs and CDSPs during lifting of the jackets, which may contain residual levels of hydrocarbons (refer to Section 2.12.1)
- the planned release of residual fluids from pipelines following cutting and prior to capping/plugging, which may contain residual levels of hydrocarbons (refer to Section 2.12.5)
- for BMA, WKF and MKA, the planned release of contents of the JLSTs after holes are drilled in these tanks to allow for free-flow of the fluids that remain inside these structures after de-inventory and cleaning works are completed (refer to Section 2.12.1)
- sediment displacement as a result of clearing of seabed sediments to allow access to cutting of pipelines and/or umbilicals (refer to Section 2.10).

The discharge of grout from KFA and KFB will occur during removal preparation activities, approximately 12 months prior to the other activities listed above and impacts to water quality have been assessed as short term and highly localised. For the other sources of planned discharges, volumes are expected to be small and quickly dissipate in the area immediately adjacent to the platforms. In addition, the chemicals used during the flushing and cleaning works in preparation for decommissioning activities are rated CHARM gold or silver or OCNS D or E. As a result, potential impacts from any residual fluids that remain in the systems after the cleaning process is completed and that may be discharged during decommissioning activities are expected to be minor and have been assessed as:

- **Consequence Level IV**.

It is not expected that potential effects from the various sources of planned discharges as mentioned above would accumulate in a manner that would pose a risk to the marine environment. As a result, potential cumulative impacts from subsea planned discharges are assessed to have an inconsequential effect at an ecosystemic or population level.

6.7.3 Demonstration of As Low As Reasonably Practicable

Table 6-33 Decision Context and justification

Decision Context
Best practice has been applied for management of planned discharges from umbilicals through the application of detailed planning and facility preparation activities prior to commencement of the removal activities within the scope of this EP, including flushing of umbilicals to minimise as far as practicable the planned discharge of residual fluids. Based on the information available on characteristics of the fluids that will be released to the marine environment, the impacts of this discharge is well understood. However, decommissioning of umbilicals and management of discharges from this source is not a common or regular practice, which can result in some level of uncertainty remaining for this activity. The environmental consequence for the impacts resulting from the planned discharges from umbilicals have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regard to the discharge of residual fluids from umbilicals. Considering some uncertainty remains on the potential impact from planned discharges – umbilical fluids, Esso believes **Decision Context B** should apply.

Table 6-34 Good Practice Controls

Good practice	Adopted	Control	Rationale
Discharge of least environmentally hazardous chemical.	Adopted – IMP7-CM1	Residual chemicals to be discharged during cutting and lifting of umbilicals have been evaluated as acceptable in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	This control requires that chemicals must be approved prior to discharge. This practice assesses chemicals that are planned to be discharged to the environment to ensure the lowest toxicity, most biodegradable and least accumulative chemicals are selected which meet the technical and safety requirements of the application.

Table 6-35 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Plugging or capping of umbilicals post cutting.	Reduced release of residual chemicals to the marine environment.	Plugging or capping umbilicals may not always be technically feasible due to the configuration of the umbilical cross section. Most umbilicals have armour wire around the perimeter and then softer hoses internally to carry the fluids. When cut, umbilicals can expand or alter the round end shape making it infeasible to 'cap' all of the hose ends where the residual liquids may remain. Therefore capping needs to be assessed on a	Partially adopted – IMP7-CM2

Control Measure	Benefit	Cost/feasibility	Adopted
		case-by-case basis. Plugging or capping of umbilicals may be undertaken where this is determined as technically feasible during detailed execution planning. Flushing of umbilical cores is completed where possible under the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012), resulting in a reduction of the presence of fluids that remain in the umbilicals that may be discharged to the marine environment during cutting and lifting operations covered under the Campaign #1 EP. Volumes of hydraulic fluid that may be released during cutting and lifting operations are considered small, and potential impact to water quality or injury/mortality of marine fauna has been assessed as inconsequential.	
Undertake assessments on all previously approved chemicals that will be discharged during cutting and lifting activities.	Confirm potential impacts from the discharge of residual chemicals during cutting and lifting of the umbilicals are reduced to ALARP.	Residual chemicals to be discharged during cutting and lifting of umbilicals have previously been assessed as acceptable for use and discharge. The planned discharge is required to enable cutting and lifting of the umbilicals and re assessment of the residual chemicals that will be discharged will not reduce any impacts of these planned discharges any further.	Not adopted
Verification of completion of flushing of umbilical cores per facility preparation works scope under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).	Verification of volumes of remaining fluids based on ability to flush allows for validation of discharge estimates used to inform the impact assessment outlined in Section 6.7.2.	Verification of completion of facility preparation works and outcomes achieved is a practical measure that could be implemented. Verification of results from facility preparation activities allows for elimination or significant reduction of uncertainty and provides the opportunity to adapt in advance where/if required.	Adopted – IMP7-CM3

6.7.4 Demonstration of acceptability

Table 6-36 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic,	✓	Not inconsistent. Planning of discharges from umbilicals to the marine environment that may occur during Campaign #1 operations included strategy and decision making for flushing activities under the scope of the

Factor	Demonstration criteria	Criteria met	Rationale
	environmental, social and equitable considerations.		*Bass Strait Environment Plan* (AUGO-EV-EMM-012) and incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV**, thus are not considered as having the potential to result in serious or irreversible environmental damage. Additional engineering risk assessment was completed to align with the precautionary principle.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned discharges from umbilicals has concluded that environmental impacts will be short term and localised in nature. Hence any impacts as a result of these planned discharges to the marine environment will not result in negative effects to the health, diversity and productivity of the environment in such manner that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The impact assessment undertaken has shown that the potential impact associated with planned discharges from umbilicals is limited to a localised short term impact and has been assessed as **Consequence Level IV** (inconsequential or no adverse effects). Hence any impacts as a result of these planned discharges to the marine environment is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	No environmental legislation was deemed relevant to this particular impact. Chronic chemical pollution is a recognised threat to the species in the following conservation management plans and advice. These discharges are not chronic and will quickly dissipate. It is also noted that no conservation/management actions are

Factor	Demonstration criteria	Criteria met	Rationale
			specified in relation to chemical discharges. The outcome from assessment of potential impacts is not inconsistent with the conservation objectives of these plans. • CMPBW. • NRPSRW. • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a). • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Outcome from assessment of potential impacts is consistent with requirements of the Upstream Water Management (ExxonMobil, 2024c).
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements, and includes processes and procedures for managing environmental impacts, such as the: *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	Relevant persons asked questions regarding potential discharges from infrastructure during removal activities. These were discussed and answered during consultations for this EP.

6.7.5 EPOs, control measures, EPSs and measurement criteria

Table 6-37 EPOs, control measures, EPSs and measurement criteria – Planned discharge from umbilicals

EPO	Control measure	EPS	Measurement criteria
IMP7-EPO1: Impacts from planned discharges from umbilicals are limited to localised, temporary changes in water. No injury or mortality of marine fauna.	IMP7-CM1: Residual chemicals to be discharged during cutting and lifting of umbilicals are evaluated as acceptable for discharge.	IMP7-EPS1.1: Residual chemicals to be discharged during cutting and lifting of umbilicals have been evaluated as acceptable in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	IMP7-MC1.1.1: Documentation in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) (refer to Section 8.11.2.1) confirms residual chemicals have been evaluated as acceptable.
	IMP7-CM2: Capping or plugging of umbilicals following cutting – where this is deemed technically feasible.	IMP7-EPS2.1: Umbilicals are capped or plugged when it is determined technically feasible and practicable during the detailed execution planning and execution stage.	IMP7-MC2.1.1: Evidence of feasibility assessment. IMP7-MC2.1.2: Records confirming capping or plugging of umbilicals was completed following cutting, if technically feasible.
	IMP7-CM3: Completion of flushing of umbilical cores as per facility preparation works scope are verified.	IMP7-EPS3.1: Verification is undertaken that flushing of umbilicals that are part of facility preparations activities (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) have been completed prior to commencement of umbilical cutting activities where practicable.	IMP7-MC3.1.1: Digital Decommissioning Management Tool provides evidence that umbilical cores were flushed as part of facilities preparation works (where practicable).

6.7.6 Residual consequence assessment

Based on the assessment presented for potential discharge from umbilicals during cutting and lifting operations, environmental impact is expected to be localised and of a short term nature, with inconsequential effects on water quality or sensitive receptors at a population level. The residual potential consequence for this impact has been determined as:

- **Consequence Level IV**.

6.8 Planned discharges – Pipeline and risers fluids

6.8.1 Sources of pipeline and riser fluids

Before decommissioning activities commence, pipelines connecting to the platforms that will be removed per the scope of this EP will be flushed. Fluids generated during this process are directed onshore via the pipelines and received at the Longford Plant to be managed through Longford Plant's existing wastewater management practices. These flushing activities are performed under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).

After flushing of the pipelines and risers is completed, they will be filled with inhibited water. Inhibited water maintains the integrity of the pipeline until removal activities occur. Inhibited water is bore, sea or fresh water conditioned with a hydrotest corrosion inhibitor that is Chemical Hazard Assessment and Risk Management (CHARM) rated Gold or Silver through the Offshore Chemical Notification Scheme or assessed as acceptable for discharge under the Esso chemical discharge assessment process (*AUGO-EV-PCE-013*). It is expected that small

concentrations of oily residues remain in the pipelines and risers, after the flushing process, with an estimated OIW content of <30ppm.

Esso has established that any chemical used as part of the flushing of these systems must be gold or silver CHARM rated under the OCNS or must be assessed as acceptable for discharge under the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) as described in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). As a result, the product selected to be used as inhibitor to treat the water that will fill the pipelines after the flushing process is complete is CRW24340. This product has been ranked silver and has been assessed as acceptable for discharge to the marine environment.

It is also noted that sampling and analysis programmes of metal coupons from representative pipeline and pigging residues were undertaken to identify potential presence of NORM and mercury in flexibles. The potential presence of trace NORM and trace mercury in sections of pipelines that are cut and removed as part of the Campaign 1 project is deemed negligible, as these contaminants may be present mostly as surface contamination in the form of scale attached to the internal walls of the pipelines, and the pipeline sections to be removed are estimated to be short in length, up to 5m from the jackets. If there is presence of traces of these contaminants in scale, it is more likely that the scale will remain attached to the pipeline during removal and transport of the section decommissioned until it arrives to the planned destination at BBMT. As a result, potential release of NORM and mercury that could be originated from the short sections of pipeline that will be removed during the Decommissioning – Campaign#1 activities, is considered negligible and is not assessed further.

6.8.2 Impacts of pipeline and risers fluids discharge

6.8.2.1 Change in water quality and injury/mortality of marine fauna

For Campaign #1, discharge of fluids from pipelines and risers sections that will be removed will happen only once during the cutting and lifting operation for each structure.

For pipelines and risers, given they will be flushed, and fluids generated during this process will be sent to the Longford Plant for management, only minor residual concentrations of hydrocarbons are expected to remain mixed with the water treated with inhibitor until decommissioning activities under the scope of this EP commence. Some of the residual fluids within pipelines and risers will be released to the marine environment during cutting and removal operations. Esso has estimated that the cleanliness target for OIW content in residual fluids remaining inside pipelines and risers is in the order of 30ppm. However, where not all prerequisite assessment criteria can be met due to practicability or constraints during flushing activities to confirm the 30ppm target, or where a diminishing returns[6] assessment cannot be made, an alternate mode of cleanliness acceptance will consider the absolute hydrocarbon volume remaining in the pipeline. For this scenario (absolute hydrocarbon volume), at least three OIW measurements shall be made immediately prior to conclusion of flushing operations to base assessment in the form of a structured risk screen or risk assessment including the following:

- calculated oil volume left in the pipeline
- consequence of loss of this volume to sea at different times and events. This will consider:
    - oily water loss from topside riser cutting works for air gapping
    - oily water loss from subsea riser cutting works. (amount lost from riser and jacket removal, and amount lost from pipeline prior to capping/plugging)
    - oily water loss from potential pipeline end states
    - consideration of pipeline location relative to shore and potential area that may be affected
    - Any mitigative actions available to further reduce OIW level.

[6] For the purposes of this section, diminishing returns is defined as where OIW measurements taken during pipeline flushing show a slowing trend in reduction of measured OIW content. For pipelines this correlates to four consecutive readings within a one hour period being within a 10ppm band as analysed by portable field instruments, or onshore laboratory where direct field measurement is not possible.

In addition, the inhibitor to be used to treat the water that will fill the pipelines and that could be released during cutting and lifting operations will be a product that has been assessed as acceptable for discharge to the marine environment.

The potential total volume that may be discharged from the pipelines during cutting and lifting operations may be significant if there is no control in place to limit those volumes, which allows for some level of uncertainty on the potential extent that may be reached by the discharge from each pipeline. As a reference, dispersion modelling for discharge of formation water from platforms during production operations that was completed as part of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) indicates that a release of between 1000 - 12,000kL/day of formation water from a facility would rapidly dilute, with an approximate mixing zone of 140m to 230m from the release location. It is noted that the concentrations of potential contaminants that are expected to be present in the fluids that will discharge from pipelines/risers during cutting and lifting operations will be less than that used in the assessment presented in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). This is because the pipelines will be subject to a thorough flushing program to ensure contaminants are reduced to ALARP, and that the corrosion inhibitor that will be added to the water that will be used to fill the pipelines from the end of the cleaning program until they are decommissioned is ranked CHARM silver. From this perspective, it is considered that potential impact from planned releases from the pipelines and risers to the marine environment will not have a significant effect on water quality and marine fauna.

To minimise the total volume of fluids remaining in the pipelines and risers after facility preparation activities are completed and that could be then released into the marine environment during cutting and lifting operations that are part of the scope of this EP, it has been established that all pipelines shall be cut approximately 5m horizontally outboard from the jacket or pipeline connector, and if required, removed individually if not safe to remove with the jacket. After the cut, a cap will be inserted into the remaining pipeline ends resting on the seafloor. This cap will limit the discharge of fluids contained in the pipelines into the marine environment to only the fluids that are present in the section of the line from the jacket or pipeline connector up to where the cut is made, which results in a discharge that is limited to a section of approximately 5m of length. Table 2-25 of Section 2.12.5 describes the estimated volumes to be released from pipelines and risers after capping or plugging of these systems has been implemented. The outcome of capping or plugging the pipelines results in an approximate combined total of 5.5L of oil and 326L of inhibitor that may be discharged from these systems during cutting and lifting operations. From an individual pipeline assessment perspective, pipeline HLA600 – MLA300 TEE is estimated to contain the largest volume of water treated with inhibitor and residual oil that may be discharged to the marine environment, with an approximate volume of 0.6L of oil and 39.6L of inhibitor. Based on this assessment, potential impacts to water quality and to marine fauna are expected to be of a short term nature, rapidly dispersing in the high energy marine environment, with no significant effects on sensitive receptors or at a population level due to the estimated low OIW content and the low risk to the environment posed by the inhibitor used. As a result, the environmental consequence has been assessed as:

- **Consequence Level IV**.

As previously described, the flushing process of the pipelines and risers is part of the planned works covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) to prepare the facilities for removal, prior to commencement of Campaign #1 activities under the scope of this EP. These preparatory works will continue through 2025 to 2027. As preparation works are completed, additional information may become available as to the residual fluids remaining in the pipelines and risers, and the residual concentration of potential contaminants. When new information is available, Esso will review the results achieved from the flushing and cleaning process against the estimates used in this EP to assess the impacts of planned discharges during the cutting and lifting of pipelines and risers to verify that there are no new or significant increased impacts to those identified and assessed in this EP. This review process will follow the Environment Plan Management of Change methodology as described in Section 8.13 of this EP and the requirements of Regulation 39 of the Environment Regulations.

6.8.2.2 Cumulative impacts

Planned discharges from pipelines and risers will be a one-off discharge to the marine environment at each location during the cutting and lifting of these structures. Pipelines will be cut at a maximum distance of 5m from the jacket, which limit the occurrence of the discharge the area immediately adjacent to the platform.

At these locations, additional activities which may result in a change in water quality or that may directly or indirectly affect marine fauna are:

- for KFA and KFB, there is a planned release of titanium iron oxide mineral sand and steel shot ballast, which is present within some of the skirt piles and will be release upon cutting and lifting the jackets (refer to Section 2.12.7)
- for KFA and KFB, planned discharge of grout (refer to Section 2.12.3)
- for KFA, KFB, WKF, BMA and MKA, planned discharge of residual fluids from umbilicals (refer to Section 2.12.4
- the planned release of contents of the ODSPs and CDSPs during lifting of the jackets, which may contain residual levels of hydrocarbons (refer to Section 2.12.1)
- for FTA, FLA, BMA, WKF, CBA and MKA, the planned release of contents of the JLSTs after holes are drilled in these tanks to allow for free-flow of the fluids that remain inside these structures after de-inventory and cleaning works are completed (refer to Section 2.12.1)
- sediment displacement as a result of clearing of seabed sediments to allow access to cutting of pipelines and/or umbilicals (refer to Section 2.10).

The discharge of grout from KFA and KFB will occur during removal preparation activities, approximately 12 months prior to the other activities listed above and impacts to water quality have been assessed as short term and highly localised. For the other sources of planned discharges, volumes are expected to be small and to quickly dissipate in the area immediately adjacent to the platforms. In addition, the chemicals used during the cleaning/flushing/purging works in preparation for decommissioning activities are rated CHARM gold or silver or OCNS D or E. As a result, potential impact from any residual fluids that remain in the systems after cleaning process is completed and that may be discharged during decommissioning activities are expected to be minor.

It is not expected that potential effects from the various sources of planned discharges as mentioned above would accumulate in a manner that would pose a risk to the marine environment. As a result, potential cumulative impacts from subsea planned discharges are assessed as to have an inconsequential effect at an ecosystemic or population level.

6.8.3 Demonstration of As Low As Reasonably Practicable

Table 6-38 Decision Context and justification

Decision Context
Industry best practice has been applied for management of planned discharge through the application of detailed planning and facility preparation activities prior to commencement of the removal activities within the scope of this EP, including flushing of pipelines and risers to reduce concentrations of oil present in these residual fluids. Based on the information available on characteristics of the fluids that could be released to the marine environment, risk of discharge is well understood. However, considering the potential total volume and release rate that may be discharged from the pipelines before controls are implemented to manage this discharge, some uncertainty still exists on the potential extent of the area that may be impacted by this release. The environmental consequence for the impacts resulting from the planned discharges from pipelines and risers have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regard to the discharge of residual fluids from pipelines. Considering some uncertainty remains on the potential impact from planned discharges – pipelines and risers fluids, Esso believes **Decision Context B** should apply.

Table 6-39 Good practice controls

Good practice	Adopted	Control	Rationale
Discharge of least environmentally hazardous chemical.	Adopted – IMP8-CM1	Residual chemicals to be discharged during cutting and lifting of pipelines have previously	This control requires that chemicals must be approved prior to discharge. This practice assesses chemicals that are planned to be discharged to the environment to ensure the lowest toxicity, most biodegradable and least bio accumulative chemicals

Good practice	Adopted	Control	Rationale
		been evaluated as acceptable in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	are selected which meet the technical and safety requirements of the application.

Table 6-40 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Capping or plugging of all pipelines post cutting.	Reduced release of chemicals to the marine environment.	Capping or plugging of pipelines after cutting operations is technically feasible. In addition, capping or plugging of these lines creates a significant environmental benefit by substantially reducing the volumes of residual fluids that would be released into the environment during cutting and lifting operations.	Adopted – IMP8-CM2
Undertake assessments on all previously approved chemicals that will be discharged during pipeline and riser cutting and lifting activities.	Confirm potential impacts from the discharge of residual chemicals during cutting and lifting of the pipelines and risers are reduced to ALARP.	Residual chemicals to be discharged during cutting and lifting of pipelines and risers have previously been assessed as acceptable for use and discharge. The planned discharge is required to enable removal of the facilities and re assessment of the residual chemicals that will be discharged will not reduce any impacts of these planned discharges any further.	Not adopted
Verification of completion of pipelines flushing and cleaning works were completed per facility preparation works scope under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).	Verification that flushing/purging activities have been completed per facility preparation scope of works allows for validation of estimates used for impact assessment from planned discharges during Campaign #1 operations covered under this EP	Verification of completion of facility preparation works and outcomes achieved is a practical measure that could be implemented. Verification of results from facility preparation activities allows for elimination or significant reduction of uncertainty and provides the operator with the opportunity to adapt in advance where/if required.	Adopted - IMP8-CM3

6.8.4 Demonstration of acceptability

Table 6-41 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning of discharges from pipelines and risers to the marine environment that may occur during Campaign #1 included strategy and decision making for flushing, purging and draining activities under the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) and incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV** after controls are implemented, thus are not considered as having the potential to result in serious or irreversible environmental damage. Additional engineering risk assessment was completed to align with the precautionary principle.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned discharges from pipelines and risers has concluded that environmental impacts will be short term and localised in nature. Hence any impacts as a result of these planned discharges to the marine environment will not result in negative effects to the health, diversity and productivity of the environment in such manner that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The impact assessment undertaken has shown that the potential impact associated with planned discharges from pipelines and risers is limited to a localised short term impact and has been assessed as **Consequence Level IV** (inconsequential or no adverse effects). Hence any impacts as a result of these planned discharges to the marine environment is not considered as having

Factor	Demonstration criteria	Criteria met	Rationale
			the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	No environmental legislation was deemed relevant to this particular impact. Chronic chemical pollution is a recognised threat to the species in the following conservation management plans and advice. These discharges are not chronic and will quickly dissipate. It is also noted that no conservation/ management actions are specified in relation to chemical discharges. Outcome from assessment of potential impacts is not inconsistent with the conservation objectives of these plans. • CMPBW. • NRPSRW. • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a). • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Outcome from assessment of potential impacts is consistent with requirements of the Upstream Water Management.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements, and includes processes and procedures for managing environmental impacts, such as the: *Environmental Chemical Discharge*

			Assessment Process (AUGO-EV-PCE-013).
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	Relevant persons asked questions regarding potential discharges from infrastructure during removal activities. These were discussed and answered during consultations for this EP.

6.8.5 *EPOs, control measures, EPSs and measurement criteria*

Table 6-42 EPOs, control measures, EPSs and measurement criteria – Planned discharges from pipeline/risers

EPO	Control measure	EPS	Measurement criteria
IMP8-EPO1: Impacts as a result of planned discharges from pipelines and risers are limited to localised, temporary changes in water. No injury or mortality of marine fauna.	IMP8-CM1: Residual chemicals to be discharged during cutting and lifting of pipelines have been evaluated as acceptable.	IMP8-EPS1.1: Residual chemicals to be discharged during cutting of pipelines and risers have previously been evaluated as acceptable in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	IMP8-MC1.1.1: Documentation in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) (refer to Section 8.11.2.1) confirms residual chemicals have previously been evaluated as acceptable.
	IMP8-CM2: Capping or plugging of all pipelines post cutting.	IMP8-EPS2.1: All pipelines are capped or plugged after cutting at a distance of up to 5m outboard from the jacket or pipeline connector.	IMP8-MC2.1.1: Records confirming capping or plugging of pipelines was completed following cutting, and location of the cut.
	IMP8-CM3: Completion of pipelines flushing and cleaning works as per facility preparation works scope have been verified.	IMP8-EPS3.1: Verification that planned flushing of pipelines and risers that are part of facility preparations activities (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) have been completed prior to commencement of pipeline/riser cutting activities.	IMP8-MC3.1.1: Digital Decommissioning Management Tool records provide evidence that: • pipelines and risers were flushed and cleaned the residual OIW concentration remaining in the pipeline is within the cleanliness targets or demonstrated diminishing returns as outlined in Section 6.8.2.

6.8.6 *Residual consequence assessment*

Implementation of the control described in the Sections above will result in a significant reduction of the total volume of residual fluids to be released, and minimisation of the potential impact to water quality and marine fauna. Based on this assessment, potential impacts to water quality and to marine fauna from planned discharges

from pipelines and risers during cutting and lifting operations are expected to be localised and be of a short term nature, with inconsequential effects on sensitive receptors or at a population level. The residual potential consequence for this impact has been determined as:

- **Consequence Level IV**.

6.9 Planned discharges –ODSPs and CDSPs

6.9.1 Sources of ODSP and CDSPs fluids

During operation of the platforms as part of production activities, the ODSPs are where all liquids from the atmospheric drains were collected in the platforms, and also where hydrocarbons were separated from the water by allowing water to flow out to sea via the subsea window, on average more than 30m below sea level. Removed hydrocarbons were then pumped either to the CDSP and from there to the skimmer vessel, or directly to the skimmer vessel. The CDSPs were used to collect all liquids from the closed drain system, and to separate the hydrocarbons from water by allowing the water to flow out to sea via the subsea window. Hydrocarbons were then pumped to the skimmer vessel by the CDSP pumps.

The ODSPs and CDSPs will be de-inventoried and cleaned during the preparation for decommissioning activities, as described in Section 2.12.1, to remove content of fluids remaining in these structures. However, it is expected that a small volume of residual fluids from the cleaning process will remain inside these structures and then released into the marine environment during lifting operations. After cleaning of ODSPs and CDSPs, these structures will be left open to atmosphere and will free drain upon lifting.

It is also noted that due to the complexity of the internal configuration of the skimmer piles, there is a possibility of the presence of isolated patches of residual fluids that may have solidified and adhered to the internal wall of the piles. This in turn may result in minor and intermittent drips of this residual fluid in the event it detaches from the internal wall of the piles during transport or transfer operations.

As part of facility preparation activities, the status of structures post cleaning will be documented in a hazardous materials register for each facility and included in the Digital Decommissioning Management Tool.

6.9.2 Impacts of discharge of internal fluids from jacket structures

Potential impacts of discharged fluids from ODSPs, CDSPs, JLSTs and flooded jacket members on receptors are:

- change in water quality
- injury/mortality to fauna.

6.9.2.1 Change in water quality

Release of residual fluids from jacket structures have the potential of impacting the water quality. Level of impact will be influenced by several factors including the volume and characteristics of the discharge (concentrations at which contaminants are present in those discharges), and consideration of the metocean conditions, which would have an effect on behaviour and fate of contaminants and its persistence in the water column.

For ODSPs and CDSPs, cleaning process to be implemented during facility preparation activities (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) scope) aims for the reduction in the concentration of contaminants of concern to the maximum extent practicable for residual fluids that are expected to remain within these structures and that consequently will be discharged in the next stage of decommissioning, during lifting operations that are covered under the scope of works of this Campaign #1 EP. As a result, cleanliness and end state targets are defined based on current best knowledge of residual fluid characteristics; consideration is also given to the specific characteristics of each system, as pile design has a significant influence on the cleanliness level that can be practicably achieved. For cleaning activities for the ODSP and CDSPs, the following apply:

- target cleanliness for all ODSPs and Generation 1 CDSPs (KFA/KFB) is an OIW content of 30ppm or below, or if this cannot be achieved - diminishing returns[7]. A maximum volume discharge during removal operations has been calculated on the conservative assumption that the 30ppm OIW concentration is uniform throughout the operating volume of the pile with an estimated total volume of residual oily fluids to be discharged of less than 1L per pile
    - target cleanliness for Generation 2 CDSPs (FTA, MKA, FLA, BMA, CBA, HLA, WKF) is an OIW content at or below 250ppm or diminishing returns:
    - 250ppm has been selected as a conservative target, acknowledging the increased complexity of the internal configuration of the Generation 2 closed piles
    - a maximum volume discharge during removal operations has been calculated on the conservative assumption that 250ppm OIW content is uniform throughout the operating volume of the pile, with an estimated total volume of residual oily fluids to be discharged of approximately 50L per pile.
- OSDPs and CDSPs will be left open to the atmosphere and will free drain upon lifting.

Residual fluids that may have solidified and remain attached to the internal walls may become viscous during transport and run down the length of the pile until it reaches the bottom of the structure and releases to the marine environment. Several factors influence the potential for drips to occur, including but not limited to temperature required by the material to change phase from solid to liquid, viscosity of the fluid, resistance of the surface of the internal wall of the pile to the flow of the fluid and length of the pile. As a result, potential drips that may occur are expected to be minor and isolated, with inconsequential effect on water quality.

The ODSP and CDSP have been in operation for many years. Both the ODSPs and CDSPs have subsea windows where separated process water can exit via displacement when liquids from the topside drains enter and where seawater can enter when hydrocarbons separated from the liquids are pumped out. Analysis of the residual water in the FTA skimmer pile reported levels of nickel and zinc above the trigger value for 99% level of protection in marine water (ANZG, 2018). During lifting of each skimmer pile, the residual water will be progressively released to sea through the water column. The volume of water to be released in such lifting is orders of magnitude less than the volumes of produced formation water that were assessed as acceptable during operation of these platforms (refer to *Bass Strait Environment Plan* (AUGO-EV-EMM-012)). Iron was also reported in the analysis which is not unexpected: although there was some seawater exchange between the skimmer piles and the sea when they were operational, it is likely that water within the ODSPs and CDSPs will have become anoxic, resulting in the potential for rust deposits on the skimmer piles' internal surfaces. This may result in turbid, discoloured water being discharged during lifting which is expected to be temporary.

As a reference, the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) presents an analysis and assessment of produced formation water discharge from production operations. A description provided in the referenced EP indicates that during platform operations, wells bring water to the surface alongside the oil and gas, then the produced formation water is separated and treated to remove hydrocarbons prior to discharge. Separation of formation water from reservoir fluids is not completely effective and separated produced formation water often contains small amounts of naturally occurring substances (such as dispersed oil) and residual process chemicals. The *Bass Strait Environment Plan* (AUGO-EV-EMM-012) established a mixing zone of produced formation water for each platform, and extent of this zone ranged between 140-230m. It is noted that release volume established for calculation of the mixing zones in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) ranged between 1000-12,000kL/day. Similarly, the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) presents the outcome from modelling conducted to predict the rates and extent of dispersion of discharges from skimmer piles as part of the oil and gas production operations. Rates of discharge modelled were 2.7m^3/hour and 8.2m^3/hour. Results indicated discharges from piles are diluted in the ranges of 5 to 35 times within 10m from the platform. Water

[7] For the purposes of this Section, diminishing returns is defined as when oil in water measurements taken during ODSPs and CDSPs de-inventory/cleaning process are within a nominated content band of measured OIW content. For the Generation 2 CDSPs, this correlates to five readings within a one hour period being within a 30ppm band as analysed by portable field instruments, or onshore laboratory where direct field measurement is not possible. For all other piles, this correlates to five consecutive hourly readings being within a 10ppm band as analysed by portable field instruments, or onshore laboratory where direct field measurement is not possible.

sampling completed at the Tuna platform validated these results, with results showing that all valid samples taken from the water column indicated that the presence of platform discharges were less than 99% species protection water quality criteria (ANZG, 2018) at 59m from the platform and beyond.

For the purpose of the assessment of potential impacts from release of residual fluids during Campaign #1 activities under the scope of this EP, it is noted that the estimated total volume to be released from ODSPs and CDSPs is several orders of magnitude less than the volumes described and assessed in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). In addition, release of residual fluids during decommissioning activities from ODSPs and CDSPs will be a one-off occurrence at each facility, and fluids will have OIW content that is below the target established for each structure (as previously described), ensuring that potential impact to receptors are reduced to ALARP.

As a result, potential impacts to water quality from release of these small volumes of residual fluids are expected to be highly localised and short term, with inconsequential effects on sensitive receptors or at a population level, with an assessed potential impact of:

- **Consequence Level IV**.

6.9.2.2 Injury/mortality to fauna

Release of residual fluids from ODSPs and CDSPs have the potential of impacting marine fauna. Level of impact will be influenced by several factors including the volume and characteristics of the discharge (concentrations at which contaminants are present in those discharges and availability of contaminants to organisms), sensitive receptors present in the location where the discharge may occur, and consideration of the metocean conditions, which would have an effect on behaviour and fate of discharged fluids and its persistence in the water. Due to the small volumes estimated to be potentially released, the low content of OIW in the fluids that may be discharged, the localised nature of the release, the fact that the discharge is limited to a one-time release at each facility during lifting operations and potential minor isolated drips during transport, and the negligible variation expected in water quality, potential impacts to marine fauna are considered to have inconsequential effects and have been assessed as:

- **Consequence Level IV**.

As previously described, the de-inventory and cleaning process of the ODSP and CDSPs is part of the planned works covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) to prepare the facilities for removal, prior to commencement of Campaign #1 activities under the scope of this EP. At the time of development of this EP, facility preparation works were underway, and they are expected to continue through 2025 to 2027. As preparation works are completed, additional information may become available on residual fluids remaining in the skimmer piles, as well as the concentration of potential contaminants in those fluids. Where new information is available, Esso will review results achieved from the facility preparation works against the estimates described in this EP for planned discharges to verify that there is no new or significant increased impact to those identified and assessed in this EP for planned discharges from these systems. This review process will follow the Environment Plan Management of Change methodology as described in Section 8.13 of this EP.

6.9.2.3 Cumulative impacts

Planned discharges from ODSPs and CDSPs will be a one-off discharge to the marine environment at each facility which will occur during the cutting and lifting of the umbilicals, and volumes expected to be discharged are small. At these locations, additional activities which may result in a change in water quality or that may directly or indirectly affect marine fauna are:

- for KFA and KFB, there is a planned release of titanium iron oxide mineral sand and steel shot ballast, which is present within some of the skirt piles and will be release upon cutting and lifting the jackets (refer to Section 2.12.7);
- for KFA and KFB, planned discharge of grout (refer to Section 2.12.3)
- the planned release of residual fluids from pipelines following cutting and prior to capping/plugging, which may contain residual levels of hydrocarbons (refer to Section 2.12.5)
- for FTA, FLA, BMA, WKF, CBA and MKA, the planned release of contents of the JLSTs after holes are drilled in these tanks to allow for free-flow of the fluids that remain inside these structures after de-inventory and cleaning works are completed (refer to Section 2.12.1)

- for KFA, KFB, WKF, BMA and MKA, planned discharge of residual fluids from umbilicals (refer to Section 2.12.4)
- Sediment displacement as a result of clearing of seabed sediments to allow access to cutting of pipelines and/or umbilicals (refer to Section 2.10).

The discharge of grout from KFA and KFB will occur during removal preparation activities, approximately 12 months prior to the other activities listed above and impacts to water quality have been assessed as short term and highly localised. For the other sources of planned discharges, volumes are expected to be small and will quickly dissipate in the area immediately adjacent to the platforms. In addition, the chemicals used during the flushing works in preparation for decommissioning activities are rated CHARM gold or silver or OCNS D or E. As a result, potential impact from any residual fluids that remain in the systems after cleaning process is completed and that may be discharged during decommissioning activities are expected to be minor.

It is not expected that potential effects from the various sources of planned discharges as mentioned above would accumulate in a manner that would pose a risk to the marine environment. As a result, potential cumulative impacts from subsea planned discharges are assessed as to have an inconsequential effect at an ecosystemic or population level.

Discharge of fluids from ODSPs and CDSPs is limited to small volumes and are expected to be rapidly dispersed in the high energy marine environment within the area adjacent to the platform. It is considered that discharges from these systems will not have a significant negative effect on water quality or the marine fauna.

6.9.3 Demonstration of As Low As Reasonably Practicable

Table 6-43 Decision Context and justification

Decision Context
Best practice has been applied for management of planned discharges from ODSPs and CDSPs through the application of detailed planning and facility preparation activities prior to commencement of the removal activities within the scope of this EP, including de-inventory and cleaning of these systems. However, each skimmer pile installed in facilities is unique in its design and is integrated into the platform jacket. This results in scarcity of information on previous local or global decommissioning experience of these particular structures and on management of discharges from these systems including cleanliness requirements. Based on the information available on characteristics of the fluids that could be released to the marine environment, risk of discharge is well understood. However, considering the uniqueness of this equipment (skimmer piles installed in the platforms under the scope of this EP) that results in challenges during the de-inventory and cleaning of the systems, some uncertainty remains. Industry best practice has been applied through detailed planning and facility preparation activities prior to commencement of Campaign #1 activities under the scope of this EP, including de-inventory and cleaning of ODSPs and CDSPs to minimise expected residual volumes to be released and reduce concentrations of contaminants present in these residual fluids. There is some uncertainty associated with potential minor quantities of solidified fluids attached to the internal wall of the skimmer piles that may detach and may result in isolated drips during transport, potentially discharging to the marine environment. The environmental consequence for the impacts resulting from the planned discharges from ODSPs and CDSPs have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regard to the discharge of residual fluids from these structures. Hence, Esso believes **Decision Context B** should apply.

Table 6-44 Good practice controls

Good practice	Adopted	Control	Rationale
N/A	N/A	N/A	N/A

Table 6-45 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Plugging of ODSPs and CDSPs.	Reduced release of chemicals to the marine environment.	Not feasible Results from front-end engineering design studies, detailed design works and experimental testing completed by Esso to define a potential plugging solution for these systems indicated that there are key complexities and considerations for implementing this control, including: • pile designs; internal obstructions (i.e. downcomers) /lack of design continuity across the platforms/integration into the platform jacket) • pile and jacket removal methodology has an impact on plug location and allowable size • defining the appropriate plug material, product did not exist and required extensive third-party engineering and testing • internal marine growth and other elements impacted bonding and sealing capability of the plug • lack of global precedence or experience for such a plugging solution. Due to such extensive technical challenges, product testing failures, and known significant feasibility risks, plugging of ODSPs and CDSPs, has been assessed as not practical.	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		In addition, the potential environmental impact from planned release of residual fluids that remains within the skimmer piles after cleaning has been assessed as **Consequence Level IV**. This assessment included consideration of the small volumes expected to be released from the skimmer piles, the low concentration of potential contaminants within the fluid, the localised nature of the release, and the absence of sensitive receptors in the area where the release may occur. Therefore, potential environmental benefit provided by this control is not considered significant. The cost and technical challenges associated to the implementation of this control has been assessed as grossly disproportionate to the potential environmental benefit that would be provided.	
Verification of completion of de-inventory and cleaning works were completed per facility preparation works scope under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).	Verification that de-inventory and cleaning activities have been completed per facility preparation scope of works allows for validation of estimates used for impact assessment from planned discharges during Campaign #1 operations covered under this EP	Verification of completion of facility preparation works and outcomes achieved is a practical measure that could be implemented. Verification of results from facility preparation activities allows for elimination or significant reduction of uncertainty, and provides the operator with the opportunity to adapt in advance where/if required	Adopted – IMP9-CM1

6.9.4 Demonstration of acceptability

Table 6-46 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate	✓	Not inconsistent. Planning of discharges from ODSPs and CDSPs to the marine environment that

Factor	Demonstration criteria	Criteria met	Rationale
	both long term and short term economic, environmental, social and equitable considerations.		may occur during Campaign #1 operations included strategy and decision making for de-inventory and cleaning activities under the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) and incorporated contemplation of both short and long term economic, environmental, social and equitable considerations. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV** thus are not considered as having the potential to result in serious or irreversible environmental damage. Additional engineering risk assessment was completed to verify ALARP assessment, and to incorporate the precautionary principle to support decision making process.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned discharges from ODSPs and CDSPs has concluded that environmental impacts will be short term and localised in nature. Hence any impacts as a result of these planned discharges to the marine environment will not result in negative effects to the health, diversity and productivity of the environment in such manner that future generations will be impacted.

Factor	Demonstration criteria	Criteria met	Rationale
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The impact assessment undertaken has shown that the potential impact associated with planned discharges from ODSPs and CDSPs is limited to a localised short term impact and has been assessed as **Consequence Level IV** (inconsequential or no adverse effects). Hence any impacts as a result of these planned discharges to the marine environment is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	No environmental legislation was deemed relevant to this particular impact. Chronic chemical pollution is a recognised threat to the species in the following conservation management plans and advice. These discharges are not chronic and will quickly dissipate. It is also noted that no conservation/management actions are specified in relation to chemical discharges. Outcome from assessment of potential impacts is not inconsistent with the conservation objectives of these plans. • CMPBW. • NRPSRW. • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a). • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Outcome from assessment of potential impacts is consistent with requirements of the Upstream Water Management.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and

Factor	Demonstration criteria	Criteria met	Rationale
			Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Relevant persons asked questions regarding potential discharges from infrastructure during removal activities. These were discussed and answered during consultations for this EP.

6.9.5 EPOs, control measures, EPSs and measurement criteria

Table 6-47 EPOs, control measures, EPSs and measurement criteria – Planned discharges from ODSPs and CDSPs

EPO	Control measure	EPS	Measurement criteria
IMP9-EPO1: Impacts as a result of planned discharges from ODSPs and CDSPs are limited to localised, temporary changes in water. No injury or mortality of marine fauna.	IMP9-CM1: Verification that de-inventory and cleaning activities have been completed as per facility preparation scope of works.	IMP9-EPS1.1: Verification that planned de-inventory and cleaning of ODSPs and CDSPs that are part of the facility preparations activities (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) have been completed prior to the commencement of HLV operations covered under this Campaign #1 EP.	IMP9-MC1.1.1: Digital Decommissioning Management Tool records provide evidence: • that ODSP and CDSPs were de-inventoried and cleaned. • of the residual OIW concentration remaining in the ODSP/CDSP.

6.9.6 Residual consequence assessment

Based on the assessment described above, the residual potential consequence has been determined as*:*

- **Consequence Level IV**.

6.10 Planned discharges – Jacket structure internal fluids

6.10.1 Sources of jacket structure fluids

Jacket structures described in this Section include JLSTs, and flooded jacket members.

The JLSTs were used to variously contain diesel, glycol, methanol or potable water. Similar to skimmer piles, JLSTs will be de-inventoried and cleaned in preparation for decommissioning activities (refer to Section 2.12.1) and left open to atmosphere via a dedicated vent line. JLSTs have a sealed bottom which prevents drainage. Therefore, after cleaning is completed, holes will be drilled in the tanks to allow for free flow of residual fluids remaining inside the tanks during lifting operations. Platforms that are part of the scope of this EP where JLSTs are present include FTA, FLA, BMA, WKF, CBA and MKA. Refer to Table 2-26 for detail on the type of product stored in each tank at each facility.

As part of removals preparation activities, the status of structures post cleaning will be documented in a hazardous materials register for each facility. This register will be used to support identification of residual materials for Campaign #1 works planning and execution.

Flooded jacket members refer to sections of the jackets where there has been ingress of seawater. To ensure actual crane lifting weights and configurations reflect what has been planned for lifting operations, any seawater inside these jacket members must be allowed to drain out of the structure while it is lifted out of the water. To achieve this, drain and vent holes will be drilled in flooded members to eliminate the potential for any entrapped seawater to be removed with the jackets. This activity will be assessed on a case-by-case basis, to determine which jacket members are flooded with seawater and therefore require this approach. Seawater that enters and becomes stagnant within these structures is not in contact with any fluids, substances or contaminants that may be of potential concern to the marine environment; however, it is likely for the seawater within these structures to have become anoxic, resulting in the potential for rust deposits on the members' internal surfaces. Upon lifting, there may be turbid, discoloured water discharged during lifting. Based on the absence of contaminants of concern in this planned discharge, it is expected there will be no impacts to water quality and marine fauna. As a result, this discharge is not assessed further.

6.10.2 Impacts of discharge of internal fluids from JLSTs

Potential impacts of discharged fluids from JLSTs on receptors are:

- change in water quality
- injury/mortality to fauna.

6.10.2.1 Change in water quality

Release of residual fluids from JLSTs have the potential of impacting the water quality. Level of impact will be influenced by several factors including the volume and characteristics of the discharge (concentrations at which contaminants are present in those discharges), location of the discharge and marine fauna present in that area, and consideration of the metocean conditions, which would have an effect on how contaminants will behave and its persistence in the water column.

From a JLSTs discharge perspective, it is noted that these structures will be cleaned by filling the tanks with seawater and subsequent skimming of diesel and draining of all liquids. Fluids removed during the cleaning process of the diesel JLSTs will be sent to the platform pipeline and then directed onshore to the Longford plant. Target cleanliness is the point of diminishing returns for OIW contents at or below 30ppm. Based on the maximum OIW set at JLSTs that were used to store diesel during platform operations, an estimated residual volume of diesel that may remain inside these tanks after the cleaning process is completed that may be released to the marine environment during lifting operations is 2L per tank.

Methanol stored in the JLST at MKA will be removed by draining/de-inventorying of the tank during facility preparation works prior to commencement of Campaign #1 activities under the scope of this EP. Resulting fluids from the cleaning of the JLST at MKA will be managed by either pumping it to the pipeline or into iso containers for transport to the Longford Plant, or by temporary storage in iso-containers and then transport to an onshore location. It is expected that residual volumes of the diluted fluid that cannot be pumped will remain in the JLST and subsequently be released to the sea when the structure is lifted during Campaign #1 removal operations. From the cleaning process planned for the JLST and based on dilution rates to be used during that stage, it is estimated that the residual volume of methanol that may remain within the JLST and be released to the sea is approximately 10L. Similarly, glycol JLST in FLA will be drained and de-inventoried, with an estimated remaining residual volume of glycol in the tank after cleaning of 25L.

As a result, potential impacts to water quality from release of these small volumes of residual fluids are expected to be highly localised and short term, with inconsequential effects on sensitive receptors or at a population level. with an impact assessed as:

- **Consequence Level IV**.

6.10.2.2 Injury/mortality to fauna

Due to the small volumes estimated to be potentially released, the low content of OIW in the fluids that may be discharged, the localised nature of the release, the fact that the discharge is limited to a one-time release at each

facility during lifting operations, and the negligible variation expected in water quality, potential impacts to marine fauna are considered to have inconsequential effects. with an impact assessed as:

- **Consequence Level IV**.

6.10.2.3 Cumulative impacts

Planned discharges from JLSTs will be a one-off discharge to the marine environment at each facility where these tanks are present, which is limited to six platforms - FTA, FLA, BMA, WKF, CBA and MKA. Volumes expected to be discharged are small. At these locations, additional activities which may result in a change in water quality or that may directly or indirectly affect marine fauna are:

- the planned release of residual fluids from pipelines following cutting and prior to capping, which may contain residual levels of hydrocarbons (refer to Section 2.12.5)
- the planned release of contents of the ODSPs and CDSPs during lifting of the jackets, which may contain residual levels of hydrocarbons (refer to Section 2.12.1)
- for WKF, BMA and MKA, planned discharge of residual fluids from umbilicals (refer to Section 2.12.4)
- sediment displacement as a result of clearing of seabed sediments to allow access to cutting of pipelines and/or umbilicals (refer to Section 2.10).

Planned releases from the sources mentioned above are expected to be of a small volume and to quickly dissipate in the area immediately adjacent to the platforms. In addition, the chemicals used during the cleaning works in preparation for decommissioning activities are rated CHARM gold or silver or OCNS D or E. As a result, the potential impact from the discharge of any residual fluids that remain in the system after the cleaning process are expected to be minor.

It is not expected that potential effects from the various sources of planned discharges as mentioned above would accumulate in a manner that would pose a risk to the marine environment. As a result, potential cumulative impacts from subsea planned discharges are assessed as to have an inconsequential effect at an ecosystemic or population level.

6.10.3 Demonstration of As Low As Reasonably Practicable

Table 6-48 Decision Context and justification

Decision Context
Industry best practice has been applied through detailed planning and facility preparation activities prior to commencement of Campaign #1, including cleaning of JLSTs to minimise expected residual volumes to be released. The type and potential concentrations of contaminants that may be present in the residual fluids that could be discharged from JLSTs are well understood. Given the small volumes, limited extent of potential impacts, the absence of sensitive environmental features in the area where the planned release of residual fluids may occur and effects on marine organisms are expected to be inconsequential. The environmental consequence for the impacts resulting from the planned discharges from jacket structure internal fluids have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regards to the discharge of residual fluids from these structures. Hence, Esso believes **Decision Context A** should apply.

Table 6-49 Good practice controls

Good practice	Adopted	Control	Rationale
N/A			

Table 6-50 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Do not drill holes in the JLSTs	Eliminates release of residual chemicals to the marine environment	JLSTs are attached to the jackets of the platforms. As a result, their removal will take place when the jackets are removed. Lifting of jackets is a complex operation that requires thorough planning and preparation. Estimated weight of the structures is considered in the calculation completed to inform lifting operations, and as such, it is a critical input to ensure safe removal of these structures. In addition to the fluids that remain within the JLSTs post-cleaning, these structures will also be susceptible to ingress of seawater. Any residual liquids remaining inside the JLST as a result of internal cleaning or from the environment post topsides removal, may result in an elevated risk of structural failure due to the dynamic sloshing effect of the free water surface moving during transport. The momentum from excessive free water surface sloshing within the JLST can cause high unplanned forces and stresses within the jacket leg resulting in damage or instability of the structure during transportation/towing. The drilling and free draining of the JLST eliminates the potential risk of structural deformation, failure or structure instability caused by sloshing, and therefore provides the conditions required for lifting operations to be conducted in a safe manner. Implementation of this control (do not drill holes in the JLSTs) creates an unacceptable safety risk and it is disproportionate to the potential environmental benefit it provides.	Not adopted
Verification of completion of de-inventory and cleaning works were completed as per facility preparation works	Verification that de-inventory and cleaning activities have been completed as per	Verification of completion of facility preparation works and outcomes achieved is a practical measure that could be	Adopted – IMP10-CM1

scope under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012).	facility preparation scope of works allows for validation of estimates used for impact assessment from planned discharges during Campaign #1 operations covered under this EP.	implemented. Verification of results from facility preparation activities allows for elimination or significant reduction of uncertainty and provides the operator with the opportunity to adapt in advance where/if required.	

6.10.4 Demonstration of acceptability

Table 6-51 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning of discharges from jacket structures to the marine environment that may occur during Campaign #1 operations included strategy and decision making for cleaning activities under the scope of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) and incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent The activities were evaluated as having the potential to result in a **Consequence Level IV** thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned discharges from jacket structures has concluded that environmental impacts will be short term and localised in nature. Hence any impacts as a result of these planned discharges to the marine environment will not result in negative effects to the health, diversity and productivity of the environment in such manner that future generations will be impacted.

Factor	Demonstration criteria	Criteria met	Rationale
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The impact assessment undertaken has shown that the potential impact associated with planned discharges from jacket structures is limited to a localised short-term impact and has been assessed as **Consequence Level IV** (inconsequential or no adverse effects). Hence any impacts as a result of these planned discharges to the marine environment is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	No environmental legislation was deemed relevant to this particular impact. Chronic chemical pollution is a recognised threat to the species in the following conservation management plans and advice. These discharges are not chronic and will quickly dissipate. It is also noted that no conservation/management actions are specified in relation to chemical discharges. Outcome from assessment of potential impacts is not inconsistent with the conservation objectives of these plans. • CMPBW. • NRPSRW. • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a). • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Outcome from assessment of potential impacts is consistent with requirements of the Upstream Water Management.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and

Factor	Demonstration criteria	Criteria met	Rationale
			Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Relevant persons asked questions regarding potential discharges from infrastructure during removal activities. These were discussed and answered during consultations for this EP.

6.10.5 EPOs, control measures, EPSs and measurement criteria

Table 6-52 EPOs, control measures, EPSs and measurement criteria – Planned discharges from JLSTs

EPO	Control measure	EPS	Measurement criteria
IMP10-EPO1: Impacts as a result of planned discharges from JLSTs are limited to localised, temporary changes in water. No injury or mortality of marine fauna.	IMP10-CM1: Verification of completion of de-inventory and cleaning works were completed as per facility preparation scope of works.	IMP10-EPS1.1: Verification that planned de-inventory and cleaning of JLSTs that are part of the facility preparations activities (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012)) have been completed prior to commencement of HLV operations covered under this Campaign #1 EP.	IMP10-MC1.1.1: Digital Decommissioning Management Tool records provide evidence that JLSTs were de-inventoried and cleaned.

6.10.6 Residual consequence assessment

Based on the assessment described above, the residual potential consequence has been determined as:

- **Consequence Level IV**.

6.11 Planned discharges – Solids

6.11.1 Sources of solid discharges

Planned discharges of solids from subsea infrastructure during decommissioning activities include the following:

- Titanium iron oxide mineral sand and steel shot ballast - This aggregate-like material is present within some of the skirt piles of older facilities. Based on the planned cut heights, this material will only be encountered at KFA and KFB in Campaign #1. This material will be released during either cutting or lifting of structures. Where internal cutting of the jacket is feasible, the titanium iron oxide mineral sand and steel shot ballast material may need to be removed to allow the abrasive water jetting cutting tool to fit inside the pile. The method to remove the steel shot and titanium iron oxide mineral sand mix is likely to be via an airlift tool or a suitable alternative. Use of airlift techniques to remove internal sediment/aggregate is common in industry. There is no viable means of capturing the materials removed from the piles using the airlift method, hence the steel shot and mineral sand will be discharged to sea. Where external cutting is required, steel shot and titanium iron oxide mineral sand mix will be released upon lifting of the jacket where this material extends above the cut height. Indicative volumes potentially to be released are shown in Table 2-27.

- Minor steel fines and garnet sand associated with cutting of structures - During cutting operations swarf will also be released to sea. Garnet will be used for high pressure water jetting. Indicative volumes of swarf and garnet are presented in Table 2-27.
- Natural accumulations of sand, grout and marine growth within piles that will be lost as part of either airlifting, or lifting of structures - Marine growth, sand and grout may potentially be present within the skirt piles of the jackets. Internal cleaning may be required to allow for internal cutting of the piles. Where internal cutting is not possible, any materials present above the cut line of the pile is expected to be released into the marine environment during lifting operations. Presence of these materials will be assessed on a case-by-case basis. Volumes expected to be released from airlifting or lifting of jackets is determined to be negligible and therefore will not be assessed further.

6.11.2 Impacts of planned discharge of solids

Impacts of discharge of solids on receptors are:

- change in water quality
- change in habitat
- injury/mortality to fauna.

6.11.3 Consequence assessment

6.11.3.1 Change in water quality

Titanium iron oxide and natural sands released during airlifting of the material or during lifting of the structures will disperse in the marine environment. Capture of this material is not technically feasible. Coarse particles are expected to settle, while fine particles are expected to remain within the water column. Fines can lead to an increase in turbidity of the water. Plume dispersion modelling has been undertaken which assessed that the maximum extent of the plume from the release source is at KFA, where it was predicted that a concentration of fines of 1mg/L could reach up to 100m from the release location. The maximum concentration assessed for titanium iron oxide is 100mg/L, which is limited to a 10m radius from the source. (Stantec Australia, 2024a), suggesting that the impact of fine particulate matter concentrations is limited to the immediate area of the facility. For turbidity, the marine water quality objectives for protection of aquatic systems are established as 0.5 – 10ntu/1.5 – 30mg/L (ANZG, 2018).

In addition, there is a risk of mobilising contaminants via release of particles in the water column during airlifting or lifting operations. Potential contaminants are those associated to aggregate-like materials, including fly-ash, bentonite and heavy metals.

The potential for effects of toxicity from the mobilisation of contaminants will depend on the particular toxicant, its concentration, level of dilution and sensitivity of the biological receptors. Metals can be essential for organisms as trace elements, however at higher concentrations they can become toxic (Stantec Australia, 2024b). High exposure to heavy metals can cause physiological stress, reduced reproductive success, and in some cases, mortality in associated invertebrates and fishes.

The maximum distance at which the plume of released material could reach from the source location is 100m at KFA. As a result, it is possible to have concentrations of mobilised contaminants available in the water column within this radius.

During cutting activities, swarf and garnet will be released into the marine environment. The composition of swarf fines is subject to the composition of the structure from where it is originated, in this case, steel. Therefore, it is expected that swarf will be comprised of mostly iron and zinc and then traces of heavy metals such as copper and nickel. Swarf volumes to be released are dependent on the cross-section area and cutting length, which for decommissioning activities is expected to be minimal, with an estimated total volume of approximately 0.20m^3. The facility at which maximum potential volume of swarf could be generated is at HLA, with an approximate volume of 0.04m^3. Considering this maximum individual volume to be released from a single facility, it is expected that the potential affected area with concentrations up to 0.2mg/L is confined to within 15m from the point of fine contents release. Beyond this immediate vicinity, the concentration of fines is expected to diminish rapidly, with no significant change in water or sediment quality predicted at distances greater than 20m from the facility (Stantec Australia, 2024a).

Garnet to be used during cutting activities is a commonly used product by the industry for waterjet cutting worldwide. It consists mostly (>97%) of natural almandine (Fe_3AL_2 $[SiO_4]_3$), and then minor concentrations of

ilmenite (<1%), quartz (<0.5%), zircon (<0.1%) and other (0.25%) components, with no presence of heavy metals or toxic compounds. Release of small volumes of garnet during cutting activities is expected to have inconsequential effects on water quality.

Based on this it is expected that potential impacts to water quality from the release of solids will be limited to the immediate vicinity of the facilities and of short duration. Therefore, **Consequence Level IV** has been identified for this impact.

6.11.3.2 Change in habitat

Coarse particles released during airlifting, cutting or lifting operations will likely settle on the seabed. Due to the small volume of material estimated to be released and then settled on the seabed, it is considered that potential impacts to current habitat characteristics and features are negligible, hence impacts have been assessed as:

- **Consequence Level IV**.

6.11.3.3 Injury/mortality to fauna

The three potential pathways of exposure of fauna to injury or mortality from the release of material during airlifting, cutting and lifting operations are via smothering by material settling on the seabed, exposure to reduced water quality, or by direct mortality of marine fauna attached to the narrow section of the jacket where marine growth will be removed to allow for cutting of the structure.

An organism's ability to survive burial and smothering due to sedimentation will vary largely depending on the particle grain size, rate of sedimentation, depth of burial and the organism's physiology and adaptation to smothering. This may vary among individual species of the same family. The predominant epifauna known to be associated with soft sediments around the facilities that are part of Campaign #1 activities include sessile species such as sponges and bryozoans, hydroids, ascidians, poriferans and mobile fauna including hermit crabs, sea stars and octopus.

In terms of infauna, sediment analysis from the seabed around HLA, CBA, KFA, FLA, WTA, BMB, BTA and DPA in Esso's Bass Strait operations during the Environmental Survey 1 (Summer) undertaken in the first quarter of 2021 provides a profile of the infaunal species in the area around the facilities. The results of this study showed that although infauna assemblages differed between sites, these differences were not pronounced. Similarly, the analysis of reference sites (away from the facilities) showed that infaunal assemblages did not differ markedly to those at facility sites. The analyses also indicated that *Corophiidae* were present as typifying species at all platforms and reference sites, with *Tanaidacea spp.* and *Ostrocoda spp*. being common at most sites. *Corophiidae, Tanaidacea spp*. and *Ostrocoda spp*. are all subcategories of small crustaceans. The abundance of these species throughout the sites probably contributed to the relatively limited variation in species assemblages across the whole range of the sites. Even FLA, the site most dissimilar to all the other sites, including reference sites, was still dominated by amphipod crustaceans (*Phoxocephalidae, Platyischnopidae, Lysianassidae, Corophiidae*, *Oedicerotidae)* like most of the other sites. Polychaete worm species were also noted as being present at the majority of facilities sampled.

Environmental Survey 1 (Summer) analysed the composition of seabed sediments present at CBA, FLA, HLA, KFA, WTA, BMB, DPA and BTA (not within the scope of this EP) and at reference sites. The composition of the seabed sediments around MKA, FTA, BMA, WKF, PCA and KFB were analysed as part of Environmental Survey 2 (Winter) in 2022. The areas surveyed showed a relatively uniform sediment grain size. In all locations the predominant sediment grain size was sand (0.063-2.0mm in diameter), with comparatively minor contributions (most often less than 10% but up to 16%) from clay- and silt-sized particles at all sites. On average, gravel-sized particles exceeded 15% at WTA (Hook S. E., 2021) and (AECOM, 2024). The size distribution did not change considerably across the Gippsland Basin area or appreciably with depth.

Some studies have been undertaken to investigate the ability of infaunal invertebrates to tolerate burial and sedimentation, although the results are highly variable depending on a number of physical factors (e.g. sediment composition, rate of smothering, duration of burial) as well as numerous physiological factors, behavioural traits and adaptations (Stantec Australia, 2024b). A study undertaken to investigate the burial survival of benthic fauna following the deposition of simulated dredged material at various depths (Bolam, 2011) found that sedimentary deposit feeders such as polychaete worms had less ability to survive sediment deposition and were unable to survive 6cm of overburden burial. More mobile species such as gastropods however exhibited relatively good vertical migration capability through sediments when buried and were able to cope well with 6cm of overburden

and almost 50% vertically migrated through 16cm of overburden, primarily when the organic content of the sediments was low (Bolam, 2011).

Based on the small volumes of material to be released, and the limited fraction of particles that would settle on the seabed, it is unlikely that thickness of layer of settled material will be greater than 1cm in the immediate vicinity of the facilities. Based on the suggested ability of infauna to evade smothering when exposed to layers <1cm thick, it is unlikely smothering will pose a significant threat to these organisms. In addition, potential loss of infauna from smothering would be limited to the immediate vicinity of the facilities and has an overall inconsequential effect on diversity or ecosystem function.

Potential exposure of marine fauna to contaminants from release of solids include those that may be present within the titanium iron oxide mineral sand and steel shot ballast that may be released during lifting operations, and/or the swarf (steel fines) and garnet sand to be released during cutting activities.

The titanium iron oxide mineral sand and steel shot ballast aggregate-like material is only present at KFA and KFB in limited volumes. Release of this material during airlifting of the material or during lifting of the structures may create a risk of exposure with marine fauna via fine particles that are dispersed in the water column, or coarser particles that settle on the seabed. For fines that disperse within the water column, it is indicated that release at a concentration of 1mg/L could reach up to 100m from the release location. Small volumes estimated for potential release for this material, the low concentrations of exposure, the very limited and localised area that may be affected, and the absence of sensitive receptors within the area at each location than may be affected indicates potential exposure of organisms to contaminants that could trigger toxicological effects with impact at population levels or ecosystemic functions is inconsequential.

The potential volumes of swarf to be released during cutting activities are estimated using the cross-section of the structure that will be cut. Maximum volume of swarf to be released at a single location is limited to approximately 0.04m^3 under a worst-case scenario, which accounts for the largest cross-section to be cut based on the largest structure where this operation may occur. The minimal estimated volumes of swarf released are expected to reach up to a distance of approximately 15m from the cut location, at concentrations <0.2mg/L. Beyond this immediate vicinity, the concentration of fines is expected to diminish rapidly, with no significant exposure of marine fauna to potential toxicological effects. Similarly, based on the composition of the garnet to be used during Campaign #1 operations (refer to Section 6.11.3), this material does not pose a toxicity risk for marine fauna.

The targeted removal of marine growth from the structure to allow for cutting activities can potentially lead to injury and mortality of organisms that are present within the specific section of the jacket required to be cleaned for cutting. It is expected that highly mobile organisms that may be present will be more resilient to this impact than sessile organisms. In addition, considering that the cross-section area and cutting length of the jacket that is required for decommissioning activities is expected to be minimal, potential impact will be localised and is not expected to have an effect over species at a population level.

6.11.3.4 Cumulative impacts

Planned discharges of solids that may be present inside the jackets will be a one-off discharge to the marine environment. Furthermore, potential release of titanium iron oxide will be limited to some of the jackets located at KFA and KFB only. The area of exposure to solids that are released from within the jackets is limited to the immediate vicinity of the facilities, and it is not expected to affect organisms at a population level. The localised nature of the release also indicates that there is no connection or overlap of solids that may be discharged at different facilities that would then create a cumulative effect.

Volumes of solids from within the jackets that are expected to be discharged are small. Additional sources of planned discharges (other than solids) during Campaign #1 activities which may result in a change in water quality or that may directly or indirectly affect marine fauna are:

- for KFA and KFB, planned discharge of grout (refer to Section 2.12.3).
- the planned release of residual fluids from pipelines following cutting and prior to capping, which may contain residual levels of hydrocarbons (refer to Section 2.12.5)
- the planned release of contents of the ODSPs and CDSPs during lifting of the jackets, which may contain residual levels of hydrocarbons (refer to Section 2.12.1)
- for KFA, KFB, WKF, BMA and MKA, planned discharge of residual fluids from umbilicals (refer to Section 2.12.4)

- for KFA, KFB, BMA, WKF and MKA, the planned release of contents of the JLSTs after holes are drilled in these tanks to allow for free-flow of the fluids that remain inside these structures after de-inventory and cleaning works are completed (refer to Section 2.12.1)
- sediment displacement as a result of clearing of seabed sediments to allow access to cutting of pipelines and/or umbilicals (refer to Section 2.10).

Planned releases from the sources mentioned above are expected to be of a small volume and to quickly dissipate in the area immediately adjacent to the platforms. In addition, the chemicals used during the cleaning/flushing/purging works in preparation for decommissioning activities are rated CHARM gold or silver or OCNS D or E. As a result, potential impact from any residual fluids that remain in the systems after cleaning process is completed and that may be discharged during decommissioning activities are expected to be minor.

It is not expected that potential effects from the various sources of planned discharges as mentioned above would accumulate in a manner that would pose a risk to the marine environment. As a result, potential cumulative impacts from subsea planned discharges are assessed as to have an inconsequential effect at an ecosystemic or population level.

Given the localised nature of the potential impact, the limited presence of sensitive receptors in the immediate vicinity of the facilities, the likely fast recovery and recolonisation by organisms, and potential effects limited to individual organisms rather than species populations, consequence level from discharge of solids to the marine environment is assessed as:

- **Consequence Level IV**.

6.11.4 Demonstration of As Low As Reasonably Practicable

Table 6-53 Decision Context and justification

Decision Context
Industry best practice selection processes will be applied for solid materials to be used during decommissioning activities (i.e. garnet), including the application of chemical assessment and selection process. Release of small volumes of titanium iron oxide, swarf and materials potentially present inside the jackets such as sand, grout and marine growth is not a common/frequent occurrence within the industry. Some uncertainty remains, however, modelling of the potential extent of the plume and the estimated potential accumulation of coarse particles on the seabed from this discharge has been completed, allowing for reduction on the uncertainty on the potential impacts from this planned release on the marine environment during Campaign #1 activities. The environmental consequence for the impacts resulting from the planned discharges of solids have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regard to the discharge of solids. Hence, Esso believes **Decision Context B** should apply

Table 6-54 Good practice controls

Good practice	Adopted	Control	Rationale
Use of least environmentally hazardous chemical (garnet) for cutting operations.	Adopted – IMP11-CM1	*Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	This practice requires that new chemicals, including those to be used for cutting activities, must be approved prior to use. This practice assesses chemicals that have the potential to be discharged to the environment to ensure the lowest toxicity, most biodegradable and least accumulative chemicals are selected which meet the technical requirements of the application.

Table 6-55 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
Capture of solids – ilmenite.	Capture of solids would prevent the release to the marine environment and would allow to manage this material through onshore disposal.	Not feasible. Ilmenite material that could be released during removal operations is limited to one leg only at KFA and one leg only at KFB. To enable the option of capturing ilmenite from these two legs, complex and extensive additional detailed design, engineering and planning would be required. As a reference, a potential alternative would contemplate a drilling system with air lift, which would be required to be installed at each facility (KFA and KFB). The installation of a drilling riser assembly would require cellar and main deck clearance as well as the opening of the main leg side walls. This is a complex technical operation, as the configuration of the strut associated strengthening has a grouted collar on the leg at both KFA and KFB which obstructs the direct line of entry and access. As a result, a modification of these legs would be required. Any modification or opening of the leg modifies the primary framing of this structure and therefore would require engineered solution with localised strengthening and reinstatement to ensure the facilities can be safely removed. Results from the assessment of the potential impact from release of ilmenite into the marine environment indicated impact is not significant, as the volume that could be discharged is small, restricted only to one leg at KFA and one leg at KFB, and the reach would be limited to the immediate vicinity of the platform, with inconsequential effects on sensitive receptors and at ecosystemic or population levels. The cost and technical effort associated with implementation of complex operations to enable this control is considered to be grossly disproportionate to the environmental benefit that would be achieved. Implementation of this control would also introduce safety risks as it would incorporate a new risk to the integrity of the facility for removal purposes.	Not adopted
Capture of solids – Garnet.	Capture of solids would prevent the release to the marine environment and would allow to manage this material through	Not feasible. For Campaign #1 operations, the preferred method for cutting jacket legs that are planned to be removed from as close as practicable to the seabed (refer to Sections 1.2 and 2.7.5 and 2.10.3 of this EP) is the option of internal cutting using the water jetting technique. For this technique, garnet is expected to be used as an aid material to the water	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
	onshore disposal.	jetting process. The adoption of internal water jet cutting is planned to allow for cut locations beneath or as close as possible to the seabed. This is the preferred option to be implemented, as it eliminates any requirement of seabed displacement that would be needed if the external cutting technique would be implemented for cutting of the jacket legs at seabed level. As the internal cuts will be at a location of the jacket beneath the seabed, the garnet released is expected to be mostly contained beneath the seabed within the localized footprint of the jacket leg. Attempts to collect any disbursed garnet may further disturb and displace seabed sediments. For cutting of jackets that are planned above the seabed (refer to Sections 1.2 and 2.7.5 and 2.10.3 of this EP), the default technique will be external cutting method. The tool/equipment to be used for external cutting will be assessed on a case-by-case basis but could include options such as a DWCM. For external cutting, use of garnet will not be required. It is assessed that capture of garnet released during internal cutting of jacket legs is not practical, and the potential impact from this release is considered inconsequential.	

6.11.5 Demonstration of acceptability

Table 6-56 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. Precautionary principle has been applied, and studies have been undertaken where knowledge gaps were identified (plume dispersion modelling). This knowledge has been applied during the assessment of environmental impacts from planned discharges – solids. The activities were evaluated as having the potential to result in a **Consequence**

Factor	Demonstration criteria	Criteria met	Rationale
			Level IV thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned discharge of solids has concluded that environmental impacts will be short term and localised in nature, with inconsequential effects from an ecosystemic and species population perspective. Hence any impacts resulting from discharge of solids will not impact the health, diversity and productivity of the environment such that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	No environmental legislation was deemed relevant to this particular impact. Chronic chemical pollution is a recognised threat to the species in the following conservation management plans and advice. These discharges are not chronic and will quickly dissipate. It is also noted that no conservation/management actions are specified in relation to chemical discharges. • CMPBW. • NRPSRW. • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a). • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*

Factor	Demonstration criteria	Criteria met	Rationale
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to the discharge of solids resulting from marine growth removal, internal pile legs deposits, or swarf from SPJ cutting activities, but outcome from assessment of potential impacts is consistent with Esso's Corporate Environmental Expectations, in particular to *"operating our business in a responsible and sustainable manner, inclusive of working to minimise environmental impacts from our operations"*.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Relevant persons asked questions regarding potential discharges from infrastructure during removal activities. These were discussed and answered during consultations for this EP.

6.11.6 EPOs, control measures, EPSs and measurement criteria

Table 6-57 EPOs, control measures, EPSs and measurement criteria – Solid discharges

EPO	Control measure	EPS	Measurement criteria
IMP11-EPO1: Impacts from planned discharges - solids are limited to localised, temporary changes in water and habitat quality.	IMP11-CM1: Garnet to be used during cutting activities evaluated as acceptable for discharge.	IMP11-EPS1.1: All garnet used during cutting activities will be evaluated prior to its use as acceptable in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	IMP11-MC1.1.1: Documentation in accordance with the *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) (refer to Section 8.11.2.1) confirms proposed garnet has been evaluated as acceptable prior to use and discharge.

6.11.7 Residual consequence assessment

Based on the assessment described above and with the control in place, the residual potential impact has been determined as:

- **Consequence Level IV**.

6.12 Planned discharge – Marine growth

6.12.1 Sources of marine growth discharges

ROV surveys of the SPJs have shown all of the submerged areas of the jackets and monopods to be extensively encrusted with marine growth. The marine growth is comprised of a variety of soft and hard bodied organisms, including anemones, sponges, soft corals, barnacles and algae. Table 6-58 includes conservative estimates of the marine growth that may remain on structures at the time of lifting - based on planned cut depth and surface area.

Table 6-58 Marine growth estimates

Facility	HLA*	KFA*	KFB*	MKA	WKF	CBA	FLA	FTA	BMA	WTA	PCA	DPA
Estimated mass of marine growth (MT)	155	119	118	159	127	233	157	227	197	84	26	26

* including support strut

Based on anecdotal evidence from other decommissioning campaigns undertaken by the contractor, an estimated 10 - 20% of this material may be released during initial removal of the jackets from the sea, and during subsequent transport on vessels, with the majority loss during the lifting conducted by the Pioneering Spirit HLV and sea fastening operations at the removal locations.

Marine growth will be discharged as a result of the following activities:

- narrow bands of marine growth will be removed from where jacket or strut cuts will be made to enable lifting
    - where subsea cutting or drilling will be performed or where the jacket or struts will be supported by the JLS
    - in areas around the cutting elevation of both jacket legs, pipe work and appurtenances to allow installation of cutting too
    - at locations where subsea rigging may be attached
    - in locations where detailed inspection is required or locations which require additional attention after the visual inspections
- during transportation and transfer of jackets, struts or monopods where marine growth will drop off the structures suspended over the water or fall on the deck of the HLV, HTV or barge and cannot be collected safely
    - marine growth which falls on the deck of the HLV during transportation of structures or transfer operations which is accessible will be aggregated on the deck and returned to the sea at a location as close as practicable to a removal location. The exception to this is marine growth sourced from the PCA/DPA monopods, which due to the different marine growth assemblages on these structures, will only be returned to the PCA/DPA location. Where this is not achievable PCA/DPA marine growth will be taken onshore for disposal
    - marine growth that collects on the HTV or barge once the jacket, strut or monopod is transferred will be collected, where safe to do so, and taken onshore for disposal
    - residual marine growth that cannot be collected will be washed off the deck of the HTV, barges and HLVs to ensure a safe working environment for vessel crew
- a waverider buoy (one or multiple) may also be installed within the OA to provide real time field measurement of wave height and wave direction to support decommissioning activities. At the completion of operations, some marine growth on the tether would be expected which would need to be cleaned off at the time of recovery.

The targeted removal of marine growth from jacket cutting/inspection locations will be conducted by an ROV utilising an ROV-held flexiclean tool or marine growth removal tool, or via high pressure water jetting. In addition, marine growth could also be released from inside the skirt piles that will require internal cleaning for removal

purposes. An airlift tool will be used to displace marine growth both to the surrounding environment and deep within the piles as particulates settle. The estimate is approximately 50% of marine growth removed in this matter will disperse to sea and 50% will settle deep within the pile itself, being effectively captured.

Topsides will be separated from the supporting jackets above the waterline. As a result, marine growth will not be present on the topsides - the impact assessment has therefore focused on the removal preparation, lifting, transit and transfer of the monopods and jacket sections.

Once a jacket has been lifted using the JLS on the HLV, jackets are tilted to an incline with the jacket structures raked towards the vessel deck. This results in an amount of structure 'overhang', where the lower portion of the jacket extends beyond the stern of the HLV (refer to Figure 2-36). Marine growth on these sections of the jacket will be released to the marine environment as it is not technically feasible to contain this during transit.

During barge or HTV transport, jackets will be stood longitudinally while monopods will be fastened horizontally on the deck. Jackets are planned to be transported on a barge or HTV in a way that will minimise any over hang of the structures with marine growth over the water (refer to Figure 6-4). Mobile organisms are predicted to depart the structures voluntarily within 24 hours of removal from water, while sessile organisms will 'slough off' due to gravity, vibrations, abrasion, and wind and wave action. The rate of loss of sessile organisms will be greatest during and shortly following (24 hours) lifting and removal but is likely to continue at reduced rates for several days (Biofouling Solutions, 2026a), hence marine growth falling from the structures could occur anywhere in the OA during transit or transfer operations.

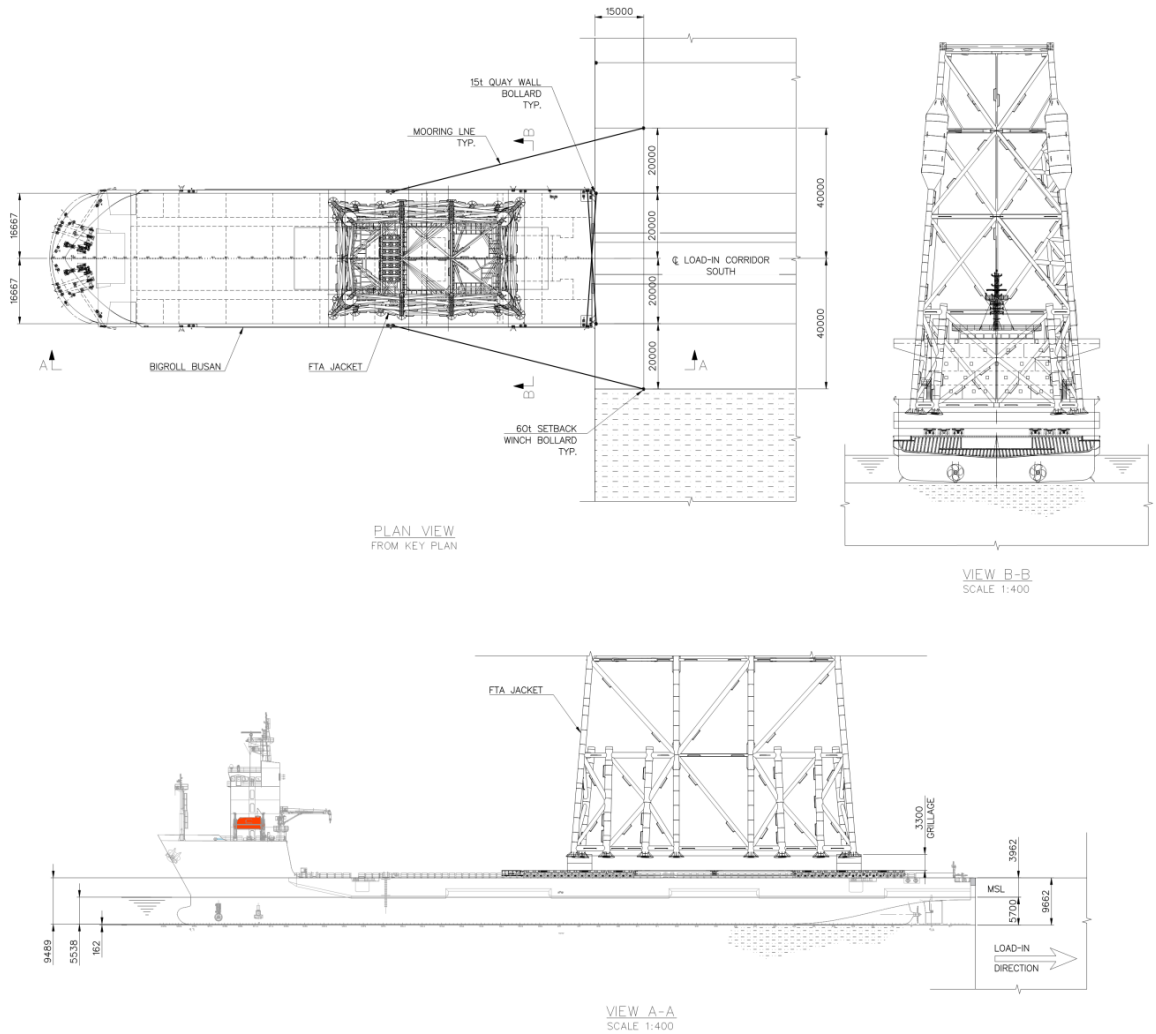

Figure 6-4 Indicative placement of jacket sections on a HTV

International standard industry practice is to dispose of marine growth dropped on vessel decks direct to the environment, in order to maintain a safe working environment for crew. Some areas of the HLV will not be

accessible during lifting, transport and transfer operations and there is risk of dropped objects such as the marine growth sloughing off the removed structures. Hence, where aggregation on deck is not practicable, residual marine growth will be washed off the vessel deck into the sea, to ensure vessel operations can continue.

Where aggregation of marine growth that falls on the deck of the HLV is safe and practicable, this will be aggregated on the deck and then returned to the sea as close as practicable to a removal location (i.e. back to a similar environment to where it originated). Given the different marine biota assemblages on the PCA and DPA monotower structures, marine growth from these locations will either be returned to the PCA/DPA locations, or where this is not practicable, transferred onshore for disposal. No marine growth originating from other facilities will be returned to the PCA/DPA locations.

DCCEEW provided feedback during relevant person consultations as to the applicability of the *Environment Protection (Sea Dumping) Act 1981* (Cth) to the loss of marine growth during Campaign #1 activities. As a result of this the following has been incorporated into this impact assessment:

- marine growth will not be transferred from a primary vessel transporting a jacket structure to a different vessel and allowed to fall or be pushed off – as this may constitute dumping under the *Environment Protection (Sea Dumping) Act 1981* (Cth) and may be an offence if a Sea Dumping Permit is not in place. This has been incorporated into the ALARP assessment described in Section 6.12.4.
- Where possible efforts should be made for the marine growth to be left at the site where the jacket was removed from. This has been incorporated into the ALARP assessment described in Section 6.12.4.

The potential risk of the spread of range expanding native species or IMS as a result of the discharge of marine growth within the OA is assessed in Section 7.3 and Section 7.4 respectively.

6.12.2 Impacts of planned discharge of marine growth

The potential impacts of the discharge of marine growth on receptors are:

- change in water quality
- change in habitat.

6.12.3 Impact assessment

6.12.3.1 Change in water quality

During removal preparation activities, lifting or discharge of collected marine growth near the facility locations, marine growth dislodged from the structures will fall to the seabed close to the structures' original location and may survive or become food for other marine life in the area. A bulk release of marine growth may potentially cause the water quality in the vicinity of the release to deteriorate, initiated by the breakdown products of the dead marine growth (Oil and Gas UK, 2013). However due to the high energy environment, marine growth would disperse rapidly. It is considered that the majority of the loss of marine growth from the structures following removal from the sea will occur while the HLV is at the removal locations. Removal preparation involving the discharge of marine growth to enable cutting and lifting will also occur at these locations. The discharge of marine growth during transit and transfer locations will be much less, hence impacts will be negligible. During removal preparation and lifting of the structures, the marine growth is likely to disperse or fall through the water column and settle on the seabed quickly. Any changes in water quality as a result of marine growth being dislodged or discharged at the removal locations will be highly localised and temporary and hence impacts have been assessed as:

- **Consequence Level IV**.

The discharge of marine growth during transit and transfer locations will be much less, hence impacts to water quality in the remainder of the OA are expected to be inconsequential and have also been assessed as:

- **Consequence Level IV**.

6.12.3.2 Change in habitat

Deposited marine growth would initially lie on the seabed, but organic material would be broken down which could cause localised nutrient enrichment, biological oxygen demand increase and proliferation of the types of organisms involved in the breakdown of organic material on the seabed (Oil and Gas UK, 2013). Once the marine growth is broken down, it is considered that only shells and other hard structures relating to the organisms in the marine growth would remain. This may lead to short term changes to the benthic habitat in the area in which the

marine growth was discharged. If marine biota was alive and discharged to an area where it could successfully colonise, this may lead to changes to the habitat in place at that location – noting that the risk of species that are considered to be invasive or have caused environmental impacts as a result of their expansion of range are assessed in Sections 7.4 and 7.3 respectively.

The marine growth on the jacket structures is dominated by jewel anemones (*Corynactis australis*), which is a native species. The findings of decommissioning marine ecology surveys suggest that >95% of the upper 55m section of the jackets are occupied by the jewel anemone and various forms of marine sponges with very little, if any, unoccupied space. Jewel anemones are encrusting species that are not known from any other offshore reef environments in this region, with reports of its occurrence typically associated with inshore rocky reefs and other artificial structures such as mussel farms (McLean, et al., 2022). This particular species has a broad distribution in south-eastern Australia including a recorded observation of this species at Wilsons Promontory (Australian Museum, 2020). Operational observations suggests that desiccation and mortality of jewel anemone may reasonably occur within 48 hours of the jacket removal. A literature review identified a related species, *Tubastraea occidentalis*, whose morphology provides higher levels of protection than the jewel anemone requires at least four days exposure for 100% mortality (Biofouling Solutions, 2026a)

6.12.3.2.1 REMOVAL LOCATIONS

It is considered that the majority of the loss of the marine growth from the structures following removal from the sea will occur while the HLV is at the removal locations, due to the physical disruption caused by cutting, lifting and fastening to the HLV. During lifting at the removal locations, marine organisms dislodged from the structures will fall to the seabed close to the structures' original location and will either survive in that location or become food for other marine life in the area. Mobile organisms (e.g. fish, crustaceans) will be dislodged and return to the sea close to the structure's original location, while sessile encrusting organisms may be retained on the structure. At this time, organisms re-entering the sea are likely to be viable and, depending on reproductive state, some may release propagules as a response to physical stress (Biofouling Solutions, 2026a).

Given the marine organisms are being returned to the area in which they have been taken from and will either survive or biodegrade naturally in the marine environment if conditions are not suitable for their survival, removal operations at facility locations are expected to result in inconsequential changes to the habitats at these locations. As a result, the consequence level for impacts to habitat as a result of the planned discharge of marine growth at removal locations is assessed as:

- **Consequence Level IV**.

6.12.3.2.2 TRANSIT AND TRANSFER OPERATIONS

During transit from the removal locations to a transfer area, the marine growth on the structures which is now out of the water will progressively desiccate and some will fall off the structures or to the deck of the HLV where it will be discharged to the sea when it cannot be collected safely. Transit times for jackets within the OA will vary between locations and sea state conditions experienced at the time however transits are expected to take between two and ten days from the structures being lifted from the water to the HTV or barges exiting the OA for onward transport to the ORC (Biofouling Solutions, 2026a). The removal of the platforms is envisaged to occur during spring and summer, when temperatures are warm and sea breezes are frequent. This is beneficial in that both can accelerate rates of desiccation of biofouling organisms and reduce survival periods for marine growth (Biofouling Solutions, 2026a), hence reducing the likelihood that marine growth will enter the water alive.

The discharge of marine growth during transit will be limited to those amounts that fall off the structures as they desiccate and are subject to wind and wave action. The discharge of marine growth during transit is expected to be spread over a wide area as the HLV travels and will be dispersed in the marine environment. It is considered unlikely this discharged marine growth will have any adverse impacts on the marine environment in the OA due to this wide dispersal. The lack of suitable hard substrate habitat in the OA similar to that of their original habitat at the jacket structures indicates survival is unlikely and they will biodegrade in the marine environment.

Although the majority of marine growth is likely to desiccate and die between the time of removal and transfer to a HTV or barge, it is possible that living marine growth could also be dislodged during transfer operations. Given that the marine growth present on the jacket structures has a preference for hard substrate environments, as shown by its colonisation of the jacket structures, it is unlikely that dislodged marine growth will colonise areas and change the existing habitat if it falls into the sea in areas where hard substrate is not present.

The vast majority of the OA is characterised as sandy flats/bare substrate, with very limited hard substrate habitat. Areas of hard substrate and rocky reefs which fall within the definition of the 'shelf rocky reefs and hard substrate KEF (refer to Section 3.3) are known to be present at patchy outcrops associated with the South-east Reef (adjacent to FTA, CBA and HLA) and in the east and west areas within the proposed primary transfer area. The transfer areas are depicted in Figure 2-46, while the key habitat areas in the OA are depicted in Figure 6-5. The locations of the KEFs within the OA are shown in Figure 3-7.

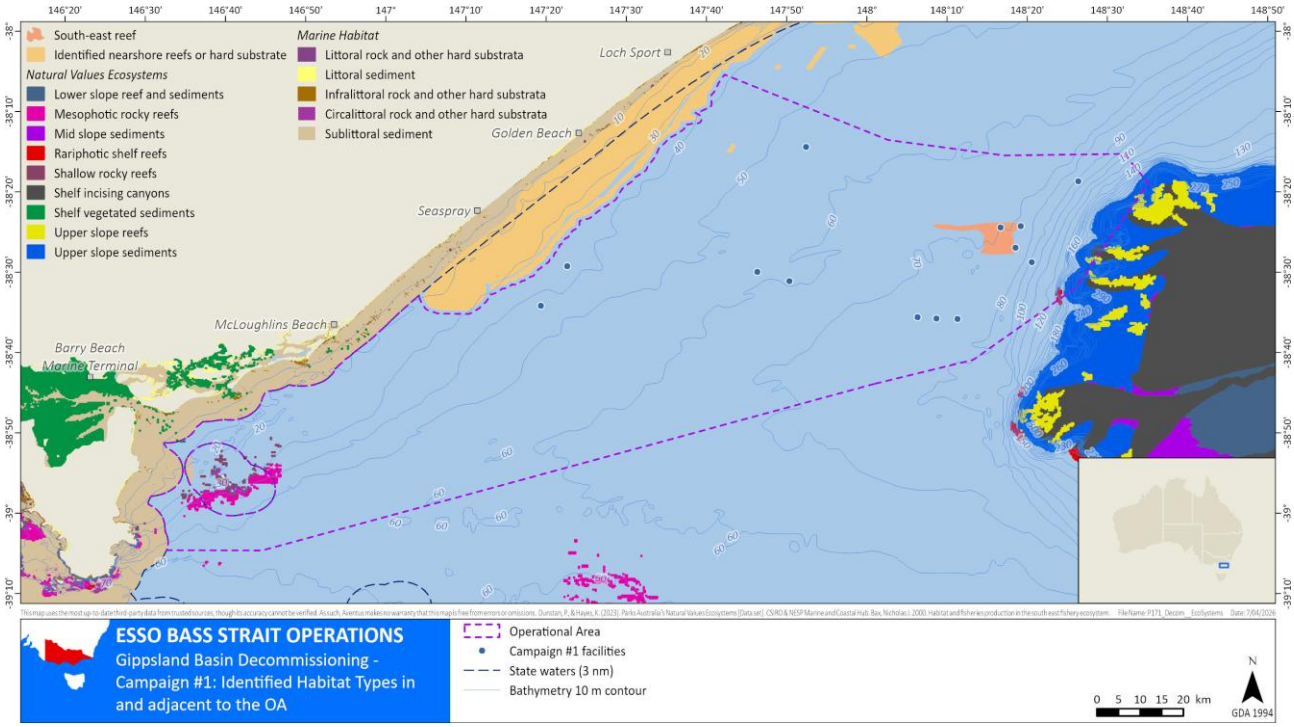

Figure 6-5 Identified habitat types in and adjacent to the OA

Key areas of hard substrate which are outside the OA, but adjacent to the boundary include:

- near shore reefs to the east of Corner Inlet, the location and extent of which was derived from the Statewide Marine Habitat Map 2023 mapping dataset developed by DEECA (Institute for Marine and Antarctic Studies, 2023) which provides information on broad habitat complexes and knowledge of the ecological diversity across Victoria's State waters.
- around Wilsons Promontory, outside the southwestern part of the OA.

Given the presence of hard substrate habitat and rocky reef KEFs within the primary transfer area, the potential consequence of marine growth discharge which may result in a change in habitat during transit and at transfer locations has been assessed as:

- **Consequence Level III**.

6.12.4 Demonstration of As Low As Reasonably Practicable

Table 6-59 Decision Context and justification

Decision Context
There is some uncertainty as to the extent of impacts to existing habitats as a result of the discharge of marine growth during transit and at the transfer locations given this activity is an infrequent or non-standard activity. The environmental consequence for the impacts resulting from the planned discharge of marine growth have been assessed as **Consequence Level III** or **Consequence Level IV**. Stakeholder interest has been noted regarding the discharge of marine growth as a result of removal activities. Hence, Esso believes **Decision Context B** should apply.

Table 6-60 Good practice controls

Good practice	Adopted	Control	Rationale
None identified			

Table 6-61 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
Bulk removal of all marine growth at location of current platform.	Removed marine growth remains at original location.	Removal of all marine growth at the platform locations is not considered viable due to restricted access to structural members which are internally positioned within each jacket; difficulty working within the splash zone and other more complex safety considerations associated with extensive marine growth removal based on the nature and scale of the entire upper jacket sections.	Not adopted
Treatment of marine growth with biocides.	Marine growth mortality to eliminate potential translocation of living specimens.	Treatment can only be facilitated once jackets are lifted. The jacket size and lack of access make the application of biocide unfeasible. Application also has safety challenges due to the size of the jackets.	Not adopted
Suspension of jackets out of water at removal location for prolonged periods of time.	Dried marine growth dies and falls off at original location.	Safe lifting of a live load such as this will be completed under a strict weather window and requires jackets to remain suspended for the shortest achievable time. Remaining offshore with a load on slings is not an acceptable safe practice globally.	Not adopted
Collection of marine growth that falls on the HLV vessel deck and transfer onshore for appropriate disposal.	Reduces the amount of marine growth discharged to the marine environment.	Marine growth that falls to the deck of the HLV while jacket structures are being transported or transferred to a HTV or barge will be aggregated on deck where it is safe and practicable to do so. This marine growth will be returned to the sea as close as practicable to the next removal location (refer to Table 6-63). Where the marine growth can be returned to a similar location to where it came from, impacts to habitat within the OA are not anticipated. The IMS study undertaken and discussed in Section 7.4 also concluded that the likelihood of any IMS being present on the jacket structures is Likelihood Category C (unlikely) or Likelihood Category D (very unlikely). Hence the environmental benefits of transferring all marine growth which falls on the deck onshore for disposal is not considered to outweigh the cost and potential onshore impacts such as nuisance odour and the need to landfill or compost the marine	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
		growth which would arise as a result of onshore storage and disposal.	
Where possible efforts should be made for the marine growth to be left at the site where the jacket was removed from.	This feedback was provided by DCCEEW Sea Dumping team during relevant person consultation for this EP and has been considered as part of the ALARP assessment.	It is considered the majority of marine growth loss to sea will occur when the jacket is cut and lifted, hence will remain at the location where the jacket was removed from. Returning marine growth aggregated on the deck of the HLV to as close as practicable to the actual location where the jacket was removed from was considered as part of this ALARP assessment. However, this was not adopted for the following reasons: • returning to the same removal location to discharge the aggregated marine growth is not practical given the limited HLV execution window in which the Campaign #1 activities must be undertaken and may result in the entirely of the scope not being completed • evidence from pre decommissioning surveys that the marine biota present on the Campaign #1 jacket sections in comparable water depths is similar • the likelihood of the presence of IMS on the jacket structures being assessed as Likelihood Category C (unlikely) or Likelihood Category D (very unlikely) (refer to Section 7.4.3.2). As a result, the environmental benefits of the return of aggregated marine growth to the location where it was removed from are not considered to outweigh the cost and logistical impacts of implementing this control. Aggregated marine growth will instead be returned to the sea as close as practicable to the next jacket removal location. The exception to this is marine growth from the PCA/DPA locations, where the marine biota assemblages have been observed to be different to those seen at other jacket facilities and these facilities are closer to nearshore reef areas. Marine growth sourced from the PCA/DPA locations will either be returned to the PCA/DPA removal locations, or if this is not possible, taken onshore for disposal. No marine originating from other facilities will be returned to the PCA/DPA locations.	Partially adopted – IMP12-CM1

Control measures	Benefit	Cost/feasibility	Adopted
Marine growth will not be transferred from a primary vessel transporting a jacket structure to a different vessel and allowed to fall or be pushed off.	This feedback was provided by DCCEEW Sea Dumping team during relevant person consultation for this EP and has been considered as part of the ALARP assessment.	Marine growth that falls to the deck of the HLV while jacket structures are being transported will be aggregated on deck where it is safe and practicable to do so. This aggregated marine growth will not be transferred to a different vessel (i.e. barge, HTV or supply vessel) and then allowed to fall or be pushed off. The aggregated marine growth will be returned to the sea as close as practicable to the next jacket removal location from the HLV (refer to IMP12-CM1). The exception to this is marine growth from the PCA/DPA locations, where the marine biota assemblages have been observed to be different to those seen at other jacket facilities and these facilities are closer to nearshore reef areas. Marine growth sourced from the PCA/DPA locations will either be returned to the PCA/DPA removal locations, or if this is not possible, taken onshore for disposal.	Adopted – IMP12-CM2
Avoidance of Key Ecological Features - i.e. hard substrate and shelf rocky reefs as defined in the South-east marine regional profile (DoE, 2015a) which are present in the OA - during transit activities	Minimises the risk of released marine growth establishing and impacting habitat values associated with the KEF.	KEFs located in the OA are depicted in Figure 3-7. There are two KEFs that occur in the OA: • the Upwelling East of Eden which is located to the far east of the OA. The location of this feature in relation to the facilities to be removed means it is very unlikely transit activities will occur within or near this KEF. • a KEF referred to as 'shelf rocky reefs and hard substrate' which is referenced in the South-east marine regional profile (DoE, 2015a), but is not mapped. Locations where hard substrate and rocky reefs which fall within the definition of this KEF are depicted in Figure 3-7 based on literature, publicly available data and Esso offshore environmental survey results. No other KEFs are present in the OA. The FTA SPJ is located within the area known as South-east reef (which meets the definition of the shelf rocky reefs/hard substrate KEF) while CBA and HLA are located immediately adjacent. Avoidance of this feature during transit of the FTA jacket is not feasible. Avoiding transit over South-east reef is also	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
		not practicable for CBA and HLA as this would result in the need for the HLV to transit via a protracted, indirect route to the transfer location with a jacket onboard, hence increasing potential safety risks. Marine growth released during transit within the South-east reef is likely to be alive, given the short timeframe from removal of the jacket and transit through this feature. However given the proximity of the jackets to this feature (in the case of FTA within the mapped extent), it is unlikely this will result in any appreciable impacts to the habitat within the KEF, as the species likely already exist at this location, or if conditions at the release duration are significantly different to those provided by the jacket structures, will be unable to survive and establish. While known areas which meet the definition of hard substrate and rocky reefs KEF are depicted in Figure 3-7, other areas of hard substrate/rocky which have not been mapped may also be present within the OA. The discharge of marine growth during transit to the transfer area is expected to be spread over a wide area as the HLV travels and will be widely dispersed in the marine environment. Establishment of any species present within the marine growth to an extent that would result in impacts to the values of unmapped areas of hard substrate is considered very unlikely, as this would require a number of conditions to be met, with each successive stage becoming more unlikely. Jacket sections will either be fully inboard on a HTV or barge longitudinally for transport from the transfer location to the boundary of the OA (and onward to BBMT) – refer to IMP12-CM3. This minimises the loss of marine growth to the environment during this activity. Avoidance of all hard substrate areas which meet the definition of the shelf rocky reefs and hard substrates KEF in the OA would require an extensive exercise of seabed surveying across the OA to identify and map all areas of hard substrate for inclusion into vessel systems and/or the use of 'real time' methods during the execution campaign to identify hard substrate as the HLV is in transit. As environmental impacts to habitats have been assessed as either consequence level III (potential short term, minor) or consequence	

Control measures	Benefit	Cost/feasibility	Adopted
		level IV (inconsequential or no impact),the avoidance of KEFs (in particular the shelf rocky reef/hard substrate KEF) during transit activities undertaken within the OA is not considered to result in a reduction to any potential environmental impacts that would outweigh the cost, practicality and schedule implications resulting from implementing this control. Hence it has not been adopted.	
Avoidance of Key Ecological Features - i.e. hard substrate and shelf rocky reefs as defined in the South-east marine regional profile (DoE, 2015a) which are present in the OA - during transfer operations	Minimises the chance of released marine growth establishing in other areas of the OA.	The habitat types in the OA (including the primary and secondary transfer areas) have been mapped in Figure 6-5. This mapping indicates there is no seagrass habitat in the OA. Mapped areas of hard substrate and rocky reefs which meet the definition of the 'hard substrate and rocky reef are present within the proposed primary transfer area (refer to Figure 6-5). Mobile species present in the marine growth on the jacket structures is predicted to depart or drop off within 1 day of removal from the sea (Biofouling Solutions, 2026a), hence they are very unlikely to still be present on jacket structures when they arrive at the primary transfer location. The rate of release of marine growth is expected to be highest during removal activities at the facility locations and then decrease during transit and transfer. The marine growth will be exposed to air for periods between 2 and 10 days prior to their departure from the transfer area and hence organisms such as jewel anemones, encrusting sponges and colonial ascidians will have desiccated considerably and may form a leathery layer from which gradual but highly reduced release will occur (Biofouling Solutions, 2026a). As detailed in Section 7.3 and 7.4, the likelihood of the spread of native species and IMS within the OA via biofouling (release of marine growth) as a result of removal, transit and transfer activities was assessed as 'very highly unlikely' for all of the IMS included in the assessment, 'unlikely' for the jewel anemone and 'very highly unlikely' for the long spined sea urchin (Biofouling Solutions, 2026a). The study undertaken to assess these likelihoods included consideration of the presence of hard substrate areas in and adjacent to the OA.	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
		Given the reduced likelihood of the marine growth being present (mobile species) or viable (sessile species) by the time the jacket structures arrive at the transfer location, a potential change to the habitats in this area as a result of marine growth discharge is considered unlikely. Environmental impacts to habitats (including KEFs) at the primary transfer area have been assessed as consequence level III (potential short term, minor) Avoidance of these areas will restrict the HLV from selecting the most appropriate location based on the conditions, to undertake transfers safely and efficiently. The HLV size, coupled with the HTV/barge and support vessel spread present during transfer operations makes avoidance of all hard substrate (mapped or unmapped)in the primary transfer area impractical. In order to avoid the mapped areas of hard substrate located in the east and west of the primary transfer area transfer (refer to Figure 3-7) may (depending on weather conditions) need to occur closer to sensitive environments in and around Corner Inlet (refer to Figure 2-46) in preference to the southern end of the primary transfer area which is more exposed. Any reduction to potential environmental impacts as a result of this potential control are not considered to outweigh the cost, practicality and schedule implications resulting from implementing this control, hence it has not been adopted.	
Minimise the amount of marine growth falling off during **removal** of structures	Parks Victoria suggested this potential mitigation measure during relevant person consultations for this EP. While noting this was suggested in the context of potential mitigation measures for the introduction or spread of IMS, this is considered to be equally applicable to the planned discharge of marine growth.	It is considered the majority of marine growth loss to sea will occur when the jacket is cut and lifted, hence will remain at the location where the jacket was removed from. Given the size of the jacket sections to be cut and lifted, potential actions to contain or minimise the amount of marine growth lost during activities at the removal locations are not practicable. Additionally, impacts to water or habitat quality in the removal locations as a result of the planned discharge of marine growth have been assessed as Consequence Level IV (inconsequential or no adverse effects).	Not adopted
Minimise the amount of marine growth falling off during **transport** of structures		<u>During transport of structures from removal locations to the transfer location:</u> The structures will be transported from the removal locations to the transfer location either on the deck of the HLV (if the 5000	Adopted IMP12-CM1

Control measures	Benefit	Cost/feasibility	Adopted
		tonne crane is used to lift the jacket sections) or on the HLV JLS (refer to Section 2.8.1and 2.8.2). Minimisation of marine growth falling to the sea from the jacket sections which will be transported on the JLS and overhang the vessel is not technically feasible for the reasons outlined in Section 6.12.1. However minimisation of the amount of marine growth released to the marine environment along the transport route will be undertaken by aggregating any fallen marine growth on the HLV deck where this is safe and practicable to do so, and returning this to the sea at the next removal location (consistent with control measure IMP12-CM1 in Table 6-63). During transport of structures from the OA to the onshore reception centre at BBMT: As depicted in Figure 6-4, during transport from the sheltered water transfer location to the edge of the OA (then onward to BBMT) via a HTV (or barges which are not shown in Figure 6-4), jacket sections will be inboarded or loaded longitudinally. This alignment minimises the 'overhang' of the jacket sections from the side of the vessels, hence limiting the loss of marine growth to the environment during transport from the transfer location. Marine growth that collects on the deck of the barges/HTV during transit from the transfer area will be collected, where safe to do so, and taken onshore for composting or disposal in accordance with EPA Victoria regulations. In all cases during transport, residual marine growth that cannot be collected will be washed off the deck of the HTV, barges and HLVs to ensure a safe working environment for vessel crew.	IMP12-CM3 IMP12-CM4

6.12.5 Demonstration of acceptability

Table 6-62 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic,

Factor	Demonstration criteria	Criteria met	Rationale
			environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level III** or **Consequence Level IV** impact thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned discharge of marine growth has concluded that environmental impacts will be short term and localised in nature, with inconsequential effects from an ecosystemic and species population perspective. Hence any impacts resulting from discharge of marine growth will not impact the health, diversity and productivity of the environment such that future generations will be impacted
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	Aspects relating to the applicability of the *Environment Protection (Sea Dumping) Act 1981* (Cth) have been addressed.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to the discharge of marine growth, but outcome from assessment of potential impacts is consistent with Esso's Corporate Environmental Expectations, in particular to *"operating our business in a responsible and sustainable manner, inclusive of working to minimise*

Factor	Demonstration criteria	Criteria met	Rationale
			environmental impacts from our operations".
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Feedback from DCCEEW and Parks Victoria has informed the EPOs, EPSs and measurement criteria included in Table 6-63.

6.12.6 EPOs, control measures, EPSs and measurement criteria

Table 6-63 EPOs, control measures, EPSs and measurement criteria – Discharge of marine growth

EPO	Control measure	EPS	Measurement criteria
IMP12-EPO1: Impacts as a result of the planned discharge of marine growth are limited to localised, temporary changes in water quality and habitat.	IMP12-CM1: Marine growth that falls during transport aboard the HLV will be returned to the sea as close as practicable to the next jacket removal location.	IMP12-EPS1.1: Marine growth that falls on the HLV vessel deck in accessible areas will be aggregated and held onboard prior to returning to sea as close as practicable to the next removal location. Marine growth originating from the PCA/DPA monopods will only be returned to the PCA/DPA removal location or will be transferred onshore for disposal. No marine growth originating from other facilities will be returned to the PCA/DPA locations.	IMP12-MC1.1.1: Standard Operating Procedure as referenced within Allseas EMP and PCA and DPA lift plan. IMP12-MC1.1.2: Marine growth management/discharge log.
	IMP12-CM2: Marine growth will not be transferred from a primary vessel transporting a jacket structure to a different vessel and allowed to fall or be pushed off.	IMP12-EPS2.1: Aggregated marine growth will not be transferred from a primary vessel to a different vessel and then be allowed to fall or be pushed off – except when this is unavoidable as part of normal safe operation of the vessel.	IMP12-MC2.1.1: Marine growth management/discharge log.
	IMP12-CM3: Jacket structures will either	IMP12-EPS3.1: Inboarding or longitudinal placement of	IMP12-MC3.1.1: Transfer procedures include the

EPO	Control measure	EPS	Measurement criteria
	be fully inboard or placed onto HTVs or barges longitudinally (lengthways) to ensure there is minimal overhang of the structures outside of the vessel.	removed jacket sections on HTVs/barges has been undertaken to minimise the potential for marine growth to drop to the marine environment during transit from the transfer location to BBMT.	requirement for jacket structures to be placed longitudinally. IMP12-MC3.1.2: Jacket grillage on HTVs/barges installed (as built) for inboarding or longitudinal placement.
	IMP12-CM4: Marine growth that falls on HTV/barges during transit from the transfer area will be collected, where safe to do so, and taken onshore.	IMP12-EPS4.1: Marine growth that falls on the deck of the barges/HTV during transit from the transfer area has been collected, where safe to do so, and taken onshore for composting or disposal in accordance with EPA Victoria regulations. Residual marine growth that cannot be collected will be washed off the deck to ensure a safe working environment for vessel crew.	IMP12 -MC4.1.1: Marine growth management/discharge log. IMP12-MC4.1.2: Waste disposal records demonstrate waste was transferred onshore and disposed of in accordance with regulatory requirements.

6.12.7 Residual consequence assessment

Based on the assessment described above, the residual potential consequence has been determined as follows:

- change in water quality or habitat at removal locations - **Consequence Level IV**
- change in water quality at transit and transfer locations - **Consequence Level IV**
- change in habitat at transit and transfer locations – **Consequence Level III.**

6.13 Sound emissions

6.13.1 Sources of sound emissions

Sound emissions during decommissioning activities are mostly associated with vessel operations. Table 6-64 summarises the sources of sound that will be generated from Campaign #1 activities.

Table 6-64 Summary of sound sources

Sound source	Type of sound	Duration of operations
Pioneering Spirit.	Continuous: • propulsion, thrusters/operation of DP systems, onboard machinery.	Approximate duration of operations for this vessel is estimated to be five months.
Support vessels (e.g. *Fortitude* or similar CSV).	Continuous: • propulsion, DP thrusters, onboard machinery.	Approximate duration of operations for this vessel is estimated to be <12 months.

Sound source	Type of sound	Duration of operations
Support vessels – Tugs or HTVs.	Continuous: • propulsion, DP thrusters, onboard machinery.	Approximate duration of operations for these vessels is estimated to be five months.
Support vessels – others (i.e. supply vessels).	Continuous: • propulsion, DP thrusters, onboard machinery.	Operation of other support vessels will be on an intermittent basis and will be dependent on specific requirements from Campaign #1 vessels that are conducting removal operations.
ROV.	Continuous: • small motor and propeller.	ROVs are expected to perform a variety of activities. Duration of operation is bound to the specific type of activity. Estimated duration ranges between one and eight hours.
Cutting tools.	Continuous: • operation of tools.	Subsea cutting of structures during decommissioning activities will be required to allow execution of operations such as lifting/removal of jacket legs, struts, pipeline risers, umbilicals and flexibles. Options to complete subsea cutting may include but are not limited to shear or DWCM tools. Cutting tools will be operated either via a ROV or via a deck mounted hydraulic power unit and control umbilical.
Other subsea tools.	Continuous: • operation of tools	Other subsea tools such as chain cutters, buckets or rippers may be required as contingency in the event debris, grout bags, unexpected hard substrate or grout is encountered and obstructs the cutting of jackets or pipelines at the seabed.
Helicopters.	Continuous: • rotor operation.	Approximate number of helicopter round trips is estimated to be 114 for the duration of Campaign #1 activities.

Table 6-65 defines the acoustic terms used throughout this Section.

Table 6-65 Acoustic terminology used in this impact assessment

Term	Definition
Sound	A time-varying pressure disturbance generated by mechanical vibration waves travelling through a fluid medium such as air or water.
Decibel (dB)	Sound is measured on a logarithmic scale that expresses the ratio of two values of a physical quantity. It is used to measure the amplitude or 'loudness' of a sound. As the dB scale is a ratio, it is denoted relative to some reference level, which must be included with dB values if they are to be meaningful. The reference pressure level in underwater acoustics is 1µPa, whereas the reference pressure level used in air is 20µPa, which was selected to match human hearing sensitivity. As a result of these differences in reference standards, sound levels in air are not equal to underwater levels.

Term	Definition
	There are four main metrics for underwater sound (ISO/DIS 18405.2:2017) – SEL, Sound Pressure Level (SPL), PK and PK-PK, all described in this Table.
Frequency	The rate of oscillation of a periodic function measured in cycles-per-unit-time. The reciprocal of the period. Unit: Hz. 1Hz is equal to 1 cycle per second.
Source level	A measure of sound pressure at a nominal distance of 1m from a theoretical point source that radiates the same total sound power as the actual source. Source level can be expressed as a SPL, SEL or PK. Unit: dB re 1μPa^{2}m^2 (pressure level) or dB re 1μPa^{2}m^{2}s (exposure level).
Non-impulse sound	Sound sources that produce sounds that can be broadband, narrowband or tonal, brief or prolonged, continuous or intermittent and typically do not have a high peak sound pressure with rapid rise time that impulsive sounds do. Examples of non-impulsive sound sources include marine vessels, machinery operations/construction (e.g. drilling), certain active sonar (e.g. tactical), and vibratory pile drivers.
Sound exposure level (SEL)	A measure related to the sound energy in one or more pulses, or the ratio of the time-integrated squared sound pressure to the specified reference value. Unit: dB re 1μPa^2·s.
Peak-to-peak sound pressure (PK-PK) Impulsive sounds	Sum of the peak compressional pressure (highest pressure variation) and the peak rare factional pressure (lowest pressure variation) during a specified time interval. PK-PK is the difference between the minimum and maximum instantaneous sound pressure levels in a stated frequency band attained by an impulsive sound. Unit: dB re 1μPa.
Zero-to-peak sound pressure (PK)	The greatest magnitude of the sound pressure during a specified time interval. PK levels are modelled to assess mortality and potential mortality to fish larvae and eggs, fish and turtles. A simple sound wave and three common methods to characterise the loudness of sounds, including zero-to-peak sound pressure. Unit: dB re 1μPa.
Root-mean-square SPL	The decibel ratio of the time-mean-square sound pressure, in a stated frequency band, to the square of the reference sound pressure over the duration of the acoustic event (i.e. the duration of a single sound pulse). Because the SPL represents the effective sound pressure over the full duration of the acoustic event rather than the maximum instantaneous peak pressure (PK or PK-PK), it is regularly used to represent the effective or perceived loudness of a sound and to assess the potential for a behavioural response from marine fauna. Unit: dB re 1μPa.
Temporary Threshold Shift (TTS) in hearing	TTS is the temporary loss of hearing sensitivity caused by excessive noise exposure. Exposure to sufficiently intense sound may lead to an increased hearing threshold in any living animal capable of perceiving acoustic stimuli (Finneran J. , 2016). If this shift is reversed and the hearing threshold returns to normal, the effect is called a TTS. The onset of TTS is often defined as threshold shift of 6dB above the normal hearing threshold (Southall, et al., 2019).

Term	Definition
	Impairment to the hearing apparatus of a marine animal may result from a fatiguing stimulus measured in terms of SEL, which considers the sound level and duration of the exposure signal. Intense sounds may also damage the hearing apparatus independent of duration, so an additional metric of peak pressure (PK) is needed to assess acoustic exposure impairment risk.
Permanent Threshold Shift (PTS) in hearing	PTS is the permanent loss of hearing sensitivity caused by excessive noise exposure. It is considered an auditory injury. If a TTS does not return to normal, the residual shift is called a PTS.
Auditory Injury (AUD INJ)	Damage to the inner ear that can result in destruction of tissue, such as the loss of cochlear neuron synapses or auditory neuropathy (NMFS, 2024). AUD INJ includes, but is not limited to PTS.
Behavioural response	Behavioural response in the context of this assessment refers to a response from a cetacean that is specifically triggered by the generation of underwater sound. Behavioural response to underwater noise from cetaceans could include the avoidance of the area where the noise source is located, changing vocalisation, or cessation of the behaviour that the cetacean was conducting before the exposure to underwater noise occurred. The context of sound exposure plays a critical and complex role in behavioural responses in marine mammals (Gomez, et al., 2016). For example, different species (and different individuals or groups within a species) may respond differently to varying levels of sound depending on their behaviours and motivation at the time (depending on whether they're foraging, socialising, resting or mating) and other factors such as the type of sound, duration of exposure, and the suddenness of the onset of the received sound (Ellison, Southall, Clark, & Frankel, 2012) (Gomez, et al., 2016). The US National Marine Fisheries Service (NMFS) currently uses a step function (all-or-none) threshold of 120dB re 1µPa SPL (unweighted) for non-impulsive sounds to assess and regulate noise-induced behavioural impacts on marine mammals (NOAA, 2024). The 120dB re 1µPa threshold is associated with continuous sources and was derived based on studies examining behavioural responses to drilling and dredging (NMFS, 2018), referring to Malme et al. (1983), (Malme, Miles, Clarke, Tyack, & Bird, 1984), and (Malme, Würsig, Bird, & Tyack, 1986), which were considered in (Southall, et al., 2007). (Malme, Würsig, Bird, & Tyack, 1986) and found that playback of drillship noise did not produce clear evidence of disturbance or avoidance for levels below 110dB re 1µPa (SPL), possible avoidance occurred for exposure levels approaching 119dB re 1µPa. Malme et al. (1984) determined that measurable reactions usually consisted of rather subtle short-term changes in speed and/or heading of the whale(s) under observation. It has been shown that both received level and proximity of the sound source is a contributing factor in eliciting behavioural reactions in humpback whales (Dunlop, et al., 2017), (Dunlop, et al., 2018). Whilst newer research by (Southall, et al., 2021) provides recommendations and discusses the nuances of assessing behavioural response, the authors of this research do not recommend new numerical thresholds for onset of behavioural responses for marine mammals.
Masking	Acoustic masking may occur when a noise impedes the ability of an animal to perceive a signal (Erbe, Reichmuth, Cunnigham, Lucke, & Dooling, 2016) (Wood, Southall, & Tollit, 2012). For this to occur the noise must be loud enough, have similar frequency content to the signal, and must happen at the same time (Wood, Southall, & Tollit, 2012). Masking and the potential effects of masking on communication and listening space of marine mammals are not fully understood and remain an area of active research (Cunnigham & Mountain, 2014) (Tenneson & Parks, 2016) (Cholewiak, et al., 2018)

Term	Definition
	(Dunlop, The effect of vessel noise on humpback whale, Megaptera novaeangliae, commiunication behaviour, 2016) (Gabriele, Ponirakis, Clark, Wombe, & Vanselow, 2018) (Putland, Merchant, Farcas, & Radford, 2018). Currently, there are no specific received level thresholds for reliably assessing or regulating masking responses to underwater noise (Gomez, et al., 2016).
Low-frequency cetaceans (LFCs)	The LFC group contains the mysticetes (baleen whales). Although there have been no direct measurements of hearing sensitivity in any mysticete, an audible frequency range of approximately 10Hz to 30kHz has been estimated from measured vocalization frequencies, observed reactions to playback of sounds, and anatomical analyses of the auditory system. A natural division may exist within the mysticete whales, with some species (e.g. blue, fin) having better LF sensitivity and others (e.g. humpback, minke) having better sensitivity to higher frequencies; however, at present there is insufficient knowledge to justify separating species into multiple groups. Therefore, a single species group is used for all mysticetes (NMFS, 2024).
High-frequency cetaceans (HFCs)	The HFC group contains most delphinid species (e.g. bottlenose dolphin, common dolphin, killer whale, pilot whale), monodonts (belugas, narwhals), beaked whales, and sperm whales (but not pygmy and dwarf sperm whales of the genus Kogia, which are treated as very high frequency species). Hearing sensitivity has been directly measured for several species within this group using psychophysical (behavioral) or auditory evoked potential measurements (NMFS, 2024).
Very high-frequency (VHF) cetaceans	The VHF cetacean group contains the porpoises, river dolphins, pygmy/dwarf sperm whales, *Cephalorhynchus* species, and some *Lagenorhynchus* species. Hearing sensitivity has been measured for several species within this group using behavioural or auditory evoked potential measurements. VHF cetaceans generally possess a higher upper-frequency limit and better sensitivity at higher frequencies compared to the HF cetacean species (NMFS, 2024).

6.13.1.1 Campaign #1 vessels

The marine spread that will be part of Campaign# 1 is comprised of a variety of vessels, including but not limited to, the HLV *Pioneering Spirit*, two CSVs, supply vessels, HTVs or barges, and tugs. A description of the vessels is presented in Section 2.6.1 of this EP.

Underwater sound that radiates from vessels is produced mainly by propeller and thruster cavitation. Typical sound levels generated by vessels are broadband with most of the energy emitted below a few kilohertz. Sound from onboard machinery, particularly sound below 200Hz, dominates the sound spectrum before cavitation begins (Spence, et al., 2007). Sound levels increase with increasing vessel size and sound levels tend to be the highest when thrusters are used to position the vessel (DP) and when the vessel is transiting at high speeds.

When maintaining position, noise emitted from the vessel will vary based on the number of thrusters that need to be active during the operation and the amount of power or energy at which the thrusters that are active are required to operate for the vessel to maintain position. Factors influencing the amount of power required to hold position include wind speed and ocean currents. Thrusters are expected to operate at lower power levels to hold position under calm weather conditions. Vessels that will take part in the decommissioning activities will operate under the International Guidelines for The Safe Operation of Dynamically Positioned Offshore Supply Vessels (IMCA, 2022) which means that vessels most often operate at levels less than 50% of thruster capacity. These guidelines are used to develop the Activity Specific Operating Guidelines (ASOG) for each vessel and include safe operating limits (based on relevant factors and primarily include power consumption and thruster output levels).

6.13.1.2 Remotely Operated Vehicle

In recognition that there is little information about the acoustic signatures of ROV and other subsea vehicles, Stimpert, Madrigal, Wakefield, & Yoklavich (2019) reported on a study undertaken to investigate the sound generated by an ROV and also a human-occupied submersible. A continuously recording passive acoustic monitor

was attached to a stationary surveillance platform in rocky habitat off southern California (120m water depth) and collected data over six days in October 2016 during which ROV and the human-occupied submersible activities were underway, with passes of the vehicles 1m to 3m from where the passive acoustic monitor was located. Underwater noise in the area during the time of the experiment was estimated at 99 +/−3dB re 1µPa RMS (50–500Hz) with calm sea and wind conditions. This level of sound is below that which could cause behavioural effects on marine fauna.

Based on the results (Stimpert, Madrigal, Wakefield, & Yoklavich, 2019), sound emanating from this operation will have negligible impacts on marine mammals and fish. As a result, it is not expected that sound generated from ROV operations in the water column or at the seabed would contribute to underwater sound levels to any discernible extent, and is therefore not assessed further in this EP.

6.13.1.3 Remotely Operated Vehicle cutter tool

During decommissioning, subsea cutting will be required to allow for activities such as removal of jacket legs, struts, pipeline risers, umbilicals and flexibles. Options to complete subsea cutting include but are not limited to shear or DWCM tools. Cutting operations will be done by/with assistance of a ROV.

Underwater sound measurement data during an underwater diamond wire cutting of a 32' conductor (10m above the seafloor in approximately 80m depth) found that the sound radiated was not easily discernible above the background noise at the closest recorder located 100m from the source and was primarily detectable at higher acoustic frequencies (above around 5kHz) (Pangerc, Robinson, Theobald, & Galley, 2017). Sporadic presence of seals at the platform locations have been documented, however no interaction of these species with ROVs or cutting tools have been recorded, indicating it is likely they move away from the underwater sound source. In another study, the US Navy measured underwater sound levels when a diamond wire cutter was cutting caissons for replacing piles. They reported an average SPL for a single diamond wire cutter at 136.1 to 141.4dB SPL at 10m (Fairweather Science LLC, 2019). This measurement was backpropagated using spherical spreading (20log10(R)) to estimate the broadband ESL for the cutter of 161.3dB re 1µPa^{2}m^{2}s (Muellenmeister, Connell, & Koessler, 2023).

Based on the results of these three studies, it is not expected that sound generated from ROV subsea cutting operations would add significantly to sound levels emanating from louder sources of sound such as decommissioning activity vessels.

6.13.1.4 Other subsea tools

During execution of Campaign #1 operations, the primary cutting methods are those described in Section 6.13.1.3. However, there are additional subsea tools that could be used as contingency options in the event unexpected conditions are identified during removal operations – refer to Section 2.7.6. These additional tools may be required only if the jacket legs that are intended to be removed at seabed level cannot be cut internally, and if there is presence of rock, grout or other hard material adjacent to the jacket legs that prevents access for external cutting. This is also applicable to cutting of pipelines, when there are obstructions present in the seabed adjacent to the pipeline cut location. In the event the use of these additional tools is required, its application will be limited, in order of priority, to moving away obstructions such as rocks or grout that may be blocking access to the jacket leg or pipeline which needs to be cut to execute removal activities, or to cut these obstructions if they are fixed at the location and can't be freely moved or pushed by these tools.

- Chain cutter - Generally, a chain cutter is design with teeth that allow the use of this tool for various applications, including cutting of rock, grout or other types of hard materials.
- Underwater noise modelling (Barham, 2017) indicated that noise levels from rock cutting operations that could trigger a behavioural response from LFC (established as 120dB) could extend up to 570m from the noise source. Based on available information from underwater noise modelling, it is not expected that the use of these alternative cutting options will result in a significant impact to the marine environment. For assessment of potential impacts associated to the use of this tool, the description and assessment on the use of cutting tools, as described in Table 6-66 (Scenarios 1 and 3) of this EP, is considered to be representative of the operation of the chain cutter.
- Ripper - The ripper is a tool that can be used to break hard material such as grout or rock that may be required to be cleared from a specific location to enable cutting operations of jacket legs or pipelines. It consists of a single tooth that is used to penetrate the hard material and break it into smaller, loose pieces that can then be moved away from the area immediately adjacent to where the cut line of the leg or pipeline is located. Analysis of potential noise that is associated to this tool is presented in Section 6.13.3.7 of this EP.

- Bucket - The use of a bucket in the context of clearing hard material such as grout or rocks that may be obstructing the area adjacent to the jacket legs or pipelines at the cut location, thus preventing access for external cutting of these structures, is to move or push those obstructions away from the area that requires to be cleared. It is not expected that potential noise that could be generated from the moving or pushing of hard material to allow access to the jackets or pipelines cut location will have an adverse effect on marine fauna, and therefore is not assessed further in this EP.

6.13.1.5 Helicopters

Helicopters will be used to transport personnel to and from main Campaign #1 vessels, which is estimated to be approximately three flights per week. Helicopter operations produce strong underwater sounds for brief periods when the helicopter is directly overhead (Richardson, Greene, Malme, & Thomson, 1995). The received sound level underwater depends on the helicopter altitude and lateral distance from the receiver depth, and water depth.

Sound emitted from helicopter operations tends to be below 500Hz and sound pressure is greatest at surface in the water directly below a helicopter, but this diminishes quickly with depth. Reports using the data for a Bell 214 helicopter (stated to be one of the noisiest types of helicopters) show it being audible in the air for four minutes before it passed over underwater hydrophones, and detectable underwater for 38 seconds at 3m depth and 11 seconds at 18m depth. The peak received sound levels diminishes with increasing helicopter altitude, but the duration of audibility often increases with increased altitude (Richardson, Greene, Malme, & Thomson, 1995). Noise from helicopter activities will be localised, short term and infrequent.

Given this short duration of underwater exposure and the limited number of flights each week, helicopter noise is not considered to be significant in contributing to potential impacts to marine fauna and is not considered to contribute to cumulative impacts of noise sources, and is therefore not assessed further in this EP.

6.13.2 Impacts of sound emissions

Impacts of sound emissions on receptors are:

- change in fauna behaviour, including preventing use of BIAs
- injury/mortality of fauna.

6.13.3 Consequence assessment

Esso commissioned JASCO Applied Sciences (Australia) Pty Ltd (JASCO) to undertake a modelling study of non-impulsive underwater sound emissions from vessel operations for Campaign #1 activities (Li, Connell, Warren, & Koessler, 2024) (Appendix I).

Underwater sound modelling predicts the distances from operations at which underwater sound levels reach noise effect thresholds and criteria. Due to the variety of species considered, there are several different thresholds for evaluating effects, including: mortality, injury, temporary reduction in hearing sensitivity, and behavioural disturbance.

For the adequate identification and assessment of potential impacts from vessel operations, scenarios chosen for modelling, which are described in Section 6.13.3.1, were based in key criteria including:

- Locations where vessel operations will be conducted - This criterion included selection of locations for operations at platforms that provided representative information and coverage of the OA by including input data from shallow waters and deep waters in areas of the Bass Strait where removal of platforms will take place. Representative locations modelled also accounted for transfer operations and HLV mode change operation. For these operations, representative locations selected for modelling are in the area of highest environmental sensitivity, towards the western end of the OA, where potential vessel operations would be in the closest proximity to Wilsons Promontory and Corner Inlet.
- Simultaneous vessel operations at relevant locations - Input data for modelling considered operations where more than one vessel is expected to be required. This criterion allows for adequate assessment of potential cumulative impacts as a result of presence of various sources of noise at the same point in time for relevant locations.
- Sensitive receptors identified within the OA - Transfer operations/HLV mode change operations are subject to various factors such as metocean conditions. Therefore, exact location where these activities will take place within the OA can vary and will be ultimately defined closer to or as close as possible to the time when decommissioning activities are planned to commence. As a result, and to provide for an

adequate identification and assessment of potential impacts from vessel operations during Campaign#1 activities, the locations chosen to model underwater noise during transfer/HLV mode change operations are the most environmentally sensitive locations within the OA, located towards the western end of the OA in proximity to State Waters near Wilsons Promontory and Corner Inlet.

In addition to the noise modelling completed for the operations and scenarios described above, an analysis of potential noise associated to the use of the ripper cutting tool is presented in Section 6.13.3.7.

6.13.3.1 Modelling scenarios

The noise modelling study completed by JASCO for Campaign #1 considered several sound sources associated with vessel operations, including simultaneous noise from multiple sources to inform cumulative impact assessment. The following sound-producing activities were considered:

- *Pioneering Spirit* as a HLV under DP and in transit
- *Fortitude* as a CSV under DP
- vessel noise from PSV
- vessel noise from tug/towed barge under DP
- cutting tool noise from a ROV performing underwater cutting of subsea infrastructure.

Table 6-66 presents the scenarios modelled for Campaign #1. These scenarios are based on representative expected vessel operations that will be conducted during the execution of Campaign #1, as described in Section 2 of this EP. Scenarios include simultaneous vessel operations that are expected to occur during Campaign #1 activities, which can be identified as the worst-case scenario for generation of underwater noise during decommissioning operations.

Table 6-66 Underwater noise – Modelling scenarios

Scenario	Description	Location
1	Operation of a CSV under DP holding position while conducting subsea cutting activities (via cutting tool operated from a ROV).	DPA
2	Operation of the HLV under DP holding position while conducting platform removal operations.	KFA
3	Simultaneous operations of the HLV and a CSV under DP holding position, and subsea cutting activities via cutting tool operated from a ROV, during platform removal operations.	KFA
4	Simultaneous operations of the HLV, a CSV and a PSV under DP holding position during mode change operations for the *Pioneering Spirit*.	Representative Transfer Location (Transfer Location A – (TLA))
5	Simultaneous operations of the HLV, a CSV and a PSV under DP holding position during mode change operations for the *Pioneering Spirit*.	Representative Transfer Location (Transfer Location B – (TLB))
6	Simultaneous operations of the HLV under DP holding position and tugs assisting with barge manoeuvres, during operations to transfer removed platform sections that are on the HLV, onto the barges for final transport.	Representative Transfer Location (TLA)
7	Simultaneous operations of the HLV under DP holding position and tugs assisting with barge manoeuvres, during operations to transfer removed platform sections that are on the HLV, onto the barges for final transport.	Representative Transfer Location (TLA)

Scenario	Description	Location
8	HLV transiting between platforms and transfer location.	Transit - KFA to Representative TLB
9	HLV transiting between platforms and transfer location.	Transit - KFA to Representative TLB

6.13.3.2 Criteria used for noise modelling

Vessel operation will be the main source of underwater noise during Campaign #1 activities. There are additional sources of noise such as operation of ROV and cutting tools for subsea cutting activities, and helicopter operations for crew change. However, these two additional sources are not expected to significantly contribute to underwater noise levels during vessel operations.

The following information was considered for noise modelling:

- Vessels – HLV:
    - *Pioneering Spirit* is the HLV that will conduct removal operations for Campaign #1
    - while in operation, it will hold position using thrusters under DP
    - there are no measurements of the underwater sound source level of the *Pioneering Spirit*. As a result, the source levels for this vessel under DP had been calculated using the source levels associated with the Allseas *Solitaire* vessel. The *Solitaire's* source level and spectrum was previously measured during the installation of the Nord Stream 2 pipeline project as part of a monitoring study presented in Tougaard and Griffiths (2020)
    - the *Solitaire* has installed thruster power of 55,500kW, and the median broadband source level from several measurements for the Solitaire was 188.0dB re 1µPa^{2}m^{2}s. On the other hand, *Pioneering Spirit* has installed thruster power of 72,600kW. To account for the difference in thruster power, the source levels of the *Solitaire* was scaled by the difference in installed thruster power with the *Pioneering Spirit*, resulting in an assessed potential source level of 189.2db re 1µPa^{2}m^{2}s for the HLV. This is standard practice for noise modelling exercises when surrogate vessels must be used to account for measured data and source levels
- Vessels – CSV:
    - *Fortitude* vessel is representative of the CSV that will be used to support removal preparation works for Campaign #1
    - while conducting operations at the facilities, the CSV it will hold position using thrusters under DP. The *Fortitude* has a total of 21,750kW installed thruster power capacity comprising two 2500kW bow thrusters, two 3350kW retractable azimuth thrusters, and three 3350kW main propulsion thrusters
    - there are no measurements of the underwater sound source level of the *Fortitude*. As a result, the source levels for this vessel under DP had been calculated using the source levels associated with the *Skandi Feistein* vessel. The *Skandi Feistein* was used previously as a surrogate vessel for the *Fortitude* (Li, Connell, Warren, & Koessler, 2024). Li, Connell, Warren, & Koessler (2024) estimated the source levels of the *Fortitude* by considering the engineering field data and source levels for *Skandi Feistein* as reported in (McPherson, et al., 2021). A regression analysis of source level versus actual thruster engine power under DP was conducted, resulting in a regression relationship between the two variables. Using this relationship and a total power usage of 45%, the broadband source level (BBSL) of the *Fortitude* while under DP was modelled as 185.3dB re 1µPa^{2}m^{2}s
- Vessels – PSV:
    - *Pioneering Spirit* and a CSV (*Fortitude or similar)* will be the main vessels conducting removal operations during Campaign #1. However, there will be sporadic operations from additional vessels to support decommissioning activities. The PSV *Alegria* was selected as a representative vessel for those additional support operations.
    - the *Alegria* has 8053kW of installed thruster power and dimensions 82.88m length, 19.3m beam and 6.31m draft. There are no measurements of the underwater sound source level of the *Alegria*. As a result, the same procedure described above for the *Fortitude* was completed for the PSV. A

regression curve between source level versus actual thruster engine power was used to estimate the source level of the *Alegria* while on DP. Using regression correlation with a total power usage of 45%, the broadband source level (BBSL) of the *Alegria* while under DP was modelled as 181.0dB re 1µPa^{2}m^{2}s

- Vessels – Tugs:
    - where barges are used at the transfer location to receive removed structures by the *Pioneering Spirit* and the CSV (*Fortitude* or similar*)* vessels and transport them to an ORC, tugs are required to tow those barges
    - modelled Scenarios 6 and 7 (Appendix I) considered the tugs providing support operations, manoeuvring the barges as required for transfer of structures from the HLV onto the barges. The MMA *Mermaid Cove* has been identified as a representative tug for this operation. The MMA *Mermaid Cove* was purpose built to be an offtake support vessel with 4700kW of maximum installed thruster power and 70.3t bollard pull with an overall length, beam, and draft of 52.35m, 14.6m, and 4.9m
    - estimates of the source levels for the MMA *Mermaid Cove* were based on a surrogate vessel, the *Siem* anchor handling tug supply vessel, and its specifications were used to form a basis for vessel source level estimation for acoustic modelling purposes. The *Siem*, which is an anchor handling tug, was selected as a surrogate vessel as it presents an adequate representation of the power that would be required by a tug during pushing and/or manoeuvring operations. The monopole source levels (MSLs) and spectra for the surrogate vessel were measured by JASCO (McPherson, et al., 2021) and scaled to the MMA *Mermaid Cove* based on the ratio of maximum installed thruster power. The broadband (10Hz to 25kHz) source level of the MMA *Mermaid Cove* under DP was modelled as 187.2dB re 1µPa^{2}m^2 s.

6.13.3.3 Noise effect criteria

To assess the potential effects of a sound-producing activity, it is necessary to first establish exposure criteria (thresholds) for which sound levels may be expected to have an adverse effect on animals. Since 2007, several expert groups have developed SEL-based assessment approaches for evaluating AUD INJ, with key works including (Southall, et al., 2007) (Finneran, et al., 2017) (Popper, et al., 2014) (Southall, et al., 2019) (NOAA, 2024). In addition, in October 2024 National Oceanic Atmospheric Administration (NOAA), through the NMFS released a *2024 Update to: Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing* (NMFS, 2024), which includes the updated *Appendix A: Finneran Technical Report* (Finneran J. J., 2024).

Two sound level metrics, SPL and SEL, are commonly used to evaluate non-impulsive noise and its effects on marine life. Marine mammal thresholds include levels associated with behavioural response, PTS and TTS. The marine mammal functional hearing groups considered were low-, high- and VHF cetaceans and otariid seals. Thresholds for fish include recoverable injury and TTS, and the thresholds for sea turtles include PTS and TTS. Estimated underwater acoustic levels were presented as sound pressure levels (SPL, Lp), and accumulated sound exposure levels (over 24 hours) (SEL_{24hour}, $L_{E,24hour}$), as appropriate for non-impulsive (continuous) noise sources.

JASCO completed the underwater noise modelling for Campaign #1 using the literature that was current at the time of the modelling. As a result, the following thresholds and guidelines were chosen because they represented the best available science at that time:

- frequency-weighted accumulated sound exposure levels (SEL; $L_{E,24hour}$) from Southall, et al., (2019) for the onset of PTS and TTS in marine mammals for non-impulsive sound sources
- marine mammal behavioural threshold based on the current interim US National Oceanic and Atmospheric Administration criterion for marine mammals of 120dB re 1µPa (SPL; Lp) for non-impulsive sound sources
- sound exposure guidelines for fish, fish eggs, and larvae (Popper, et al., 2014).

The updated guideline (NMFS, 2024) incorporates the term AUD INJ, which is inclusive of PTS. The guideline also focuses on updates to information relevant to TTS and AUD INJ in marine mammals, however there is no mention or reference to updates to the current marine mammal thresholds and auditory weighting functions for behavioural disturbance. As such, for this specific parameter, the NOAA (2018) guidelines are still current.

There is a minor change on the thresholds established for LFCs for both TTS and PTS, and the auditory weighting and exposure function was slightly increased for LFCs. For otariid seals, these criteria also present changes when

compared to the version that was current at the time of modelling. Based on the minor extent at which the thresholds for LFCs were updated versus the thresholds used by JASCO for the Campaign #1 report, it is considered the outcomes from the JASCO modelling are still representative of the operational conditions and potential impact. It is also considered that controls that are presented in Section 6.13.6 adequately address potential effects on marine mammals for TTS and PTS (now AUD INJ). Furthermore, there are no BIAs present within the EMBA for otariid seals and therefore it is not expected that any potential difference in the extent or reach of underwater noise that could have an adverse effect on this species based on the updated data from the NMFS guidelines (NMFS, 2024) would result in impact to sensitive areas where important behaviours for otariid seals are established.

The updated guidelines (NMFS, 2024) also introduce thresholds for in-air noise exposure for AUD INJ and TTS for marine mammals. However, potential in-air exposure to noise produced during Campaign #1 activities is not considered to pose a risk to marine fauna. Sections 6.13.1 and 6.13.1.4 of this EP present a description and assessment of this specific potential source of noise.

Similarly, in April 2025 the US Navy released a report with a revision of the criteria thresholds for US Navy acoustic and explosive effects (Accomado, et al., 2024) that included information relevant to marine mammals auditory weighting functions and exposure functions, and sea turtle auditory and behavioural criteria and thresholds based on current state of scientific knowledge regarding the characteristics of sound that have the potential to impact these species. The proposed auditory weighting and exposure function parameters for marine mammals remain as per description in the updated guidelines (NMFS, 2024). For sea turtles, the US Navy 2025 report (Accomado, et al., 2024) presents an amendment to the thresholds proposed previously by Finneran (Finneran, et al., 2017). While the weighting value for turtles may suggest a larger impact distance than previously modelled, the existing results are still considered to provide a sufficient representation of the likely scale and intensity of effects to support robust evaluation of potential impacts, also considering the absence of areas within the OA that are used by turtles to conduct important behaviours such as aggregation, nesting/reproduction, foraging, resting or migration.

Based on this analysis, Table 6-67 presents the criteria used for noise exposure for marine mammal by JASCO for Campaign #1 activities. Table 6-67 also presents added columns with information on the thresholds from the updated guideline (NMFS, 2024). Table 6-68 presents the criteria used for noise exposure for fish, and sea turtles (Popper, et al., 2014), while Table 6-69 shows the criteria for sea turtles (Finneran, et al., 2017).

Table 6-67 Criteria for effects of non-impulsive noise exposure for marine mammals: unweighted SPL and weighted SEL_{24h} thresholds

Hearing group	NOAA (2019)	Southall et al. (2019)		NMFS (2024)	
	Behaviour	PTS onset thresholds (received level)	TTS onset thresholds (received level)	AUD INJ onset thresholds	TTS onset thresholds
	SPL (Lp; dB re 1µPa)	Weighted SEL_{24hour} ($L_{E,24hour}$; dB re 1µPa^2s)	Weighted SEL_{24hour} ($L_{E,24hour}$; dB re 1µPa^2s)	AUD INJ onset: SEL_{24hour} (dB re 1µPa^2s)	TTS onset: SEL_{24hour} (dB re 1µPa^2s)
LFCs	120	199	179	197	177
HFCs		198	178	201	181
Very High-Frequency Cetacean (VHFCs)		173	153	181	161
Phocid seals		201	181	195	175
Otariid seals		219	199	199	179

Table 6-68 Criteria for vessel noise exposure for fish and sea turtles, adapted from Popper, et al. (2014)

Type of animal	Mortality and potential mortal injury	Impairment			Behaviour
		Recoverable injury	TTS	Masking	
Fish - No swim bladder (particle motion detection)	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish - Swim bladder not involved in hearing (particle motion detection)	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish - Swim bladder involved in hearing (primarily pressure detection)	(N) Low (I) Low (F) Low	170 dB SPL for 48 h	158 dB SPL for 12 h	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Sea turtles	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Sound pressure level dB re 1µPa.

Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N) – tens of metres, intermediate (I) – hundreds of metres, and far (F) – thousands of metres

Frequency-weighted accumulated sound exposure levels (SEL; $L_{E,24hour}$) from (Finneran, et al., 2017) for the onset of PTS and TTS in sea turtles.

Table 6-69 Acoustic effects of continuous noise on sea turtles weighted SEL_{24hour}

(Finneran, et al., 2017)		(Accomado, et al., 2024)	
PTS onset thresholds (received level)	TTS onset thresholds (received level)	AUD INJ onset thresholds (received level)	TTS onset thresholds (received level)
Weighted SEL_{24hour} ($L_{E,24hour}$; dB re 1µPa²s)	**Weighted SEL_{24hour} ($L_{E,24hour}$ dB re 1µPa²s)**	**Weighted SEL_{24hour} ($L_{E,24hour}$ dB re 1µPa²s)**	**Weighted SEL_{24hour} ($L_{E,24hour}$ dB re 1µPa²s)**
220	200	198	178

$L_{E,24h}$ denotes cumulative sound exposure over a 24 hour period and has a reference value of 1µPa²s.

6.13.3.4 Modelling results

The results from the JASCO report (Li, Connell, Warren, & Koessler, 2024) assessed distances from vessel operations where underwater sound levels reached thresholds corresponding to various levels of potential impact

to marine fauna. Due to the variety of species considered, several different thresholds were used for evaluating effects, including mortality, injury, temporary reduction in hearing sensitivity, and behavioural disturbance.

To evaluate the potential for accumulated sound exposure levels (SEL), the duration of the SEL accumulation was defined as integrated over a 24-hour period. The SEL_{24hour} is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The report indicates that underwater noise will vary based on the specific activity and the location where the activity takes place. Results provides an indication of potential effects from stand-alone vessel operations, as well as noise generated from simultaneous operations during Campaign #1. The inclusion of expected simultaneous vessel operations during decommissioning activities provides information of potential cumulative effects.

6.13.3.5 Noise modelling – Additional considerations

Noise modelling conducted for Campaign #1 was based on best available information at the time of modelling. Input data and methods are based on a conservative approach and consequently, results obtained from the modelling report are considered to be worst-case and not characteristic of real operational conditions. For underwater noise impact assessment, the following factors will be considered in addition to the noise modelling results for vessel operations during Campaign #1 operations:

- SEL_{24hour}:
    - the duration of the SEL accumulation was defined as integrated over a 24-hour period. The SEL_{24hour} is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The corresponding SEL_{24hour} radii represent an unlikely worst-case scenario. Under real conditions, it is not expected that marine mammals, fish or turtles will remain in a fixed position in proximity to the sound source location for a period of 24 hours. Therefore, a reported radius for SEL_{24hour} criteria does not mean that marine fauna travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with impairment if it remained in a fixed position in proximity to the sound source location for a continuous period of 24 hours
    - duration of HLV vessel operations for Campaign #1 is approximately five months. However, during this period source of underwater sound emissions will be limited to the specific location at which the vessel is operating at. It is also noted that there is a significant portion of the planned decommissioning period where the HLV will be transiting between facilities, or between a facility and a transfer location. During transit, HLV is expected to produce significantly less underwater noise than when conducting lifting or transfer operations. As a result, it is expected that HLV DP operations for holding position for lifting of structures or during transfer operations will be limited to a short duration of time (less than 12 hours for each lifting operation, and less than 24 hours for each transfer operation) and will occur at one specific location within the OA at a time, until the Campaign #1 scope is completed. There is also the potential for generation of underwater noise during the HLV holding position for mode change operations. This specific activity will occur only once during the life of Campaign #1 activities and is expected to have a duration of approximately four days
- Surrogate vessel:
    - the Allseas *Solitaire* was chosen as a suitable surrogate vessel to determine potential sound source levels for *Pioneering Spirit* while operating under DP, based on comparable installed thruster power capacity and size of that particular vessel (as described in Section 6.13.3.2)
    - measurement of underwater sound source levels for the *Solitaire* was completed while that vessel was conducting pipe-lay operations for the Nord-Stream 2 pipeline project (Tougaard, 2020). It is expected that power required by a vessel during pipe-lay operations (due to holding position while maintaining tension on active pipe being laid) is greater than that required by a vessel to hold position during heavy lift activities, as is the case of the HLV for Campaign #1 operations; however, it was not possible to include this consideration as input data for the noise modelling exercise completed for *Pioneering Spirit* operations. As a result, the method to scale the source levels from the *Solitaire* to account for the difference in thruster power with the *Pioneering Spirit*, although an industry standard practice and commonly used in several

underwater noise modelling reports, has limitations on input data that prevents a more accurate representation of differences on specific vessel operations for underwater noise modelling. It is therefore considered that the outcome from the noise modelling report for Campaign #1 operations is worst-case and of a highly conservative nature.

- *Pioneering Spirit* power utilisation under real operational conditions – Historic data:
  - input data and methodology used by JASCO for the underwater noise modelling followed best industry practice and is based on available data at the time of the underwater noise modelling exercise. For *Pioneering Spirit*, total installed thruster capacity was used as the basis to identify potential sound source levels generated by the vessel while holding position for decommissioning operations
  - however, there is a limitation to this assumption, as the typical thruster power levels at which the *Pioneering Spirit* commonly operates could not be accounted for as a consideration in the modelling exercise. Data from the latest 20 removal/lift operations completed by *Pioneering Spirit*, which represents over 90 hours of critical DP operations within designated 500m zones, indicates that for 53% of the time, power utilisation required by the vessel to hold position was below 5% of its total installed thruster power. Data also shows that the maximum thruster power *Pioneering Spirit* had to use during those recent 20 lifts was between 50% and 55%, and this specific power usage accounted for only 1% of the total power utilisation of the vessel while on DP holding position (refer to Figure 6-6). Data shows that from the 90 hours of critical DP operations during the latest 20 lifts, the thrusters operated at a capacity below 20% for at least 90% of the time, which accounts for approximately 81 hours

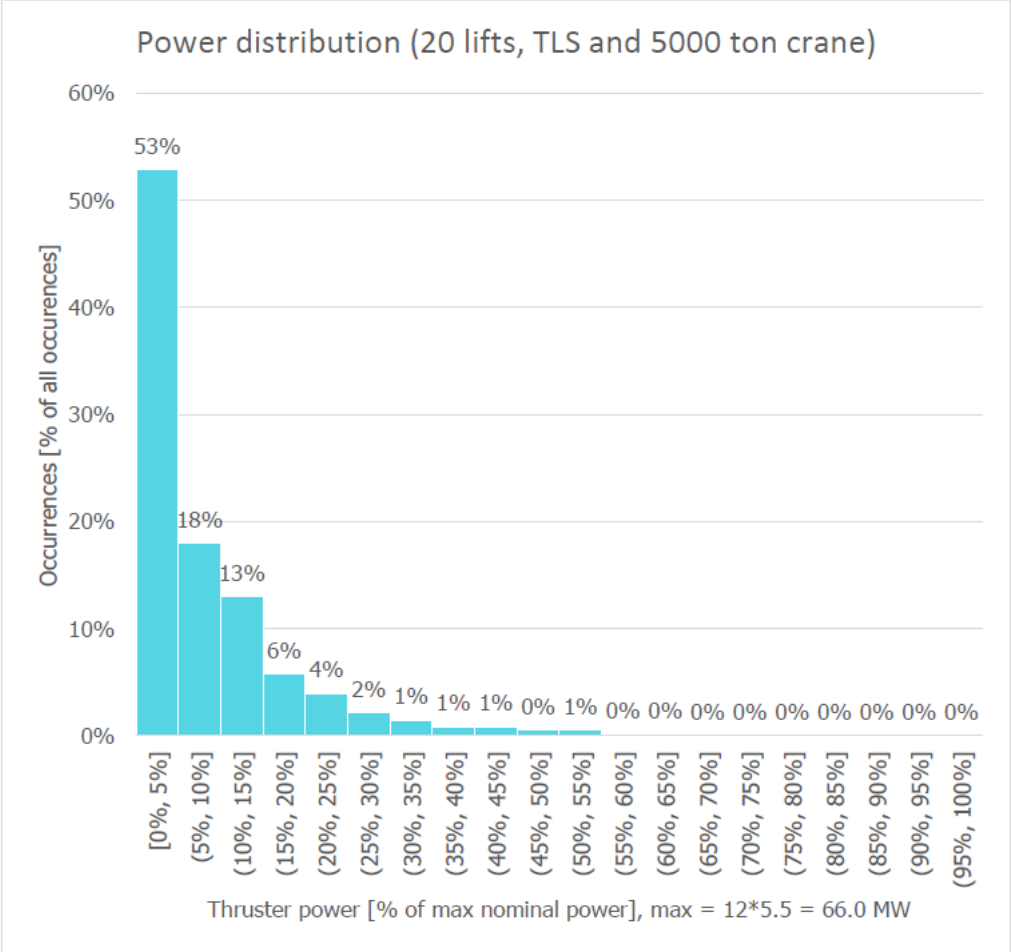

Figure 6-6 *Pioneering Spirit* thruster power utilisation from recent lifts (20)

- *Pioneering Spirit* power utilisation under real operational conditions – Assumed estimated operational conditions:

- there are external environmental factors such as wind speed, wave height and currents that influence the power usage the vessel will require during decommissioning activities. Consequently, the exact thruster power utilisation the vessel will require when conducting removal operations cannot be determined in advance. However, as part of the planning process, the potential power the vessel may require to hold position was estimated based on historical weather data at the locations where decommissioning activities will take place. Table 6-70 presents the weather data obtained for a base case, which considered annual wave heights, annual current speed, and wind rose data from the HLA platform, and the estimated power utilisation required by the *Pioneering Spirit* for operations when base case weather conditions are present

Table 6-70 Weather conditions and estimation of vessel thruster power utilisation – Base case and rough weather case

Thruster utilisation	Wind speed (kn)	Wave height (Hs - m)	Current speed (m/s)	Mean thruster power (%)
Base case	20	2.0	0.5	11-14
Rough weather case	25	2.5	1.0	34 - 43

- vessel power utilisation estimated for a base case for Campaign #1 activities is consistent with the data presented in Figure 6-6, which shows that for the most recent 20 lift operations the *Pioneering Spirit* has completed, 84% of the times, power utilisation was below 15% of the total installed thruster power capacity
- as part of the planning of decommissioning activities at Gippsland Basin, and to ensure safety of operations during Campaign #1 activities, metocean conditions estimates will be confirmed at the time vessel operations are underway for the decommissioning activities

- Vessel limitations – Equipment safety considerations:
  - in the absence of more detailed available data, total installed thruster power of the *Pioneering Spirit* was considered for the modelling exercise. However, the vessel will not operate the thrusters at full capacity, as this will risk the integrity of the thrusters. It is expected that *Pioneering Spirit* will operate its DP system based on the ASOG developed for this vessel. As a result, input data used for the model is highly conservative, and underwater noise levels from vessel operations under this conservative approach are expected to be greater to those expected under real operational conditions.

6.13.3.6 Impact to marine fauna

Due to the high mobility of many fish and most turtles and marine mammals, noise sources from vessel operations that are a continuous broadband are related mostly to behavioural disturbances rather than injury or mortality. For purposes of assessing potential impacts from underwater noise, the sound EMBA refers to the distance at which underwater sound emissions from vessel operations can trigger behavioural response from marine fauna .Based on results from the noise modelling report from JASCO potential distances at which PTS, TTS and behavioural response could be triggered on marine fauna will vary depending on the specific type of activity or vessel operation being conducted and the specific species that could be exposed to the noise. In total, nine different operational scenarios were modelled. However, for the purposes of impact assessment of underwater noise and unless otherwise specified in this assessment, the operational scenario/activity with the furthest reach of noise will be used as the basis for assessing effects on marine fauna. This approach allows for consideration of the worst-case scenario, however, noting that controls to be implemented to manage potential impacts from underwater noise (see Section 6.13.4) will be determined based on the noise modelling results for the most appropriate/representative scenario to the specific activity to be conducted during removal operations.

6.13.3.6.1 PLANKTON

There is no data on mortality and potential mortality, injury, impairment and behaviour on plankton (Popper, et al., 2014). Therefore, the guidelines provided in (Popper, et al., 2014) are considered for this activity (Table 6-68). There are low risks to plankton for impairment, behaviour, mortality and potential mortal injury. Based on this

evaluation, the impact consequence for plankton resulting from underwater noise generated by vessel operations is assessed as **Consequence Level IV** at an ecosystem and population level.

6.13.3.6.2 FISH

There is no direct evidence of mortality or potential mortality to fish from vessel sound emissions. The risks of mortality and potential mortality, and recoverable injury impacts to fish with no swim bladder (sharks) or where the swim bladder is not involved in hearing is low and that TTS may be a moderate risk at near distances (tens of metres) from the vessel (Popper, et al., 2014). White shark reproduction and foraging BIAs occur in the OA, as shown in Figure 3-6. However, sharks do not possess a swim bladder and are therefore not significantly affected by underwater sound. This is evidenced in the *Recovery Plan for the White Shark (Carcharodon carcharias)* (DSEWPAC, 2013a), as underwater noise is not listed as a threat to this species.

Behavioural impacts to fish from the activity will be limited to behavioural responses within metres of the noise source. Fish (including sharks and rays) may be temporarily displaced from the immediate vicinity of the sound source.

The 48-hour threshold for recoverable injury for fish with a swim bladder involved in hearing (170dB re 1µPa (Popper, et al., 2014) (Table 6-68) was reached at a maximum distance of 20m from the sound source.

Because pelagic fish are unlikely to remain in a fixed position for long periods of time (i.e. they will swim away from the sound source), it is not anticipated fish will be exposed for a period of 48 continuous hours to underwater noise at levels at which potential risks of mortality or injury could occur. Additionally, the sound emitted from vessel operations will be mostly of short duration (<24 hours). As a result, impact from continuous sound from DP are likely to be insignificant.

Based on this evaluation, the consequence for fish resulting from underwater noise generated by vessel operations is assessed as:

- **Consequence Level IV**.

6.13.3.6.3 TURTLES

The *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017) identifies noise interference as a threat to turtles. It details that exposure to chronic (continuous) loud noise in the marine environment may lead to avoidance of important habitat.

In 2006, the Working Group on the Effects of Sound on Fish and Turtles was formed to develop sound exposure criteria for fish and turtles. The Working Group developed guidelines with specific thresholds for different levels of effects for several species' groups including turtles (Popper, et al., 2014) (Table 6-68). (Popper, et al., 2014) noted that there is no direct evidence of mortality or potential mortal injury to sea turtles from vessel sound emissions.

Using semi-quantitative analysis, (Popper, et al., 2014) suggests that there is a low risk to marine turtles from shipping and continuous sound except for TTS near (tens of metres) to the sound source, and masking at near, intermediate (hundreds of metres) and far (thousands of metres) distances and behaviour at near and intermediate distances from the sound source.

Results from the JASCO modelling study for Campaign #1 activity (Li, Connell, Warren, & Koessler, 2024) indicates the SEL_{24hour} threshold for PTS in marine turtles would only extend to a maximum of 20m from the sound source (Scenarios 2, 3, 4 and 6). For TTS, study indicates underwater noise levels that exceed this threshold would only extend up to 380m from the sound source. In addition, it is not considered that the updated thresholds for AUD INJ and TTS on sea turtles proposed by the US Navy 2025 (Accomado, et al., 2024) would have a significant effect on the potential impact as assessed in this EP, including consideration that it is not credible that marine turtles will remain within close proximity from the sound source for more than 24 continuous hours, and also the fact that no BIAs were identified for marine turtles within the OA, which suggests potential impacts, if any, will be limited to individual turtles.

Based on this information, marine turtles may exhibit avoidance behaviour within the EMBA. Potential impacts will be of short duration and localised, with insignificant effect on a population level. As a result, the consequence level for turtles is assessed as:

- **Consequence Level IV**.

6.13.3.6.4 MARINE MAMMALS

Marine mammal species share basic hearing anatomy and physiology with their terrestrial ancestors but have broader hearing frequency ranges due to the much higher sound speed underwater compared to in air. Odontocetes (toothed whales and dolphins) hear best at higher frequencies, generally in the ultra-sonic range (>20,000Hz), with no responsive hearing below 500Hz (0.5kHz). Mysticetes (baleen whales, such as humpback whales, PBW and SRW) hear better at lower frequencies (Wartzok & Ketten, 1999) (Mooney, Yamato, & Branstetter, 2012), generally at infrasonic frequencies as low as 10 - 15Hz (Ketten, 2004). The optimal hearing frequency range for baleen whales is between ~20-1000Hz (McCauley R. , 1994).

Sound is very important to whales and dolphins for effective feeding, navigation and communication. For example, mysticetes communicate at low frequencies (20Hz to approximately 5kHz) using predominantly tonal type calls. Odontocetes communicate using both tonal signals (up to approximately 30kHz) and echolocation clicks (peak frequencies range from approximately 40 – 130kHz), which they also use for hunting and navigation (Springer, 2000).

PHYSIOLOGICAL IMPACTS

Physiological impacts such as physical damage to the auditory apparatus (e.g. loss of hair cells or permanently fatigued hair cell receptors), can occur in marine mammals when they are exposed to intense or moderately intense sound levels and could cause permanent or temporary loss of hearing sensitivity.

A TTS is hearing loss from which an animal recovers, usually within a day at most, whereas PTS is hearing loss from which an animal does not recover (permanent hair cell or receptor damage). TTS occurs at lower exposure levels than PTS.

BEHAVIOURAL IMPACTS

Underwater sound may have non-physiological (i.e., behavioural) effects on cetaceans including:

- increased stress levels
- disruption to underwater acoustic cue
- masking
- behavioural changes
- displacement.

Behavioural responses to underwater sound are difficult to determine because animals vary widely in their response type and strength, and the same species exposed to the same sound may react differently (Nowacek, Johnson, & Tyack, 2004) (Gomez, et al., 2016) (Southall, Nowaceck, Miller, & Tyack, 2016). An individual's response to a stimulus is influenced by the context in which the animal receives the stimulus and how relevant the individual perceives the stimulus to be. A number of biological and environmental factors can affect an animal's response—behavioural state (e.g. foraging, travelling or socialising), reproductive state (e.g. female with or without calf, or single male), age (juvenile, sub-adult, adult), and motivational state (e.g. hunger, fear of predation, courtship) at the time of exposure as well as perceived proximity, motion and biological meaning of the sound and nature of the sound source.

Animals might temporarily avoid anthropogenic sounds but could display other behaviours such as approaching novel sound sources, increasing vigilance, hiding and/or retreating, that might decrease their foraging time (Purser & Radford, 2011). Some cetaceans might also respond acoustically in a range of ways, including by increasing the amplitude of their calls (Lombard effect), changing their spectral (frequency content) or temporal vocalisation properties, and in some cases, cease vocalising (McDonald, Hildebrand, & Webb, 1995) (Parks, Clark, & Tyack, 2007) (Di Lorio & Clark, 2010) (Castellote, Clark, & Lammers, 2012) (Hotchkin & Parks, 2013) (Blackwell, et al., 2015). Masking can also occur (Erbe, Reichmuth, Cunnigham, Lucke, & Dooling, 2016).

The EPBC Act PMST reports for the EMBA (Appendix D) found that four species of threatened cetaceans are likely to, or known to occur within the EMBA:

- Blue whale (PBW subspecies) (endangered)
- SRW (endangered)
- fin whale (vulnerable)
- sei whale (vulnerable).

These whales are also listed as migratory and are classified as LFCs with respect to the assessment of underwater noise impacts. There are also a number of listed migratory whales reported within the EMBA as well as a number of other species listed as cetaceans and/or marine species, including dolphins and seals (Appendix D).

A description on potential underwater sound impacts to marine mammals present within the OA is presented below.

SEALS

Both the Australian and New Zealand fur seals (otariid seals) may occur within the EMBA. Results from the PMST report for the EMBA of Campaign #1 (Appendix D) identified these two species are listed marine species under the EPBC Act, however, are not categorised as threatened or migratory species, and no BIAs for seals were identified in the area.

Australian fur seal breeding populations are known to have expanded from Kanowna Island (southwest of Wilsons Promontory) to Rag Island (Parks Victoria, 2017), which is part of the group of islands that are located within the Seal Islands Wildlife Reserve. Rag Island is within the OA of Campaign #1. The conservation outcomes for the coastal asset (including islands) of the Wilsons Promontory Marine National Park, which is inclusive of Rag Island, does not identify underwater noise as a threat to achieve the conservation outcomes established for this asset.

Results from the underwater noise study completed by JASCO for Campaign #1 activities indicates that PTS thresholds for seals are not triggered by vessel operations. Results also indicate that underwater noise levels at which TTS thresholds could be triggered are limited to a maximum of 120m from the sound source. Considering the dimensions of the HLV, with a hull length of 382m and a breadth of 123.7m, the distance at which TTS impacts to seals could occur are mostly confined within the footprint of the vessel, resulting in a low likelihood of exposure.

Vessel operations during Campaign #1 activities will be of short duration and localised. Anecdotally, seals are observed to regularly haul out on Esso's platform jackets in Bass Strait, even during supply operations, and they do not appear to be significantly perturbed or disturbed by noise emanating from platform and vessel operations. Intermittent vessel operations in Commonwealth waters including the area towards seal islands and the southeast of Wilsons Promontory are not inconsistent with the conservation outcomes from the *Conservation Action Plan for Parks and Reserves Managed by Parks Victoria. Wilsons Promontory* (Parks Victoria, 2017), as underwater noise is not an identified threat to this species. In addition, as established in this EP, there are no BIAs for Otariid seals within or in proximity of the EMBA, therefore it is anticipated Campaign #1 vessel activities will have inconsequential effects on areas of important behaviours for this species.

As a result impacts to seals are predicted to be limited to temporary avoidance of the immediate area of the vessel. It is assessed as:

- **Consequence Level IV**.

HIGH FREQUENCY CETACEANS

The PMST report for the EMBA identified several migratory species (Appendix D), several dolphin species, beaked and toothed whales, however, no BIAs or biologically important behaviours were identified within the EMBA and therefore they are not assessed further.

Potential impacts to high-frequency cetaceans are predicted to be temporary avoidance of the area nearby where removal activities will be conducted if a whale approaches to close proximity of the vessels, with an assessed:

- **Consequence Level III**.

LOW FREQUENCY CETACEANS

The PMST report for the activity (Appendix D) identified blue whales (PBW sub-species) are likely to be present within the EMBA, and SRW are known to be present within the EMBA. These two species are listed as migratory, threatened species in the EPBC Act. In addition, the following BIAs have been identified to overlap with the noise EMBA:

- PBW: foraging BIA
- SRW: migration and reproduction BIAs.

The reproduction BIA for the SRW is also categorised as Habitat Critical to Survival (HCTS) of this species (DCCEEW, 2024f). The area designated as reproduction BIA (and HCTS) for the SRW is located within coastal waters across south-southeast Australia. When compared against the OA for Campaign #1, this reproduction BIA

does not overlap the OA. Table 6-71 presents the percentages at which BIAs for PBW and SRW overlaps with the EMBA and the OA of Campaign #1.

Table 6-71 Campaign #1 overlap with PBW and SRW BIAs

Species	BIA	Overlap with EMBA (%)	Overlap with OA (%)
PBW	Foraging	3.1	30.8
SRW	Migration	0.2	4.6
	Reproduction*	5.2	No overlap

* Also categorised as a HCTS area for SRWs.

Based on the underwater noise modelling results (Li, Connell, Warren, & Koessler, 2024), the maximum areas from the sound source where noise levels are above the PTS and TTS thresholds for LFCs are 0.45km^2 and 93.2km^2 respectively. These areas represent a very small portion of the total PBW known foraging BIA, estimated to be approximately 0.00025% for PTS and 0.05% for TTS. Similarly, when PTS and TTS areas identified in the JASCO report (Li, Connell, Warren, & Koessler, 2024) are compared against the migration BIA for SRW, the estimated percentage of the area that PTS and TTS areas represent against the total migration BIA for SRW is approximately 0.00002% for PTS and 0.004% for TTS. Given these small spatial overlays, if the activity has a temporal overlap with the presence and/or foraging of PBWs or migrating SRWs, it is unlikely to result in preventing cetaceans of using this BIA. In addition, it is not credible that a cetacean will remain in the same location exposed to the noise source for a continuous period of more than 24 hours, resulting in an unlikely and inconsequential impact. The same negligible impacts apply to other marine mammals that may be migrating through or foraging in the activity area at the time of the activity.

From a horizontal distance perspective, the furthest distance at which sound generated from vessel operations exceeds thresholds for LFCs where injury or disruption of behaviour could occur are 410m for PTS, 6.1km for TTS and 25km for behavioural response. As described in Section 6.13.3.5 of this EP, distances at which these thresholds may be triggered are based on a conservative, worst-case scenario, with conservative input data used as part of the underwater noise modelling exercise. As a result, it is expected vessel operations will generate lower noise levels than those described in the JASCO report.

A detailed assessment on potential impacts to PBW and SRW is shown below in Section 6.13.3.8. Impacts to other LFCs is assessed as a:

- **Consequence Level III**.

PYGMY BLUE WHALES

As PBW are listed as endangered under the EPBC Act and the sound EMBA overlaps with a foraging BIA established for this species, it is appropriate that the principles of ESD as described in Part 3A of the EPBC Act be applied.

The time and location of the appearance of the PBW generally coincides with the upwelling of cold water in summer and autumn along the Bonney Upwelling and the associated aggregations of krill that they feed on (Gill & Morrice, 2003). The Bonney Upwelling generally starts in the eastern part of the Great Australian Bight in November or December and spreads eastwards to the Otway Basin around February as southward migration of the subtropical high-pressure cell creates upwelling favourable winds. Sighting data indicates that blue whales are seasonally distributed (Gill P. C., et al., 2011) (McCauley, Gavrilov, Jolliffe, Ward, & Gill, 2018). In addition, an acoustic noise logger in Bass Strait has picked up acoustic detections from PBW in May – June (per the CMPBW). As a result, peak period of potential presence of PBW in the Bass Strait area is expected to occur towards the second quarter of the year (April -June), which suggest there is a low probability of overlap of Campaign #1 activities with peak presence of PBWs in the area. However, in the context of potential impacts from underwater noise emissions from vessel operations, a precautionary approach has been taken in assuming that blue whales may be present, albeit in relatively low numbers, in the Bass Strait at any time of year.

The CMPBW requires that "*anthropogenic noise in BIAs be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area*". *Guidance on key terms within the Blue Whale*

Conservation Management Plan (DAWE & NOPSEMA, 2021) defines the requirements further *"to ensure that any blue whale can continue to forage with a high degree of certainty in a Foraging Area, and that any blue whale is not displaced from a Foraging Area"*. Note that the CMPBW defines the Bass Strait, where vessel operations will take place, as a "*possible foraging area*" for PBWs. *Guidance on key terms within the Blue Whale Conservation Management Plan* (DAWE & NOPSEMA, 2021) also indicates the broader term 'foraging' encompasses 'Foraging Area', 'Known Foraging Area' and 'Possible Foraging Area'. In addition, this guidance suggests a whale could be displaced from a foraging area if stopped or prevented from foraging, caused to move when foraging, or stopped or prevented from entering a foraging area. A whale is considered to be displaced from a foraging area if foraging behaviour is disrupted, regardless of whether the whale can continue to forage elsewhere within that foraging area.

Adopting the controls defined in Section 6.13.6 of this EP aim to prevent or minimise impacts to PBW that may be foraging. Guidance on Key Terms within the Blue Whale Conservation Management Plan (DAWE & NOPSEMA, 2021) regarding the definition of 'displaced from a foraging area' states that mitigation measures must be implemented to reduce the risk of displacement occurring during operations where modelling indicates that behavioural disturbance within a foraging area may occur. The implementation of the control measures in Section 6.13.6 means that blue whale displacement from a foraging area is unlikely to occur. As such, the activity will be managed in a manner that is not inconsistent with the CMPBW, specifically Action Area A.2 - Assessing and addressing anthropogenic noise. A detailed assessment of the requirements from the CMPBW and how they are met by the Campaign #1 is outlined in Table 6-53.

In addition, since 2022 Esso maintains a record of whale sightings from vessels that are conducting activities associated with Esso Bass Strait operations. Information recorded up to August 2025 indicates there were 211 recorded whale sightings, however only six of those records were related to a blue whale sighting. Based on the visual evidence collected from these observations, presence for PBWs in the vicinity of facilities within the Bass Strait where vessels conduct operations is not a common occurrence.

Table 6-72 Analysis of Campaign #1 activities against the CMPBW

Description	Justification
A1 - Maintain, implement, and improve efficacy of current legislative and management protection	
1. Continue or improve existing legislative management actions.	This EP will consider and implement as applicable the following Commonwealth legislation and management arrangements: • Part 8 Division 8.1 of the EPBC Regulations • *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a) • *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b).
A2 – Assessing and addressing anthropogenic noise	
2. Assessing the effect of anthropogenic noise on blue whale behaviour.	The use of JASCO reports and summarised underwater sound reports assist with the commitments that Esso has in relation to this EP.
3. Anthropogenic noise in BIAs will be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area.	The OA and sound EMBA overlaps with the PBW foraging BIA. It is acknowledged that PBWs could be present in the area, although in small numbers, at any time of the year, however indicative peak PBW season (expected to occur towards April to June) is outside the period when HLV operations are expected to occur. Even though there is a very low probability of PBWs being present in the area at the time when vessel operations take place, Esso will apply

Description	Justification
	the precautionary approach, and will implement controls as described in Section 6.13.4. It is considered with these controls in place and the extension of the area that comprises the foraging BIA of the PBW, that the activities will not prevent any PBW from utilising the area or cause auditory impairment
5. Ensuring behavioural impacts are considered when developing and updating policy documents on the management of cetaceans and anthropogenic noise.	The OA overlaps a minor percentage of the PBW foraging BIA. The incorporation of the BIA into this EP demonstrates that Esso have considered the impacts of the Campaign #1 activities on PBW foraging. Esso has committed to control measures that will prevent and or mitigate potential impacts from removal operations (refer to Section 6.13.6).

PTS and TTS effects on cetaceans are not considered credible due to the extended duration (24 hours) for which an individual would need to remain in proximity to the sound source. In addition, distance modelled at which underwater noise levels could trigger PTS on LFC is mostly limited to the footprint of the vessel, indicating that a PBW would have to remain immediately adjacent to the Campaign #1 vessels during a continuous period of 24 hours to be susceptible to PTS. The occurrence of this scenario is not credible. However, as the OA is located within the PBW foraging BIA, there is potential for behavioural response to be triggered within this area due to underwater noise during vessel operations. This is considered acceptable because:

- as there is limited data available on PBW within the region, a precautionary approach (**Decision Context B**) has been adopted in considering controls to minimise and/or mitigate potential impacts from underwater noise (refer to Section 6.13.4)
- if PBWs are present, they are unlikely to be present in large numbers
- if PBWs are present, they are assumed to be foraging or transiting only. The OA defined for Campaign #1 is not identified to be within or in proximity to a reproduction location for PBWs
- the CMPBW states that:
    - shipping and industrial noise are classed as a 'minor' consequence (defined as: individuals are affected but no effect at a population level)
    - *"It is the high intensity signals with high peak pressures received at very short range that can cause acute impacts such as injury and death."* As vessel noise expected to be generated during decommissioning operations is a continuous noise source and does not have high intensity signals, it is unlikely that it would cause injury to foraging PBWs
- the OA is located at a distance of approximately 415km from the Bonney Coast Upwelling KEF, which is a known feeding and aggregation area for PBWs (Gill P. C., et al., 2011) (McCauley R. D., 1998). Therefore, vessel operations for Campaign #1 will not have any impact to PBWs ability to forage in that particular key aggregation area
- PTS and TTS effects on PBWs from vessel operation during Campaign #1 activities are not considered credible due to the extended duration (24 hours) for which an individual would need to remain in proximity to the sound source. In the same manner, vessel operations at a single location will be mostly short term. As a result, a temporary and intermittent potential impact of short duration may occur at the specific location at which the vessel is operating if a PBW is present in the proximity to that location
- there is a low likelihood that temporal overlap of vessel operations with the presence of foraging PBW will result in behavioural changes that affect ongoing foraging or migration of these species, The visual evidence collected from vessel sightings since 2022 indicates presence of PBWs in the area of operations is not a common occurrence. In addition, the vastness of the ocean in which the foraging behaviour take place and where foraging resources are available, and the small percentage of area covered by the sound EMBA when compared against the total area established as the BIA for PBWs indicates there will not be impacts to PBWs at a population level.

Based on this assessment, potential impacts to PBWs is considered inconsequential at a species population level. Potential short term and localised impacts may occur. Considering the precautionary approach, the overlap of the OA with the PBW foraging BIA, and the associated uncertainty on the potential behavioural response from individuals while foraging if presence of a PBW in the area coincide at a given point in time with the area vessel operations are taking place, the underwater sound impact is assessed as:

- **Consequence Level III**.

SOUTHERN RIGHT WHALES

The OA and the sound EMBA both overlap with the SRW migration BIA. In addition, results from the underwater noise model indicates that sound EMBA from one out of the nine scenarios modelled overlaps with the SRW reproduction BIA; there is also a second scenario modelled where the behavioural response threshold extends near, but not within, the reproduction BIA, which is also defined as a HCTS for this species (DCCEEW, 2024f). For these two scenarios, source of underwater sound from vessel operations are associated with transfer operations of removed structures from the HLV onto barges or a HTV in sheltered waters (within Commonwealth waters), and at some extent, to the operations related to HLV lifting system mode change. The requirement to conduct transfer operations and HLV mode change operations closer to the coastline, in a sheltered location, is to ensure operations are carried out in a safe manner. For this activity, metocean conditions are critical and can significantly influence the ability of the vessels to complete these operations. Sheltered waters located closer to shore provide more favourable weather conditions that allow for transfer operations to be conducted in a manner where potential risks to personnel, equipment, vessels and the environment are minimised. The nature of the transfer operation requires sheltered weather conditions (minimal sea states) to enable:

- transfer of the jackets/topsides from the HLV onto the HTV or barges
- transfer of personnel from the HLV onto the HTV or barges to undertake weld down of these structures on the HTV or barges
- vessels working in proximity to each other.

It should be noted that execution of this work at open water locations, with unrestricted weather conditions, would significantly increase risks to personnel, equipment, vessels and the environment. As a result, during execution of Campaign #1 operations, a decision criteria process will be implemented to define locations where transfer operations by the HLV and the CSV will take place, as well as the location where HLV mode change operation will occur. This selection criteria include consideration of both safety and environmental factors that are relevant to the operations. Refer to Section 2.8.2 for further detail on this process.

Mapping of BIAs available from the AMSIS (Geoscience Australia, 2025) indicates the reproduction BIA for the eastern SRW population covers the coastal waters located between the northeast corner of New South Wales to the southeast coast of South Australia, and across the Tasmanian coastline. The SRW reproduction BIA is limited to coastal, State waters, extending up to approximately 2.5km from the coastline along the entire defined reproduction corridor. Breeding period as shown in this source is suggested to occur approximately from May to September, and migration period is suggested to occur approximately from April to October. SRW BIAs and HCTS are also depicted in the *National Recovery Plan for the Southern Right Whale* (NRPSRW) (DCCEEW, 2024f), with Figure 4 and Figure 5 from this recovery plan indicating the same reproduction and migration periods as the AMSIS tool, including a statement in each figure informing that the "*Southern right whale BIAs are designated on reliable information on species occurrence and biologically important behaviour, including direct observational data and satellite tracking information*". However, Section 2.8.1 of the NRPSRW also indicates that SRW in Australian waters predominantly occupy shallow waters to calve and nurse their young from May to October.

The NRPSRW indicates presence of SRWs in Australian waters may vary, however, the peak period of abundance tends to be late July and August. Females accompanied by a calf may occupy the calving grounds for two to three months between June and September. This is consistent with additional description on abundance and population trends presented in the Recovery Plan, where it is stated that '*Based on breeding females sighted across the period 1996 to 2017 prior to the post-breeding southward migration (i.e. month of September), an estimate of population size for the eastern population resulted in 268 (146-650) whales…*' (DCCEEW, 2024f).

SRWs demonstrate high fidelity to feeding and breeding areas. The NRPSRW suggests four historic use areas based on available information. SRWs are consistently observed in two of these four areas, namely in the southeast of South Australia and the southwest of Victoria. In the two other high historic use areas, located off the southeast coast of Tasmania and near Eden on the border between Victoria and New South Wales, they are less consistently

observed. The recovery plan also indicates that there is no current published evidence for consistent re-occupation of areas by the eastern SRW population other than some bays in southwest Victoria, however there are increasingly regular records of short-term use by mother-calf pairs along the Victorian, Tasmanian, and southern New South Wales coastline from May to September. In these areas, small but growing numbers of calving and non-calving whales have been observed to regularly aggregate for short periods (days to weeks). These include coastal waters between Binalong Bay to South-East Cape in Tasmania, the Gippsland coast in Victoria and in numerous protected bays generally south of the New South Wales Central Coast, potentially extending north as far as Port Macquarie (DCCEEW, 2024f).

According to the NRPSRW, the only established calving aggregation location for SRWs in the southeast area of Australia is Logan's Beach, located near Warrnambool, Victoria, and that there has been expansion and re-occupation into historic breeding areas as the population has increased in abundance, with whales now utilising areas such as Geographe Bay (Western Australia), Fowlers Bay (South Australia) and Encounter Bay (South Australia).

Similarly, information available in *CoastKit Victoria* (DEECA, 2023a) indicates that marine mammal areas associated to SRW are present towards the western end of Victoria, in coastal waters near Lorne, Apollo Bay, Moonlight Head, and between Warrnambool and Port Fairy including an area identified as a SRW calving location at Logans Beach. All these areas are located at more than 240km from the western boundary of the OA established for the Campaign #1 activities.

In addition to the fact that currently there are no established calving aggregation locations within the area where decommissioning activities will take place, it is also unlikely that calving whales would remain within the OA, as the whales prefer to occupy depths of less than 10m within 1km from the coastline. Platforms that will be decommissioned during Campaign #1 activities are located more than 20km away from the SRW reproduction BIA at the closest point (at DPA), and up to approximately 78km distance (at KFB). As a result, it is not expected underwater sound from vessel operations at the platforms will have any effect on SRWs that may be present within the reproduction BIA. It is also anticipated that transit of vessels between facilities, or between facilities and transfer locations, would not have any adverse effect on SRW within the reproduction BIA area. On the other hand, vessel operations to transfer removed structures from the HLV onto barges or a HTV, or the completion of the HLV mode change operation may be conducted at sheltered waters that are closer to shore, however still within Commonwealth water limits. Therefore, a temporary overlap of the sound EMBA with the SRW reproduction BIA or the area adjacent to this BIA may occur during these specific activities, dependent on the location of the transfer operations and the HLV mode change operation, as generation of underwater sound during transfer operations at levels that may trigger a behavioural response from LFC extends up to approximately 25km from the noise source.

Results from the underwater noise modelling by JASCO indicates noise at which PTS thresholds for marine mammals are exceeded extends up to 410m from the source. Considering the dimensions of the HLV, with a hull length of 382m and a breadth of 123.7m, it is expected that underwater noise within PTS threshold levels will be limited to the immediate vicinity of the location of the vessel. The reproduction BIA of the SRW will not be affected by noise levels that could generate PTS to this species. Underwater sound within TTS and behavioural response thresholds may overlap or reach to a distance near the reproduction BIA of the SRW. TTS effects on SRW from vessel operations during Campaign #1 activities are not considered credible due to the extended duration (24 hours) for which an individual would need to remain in proximity to the sound source. In the same manner, underwater noise generated by thrusters to allow the HLV to maintain position during lifting operations, during transfer operations, or during the one-off HLV vessel mode change operation, will be intermittent and short-term at each location, with noise from the vessels reduced as soon as each individual operation is completed and vessel changes from an operational mode to a transit mode to travel from one location to the next.

In the same manner, HLV operations for Campaign #1 activities, including those activities associated with transfer operations and vessel transit between the facilities and the transfer locations, will be limited to the months between September and February; as a result, underwater noise from vessel operations during the core period for presence of SRWs, which tends to occur between July and August, will be avoided, with a potential overlap during HLV operations limited to the last two months of the suggested reproduction season (September and October). This significantly reduces the probability of temporary overlap of vessel operations with presence of calving SRWs within or in proximity the reproduction BIA.

The SRW is a highly mobile migratory species that travel thousands of kilometres between habitats used for essential life functions. Feeding has not been observed in coastal Australian waters, although other parts of the

Australian Exclusive Economic Zone may be utilised for feeding (DCCEEW, 2024f). For the eastern SRW population, there has been a 25% increase of foraging at higher latitudes (DCCEEW, 2024f), which are closer to Antarctic waters. SRWs tagged at Auckland Islands off New Zealand demonstrated consistent westward migratory movements to offshore waters south of the Head of the Bight (South Australia) and Western Australia (DCCEEW, 2024f).

There is the potential for migrating SRWs, including mother-calf pairs to be present within the OA at the time of the Campaign #1 activity, particularly during September when it is suggested that the post-breeding southward migration may occur (DCCEEW, 2024f). As previously mentioned, SRW are a highly mobile migratory species, therefore a temporary overlap of the sound EMBA from vessel operations with migrating whales is not expected to have as significant impact on the species. In addition, in light of the small percentage of area covered by the sound EMBA associated to vessel operations when compared to the total area covered by the BIAs in which migratory and reproduction behaviours take place, it is not likely whales will be restricted or deterred from accessing areas where these biologically important behaviours are known to occur (i.e. reproduction areas in shallow coastal waters). Moreover, and based on available information to date, the eastern population of SRWs prefer aggregation areas located towards southwest Victoria, such as Logan's beach, and other areas within South Australia. These key calving and aggregation areas are located hundreds of kilometres away from the OA.

In addition, since 2022 Esso maintains a record of whale sightings from vessels that are conducting activities associated with Esso Bass Strait operations. Up to August 2025 there were 211 recorded whale sightings, however none of those records were related to a SRW sighting. Based on the visual evidence collected from these observations, presence for SRWs in the vicinity of facilities within the Bass Strait where vessels conduct operations is not a common occurrence.

As a result, occasional overlap of vessel operations with presence of migrating whales may be possible, however is not considered to have a significant effect on this species.

The potential impacts from underwater sound emissions generated by vessel operations during Campaign #1 activities were also assessed against the applicable recovery actions in the NRPSRW (Table 6-73).

Table 6-73 Analysis of Campaign #1 activities against the *National Recovery Plan for Southern Right Whale* (DCCEEW, 2024f)

Description	Justification
A1 - Maintain, implement, and improve efficacy of current legislative and management protection for SRW	
1. Maintain, implement, and improve efficacy of existing legislation and management arrangements (e.g. managements plans and guidelines) as listed under Section 1.2 of the NRPSRW.	This EP will consider and implement as applicable the following Commonwealth legislation and management arrangements, in line with advice outlined in Section 1.2.1 of the NRPSRW (DCCEEW, 2024f): • Part 8 Division 8.1 of the EPBC Regulations • *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a) • *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b) (see A5.4 below) • NRPSRW • *South-east marine region profile: A description of the ecosystems, conservation values and uses of the South-east Marine Region* (DoE, 2015a) • *South-east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025).
A5 - Assess, manage, and mitigate impacts from anthropogenic underwater noise	

Description	Justification
2. Actions within and adjacent to SRW BIAs and HCTS should demonstrate that it does not prevent any SRW from utilising the area or cause auditory impairment.	The OA and sound EMBA overlaps with the SRW migration BIA. In addition, due to vessel operational safety considerations, the activities of transferring removed structures from the HLV onto barges or HTV need to be conducted in sheltered locations where metocean conditions are favourable. As a result, transfer operations will occur in Commonwealth waters, however in proximity to the coastal waters band established as a SRW reproduction BIA (also defined as a HCTS for this species). The potential for auditory impairment during decommissioning activities is when the vessels are utilising DP thrusters and a whale is located within the sound EMBA identified for PTS and TTS thresholds. However, as whales are highly mobile and are not expected to remain within the PTS or TTS areas of exposure for 24 continuous hours, it is not considered likely auditory impairment to SRW will occur. In addition, distance at which PTS effects on SRWs could be triggered from vessel operations is limited mostly to the footprint of the vessels and immediate adjacent area, which further reduces the likelihood of a whale to be exposed to levels of noise that could cause PTS. It is also determined that underwater sound at levels that could trigger PTS effects on LFC will not overlap with the SRW reproduction BIA. HLV vessel operations will be conducted from September to February , which is outside the peak period for presence of SRWs in Australian waters and its core breeding season (July-August), however, the decommissioning activities overlaps with the last two months of the overall reproduction and migration seasons suggested for SRW (September and October). Decommissioning activities are located hundreds of kilometres away from known or preferred aggregation and calving areas of the SRW eastern population, which are identified mostly towards the southwest of Victoria and the southeast of South Australia. As a result, no impacts to these known aggregation and calving locations utilised by SRWs have been identified from Campaign #1 activities. Sound EMBA during decommissioning operations, inclusive of lifting, transit/transport and transfer operations may have a temporary overlap with migrating SRWs. in addition, sound EMBA during decommissioning operations that are limited to areas closer to the coast such as transfer operations or the HLV mode change operation may temporarily overlap with the SRWs reproduction BIA. However, considering the short duration of the event due to the high mobility of the SRW and the small percentage of area the sound EMBA represents of the total migration and reproduction BIAs, it is not expected vessel operations will prevent SRWs from migratory movement or reproduction behaviours within these BIAs. Considering there is some level of uncertainty on potential overlap between decommissioning activities and SRWs that may be present in the area at the time when operations are underway, Esso will apply the precautionary approach by implementing controls to manage this potential overlap. The controls in place (refer to Section 6.13.6) will ensure that potential impacts to SRWs are managed adequately, allowing whales to continue using the area and preventing potential harm.

Description	Justification
	Given that decommissioning activities will take place outside core presence period of SRWs, and with the controls proposed for vessel operations in this EP, it is considered the activities will not prevent any SRW from utilising the area and will not cause auditory impairment.
3. Actions within and adjacent to SRW BIAs and HCTS should demonstrate that the risk of behavioural disturbance is minimised.	The OA, and therefore, the sound EMBA from vessel operations overlaps with the SRW migration BIA. In addition, due to vessel operational safety considerations, the activities of transferring removed structures from the HLV onto barges or HTV, as well as the one-off HLV mode change operation need to be conducted in sheltered locations closer to shore where metocean conditions are favourable. As these operations will occur in Commonwealth waters, however in closer proximity to the coastal waters band established as a SRW reproduction BIA (also defined as a HCTS for this species), sound EMBA may overlap with or extend to the proximity of this BIA. HLV operations will be conducted from September to February which is outside the peak period for presence of SRWs in Australian waters and its core breeding season (July-August), however, the decommissioning activities overlaps with the last two months of the overall reproduction and migration season suggested for SRW (September and October). Decommissioning activities will be conducted hundreds of kilometres away from known or preferred aggregation areas of the SRW eastern population, which are identified mostly towards the southwest of Victoria and the southeast of South Australia. As a result, no impact to these known aggregation and calving locations utilised by SRWs have been identified for decommissioning activities. Potential exposure of SRWs to sound levels that may trigger a behavioural response is expected to be limited to whales that may be transiting or passing through the area when Campaign #1 activities are underway. The sound EMBA may have a temporary overlap with migrating SRWs; however, considering the likely short duration of this potential overlap due to the high mobility of the SRW, and the small percentage of area the sound EMBA represents of the total migration BIA, it is not expected vessel operations will prevent SRWs from migratory movement within the BIA. Underwater sound generated during decommissioning activities associated with vessel operations where the platforms are located and during transit of the vessels between facilities, and between facilities and the transfer location, at levels that may trigger behavioural response on LFC will not overlap with the SRW reproduction BIA. However, underwater noise generated during transfer operations and the HLV mode change activity may overlap with the SRW reproduction BIA at levels that may trigger behavioural response. Transfer operations and the HLV mode change activity may overlap with the reproduction BIA, however, this will take place outside the peak presence period of SRWs and at a significant distance from known SRW aggregation areas. Considering there is some uncertainty on potential overlap between decommissioning activities and SRWs that may be present in the area at the time when

Description	Justification
	operations are underway, Esso will apply the precautionary approach and will implement controls to manage this potential overlap. The controls in place will ensure that potential impacts to SRWs are managed adequately, allowing whales to continue using the area and minimising potential exposure to harm.

4. Ensure environmental assessments associated with underwater noise generating activities include consideration of national policy (e.g. *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b) and guidelines related to managing anthropogenic underwater noise and implement appropriate mitigation measures to reduce risks to SRW to the lowest possible level.	Although seismic surveys are not an activity covered under the scope of this EP, the control measures proposed in this EP do align with *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b). A list of management procedures listed in the Policy Statement that are addressed by implementation of proposed controls in this EP to manage impacts from underwater noise are shown below. A more detailed description is provided in Section 6.13.6.
	
	• A2: Trained crew:
	  - for the execution of Campaign #1 activities, there will be sufficient trained crew to ensure operations are conducted in alignment with policy and regulations to manage underwater noise and reduce risk to SRWs.
	• A3.1: Pre-start-up visual observations:
	  - observations for SRWs prior to start vessel safety-critical operations.
	• A3.3 Start-up delay procedure:
	  - Adapt works if SRW is seen prior to supply vessel works or adapt HLV/CSVs safety-critical operations commencing as per procedure described in Table 6.76.
	• A3.4: Operations procedure:
	  - Procedures will be in place to ensure continuous daylight visual observations take place during the execution of Campaign #1 activities.
	• A3.6: Night-time and low visibility procedures:
	  - A night-time and low visibility procedure is adopted in this EP to inform vessel operations (refer to Section 6.13.6).
	• A4: Compliance and sighting reports:
	  - Esso's responsibility to notify DCCEEW within three days if there is a cetacean vessel strike.
	• B1: Marine mammal observer (MMO):
	  - Esso will incorporate MMOs as part of the crew required onboard the HLV during Campaign #1 activities.
	• B3: Spotter vessel(s) and aircraft:
	  - Esso will incorporate pre-start aerial surveys before the start of vessel safety-critical operations when conditions allow and distances at which behavioural

Description	Justification
	threshold on PBWs or SRWs, could be triggered is estimated to be greater than 9.5km from the sound source. • B.6: Adaptive management: - Esso will implement an adaptive whale management plan for Campaign #1 to allow for adequate management of operations where there is an increase in the likelihood of encountering whales. The adaptive management plan will include procedures mentioned separately in this EP (refer to Section 6.13.6), such as actions to be implemented if/when there are reported sightings of SRWs, and daytime and night-time operation procedures, to manage underwater noise and reduce risk to SRWs.
5. Quantify risks of anthropogenic underwater noise to SRWs, including studies aimed to measure physiological effects, behavioural disturbance, and changes to acoustic communication (e.g. masking of vocalisations) to whales	Use of JASCO reports (Li, Connell, Warren, & Koessler, 2024) to provide modelling results, which assisted with identifying and assessing potential impacts to marine fauna (including SRWs), and deciding the control measures that are proposed for implementation during vessel operations to manage the potential impacts identified.
A6 - Manage, minimise, and mitigate the threat of vessel strike	
1. Assess risk of vessel strike to SRW in BIAs.	To reduce the risk of vessel strike, vessel crew will be assigned with responsibilities of marine fauna observation as described in Section 6.13.6. There will be continuous observation for marine megafauna and other marine users. Section 7.1.5 of this EP details the risk assessment of physical interaction with marine fauna and describe the controls to be implemented to manage this risk.
3. Ensure environmental impact assessments and associated plans consider and quantify the risk of vessel strike and associated potential cumulative risks in BIAs and HCTS.	Vessel strike consequence was identified as 'major' in the NRPSRW. The risk assessment, described in Section 7.1.5 of this EP, considered the location of Campaign #1 activities and its overlap or proximity to SRW BIAs and HTCs, as well as information sources such as the *National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna* (Commonwealth of Australia, 2017c). In turn, this provided the basis for identification of adequate preventative and mitigation measures for vessel operations.
5. Ensure all vessel strike incidents are reported in the National Ship Strike Database managed through the Australian Marine Mammal Centre, Australian Antarctic Division	Esso will report SRW vessel strike incidents to these authorities, additional to DCCEEW and NOPSEMA.

Based on this assessment, it is not anticipated vessel operations in the area where the facilities/platforms are located, and during transit of the vessels between facilities and between facilities and the transfer location will have a significant impact on SRWs. However, given the increased sensitivity of SRW in coastal waters, where a reproduction BIA and associated HCTS have been established for this species, transfer operations and the HLV mode change operation have a potential to trigger behavioural response on SRWs that may be present in the area when these operations are underway.

Underwater noise generated during these operations closer to the reproduction BIA will be localised and short term, and vessel operations will not impact known areas for aggregation and calving of SRWs. In addition, controls will be implemented to manage and reduce impacts to SRWs that may potentially be generated from vessel operations during decommissioning activities; these controls are described in Section 6.13.4 of this EP. However, considering the sensitivity of SRWs and following the precautionary approach, the impact is assessed as:

- **Consequence Level III**.

6.13.3.7 Contingency subsea tool – Ripper

There is limited information available on sound source levels for this type of tool. For the purpose of this EP, the assessment of potential noise generated by a ripper tool and its potential effect on the marine environment is based on information available for the Xcentric XR-60 tool, a hydraulic ripper tool that generates a non-impulsive sound (Connell S.C, Koessler M.W and McPherson C.R, 2023). The referenced noise modelling for the hydraulic Xcentric ripper aimed to provide information on characterisation of this sound source for underwater trenching activities to determine how the sound is propagated considering environmental properties of the location modelled, and presents estimated underwater acoustic levels (expressed as sound pressure levels – SPL, L_P -, and accumulated sound exposure levels – SEL, L_E). This study indicates that a broadband source level of 184.8dB re 1 μ Pa^2m^2s was calculated for the Xcentric ripper tool, with the main source of noise at a nominal 1m above the seafloor.

According to Santos (Santos, 2023) the scenario chosen for modelling noise generated by the Xcentric ripper tool considered a rock breaking activity in an area of hard rock. This scenario is effectively representing the use of the ripper tool to cut through hard rock/substrate as part of a pipeline trenching activity. The potential use of a ripper tool for Campaign #1 operations is different to the scenario modelled for the Xcentric ripper tool, as for Campaign #1 the ripper would only be used to move (where possible) or make targeted cuts in obstructions such as grout or rock present on the seabed adjacent to the jacket legs or pipelines at the cut location. When compared to the scenario of breaking a more consolidated hard rock present within the top layer of the seabed, the grout or rock obstructions that may need to be cut during Campaign #1 operations are likely to have less resistance to penetration and breaking, resulting in less effort from the tool and potentially less noise generated. Based on this consideration, the use of the report (Connell S.C, Koessler M.W and McPherson C.R, 2023) is deemed to be a conservative approach for assessing potential noise impacts associated with the potential use of a ripper tool during decommissioning activities.

Results from the noise modelling (Connell S.C, Koessler M.W and McPherson C.R, 2023) indicated the following for the hydraulic Xcentric ripper:

- PTS - Potential distances from the sound source at which noise levels could trigger PTS effects was limited to a maximum of 180m for LFC. No PTS effect was anticipated for other species such as sirenians or sea turtles
- TTS - Potential distances from the sound source at which noise levels could trigger TTS effects was assessed as a maximum of 3.8km for LFC, 110m for sirenians and 50m for sea turtles. For fish with a swim bladder involved in hearing, the distance at which the 12 hours exposure threshold could potentially trigger a TTS effect is limited to 90m from the sound source
- Behavioural response - Results from the noise modelling indicated that the distance at which noise generated by the Xcentric ripper could trigger a behavioural response from marine mammals could extend up to 14.7km.

As described in Section 6.13.1.4, use of the ripper is only anticipated in the event that internal cutting of jacket legs at seabed level is not possible, and if there is presence of hard material such as grout or rocks adjacent to the cut location of jacket legs or pipelines that need to be cleared from the location if these items are obstructing access for external cutting. In addition, actions to clear these obstructions if required, would prioritise moving or pushing them away rather than cutting them, or cut them if the obstructions are fixed and can't be moved or pushed by the equipment available.

Cutting of jacket legs and pipelines is planned to be executed by the CSV. Therefore, in the event that the use of additional subsea tools such as the ripper is required, this activity is anticipated to also take place using the CSV. The scenarios in which this contingency tool may be required is limited to three platforms (FTA, WTA and BMA) and pipelines at the cut location.

Based on the location of the platforms and the potential extent of underwater noise that may be generated by the ripper tool, PTS and TTS effects on cetaceans are not considered credible. Marine mammals would need to remain continuously exposed to specific sound pressure levels for a period of 24 hours. In addition, distance modelled at which underwater noise levels could trigger PTS on LFC is limited to the footprint of the vessel, indicating that a LFC such as a PBW or a SRW would have to remain immediately adjacent to the location where the ripper tools is being used for a continuous period of 24 hours. The occurrence of this scenario is considered not credible.

From a behavioural response perspective, the distance at which LFC could be exposed to sound levels of 120dB may extend up to 14.7km from the sound source. As a reference, the facility that is located closest to the shoreline is DPA, at approximately 21km from the coast. As a result, it is not anticipated that noise from the use of the ripper that could trigger a behavioural response on LFC will overlap with the SRW reproduction BIA (also identified as a HCTS for this species). However, as the OA is located within the PBW foraging BIA and the SRW migration BIA, there is potential for a behavioural response to be triggered by underwater noise to whales within this area during the operation of the ripper tool.

Based on this assessment, potential impacts to LFC, mainly PBWs and SRWs, is considered inconsequential at a species population level. Potential short term and localised impacts may occur. Considering the precautionary approach, the overlap of the OA with the PBW foraging BIA and the SRW migration BIA, the underwater sound impact is assessed as:

- **Consequence Level III**.

6.13.3.8 Cumulative impacts

Underwater noise modelling completed by JASCO for the Campaign #1 activities considered a range of different scenarios, most of them which included simultaneous operations of vessels, ROVs and subsea cutting activities (Li, Connell, Warren, & Koessler, 2024). As a result, it is considered that potential cumulative effects from vessel operations associated to Campaign #1 activities have been addressed in Sections 6.13.3.1 to 6.13.3.6.

Offshore activities in the Bass Strait by other oil and gas operators includes the following:

- Basker Manta Gummy Closure Project Phase 2 (Cooper Energy Limited): Environment Plan for this activity was accepted by NOPSEMA on the 13 February 2024. Activities to be undertaken by Cooper Energy under this EP are:
    - campaign to remove flowlines, umbilicals and any remaining infrastructure above the mud line. This Campaign is expected to occur at any time between 2024 and 2026
    - decommissioning activities, which will be completed by the end of 2026
    - post-decommissioning activities such as monitoring, to be finalised by the end of 2027.
- Gippsland Offshore Operations (Cooper Energy (PBF) Pty Ltd): Environment Plan for this activity was accepted by NOPSEMA on the 21 October 2024. Activities to be undertaken by Cooper Energy under this EP include the IMR activities. Indicatively, vessel based IMR activities are expected to occur every one to two years, with an estimated duration of between two to four weeks, and up to approximately eight weeks in the unlikely event a major repair is required.

HLV operations for lifting of topsides and jackets will be conducted within the ATBA for Esso operations in the Bass Strait. Operations from other oil and gas operators in the area are limited, with potential sporadic, short term IMR activities that would take place several kilometres away from the nearest Esso Bass Strait facilities. As a result, it is not expected Campaign #1 activities will overlap with vessel operations from other operators that could result in cumulative underwater noise impacts.

Currently planned offshore activities in the Bass Strait for Esso operations include the following:

- **Jack-Up Rig P&A EP** - The EP for this activity was accepted by NOPSEMA on 8 October 2024. The pre-start notification for activities under the scope of this EP was made in October 2024. The P&A program is estimated to have a duration of 12 months to 16 months and is expected to be completed by early 2026
- **Jack-Up Rig Kipper Stage 1B drilling EP** - The EP for this activity was accepted by NOPSEMA on 9 January 2025. Earliest expected start of activities under the scope of this EP is 2025. Duration of activities is estimated in approximately 90 days; however, duration is dependent on weather, scheduling and operations performance

- **Geophysical and Geotechnical (G&G) Investigations EP** - The EP for this activity was accepted by NOPSEMA on 17 March 2025. Currently there are no specific dates available on when G&G activities will take place, however it is stated that activities could happen at any time within the duration of the EP (five years from the date of approval by NOPSEMA). The EP describes that G&G survey campaigns are typically 20 to 60 days in duration, with a maximum duration of G&G campaigns to be no more than a combined total of 180 days per calendar year
- **Jack-up Turrum Phase 3 Drilling** - Esso is planning to undertake drilling operations at the Marlin B platform. Environment Plan for this activity was accepted by NOPSEMA on the 19 May 2025. The expectation for commencement of the activity is towards the fourth quarter 2025, dependent on factors such as weather and operational constrains. It is expected that activities covered in the scope of the Turrum Phase 3 Drilling operations will have a duration of 300 days.

It is not expected that Jack-Up Rig operations from the projects described above will overlap with operations of the HLV during Campaign #1 activities. In addition, currently there is no indication on overlap with G&G activities, however this is dependent on factors such as weather, operational schedules and vessel and equipment availability. In any case, and due to the safety-criticality of the HLV operations, no additional activities from vessels that are not associated with Campaign #1 activities are expected to be occurring in proximity of the location where the HLV is operating. As a result, it is not expected that Campaign #1 activities will overlap with vessel operations from other projects within the Bass Strait that could result in cumulative underwater noise impacts.

From a wind energy projects perspective, the Australian government has granted 12 feasibility licences for offshore wind projects off Gippsland's coast. From these 12 projects, six overlap at some extent with the OA for Campaign #1. Offshore wind farm projects are currently in early stages of planning, with processes for environmental and other approvals currently under way.

There is potential for cumulative underwater sound emissions generated from overlapping Campaign #1 activities and wind farm operations. Currently there is high uncertainty on exact timing when early offshore works (geophysical surveys) and construction activities of wind farms will take place. However, based on communications held between Esso and wind farm operators, the following information is provided. Note that the timing presented below is only indicative and is subject to change at any time by the wind farm operators, based on regulatory aspects or other projects' requirements. Esso maintains an open line of communication with wind farm operators to ensure the Company is aware of updates from the offshore wind industry that may be relevant to Campaign #1 activities in a timely manner.

- Gippsland Dawn Project (Bluefloat) – Information available at the end of 2024 suggested geophysical survey may occur from third quarter 2025. Approximate duration is between one to three months. However, latest information as of July 2025 indicates that feasibility license has been withdrawn, resulting in this project no longer considered as a source of potential cumulative impacts from a Campaign #1 perspective.
- Navigator North Project (RES Group/Origin) – Preliminary information available suggests construction activities may begin in 2029. Additional information communicated by this project indicates the following:
    - field surveys and environmental studies may take place between late 2025 to 2027
    - completion of environmental impact statement, as well as environmental and planning approvals planned for 2027 - 2028
    - estimated approval decision, commercial detailed design, management plans, financial and procurement to take place in 2029
    - early fabrication and construction program to take place in 2030
    - first power and commercial operations to take place between 2032 to 2034.
- Blue Mackerel North Project (Parkwind and Beach) – Geophysical survey commenced November 2024 and is expected to take up to 40 days. Preliminary information available suggests geotechnical survey will commence during the first half of 2025, and construction of the Project, after approvals are granted, are estimated to commence in 2029. Commercial operations expected to begin in 2032.
- Aurora Green Project (Iberdrola Australia) – Preliminary information available suggest geophysical and geotechnical surveys may occur between late 2024 and early 2025. No information is available on the estimated timing for construction operations. Latest information from June 2025 indicates the Offshore Infrastructure Regulator has approved the feasibility stage management plan. If all approvals are obtained the first phase of the project plans to be operational by 2033.

- Great Eastern Offshore Wind Farm Project (Corio Generation) – Preliminary information available suggests offshore site investigations may occur between first quarter 2025 and first quarter 2027. Construction is estimated to begin in 2028, and operations are estimated to begin in 2032.
- Star of the South (Southerly Ten) – Information available indicates the operator is currently preparing environmental assessments to seek required approvals and 'may commence construction by the end of the decade'. Latest update from May 2025 indicates there is an increase to licence area, a reduction in the number of turbines and export cables, and an increase to the number of offshore substations planned. All necessary approvals are still pending, with confirmation that current expectation is for construction to start later this decade, targeting first power around 2030.

Based on this information, it is not expected that Campaign #1 activities will overlap with vessel operations from wind farm operators that could result in underwater noise cumulative impacts.

This EP considers direct and indirect impacts from activities conducted within Commonwealth waters (including off-title areas) across the OA as described in Section 3.1. Campaign #1 activities conducted outside of the OA will be subject to applicable approvals under Victorian and Commonwealth environment laws, and are not within the scope of this EP.

Esso intends to prepare and submit a staged referral under the EPBC Act to DCCEEW. The second stage of the referrals will cover aspects associated with the transportation of decommissioned assets through State waters and offloading and set down at the Barry Beach Marine Terminal.

6.13.4 Demonstration of As Low As Reasonably Practicable

Table 6-74 Decision Context and justification

Decision Context
Decommissioning activities using HLVs is a common and well understood practice in the industry, and industry best practice has been applied for removal operations through the implementation of detailed planning and facility preparation activities to maximise efficiency of the decommissioning project. However, there is the potential for some uncertainty in relation to the level of impact from HLV operations in the Bass Strait area, particularly due to the potential presence of SRWs in areas where important behaviours occur that may temporarily overlap with underwater noise generated during vessel operations. The environmental consequence for the impacts resulting from underwater sound emissions have been assessed as **Consequence Level III** or **Consequence Level IV**. Stakeholder interest has been noted regarding underwater sound emissions as a result of removal activities. There are no conflicts with Company values. Hence, Esso believes **Decision Context B** should apply.

Table 6-75 Good practice controls

Good practice	Adopted	Control	Rationale
Comply with Part 8 Division 8.1 of the EPBC Regulations.	Adopted – IMP13-CM1	Application of the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a).	The *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a) were developed jointly by all State and Territory governments through the Natural Resource Management Ministerial Council. Although they were developed with the purpose of providing information to commercial tourism operators and the general public on how to watch whales and dolphins safely and consistently with the EPBC Act, they also provide a list of requirements that are often adopted by the oil and gas industry to minimise the risk of cetacean strike occurring, but also to reduce potential for disturbance. This also has the effect of ensuring a minimum distance

Good practice	Adopted	Control	Rationale
			from vessels and aircraft that produce sound emissions. Application of this control during Campaign #1 operations is a feasible, standard good practice that allows for compliance with legislation on interaction with cetaceans as per the EPBC regulations Part 8 – Division 8.1. The control is to be implemented across all vessel operations that are within the scope of this EP, including facility lifting/removal, vessel transit, and transfer operations.
Preventative maintenance.	Adopted – IMP13-CM2	Preventative maintenance program.	Periodic maintenance of equipment and machinery is a standard practice that allows operators to maintain vessels, ROVs and aircraft operating safely and in accordance with manufacturer's specifications and class/classification society requirements (where applicable). An adequate maintenance program covers equipment and machinery that is associated with generation of noise and vibrations. Equipment and machinery that is adequately maintained is more likely to have lower emissions of noise and vibrations, which in turn may reduce the level of underwater noise that is produced from vessel and aircraft operations. Application of this control during Campaign #1 operations is a feasible, standard good practice.

Table 6-76 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Do not undertake the activity.	Eliminates underwater sound generation.	Not feasible. General Direction 817 indicates Esso must complete all preparatory decommissioning activities and commence the topside dismantling campaign as soon as reasonably practicable, and no later than 30 September 2027, associated with facilities listed in Schedule 3 of the Direction.	Not adopted
Marine fauna observations by trained vessel crew.	Continuous fauna observations reduce the uncertainty on presence of whales in the proximity of the vessel during Campaign #1 activities and allows for adaptive management actions to be undertaken where required.	Routine bridge watchkeeping tasks are focused on navigational safety, situational awareness, DP monitoring, oversight of bridge alarms, communications, and compliance with COLREGs. Including marine fauna observation responsibilities as an additional task for bridge watchkeeping in areas where there is presence of sensitive species is a measure widely used within the offshore oil and gas industry. Marine fauna observations tasks appointed to vessel crew (officer of the watch) may conflict with other watch responsibilities such as periods that coincide with high navigational workload (e.g. manoeuvring, DP adjustments, or SIMOPS). Additional measures to ensure that continuous fauna observations are not interrupted will be put in place. Examples of additional measures include: • increase in bridge watch activities • temporary assignment of dedicated crew for fauna observations when the Officer of watch can't conduct this task due to overlap with other watch responsibilities (navigational safety, situational awareness, DP monitoring, oversight of bridge alarms, communications). For effective implementation of the marina fauna observation task, relevant vessel crew must be adequately trained to allow for accurate sensitive species (for instance, whales) observation and identification as part of their routine watch duties. Vessels also must comply with AMSA Marine Order 28 – Division 3 (*Standards for watchkeeping*) to ensure personnel are fit to complete the task. In addition, equipment and tools such as binoculars and identification charts of marine megafauna relevant to the area of operations must be readily available to vessel crew to support marine fauna observations. Continuous fauna observations must be conducted during daylight hours.	Adopted – IMP13-CM3

Control Measure	Benefit	Cost/feasibility	Adopted
		Vessel crew must also be provided with a Campaign #1 EP-specific environment awareness induction to further reinforce requirements in whale observation, species identification, reporting requirements, regulatory and compliance obligation, and adaptive management actions. Distance up to which marine fauna observers can see and identify whales is limited by factors such as metocean conditions and the height of the observation post. The higher the location in the vessel from where marine fauna observations are made, the greater is the distance that can be reached by the observer. As a reference, marine fauna observations conducted during P&A projects completed by Esso in the Bass Strait have indicated ability to observe whales from a project vessel to a distance of up approximately 9.5km in clear conditions.	
Limit the durations of lifting, transfer and mode change operations.	Reduces the duration of the generation of underwater sound from HLV operations.	Not feasible. Lifting, transfer and mode change operations are vessel safety critical operations (refer to Section 2.8.5). Limiting the duration of these activities is not safe or practical. The area where transfer operations and the HLV mode change operation may take place is located hundreds of kilometres from known SRW regular aggregation locations (i.e. Logan's Beach in Warrnambool) and also from areas where reoccupation or expansion of SRW breeding areas has occurred such as Geographe Bay, Fowlers Bay and Encounter Bay. Alternative controls, as presented in Section 6.13.6 of the EP, will be in place to manage potential underwater noise impacts from vessel operations during Campaign #1 activities.	Not adopted
Timing of vessel operations: • Only conduct HLV operations outside of indicative peak PBW season, estimated to occur	Prevents generation of underwater sound from HLV operations during indicative peak season of PBW (April - June). It is acknowledged that PBWs could be present in the area of operations, although in small numbers, at any time for the year. However,	HLV operations for Campaign #1 activities have been planned to take place from September to February. Commencing HLV operations in September does not preclude Esso from complying with General Direction 817, which indicates Esso must complete all preparatory decommissioning activities and commence the topside dismantling campaign as soon as reasonably practicable, and no later than 30 September 2027, associated with facilities listed in Schedule 3 of the Direction.	Adopted – IMP13-CM4

Control Measure	Benefit	Cost/feasibility	Adopted
between April to June in the Bass Strait area.	avoiding the key indicative peak season of PBWs in the area will significantly reduce the potential for overlap of HLV operations with presence of individuals from this species in the area.		
Timing of operations: • Only conduct vessel operations outside of migration and reproduction seasons of SRW in Australian waters, estimated to occur between April to October).	Prevents generation of underwater sound from vessel operations during migration and reproduction season of the SRW.	Not feasible. General Direction 817 indicates Esso must complete all preparatory decommissioning activities and commence the topside dismantling campaign as soon as reasonably practicable, and no later than 30 September 2027, associated with facilities listed in Schedule 3 of the Direction. Planning and execution of decommissioning activities must consider safety aspects of the operation, and is also conditioned by several factors, including but not limited to: • completion of facility preparation activities are required prior to the arrival of the HLV, which are necessary to enable platform lifting operations • availability of support vessels for facility preparation works for removal. Preparation works for removals to be undertaken by CSVs are significantly influenced by timing at which the HLV is available, to safely and adequately manage the integrity of facilities • availability of HLV capable of performing decommissioning via single lift method • metocean conditions. As part of the scope of this EP, prior to the arrival of the HLV, CSVs will be conducting facility preparation works for removal at the platforms. Estimated timing of these preparation works is described in Section 2.3 of this EP. The first CSV preparation works campaign is likely to take place outside the SRW migration and reproduction seasons. However, the final removal preparation works by the CSV may take part during this season in 2027. This may be required to allow lifting operations by the HLV to commence before the date specified in the General Direction (September 2027). As a	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		result, CSV operations may take place at any given month of the year. The SRW reproduction BIA and HCTS is not expected to be impacted by underwater sound that may be generated during CSV operations as part of Campaign #1. HLV operations for decommissioning activities have been planned to take place from approximately September to February. This results in a partial overlap of HLV operations with the SRW migration and reproduction seasons that is likely to be limited to September and October. However, it is expected that only underwater noise from transfer operations and HLV mode change operation may potentially overlap with the HCTS and reproduction BIA of the SRW. Underwater noise that may be generated by vessel operations at the platform locations and during transit between the platforms and between the platforms and the transfer area is not expected to have an effect on these SRW sensitive areas. The area where transfer operations and the HLV mode change operation may take place is located hundreds of kilometres from known SRW regular aggregation locations (i.e. Logan's Beach in Warrnambool) and also from areas where reoccupation or expansion of SRW breeding areas has occurred such as Geographe Bay, Fowlers Bay and Encounter Bay. Alternative controls, as presented in Section 6.13.6 of the EP, will be in place to manage potential impacts from vessel operations to SRWs during the months that are indicated to overlap with the migration and reproduction seasons (April to October).	
Implement a buffer zone between the SRW reproduction BIA and adjacent area, and transfer operations and the HLV mode change operation.	Reduces potential exposure of SRW to underwater noise.	The OA defined for Campaign #1 is located in its entirety within Commonwealth waters. The OA does not overlap with the SRW reproduction BIA, however the reproduction BIA is present along the Gippsland coastline, near the northern boundary of the OA. HLV operations for Campaign #1 activities, including transfer operations and HLV mode change operation, have been planned to take place between approximately September to February, which is outside peak presence period of SRWs in Australian waters, but this period still overlaps with the suggested last two months of the reproduction season (September and October). Transfer operations of removed structures from the HLV onto barges or a HTV, and the HLV mode change operation are safety-critical activities that are highly dependent on metocean conditions. These activities require a sheltered location, closer to the coastline, to ensure operations are carried out in a safe manner. Sheltered waters provide more favourable weather conditions, significantly influencing in a positive manner the ability of the vessels to	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		complete these operations with reduced potential risks to personnel, equipment, vessels and the environment. As a result, limiting these operations to areas further away from sheltered water environments would result in both a significant increase in safety risk and significant increase in potential activity duration while waiting for appropriate operational conditions to conduct transfers. The OA is located hundreds of kilometres away from known regular aggregation locations (i.e. Logan's Beach in Warnambool) and from areas where reoccupation or expansion of SRW breeding areas has occurred such as Geographe Bay, Fowlers Bay and Encounter Bay. This control is considered to provide a limited environmental benefit, however, significantly increasing the safety risk to vessel crew, equipment and other users of the sea, as well as the overall duration of vessel operations during decommissioning activities. The cost associated with the increased safety risk resulting from the implementation of this measure is disproportionate to the potential benefit achieved.	
Adaptive management: • Shut down DP thrusters on vessels if PBWs and SRWs are sighted near the vessel.	Reduces the potential for auditory injury (including PTS), TTS and behavioural impacts.	Not feasible. Operation of the DP system is required to ensure vessels keep station when conducting decommissioning activities, mostly during removal operations such as lifting of platforms and transfer of structures from HLV onto barges or HTVs. Operation of the DP system by vessels during Campaign #1 activities allows the vessels to maintain station and therefore is of paramount importance to ensure operations can be conducted in a safe manner. Therefore, preventing its use would result in an unacceptable risk to crew, vessels, equipment and to other users of the sea. This also would significantly increase the risk of occurrence of incidents that could result in negative environmental consequences. This control measure is not feasible as it would lead to disproportionate and unacceptable safety risks, and an increased risk of impact to the environment from the occurrence of unplanned events.	Not adopted
Limit vessel thruster power to maximum 75%	Reduces the potential for auditory injury (including PTS), TTS and	Operation of the DP system is required to ensure vessels keep station when conducting decommissioning activities, mostly during preparation works for removals by CSV, removal operations by the HLV, and transfer of structures from HLV onto barges or HTVs.	Adopted – Subject to safety

Control Measure	Benefit	Cost/feasibility	Adopted
on main Campaign #1 vessels (HLV and CSVs).	behavioural impacts to marine fauna from underwater noise.	Operation of the DP system especially by the HLV and the CSVs during Campaign #1 activities allows the vessels to maintain station and therefore is of paramount importance to ensure operations can be conducted in a safe manner. The power at which thrusters need to operate to hold position will vary based on specific vessel operation to be conducted and weather conditions present at the time of operations. When metocean conditions are calm, vessels are expected to require less thruster power to hold position. Thruster power levels are optimised to the operating modes and conditions, and for efficiency reasons are maintained at the minimum power to safely maintain position. It is not safe to adjust thruster power outside of operationally defined ranges. Limitations: Vessels must be able to hold station to safely undertake decommissioning activities. Activities will be suspended in the event that thruster power levels need to exceed safety levels identified in the Thruster and Generator Operating Strategy and/or the ASOG. Weather forecasts will aid in anticipating estimated thruster power likely to be required, and its influence on conducting removal activities.	considerations - IMP13-CM5
Marine mammal observations by trained MMOs from the HLV.	Continuous marine mammal observations by specialised personnel further reduces the uncertainty on presence of whales in the proximity of the HLV during Campaign #1 activities and allows for adaptive management actions to be undertaken where required.	Engaging MMOs for HLV operations allows for trained experts to conduct searches and identification of whales, and implementation of adaptive management actions where required. MMOs are exclusively dedicated to the task of continuous coverage of the area of HLV operations during daylight hours in search for marine mammals. MMOs with recognised training and experience in whale observation, distance estimation and reporting in accordance with Part A.2 and B.1 of *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b) will be onboard the HLV for the duration of the activity. HLV must also comply with AMSA Marine Order 28 – Division 3 (*Standards for watchkeeping*). Having MMOs on the HLV, which is the main source of underwater noise during Campaign #1 activities, provides further support to the efforts of visual survey and identification of whales, and triggering of adaptive management measures where required. At least one MMO will be on shift on the HLV during daylight hours, with an additional MMO available to take over the previous shift or assist the MMO on shift as required.	Adopted - IMP13-CM6

Control Measure	Benefit	Cost/feasibility	Adopted
		The distance up to which MMOs can see and identify whales from a vessel is limited by factors such as metocean conditions and the height of the observation post. The higher the location in the vessel from where marine mammal observations are made, the greater is the distance that can be reached by the MMO. As a reference, marine fauna observations conducted during P&A projects with a similar bridge height as the *Pioneering Spirit* completed by Esso in the Bass Strait have indicated ability to observe whales to a distance of up to approximately 9.5km in clear conditions. The environmental benefits of having MMOs onboard the HLV outweighs the costs of implementing this control measure and is considered best practice.	
Marine mammal observations by trained MMOs from the CSVs and other support vessels.	Continuous marine mammal observations by specialised personnel further reduces the uncertainty on presence of whales in the proximity of CSVs and other support vessels during Campaign #1 activities and allows for adaptive management actions to be undertaken where required.	Having MMOs conducting marine mammal observations from the CSVs and other support vessels when these vessels are in proximity to the HLV will not result in a significantly better outcome for detection and identification of whales, as there are already MMOs assigned to conduct continuous marine mammal observations from the HLV. In addition, CSVs and other supply vessels will have trained crew as fauna observers onboard, with responsibilities on whale detection and identification. Training aims to build capabilities to provide an adequate resource to detect and identify whales and trigger adaptive management measures. Watchkeeping duties by vessel crew will include continuous fauna observations during daytime hours, including when vessels are operating as stand-alone vessels away from the HLV. The costs associated with the addition of MMOs on the CSVs and other support vessels is disproportionate to the potential environmental benefits.	Not adopted
Pre-activity and activity vessel-based observations for turtles (particularly leatherback turtles).	Increases awareness of the presence of marine turtles in proximity to the area where vessel operations take place.	There are no turtle nesting beaches in Bass Strait. The *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017) details noise interference as a threat, however the absence of turtle BIAs in Bass Strait, non-existence of nesting locations, and known low abundance of turtles in this area, indicates that vessel operations in the Bass Strait associated to Campaign #1 activities are not inconsistent with the objectives established in the plan, specifically with Actions A.5 (Assess, manage, and mitigate impacts from anthropogenic noise).	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		Vessel-based surveys for smaller fauna such as turtles do not guarantee that they will be sighted. Observations can be hampered by glare, rough seas, mist/fog. Based on this evidence, pre-activity and activity surveys for turtles would not result in a significant additional environmental benefit.	
Pre-activity and activity vessel-based observations for white shark.	Increases awareness of the presence of white sharks in proximity to the area where vessel operations take place.	White sharks do not have a swim bladder, therefore underwater sound is unlikely to impact this species. The *Recovery Plan for the White Shark (Carcharodon carcharias)* (DSEWPAC, 2013a) does not list underwater sound as a threat. As a result, vessel operations in the Bass Strait associated to Campaign #1 activities are not inconsistent with the objectives established in the Plan. Vessel-based surveys do not guarantee that white sharks will be sighted. Observations can be hampered by glare, rough seas, mist/fog. Based on this evidence, pre-activity and activity surveys for white sharks would not result in a significant additional environmental benefit.	Not adopted
Pre-activity aerial survey prior to commencement of vessel safety-critical operations when distances at which behavioural threshold on SRWs or PBWs could be triggered is estimated to be greater than approximately 9.5km from the sound source. *Refer to Section 2.8.4 of this EP for definition of vessel safety-critical operations Note: this control is subject to consideration of vessel safety-critical operations.	Increases the confidence of presence or absence of PBW or SRW within the area in which underwater noise from Campaign #1 operations may trigger a behavioural response from these cetaceans. Pre-activity aerial surveys are a non-invasive detection method that provides coverage of a large area of the sea efficiently and rapidly, increasing the distance range that MMOs can	Aerial surveys may be performed by fixed wing aircraft, helicopters, drones etc. Advantages and limitations of this technique are well understood, and it is widely used for detection and monitoring of whales, especially by the scientific/research community. The maximum distance up to which underwater sound generated by some of the vessel operations during Campaign #1 could trigger a behavioural response in LFCs is approximately 25km, which is beyond the approximate 9.5km maximum distance reach of trained vessel crew or a MMO when conducting vessel-based observations. As a result, pre-activity aerial survey provides an additional tool to detect whales in such a way that there is greater ability to cover the total area where whales could be exposed to a behavioural response from underwater sound generated from some of the vessel operations. Pre-activity aerial surveys require support from a trained MMO for a more accurate detection and identification of marine mammals. Timing of a pre-activity aerial survey must consider the high mobility nature of PBWs and SRWs in this area. As a result, this activity will be planned to occur within a reasonable timeframe prior to commencement of the safety-critical HLV lifting operations.	Adopted – Subject to safety considerations - IMP13-CM7

Control Measure	Benefit	Cost/feasibility	Adopted
	monitor when compared against a vessel-based survey approach.	Limitations: Aerial surveys introduce safety risks and are subject to weather condition limitations including but not limited to fog and strong winds.	
Adaptive management: • Adaptive whale management plan for PBWs and SRWs.	Implementation of adaptive actions when sensitive whale species (PBWs and SRWs) are sighted allows for prevention and/or mitigation of potential impacts to these species from vessel operations.	An adaptive whale management plan incorporates a series of measures that may be implemented during vessel operations to prevent and/or minimise impacts to whales. Types of adaptive management actions to be included as part of the adaptive whale management plan will vary based on considerations of specific sensitive species that may be present in the area where operations will take place, and the particularities and characteristics of each activity/vessel operation. Adaptive management actions are to take effect when distance at which PBWs or SRWs are observed from the sound source (i.e. vessels) could trigger PTS, TTS or a behavioural response. For Campaign #1 adaptive management measures to be included in the adaptive whale management plan will focus on PBWs and SRWs. Adaptive management actions will be triggered based on information that is provided by the vessel crew with marine fauna observation responsibilities, and by MMOs (including MMOs sightings from HLV-based observations and from the pre-activity aerial surveys observations) while conducting their routine daytime hours marine fauna observation task Adaptive management measures to be implemented for vessel operations during Campaign #1 are described below: • Delay supply vessel operations as follows: - When PBWs or SRWs have been sighted from a Campaign #1 vessel within the previous 30 minutes before a support vessel approaches the Campaign #1 vessel for re-supply operations, the supply vessel will not be allowed to come to proximity of the Campaign #1 vessel. - Authorisation for the supply vessel to resume approach to the Campaign #1 vessel will only be granted when no PBW or SRW sightings have been made for a period of 30 minutes, or before this time if there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered. - Where/if required, adjust supply vessel route to avoid the predicted path of the whales (based on the visual observations).	Adopted - Subject to safety considerations - IMP13-CM8

Control Measure	Benefit	Cost/feasibility	Adopted
		• If PBWs or SRWs are observed while the supply vessel is alongside the Campaign #1 vessel, suspend supply operations if safe to do so as follows: - Where possible and safe to do so, supply vessel is to stop supply operations and move away from the Campaign #1 vessel, in the opposite direction of where the whale was sighted, and minimise power utilisation of thrusters where safe to do so. - Authorisation for the supply vessel to resume supply operations will only be granted when no PBW or SRW sightings have been made for a period of 30 minutes, or before this time if there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered. • If a PBW or SRW is sighted within the area in which behavioural response may be triggered before the HLV (and CSV as applicable) commence vessel safety-critical operations, adapt operations to reduce the potential impact to whales as follows: - Safety critical operations may only commence when: ▪ HLV thruster utilization required for the specific operation is less than 50% of its installed thruster capacity, or ▪ 30 minutes have passed since the last PBW or SRW sighting within the area in which behavioural response may be triggered, or ▪ there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered - avoid approaching the direction in which the whale was located until 30 minutes have passed after the last sighting, or before this time if there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered. - where/if required, adjust vessel transit route to avoid the predicted path of the whales (based on the visual observations). Note that this measure is not applicable to the HLV and CSV when the vessels have commenced safety-critical operations. The area in which behavioural response from PBWs and SRWs may be triggered is defined by the distance up to which the 120 dB threshold may extend from the location of the noise source, as estimated for the activity. Implementation of adaptive management actions is a standard practice across the offshore oil and gas industry, particularly for vessel operations.	

Control Measure	Benefit	Cost/feasibility	Adopted
		Implementation of adaptive management measures also aligns with the CMPBW and the NRPSRW, which include adaptive management as one of the criterion to be considered and implemented by projects when there is a probability of overlap of proposed operations with sensitive areas where SRWs may be present. The environmental benefits of implementing an adaptive whale management plan outweighs the costs of implementing this control measure.	
Adaptive management: Night-time and low visibility procedure for PBWs and SRWs	Reduces the potential for auditory injury (including PTS), TTS and behavioural impacts to PBWs and SRWs.	A night-time and low visibility procedure incorporates a series of measures that allow for increased awareness of presence of whales in the area of interest and planning of vessel operations to reduce potential risks to whales. Potential cost for Campaign #1 includes: • Suspending vessel operations during night-time or low visibility conditions due to PBW or SRW sighting reports will result in delays to the removal operation schedule. In addition, considering single-lift removal operations requires a specialised HLV, the Allseas *Pioneering Spirit* vessel has been engaged to conduct these operations on behalf of Esso. Given the limited availability of HLVs with capabilities for single-lift operations and contractual commitments from the *Pioneering Spirit* with other projects, there is a limited time-window available to complete the Campaign #1 removal activities per the scope of works described in this EP. Therefore, completion of the removal activities, as per scope of works described for Campaign #1, the project may be put at risk if suspension of vessel operations during night-time or low visibility conditions are required. Based on descriptions provided in Sections 6.13.3.6.4 and 6.13.3.7, the likelihood of the presence of PBWs and SRWs within the OA, and potential for overlap of these cetaceans with vessel operations during execution of Campaign #1 activities is low. The potential environmental benefit from this control includes: • Marine mammal observations by fauna observers and MMOs are limited to day-light hours and when visibility is fair/good. Implementation of a night-time and low visibility procedure allows for a systematic process to be in place to reduce the uncertainty on potential presence of PBWs and SRWs in the area of operations at night or when visibility during daytime hours is affected by weather conditions.	Adopted – Subject to safety considerations - IMP13-CM9

Control Measure	Benefit	Cost/feasibility	Adopted
		This measure would also allow for consideration of the precautionary principle approach as part of the decision criteria for vessel operations at night-time or during low visibility conditions. For Campaign #1, a standard approach for night-time and low visibility operations, and that is consistent with advice provided in the *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b) is considered to provide environmental benefits to SRWs and PBWs This control would be considered as follows: Adapt vessel operations when PBWs or SRWs have been observed within the area in which behavioural response may be triggered prior to night-time or before low visibility conditions occur before the HLV (and CSV as applicable) commence vessel safety-critical operations, if the following criteria is met: • there have been three or more sightings of PBWs or SRWs reported during the three-hour period preceding night-time and/or low visibility occurring, within the area in which behavioural response may be triggered, and/or • there has been a sighting of a PBW or SRW within the 30 minutes period prior to night-time and/or low visibility occurring, within the area in which behavioural response may be triggered. When either of these criteria are met, vessel safety-critical operations will not commence unless the following criteria are achieved: • HLV thruster utilization required for the specific operation is less than 50% of its installed thruster capacity, or Additional actions include: • avoid approaching the direction in which the whale was located, and • where required, adjust vessel transit route to avoid the predicted path of the whales (based on the visual observations). When night-time or low visibility conditions end, vessel operations will observe the controls established for day-time operations (refer to IMP13-CM8 - '*Adaptive management: Adaptive whale management plan for PBWs and SRWs*').	

Control Measure	Benefit	Cost/feasibility	Adopted
		Note that this measure is not applicable to HLV and CSV when the vessels have commenced safety-critical operations. The area in which behavioural response from PBWs and SRWs may be triggered is defined by the distance up to which the 120 dB threshold may extend from the location of the noise source, as estimated for the activity.	
Passive Acoustic Monitoring (PAM).	Increases the confidence that presence of PBW or SRW in the area nearby where removal activities are taking place is noted	As a cetacean detection method, PAM has been used to detect whales that vocalise at high frequencies/intensities such as HFCs and VHFCs (e.g. sperm whales) and, in conjunction with visual monitoring, can enhance cetacean detection effectiveness. PAM has the advantage of potentially detecting cetaceans during night hours and during periods of poor visibility when they cannot be visually detected. Although PAM can be a valuable tool in identifying the presence of cetaceans, the following factors limit its effectiveness: • most suitable for HFCs and VHFCs, which are known to emit regular distinctive clicks and high frequency calls during long dives. HFCs and VHFCs are of lower concern in the Gippsland Basin region compared to LFCs. It is difficult for PAM to pick up vocalisations of LFCs such as blue whales and SRW • PAM detections may not reliably determine whale behaviour as accurate as visual observations. • rely on individual vocalisations within the detection range • PAM is not a typical control for vessel operations. Underwater noise from vessels at close range may interfere with the PAM system. Background signals and underwater sounds such as vessel noise presents an added challenge to effectively distinguish marine mammal noise • some PAM arrangements such as systems mounted on buoys are affected by weather and can present a navigations risk for other users of the sea • to increase reliability of the PAM system, accurate background data from the environment in which it will operate and detailed characterisation of vocalisation from target species is required • detection of a target species by a PAM system requires validation by a trained operator, or a visual confirmation by a Marine Fauna Observer or MMO.	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		Implementation of PAM systems do not result in a discernible reduction in risk. Currently there is limited confidence in operational reliability for this application. LFCs surface to breathe more regularly than deeper water HFCs and VHFCs, which result in an increased likelihood of LFCs to be detected by MMOs and Marine Fauna Observers during vessel-based surveys and MMOs during aerial-based surveys, resulting in a reduction of the overall added benefit from implementation of PAM surveys. The cost of implementing PAM is grossly disproportionate to the environmental benefit.	
Deploy bubble curtains around the HLV.	Reduces the potential for auditory injury (including PTS), TTS and behavioural impacts.	Bubble curtains are most useful for projects that are fixed in position and involve piling or detonation of explosives; it is not a typical control for mobile vessel operations. The bubble curtain (perforated hose) is deployed to the seabed and encompasses the noise source in an aim to obscure noise transmission, resulting in a reduction of received sound levels to receptors outside of the bubble curtain. Circa 15dB noise attenuation has been reported for impulsive noise from piling; efficacy is dependent on various factors. The deployment of bubble curtains for this activity is limited by the following factors: • there is high uncertainty on its applicability for managing noise from HLV operations for Campaign #1 activities • size of HLV: the bubble curtain is required to cover the area around the vessel and fixed facility or adjacent vessel. This would require a significant length for the curtain • the highly mobile nature of the Campaign #1 activities, where the HLV will be moving between platforms and the OA for transfer activities. This results in significant logistic limitations for the implementation of this control • bubble curtains are drastically impacted by currents. Current speeds and directional shifts with wind and tide would result in bubble curtains being distorted and a reduced effectiveness of noise attenuation • bubble curtains are most often placed on the seafloor. This may generate resuspension of sediments • additional support vessels would be required to deploy and retrieve the bubble curtain(s). This results in additional sources of underwater noise, artificial light and emissions to air. It would also result in additional potential impacts from	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		interactions with other users of the sea and increase the risk of occurrence of unplanned events with negative environmental consequences. Due to depth, large compressors are likely required to deliver air through the bubble curtain to the outlets from where the bubbles will be released into the water column. This control measure is not technically feasible for HLV decommissioning activities.	
Dedicated spotter vessel.	Monitoring and detection. Increases the confidence that there are no PBW or SRW in the area where removal activities will occur.	Deploying a dedicated spotter vessel may extend the range at which fauna observations can be made. Using a dedicated spotter vessel introduces additional environmental impacts such as an additional underwater noise source, additional air emissions and additional risk of unplanned interactions with marine fauna and/or other users of the sea (e.g. fishery operations, recreational/tourism activities). The nature of the type of vessel that is engaged as the dedicated spotter vessel substantially influences the ability for fauna observations, as the range at which detections can be made is directly influenced by the height of the observer (i.e. the greater the height of the observer, the greater the detection range). Local charter vessels (e.g. fishing boats <20m length) produce relatively low underwater noise levels, however the fauna observer can only be stationed 3 - 4m above the sea. This is substantially less than the approximate 10m elevation platform available from which a fauna observer can complete visual surveys onboard a typical CSV. Using a larger vessel as a dedicated spotter vessel with an available platform that provides a good range of visibility to fauna observers could introduce additional underwater noise. The use of small fishing or charter vessels as dedicated spotter vessels also increase safety risks associated to metocean conditions for navigation. Given this EP proposes a pre-activity aerial survey to cover a broad extent of the area at which potential underwater noise from vessel operations could result in a behavioural response from cetaceans, and additional fauna observations are to be conducted from decommissioning activity vessels, using a dedicated spotter vessel provides no additional benefit - cost is grossly disproportionate to the potential benefit.	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
Thermal/Infrared cameras.	Increases the confidence that there are no PBW or SRW in the area where removal activities will occur.	Thermal infrared systems are dependent on animal surfacing and revealing parts of its warm body or its exhalation (blow). The apparent temperature difference between the marine mammal body or blow and the sea surface provides a thermal contrast, which can be detected using a thermal imaging sensor (Verfuss, et al., 2018). Thermal infrared systems are designed to be mounted on a vessel. The location at which the system is mounted will directly influence the effectiveness of operation of the cameras, with a preferred location having a free 360 degrees vision and is located in the upper sections of the vessel for increased monitoring range. However, the location where the thermal infrared system is mounted will be dependent on vessel layout and space availability, thus having a potential significant limitation to the benefit that this system can provide. In addition, thermal infrared systems are heavily influenced by environmental factors such as weather conditions, To date there is limited information available on the effectiveness of thermal infrared systems to detect whales. Verfuss, et al. (2018) mentions that two reports that evaluated the detection performance of the system on free living whales indicated large whale blows or surface displays were detected at distances up to 5 - 8km under ideal conditions, with detection of small whales reduced significatively. The author indicates there was a consensus that large cetaceans can be detected at ranges of up to 2km using these systems (Verfuss, et al., 2018). Thermal infrared cameras can provide information on detection of whales during night-time hours, however the system doesn't have the capability of detecting the species that is being detected as it only measures the difference in temperature between the sea surface and the blow or the displayed part of the body of the whale when surfacing. There are thermal infrared systems that can provide automatic detection of species observed, however these automated systems are very recent and are mostly in the development stage, and there is currently high uncertainty on the effectiveness and reliability of species identification of these systems. Based on this uncertainty, Smith, et al. (2020) describes this method as having most value as a 'bellringer' for MMOs instead of a standalone detection system. Furthermore, the detection range at which thermal infrared systems can detect whales is not different to the distance up to which marine fauna observers and dedicated MMOs are able to detect whales.	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
		Implementing thermal infrared systems doesn't provide a tangible additional benefit to that already provided by other marine mammal observation controls proposed in this EP. The cost of implementing these systems is grossly disproportionate to the environmental benefit gained.	

* Refer to Section 2.8.5 of this EP for definition of vessel safety-critical operations.

A summary of the controls to be implemented and stage/vessel of the project that is applicable to each control is shown in Table 6-77.

Table 6-77 Summary of ALARP controls for underwater noise and application for Campaign #1

Control	Applies to:	
	Stage of project/activity (Preparation/lifting/transport/ transfer/mode change)	**Vessel (HLV/CSVs/tugs/barges/ HTVs/supply vessels)**
Comply with Part 8 Division 8.1 of the EPBC Regulations, and Application of the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a).	All stages of Campaign #1.	All Campaign #1 vessels.
Preventative maintenance program.	All stages of Campaign #1.	All Campaign #1 vessels.
Only conduct HLV operations outside of indicative peak PBW season, estimated to occur between April to June in the Bass Strait area.	All stages of Campaign #1	HLV.
Marine fauna observations by trained vessel crew.	All stages of Campaign #1.	• HLV • CSVs • Supply vessels.
Marine mammal observations by trained MMOs from the HLV.	All stages of Campaign #1.	HLV.
Pre-activity aerial survey prior to commencement of vessel operations when distances at which behavioural threshold on SRWs and PBWs could be triggered is estimated to be greater than 9.5km from the sound source.	• Preparation (CSV operations if using a ripper tool) • Lifting operations. • HLV mode change. Note: this control is subject to consideration of vessel safety-critical operations	• HLV. • CSVs
Limit vessel DP power to maximum 75%[1].	All stages Campaign #1.	• HLV • CSVs
Adaptive whale management procedure for PBWs and SRWs[2].	All stages of Campaign #1.	• HLV • CSVs • Supply vessels.
Night-time and low visibility procedure for PBWs and SRWs[2]	All stages of Campaign #1.	All Campaign #1 vessels.

[1] This control is subject to vessel safety considerations.

[2] This control is subject to consideration of safety considerations, including vessel safety-critical operations.

6.13.5 Demonstration of acceptability

Table 6-78 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The precautionary principle has been applied, and studies have been undertaken where knowledge gaps were identified (underwater noise modelling). This knowledge has been applied during the assessment of environmental impacts as a result of underwater noise from vessel operations. Impact assessment also considers the precautionary principle by integrating the sensitivity of the SRW, especially due to the presence of a reproduction BIA (also identified as a HCTS) for this species near the northern boundary of the OA. As a result, adequate control measures have been proposed in this EP to manage and minimise potential effect of vessel operations on marine mammals, and especially on SRWs and PBWs.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for sound emissions has concluded that environmental impacts will be short term and localised in nature. Due to the sensitivity of the SRW reproduction BIA present near the northern boundary of the OA, controls have been proposed to adequately manage and minimise the potential impact. As a result of the controls to be implemented, any potential impacts from sound emissions during vessel operations will not impact the health, diversity and productivity of the environment such that future generations will be impacted.

Factor	Demonstration criteria	Criteria met	Rationale
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The impact assessment undertaken has shown that the potential residual impact consequence level to marine fauna after implementation of controls associated with sound emissions is limited to a localised short term impact (refer to Section 6.13.7). Assessment included consideration of the proximity of the northern boundary of the OA to a sensitive area for SRWs (reproduction BIA – also identified as a HCTS). Campaign #1 activities covered under the scope of this EP have been assessed against the CMPBW and the NRPSRW. This assessment included the identification of required controls to be implemented by Esso during vessel operations to minimise uncertainty of, and adequately manage, potential impacts to PBW and SRW, to ensure vessel operations from Campaign #1 are not inconsistent with the abovementioned plans. As a result, vessel operations will be managed in such a way that underwater sound emissions are minimised to the extent practicable, and these operations are considered as not having the potential to affect biological diversity and ecological integrity when controls presented in this EP are in place.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	Requirements of Part 8 Division 8.1 of the EPBC Regulations, although more relevant to tourism activities (e.g. whale watching), have been adopted. Noise interference is a recognised threat to the species in the following conservation or recovery management plans and advice. The proposed controls are consistent with conservation/management actions in: • CMPBW • *Conservation Advice for Humpback Whales* (TSSC, 2022) • NRPSRW • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a)

Factor	Demonstration criteria	Criteria met	Rationale
			• *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b) • *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017) • *Recovery Plan for the White Shark (Carcharodon carcharias)* (DSEWPAC, 2013a) • *Conservation Action Plan for Parks and Reserves Managed by Parks Victoria. Wilsons Promontory* (Parks Victoria, 2017).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "*comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist*"
	Meets ExxonMobil Environmental Standards.	✓	Impact assessment process and controls proposed meet the strategic objectives of the business and the Environmental policy.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	Relevant persons concerns have been considered.

6.13.6 EPOs, control measures, EPSs and measurement criteria

Table 6-79 EPOs, control measures, EPSs and measurement criteria – Sound emissions

EPO	Control measure	EPS	Measurement criteria
IMP13-EPO1: There is no auditory injury (including PTS) or TTS to cetaceans from sound emissions, and whales (PBWs and SRWs) are not displaced from BIAs or prevented from accessing and utilising these areas to conduct important behaviours such as foraging, breeding or migrating during Campaign	IMP13-CM1: Application of the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a).	IMP13-EPS1.1: Vessel and aircraft operations within the OA will comply with requirements established in Part 8 Division 8.1 of the EPBC Regulations, and align with the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a), specifically with: • identification and training of personnel who will hold responsibilities for ensuring compliance with legal requirements established in Part 8 Division 8.1 of the EPBC Regulations and the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a), prior commencement of operations covered under the scope of works for decommissioning activities • helicopters will not fly lower than 500m when within 500m horizontal distance of a cetacean except when landing or taking off and will not approach a cetacean from head on • other aircraft (drones, fixed-wing aircraft) will not fly lower than 300m when within 500m horizontal distance of a cetacean except if landing or taking off from a project vessel is required. Other aircraft will not approach a cetacean from head on • caution zone: vessels will not approach closer than 150m from a dolphin and/or 300m from a whale • vessels will not travel at a speed of more than 6kn when a dolphin or whale is sighted within 300m from the vessel. Vessels must also move away from the dolphin/whale at a constant speed of <6kn.	IMP13-MC1.1.1: Roles and responsibilities as described in the Allseas EMP and related vessel subcontractors appropriate management plan. IMP13-MC1.1.2: Induction records of vessel crew members and aircraft operator(s) on the requirements from, and how to comply with, Part 8 Division 8.1 of the EPBC Regulations and the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a). IMP13-MC1.1.3: Training records of relevant vessel crew and aircraft operator(s) members on marine fauna observations engaged. IMP13-MC1.1.4: Daily vessel or aircraft reports including actions implemented during vessel operations if/when whales and dolphins were sighted within the distances established under Part 8 Division 8.1 of the EPBC Regulations.
	IMP13-CM2: Preventative	IMP13-EPS2.1: All vessels taking part in Campaign #1 operations will have a maintenance program in place that includes plant and equipment that	IMP13-MC2.1.1: Maintenance program for key underwater noise-generating equipment (i.e. thrusters).

EPO	Control measure	EPS	Measurement criteria
#1 operations	maintenance program.	generates noise and/or vibration. The maintenance program is executed as per planned schedule.	IMP13-MC2.1.2: Records of maintenance completed for key underwater noise-generating equipment (i.e. thrusters).
	IMP13-CM3: Marine fauna observations by trained vessel crew.	IMP13-EPS3.1: Implementation of continuous daylight hours marine fauna observations by trained vessel crew during completion of Campaign #1 activities as follows: • prior to commencement of vessel operations, covered under the Campaign #1 scope, identify vessel crew that will hold responsibilities for fauna observations as part of their role description/watchkeeping duties • prior to commencement of vessel operations covered under the Campaign #1 scope, the relevant vessel crew must be trained on marine fauna observations (focusing on sensitive marine fauna that may be present within the area where removal activities will be conducted) continuous daylight hours marine fauna observations by relevant vessel crew takes place during vessel operations.	IMP13-MC3.1.1: Roles and responsibilities as described in the Allseas EMP and related vessel subcontractors appropriate management plan. IMP13-MC3.1.2: Training records of relevant vessel crew members on marine fauna observations, inclusive of awareness of the adaptive whale management plan engaged. IMP13-MC3.1.3: Records demonstrating vessel crew assigned with marine fauna observation responsibilities undertake this task. IMP13-MC3.1.4: Daily vessel reports and actions (refer to adaptive whale management) implemented during vessel operations based on recommendations/reports from the vessel crew that is conducting fauna observations. IMP13-MC3.1.5: Inspection records demonstrate compliance with AMSA Marine Order 28.
	IMP13-CM4: Avoid HLV operations during the indicative peak PBW season, estimated to occur between April and June in	IMP13-EPS4.1: HLV operations will avoid key periods where PBWs may be present within the OA, These key periods are estimated to be between April and June - while HLV operations are planned to take place between September and February.	IMP13-MC4.1.1: HLV operations schedule (planned and executed).

EPO	Control measure	EPS	Measurement criteria
	the Bass Strait area.		
	IMP13-CM5: Limit vessel thruster power to maximum 75% on main Campaign #1 vessels (HLV and CSVs).	IMP13-EPS5.1: Set a maximum limit for thruster operation by the HLV and CSVs of 75% of the total installed capacity, subject to safety considerations.	IMP13-MC5.1.1: Vessel DP logs of thruster operation during vessel activities.
	IMP13-CM6: Marine mammal observations by trained MMOs from the HLV.	IMP13-EPS6.1: For HLV operations, specialised personnel (MMOs) will be engaged to conduct continuous daylight hours HLV-based marine mammal observations. Considerations include: • prior to commencement of HLV vessel operations covered under the Campaign #1 scope, engage specialised MMOs for HLV-based vessel operations • MMOs must have relevant training and experience in marine mammal observations • ensure continuous daylight hours marine mammal observations by MMOs during HLV operations.	IMP13-MC6.1.1: Record of engagement of MMOs and roles and responsibilities. IMP13-MC6.1.2: Training records and/or training certificates and/or curriculum vitae of MMOs engaged that demonstrate suitable qualifications. IMP13-MC6.1.3: Daily MMOs report. IMP13-MC6.1.4: Daily HLV reports and actions implemented during vessel operations based on recommendations/reports from MMOs. IMP13-MC6.1.5: Inspection records demonstrate compliance with AMSA Marine Order 28.
	IMP13-CM7: Pre-activity aerial survey prior to commencement of vessel safety-	IMP13-EPS7.1: Implement pre-activity aerial surveys for marine mammal observations before the start of vessel safety-critical operations when estimated distance at which behavioural threshold for LFC could be triggered is >9.5km from the sound source, as follows: • prior to commencement of vessel operations covered under the Campaign #1 scope, engage aircraft/drone/helicopter service provider for daytime pre-activity aerial surveys.	IMP13-MC7.1.1: Contract/agreement of services with providers, including type of aircraft to be used for the pre-activity aerial surveys. IMP13-MC7.1.2: Record of engagement of MMOs and roles and responsibilities.

EPO	Control measure	EPS	Measurement criteria
	critical operations when distances at which behavioural threshold on SRWs or PBWs could be triggered is estimated to be greater than approximately 9.5km from the sound source. *Refer to Section 2.8.4 of this EP for definition of vessel safety-critical operations Note: this control is subject to consideration of vessel safety-critical operations.	• prior* to commencement of vessel safety-critical operations, and if distance estimated for triggering of behavioural response on SRWs or PBWs is >9.5km, conduct pre-activity aerial survey of the area where removal operations will take place. This action is planned to be undertaken for each vessel safety-critical operation when distance criteria of >9.5km is met and when weather conditions and light make it safe to execute. • A trained/competent MMO must be engaged to support the pre-activity aerial survey	IMP13-MC7.1.3: Training records and/or training certificates and/or curriculum vitae of MMOs engaged that demonstrate suitable qualifications. IMP13-MC7.1.4: Records with evidence (date and time) of pre-activity aerial surveys completed during Campaign #1 operations. IMP13-MC7.1.5: Records with evidence (date and time) of HLV operations prior to commencing vessel safety-critical operations. IMP13-MC7.1.6: MMO pre-activity aerial survey reports.
		IMP13-EPS7.2: Implement pre-activity aerial survey for marine mammal observations before subsea cutting activities when use of a ripper tool is expected.	IMP13-MC7.2.1: Contract/agreement of services with provider, including type of aircraft to be used for the pre-activity aerial surveys. IMP13-MC7.2.2: Record of engagement of MMOs and roles and responsibilities. IMP13-MC7.2.3: Training records and/or training certificates and/or curriculum vitae of MMOs engaged that demonstrate suitable qualifications. IMP13-MC7.2.4: Records with evidence (date and time) of pre-activity aerial surveys completed during Campaign #1 operations. IMP13-MC7.2.5: Records with evidence (date and time) of CSV operations prior to commencing subsea cutting operations when use of the ripper tool was expected. IMP13-MC7.2.6: MMO pre-activity aerial survey reports.

EPO	Control measure	EPS	Measurement criteria
	IMP13-CM8: Adaptive management: Adaptive whale management plan for PBWs and SRWs.	IMP13-EPS8.1: Implementation of a whale adaptive management plan that includes specific actions to prevent or reduce potential impact to PBWs and SRW, including: • Delay supply vessel operations as follows: - when PBWs or SRWs have been sighted from a Campaign #1 vessel within the 30 minutes prior supply operations commence, supply vessel will not be allowed to come alongside the Campaign #1 vessel. - based on the visual observations made of the PBW or SRW, select the most suitable transit route for the supply vessel that allows avoidance of the likely/predicted path of the whale that was observed. - authorisation for supply vessel to resume approach towards the Campaign #1 vessel will only be granted when no PBW or SRW sightings have been made for a period of 30 minutes, or before this time if there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered. • If PBWs or SRWs are observed while the supply vessel is alongside the Campaign #1 vessel, suspend supply operations if safe to do so as follows: - supply vessel is to stop supply operations and move away from the project vessel, in the opposite direction of where the whale was sighted and then reduce DP operation. - authorisation for supply vessel to resume supply operations will only be granted when no PBW or SRW sightings have been made for a period of 30 minutes, or before this time if there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered. • If a PBW or SRW is sighted within the area in which behavioural response may be triggered before the HLV (and CSV as applicable)	IMP13-MC8.1.1: Whale sighting records (trained vessel crew and/or MMOs daily reports). IMP13-MC8.1.2: Schedule or records of vessel supply activities (planned and executed). IMP13-MC8.1.3: Records (i.e. vessel master logs) of actions implemented by the vessels prior or during supply operations if/when PBWs or SRWs are sighted. IMP13-MC8.1.4: Record (i.e. vessel master logs) of actions implemented by HLV or CSV prior to the start of vessel safety-critical operations if/when PBW or SRW are sighted during the pre-activity aerial survey.

EPO	Control measure	EPS	Measurement criteria
		commence vessel safety-critical operations, adapt operations to reduce potential impact to whales as follows: - Safety critical operations may only commence when: ▪ HLV thruster utilization required for the specific operation is less than 50% of its installed thruster capacity, or ▪ 30 minutes have passed since the last PBW or SRW sighting within the area in which behavioural response may be triggered, or ▪ There is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered - avoid approaching the direction in which the whale was located until 30 minutes have passed after the last sighting, or before this time if there is visual confirmation that PBWs or SRWs have exited the area in which behavioural response may be triggered. - Where/if required, adjust vessel transit route to avoid the predicted path of the whales (based on the visual observations). Note that this measure is not applicable to the HLV and CSV when the vessels have commenced safety-critical operations at the time of the sighting. The area in which behavioural response from PBWs and SRWs may be triggered is defined by the distance up to which the 120 dB threshold may extend from the location of the noise source, as estimated for the activity.	
	IMP13-CM9: Adaptive management: Night-time and low visibility procedure for	IMP13-EPS9.1: Implementation of a whale adaptive management plan that includes a night-time and low visibility procedure with specific actions to prevent or reduce potential impact to PBWs and SRW, including: • Adapt vessel operations when PBWs or SRWs have been observed within the area in which behavioural response may be triggered prior to night-time or before low visibility conditions occur before the HLV (and CSV as applicable) commence vessel safety-critical operations, if the following criteria is met:	IMP13-MC9.1.1: Whale sighting records (marine fauna observers and/or MMOs daily reports). IMP13-MC9.1.2: Schedule or records of vessel operations (planned and executed). IMP13-MC9.1.3: Record of actions implemented by Campaign #1 vessels if criteria 1 and/or 2, were met.

EPO	Control measure	EPS	Measurement criteria
	PBWs and SRWs.	- There have been three or more sightings of PBWs or SRWs reported during the 3-hour period preceding night-time and/or low visibility occurring, within the area in which behavioural response may be triggered, and/or: - There has been a sighting of a PBW or SRW within the 30 minutes period prior to night-time and/or low visibility occurring, within the area in which behavioural response may be triggered. • When either of these criteria are met, vessel safety-critical operations will not commence unless the following criteria are achieved: - HLV thruster utilization required for the specific operation is less than 50% of its installed thruster capacity, or Additional actions include: - avoid approaching the direction in which the whale was located - where/if required, adjust vessel transit route to avoid the predicted path of the whale(s) (based on the visual observations). When night-time or low visibility conditions end, vessel operations will observe the controls established for day-time operations, (refer to IMP13-CM8 - '*Adaptive management: Adaptive whale management plan for PBWs and SRWs*'). Note that this measure is not applicable to HLV and CSV when these specific vessels have commenced vessel safety-critical operations at the time of the sighting. The area in which behavioural response from PBWs and SRWs may be triggered is defined by the distance up to which the 120 dB threshold may extend from the location of the noise source, as estimated for the activity.	

*Timing of the aerial survey will be determined when Campaign #1 operations commence. However, period between pre-activity aerial survey completion and start of vessel safety-critical activities cannot be longer than 2 hours.

6.13.7 Residual consequence assessment

With the above controls in place, the residual potential consequence has been determined as*:*

- **Consequence Level III.**

6.14 Light emissions

6.14.1 Sources of light emissions

Light emissions from Campaign #1 activities in the Gippsland Basin will be limited to those associated with vessel operations. Platforms to be decommissioned will be non-operational and therefore there will be no sources of light from topsides such as flares, cranes, accommodation and other installations. Light from platforms will be restricted to a standard light for navigation aid. Subsea activities performed by ROVs are also a source of light emissions.

Light sources from vessels operating during Campaign #1 activities include:

- navigation and safety lights
- operational lights required during removal of facilities and transfer operations
- emergency lighting.

Light emissions from ROVs while conducting subsea operations are considered to be localised and limited to the immediate area where ROV is operating, confined to only metres from the source. As light emitted underwater is rapidly absorbed within the water column surrounding the light source, potential light emissions from ROV operations are considered negligible and therefore are not assessed further.

6.14.2 Impacts of light emissions

Impacts of light emissions on receptors are:

- change in fauna behaviour
- injury/mortality of fauna
- change in visual amenity.

According to the *National Light Pollution Guidelines for Wildlife* (Commonwealth of Australia, 2023) (NLPGW), artificial light has the potential to affect wildlife that use visual cues for orientation, navigation or other purposes. Artificial light at night can disrupt critical behaviours such as foraging, reproduction and dispersal of fauna and can cause disruption and displacement of specific species from important habitat. Where this occurs in threatened and listed species that are impacted by multiple sources, artificial light can add to the complexity to recovery of these species. Important habitat includes areas of importance designated through recovery plans and conservation advice, BIAs, and internationally and nationally important habitat (with relevant ecological values for light sensitive fauna). Marine fauna with the greatest sensitivity to light are marine turtles, seabirds and shorebirds, and fish.

It is also noted in the NLPGW that not all species respond in the same manner to artificial light. Most animals are sensitive to ultraviolet (UV)/violet/blue light, while some birds are sensitive to longer wavelength yellow/orange light. As a result, potential impacts from light emissions are dependent on specific species exposed to the light source, wavelength and intensity of the light source, distance up to which artificial light extends to, season/time of the year when artificial light is emitted, and physiological sensitivity and resilience of species exposed to artificial light. This includes the development stage of the animal; for instance, it is suggested that fledglings are more vulnerable to disorientation induced by artificial lights than adult birds (Atchoi, et al., 2024) (Burt, et al., 2024).

The impact assessment has considered the recommendations from the *National Light Pollution Guidelines for Wildlife* (NLPGW), in conjunction with a light spill modelling for vessel operations (ERM, 2024). The impact assessment has considered the recommendations from the *National Light Pollution Guidelines for Wildlife* (NLPGW) (Commonwealth of Australia, 2023), in conjunction with a light spill modelling for vessel operations (ERM, 2024). The aim of the guidelines is that artificial light is managed so wildlife is not disrupted within or displaced from important habitat, and that wildlife is able to undertake critical behaviours such as foraging, reproduction and dispersal. As a result, a 20km buffer at four representative locations, including two locations to represent areas where transfer operations may take place, was considered to identify sensitive receptors that could be potentially impacted by light from vessel operations during Campaign #1. Furthermore, the representative locations that were selected for transfer operations/HLV mode change operation are located in

close proximity to the most environmentally sensitive areas present nearby the western end of the OA, towards Wilsons Promontory and Corner Inlet, This selection of the representative transfer locations/HLV mode change location allows for an adequate environmental assessment that represents and covers the potential interaction of Campaign #1 operations with these sensitive areas.

After initial identification of sensitive receptors within the 20km buffer at each representative location, results from light spill modelling for vessel operations were used to further refine the area that could be exposed to impacts from light emissions during Campaign #1 activities. Maximum reach for light emissions during vessel operations at levels that could potentially have an effect on seabirds and shorebirds was estimated up to 7.2km from the source (ERM, 2024).

For the adequate identification and assessment of potential impacts from light emissions during vessel operations, scenarios chosen for modelling, which are shown in Table 6-81, were based in key criteria including:

- Locations where vessel operations will be conducted - This criterion included selection of locations for operations at platforms that provided representative information and coverage of the OA by including input data from areas closer and further from shore where removal of platforms will take place. Representative locations modelled also accounted for transfer operations and HLV mode change operation. For these operations, representative locations selected for modelling are in the area of highest environmental sensitivity, towards the western end of the OA, where potential vessel operations would be in the closest proximity to Wilsons Promontory and Corner Inlet.
- Simultaneous vessel operations at relevant locations - Input data for modelling considered operations where more than one vessel is expected to be required. This criterion allows for adequate assessment of potential cumulative impacts as a result of presence of various sources of light emissions at the same point in time for relevant locations.
- Sensitive receptors identified within the OA - Transfer operations/HLV mode change operation are subject to various factors such as metocean conditions. Therefore, the exact location where these activities will take place within the OA can vary and will be ultimately defined at, or as close as possible to, the time when decommissioning activities are planned to commence. As a result, and to provide for an adequate identification and assessment of potential impacts from vessel operations during Campaign #1 activities, the locations chosen to model light emissions during transfer/HLV mode change operations are the most environmentally sensitive locations within the OA, located towards the western end of the OA in proximity to State waters near Wilsons Promontory and Corner Inlet.

Results from the identification of sensitive fauna within the area assessed are described below in Section 6.14.2.1.

6.14.2.1 Identification of light sensitive fauna.

6.14.2.1.1 PLANKTON AND FISH

Plankton species, including both phytoplankton and zooplankton, are a key component in oceanic food chains. Phytoplankton are autotrophic planktonic organisms living within the photic zone that spend either part or all of their lifecycle drifting with the ocean currents. They are the start of the food chain in the ocean (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). Phytoplankton communities are largely comprised of protists, including green algae, diatoms, and dinoflagellates (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). Phytoplankton are dependent on oceanographic processes (e.g. currents and vertical mixing), that supply nutrients needed for photosynthesis. Thus, phytoplankton biomass is typically variable (spatially and temporally), but greatest in areas of upwelling, or in shallow waters where nutrient levels are high. Zooplankton is the faunal component of plankton, comprised of small protozoa, crustaceans (such as krill) and the eggs and larvae from larger animals. More than 170 species of zooplankton have been recorded in eastern and central Bass Strait, but it has been found that seven dominant species make up 80% of individuals. As with phytoplankton, zooplankton biomass appears to be higher in the shallow waters of the shelf (ERM, 2024).

Bony fish are a diverse group of fish that have skeletons primarily composed of bone tissue, as opposed to cartilage; most living species of fish are bony fish. The vast majority of fish are members of *Osteichthyes*, which is an extremely diverse and abundant group consisting of 45 orders, and over 435 families and 28,000 species. It is estimated that there are over 500 species of fish found in the Gippsland Basin, including a number of species of importance to commercial and recreational fisheries (LCC, 1993). Fish species listed under the EPBC Act that may occur in the OA are blue warehou, southern bluefin tuna, orange roughy, eastern gemfish, and eastern dwarf galaxias, all of which are considered conservation dependent except eastern dwarf galaxias which is endangered.

The OA overlaps with a reproduction BIA and a forging BIA for the white shark. However, the *Recovery Plan for the White Shark (Carcharodon carcharias)* (DSEWPAC, 2013a) does not identify light emissions as a threat for this species.

6.14.2.1.2 MARINE REPTILES – TURTLES

The *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017), lists light pollution as a key threat to turtles, however this relates specifically to turtle hatchlings and nesting sites. There is no evidence to suggest that adult or juvenile turtles are impacted by artificial light when they are offshore (Marangoni, et al., 2022).

There is some conflicting evidence to suggest turtles may be attracted to vessels offshore where fish aggregate. (Wang, Boles, Higgins, & Lohmann, 2007) found that juvenile loggerheads were attracted to lightsticks associated with longline fisheries in a laboratory setting. Contradicting evidence found that using LEDs or chemical lightsticks in commercial bottom gill net fishery was found to reduce green turtle by catch (Scott, et al., 2010). There is also evidence that hatchlings orientate to artificial lighting even after reaching the ocean (Cruz, Shillinger, Robinson, Tomillo, & Paladino, 2018), however no marine turtle nesting is known to occur in the region.

6.14.2.1.3 BIRDS

Birds in the marine environment may include both seabirds and shorebirds:

- seabirds refers to those species of bird whose normal habitat and food sources are derived from the ocean (both coastal and pelagic); seabirds include such species as pelicans, gannets, cormorants, albatrosses and petrels
- shorebirds (sometimes referred to as wading birds) refers to those species of bird commonly found along sandy or rocky shorelines, mudflats, and shallow waters; shorebirds include such species as plovers and sandpipers.

The *Wildlife Conservation Plan for Seabirds* (DAWE, 2020b) and the *Wildlife Conservation Plan for Migratory Shorebirds* (DoE, 2015b) identifies artificial light as a disturbance threat to these species. Seventy-eight listed threatened or migratory seabird and shorebird species were identified as potentially occurring within 20km of the two representative platform locations (DPA and KFA) and the two representative locations for transfer operations.

ALBATROSSES

There are sixteen species of albatrosses identified within the 20km buffers, and all except five (Buller's albatross, grey-headed albatross, Indian yellow-nosed albatross, northern Buller's albatross, and sooty albatross) have been identified as using the area for foraging, feeding or related behaviours. Albatross species in Australia forage in higher latitude, maritime waters from Western Australia to Queensland, predominantly southwards of the parallel of 25°S. Many of these species distribute widely across the world's oceans in the higher latitudes of the Southern Hemisphere (Commonwealth of Australia, 2022).

Albatrosses are wide-ranging, opportunistic predator with a diverse diet depending on the availability of food, including cephalopods, crustaceans, cyclostomes, fish and tunicates, although diet is not well known for several species (Commonwealth of Australia, 2022). Six BIAs for foraging have been identified for the following albatross species: black-browed, Buller's, Campbell, Indian yellow-nosed, shy, and wandering. There is only one species, the shy albatross, that is known to breed within the waters off mainland Australia, and this occurs outside of the area assessed for light emissions.

PETRELS

Within the 20km buffers, there are three species of petrels that may occur (blue petrel, Gould's petrel, and southern giant petrel), one species of petrel where foraging is likely to occur (northern giant petrel), and one species of petrel that is likely to occur (white-bellied storm petrel). Similar to albatrosses, the petrels in Australia forage in higher latitude, maritime waters from Western Australia to Queensland, predominantly southwards of the parallel of 25°S. Many of these species distribute widely across the world's oceans in the higher latitudes of the Southern Hemisphere. Petrels are wide-ranging, opportunistic predators with a diverse diet depending on the availability of food, including cephalopods, crustaceans, cyclostomes, fish and tunicates, although diet is not well known for several species (Commonwealth of Australia, 2022).

Two BIAs where foraging is known to occur have been identified for the white-faced storm petrel and common diving petrel. Both the common diving petrel and the white-faced storm petrel are listed as marine species under the EPBC Act, and have large populations within Australia, accounting for 5% and 25% respectively of the global

population (DoE, 2015a). Very little is known of the common diving petrel range when not breeding, but they are thought to be fairly sedentary, remaining in coastal waters adjacent to colonies. Its breeding season is variable according to locality, forming colonies with up to 1500 individuals in burrows on steep slopes and also on flat ground of oceanic islands. Common diving-petrel occurs on 53 offshore islands in Tasmania with an estimated 127,000 – 184,000 pairs. No populations estimates are available for Victoria, and the Australian trend is unknown (DAWE, 2020b). However, the South-east Marine Region profile - *'A description of the ecosystems, conservation values and uses of the South-east Marine Region'* report indicates that the common diving petrel breeds on islands off southeast Australia and Tasmania; there are 30 sites with significant breeding colonies (defined as more than 1000 breeding pairs) known in Tasmania, and 12 sites in Victoria (including Seal Island, Wilsons Promontory and Lady Julia Percy Island) (DoE, 2015a). There are 15 sites with significant breeding colonies in Tasmania, and three sites with Victoria, for the white-faced storm petrel (DoE, 2015a), however these sites don't overlap with the indicative area assessed based on NLPGW advice.

SHEARWATERS

Shearwaters represent the most abundant seabird in Australia. Within the 20km buffers, there is one species of shearwater that may occur (sooty shearwater), one species of shearwater that is likely to forage (flesh-footed shearwater), and one species of shearwater that is known to breed and forage (short-tailed shearwater). A foraging BIA and a breeding BIA have been identified for the short-tailed shearwater.

Shearwaters are typically pelagic species, except during breeding seasons where they are found on remote islands or coastal headlands. Breeding season in southeastern Australia for shearwaters is typically over summer; late-August/early-September to May (DCCEEW, 2022b) (DCCEEW, 2025a) (DCCEEW, 2025b) (DCCEEW, 2025c). Shearwater nests are usually in burrows or rock crevices.

Shearwaters are known to forage for a variety of pelagic prey, including krill, cephalopods, fish and crustaceans. Food is usually taken by pursuit-plunging, surface plunging or surface-seizing; however other methods (e.g. hydroplaning, deep plunging) may be used.

TERNS

Within the 20km buffers, there is one species of tern that may occur (little tern), one species of tern that is known to occur (Australian fairy tern), and one species of tern that is known to breed (greater crested tern). No BIAs for terns have been identified within the area assessed.

Many of the tern species are widespread and occupy beach, wetland and grassland habitats. Terns rarely swim; they hunt for prey in flight, dipping to the water surface or plunge-diving for prey (Flegg, 2002) usually for fish, squid, jellyfish, and sometimes crustaceans.

PLOVERS

Within the 20km buffer, there is one species of plover that may occur (eastern hooded plover), one species of plover that is likely to occur (greater sand plover), and four species of plover that are known to occur. Six species are wetland migratory species some of which are known to roost in the area (double-banded plover, grey plover, lesser sand plover, and Pacific golden plover). No BIAs for plovers have been identified within the area.

Many plovers feed by running along wet sand, mud or beaches and shorelines, snapping up small, aquatic, molluscs and insects for food. The nest is in a slight hollow in the ground where two to five (usually four) spotted eggs are laid and both parents incubate and care for the young. Some of the species here including the vulnerable greater sand plover and the endangered lesser sand plover are strongly migratory birds breeding in the Northern Hemisphere and wintering in sandy beaches of Asia and Australasia. While wintering in Australia, they occur in coastal areas of all states, though the greatest numbers occur in northern Australia.

There are three non-migratory species of plovers in the area, one of which is listed as vulnerable (the eastern form of the hooded plover (*Thinornis cucullatus cucullatus*)). It is a small bird that nests on the back of usually wide beaches above the high-water mark. Its main threat is human disturbance from off-leash domestic dogs (DCCEEW, 2024g).

SANDPIPERS

Within the 20km buffers, there are two species of sandpipers that are known to occur (common sandpiper and curlew sandpiper), one species of sandpipers that may occur (pectoral sandpiper), and three species of sandpipers

that are known to roost in the area (sarp-tailed sandpiper, terek sandpiper, and wood sandpiper). No BIAs for sandpipers have been identified within the area.

Sandpiper are all migratory birds breeding in the Northern Hemisphere Arctic and sub-Arctic regions and travel in large flocks when migrating. The critically endangered curlew sandpiper's (*Calidris ferruginea*) sighted population in Australia has significantly declined. In Australia the main threat for all sandpipers is from disturbance from humans and their domestic animals.

Also, in the *Scolopacidae* family are all of the other listed wetland migratory species found in the area (other than the osprey) including the snipes, knots, ruffs, godwits, sanderlings, shanks, turnstones, curlews, and whimbrel. These have similar breeding habits as the sandpipers. Their feeding habitat is coastal with large intertidal mudflats or sandflats and they roost on sandy beaches, sandbars, and spits.

There is one critically endangered species, the eastern curlew. The eastern curlew is Australia's largest shorebird and a long haul flyer. The eastern curlew takes an annual migratory flight to Russia and northeastern China to breed, arriving back home to Australia in August to feed on crabs and molluscs in intertidal mudflats. Recorded numbers are in decline in Australia and, like the sandpipers, this is largely attributed to the decline in wetlands in Asia. In Australia threats include human disturbance as well as habitat loss and degradation, changes to the water regime and invasive plants (DCCEEW, 2023b).

LITTLE PENGUIN

The little penguin Australian population is large but not thought to exceed one million birds (DoE, 2015a). Bass Strait has the largest proportion (approximately 60%) of the known breeding colonies in Australia. Individuals exhibit strong site fidelity, returning to the same breeding colony each year to breed (Gillanders, et al., 2013). Little penguins nested almost exclusively in rock crevices and burrows near the ocean (Weerheim, Klomp, Brunstig, & Komdeur, 2003). The diet of a little penguin includes small school fish, squid and krill. Little penguins are also an important component of the Australian and New Zealand fur seals' diet (Natural Resources Committee, 2011).

Breeding is known to occur within the 20km buffers of representative locations for transfer operations. A study was conducted between 2008 and 2011 on 13 of the 15 islands adjacent to Wilsons Promontory in northern-central Bass Strait, southeastern Australia, during November – early February (Schumann, Dann, & Arnould, 2013). This study reported that little penguins were known to occur on all 13 islands (Anser, Citadel, Cliffy, Dannevig, Great Glennie, Kanowna, Mchugh, Norman, Notch, Rabbit, Rabbit Rock, Rag, and Seal Islands).

FAIRY PRION

The vulnerable fairy prion (southern) is likely to occur within the 20km buffers, however no BIAs for fairy prions have been identified in the area. Breeding is known to occur at Kanowna Island off the coast of Victora with 1000 – 4000 breeding pairs of fairy prions, representing 1 - 4% of the Bass Strait population (Fromant, Eizenberg, Poupart, Bustamante, & Arnould, 2022). This island is outside the 20km buffer area indicated by the NLPGW for assessment of light emissions. During the non-breeding season, it frequents sub-tropical waters, and it feeds by plucking food off the ocean surface.

A study of year-round at-sea movements of fairy prions from southeastern Australia (Fromant, Eizenberg, Poupart, Bustamante, & Arnould, 2022) found during the breeding season, individuals foraged primarily along the continental shelf-edge 200 – 300km from the colony but also used pelagic waters (500 – 900km from the colony) and continental shelf areas (within Bass Strait). A colony of several hundred fairy prion burrows have been recorded at Seal Island (Harris & Deerson, 1980).

FORK-TAILED SWIFT

Within Victoria, the fork-tailed swift is widespread but sparsely scattered in all regions (Higgins P. J., 1999). The fork-tailed swift is an aerial eater, flying anywhere from 1 - 300m above the ground to forage. Feeding flight is characterised by circular flight patterns throughout areas of high prey concentration. The fork-tailed swift does not breed in Australia.

MIGRATORY WATERBIRDS

Migratory birds are species where a substantial proportion of the global or a regional population makes regular cyclical movements beyond the breeding range, with predictable timing and destinations. Many species of migratory waterbirds occur within the 20km buffers including sandpipers, plovers, and the southern fairy prion.

OTHER THREATENED BIRD SPECIES

The vulnerable blue-winged parrot breed in Tasmania, coastal southeastern South Australia and southern Victoria. They form monogamous pairs and make their nests in a tree hollow or stump, preferably one with a vertical opening. The eggs are laid on a bed of decayed wood. Their clutch size is four to six eggs. Breeding season is from October to February (Birdlife Australia, 2025a). There is a definite passage of blue-winged parrots to and from Tasmania after breeding each year, leaving in March to April and returning in August to October. Some birds, however, over-winter in Tasmania or on the Bass Strait islands.

The swift parrot and orange-bellied parrot are both critically endangered, they both breed in Tasmania, and migrate to the mainland for the non-breeding season. The swift parrot's habitat is mainly forest and it's threatened mainly by native predators and loss of forest habitat (Birdlife Australia, 2025b). The orange bellied parrot is ground feeding and inhabits salt marshes, coastal dunes, pastures, shrub lands, estuaries, islands, beaches and moorlands within approximately 10km of the coast. As with many of the migratory species, it is threatened by the loss of wetland habitat, in this case through changes to land use practices such as drainage of wetlands for grazing, alteration and destruction of saltmarsh for industrial and urban development, vegetation clearance for agricultural purposes (Birdlife Australia, 2025c).

6.14.2.1.4 PINNIPEDS

The listed Australian fur seal and New Zealand fur seal have the potential to occur in the area, with the Australian fur seal likely to occur amongst the waters surrounding the Seal Islands. A breeding colony of Australian fur seals is located on Rag Island located approximately 5.5km from one of the locations used as representative for transfer operations during decommissioning activities, and haul out sites consist of rocky islands, boulder and pebble beaches and rocky ledges. Australian fur seals are considered listed marine species with populations in recovery (Kirkwood, et al., 2010) and have the widest range of the pinnipeds. Breeding occurs typically between October and December with the main breeding sites occurring at Kanowna Island, the Skerries and Gabo Island.

Seals are also known to use the sea decks of offshore infrastructure as haul out sites for resting, although they are not expected to be present during decommissioning activities due to the high levels of disturbance. Seals may also forage in the offshore waters, although there are no BIAs overlapping with the OA or the EMBA for Campaign #1.

6.14.2.1.5 MARINE MAMMALS

There is a lack of data studying the effects of artificial light on the circadian rhythms of cetaceans and other marine megafauna (Stanton & Cowart, 2024). However, there is no literature to suggest that light is considered a cue for important behaviours such as feeding, migration or breeding. Some transiting cetaceans may opportunistically forage on small aggregations of fish and plankton around Campaign #1 vessels at night, however this is expected to be short term and highly localised with no adverse effects.

6.14.2.1.6 TERRESTRIAL MAMMALS

Following the recommendation from the NLPGW, initial identification of sensitive species considered a 20km buffer from locations assessed as representative of areas within the OA where Campaign #1 activities will be conducted. However, and based on the distance identified by the light modelling at which potential impacts to fauna could occur from light emitted from vessel operations during Campaign #1, sensitive species assessed in this EP are those within 7.2km from the light source. As a result, the area in which impacts from light emissions could occur is within the overall EMBA defined for the decommissioning activities, as described in Section 3 and Appendix A of this EP.

6.14.2.2 Potential effects from artificial light - Nesting and Roosting

Artificial lighting may increase risk of predation to shorebirds, potentially resulting in selection of nocturnal roost sites with lower levels of light (Rogers, Piersma, & Hassell, 2006). Some shorebirds are more responsive to predators under artificial lighting, resulting in additional energy demand and disrupting foraging (Jolkkonen, Gaston, & Troscianko, 2023). This indicates that artificial illumination of nocturnal roost sites may reduce occupation of these roost sites and consequently influence the abundance of shorebirds in nearby foraging areas.

Procellariiformes (albatrosses, petrels, prions and shearwaters) which breed in cavities and attend breeding colonies at night (Warham, 1990) are at greater risk of negative impacts from artificial light. Due to most procellariiformes having acute vision and olfaction this generates sensitivity to sensory information which can result in them being uniquely vulnerable to sensory threats, including artificial light (Friesen, Beggs, & Gaskett, 2017) (Heswall, et al., 2022).

Visiting frequency of breeding seabirds attending colonies at night is influenced by moon cycles and is likely driven by light levels (Riou & Hamer, 2008) (Rodríguez, Chiaradia, Wasiak, Renwick, & Dann, 2016). Many species of pelagic seabirds attend their colony only at night, in complete darkness, avoiding approaching their nest sites under moonlight as a predator avoidance strategy, however this may also relate to a lower foraging efficiency during moonlit nights. Such effects have been shown to influence chick provisioning where nests situated closer to higher artificial light and sound gained less weight in an overnight weight gain study (Cianchetti-Benedetti, Becciu, Massa, & Dell'Omo, 2018). (Austad, M., Oppel., S., Crymble, J., Greetham, H.R., Sahin, D., Lago, P., Metzger, B.J, Quillfeldt, P, 2023) found coastal vessel presence significantly impacted shearwater colony attendance and proposed that disruption of natural attendance patterns could have short and long-term effects on breeding success, physiological condition, and colony viability.

For shearwater and petrel species, fledgling emergence is highly synchronised and occurs under the cover of darkness shortly after sunset which are thought to be predator avoidance strategies (Collins, et al., 2023). Moon phase is not considered a predictor of the timing of peak fledging (Raine, Driskill, Rothe, & Travers, 2022), and significant illumination of seabird burrow sites could act to suppress fledging activity (per the NLPGW).

Fledglings embarking on their first flight are vulnerable to artificial light due to naivety, immature eye development and the potential association between light and food from being fed through the burrow entrance (Montevecchi, 2006) (Mitkus, Nevitt, Danielsen, & Kelber, 2016) (Rodríguez, et al., 2017). Numerous studies have documented fallout events resulting from fledglings' attraction to nearby light sources (Deppe, et al., 2017) (Raine, Borg, Raine, Bairner, & Cardona, 2007) (Rodríguez, et al., 2015) (Rodríguez, Rodríguez, & Negro, 2015) (Le Corre, Ollivier, Ribes, & Jouventin, 2002) (Reed, Sincock, & Hailman, 1985), and even light sources up to 15km away (Rodríguez, et al., 2014). However, the mechanisms for mass fledgling fall-out events are still not fully understood in part because data is often collected opportunistically through rescue programs (Brown, Wilhelm, Mastromonaco, & Burness, 2022). In a two-year study of Leach's storm petrels adjacent to a seafood processing plant, 94.9% of strandings due to artificial light were fledglings during the peak stranding period and fledglings also composed the majority during mass stranding events (Burt, et al., 2024).

A higher proportion of fledglings make it safely to sea during full moon nights than during moonless nights, representing a decrease in the severity of light pollution impacts around full moon (Rodríguez, et al., 2023). Miles, Money, Luxmoore, & Furness, (2010) suggests this effect is possibly because of the relative glare and attraction of artificial lights diminishing on nights when ambient light from the moon was particularly bright and long-lasting. Atmospheric conditions that challenge fledglings' ability to navigate and produce scattering effects on light (e.g. fog, smoke and cloud) are also thought to be a confounding factor in fall-out events (Gjerdrum, Ronconi, Turner, & Hamer, 2021).

Light-induced grounding can result in injury or mortality due to impact with the ground or man-made structures, and exposure to threats including predation or inanition as some fledglings are unable to take off without human intervention (Marangoni, et al., 2022).

6.14.2.3 Potential effects from artificial light – Nocturnal Foraging

Whilst many shorebirds are considered diurnal, it is the tidal cycle's influence on food availability that drive activity patterns rather than the day/night cycle (Burger, Howe, Hahn, & Chase, 1977). Artificial lighting has been shown to influence the nocturnal foraging behaviour in shorebirds, often resulting in improved foraging success by increasing the availability of more successful visual foraging (Santos, et al., 2010) (Dwyer, Bearhop, Campbell, & Bryant, 2012) (Pugh & Pawson, 2016).

Similarly, most seabird species are visual predators and forage most actively during the day. However, a number of species, including many albatrosses and petrels, forage at night either preferentiality or uniformly (Shealer, 2001) (Phalan, et al., 2007). Nocturnal feeders tend to feed offshore and are associated with prey that surfaces at night (Brooke, De, & Prince, 1991). Light intensity plays an important role in determining visual nocturnal foraging behaviour, where increased foraging activity has been demonstrated under moonlit conditions in many species (Phalan, et al., 2007) (Regular, Hedd, & Montevecchi, 2011) (Yamamoto, et al., 2008) and artificial light (Krüger, Paiva, Petry, & Ramos, 2017). Despite this observed effect, a study on Bulwer's petrel found no evidence of dietary shifts across lunar phases highlighting some nocturnal predators may be resilient to changes in the vertical distributions of prey (Waap, et al., 2017).

Many studies have documented the attraction of seabirds to offshore vessels (Gjerdrum, Ronconi, Turner, & Hamer, 2021) (Merkel & Johansen, 2011) (Ryan, Ryan, & Glass, 2021) (Coleman, Hollyman, Black, & Collins, 2022), though few have established the life stage of grounded birds to determine whether foraging seabirds are a key

receptor. Foraging seabirds in the vicinity of vessels may be attracted to artificial lighting which may also cause disorientation, thereby increasing the likelihood of seabird injury or mortality through collision with the vessel, or mortality from starvation due to disrupted foraging at sea (Wiese, et al., 2001). Disorientation may also result in entrapment, stranding or grounding, and interference with navigation (per the NLPGW). Fairy prions exhibit strong phototaxis, particularly towards lights on vessels (Middlemiss, Cieraad, Mander, Fischer, & Goad, 2025).

In addition, bird attraction to and disorientation by artificial light increases when visibility is poor due to rain or fog (Russell, 2005) (Montevecchi, 2006), and when lunar illumination is low (Rodríguez & Rodríguez, 2009) (Miles, Money, Luxmoore, & Furness, 2010).

Atchoi, et al., (2024) have demonstrated that light induced effects on shearwaters are comparatively reduced in adults with visual and navigational experience in comparison to fledglings. Therefore, foraging adults may be less subject to disorientation (Burt, et al., 2024).

Nonetheless, groundings appear to be correlated with light intensity and the distance from breeding colonies irrespective of age (Heswall AM, Miller L, McNaughton EJ, Brunton-Martin AL, Cain KE, Friesen MR, Gaskett AC., 2022)

6.14.2.4 Potential effects from artificial light – Migration

Decommissioning activities sit within the East Asian–Australasian Flyway which stretches from the Russian Far East and Alaska, southwards through East Asia and Southeast Asia, to Australia and New Zealand and encompasses 22 countries (Commonwealth of Australia, 2017b). During migration, waterbirds rely on a system of highly productive wetlands to rest and feed, building up sufficient energy to fuel the next phase of their journey. The species present are all migratory birds breeding in the Northern Hemisphere (e.g. Siberia/Alaska) and migrating south during their winter.

Two Ramsar wetlands are located in the proximity of the OA: Corner Inlet and Gippsland Lakes, considered of international and national importance respectively (Weller, et al., 2020). These sites are wintering destinations for trans-equatorial migratory birds (with stopovers through Asia and northern Australia) and a number of species originating from New Zealand (Williams, Gummer, Powlesland, Robertson, & Taylor, 2006).

Results from the identification of sensitive bird species within the 20km buffer from representative locations where vessel operations may take place included the presence of 30 migratory wetland species, 21 migratory marine and four migratory terrestrial species likely to be present in the area. Internationally significant populations of the bar-tailed godwit, red-necked stint, red knot, sharp-tailed sandpiper, double-banded plover and eastern curler, and nationally important populations of the curlew sandpiper, grey plover, black-tailed godwit, sanderling, common greenshank, whimbrel and ruddy turnstone are found at the Corner Inlet site, with the Nooramunga Coastal Park supporting the most significant populations (Weller, et al., 2020).

Light pollution is a particular issue for migratory shorebirds as they undertake their migratory flights at night (Geering, Agnew, & Harding, 2007). It has been found that artificial light can affect the behaviour of birds in flight, inducing unnecessary ascent and descent, long periods of circling, and other types of unusual manoeuvring that would be more energetically expensive than typical straight-path migratory flights (Van Doren, et al., 2017) (Cabrera-Cruz, Smolinsky, & Buler, 2018). Similarly, high levels of marine lighting can attract and disorient seabird species resulting in behavioural changes such as circling light sources leading to exhaustion or disrupted foraging (Longcore & Rich, 2004) (Gaston, Duffy, Gaston, Bennie, & Davies, 2014) (Rich & Longcore, 2006).

Further skyglow is now considered highly influential and a consistently positive predictor of bird migration stop-over densities (Horton, et al., 2023) and artificial lighting may override the internal magnetic compass of migratory shorebirds or nocturnal seabirds (Gauthreraux Jr & Belser, 2006). Broad-scale attraction by some seabird and shorebird species to artificial light while airborne can prevent them from selecting appropriate habitat, choosing instead areas that are well lit, but less suitable for survival, in preference to less light affected habitat.

6.14.2.5 Change in fauna behaviour, and injury/mortality of fauna

6.14.2.5.1 PLANKTON AND FISH

Plankton, fish, squid, distributions are influenced by oceanographic conditions, often involving diurnal movements within the water column driven by light (Omand, Steinberg, & Stamieszkin, 2021). The movement of organisms into the photic zone increases their availability as prey to higher order predators such as seabirds and pinnipeds. Many nocturnal predators have diets, eye structures and hunting strategies that are specialised in foraging on prey that is only available at night (Brooke, De, & Prince, 1991).

Light spill over water from vessels and platforms is known to result in aggregations of photopositive species, often comprising fish of commercial interest. Numerous light trap studies have documented the photopositive effects of artificial light in marine fish and invertebrates (Marchesan, Spoto, Verginella, & Ferrero, 2005) (Stickney, 1969) (Utne-Pal, Breen, Løkkeborg, & Humborstad, 2018) (Krafft & Krag, 2021). Lindquist, Shaw, & Hernandez, (2005) concluded from a study of larval fish populations around an oil and gas platform in the Gulf of Mexico that an enhanced abundance of clupeids (herring and sardines) and engraulids (anchovies), both of which are highly photopositive, was caused by the platforms' light fields. The concentration of organisms attracted to light results in an increase in food source for predatory species and marine predators are known to aggregate at the edges of artificial light halos (Marangoni, et al., 2022). Further, the moonlight intensity is known to affect the foraging efficiency of many procellariiformes who increase their foraging activity under full moon conditions (Rubolini, et al., 2014) (Yamamoto, et al., 2008), although no studies of skyglow have reproduced this behaviour.

Artificial light can also influence the diurnal migration of photonegative species, including most zooplankton (Forward Jr., 1988). In contrast to behaviour shown from photopositive species, normal working lights on marine research vessels have been shown to cause zooplankton and their vertebrate predators to descend away from the surface; these effects occurred at depths of up to 200m, and up to 200m horizontally from the light source (Berge, et al., 2020). A number of fish species have also been shown to avoid light (Marchesan, Spoto, Verginella, & Ferrero, 2005) (Utne-Pal, Breen, Løkkeborg, & Humborstad, 2018). Another study (Shell, 2010) indicates that plankton and fish may be directly or indirectly attracted to lights. Experiments using light traps have found that some fish and zooplankton are attracted to light sources, with traps drawing catches from up to 90m. This suggests that light could lead to aggregation at the surface of plankton and fish, and to potential increased predation.

Campaign #1 vessels require lights for safe navigation and to illuminate work areas within the vessels during night-time operations, which may result in temporary night-time attraction of marine fauna, including prey and higher order predators.

The scale of attraction to Campaign #1 vessel light sources is expected to be highly localised and not detectable at population scales for plankton, fish (including sharks), and squid. Further, the HLV activity duration is approximately five months in which vessels will be moving from one facility to another, and between the facilities and the transfer locations, with operations at transfer locations taking place over approximately 21 intermittent, non-consecutive nights. As a result, it is not expected that light will be emitted at the same location for more than one consecutive night during activities to remove facilities, and during transfer operations. There can be the potential for a one-time occurrence of light emitted at the same location for up to four consecutive nights, associated with the activity of HLV mode change operation. This specific activity will be required only once during the decommissioning activities.

Given the highly localised and short-term exposure of plankton and fish to light at each location, and the expected negligible changes in distribution and abundance of these organisms, the consequence level is assessed as:

- **Consequence Level IV**.

6.14.2.5.2 MARINE REPTILES – TURTLES

Light pollution can be an issue along, or adjacent to, turtle nesting beaches where emerging hatchlings orient to, and head towards, the low light of the horizon unless distracted by other lights which disorient and affect their passage from the beach to the sea (DoEE, 2017).

Three listed/threatened species of marine turtle may occur within the OA, although there are no BIAs or critical habitats, and all marine turtles are known to have a more northerly distribution. The *Recovery Plan for Marine Turtles in Australia 2017 – 2027* (DoEE, 2017) lists light pollution as a key threat, however this relates specifically to turtle hatchlings and nesting sites, which don't occur within the OA. In addition, mating, inter-nesting, foraging and migration behaviours are not guided by light cues, and therefore it is unlikely that turtles would be displaced or experience behavioural changes due to artificial light emissions from decommissioning activity vessels.

Therefore, it is anticipated that light emissions from vessel operations during Campaign #1 activities will not affect marine turtles and the impact is assessed as:

- **Consequence Level IV**.

6.14.2.5.3 BIRDS

Identification of sensitive receptors was based on the recommendation from the NLPGW which indicates a distance of 20km from the light source. Then, for decommissioning activities, the assessment of potential impacts considered the results of light modelling for vessel operations during Campaign #1.

There is a lack of studies establishing the relationship between seabird behaviour and light intensity (Longcore T. , 2023), and therefore no thresholds for predicting impacts have been established. Artificial light intensity that equates to a quarter moon or greater has been used as a conservative proxy to identify where impacts to seabirds and shorebirds behaviour have the potential to occur. Table 6-80 presents the criteria for artificial light impact assessment for birds, whilst Table 6-81 presents results obtained for each of the representative scenarios modelled for decommissioning activities in the Gippsland Basin.

Table 6-80 Seabird and shorebird full moon equivalent impact potential criteria

Field of view radiance (full moon equivalent ranges)	Description	Impact potential
100 – 10	Light or light glow visible. Represents a very bright light, equivalence of to up to 100 times the radiance of one moon.	Impacts are possible.
10 - 1	Light or light glow visible. Represents a bright light, equivalence of to up to 10 times the radiance of one moon.	Impacts are possible.
1 – 0.1	Light or light glow visible but will vary depending on ambient moon phase at the time of exposure, which will influence the visibility of the artificial light sources. Artificial lights will be more visible under a first quarter moon than under a full moon.	Artificial light has the potential to result in impacts, based on studies which have observed behavioural changes in seabirds at full moon (Yamamoto, et al., 2008) (Riou & Hamer, 2008).
0.1 - 0.01	Light or light glow visible. Equivalent to the light output from the first quarter moon to new moon.	Artificial light is visible above ambient conditions at new moon, but impacts are not likely.
<0.01	Light or light glow is considered ambient.	Impacts are not expected.

Table 6-81 Field of view and full moon equivalent distances

Field of view radiance (full moon equivalent ranges)	Scenario 1: CSV at DPA (range in km)	Scenario 2: HLV at DPA (range in km)	Scenario 3: CSV and HLV at KFA (range in km)	Scenario 4: HLV, CSV and PSV at representative transfer locations (range in km)
100 - 10	<0.10	<0.67	<0.70	<0.71
10 - 1	0.10 – 0.72	0.67 – 2.3	0.70 – 2.5	0.71 - 2.6
1 - 0.1	0.72 – 3.2	2.3 – 6.4	2.5 – 6.8	2.6 – 7.2
0.1 - 0.01	3.2 - 9.1	6.4 – 15.6	6.8 – 16.4	7.2 – 17.1
<0.01	>9.1	>15.6	>16.4	>17.1

Results from the light emissions modelling indicates the furthest distance at which light from vessel activities associated with Campaign #1 could potentially have an effect (behavioural changes) on seabirds and shorebirds (field of view – full moon equivalent range of 0.1 - 1 or greater) is 7.21km from the source (ERM, 2024).

NESTING AND ROOSTING

Campaign #1 activities will be conducted in the offshore marine environment, within Commonwealth waters. The activities that will occur closest to the shoreline, at a minimum distance of 5.5km (3nm) will be those associated with operations to transfer removed structures from the HLV onto barges of a HTV, and the HLV mode change operation. Removal of facilities within the scope of this EP will occur furthest away from the shoreline, with DPA being the closest platform to shore at an approximate distance of 21km.

Results indicate transfer operations to be conducted during decommissioning activities may overlap with the breeding BIA for the short-tailed shearwater, specifically islands located to the east of Wilsons Promontory (Rabbit Rock and Rabbit Island). However, overlap will be subject to location where transfer operations and mode change of the HLV take place. There is no recovery plan or conservation advice for the short-tailed shearwater, however artificial light is listed as a threat in the *Wildlife Conservation Plan for Seabirds* (DAWE, 2020b).

Other areas where possible intersections with seabird and shorebird nesting and roosting habitat may occur include:

- Seal Islands Group (Seal Islands Wildlife Reserve)
- the sand barrier islands and tidal channels of Nooramunga Marine and Coastal Park.

Wilsons Promontory Islands are considered an Important Bird Area by Birdlife International due to the presence of breeding short-tailed shearwater and pacific gulls. Schumann et al (2013) records the presence of burrowing short-tailed shearwater, common-diving petrel, fairy prion and little penguin across the majority of the islands, however there is otherwise a paucity of publicly available contemporary bird count data.

The sandy beaches and foredunes of Wilsons Promontory support high nesting densities of the threatened hooded plover (Birdlife Australia, 2023) but are considered to support less significant populations of seabird and shorebirds.

The Nooramunga islands form part of the Corner Inlet Ramsar site and supports an estimated 29,000 waders (migratory and non-migratory), including significant populations of pied oyster catcher, sooty oystercatcher, pacific gull, fairy tern, grey plover, bar-tailed godwit, red knot, red-necked stint, great knot and eastern curlew (Hale, 2017). Migratory shorebirds typically overwinter in the area during the austral summer, and adults migrate back to their breeding grounds in the Northern Hemisphere, therefore migratory shorebirds are expected to be present at foraging and roosting sites for the duration of Campaign #1 following their arrival in August/September. The site also supports breeding populations of pied oystercatchers, hooded plover, Caspian tern, fairy-tern, crested-tern and short-tailed shearwaters.

The results of light modelling for various decommissioning activity vessel scenarios indicated that artificial light intensity is highest immediately surrounding the vessels and dissipates with distance at a rate proportionate to the number and size of vessels present, which broadly correlates to the number of luminaires present.

For HLV operations at DPA light intensity is expected to dissipate to 0.01 – 0.1FME at 6.4km, which is equivalent to the light output from the first quarter moon to new moon. For KFA, where there may be presence of both the HLV and CSV (Scenario 3) at the same time, light intensity dissipated to 0.01 – 0.1FME beyond 6.8km from the light sources. Therefore, artificial light impacts to nesting and roosting behaviours along the coastline are not expected from vessel operations at the platforms.

For vessel operations during transfer activities or HLV mode change operation, it is possible that light spill extends to seabird and shorebird nesting habitat. Specifically, for the HLV mode change operation a worst-case is considered for impact assessment, which results from the simultaneous operations of the HLV, a CSV and a PSV. This vessel operation combination resulted in radiance equivalent to a first quarter moon to a full moon (0.01 – 1FME) within a range of 2.6 - 7.2km from the light source. The FME ranges also represent a conservative estimate considering that the HLV mode change operation will occur only once during Campaign #1 activities, and considering the CSV and the PSV will not be present in the area at the same location with the HLV during transfer activities.

Given the location of transfer operations are subject to change, seabirds nesting and roosting locations may or may not overlap with artificial light emitted from the vessels at levels that may have a minor, localised effect on

these species. For shorebirds, impacts to nesting and roosting significant habitats are not expected, as light spill from vessel operations will not reach intertidal roosting and nesting habitats, preventing behavioural disruption. In addition, some degree of shielding from the vessel light sources can be expected due to topographical variation and vegetation, which is not accounted for in the light model. The Seal Islands rise steeply from the ocean to a maximum of approximately 50m above sea level, therefore seabird nesting and roosting sites furthest from the light source may experience some additional shielding from direct light. As a result, if transfer operations or the HLV mode change operation are conducted towards the western end of the OA where artificial light could have an effect on nesting and roosting behaviours at Seal Islands, potential impacts are mitigated by:

- the temporary and intermittent nature of the transfer activity: approximately 21 intermittent/non-consecutive nights over an estimated period of five months that the HLV will be at the transfer area to load structures onto barges or a HTV
- the temporary nature of the HLV mode change operation: this will be a one-off activity during Campaign #1, with an estimated duration of four consecutive nights
- the moderating influence of the moon on ambient brightness for at least half of every month
- the variable topography of the islands will further aid in reducing visibility of vessel lighting, as will the predicted low intensity of sky glow due to the low levels of regional lighting.

The consequence level of the potential impact to nesting and roosting behaviours is therefore assessed as:

- **Consequence Level IV**.

From a perspective of potential impacts on fledglings, it is possible that seabird fledglings leaving the burrow on their inaugural flight may transit within the maximum distance reached by artificial light emitted from Campaign #1 vessels (7.2km during HLV mode change) and become attracted to and disoriented by vessel lighting. However, the timing of the HLV activities (September February) precludes the short-tailed shearwater exodus (April - May). Common diving petrels tend to nest earlier than most species and may fledge between November and December, and fairy prions may also fledge during January (Eizenberg, Fromant, Lec'hvien, & Arnould, 2021). The potential for fledgling groundings will be dependent of the atmospheric conditions with foggy or cloudy conditions further disorienting birds, whilst full moon conditions tend to reduce grounding events. Noting that the decommissioning activity is constrained by suitable weather conditions, there may be some protection from severe grounding events relating at least to high winds and sea state.

Impacts to fledgling seabirds, particularly cavity nesting procellariiformes on nearby islands, are considered possible given the proximity to significant nesting locations and the modelled light intensity of the vessel spread at the representative transfer locations. The vessels will be present for short periods at a time (one night) during each transfer, before moving further offshore to platform locations. Therefore, the vessels will only be present at the transfer location occasionally and intermittently during Campaign #1, across approximately 21 non-consecutive nights during the nominal five month activity. From a HLV mode change operation perspective, potential exposure of fledglings to this specific operation will be a total of only approximately four nights during the planned fivemonths of HLV decommissioning activities.

To further minimise the potential exposure of fledglings to artificial light from vessel operations, a number of measures, implemented individually or as a combination of measures that includes vessel location, timing of operations and lighting arrangements, may be implemented to reduce the likelihood of exposure from fledglings to artificial light.

The area potentially affected is limited to a localised area over a temporary and intermittent period of time. There is the potential for impacts at individuals scale, however it is not expected that impact will have an effect at population or ecosystemic levels. As a result, the consequence level for fledglings is assessed as:

- **Consequence Level III.**

NOCTURNAL FORAGING

The OA overlaps foraging BIAs for the black-browed albatross, Buller's albatross, Indian yellow-nosed albatross, Campbell albatross, shy albatross, wandering albatross, common diving petrel, white-faced storm petrel and the short-tailed shearwater. Indian yellow-nosed albatross and the Campbell albatross are foraging in the OA only during the winter months and are therefore unlikely to be present during the decommissioning activities. The recognised foraging BIAs for albatross species covers large areas. For example, the entire southeast marine region is recognised as a foraging BIA for the Indian yellow-nosed (*Thalassarche carteri*), Campbell (*Thalassarche*

impavida) and the black-browed albatross species, resulting in minor percentages of area overlap between identified BIAs and the OA.

Foraging seabirds are likely to be present in the Campaign #1 activity area at night, particularly given the presence of breeding colonies for some species nearby the western end of the OA where transfer operations and the HVL mode change operation may take place. The skyglow created by the Campaign #1 vessels may also increase foraging behaviour and efficiency in some seabirds, based on the observed effects of moonlight. It is considered that foraging adults are subject to similar impacts to fledglings albeit at significantly reduced rates due to advanced visual development and navigational experience.

For the artificial light worst-case scenario modelled for vessel operations (HLV mode change operation) results indicated that artificial light radiance of a quarter moon to new moon is reached between 2.6 - 7.2km from the source. These light radiance levels overlap a high-density seabird foraging area adjacent to breeding seabird colonies located to the west of the OA, where transfer operations may take place, and thus may attract birds foraging within the area or transiting to foraging grounds further offshore. The presence of the vessel spread during HLV removal operations is planned to be approximately five months, with the HLV present at the transfer location to conduct transfer operations on approximately 21 intermittent, non-consecutive nights, whilst HLV mode change operation will be a one-off activity with a duration of approximately four nights. Overall, Campaign #1 vessels will be constantly moving between different locations within the OA during decommissioning activities, which reduces the potential impact to be concentrated at a specific location, particularly sensitive areas located closer to the western end of the OA.

Therefore, the effect of artificial light on foraging seabirds is considered to have a possible impact on seabirds. However, impact will be localised and will be mostly limited to intermittent transfer operations and the HLV mode change operation when these activities are conducted closer to sensitive areas such as Seal Island, the eastern coastline of Wilsons Promontory, and the outer sand barriers and islands at Nooramunga Marine and Coastal Park, which represents a small percentage of the total available foraging area. As a result, the consequence level is assessed as:

- **Consequence Level III**.

MIGRATION

Migratory birds typically begin to arrive in Australia from late August onwards to December and are therefore expected to be undertaking their final migratory movements throughout the duration of Campaign #1. The OA is located near important migratory bird habitat where large numbers of migratory birds are expected to occur.

Based on light modelling results, area that may be affected by artificial light emitted during vessel operations represents a very small area within the East Asian–Australasian Flyway available to migratory birds. The presence of the vessel spread during HLV removal operations is planned to be approximately five months, with the HLV present at the transfer location to conduct transfer operations on approximately 21 intermittent, non-consecutive nights, whilst HLV mode change operations will be a one-off activity with a duration of approximately 4 nights. Vessels will be constantly moving between different locations within the OA during decommissioning activities, which reduces the potential impact from vessel operations at a single specific location, particularly sensitive areas located closer to the western end of the OA.

Any attraction of migratory birds toward Campaign #1 vessel artificial light emissions is unlikely to cause significant deviations to normal migratory paths and is expected to have minimal costs to individual energy budgets given the close proximity to suitable over-wintering destinations. The consequence level is therefore assessed as:

- **Consequence Level III**.

6.14.2.5.4 PINNIPEDS

Seals may opportunistically forage on small aggregations of fish around Campaign #1 vessels at night (SETFIA, 2007), where other predators such as white sharks may also aggregate. Artificially lit water may increase both the opportunity for predation by seals from an increased predator/prey interaction but also increase the visibility of seals in the water aiding shark predation success (Morse, et al., 2019) (Fallows, Fallows, & Hammerschlag, 2016). However, this potential impact is expected to be limited to individuals during the short duration of the activity. It is not expected that light emissions will occur at the same location for more than one consecutive night during platform lifting and removal operations, and during transfer operations. However, there is potential for the HLV

mode change operation to last up to four nights; this specific operation will occur only once during the life of the decommissioning activities, at a sheltered waters location within the OA.

Potential impacts to seals from light emissions will be highly localised, short-term and with no consequence on a population level. Therefore, the impact is assessed as:

- **Consequence Level IV**.

6.14.2.5.5 MARINE MAMMALS

There is no literature that suggest that light is considered a cue for important behaviours such as feeding, migration or breeding. (WCDS, 2004) indicates that cetaceans predominantly utilise acoustic senses to monitor their environment rather than visual sources. In addition, the Conservation Plan for PBW and the Recovery Plan for SRW don't identify light emissions as a threat to these species.

Some transiting cetaceans may opportunistically forage on small aggregations of fish and plankton around Campaign #1 vessels at night.

Potential impacts to marine mammals from light emissions will be highly localised, short-term and with no consequence on a population level or ecosystemic functions. Therefore, the impact is assessed as:

- **Consequence Level IV**.

6.14.2.6 Change in visual amenity

Artificial light from vessel operations creates a skyglow that leads to a reduced visibility of the natural night sky. The level of skyglow is dependent mostly on the intensity and number of the artificial light sources, with additional factors such as position of the lights, effect of shading on lighting where present and type of light also influencing light emissions.

The effect of the skyglow from a visual amenity perspective is more relevant in areas where night skies are a source of tourism and astronomical observations. Currently there are six officially recognised Dark Sky sites in Australia (DarkSky International, 2024), none of which are located in Victoria.

Wilsons Promontory is a popular tourist destination in Victoria. Its location away from populated urban centres results in a reduced exposure of the night sky to the skyglow effect produced by artificial lights. There are tourism initiatives within the park that benefit from natural night sky to attract visitors.

Based on light modelling results for decommissioning activities, it is not expected that impacts to visual amenity will occur from vessel operations that take place at the platforms or during transit between locations. In contrast, transfer operations and the HLV mode change operation may take place towards the western end of the OA (within Commonwealth waters) in proximity to the southeastern portion of Wilsons Promontory. In this scenario, it is possible that skyglow could be perceived from a limited area of the Wilsons Promontory Park.

Light emissions during decommissioning activities will be temporary, and the mobile nature of vessel operations results in a dispersed potential impact. Particularly for activities associated with transfer operations, it is estimated that artificial light may be emitted for approximately 21 non-consecutive nights. For the HLV mode change operation, this will be a one-off activity with an estimated duration of maximum four nights. HLV decommissioning activities will occur in spring/summer, when the duration of daylight is longer, further reducing the potential impact on visual amenity from skyglow. In addition, the single lift decommissioning method to be implemented for Campaign #1 will reduce the vessel time required to complete removal of facilities, including a reduction on the number of nights that artificial light would be produced when compared to other approaches for decommissioning such as reverse installation.

As a result, it is expected that these operations will have very limited, short-term duration, with inconsequential effect on visual amenity. Natural values of the dark sky are expected to return to its original condition immediately after emission of artificial light from vessels ceases. As a result, the consequence level is assessed as:

- **Consequence Level IV**.

Table 6-82 Assessment of light management options for seabirds from the NLPGW

Management Option	Achievable?	Justification
Implement management actions during the breeding season.	Yes	Achievable management actions are identified in this Table, including direction of lights, management of indoor light sources and implementation of a seabird management plan.
Maintain a dark zone between the rookery and the light sources.	Partially	The OA doesn't overlap with rookeries. However, during transfer operations and HLV mode change operation, artificial light from vessel operations could reach coastal areas where these habitats may be present. Implementation of controls described in Section 6.14.3 provides means to minimise the sky glow that may be generated from the vessel during night-time operations.
Turn off lights during fledgling season.	No	Operations are conducted 24-hours a day and light is necessary for personnel safety. Lighting will be reduced to the furthest extent possible for safe operations (see Section 6.14.3 of this EP).
Use curfews to manage lighting.	No	Operations are conducted 24-hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations (see Section 6.14.3 of this EP).
Aim lights downwards and direct them away from nesting areas.	Yes	Where practicable, lights will be directed towards working areas for the safety of personnel (see Section 6.14.3 of this EP).
Use flashing/intermittent lights instead of fixed beam.	No	Operations are conducted 24-hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations
Use motion sensors to turn lights on only when needed.	No	Operations are conducted 24 hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations.
Prevent indoor lighting reaching outdoor environment.	Yes	Vessels will have blinds/curtains installed in cabins (see Section 6.14.3 of this EP).

Management Option	Achievable?	Justification
Manage artificial light on jetties, wharves, marinas etc.	N/A	Not applicable to this activity.
Reduce unnecessary outdoor deck lighting on all vessels and permanent and floating oil and gas installations in known seabird foraging areas at sea.	Yes	Lighting will be reduced to that required for safe operations and by maritime legislative requirements (see Section 6.14.3 of this EP).
Night fishing should only occur with minimum deck lighting.	N/A	Not applicable to this activity.
Avoid shining light directly onto fishing gear in the water.	N/A	Not applicable to this activity.
Ensure lighting enables recording of any incidental catch, including by electronic monitoring systems.	N/A	Not applicable to this activity.
Avoid shining light directly onto longlines and/or illuminating baits in the water.	N/A	Not applicable to this activity.
Vessels working in seabird foraging areas during breeding season should implement a Seabird Management Plan to prevent seabird landings on the ship, manage birds appropriately and report the interaction.	Yes	A Seabird Management Plan will be developed and implemented for Campaign #1 activities (see Section 6.14.3 of this EP).
Use luminaires with spectral content appropriate for the species present.	No	The Campaign #1 vessel(s) are equipped with lighting required under legislation to identify itself to other vessels, reduce the risk of at-sea collision and provide for the safety of its crew.
Avoid high-intensity light of any colour.	No	The Campaign #1 vessel(s) are equipped with lighting required under legislation to identify itself to other vessels, reduce the risk of at-sea collision and provide for the safety of its crew.

Management Option	Achievable?	Justification
Shield gas flares and locate them inland and away from seabird rookeries.	N/A	Not applicable to this activity.
Minimise flaring on offshore oil and gas production facilities.	N/A	Not applicable to this activity.
In facilities requiring intermittent night-time inspections, turn on lights only while operators are moving around the facility.	No	Operations are conducted 24 hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations
Ensure industrial site/plant operators use head torches.	N/A	Operations are conducted 24 hours a day and lighting of all areas is necessary to ensure safety of the crew, the vessel and other users of the sea. As such, open areas such as the deck and other exterior areas are lit by other means, and the use of head torches would be limited to enclosed or small spaces located in the interior areas of the vessel, where other means of artificial light can't meet the needs required for the specific task. Lighting will be reduced so far as is practicable and in accordance with maritime requirements and personnel safety
Supplement facility perimeter security lighting with computer-monitored infrared detection systems.	N/A	Not applicable to this activity.
Tourism operations around seabird colonies should manage torch usage so birds are not disturbed.	N/A	Not applicable to this activity.
Design and implement a rescue program for grounded birds.	Yes	A Seabird Management Plan will be developed and implemented for Campaign #1 activities (see Section 6.14.3 of this EP). This plan will include actions to be implemented in the event of birds landing on the vessel.

Table 6-83 Assessment of light management options for shorebirds from the NLPGW

Management Option	Achievable?	Justification
Implement actions when birds are likely to be present, including for peak migratory periods.	Yes	Achievable management actions are identified in this Table, including direction of lights, management of indoor light sources and implementation of a seabird management plan.
No light source should be directly visible from foraging or nocturnal roost habitats, or from migratory pathways.	Partially	Migratory paths for shorebirds, as established in the East Asian-Australasian Flyway, covers extensive areas which includes the full extension of the Bass Strait. As result, it is not possible to eliminate visible light generated by vessel operations from the overall area identified as potential for use by shorebirds as migratory paths, as it may occur at any location within the OA. From the perspective of foraging or nocturnal roost habitats, the OA doesn't overlap with these areas. However, during transfer operations and HLV mode change operation, artificial light from vessel operations could reach coastal areas where these habitats may be present. Implementation of controls described in Section 6.14.3 provides means to minimise the sky glow that may be generated from the vessel during night-time operations.
Do not install fixed light sources in nocturnal foraging or roost areas.	N/A	Not applicable to this activity.
Prevent mobile light sources shining into nocturnal foraging and roost habitat.	Yes	Implementation of controls described in Section 6.14.3 provides means to minimise the sky glow that may be generated from the vessel during night-time operations.
Maintain a natural barrier between nocturnal foraging and roost areas and sources of artificial light.	No	This action is practical for onshore installations/fixed facilities inland. From a vessel operations perspective, it is not feasible due to the mobile nature of the light source, the extension of the OA where transfer operations and HLV mode change operation may take place, and the additional potential impacts from modification or alteration of coastal areas to implement this control.
Maintain a dark zone between nocturnal foraging and roost habitats and sources of artificial light.	Partially	The OA doesn't overlap with rookeries or with shorebird coastal foraging habitats. However, during transfer operations and HLV mode change operation, artificial light from vessel operations could reach coastal areas where these habitats may be present. Implementation of controls described in Section 6.14.3 provides means to minimise the sky glow that may be generated from the vessel during night-time operations.

Management Option	Achievable?	Justification
Use curfews to manage lighting near nocturnal foraging and roosting areas in coastal habitats.	No	Operations are conducted 24 hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations
Use flashing/intermittent lights instead of fixed beam.	No	Operations are conducted 24 hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations
Use motion sensors to turn lights on only when needed.	No	Operations are conducted 24 hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations
Manage artificial light on jetties, wharves, marinas.	N/A	Not applicable to this activity.
Reduce deck lighting to the minimum required for human safety on vessels moored near nocturnal foraging and roost areas, and those operating offshore.	Yes	Lighting will be reduced to that required for safe operations and by maritime legislative requirements (see Section 6.14.3 of this EP).
Minimise night-time flaring on offshore oil and gas production facilities.	N/A	Not applicable to this activity.
Use luminaires with spectral content appropriate for the species present.	No	Campaign #1 vessel(s) are equipped with lighting required under legislation to identify itself to other vessels, reduce the risk of at-sea collision and provide for the safety of its crew.
Avoid high-intensity light of any colour.	No	Campaign #1 vessel(s) are equipped with lighting required under legislation to identify itself to other vessels, reduce the risk of at-sea collision and provide for the safety of its crew.
Prevent indoor lighting reaching migratory shorebird habitat.	Yes	Vessels will have blinds/curtains installed in cabins (see Section 6.14.3 of this EP).

Management Option	Achievable?	Justification
In facilities requiring intermittent night inspections, turn on lights only while operators are moving around the facility.	N/A	Operations are conducted 24 hours a day and light is necessary to ensure safety of the crew, the vessel and other users of the sea. Lighting will be reduced to the furthest extent possible for safe operations
Industrial site/plant operators use personal head torches.	N/A	Operations are conducted 24 hours a day and lighting of all areas is necessary to ensure safety of the crew, the vessel and other users of the sea. As such, open areas such as the deck and other exterior areas are lit by other means, and the use of head torches would be limited to enclosed or small spaces located in the interior areas of the vessel, where other means of artificial light can't meet the needs required for the specific task. Lighting will be reduced so far as is practicable and in accordance with maritime requirements and personnel safety
Supplement facility perimeter security lighting with computer-monitored infrared detection systems.	N/A	Not applicable to this activity.

6.14.3 Demonstration of As Low As Reasonably Practicable

Table 6-84 Decision Context and justification

Decision Context
Use of artificial lights is a standard practice for safe work operations and navigation for vessels. However, there is the potential for some uncertainty in relation to the level of impact from light spill on fledglings. The environmental consequence for the impacts resulting from light emissions have been assessed as **Consequence Level III** or **Consequence Level IV**. Stakeholder interest has been noted regarding light emissions as a result of removal activities. Activities are well practised, and there are no conflicts with Company values. Hence, Esso believes **Decision Context B** should apply.

Table 6-85 Good practice controls

Good practice	Adopted	Control	Rationale
National Light Pollution Guidelines for Wildlife (Commonwealth of Australia, 2023)	Adopted – IMP14-CM1	Application of the NLPGW.	Mitigation options relevant to the activities being undertaken have been adopted from the light management actions for seabirds and migratory shorebirds provided in the NLPGW. Specifically: • implement actions when birds are likely to be present in the area • reduce unnecessary lighting outdoor, deck lighting on all vessels in known seabird foraging areas at sea and shorebird foraging and roosting areas • prevent indoor lighting reaching outdoor environment • shielding and orienting the light source to reduce light spill • implementing a Seabird Management Plan to prevent seabird landings on the ship, manage birds appropriately and report the interaction • record bird strikes.

Table 6-86 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Do not undertake the activity.	Eliminates artificial light emitted from vessels.	Not feasible. General Direction 817 indicates Esso must complete all preparatory decommissioning activities and commence the topside dismantling campaign as soon as reasonably practicable, and no later than 30 September 2027, associated with facilities listed in Schedule 3 of the Direction.	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
Do not undertake the activity during night-time.	Eliminates artificial light emitted from vessels.	Not feasible. Decommissioning of platforms, including operations to transfer removed structures from the HLV or CSV onto barges or a HTV, is a complex operation. Vessel safety-critical activities may have a duration of several hours at each location. As such, operations may extend to night-time hours. Suspending lifting/loading/offloading operations of sections of platforms (e.g. topsides, jackets) will result in an unacceptable risk to the crew, vessels and other users of the sea. Artificial light is required to complete activities in a safe manner, thus cannot be eliminated.	Not adopted
Do not undertake vessel crew change activities during night-time.	Eliminates the need for artificial light from vessels and helicopters that would otherwise be required for the safe operation of personnel transfers to/from Campaign #1 vessels.	Vessel crew transfer to/from the vessels will be required during decommissioning operations. This activity can be planned in advance to take place within specific time periods of the day. Conducting crew change during daylight hours is preferred as it reduces the risks that are associated to night-time operations. Daylight vessel crew change operations will be implemented. Crew transfer between vessels and fixed facilities will occur as required to complete the work.	Adopted – (except when required due to an emergency event) – IMP14-CM2
Implement a dark zone between nocturnal foraging and roosting habitats	Reduce the probability of exposure of foraging and nesting/roosting birds to artificial lights	Nesting and roosting habitats associated with presence of fledglings are found at inland and island locations. Similarly, habitats associated with foraging areas for shorebirds include coastal habitats such as wetlands, rocky inlets, sandy beaches and estuaries, and inland habitats. These habitats are outside the OA. Under specific vessel operations settings during transfer operations and HLV mode change operation, artificial light could partially overlap with areas within these habitats. Vessels require the use of artificial lights for safe work operations and navigation. This ensures safety of crew, the vessel and other users of the sea. As a result, eliminating the use of artificial lights at night by the vessels is not feasible. Transfer operations of removed structures from the HLV onto barges or a HTV, and the HLV mode change operation are vessel safety-critical operations that are highly dependent on metocean conditions. These activities require a sheltered location, closer to the coastline, to	Partially adopted – IMP14-CM3

Control Measure	Benefit	Cost/feasibility	Adopted
		ensure operations are carried out in a safe manner. Sheltered waters provide more favourable weather conditions, significantly influencing in a positive manner the ability of the vessels to complete these operations while reducing potential risks to personnel, equipment and vessels. Operations within sheltered waters also reduce the potential risk of occurrence of unplanned events that could result in environmental impacts. Artificial lights from the HLV operations could have an impact on fledglings present in nesting and roosting habitats or in potential foraging coastal habitats for shorebirds. Implementation of a set of controls as described in this Table (i.e.: management of internal lights, orientation of lights, and avoiding presence of non-essential vessels during transfer operations or HLV mode change operation at night-time would effectively reduce the distance up to which the light glow generated during night-time vessel operations would reach, minimising the potential overlap with sensitive areas	
Limit external lighting to that required for safe works operations and navigation.	Reduces artificial light emitted from vessels. Parks Victoria suggested this mitigation measure during relevant person consultations for this EP.	During transit at night, vessels are required to use artificial lights for safe navigation. During vessel operations at night for decommissioning activities, in addition to lighting that is required for safe navigation, work areas such as the deck need to be lit to allow safe operations by the vessel crew. For crew works at night within the exterior areas of the vessel, light can be limited to the specific areas of the vessel where works are taking place.	Adopted – Subject to safety considerations - IMP14-CM4
For transfer operations and during the HLV mode change operation, limit presence of Campaign #1 support vessels in proximity to the HLV to only those required to complete these operations in a safe manner.	Reduces artificial light emitted from presence of vessels in the area.	Total artificial light emitted by Campaign #1 vessels can increase when vessels are located in proximity to each other. Transfer activities and HLV mode change operations require the presence of various support vessels nearby the HLV to complete these operations. During transfer activities and HLV mode change operations, limiting vessels present in the area to those strictly necessary for the safe execution of these activities will result in reduction of artificial light emitted.	Adopted – Subject to safety considerations - IMP14-CM5
Manage light spill from internal light sources.	Reduces light spill from internal vessel lights to the	Internal lights from accommodation cabins can reach the outdoor environment, adding to the overall light spill during vessel operations.	Adopted – IMP14-CM6

Control Measure	Benefit	Cost/feasibility	Adopted
	outdoor environment.	Installation of blinds and/or curtains in the accommodation windows of main vessels (HLV/CSVs) and their use at night-time when cabin lights are on is required to allow management of this light source. Benefit of this control outweighs the cost.	
Shielding and/or orienting of vessel light, where practicable	Reduces artificial light spill from vessels to the environment	Shielding or correct orientation of lights from vessels reduces the brightness and intensity of the light emitted to the environment. Similarly, preventing lights to emit light towards the horizon where possible, and instead, directing and concentrating them towards the specific work areas required to be lit, will reduce the potential skyglow effect produced by vessel lights. There are specific lighting requirements for work areas within the vessel and for safe navigation that must be observed to ensure safety of crew, the vessel and other users of the sea. Shielding and orientation of lights must consider and prioritise safe operation conditions for vessel crew.	Adopted – Subject to safety considerations – IMP14-CM7
Trained vessel crew on management of artificial lighting.	Allows for efficient use of artificial light within the vessel, reducing unnecessary light spill into the environment This measure also allows for implementation of the Seabird Management Plan.	Training of vessel crew provides them with the knowledge and competency to implement an efficient use of artificial light. It also allows for effective implementation of the Seabird Management Plan. Environmental training is a standard process within vessel operations. Additional resources are required to address specific topics such as artificial light and management/controls for operations within the Gippsland Basin, including sensitive receptors such as areas and marine fauna located nearby Wilsons Promontory and islands. However, additional cost associated to artificial light training is not significant. Benefit of training on the management of artificial lighting, including understanding of the Seabird Management Plan, outweighs the cost of implementation of this measure.	Adopted – IMP14-CM8
Seabird Management Plan.	Allows for prevention, mitigation and management of potential impact to birds, following an adaptative management approach.	Development and implementation of a Seabird Management Plan requires additional resources; however, they are considered to be low cost. A Seabird Management Plan provides a tool that clearly outlines the actions to be implemented during vessel operations, positively acknowledging and addressing presence of birds within the OA.	Adopted – IMP14-CM9

Control Measure	Benefit	Cost/feasibility	Adopted
		Benefit of development and implementation of a Seabird Management Plan outweighs the cost.	
Do not take safe harbour at sheltered waters in rough weather events that pose a risk to the safety of the vessel.	Prevents artificial light at sheltered waters from vessels taking refuge from rough weather.	During transit of the vessel and for decommissioning activities, the vessel relies on the DP system to maintain course/position. Metocean conditions influence the level at which the DP system is required to be used. During calm weather, it is expected the vessel will require less power to maintain course/position. On the contrary, during rough weather conditions, it is expected the power required by the vessel to maintain course/position will be higher. There are limits at which the vessel's DP system can operate. When vessel is in open water, it is likely to be more exposed to potential risks from rough weather conditions. Vessel Master must ensure the safety of the vessel and the crew on board. Seeking refuge in more sheltered waters during rough weather conditions is a safety-critical element, and prohibiting this measure would result in an unacceptable risk to vessel crew. This may also lead to potential unplanned events involving other users of the sea or negatively affecting the environment. This control measure is not feasible and would lead to disproportionate and unacceptable safety risks, and an increased risk of impact from unplanned releases into the marine environment.	Not adopted

A summary of the controls to be implemented and stage/vessel of Campaign #1 that is applicable to each one is shown in Table 6-87.

Table 6-87 Summary of ALARP controls for light emissions and application for Campaign #1

Control	Applies to:	
	Stage of project/activity (Lifting/transport/transfer/ mode change)	Vessel (HLV/CSVs/tugs/barges/HTVs/ supply vessels)
Application of the NLPGW.	All stages of Campaign #1.	All Campaign #1 vessels.
Do not undertake vessel crew change operations during night-time.	All stages of Campaign #1.	All Campaign #1 vessels.
Limit external lighting to that required for safe works operations and navigation.	All stages of Campaign #1.	All Campaign #1 vessels.

Control	Applies to:	
	Stage of project/activity (Lifting/transport/transfer/ mode change)	**Vessel (HLV/CSVs/tugs/barges/HTVs/ supply vessels)**
For transfer operations and during the HLV mode change operation, limit presence of Campaign #1 support vessels in proximity to the HLV to only those required to complete these operations in a safe manner.	Transfer operations. HLV mode change.	HLV CSVs Supply vessels.
Manage light spill from internal light sources.	All stages of Campaign #1.	HLV CSVs.
Shielding and/or orienting of vessel light, where practicable.	All stages of Campaign #1.	All Campaign #1 vessels.
Trained vessel crew on management of artificial lighting.	All stages of Campaign #1.	All Campaign #1 vessels.
Seabird Management Plan.	All stages of Campaign #1.	All Campaign #1 vessels.

6.14.4 Demonstration of acceptability

Table 6-88 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent The activities were evaluated as having the potential to result in a **Consequence Level III.** They are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present	✓	Not inconsistent.

Factor	Demonstration criteria	Criteria met	Rationale
	generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.		The impact assessment undertaken for planned light emissions has concluded that environmental impacts will be short term and localised in nature, with inconsequential effects from an ecosystemic and species population perspective. Hence any impacts resulting from light emissions will not impact the health, diversity and productivity of the environment such that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The potential impact associated with this aspect is limited to an intermittent, temporal impact in a small, localised area, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	Management actions for seabirds and migratory shorebirds contained in the NLPGW have been adopted where relevant. Light pollution is a recognised threat to a number of species of marine fauna. The proposed decommissioning activity is consistent with conservation and management actions contained in the following plans: • *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017). • NLPGW • *National Recovery Plan for Albatrosses and Petrels* (Commonwealth of Australia, 2022). • Wildlife Conservation Plan for Migratory Shorebirds (DoE, 2015b). • *Wildlife Conservation Plan for Seabirds* (DAWE, 2020b)

Factor	Demonstration criteria	Criteria met	Rationale
			• *Conservation Action Plan for Parks and Reserves Managed by Parks Victoria. Wilsons Promontory* (Parks Victoria, 2017)
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to light emissions, but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	Feedback provided by relevant persons in relation to light impacts has been considered.

6.14.5 EPOs, control measures, EPSs and measurement criteria

Table 6-89 EPOs, control measures, EPSs and measurement criteria – Light emissions

EPO	Control measure	EPS	Measurement criteria
IMP14-EPO1: No injury/ mortality, or significant change in behaviour of fauna, resulting from artificial light emissions from vessels operations during Campaign #1 activities.	IMP14-CM1: Application of the NLPGW.	IMP14-EPS1.1: Implementation of light emissions management measures that are consistent with advice from the NLPGW.	IMP14-MC1.1.1: Evidence of measures implemented and consistency with the NLPGW.
	IMP14-CM2: Do not undertake vessel crew change activities during night-time (except when required in the event of an emergency).	IMP14-EPS2.1: Vessel crew change is only conducted during daytime hours.	IMP14-MC2.1.1: Evidence of crew change operations: • helicopter schedule (planned versus executed) for crew change operations • vessel records for crew change operations (planned versus executed).
	IMP14-CM3: Implement a dark zone between nocturnal foraging and roosting habitats (when operationally feasible, by means of reducing number of vessels during SIMOPS, or increasing the distance to these habitats when safe to do so).	IMP14-EPS3.1: Only essential support vessels for transfer or HLV mode change operations may approach the HLV during night-time.	IMP14-MC3.1.1: Planning records (i.e.: SIMOPS plan) for transfer and HLV mode change operations, with description of vessels required to complete these operations.
	IMP14-CM4: Limit external lighting to that required for safe works operations and navigation.	IMP14-EPS4.1: Vessel crew change is only conducted during daytime hours (except when required in the event of an emergency).	IMP14-MC4.1.1: Evidence of crew change operations: • helicopter schedule (planned versus executed) for crew change operations • vessel records for crew change operations (planned versus executed).
		IMP14-EPS4.2: Only essential support vessels for transfer or HLV mode change operations may	IMP14-MC4.2.1: Planning records (i.e.: SIMOPS plan) for transfer and HLV mode change operations, with

EPO	Control measure	EPS	Measurement criteria
		approach the HLV during night-time.	description of vessels required to complete these operations.
		IMP14-EPS4.3: Lights are oriented towards the work areas.	IMP14-MC4.3.1: Records of lighting inspections.
	IMP14-CM5: For transfer operations and during the HLV mode change operation, limit presence of Campaign #1 support vessels in proximity to the HLV to only those required to complete these operations in a safe manner.	IMP14-EPS5.1: Only essential support vessels for transfer or HLV mode change operations may approach the HLV during night-time.	IMP14-MC5.1.1: Planning records (i.e.: SIMOPS plan) for transfer and HLV mode change operations, with description of vessels required to complete these operations.
	IMP14-CM6: Manage light spill from internal light sources.	IMP14-EPS6.1: Blinds/curtains are installed in the HLV and CSVs, and are used during night-time operations when the cabin light is on.	IMP14-MC6.1.1: Evidence of blinds installed/available at each cabin. IMP14-MC6.1.2: Training/induction records of all vessel crew that includes awareness of the requirement to have cabin blinds closed at night time.
	IMP14-CM7: Shielding and/or orienting of vessel light, where practicable (subject to safety considerations).	IMP14-EPS7.1: Lights are oriented towards the work areas.	IMP14-MC7.1.1: Records of lighting inspections.
	IMP14-CM8: Trained vessel crew on management of artificial lighting.	IMP14-EPS8.1: All vessel crew is trained on management of light emissions.	IMP14-MC8.1.1: Training records of vessel crew members on management of light emissions, inclusive of awareness of the Seabird Management Plan.
		IMP14-EPS8.2: Relevant vessel crew is trained on the Seabird Management Plan.	IMP14-MC8.2.1: Roles and responsibilities as described in the Allseas EMP and related vessel subcontractors appropriate management plan. IMP14-MC8.2.2: Training records of relevant vessel crew members on the Seabird Management Plan.

EPO	Control measure	EPS	Measurement criteria
			IMP14-MC8.2.3: Reports on implementation of the Seabird Management Plan.
	IMP14-CM9: Seabird Management Plan.	IMP14-EPS9.1: Development and implementation of a Seabird Management Plan.	IMP14-MC9.1.1: Seabird Management Plan IMP14-MC9.1.2: Evidence of implementation of actions established in the Seabird Management Plan.

6.14.6 Residual consequence assessment

With the above controls in place, the residual potential consequence has been determined as:

- **Consequence Level III**.

6.15 Emissions to air

6.15.1 Sources of emissions to air

The use of fuel used by Campaign #1 vessels to power engines, generators and mobile and fixed plant, as well as the use of helicopters to transfer personnel to and from Campaign #1 vessels during decommissioning operations will result in gaseous emissions of GHG pollutants such as carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O), and non-GHG emissions such as sulphur oxides (SO_X) and nitrous oxides (NO_X).

In this Section, GHG emissions are described and assessed considering the *Greenhouse Gas Protocol: A Corporate Accounting and Reporting Standard* (WRI & WBCSD, 2004), the National Greenhouse Energy Reporting (Measurement) Determination 2008 (Cth), and the Australian National Greenhouse Accounts Factor (DCCEEW, 2023c). In addition, GHG emissions have been separated into direct emissions and indirect emissions, aligned with the definitions of the *GHG Protocol Scope 2 Guidance: An amendment to the GHG Protocol Corporate Standard* (World Resources Institute, 2015) and National Greenhouse and Energy Reporting Scheme (Clean Energy Regulator, 2025). GHG emissions are measured in tonnes of CO_2-equivalent (tCO_2-e), which accounts for the global warming potential of all the non-CO_2 GHGs.

For the purposes of this activity, the following applies:

- Direct emissions – Emissions associated with the offshore activity within the OA, specifically emissions associated to the operation of vessels (i.e. combustion of MGO from the vessel engines, generators and fixed and mobile deck equipment during the activity). Since the vessels for decommissioning activities are operated by Allseas (vessel contractor), these emissions will be reported by Allseas rather than Esso.
- Indirect emissions – Emissions associated with additional support operations within the OA such as combustion of aviation fuel used by the helicopters to transfer personnel between shore and Campaign #1 vessels where required. Additional emissions that have been classified as indirect emissions are those from vessel operations that, although not directly related to the lifting and removal of facilities in Commonwealth waters to be conducted by HLV and CSVs, will be required to support the satisfactory completion of Campaign #1. These indirect emissions cover emissions from vessel operations, specifically tugs/barges or the HTV, that are dedicated to transporting removed structures from the transfer location(s) to the Barry Beach Marine Terminal.

The transit of tugs/barges or the HTV within State waters to transport decommissioned infrastructure from the OA to Barry Beach Marine Terminal is not covered under the scope of this EP. However, for the assessment of indirect impacts associated with air emissions these are described in this Section for information.

Approximate fuel combustion from vessels during Campaign #1 activities is shown in Table 6-90.

Table 6-90 Sources of GHG and other air emissions from the activity

Activity	Emission Type	Estimated fuel use rate	Estimated duration of source of emissions	Estimated total volume of fuel to be used
Vessel operations at platforms	Direct	116.10t/d	*Pioneering Spirit*: 122 days Primary CSV (*Fortitude* or similar): 309 days Additional support CSV: 54 days	15,407t
Vessels in transit between locations within the OA	Direct	313.90t/d	*Pioneering Spirit:* 22 days Primary CSV (*Fortitude* or similar): 54 days Additional support CSV: 9 days	5,691t
Helicopter operations for vessel support (HLV and CSVs)	Indirect	0.308km/L	88 round trips - approximately 560km per round trip	148,571L
As left survey	Direct	12.90t/d	2 days	25.80t
Indirect transport of structures to Barry Beach Marine Terminal	Indirect	6.02t/d (per tug during working trips), and 8.60t/d (per tug in-between trips)	6 tugs. Estimated number of days per tug are as follows: - Working/during trips: 104 days - In between trips: 40 days	5,820t

6.15.2 Impacts of atmospheric emissions

Impacts of air emissions from Campaign #1 activities are:

- change in air quality
- contribution to the global GHG effect.

6.15.2.1 Change in air quality

Vessel operations during Campaign #1 will emit combustion gases to the atmosphere that could result in a change of air quality. Emissions and volumes generated will be influenced by factors such as type of fuel used during the operations, efficiency and maintenance of systems/equipment that emits combustion gases, length of the activity and the number of vessels involved in the operations. Fuel to be used by the main vessels is MGO. For lifting operations and transit to/from transfer locations, the *Pioneering Spirit* and the primary CSV will be operating mostly as stand-alone vessels; however, based on operational conditions, these two vessels may operate simultaneously during lifting works at KFA and KFB. In addition, it is expected the *Pioneering Spirit* will be working nearby other vessels during lifting system mode change activities and during transfer of loads from the *Pioneering Spirit* onto barges or heavy transport vessels.

Fuel usage from the *Pioneering Spirit* while holding position is expected to be one third of the usage required when the vessel is transiting from one location to the next. As a result, it is expected that air emissions while the vessel is at a fixed location will be significantly lower than those when vessel is moving between locations. This

results in a reduced exposure to air pollutants at a single location, reducing the potential for impacts to air quality in the immediate vicinity of platforms or transfer locations.

Given the nature of the activities to be undertaken during Campaign #1 activities, operations of helicopters to transport personnel to/from vessels, and the operation of vessels between transfer location(s) and Barry Beach Marine Terminal are limited to the following:

- 88 helicopter round trips are estimated for the duration of decommissioning activities to support HLV and CSV operations. These trips will be intermittent and only as required
- for the purposes of emission estimation, the total number of vessel movements required to transport removed infrastructure from the OA to the Barry Beach Marine Terminal was estimated to be approximately 26 trips (based on the option of using tugs and barges to complete this operation). From a human health impact perspective, emissions to air are temporary and will not occur in the vicinity of established communities. The closest facility to shore that forms part of decommissioning activities is DPA, located 21km from shore. No impacts to human health are expected from air emissions during vessel operations for Campaign #1.

Potential receptors above the sea surface that may be exposed to reduced air quality include seabirds and marine fauna that surface for air (e.g. cetaceans). Locations where emissions to air will occur are likely to overlap with foraging BIA for the PBW and birds such as albatrosses, the short-tailed shearwater and the common diving petrel, as well as within the migration and reproduction BIAs for the SRW.

Due to the mobile nature of the emission sources and the planned timeframe in which decommissioning activities will be completed, potential air emissions are anticipated to be temporary, of a dispersive nature, and will quickly dissipate. The potential for any exposure to reduced air quality is not expected to affect the health of marine fauna. Indirect air emissions from removal activities, such as those generated from the operation of helicopters for vessel crew transfer during Campaign #1 activities, or the operation of vessels associated with the transport of removed facilities from the transfer location(s) to Barry Beach Marine Terminal will be intermittent, of short duration and will not be concentrated at a single location, thus reducing the concentration of emissions that are emitted within a specific area. As a result, air emissions are assessed as having inconsequential effects on air quality.

6.15.2.2 Cumulative impacts

From a cumulative effects perspective, platforms at which vessels will be operating for removal activities will be de-staffed and non-operational. As a result, there will be no air emission sources at or nearby platforms other than those associated with vessel operations for decommissioning activities. Simultaneous vessel operations during decommissioning activities are limited and may only occur when conducting lifting operations for isolated removal activities at KFA and KFB, as well as during transfer operations and during *Pioneering Spirit* lifting system mode change operations. In addition, there is a 500m PSZ radius established for vessel operations during decommissioning activities. It is unlikely that vessels that are not related to Campaign #1 will be in close vicinity to areas where Campaign #1 vessels will be operating. As such, no cumulative impacts to air quality are expected from decommissioning activities.

Based on this analysis, potential impacts to air quality will be short-term, temporary and with inconsequential effect. Therefore, the impact is assessed as:

- **Consequence Level IV**.

6.15.2.3 Contribution to the global GHG effect

GHG emissions from Campaign #1 activities have been estimated using the Australian National Greenhouse Accounts Factor (DCCEEW, 2023c). Estimated emissions are presented in Table 6-91.

Table 6-91 Predicted GHG emissions from the activity

Source	Emission type	Estimated volume to be used	Estimated duration of source of emissions	Estimated total emissions (tCO_2-e)
Vessel operations at platforms	Direct	116.10t/d	*Pioneering Spirit*: 122 days	66,622

Source	Emission type	Estimated volume to be used	Estimated duration of source of emissions	Estimated total emissions (tCO_2-e)
			Primary CSV (e.g. *Fortitude*): 309 days Additional support CSV: 54 days	
Vessels in transit between locations within the OA	Direct	313.90t/d	*Pioneering Spirit:* 22 days Primary CSV (e.g. *Fortitude*): 54 days Additional support CSV: 9 days	24,607
Helicopter operations for vessel support (HLV and CSVs)	Indirect	0.308km/l	88 round trips - approximately 560km per round trip	480
As left survey	Direct	12.90t/d	2 days	112
Transfer of structures into Barry Beach Marine Terminal	Indirect	6.02t/d (per tug during trips), and 8.60t/d (per tug in-between trips)	6 tugs. Number of days per tug are as follows: - Working days: 104 - Idle/slow transit: 40	25,169

In total, it is estimated that 116,991t CO_2-e of direct GHG emissions will be generated from decommissioning activities, which represents approximately 7% of ExxonMobil's Australian total direct emissions, based on data for the 2022-2023 financial year.

DEECA (DEECA, 2023b) informs that net GHG emissions for the State were 84.7Mt CO_2-e. In this context, the estimated direct GHG emissions to be generated by decommissioning activities would contribute the equivalent of 0.11% of Victoria's 2022 emissions.

Indirect emission sources from decommissioning activities are estimated to be 25,649t CO_2-e and include helicopter operations for movement of personnel to and from vessels, and the transport of removed facilities from the OA to Barry Beach Marine Terminal. When compared to the state emissions reported for 2022, indirect emissions associated to decommissioning activities would contribute the equivalent of 0.03% of Victoria's 2022 emissions.

In total, direct and indirect emissions estimated from decommissioning activities would represent the 0.14% of Victoria's emissions as reported for 2022.

While these emissions add to the GHG load in the atmosphere, which adds to global warming effect, they are small on a State, national and global scale. In addition, these emissions will be temporary and limited to the duration of decommissioning activities. These emissions will cease when vessel operations associated with Campaign #1 are completed.

The general vessel operation activity for decommissioning activities is similar to vessel operations for other industrial or commercial activities contributing to the accumulation of GHG in the atmosphere. Furthermore, indirect emissions are estimated to account for less than a quarter of the overall emissions from the decommissioning activities and are assessed as not presenting a significant potential for impact to air quality in the area. Therefore, **Consequence Level IV** has been assessed for impacts from air emissions during development of Campaign #1 operations.

6.15.3 Demonstration of As Low As Reasonably Practicable

Table 6-92 Decision Context and justification

Decision Context
Emissions to air from fuel combustion generated by Campaign #1 vessels during decommissioning activities is a common occurrence both nationally and internationally. Managing the impacts from emissions to air is well understood with good practice controls that are well implemented by the industry and emissions will dissipate rapidly. The environmental consequence for the impacts resulting from air emissions have been assessed as **Consequence Level IV**. No objections or claims were raised by relevant persons with regard to emissions to air. Esso believes **Decision Context A** should apply.

Table 6-93 Good practice controls

Good practice	Adopted	Control	Rationale
MARPOL Annex VI Regulations for the Prevention of Air Pollution from Ships.	Adopted – IMP15-CM1	Comply with MARPOL Annex VI.	The vast majority of commercial ships are built to and surveyed for compliance with the standards laid down by classification societies. The role of vessel classification and classification societies has been recognised by the IMO across many critical areas including the SOLAS, the 1988 Protocol to the International Convention on Load Lines and MARPOL. A vessel built in accordance with the applicable Rules of an IACS member society may be assigned a class designation relevant to the IMO Rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex VI entered into force in 2005, and it aims to limit the harmful effects of air pollution and GHG emissions from international shipping on human health and the environment. Specifically, this Annex requires vessels (as appropriate to class) hold an International Air Pollution Prevention certificate for each diesel engine of >130kW; vessel engine nitrous oxides (NO_x) emission levels comply with Regulation 13; sulphur content of any fuel oil used on board is <0.5%; and ongoing maintenance of engines, generators and deck equipment to ensure efficient operation. It sets limits to sulphur oxides (SO_x) and NO_x emissions from ship exhausts and prohibits deliberate emissions of ozone depleting substances; designated emission controls areas set more

Good practice	Adopted	Control	Rationale
			stringent standards for SO_x, NO_x and particulate matter. An additional chapter adopted in 2011 covers mandatory technical and operational energy efficiency measures aimed at reducing GHG emissions from ships (MARPOL).
Preventative maintenance	Adopted – IMP15-CM2	Preventative maintenance program	Development and implementation of a preventative maintenance program ensures condition of plant and equipment within the vessel is adequate and that equipment operates efficiently, reducing emissions of air pollutants from combustion processes.

Table 6-94 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
None identified	N/A	N/A	N/A

6.15.4 Demonstration of acceptability

Table 6-95 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV** thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The impact assessment undertaken for planned air emissions has concluded that environmental impacts will be short term and localised in nature, with inconsequential effects from an ecosystemic and species population perspective. Hence any impacts resulting from discharges to air will not impact the health, diversity and productivity of the environment such

Factor	Demonstration criteria	Criteria met	Rationale
			that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short term impact, which is not considered as having the potential to affect biological diversity and ecological integrity
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The requirements of MARPOL Annex VI have been adopted. The following legislative and other requirements are considered relevant as they apply to the implementation of MARPOL in Australia: • *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Cth) • *Navigation Act 2012* (Cth) – Chapter 4 (Prevention of Pollution) • Marine Order 97 (Marine pollution prevention – air pollution) 2022.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Impact assessment process and controls proposed meet the strategic objectives of the business and the Environmental policy.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements

Factor	Demonstration criteria	Criteria met	Rationale
			• OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Relevant person concerns have been considered/addressed through the consultation process.	✓	No relevant person concerns have been raised concerning emissions to air.

6.15.5 EPOs, control measures, EPSs and measurement criteria

Table 6-96 EPOs, control measures, EPSs and measurement criteria – Emissions to air

EPO	Control measure	EPS	Measurement criteria
IMP15-EPO1: Impacts from air emissions during Campaign #1 activities are limited to localised, short term effects in the immediate area of operations.	IMP15-CM1: Comply with MARPOL Annex VI.	IMP15-EPS1.1: Campaign #1 vessels are compliant with MARPOL Annex VI.	IMP15-MC1.1.1: Vessel International Air Pollution Prevention certificate. IMP15-MC1.1.2: Vessel International Energy Efficiency certificate. IMP15-MC1.1.3: Vessel statement of compliance for fuel consumption.
	IMP15-CM2: Preventative maintenance program.	IMP15-EPS2.1: All vessels taking part in Campaign #1 operations will have a maintenance program in place that includes plant and equipment that generates emissions to air. The maintenance program is executed as per planned schedule.	IMP15-MC2.1.1: Maintenance program in place for key air emission-generating equipment (i.e. generators). IMP15-MC2.1.2: Records of maintenance completed for key air emission-generating equipment (i.e. generators).

6.15.6 Residual consequence assessment

With the above controls in place, the residual potential consequence has been determined as*:*

- **Consequence Level IV**.

6.16 Waste generation and management

6.16.1 Sources of waste

The decommissioning campaign will generate waste from a variety of sources such as:

- vessel operations (e.g. used personal protective equipment and other consumables)
- removed platform topsides and jacket structures, inclusive of any residual equipment or materials that are present within these structures.

6.16.1.1 Vessel operations

Campaign #1 vessels will generate a variety of wastes, including domestic and industrial wastes. Waste streams that will be generated as part of routine vessel operations include (but are not limited to):

- lubricating oils, hydraulic fluids, cleaning and solvents
- oil filters and batteries
- oily rags
- paint, aerosol cans
- medical wastes
- food waste
- packaging– paper, cardboard, bottles, cans etc.

Vessel waste management procedures will be in place to address the following topics:

- compliance requirements
- waste identification and classification
- waste registration and reporting
- waste storage and segregation
- signage, labelling and placarding
- waste inspections
- waste handling
- waste transportation and tracking
- communication and training.
- incident reporting.

6.16.1.2 Removed topsides and jackets

Waste streams that will be generated by the dismantling operations of the removed topsides and jackets as part of Campaign #1 activities sections include (but are not limited to):

- steel
- grout/cement
- residuals (e.g. hydrocarbons) remaining in the integrated storage tanks within some SPJs
- marine growth
- topsides plant and equipment and associated residuals (e.g. hydrocarbons)
- construction materials (e.g. living quarters).

The estimated weights of materials and general waste material categories contained within the structures to be removed from the title areas, as part of the Campaign #1 activities, and transported onshore for dismantling and offsite recycling or disposal are presented in Table 6-97 and Table 6-98 respectively. The estimates presented are upper end of range estimates derived using a range of sources, including:

- weight control reports
- review of existing documentation
- bench marking of similar aged facilities
- facility site inspections
- targeted intrusive sampling.

The material inventories have been developed to a level of accuracy sufficient for works planning purposes.

Table 6-97 Type and estimated weight of waste material contained within the topside structure

6.16.1.3 Approach to waste management

This EP considers direct and indirect impacts from activities conducted within Commonwealth waters (including off-title areas) across the OA as described in Section 3.1.

Esso is committed to applying waste hierarchy principles to the management of decommissioning waste to maximise beneficial re-use/recycling of materials and minimise the amount of waste requiring disposal to landfill to the extent practicable.

All wastes generated during Campaign #1, will be handled and disposed of in accordance with waste management plans to be prepared by either Allseas or the onshore dismantling contractor as applicable.

All waste streams will be managed in accordance with applicable regulatory requirements and in accordance with international guidance where applicable, including but not limited to:

- *Hazardous Waste (Regulation of Exports and Imports) Act 1989* (Cth) which implements the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal, 1989
- *Environment Protection Act 2017* (Vic)
- Environment Protection Regulations 2021 (Vic)
- Environment Protection Authority licensing requirements for the receipt of the removed structures and dismantling operations at the ORC at the Barry Beach Marine Terminal

- MARPOL.

Esso has contracted experienced contractors for the decommissioning of the Campaign #1 structures. Selection of these contractors was managed through Esso's contracting process which confirms contractors have experience in the handling and disposal of relevant waste streams as appropriate to their respective scopes of work. Esso will also ensure contractors have necessary licences and permits to ensure the waste handling, management and offsite disposal is undertaken in accordance with applicable regulatory requirements.

6.16.1.4 Onshore Reception Centre for receipt of removed structures and dismantling operations

It is noted that on shore receipt of the removed structures and dismantling operations is outside the OA and not a petroleum activity for the purpose of this EP.

For information, it is intended that the removed structures will be transferred to the ORC at Barry Beach Marine Terminal for temporary storage and management prior to dismantling operations and subsequent off-site recycling or disposal of the waste materials. The Barry Beach Marine Terminal is an industrial facility that has been used as the main supply depot to support Esso's Bass Strait operations for over 50 years. Each year it facilitates the warehousing and transport of thousands of tonnes of food, supplies, fuel, equipment and waste (including reportable priority waste materials) to and from Esso's offshore installations.

The Barry Beach Marine Terminal has an existing site Victorian Environment Protection Authority operating licence (Permission ID: OL000010294) that allows for reportable priority waste management and bulk storage as part of Esso's ongoing operations. Esso will be working with the Victorian Environment Protection Authority on the relevant licensing requirements for the receipt of the removed structures and subsequent dismantling operations.

Indirect decommissioning related activities outside Commonwealth waters will occur in three stages, each subject to a referral to DCCEEW under the EPBC Act. The stages are:

- Stage 1 – ORC early works.
- Stage 2 – Transportation and offloading operations.
- Stage 3 – Dismantling operations.

The Stage 1 referral for establishment of the ORC was submitted to DCCEEW in April 2025 and the referral decision made was not a controlled action. Esso is currently preparing the EPBC Act referral for the transportation and offloading operations (Stage 2) and it is anticipated for submittal in fourth quarter 2025/first quarter 2026.

General and hazardous wastes derived from vessel operations (as described in Section 6.16.1.1) will be managed separately by the vessel operator to ensure materials are appropriately segregated, stored on board in suitable containers and labelled appropriately for transport back to shore for recycling/disposal in accordance with local regulations and the Allseas Waste Management Plan. Transfer will be via smaller supply vessels consistent with existing operations.

6.16.1.5 Waste segregation and disposal

Vessel operations will generate relatively small quantities of waste. Vessel waste will be classified, segregated and stored securely on-board to ensure appropriate handling and disposal of any hazardous, non-hazardous and recyclable materials. Hazardous wastes generated by vessels will be classified and managed in accordance with Allseas waste management procedures and local regulatory requirements. This will include ensuring hazardous materials are disposed of by suitably licenced contractors to appropriately licenced waste facilities.

The majority of the Campaign #1 waste will be steel material which will be derived from the dismantling of the topsides and jacket substructures. Current estimates anticipate that the majority (>95%) of the total mass of materials contained within the structures removed from the title areas during Campaign #1 activities will be able to be recycled.

As part of removals preparation activities, the status of structures prior to decommissioning will be documented in a hazardous materials register for each facility. This register will be used to support identification of residual hazardous materials for Campaign #1 works planning and execution. A small percentage of the total Campaign #1 materials are considered hazardous waste (classified as 'reportable priority waste' under the *Environment Protection Act 2017* (Vic) waste classification). The hazardous material is mostly asbestos and is mostly contained within materials used in the living quarters construction. Very small quantities of other hazardous materials, such as post cleaning residues of hydrocarbons, NORM or mercury may be present within limited locations within some topsides processing plant, equipment and inside the piping associated with some of the structures. Trace NORM

and mercury residues are contained in the form of internal scale. These residues are not mobile and are not considered to pose a hazard during transit or storage. Similarly, the potential presence of NORM scale in sections of pipelines that are cut and removed as part of the Campaign1 project is deemed negligible, as these sections are estimated to be short in length, up to 5m from the jackets.

All hazardous waste generated during the onshore dismantling operations will be classified, segregated, documented, stored appropriately in suitable containers and labelled prior to offsite transportation to a licensed waste facility for waste treatment/disposal. Recyclable hazardous wastes, such as oils, batteries and electrical equipment will also be segregated from non-recyclable materials for appropriate offsite waste recycling or disposal. All hazardous wastes will be disposed of onshore at a licensed facility in accordance with the onshore dismantling contractor's waste management plan and applicable regulations.

Disposal options for non-metallic recyclable or energy recovery suitable wastes, such as plastic, will be assessed based on the economics and practicality of offsite processing including any acceptance requirements of the waste facilities available in the marketplace at the time. It is noted that this a developing market and options available at the time of writing this EP may differ materially from what might be available in and from 2028.

Some of the marine growth attached to the jacket structures will be discharged to sea in as discussed in Section 6.11.7. Marine growth that remains on the structures when loaded onto shore will be managed and disposed of in accordance with the dismantling contractor's waste management plan.

Indicative waste disposal approaches are indicated in Table 6-99. Waste disposal options are subject to inspection and sampling of the segregated waste material following onshore dismantling operations as well as consideration of waste disposal facilities available at the time, economics and logistics. The onshore dismantling contractor will apply the waste management hierarchy principles in deciding the adopted waste disposal approach for each waste stream generated during dismantling operations.

Where it is deemed that no practicable alternative waste disposal approach exists, material requiring landfill will be disposed of at an appropriate facility.

Table 6-99 Indicative waste disposal approach

Materials	Combined topsides and jackets – maximum estimated total mass (MT)	Indicative disposal approach
Steel (all types)	56,250	Recycle where practicable
Other metals (aluminium, copper, etc.)	426	Recycle where practicable
Grout/concrete	1244	Recycle where practicable, potential landfill
Cemented iron ore	2838	Recycle where practicable, potential landfill
Anodes	528	Recycle where practicable
Reusable equipment	1081	Re-use where practicable, potential recycle or landfill
Marine growth	1626	Compost where practicable, potential landfill
Plastics/nylon/rubber	33	Recycle or waste to energy where practicable, potential landfill
Wood	187	Recycle, waste to energy, potential landfill

Materials	Combined topsides and jackets – maximum estimated total mass (MT)	Indicative disposal approach
Insulation materials (Non asbestos)	160	Dispose to landfill
Non-hazardous construction materials/general waste	555	Dispose to landfill
Hazardous waste (including asbestos)	402	Dispose (including treatment as necessary) via licenced hazardous waste facilities
Batteries	36	Recycle
Electrical equipment	482	e-waste facility
Total	65,849	

It is anticipated that the vast majority of materials (including the steel to be recycled) will be able to be received by facilities within Victoria, thus minimising travel distances. The volumes of materials estimated are typical of other large scale industrial decommissioning projects.

Steel generated from the dismantling of the structures will be cut down to sizes able to be transported from Barry Beach Marine Terminal in conventional truck haulage as well as to sizes acceptable to be received at steel recycling facilities. It is estimated that the dismantling of the structures and transportation of the waste material for offsite recycling or disposal will take approximately two to three years to complete. All waste requiring transport by road from Barry Beach Marine Terminal will be carried in appropriately licenced vehicles in accordance with the dismantling contractor's waste management plan. Waste materials will be tracked from its point of generation offshore to shore and then to the final disposal facility by the respective waste handling contractors using the contractors waste tracking systems and procedures. Heavy vehicles will adhere to approved transport routes between Barry Beach Marine Terminal and receiving facilities.

6.16.2 Impact assessment

The generation of waste associated with Campaign #1 will contribute waste to landfills and requires management to ensure handling and disposal is in accordance with regulatory requirements to minimise impacts to environmental receptors. The generation and management of waste is considered to have an impact assessed as:

- **Consequence Level IV**.

This is because:

- the nature of the materials and activity is well understood and industry practice is well established and required management practices are well understood
- the majority of waste material is expected to be able to be recycled, minimising the potential impacts to landfill.

6.16.3 Demonstration of As Low As Reasonably Practicable

Table 6-100 Decision Context and justification

Decision Context
The potential impacts associated with waste generation and management are well understood and able to be managed effectively in accordance with regulatory requirements. Waste management controls are understood and well implemented by the industry, however the generation and management of waste

Decision Context
resulting from the removal of large offshore structures is a non-standard activity undertaken in the Bass Strait area. The environmental consequence for the impacts resulting from light emissions have been assessed as **Consequence Level IV**. Stakeholder interest has been noted regarding light emissions as a result of removal activities. Stakeholders have expressed interest in waste management. Concerns raised during relevant persons consultations have been considered/addressed. Hence, Esso believes **Decision Context B** should apply.

Table 6-101 Good practice controls

Good practice	Adopted	Control Measure	Rationale
MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships.	Adopted – IMP16-CM1	Compliance with MARPOL Annex V and associated Marine Order 96 (Marine pollution prevention — sewage) 2018 and Marine Order 95 (Marine pollution prevention — garbage) 2018 (as appropriate to vessel class).	MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships specifically requires that food waste is macerated or ground to particle size <25mm. Macerated food waste may be discharged no less than 3nm from shore and unmacerated food waste no less than 12nm (and not within the PSZ of fixed platforms) whilst enroute. Adoption of this control is routine for vessel operations and reduces the probability of unacceptable garbage being discharged to sea. Control is feasible, standard practice with minimal cost.
Waste disposal activities will comply with relevant legislation.	Adopted – IMP16-CM2	Waste practices will comply with relevant provisions of applicable international, State and Commonwealth legislation.	Compliance with legislation is feasible, standard industry practice.
Waste will be managed in accordance with the contractor's waste management plan.	Adopted – IMP16-CM2	The removals and onshore dismantling contractors will each develop a waste management plan which considers the waste materials they are responsible for. The plan will include consideration of waste hierarchy principles and include details on the appropriate segregation, temporary storage, transfer or disposal of wastes. The plan will also note applicable regulatory	The development of waste management plans is considered feasible, standard industry practice.

Good practice	Adopted	Control Measure	Rationale
		requirements, tracking and reporting obligations.	

Table 6-102 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Re-use/re-purpose platform structures.	Resource efficiency.	Opportunities to re-use or re-purpose the platform jackets and topsides for other projects or purposes was explored. No viable proposals were identified within the required timeframe for decommissioning decision making.	Not adopted
Abandon structures in situ.	No onshore processing or landfill disposal.	Removal of the structures included in the Campaign #1 scope provides greater benefit (through safe navigation) to other users of the sea on balance.	Not adopted

6.16.4 Demonstration of acceptability

Table 6-103 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations. The waste management hierarchy for decommissioning prioritises recycling over disposal.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The aspect was evaluated as having the potential to result in a **Consequence Level IV** impact thus is not considered as having the potential to result in serious or irreversible environmental damage
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or	✓	Not inconsistent. The impact assessment undertaken for planned waste generation and management has concluded that environmental impacts will be short term and localised in nature, with

Factor	Demonstration criteria	Criteria met	Rationale
	enhanced for the benefit of future generations.		inconsequential effects from an ecosystemic and species population perspective. Hence any impacts resulting from planned waste generation and management will not impact the health, diversity and productivity of the environment such that future generations will be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	✓	Not inconsistent. The potential environmental impact associated with this aspect is limited to a localised short term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	All waste streams will be managed and disposed of in accordance with applicable regulatory requirements and in accordance with international guidance where applicable, including but not limited to: • *Hazardous Waste (Regulation of Exports and Imports) Act 1989* (Cth) which implements the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal, 1989 • *Environment Protection Act 2017* (Vic) • Environment Protection Regulations 2021 (Vic) • MARPOL.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Impact assessment process and controls proposed meet the strategic objectives of the business and the Environmental policy.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management

Factor	Demonstration criteria	Criteria met	Rationale
			objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Relevant persons concerns have been considered and addressed.

6.16.5 EPOs, control measures, EPSs and measurement criteria

Table 6-104 EPOs, control measures, EPSs and measurement criteria – Waste generation and management

EPO	Control measure	EPS	Measurement criteria
IMP16-EPO1: Impacts as a result of waste from vessels are limited to localised, temporary changes in water and habitat quality.	IMP16-CM1: Compliance with MARPOL Annex V and associated Marine Order 96 (Marine pollution prevention — sewage) and Marine Order 95 (Marine pollution prevention — garbage) (as appropriate to vessel class).	IMP16-EPS1.1: Campaign #1 vessels are compliant with MARPOL Annex V and associated Marine Order 95 (Marine pollution prevention — garbage) requirements as appropriate to vessel class.	IMP16-MC1.1.1: Vessel maintains a Garbage Record Book IMP16-MC1.1.2: Garbage Management Plan current and implemented. IMP16-MC1.1.3: Preventative maintenance system records demonstrate macerator/s are maintained as required.
IMP16-EPO2: Campaign #1 waste is managed in compliance with regulatory requirements.	IMP16-CM2: Waste practices will comply with relevant provisions of applicable international, State and Commonwealth legislation.	IMP16-EPS2.1: All waste streams will be managed and disposed of in accordance with applicable regulatory requirements, including but not limited to: • *Environment Protection Act 2017* (Vic)	IMP16-MC2.1.1: Waste management plan documentation. IMP16-MC2.1.2: Vessel waste disposal records demonstrate disposal of waste was compliant with relevant

EPO	Control measure	EPS	Measurement criteria
		• *Environment Protection Regulations* 2021 (Vic).	Commonwealth and State legislation.
IMP16-EPO3: Campaign #1 waste to landfill is minimised.	IMP16-CM3: Removals and onshore dismantling contractors waste management plans.	IMP16-EPS3.1: The development of waste management plans will include consideration of the waste hierarchy principles to minimise disposal of waste to landfill where practicable.	IMP16-MC3.1.1: Waste management plan documentation.

6.16.6 Residual Consequence assessment

With the above controls in place, the residual potential consequence has been determined as:

- **Consequence Level IV**.

7 Environmental risk assessment

This Section describes the outcome of the environmental risk assessment of unplanned events associated with activities described in this EP. Environmental impacts associated with planned activities are covered in Section 6.

The purpose of the risk assessment is to ensure that all risks associated with the activity are identified and evaluated, and the resulting risks are demonstrated to be reduced to ALARP and acceptable levels in accordance with the Esso impact and risk assessment methodology outlined in Section 5.

A summary of the risk assessment is included in Table 7-1. Inherent consequence level does not take any mitigating controls into consideration, the residual consequence level reflects the post control consequence. Multiple consequence and likelihoods included in the table reflect where consequences and likelihoods have been assessed for more than one receptor, or scenario, within a risk assessment.

Table 7-1 Summary risk assessment

Identifier	Hazard	Inherent Consequence Level	Residual Consequence Level (s)	Likelihood Category (s)	Risk Category
1	Physical interaction - Other users of the sea	III	III	D	4
2	Physical interaction – Marine fauna	III	III/IV	B/D	4
3	Physical interaction – Translocation of native species	II/III	II/III	C/D/E	3/4
4	Physical interaction – Introduction of IMS	III	III	D/E	4
5	Accidental release – Dropped objects	I/IV	I/IV	D/E	3/4
6	Accidental release – Solid Waste	III	IV	D	4
7	Accidental release – LOC hazardous or non-hazardous substances	IV	IV	D	4
8	Accidental release – LOC of refined oils (MGO)	I/II/III	I/II/III	E	3

7.1 Physical interaction – Other users of the sea

7.1.1 Causes of physical interaction with other users of the sea

The movement of Campaign #1 vessels such as the HLV, CSVs, barges, HTVs, tugs and other support vessels within the OA, has the potential to result in adverse interactions (such as collision) with other marine users such as commercial and recreational fishing vessels, merchant shipping vessels and vessels undertaking tourist activities and supporting other marine industries.

It is also recognised that partially removed facilities will remain in place on the seafloor following the completion of Campaign #1. Materials remaining will vary from location to location and are listed in Section 2.17. Examples of materials that may remain include sections of pipelines, umbilicals and other ancillary equipment, the concrete substructure at BMB, some remaining lower jacket sections and other items listed within the subsea materials register. This has the potential to result in interactions between this remaining infrastructure and other users of the sea, particularly commercial fishing vessels which undertake trawling.

Following removal of the topsides and module support frame during Campaign #1, the BMB concrete substructure will remain above sea level and will be fitted with a navigation aid, consistent with maritime requirements and discussions with AMSA, to minimise the marine safety hazards associated with this structure.

A waverider buoy may be temporarily installed within the OA during the execution timeframe to provide real time field measurements of wave height and wave direction to support Campaign #1 activities. A typical waverider buoy arrangement includes a buoy which floats on the ocean surface and a tether from the buoy to a clump weight which would be sitting on the seafloor. There is minor risk to other users if the buoy is separated from its tether or if a vessel collides with the buoy.

7.1.2 Risk assessment

If an interaction with a Campaign #1 vessel or partially removed infrastructure was to occur, potential socioeconomic consequences may result to other users of the sea, particularly commercial fishing licence holders, such as:

- loss of income due to having to replace/repair vessels and equipment
- loss of income due to loss of fishing catch.

Potential environmental consequences, should an interaction occur and result in a LOC of fuel from a vessel are considered in Section 7.7.5.

Commercial shipping is excluded from the majority of the OA via the presence of the ATBA and TSS (refer to Section 6.2.3.2), hence the risk of an interaction between a commercial ship and Campaign #1 vessels is not considered credible. The PCA and DPA monotowers are not located within the ATBA and part of the transport route from the facilities to the transfer area will also occur outside the ATBA. However, given the proximity of these facilities and the transport route to the shore, and the presence of the two TSSs to direct vessels around the ATBA, large commercial vessels are not expected to be transiting in the vicinity of PCA or DPA and within the transport route.

An additional TSS has been established to the south of Wilsons Promontory to separate the opposing flows of traffic and to keep vessels clear of the island groups in the area (AHO, 2024). Given the presence of this TSS and local geographic features, it is not expected that commercial shipping vessels will be transiting through or near sheltered waters closer to Wilsons Promontory where transfer operations may take place.

The PSZs will remain in place until such time that NOPSEMA remove those exclusions and as such, users of the sea will continue to be excluded from the PSZ areas, where removal activities will take place, per existing practice. During transfers of removed equipment to a barge or HTV, an additional 500m exclusion zone will be in place around the HLV.

Marine users will be requested to avoid Campaign #1 vessel exclusion zones during activities to ensure the safety of both Campaign #1 vessels and third-party vessels.

Esso have consulted with fishing industry bodies representing both Commonwealth and State fisheries, as well as individual fishing licence holders, with wind energy licence holders and recreational fishers (refer to Section 4). Stakeholders were interested in understanding if any navigation aids were to be installed post completion of Campaign #1. It was noted that only BMB would have a navigation aid installed post topsides removal due to the concrete substructure remaining above sea level. In all other cases, the depth of materials is considered sufficient for safe navigation. It is recognised that remaining infrastructure does represent a trawling hazard however there are existing trawling hazards, such as pipelines, that are not visually identified. The locations of the former jackets will remain marked on navigation charts as a hazard and users will need to take appropriate measures to safely navigate around remaining items. Esso noted there is an existing fishing tribunal to address damage to fishing gear and the existing tribunal will continue to operate while Esso continues with ongoing operations and decommissioning removal activities in the region.

Relevant authorities will be informed to ensure navigation charts can be updated to reflect changed conditions.

Risks associated with interaction with a waverider buoy are considered negligible.

The socioeconomic consequence of an unplanned interaction between another user of the sea and a vessel undertaking Campaign #1 removal activities, or a partially removed structure is assessed to be:

- **Consequence Level III**.

The likelihood of such an event occurring has been assessed as **Likelihood Category D** (very unlikely).

7.1.3 Demonstration of As Low As Reasonably Practicable

Table 7-2 Decision Context and justification

Decision Context Decision Context
Esso has been operating in this part of Bass Strait for 60 years, with other marine users well aware of Esso's facilities and the presence of seafloor obstructions. The risks associated with marine user interactions are well managed via existing legislative control measures (PSZs), vessel exclusion zones and notifications. These controls are understood and well implemented by the industry. The socioeconomic consequence of the impacts resulting from the potential interaction with other users of the sea has been assessed as **Consequence Level III**. The risk of the physical interaction with other users of the sea has been assessed as **Risk Category 4**. Stakeholder interest has been noted regarding the risk of interactions with other marine users as a result of removal activities, however relevant persons concerns have been considered/addressed. There are no conflicts with Company values. Hence, Esso believes **Decision Context A** should apply.

Table 7-3 Good practice controls

Good practice	Adopted	Control	Rationale
PSZ.	Adopted – RSK1-CM1	PSZs are in place around the facilities to be removed.	NOPSEMA is responsible for administration of PSZs as provided for in the OPGGS Act. PSZs are specified areas surrounding petroleum wells, structures or equipment which vessels or classes of vessel are prohibited from entering or being present in. Removal activities will take place within PSZs, hence this control minimises the risk of other marine users encroaching on Campaign #1 vessels during removal.
Safety exclusion zones.	Adopted – RSK1-CM2	Establishment of safety exclusion zones around Campaign #1 vessels for activities undertaken outside a PSZ.	Safety exclusion zones around vessels during activities undertaken outside a PSZ – for example during transfer operations will ensure other users of the sea are aware of the presence of Campaign #1 vessels, hence reducing the risk of adverse interactions.
Vessel compliance with *Navigation Act 2012* (Cth) requirements.	Adopted – RSK1-CM5	Campaign #1 vessels are compliant with relevant navigation safety requirements under the *Navigation Act 2012* (Cth) and subsidiary Marine Orders.	This is a legislative requirement and hence must be adopted.

Good practice	Adopted	Control	Rationale
Ensure other users of the sea are aware of exclusion zones and vessel operations prior to removal activities commencing.	Adopted – RSK1-CM4	Notify AHO prior to commencing removal activities.	Under the *Navigation Act 2012* (Cth), the AHO is responsible for maintaining and disseminating hydrographic and other nautical information and nautical publications including Notices to Mariners. Details of the PSZ and other vessel exclusion zones will be published in Notices to Mariners, thus enabling other marine users to avoid the area and minimise the risk of interaction with Campaign #1 vessels.
	Adopted – RSK1-CM3	Notify AMSA Joint Rescue Coordination Centre prior to commencing removal activities.	Relevant details will be provided to the JRCC Joint Rescue Coordination Centre to enable AUSCOAST warnings to be disseminated.
Navigational charts.	Adopted – RSK1-CM7	The locations of partially removed infrastructure which remains on the seabed following Campaign #1 will continue to be marked on navigational charts administered by the AHO.	AHO will be notified following the completion of removal activities to allow navigation charts to be updated as required to reflect changed conditions. This administrative control will ensure other marine users are aware of their ongoing presence.
Ongoing engagement with key other users of the sea (commercial fisheries) within the OA	Adopted – RSK1-CM8	Ongoing consultation (via quarterly stakeholder forums) with commercial fisheries with licences in the ATBA to ensure licence holders are aware of changes to facility status after Campaign #1.	This administrative control will ensure commercial fishermen who may fish in the area are aware of the ongoing presence of partially removed infrastructure.

Table 7-4 Engineering risk assessment

Control measure	Benefit	Cost/feasibility	Adopted
Remove all facilities to below the seabed in this decommissioning campaign.	The risk of interaction with partially removed facilities is eliminated.	Section 1.3.1 of the EP outlines the rationale for the partial removal of the facilities located in deeper water in Campaign #1.	Not adopted

Control measure	Benefit	Cost/feasibility	Adopted
Operation of permanent navigation aids on partially removed facilities - where infrastructure remains above the sea surface (topsides removed)	Continued visual identification of the presence of infrastructure remaining.	Control is feasible and the benefits outweigh the cost of installation and ongoing operation.	Adopted – RSK1-CM6
Operation of permanent navigation aids at the locations of partially removed facilities – where infrastructure remains below the sea surface.	Visual identification of the location of infrastructure remaining below the sea surface.	This control is considered unfeasible given depths of the water column and the sea state conditions in Bass Strait. Previous experience has indicated that potentially feasible visual aids such as buoys are prone to detaching, hence would not be an effective control and may become a hazard to fishing and marine life. Surveillance and maintenance of buoys would increase helicopter or marine personnel exposure. The benefits of installing surface visual aids are not considered to outweigh cost and safety considerations.	Not adopted
Existing Esso processes (the Fisherman's Tribunal) are in place to mitigate the impact of an interaction with a commercial fishing vessel, if this occurs.	Minimise any impacts to commercial fishing vessels in the event of an adverse interaction with partially removed infrastructure.	Feasible and benefits outweigh any cost – process is already implemented.	Adopted – RSK1-CM9

7.1.4 Demonstration of acceptability

Table 7-5 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events.	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 4** (the lowest category) and therefore considered acceptable.
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic,	✓	Not inconsistent. Long term and short term economic, environmental, social and equitable considerations have been incorporated into the assessment of risks to other users of the sea as a result of the removal

Factor	Demonstration criteria	Criteria met	Rationale
	environmental, social and equitable considerations.		and transfer activities and the ongoing presence of partially removed facilities on the seabed. The removal campaign and the ongoing presence of the partially removed facilities on the seabed do not significantly impinge on the rights of other users of the sea (particularly commercial fishers) to access resources now and into the future.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The risks of physical interaction with other marine users as result of vessel activities and infrastructure on the seabed are well understood and have been managed throughout the decades of Esso operations in Bass Strait. There is not considered to be the risk of serious or irreversible environmental damage as a result of the unlikely event of an interaction between another user of the sea and a Campaign #1 vessel, or partially removed infrastructure.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The risk of physical interaction with Campaign #1 vessels and partially removed infrastructure is short term in nature and will not impact upon the environment such that future generations cannot meet their needs.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	Not relevant	This principle is not considered relevant to this risk assessment, as potential consequences of an interaction with other marine users are socioeconomic rather than environmental.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	Legislation and other requirements considered as relevant include: OPGGS Act: • Section 619 prohibits unauthorised vessels from entering a PSZ • *Navigation Act 2012* (Cth) – Chapter 6 (Safety of Navigation) Part 6 deals with safe navigation including provisions about reporting of movement of vessels.

Factor	Demonstration criteria	Criteria met	Rationale
			Marine Orders are made under the: • *Navigation Act 2012* (Cth) • *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Cth) • *Protection of the Sea (Harmful Anti-fouling Systems) Act 2006* (Cth) • Marine Orders 1 to 98 – Give effect to international obligations and standards and apply to regulated Australian vessels, foreign vessels, and some domestic commercial vessels • Marine Order 18 (Measures to enhance maritime safety) 2013 • Marine Order 27 (Safety of navigation and radio equipment) 2016 • Marine Order 30 (Prevention of collisions) 2016 • Rule 10 of COLREGs.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 10: Managing Community Risk objective to maintain public awareness

Factor	Demonstration criteria	Criteria met	Rationale
			and confidence in the OI of operations and facilities.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Stakeholders were advised that existing PSZ and fishing tribunal processes will remain in place. The proposed BMB navigation aid configuration and type was discussed and agreed with AMSA. Relevant persons concerns have been considered/addressed.

7.1.5 EPOs, control measures, EPSs and measurement criteria

Table 7-6 EPOs, control measures, EPSs and measurement criteria – Physical interaction, other users of the sea

EPO	Control measure	EPS	Measurement criteria
RSK1-EPO1: No adverse interactions with other marine users during removal and transfer operations.	RSK1-CM1: PSZs are in place around the facilities to be removed.	RSK1-EPS1.1: PSZs are in place around the Campaign #1 facility removal locations and prevent unauthorised access during removal activities.	RSK1-MC1.1.1: PSZs are gazetted and published on the NOPSEMA website. RSK1-MC1.1.2: Any incursions by unauthorised vessels into the PSZs during removal operations are recorded as an incident and investigated.
	RSK1-CM2: Safety exclusion zones around Campaign #1 vessels for activities undertaken outside a PSZ.	RSK1-EPS2.1: A 500m radius safety exclusion zone is in place around the HLV and other Campaign #1 vessels during transfer operations, which is enforced by the HLV.	RSK1-MC2.1.1: Notice to Mariners issued to communicate safety exclusion zone during removal and transfer operations. RSK1-MC2.1.2: Any incursions by unauthorised vessels into the safety exclusion zones during removal or transfer operations are recorded as an incident and investigated.
	RSK1-CM3: Notify AMSA Joint Rescue Coordination Centre prior to commencing removal activities.	RSK1-EPS3.1: AMSA Joint Rescue Coordination Centre (JRCC) notified before removal activities commence to enable AMSA to distribute an AUSCOAST warning.	RSK1-MC3.1.1: Records confirm that information to distribute AUSCOAST warning/s was provided to the JRCC before removal operations commenced. RSK1-MC3.1.2: Issued AUSCOAST warning/s dated prior to, or on the date activities commenced.
	RSK1-CM4: Notify AHO prior to	RSK1-EPS4.1: AHO notified before removal activities commence to	RSK1-MC4.1.1: Issued Notice to Mariners dated prior to, or on the date removal preparation

EPO	Control measure	EPS	Measurement criteria
	commencing removal activities.	allow generation of navigation warnings (including Notice to Mariners).	activities (with the CSV) and removal operations (with the HLV and CSV/s) commenced.
	RSK1-CM5: Campaign #1 vessels are compliant with relevant navigational safety requirements.	RSK1-EPS5.1: Campaign #1 vessels are compliant with relevant navigation safety requirements under the *Navigation Act 2012* (Cth) and subsidiary Marine Orders.	RSK1-MC5.1.1: Inspection records demonstrate compliance with relevant navigation safety requirements under the *Navigation Act 2012* (Cth) and subsidiary Marine Orders.
RSK1-EPO2: No adverse interactions with other marine users and partially removed infrastructure.	RSK1-CM6: Operation of permanent navigation aids on partially removed facilities - where infrastructure remains above the sea surface	RSK1-EPS6.1: A remotely monitored navigation aid will be in place on the BMB concrete substructure to provide ongoing visual identification of the structure following removal of the topsides.	RSK1-MC6.1.1: Remote monitoring records demonstrate correct operation of the navigation aid.
	RSK1-CM7: The locations of partially removed infrastructure which remains on the seabed following Campaign #1 will continue to be marked on navigational charts administered by the AHO.	RSK1-EPS7.1: The locations of partially removed infrastructure which remains on the seabed following Campaign #1 will continue to be marked on navigational charts administered by the AHO to advise marine users of their presence.	RSK1-MC7.1.1: Records show that: • the AHO has been notified of the locations of the partially removed infrastructure.
	RSK1-CM8: Ongoing consultation (via quarterly stakeholder forums) with commercial fisheries with licences in the ATBA to ensure licence holders are aware of changes to facility status after Campaign #1.	RSK1-EPS8.1: Commercial fisheries with licences in the ATBA will be notified of the changes to facility status via ongoing quarterly stakeholder forums.	RSK1-MC8.1.1: Minutes of quarterly stakeholder forums confirm the locations and particulars (i.e. height above seabed) of the partially removed infrastructure are communicated to commercial fishing stakeholders.
RSK1-EPO3: Mitigate the impacts of adverse interactions with commercial fishing vessels and partially	RSK1-CM9: Existing Esso processes (the Fisherman's Tribunal) are in place to mitigate the impact of an interaction with	RSK1-EPS9.1: The current model for compensation for claims of equipment damage as a result of interaction with Esso facilities, the	RSK1-MC9.1.1: Records of Fisherman's Tribunal meetings verify this process remains in place.

removed infrastructure, in the event that an interaction occurs.	a commercial fishing vessel, if this occurs.	Fisherman's Tribunal, will remain in place, until such time as all Bass Strait operations are decommissioned.	

7.1.6 Residual risk ranking

Table 7-7 Residual risk ranking outcome

Consequence Level	Likelihood Category	Risk Category
III	D	4

7.2 Physical interaction – Marine fauna and seabirds

7.2.1 Causes of physical interaction with marine fauna

The jacket structures and waters within the OA are suitable habitat for marine fauna such as whales, dolphins, seals and seabirds (collectively referred to as marine fauna in this Section).

Vessel movements and structural lifting/removal activities have the potential to result in unplanned physical interactions with marine fauna through:

- vessel or equipment (hull, propeller) collision with marine fauna resulting in injury or mortality
- disturbance of fur seals including those hauled out on structures or support vessels
- disturbance of adult seabirds on structures
- loss of eggs or juvenile seabirds if present on structures at the time of lifting
- attraction of seabirds to vessels due to presence of marine growth.

Impacts to fauna from vessel noise and light are not considered as these are discussed in Sections 6.13 and 6.14 respectively.

A waverider buoy may be installed within the OA. A typical waverider buoy arrangement includes a buoy which floats on the ocean surface and a tether from the buoy to a clump weight which would be sitting on the seafloor. Potential interactions associated with this activity are mostly associated with vessel operations during installation and retrieval and as such are included in the previously listed interactions.

7.2.2 Risks of physical interaction with marine fauna

Interaction with marine fauna has the potential to result in:

- disturbance to marine fauna
- injury/mortality to marine fauna.

7.2.3 Risk assessment

7.2.3.1 Injury/mortality to fauna as a result of vessel or equipment strike

Several marine turtle species including species listed as either threatened and/or migratory under the EPBC Act may occur within the OA, however no critical habitat or BIAs for turtles have been identified.

Several marine mammals (e.g. whales, dolphins, seals) including those listed as either threatened and/or migratory under the EPBC Act have the potential to occur within the OA. The PBW has a foraging habitat BIA overlapping the OA and the SRW migration BIA also overlaps the OA.

Cetaceans are naturally inquisitive marine mammals that are often attracted to offshore vessels and facilities. The reaction of whales to the approach of a vessel is quite variable. Some species remain motionless when in the vicinity of a vessel, while others are curious and often approach ships that have stopped or are slow moving, although they generally do not approach, and sometimes avoid, faster-moving ships (Richardson, Greene, Malme, & Thomson, 1995).

Although collisions with marine fauna can happen anywhere in Australian waters, the risk of collision is greater in breeding areas and along seasonal migration routes. Collision risk also increases in shallower waters where a vessel has less under-keel clearance, leaving an animal less room to avoid the vessel (AMSA, 2023). Larger vessels with reduced manoeuvrability moving in excess of 10kn may cause fatal or severe injuries to cetaceans, with the most severe injuries caused by vessels travelling faster than 14kn (Laist, Knowlton, Mead, Collet, & Podesta, 2001).

Of the Campaign #1 activities described in this EP, transit between facility locations and transfer location when a load is present on the *Pioneering Spirit*, is considered a safety-critical activity. Speed will be determined by the vessel master based on consideration of several factors including but not limited to megafauna safety, sea state, forecast conditions and load carrying safety requirements. Vessel speed during this transit may reach speeds of up to 10kn when assessed by the vessel master as appropriate.

The Australian and New Zealand fur seals are highly agile species that haul themselves onto rocks and oil and gas platform structures. As such, it is likely that they will avoid any collision with moving support vessels. Seals are frequently encountered during routine operations at SPJs.

Vessel strike data from (1997 - 2015) for marine species in Australian waters was reviewed and identified the following (Peel, Smith, & Childerhouse, 2016):

- off the Victorian coast there are fewer than 10 records of vessel strikes with whales (historic and modern records)
- whales including the humpback whale (*Megaptera novaeangliae*), PBW, Antarctic blue whale (*Balaenoptera musculaus interndedia*), SRW, dwarf minke (*Balaenoptera acutorostrata*), Antarctic minke whale (*Balaenoptera bonaerensis*), fin whale (*Balaenoptera physalus*), Bryde's whale (*Balaenoptera edeni*), pygmy right whale (*Caperea marginata*), sperm whale (*Physeter macroephalus*), pygmy sperm whale (*Kogia breviceps*) and pilot whale species were identified as having interacted with vessels. The humpback whale exhibited the highest incidence of interaction followed by the SRW. A number of these species may be observed in the waters within the vicinity of the OA
- dolphins including the Australian humpback (*Sousa sahulensis*), common bottlenose (*Tursiops truncates* s. str.), Indo-Pacific bottlenose (*Tursiops aduncus*) and Risso's dolphin (*Grampus griseus*) species were also identified as interacting with vessels. The common bottlenose dolphin exhibited the highest incidence of interaction. A number of these species may be observed within the vicinity of the OA
- no vessel interaction reports were recorded during the period for either the Australian or New Zealand fur seal. There have been incidents of seals being injured by boat propellers however all indications are rather than 'boat strike' these can be attributed to be the seal interacting/playing with a boat, with experts indicating the incidence of boat strike for seals is very low.

Limited equipment (such as ROVs) will also be used as part of the Campaign #1 activities. Seals are inquisitive and have been known to investigate and interact with such equipment/activities. Based on operational experience, no credible injury or mortality risk to marine mammals or turtles from ROV/underwater equipment use was identified.

7.2.3.2 Injury/mortality to marine seabirds which may be present on facilities

The OA is within foraging BIAs for a number of seabird species including:

- black browed albatross *(Thalassarche melanophris*)
- Campbell albatross (*Thalassarche impavida*)
- Indian yellow nosed albatross (*Thalassarche carteri*)
- wandering albatross (*Diomedea exulans*)
- antipodean albatross (*Diomedea antipodensis*)
- Buller's albatross (*Thalassarche bulleri*)
- shy albatross (*Thalassarche cauta*)
- common diving petrel (*Pelecanoides urinatrix*)
- white-faced storm petrel (*Pelagodroma marina*)
- short-tailed shearwater (*Ardenna tenuirostris*).

Decommissioning operations may disturb foraging birds and temporarily displace them into other areas within the region. Risks associated with potential foraging disturbance are considered negligible. It is considered unlikely that any of these species will elect to opportunistically nest on the platforms. Several species, such as the shy albatross, are known to have strong affiliations with specific breeding colony sites that they are known to return to while others, such as the short-tailed shearwater, nest in burrows.

A review of species identified in the EPBC Act Protected Matters Report – OA (refer to Appendix C) identified a small number of species with a higher potential to roost or opportunistically nest on structures during the timeframe prior to, or during, the Campaign #1 removal activities. These include:

- silver gull (*Chroicocephalus novaehollandiae*)
- great cormorant, (*Phalacrocorax carbo*)
- black faced cormorant (*Phalacrocorax fuscescens*)
- Australasian gannet (*Morus serrator*)
- greater crested tern (*Thalasseus bergii*)
- Pacific gull (*Larus pacificus*).

Roosting is known to occur on offshore platforms, particularly on open areas such as the helicopter deck. Roosting birds may move freely away from activities and startle responses such as flying away from a disturbance are unlikely to be detrimental. As structures will be permanently removed, dispersed birds will need to find alternate roosting locations in the region. Risks associated with potential roosting disturbance are considered negligible.

There is very limited anecdotal accounts of historical nesting on structures, typically in inaccessible areas such as the flare boom as described in the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). It is recognised however, that facilities in stasis are more likely to be opportunistically utilised due to the lack of activity.

In the event eggs or birds unable to successfully relocate on their own (e.g. chicks) are present on the structures at the time of removal, it is recognised that there is no practical and safe means to collect and relocate individuals and mortality may occur. Whilst EPBC listed, none of the identified potential nesting species have a threatened or migratory status and none of the relevant BIAs for any of these species occur within the OA. Population dynamic risks to these species associated with potential nesting or juvenile bird mortality are considered negligible.

7.2.3.3 Injury/mortality to marine seabirds which may attracted to vessels due to presence of marine growth

The presence of marine growth attached to the structures lifted onto the HLV, or that falls on the deck of the vessel or immediately adjacent to the vessel during lifting, transport and transfer operations, may attract seabirds. Refer to Section 6.12 for further information on the presence of marine growth during Campaign #1 operations.

Based on past decommissioning projects conducted by the vessel contractor (Allseas), seabirds may be observed near the vessel after the presence/collection of marine growth on deck. However, this observation has predominantly been in the form of individual seabirds rather than aggregation of large groups/flocks. Typically, solitary seabirds that may be attracted to the vessel remain in proximity for a very short period of time, with behaviour stopping as soon as marine growth is removed/cleaned/contained from the deck. There is no consistent pattern of seabirds following a vessel after marine growth has been managed.

The presence of marine growth on the vessel, including that attached to the structures removed and that which has dislodged and falls on the deck or immediately adjacent to the vessel, is intermittent and of short duration, reducing the potential risk of interaction with seabirds that would result in injury/mortality.

7.2.3.4 Injury/mortality to seals which may haul out onto facilities or vessels

Fur seals are frequently observed by offshore operators aggregating and feeding in the water around the platforms and hauling out on the lower, accessible parts of the structures. They have also been known to occasionally haul out on small stationary vessels such as support vessels. It is theorised that the larger size and sound levels associated with the *Pioneering Spirit* HLV may deter fur seals and encourage them to relocate to elsewhere in the region during activities however, for the purpose of this EP, the possibility of interactions with hauled out seals on structures and support vessels has been considered. Routine offshore operational experience to date is that seals can easily be moved away (off platforms or vessels) when required without any physical contact. Visual cues and noise such as waving arms, clapping of hands or tapping of handrails has been found to be sufficient to encourage seals to safely re-enter the water when needed. In the case of jacket removal (post topside removal), reboarding of the structure may not likely be required. As such there may be a need to use a noise producing device (such as a drone with a speaker) to remotely provide the audio cue to encourage any hauled out seals to re-enter the water. Risks associated with the interaction of hauled out seals are considered negligible.

Of all the fauna interactions discussed in this EP, vessel collision with marine fauna during vessel movements is considered the highest potential consequence.

If a fauna strike occurred and resulted in death, it is not expected that it would have a detrimental effect on the overall population. Consequently, the potential consequence from fauna strike is considered to be **Consequence Level III** as this type of event may result in a localised, short term impact to species of recognised conservation value but is not expected to affect the population or local ecosystem function. The likelihood of such interactions causing severe injury or death of an individual is considered **Likelihood Category D** (very unlikely) during these activities.

During consultation, stakeholders asked how interactions with marine mammals would be managed. Esso noted that vessels would comply with Division 8.1 of the EPBC Regulations requirements.

7.2.4 Demonstration of As Low As Reasonably Practicable

Table 7-8 Decision Context and justification

Decision Context
Offshore petroleum operations are widely undertaken both locally, nationally, and internationally, however the removal of large structures from the offshore environment with potential wildlife present on these structures is a non-standard or infrequent event. The risk of cetacean vessel strike is well managed via legislative control measures that are considered industry best practice. These controls are well understood and implemented by the industry. However, these legislative controls do not eliminate the risk of death or injury to seals via interaction with vessels. The environmental consequence of the impacts resulting from the potential interaction with other users of the sea has been assessed as **Consequence Level III**. The risk of the physical interaction with marine fauna and seabirds has been assessed as **Risk Category 4**. No objections were raised by relevant persons with regard to the risk of physical interaction with marine fauna and seabirds. Hence, Esso believes **Decision Context B** should apply.

Table 7-9 Good practice controls

Good practice	Adopted	Control	Rationale
Part 8 Division 8.1 of the EPBC Regulations. *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a).	Adopted – RSK2-CM1	Operations within the OA will comply with requirements established in Part 8 Division 8.1 of the EPBC Regulations, and align with the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a)	The Vessel Master has responsibility for ensuring the requirements of these regulations and guidelines are followed. The guidelines describe strategies to ensure whales and dolphins are not harmed during offshore interactions with people. These guidelines were developed jointly by all State and Territory governments through the Natural Resource Management Ministerial Council and, although more relevant for tourism activities, provide a list of requirements that are often adopted by the oil and gas industry to minimise the risk of cetacean strike occurring. Note: Both the lack of visibility of seals in the water and number of seals in close proximity to oil and gas offshore installations make applicability of these guidelines to seals impracticable. Furthermore, fauna interaction management actions as described in the guidelines will not prevent seals approaching/playing with vessels.

Good practice	Adopted	Control	Rationale
Management of hauled out seals	Adopted – RSK2-CM2	Seals to be encouraged back into the water on as needed basis using non-contact methods (e.g. arm waving, clapping, tapping handrails). Use of a speaker to be trialled during facility preparation activities - to validate its suitability for use as an alternative deterrent method where personnel will not board the facility. Sound levels will be limited to ensure no harm.	Seals may be present hauled out on SPJs or vessels and may need to be moved on to facilitate operations. Australian fur seals are a protected species and physical contact with wildlife is to be avoided. Offshore experience is that non-contact methods are effective and sufficient to ensure seal and worker safety.

Table 7-10 Engineering risk assessment

Control Measure	Benefit	Cost/feasibility	Adopted
Grates on vessel tunnel thrusters.	Grates on vessel tunnel thrusters would prevent entrapment of marine mammals, in particular seals which are known to approach/play with vessels while stationary on DP.	Support vessels (such as those used to deploy ROVs) do not always have grates on tunnel thrusters, however it is more common for larger PSVs. Adding grates to thrusters significantly impacts efficiency of vessels leading to increased fuel usage and air emissions, particularly for small vessels. Further, grates lead to increased potential for marine growth (which further reduces efficiency of thrusters). Retrofitting of grates to vessels requires dry docking at significant schedule and cost implications, also impacting operability and efficiency of vessels.	Not adopted
Bird deterrent devices.	The objective of the bird deterrent is to remove or significantly reduce bird presence on the platforms. A number of different deterrent devices are commercially available however results can be variable.	In the past, a laser bird deterrent was trialled at the Esso onshore aircraft hangars used for helicopter operations however, the system was not successful and currently, no bird deterrents are in use either on or offshore. Some onshore facilities such as airports utilise falconry to deter birds however	Not Adopted

Control Measure	Benefit	Cost/feasibility	Adopted
	Some devices broadcast recorded bird distress signals and predator calls intended to frighten, confuse and disorientate birds while other devices use noise blasts to scare off birds. Some systems also use lasers in conjunction with noise.	that approach is not considered practicable for offshore operations. In order to better understand the potential for birds to be present on, and for nesting to occur on the facilities once they are unstaffed, Esso will perform opportunistic observation of facilities during offshore activities at selected platforms during the 2025/26 summer period. If substantial nesting is observed, the use of a deterrent device will be re-assessed on an individual facility basis however the variable success of deterrents, logistics of access to the facilities for installation and maintenance of deterrents and the low risk assessed mean that the use of deterrents is not currently considered justified.	
Seal deterrent device.	Audible or physical deterrent devices such as seal crackers have been extensively used in the aquaculture industry in Australia to deter seals from facilities. The seal crackers are small explosive devices thrown into the water to detonate under the surface. Other example devices used by the aquaculture industry include bean bags filled with lead shot which are thrown at seals. Seal deterrent devices have been shown to be effective in certain situations however also been attributed to injury of seals in some cases.	Years of offshore experience with seal presence on and around SPJs and vessels during activities indicates that use of such devices is not necessary. Vessel strike or injury through interaction with equipment has not been an issue experienced to date and is not expected.	Not adopted
Bulk removal of all marine growth at location of current platform.	Removed marine growth remains at original location and will not attract birds.	Removal of all marine growth at the platform locations is not considered viable due to restricted access to structural members which are internally positioned within each jacket; difficulty working within the splash zone and other more complex safety considerations associated with extensive marine growth removal based on the nature and scale of the entire upper jacket sections.	Not adopted

Control Measure	Benefit	Cost/feasibility	Adopted
Vessel contractor waste management procedure.	Reduces the likelihood for interaction with seabirds by minimising the amount of marine growth that is available on the deck of the vessel.	Development and implementation of a waste management procedure that includes actions for adequate management of marine growth that dislodges from the structures (i.e. jackets) and fall on the deck. There are limitations to the collection of marine growth that falls on the deck, including safety considerations such as 'no go zones' established in areas of the deck during transport of structures, where it is not safe for vessel crew to enter. As a result, the waste management plan must include such considerations to allow for an efficient and feasible implementation. Development and implementation of a waste management procedure that incorporates management of marine growth is considered practicable.	Adopted – RSK2-CM3
Seabird Management Plan.	Allows management of the potential risk to seabirds from interaction with vessels.	Development and implementation of a Seabird Management Plan requires additional resources; however, they are considered to be low cost. A Seabird Management Plan provides a tool that clearly outlines the actions to be implemented during vessel operations, positively acknowledging and addressing the presence of seabirds within the OA and potential interactions due to the presence of marine growth attached to the structures loaded on the vessel or marine growth that has dislodged from these structures and falls on the deck. Benefit of development and implementation of a Seabird Management Plan outweighs the cost.	Adopted-RSK2-CM4

7.2.5 Demonstration of acceptability

Table 7-11 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 4** (the lowest category) and therefore considered acceptable.

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The risks of physical interactions with marine fauna and seabirds were assessed as having the potential to result in a residual **Risk Category 4** thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The risk of physical interaction with fauna is unlikely to result in a detrimental effect on the overall population of any of the species assessed and will not impact upon the environment such that future generations cannot meet their needs.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	Requirements of the EPBC Regulations – Part 8 Division 8.1: Interacting with cetaceans, although more relevant for tourism activities, have been adopted.

Factor	Demonstration criteria	Criteria met	Rationale
			Vessel disturbance is a recognised threat to the species in the following conservation management plans and advice. The proposed controls are consistent with conservation/management actions in: • CMPBW • Conservation Advice for Humpback Whales (TSSC, 2022) • NRPSRW • *Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015a) • *Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015b) • *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017) • *Conservation Advice for Leatherback Turtles* (DEWHA, 2008a). • National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna (Commonwealth of Australia, 2017c).
Internal context	Consistent with Esso's Environment Policy	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil OIMS Objectives	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements. • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Relevant persons concerns have been considered.

7.2.6 EPOs, control measures, EPSs and measurement criteria

Table 7-12 EPOs, control measures, EPSs and measurement criteria – Physical interaction- Marine fauna and seabirds

EPO	Control measure	EPS	Measurement criteria
RSK2-EPO1: No vessel strike injury is caused to whales or dolphins as a result of vessel operations during Campaign #1 activities.	RSK2-CM1: Operations within the OA will comply with requirements established in Part 8 Division 8.1 of the EPBC Regulations, and align with the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a).	RSK2-EPS1.1: Operations within the OA will comply with requirements established in Part 8 Division 8.1 of the EPBC Regulations, and align with the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a), specifically with: • identification and training of personnel that will hold responsibilities on ensuring compliance with legal requirements established in Part 8 Division 8.1 of the EPBC Regulations and the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a), prior to commencement of operations covered under the scope of works for decommissioning activities • caution zone: vessels will not approach closer than 150m from a dolphin and/or 300m from a whale. • vessels will not travel at a speed of more than 6kn when a dolphin or	RSK2-MC1.1.1: Roles and responsibilities as described in the Allseas EMP and related vessel subcontractors appropriate management plan. RSK2-MC1.1.2: Induction records of vessel crew members and aircraft operator(s) on the requirements from, and how to comply with, Part 8 Division 8.1 of the EPBC Regulations and the *Australian National Guidelines for Whale and Dolphin Watching 2017* (Commonwealth of Australia, 2017a). RSK2-MC1.1.3: Training records of relevant vessel crew and aircraft operator(s) members on marine fauna observations engaged. RSK2-MC1.1.4: Daily reports including actions implemented during vessel operations if/when whales and dolphins were sighted within the distances established under Part 8 Division 8.1 of the EPBC Regulations.

EPO	Control measure	EPS	Measurement criteria
		whale is sighted within 300m from the vessel. Vessel must also move away from the dolphin/whale at a constant speed of <6kn.	
RSK2-EPO2: No physical contact interaction with hauled out fur seals if present on structures or vessels at the time of operations.	RSK2-CM2: Seals to be encouraged back into the water on as needed basis using non-contact methods (e.g. arm waving, clapping, tapping handrails).	RSK2-EPS2.1: Crew will receive training (during environmental inductions) on the requirement to use non-contact methods (arm waving, sound, tapping handrails etc.) to encourage hauled out seals into the water when needed to facilitate access to or lifting of a structure.	RSK2-MC2.1.1: Induction records of vessel crew members.
RSK2-EPO3: No injury/mortality of seabirds from interaction with vessel that is caused by their attraction to the presence of marine growth.	RSK2-CM3: Vessel contractor waste management procedure.	RSK2-EPS3.1: Development and implementation of a waste management procedure.	RSK2-MC3.1.1: Waste management procedure documentation.
	RSK2-CM4: Seabird Management Plan.	RSK2-EPS4.1: Development and implementation of a Seabird Management Plan.	RSK2-MC4.1.1: Seabird Management Plan. RSK2-MC4.1.2: Evidence of implementation of actions established in the Seabird Management Plan.

7.2.7 Residual risk ranking

Fauna strike.	III	D	4
Seabird egg or chick mortality.	IV	B	4

Scenario	Consequence Level	Likelihood Category	Risk Category
Injury/mortality of seabirds linked to the presence of marine growth.	IV	B	4
Fauna disturbance.	IV	B	4

7.3 Translocation of native species

7.3.1 Causes of the spread of native species

As discussed in Section 6.11.7, the facility jackets are almost entirely covered in marine growth. During lifting, any marine growth dislodged from the structures will fall to the seabed close to the structures' original location and will either survive in their new location or become food for other marine life in the area. During transit, and transfer, the marine growth now out of the water will progressively desiccate and some will fall off the structures. During transport, jackets are held on an incline with the jacket structures raked towards the vessel deck, hence some marine growth will fall off the structures into the marine environment.

Campaign #1 vessels will also take on and discharge ballast water within the OA during lifting and transfer operations. Hence larvae, fragments and individual organisms could be translocated through the OA and to adjacent areas via this pathway.

7.3.2 Risks of the spread of native species

Desktop based studies have been undertaken to evaluate the likelihood and consequences of the Campaign #1 decommissioning activities translocating IMS, harmful micro-organisms (HMOs) or range expanding native species within the OA and potentially into adjacent Victorian State waters (Biofouling Solutions, 2026a). The first study (Biofouling Solutions, 2026a) considered the potential spread of IMS from activities undertaken within the OA, while the second study evaluated the risk of the spread of IMS as a result of Campaign #1 activities undertaken within Victorian State Waters (outside the OA) (Biofouling Solutions, 2026b). The methodology and approach of these studies is described further in Section 7.4.

For native species the studies undertaken focused on two species:

- the long-spined sea urchin (*Centrostephanus rodgersii*) which have occasionally been observed in ROV survey footage of SPJs. The long-spined sea urchin is considered a range expanding native species of New South Wales that is known to exist in the Bass Strait region and down the eastern coast of Tasmania. The long-spined sea urchin was first observed as far south as Tasmania in the late 1970s (Ling & Keane, 2018) and is considered invasive due to its ability to overgraze kelp beds, forming and maintaining stable barrens. *C.rodgersii* has been reported from the southern tip of Wilsons Promontory and from reefs approximately 150km to the east of Corner Inlet, but it has not been observed on coastal reefs between these locations (Biofouling Solutions, 2026a). Observations were made of a small number (six) of the long-spined sea urchins on several platforms during pre-decommissioning environmental surveys on the WTA jacket. Additional review of extensive ROV footage during the study noted only a single individual on the base of the FLA jacket
- the jewel anemone (*Corynactis australis*) which is by far the most abundant species present on the jacket structures, covering up to 98% of the jacket area in some instances (McLean, et al., 2022). Jewel anemones are not known from any other offshore reef environments in this region, with reports of its occurrence typically associated with inshore rocky reefs. There was low coverage of jewel anemones in the benthic surrounds immediately adjacent to SPJs.

The risk assessment outlined in this Section has therefore focused on these two species.

The translocation of *C.rodgersii* and *C.australis* from BBMT to the OA via the HTVs or barges return journey following offloading of removed structures was also assessed within the second study. This pathway was ruled out as neither species have been identified as being present at BBMT or Corner Inlet (Biofouling Solutions, 2026b). Hence this pathway is not considered further in this section.

7.3.3 Risk assessment

7.3.3.1 Consequence evaluation

The translocation of native species due to decommissioning activities (that would not have occurred through existing range expansion processes) may have either negative or positive consequences to the species and the receiving environment, depending on the vulnerability of the native species, and the ecosystem service of any displaced species within the receiving environment. A native species which is present in a habitat may not necessarily be considered invasive and therefore not have a negative impact on the receiving environment. However, where invasive potential exists, colonisation could result in changes to ecosystem dynamics which could result in changes to the functions, interests or activities of other users.

If a new population of the jewel anemone was to establish along the coastline or nearshore or deeper natural reefs in or adjacent to the OA, it would likely persist for years, however given the given the high-energy offshore and wave-exposed nearshore environments, and the presence of diverse existing biological assemblages, new populations of anemones, while they may form dense aggregations, are expected to remain relatively localised (Biofouling Solutions, 2026a). The consequence severity of the translocation of the jewel anemone within the OA and adjacent areas has been assessed as **Consequence Severity III.**

The long-spined sea urchin is actively expanding its range and is known to exist in the Bass Strait region and down the eastern coast of Tasmania. Parks Australia provide information during relevant person consultation for this EP that while the long-spined sea urchin has been observed in the subtidal areas of Wilsons Promontory, it has not caused issues. In eastern Victoria *C.rogersii* have created extensive barrens on reefs within marine parks within as well as on many other reefs outside parks in the region (Beware Reef Marine Sanctuary and Cape Howe Marine National Park) (Parks Victoria, 2022). If a new population of long-spined sea urchins was to establish along the coastline, nearshore or deeper natural reefs in or adjacent to the OA, it would also likely persist for years. Given the ecological and socioeconomic impacts this species has been known to cause in other areas, a higher consequence rating of **Consequence Severity II** has been assessed.

7.3.3.2 Likelihood evaluation

The process that underlies the successful establishment of a native species in a new location is complex and contains numerous interacting biological and environmental factors (Biofouling Solutions, 2026a). Successful translocation and establishment of a native species in another area, via the Campaign # 1 decommissioning activities would require the following steps:

- the presence of the species on a structure being removed
- the presence of larvae, spores, fragments or individuals being present at the jacket locations and taken up in vessel ballast water during lifting activities at the removal locations
- survival of the species during lifting, transit and transfer of the removed structures
- release of the species within the OA either by ballast water discharge or the release of biofouling off the removed structure
- successful establishment of a viable new local population in a suitable habitat.

7.3.3.2.1 PRESENCE OF THE SPECIES ON THE JACKET STRUCTURES

During Environmental Survey 1 (Summer) and Environmental Survey 2 (Winter) undertaken on the jackets, the long-spined sea urchin was observed in very low numbers on platforms, possibly due to the depth of the surveys, a lack of crevices/niches on shallower platform sections, and a low cover of their primary food source, macroalgae, although they can capture drift algae. Low abundance may also be linked to space competition with the jewel anemone (McLean, et al., 2022). Additional review of more than 500 ROV videos collected during structural surveys from 2020 - 2024 on the jackets by an experienced specialist only identified two specimens of the long-spined sea urchin on the Campaign #1 jackets (at WTA and at the base of FLA) (Biofouling Solutions, 2026a). The dominant presence of the jewel anemone on all jacket structures was observed during the environmental surveys and was confirmed by the review of the additional ROV footage.

The likelihood of the long-spined sea urchin being present on the jacket structures is assessed as **Likelihood Category C** (unlikely)**,** while the likelihood of the jewel anemone being present is assessed as **Likelihood Category A** (very likely)**.**

7.3.3.2.2 RELEASE AND ESTABLISHMENT VIA MARINE GROWTH DISCHARGE

Anemones are small organisms that loose water rapidly and desiccate quickly and are therefore unlikely to drop off in large quantities due to gravity alone. However, the vibrations, abrasion, and other physical forces they will be subject to during platform lifting and placement onto the *Pioneering Spirit* are predicted to result in considerable release at the lifting locations (Biofouling Solutions, 2026a). Although long-spined sea urchins have been assessed as being unlikely to be present on the jacket structures at the time of lifting, if any are present on the jackets it is expected that a percentage of these will likely be dislodged at the lifting location due to the movement forces associated with the lifting activity.

Transit times for jackets within the OA will vary between locations and sea state conditions experienced at the time however transits and transfer operations are expected to take between two and ten days from the structures being lifted from the water until the HTV or barges exit the OA for onward transport to the ORC (Biofouling Solutions, 2026a). Minimal (if any) release of marine growth will occur from the PCA, DPA, and WTA jackets since they will be entirely inboard while loaded onto the HLV; however more marine growth will be released to the water during transit and transfer activities from the other jacket sections if these are transported on the HLV jacket lifting system.

Campaign #1 activities are scheduled to occur during spring and summer, when temperatures are warm and sea breezes are frequent. This is beneficial in that both can accelerate rates of desiccation of biofouling organisms and reduce survival periods for marine growth (Biofouling Solutions, 2026a), hence reducing the likelihood that native species will enter the water alive. A literature review did not identify mortality data for *C.rodgersii* however similar species of urchins *Tripneustes gratilla* and *Heliocidaris erythrogramma* were noted to have a 0 - 20% mortality following 24 hours at 12°C but 100% mortality at 27°C. (Bennett, Mos, & Dworjanyn, 2024) Additionally it has been concluded in the study undertaken that if long-spined sea urchins were present on the jacket structures it would be expected they would depart or drop off the jackets within one day of their removal from the sea (Biofouling Solutions, 2026a).

The study assessed that if long-spined sea urchins or jewel anemone were released by dropping off the structures in proximity (less than 10km) of natural reefs within the OA, or close to the southwestern boundary of the OA (the sheltered area used as an example of where transfer will most likely take place) and within 24 hours (for long-spined sea urchins) and 48 hours (jewel anemones) of removal from the sea, anemones and urchins could conceivably survive and become established (Biofouling Solutions, 2026a). Given that the two native species of interest identified have a preference for hard substrate environments, the boundary of the OA has been established to avoid transit over the main nearshore reef areas (refer to Figure 3-1).

The vast majority of the OA is characterised as sandy flats/bare substrate and is not considered suitable habitat for the jewel anemone or the long-spined sea urchin. Areas of hard substrate within the OA are largely limited to other anthropogenic structures (where exposed) and the patchy outcrops associated with the South East Reef (adjacent to FTA, CBA and HLA). These areas have likely been exposed to the potential establishment of the long-spined sea urchin in the past as this species has been recorded in the broader region for several decades.

The likelihood of the translocation and successful establishment of long-spined sea urchin and the jewel anemone as a result of the removal, transit and transfer activities has been conservatively assessed as **Likelihood Category C** (unlikely) for both species, for the long-spined sea urchin due to the activities occurring within its reproduction and spawning season and for the jewel anemone based on the fact that survival rates for this species when removed from the water are more uncertain (Biofouling Solutions, 2026a).

For Campaign #1 activities to result in the spread of range expanding native species to habitats in or adjacent to the OA, two dependant events (the presence of the native species on the removed infrastructure and the survival and establishment of the species in the new location) would need to occur. Hence the likelihoods assessed for both of these events have been multiplied to arrive at the likelihood of this event occurring, which is **Likelihood Category E** (very highly unlikely) for the long-spined sea urchin, and **Likelihood Category C** (unlikely) for the jewel anemone.

7.3.3.2.3 RELEASE AND ESTABLISHMENT VIA BALLAST WATER DISCHARGE

Vessels will take up and discharge ballast water within the OA throughout the Campaign #1 activities. Consideration of the probabilities of (i) the presence of the species on the jackets (refer to Section 7.3.3.2.1), and (ii) larvae, spores, fragments, or individuals being released into the water surrounding the platforms during lifting of topsides or jackets, and (iii) this material being taken up with ballast water if released, and (iv) survival and local

establishment if taken up in ballast water and released indicated that the likelihood of ballast water operations spreading the jewel anemone within the OA is **Likelihood Category D** (very unlikely) and for the long spined sea urchin this likelihood was **Likelihood Category E** (very highly unlikely)**.** The higher likelihood for the jewel anemone is based on their abundant presence on the jackets and their ability to reproduce by fragmentation (Biofouling Solutions, 2026a) .

The risk of the Campaign #1 activities spreading the jewel anemone within or adjacent to the OA has been assessed as Risk Category 3 and for the long spined sea urchin Risk Category 4 for both biofouling and ballast water pathways.

7.3.4 Demonstration of As Low As Reasonably Practicable

Table 7-14 Decision Context and justification

Decision Context
The removal, transit and transfer of structures and the associated risk of the translocation of native species is an infrequent or non-standard activity in the geographical area The risk is amenable to assessment using well established data and methods (this has been undertaken). The environmental consequence of the impacts resulting from the translocation of native species assessed as **Consequence Level II** or **Consequence Level III**. The risk of the translocation of native species has been assessed as **Risk Category 3** or **Risk Category 4**. Some stakeholder interest has been noted with regard to the translocation of native species as a result of the Campaign #1 activities. Hence, Esso believes **Decision Context B** should apply.

Table 7-15 Good practice controls

Good practice	Adopted	Control	Rationale
None identified			

Table 7-16 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
Removal of all marine growth at location of current platform.	Removed marine growth remains at original location.	Substantial marine growth cannot feasibly be removed because of restricted access to structural members internally positioned within each jacket; inability to work effectively in splash zone and more complex safety considerations based on the nature and scale of removal.	Not adopted
Collection of marine growth that falls on the HLV vessel deck and transfer onshore for appropriate disposal.	Reduces the risk of the spread of native species to nearshore reef areas by reducing the amount of marine growth discharged to the marine environment.	Marine growth that falls to the deck of the HLV while jacket structures are being transported or transferred to a HTV or barge will be aggregated on deck where it is safe and practicable to do so. This marine growth will be returned to the sea as close as practicable to the next removal location. Where the marine growth can be returned to a similar location to where it came from, the risk of the spread of native species to nearshore reef area where they could potentially establish is mitigated. The IMS study undertaken and discussed in Section 7.4 also concluded that the likelihood of the long-spined sea urchin being present on	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
	Feedback from Parks Victoria during relevant person consultations suggested a potential mitigation measure of minimising the marine growth that falls to the sea during removal and transit. While noting this was suggested in the context of potential mitigation measures for the introduction or spread of IMS, this is considered equally applicable to the risk of the translocation of native species.	the jacket structures is very unlikely. Hence the environmental benefits of transferring all of the collected marine growth onshore for disposal is not considered to outweigh the cost and potential onshore impacts such as nuisance odour and the need to landfill or compost the marine growth which would arise as a result of onshore storage and disposal.	
Minimise the amount of marine growth falling off during **removal** of structures	Parks Victoria suggested this potential mitigation measure during relevant person consultation for this EP. While noting this was suggested in the context of potential mitigation measures for the introduction or spread of IMS, this is considered to be equally applicable to the translocation of native species.	It is considered the majority of marine growth loss to sea will occur when the jacket is cut and lifted, hence will remain at the location where the jacket was removed from. Given the size of the jacket sections to be cut and lifted, potential actions to contain or minimise the amount of marine growth lost during activities at the removal locations are not practicable. Given the marine growth is falling within the location from which it was taken from, the release of marine growth at the removal locations does not pose a risk of native species translocation.	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
Minimise the amount of marine growth falling off during **transport** of structures	Feedback from Parks Victoria during relevant person consultation suggested a potential mitigation measure of minimising the marine growth that falls to the sea during removal and transit. While noting this was suggested in the context of potential mitigation measures for the introduction or spread of IMS, this is considered to be equally applicable to the spread of native species.	<u>During transport of structures from removal locations to the transfer location:</u> The structures will be transported from the removal locations to the transfer location either on the deck of the HLV (if the 5000 tonne crane is used to lift the jacket sections) or on the HLV JLS (refer to Section 2.8.1and 2.8.2). Minimisation of marine growth falling to the sea from the jacket sections which will be transported on the JLS and overhang the vessel is not technically feasible for the reasons outlined in Section 6.12.1. However minimisation of the amount of marine growth released to the marine environment along the transport route will be undertaken by aggregating any fallen marine growth on the HLV deck where this is safe and practicable to do so and returning this to the sea at the next removal location (RSK3-CM1). <u>During transport of structures from the OA to the onshore reception centre at BBMT:</u> As depicted in Figure 6-4, during transport from the sheltered water transfer location to BBMT via a HTV (or barges which are not shown in Figure 6-4), jacket sections will be loaded longitudinally. This alignment minimises the 'overhang' of the jacket sections from the side of the vessels, hence limiting the loss of marine growth to the environment during transport from the transfer location to BBMT (RSK3-CM2). Marine growth that collects on the deck of the barges/HTV during transit from the transfer area to BBMT will be collected, where safe to do so, and taken onshore for composting or disposal in accordance with EPA Victoria regulations. Residual marine growth that cannot be collected will be washed off the deck to ensure a safe working environment for crew (RSK3-CM3).	Adopted RSK3–CM1 RSK3-CM2 RSK3-CM3
Return marine growth back to its original location	This feedback was provided by DCCEEW Sea Dumping team during relevant person consultation for this EP and has been considered as part of the ALARP assessment.	It is considered the majority of marine growth loss to sea will occur when the jacket is cut and lifted, hence will remain at the location where the jacket was removed from. Returning marine growth aggregated on the deck of the HLV to as close as practicable to the actual site where the jacket was removed from was considered as part of this ALARP assessment. However, this was not adopted for the following reasons: • returning to the same removal location to discharge the marine growth is not practical given the limited HLV execution window in which the Campaign #1 activities must be undertaken and may result in the entirely of the scope not being completed	Partially adopted – RSK3-CM1

Control measures	Benefit	Cost/feasibility	Adopted
		• evidence from pre decommissioning surveys that the marine biota present on the Campaign #1 jacket sections to the removed in deeper waters is similar • the likelihood of the presence of the long-spined sea urchin on the jacket structures being assessed as Likelihood Category D (very unlikely). As a result, the environmental benefits of the return of collected marine growth to the location where it was removed from are not considered to outweigh the cost and logistical impacts of implementing this control. Aggregated marine growth will instead be returned to the sea as close as practicable to the next jacket removal location (RSK3-CM1). The exception to this is marine growth from the PCA/DPA locations, where the marine biota assemblages have been observed to be different to those seen at other jacket facilities and these facilities are closer to nearshore reef areas. Marine growth sourced from the PCA/DPA locations will either be returned to the PCA/DPA removal locations, or if this is not possible, taken onshore for disposal. No marine originating from other facilities will be returned to the PCA/DPA locations.	
Avoidance of Key Ecological Features – i.e. hard substrate and shelf rocky reefs as defined in the South-east marine regional profile (DoE, 2015a) which are present in the OA - during transit activities	Minimises the chance of native species released in marine growth establishing and impacting habitat values associated with the KEF.	KEFs located in the OA are depicted in Figure 3-7. There are two KEFs that occur in the OA: • the Upwelling East of Eden which is located to the far east of the OA. The location of this feature in relation to the facilities to be removed means it is very unlikely transit activities will occur within or near this KEF. • a KEF referred to as 'shelf rocky reefs and hard substrate' which is referenced in the South-east marine regional profile (DoE, 2015a), but is not mapped. Locations where hard substrate and rocky reefs which are considered to fall within the definition of this KEF are depicted in Figure 3.7 based on literature, publicly available data and Esso offshore environmental survey results. No other KEFs are present in the OA. The FTA SPJ is located within the area known as South-east reef (which meets the definition of the shelf rocky reefs/hard substrate KEF) while CBA and HLA are located immediately adjacent. Hence avoidance of this feature during transit of the FTA jacket is not feasible. Avoiding transit over South-east reef is also not practicable for CBA and HLA as this would result in the need for the HLV to transit via a protracted, indirect route to the transfer location with a jacket onboard.	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
		Marine growth released during transit within the South-east reef is likely to be alive, given the short timeframe from removal of the jacket and transit through this feature. However given the proximity of the jackets to this feature (in the case of FTA within the mapped extent), it is unlikely this will result in any appreciable impacts to the habitat within the KEF, as the species likely already exist at this location, or if conditions at the release duration are significantly different to those provided by the jacket structures, will be unable to survive and establish. While known areas which meet the definition of hard substrate and rocky reefs KEF are depicted in Figure 3-7, other areas of hard substrate/rocky which have not been mapped may also be present within the OA. The discharge of marine growth during transit to the transfer area is expected to be spread over a wide area as the HLV travels and will be widely dispersed in the marine environment. Establishment of any native species present within the marine growth to an extent that would result in impacts to the values of unmapped areas of hard substrate is considered very unlikely, as this would require a number of conditions to be met, with each successive stage becoming more unlikely. Jacket sections will either be fully inboard or be placed on a HTV or barge longitudinally for transport from the transfer location to the boundary of the OA (and onward to BBMT) – refer to RSK3-CM2. This minimises the loss of marine growth to the environment during this activity. Avoidance of all hard substrate areas which meet the definition of the shelf rocky reefs and hard substrates KEF in the OA would require an extensive exercise of seabed surveying across the OA to identify and map all areas of hard substrate for inclusion into vessel systems and/or the use of 'real time' methods during the execution campaign to identify hard substrate as the HLV is in transit. As the risk of the translocation of native species has been assessed as Risk Category 3 or Risk Category 4 the avoidance of KEFs (in particular the shelf rocky reef/hard substrate KEF) during transit activities undertaken in the OA is not considered to result in a reduction to the risk of the translocation of native species that would outweigh the cost, practicality and schedule implications resulting from implementing this control. Hence it has not been adopted.	
Avoidance of Key Ecological Features -i.e. hard substrate and shelf	Minimises the chance of any RES released within marine growth establishing in other areas of the OA.	Mapped areas of hard substrate and rocky reefs which meet the definition of the 'hard substrate and rocky reef are present within the proposed primary transfer area (refer to Figure 6-5). Mobile species present in the marine growth on the jacket structures is predicted to depart or drop off within 1 day of removal from the sea (Biofouling Solutions, 2026a), hence	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
rocky reefs as defined in the South-east marine regional profile (DoE, 2015a) which are present in the OA - during transfer activities		they are very unlikely to still be present on jacket structures when they arrive at the primary transfer location. The rate of release of marine growth is expected to be highest during removal activities at the facility locations and then decrease during transit and transfer. The marine growth will be exposed to air for periods between 2 and 10 days prior to their departure from the transfer area and hence organisms such as jewel anemones, encrusting sponges and colonial ascidians will have desiccated considerably and may form a leathery layer from which gradual but highly reduced release will occur (Biofouling Solutions, 2026a). Given the reduced likelihood of the marine growth being present (mobile species) or viable (sessile species) by the time the jacket structures arrive at the transfer location, a potential change to the habitats in this area as a result of marine growth discharge is considered unlikely. Avoidance of these areas will restrict the HLV from selecting the most appropriate location based on the conditions, to undertake transfers safely and efficiently. The HLV size, coupled with the HTV/barge and support vessel spread present during transfer operations makes avoidance of all hard substrate (mapped or unmapped) in the primary transfer area impractical. In order to avoid the mapped areas of hard substrate located in the east and west of the primary transfer area (refer to Figure 3-7) transfers may (depending on weather conditions) need to occur closer to sensitive environments in and around Corner Inlet (refer to Figure 2-46) in preference to the southern end of the primary transfer area which is more exposed. The risk of the Campaign #1 activities spreading the jewel anemone within or adjacent to the OA has been assessed as Risk Category 3 and for the long spined sea urchin Risk Category 4 for both biofouling and ballast water pathways. The study undertaken to assess these risks included consideration of the presence of hard substrate areas in and adjacent to the OA. Given these lower assessed risks, any reduction to the risk of the spread of native species potential environmental impacts as a result of this measure are not considered to outweigh the cost, practicality and schedule implications, hence it has not been adopted.	
The use of pre activity surveys or vessel sounders to identify hard substrate or rocky reef areas, which would fall within the	Allows identification of areas considered to fall within the definition of the shelf rocky reefs and hard substate KEF, for avoidance during transit and	As discussed above, the avoidance of areas which may fall within the definition of the shelf rocky reefs and hard substrate KEF during transit or transfer operations has not been adopted. The implementation of this measure is not considered to result in a reduction of the risk of the spread of native species which would outweigh the resulting cost, practicality and schedule implications. In particular, the implementation of 'real time' identification methods and subsequent avoidance of hard substrate will impact the ability for the removals work to be completed,	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
definition of the KEF as defined in the South-east marine regional profile (DoE, 2015a).	transfer/mode change activities.	with no material change to the risk of the translocation of native species. The HLV size and weight with structures onboard also restrict the ability of the vessel to pivot and change location to avoid hard substrate areas - if identified in real time during transit. The adoption of measures such as pre activity surveys or the use of vessel equipment to identify potential unmapped areas of hard substrate and rocky reefs, which may fall within the definition of the KEF for avoidance is not proposed for the Campaign #1 activities, given the practicality considerations and the fact that avoidance of such areas is not proposed.	
Treatment of marine growth with biocides.	Marine growth mortality to eliminate potential translocation of living specimens.	Treatment can only be facilitated once jackets are lifted. The jacket size and lack of access make application of biocide unfeasible. Application also has safety challenges due to the size of the jackets.	Not adopted
Suspension of jackets out of water at removal location for prolonged periods of time.	Dried marine growth that falls off remains at original location.	Safe lifting of a live load such as this will be completed under a strict weather window and requires jackets to remain suspended for the shortest achievable time. Remaining offshore with a load on slings is not an acceptable safe practice globally.	Not adopted

7.3.5 Demonstration of acceptability

Table 7-17 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 3** (jewel anemone) or **Risk Category 4** (long-spined sea urchin) and is therefore considered acceptable.
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack	✓	Not inconsistent. The habitat with the potential to be impacted is characterised by soft

Factor	Demonstration criteria	Criteria met	Rationale
	of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.		sediment and shell/rubble seabed. A study has been undertaken with third-party experts to better understand and assess the risk associated with this aspect. It is not considered that there is significant scientific uncertainty associated with this aspect.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The risk of translocations of native species is unlikely to result in a detrimental effect on the overall population of any of the species assessed and will not impact upon the environment such that future generations cannot meet their needs.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	There are no prescriptive legislative requirements concerning the translocation of range-expanding native species.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"*
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements.

Factor	Demonstration criteria	Criteria met	Rationale
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Parks Victoria feedback has been incorporated into the risk assessment. Although this feedback was provided in the context of potential mitigations for the introduction and spread of IMS, the feedback is considered to be equally as application to the risk of translocation of native species.

7.3.6 EPOs, control measures, EPSs and measurement criteria

Table 7-18 EPOs, control measures, EPSs and measurement criteria – Translocation of native species

EPO	Control measure	EPS	Measurement criteria
RSK3-EPO1: No translocation of native species within the OA or to adjacent areas.	RSK3-CM1: Marine growth which falls on the deck of the HLV will be returned to the sea as close as practicable to the next removal location.	RSK3-EPS1.1: Marine growth that falls on the HLV vessel deck in accessible areas will be aggregated and held onboard prior to returning to sea as close as practicable to the next removal location. Marine growth originating from the PCA/DPA monopods will only be returned to the PCA/DPA removal location, or will be transferred onshore for disposal. No marine growth originating from other facilities will be returned to the PCA/DPA locations.	RSK3-MC1.1.1: Standard Operating Procedure as referenced within Allseas EMP and PCA and DPA lift plan. RSK3-MC1.1.2: Marine growth management/discharge log.
	RSK3-CM2: Jacket structures will either be fully inboard or placed onto HTVs or barges longitudinally (lengthways) to ensure there is minimal overhang of the structures outside of the vessel.	RSK3-EPS2.1: Inboarding or longitudinal placement of removed jacket sections will be undertaken to minimise the potential for marine growth to drop to the marine environment during transit from the transfer location to BBMT.	RSK3-MC2.1.1: Transfer procedures include the requirement for jacket structures to be inboard or placed longitudinally. RSK3-MC2.1.2: Jacket grillage on HTVs/barges installed (as built) for inboarding or longitudinal placement.
	RSK3-CM3: Marine growth that falls on HTVs/barges	RSK3-EPS3.1: Marine growth that collects on the deck of HTVs/barges during transit from the	RSK3-MC3.1.1: Marine growth management/discharge log. RSK4-MC3.1.2: Waste disposal records demonstrate waste was transferred

	during transit from the transfer area to BBMT will be collected, where safe to do so, and taken onshore.	transfer area to BBMT will be collected, where safe to do so, and taken onshore for composting or disposal in accordance with EPA Victoria regulations. Residual marine growth that cannot be collected will be washed off the deck to ensure a safe working environment for vessel crew.	onshore and disposed of in accordance with regulatory requirements.

7.3.7 Residual risk ranking

Table 7-19 Residual risk ranking outcome

Species	Consequence Level	Likelihood Category	Risk Category
Spread via loss of marine growth from jackets			
Jewel anemone	III	C	3
Long-spined sea urchin	II	E	4
Spread via ballast water discharge			
Jewel anemone	III	D	4
Long-spined sea urchin	II	E	4

7.4 Introduction or spread of Invasive Marine Species

7.4.1 Causes of the introduction or spread of Invasive Marine Species

An IMS is a species occurring as a result of human activities, beyond its normal distribution and which threatens valued environmental, agricultural or other social resources by the damage it causes (DCCEEW, 2021d). Not all non-indigenous marine species introduced into new environments will cause demonstrable effects, some are relatively benign, and few have spread widely beyond ports and harbours.

Vessels are the primary transport vector for the introduction or translocation of IMS, which is comprised of several sub-vectors, such as (Hewitt CL and Campbell ML, 2010):

- biofouling on the hull, sea chests, propeller, rudder, exposed surfaces of water piping, thruster tunnels and other niche areas
- the boring of organisms into the structure of the vessel (primarily limited to wooden hulled vessels)
- the uptake of organisms in association with wet or dry ballast

Several vessels will need to relocate to Bass Strait to facilitate the execution of Campaign #1. These vessels may come from elsewhere within Australian waters or be mobilised from overseas such as in the case of the *Pioneering Spirit* HLV. As a result, the following Campaign #1 activities have the potential to result in the introduction of IMS to the OA from other areas outside the OA:

- biofouling of vessel hulls and niches
- discharge of ballast water from Campaign #1vessels

- the transit of barges or HTV from BBMT back to the OA following offloading of jacket sections at the ORC.

The following Campaign #1 activities have the potential to result in the spread of IMS within the OA or to areas adjacent to the OA:

- biofouling of vessel hulls and niches
- biofouling of immersible retrievable equipment (e.g. ROVs)
- discharge of ballast water from Campaign #1 vessels
- transport of the removed jacket sections through the OA to a transfer area, their subsequent transfer to a barge or HTV and onward transit to the OA boundary, if the following conditions are met:
    - IMS are present on the removed infrastructure
    - viable IMS are released to the marine environment during transport or transfer activities
    - released IMS survive and find suitable habitat to allow establishment in the area.

Desktop-based studies have been undertaken for the Campaign #1 activities with the objective of evaluating the likelihood and consequence of the spread of IMS, HMOs, and range-expanding native species during Campaign #1 activities. The first study (Biofouling Solutions, 2026a) considered the potential spread of IMS from activities undertaken within the OA, while the second study evaluated the risk of the spread of IMS as a result of Campaign #1 activities undertaken within Victorian State Waters (outside the OA) (Biofouling Solutions, 2026b). These studies have been used to inform this risk assessment, with the second study relevant for the assessment of the potential pathway of introduction of IMS to the OA via the transit of barges or HTV from BBMT back to the OA following offloading of jacket sections. While the spatial extent of the second study was Victorian State Waters, the study considered habitats in the immediate vicinity of the primary transfer area (refer to Figure 2-46), hence the study results are considered appropriate to inform this risk assessment.

To achieve the objective of the IMS studies, the following steps were undertaken:

- identification of the IMS and HMOs that should be included in the assessment
- identification of the potential mechanisms for the spread of IMO or HMOs via the Campaign #1 activities
- determination of the likelihood of the IMS or HMO presence on the Campaign #1 facilities, using multiple lines of evidence
- determination of the likelihood of the release of IMS or HMOs within the OA during Campaign #1 removal, transport and transfer activities – via the release of marine growth present on the facility jackets or via vessel ballast water discharges. The IMS studies assumed as a basis that any vessels involved in the removal and transfer activities posed no legacy biofouling risk as such risks would be mitigated by legislative compliance with the *Biosecurity Act 2015* (Cth) and Esso IMS risk assessment procedure
- determination of the likelihood of the establishment (following release) of IMS or HMOs within or adjacent to the OA
- determination of the ecological consequences of any spread of IMS or HMOs within the OA
- using the likelihood and consequences identified, assessment of the overall risk of the Campaign #1 activities spreading IMS and HMOs within and adjacent to the OA.

The spatial area considered within the first IMS study was the entirely of the OA, however particular focus was given to the southwestern part of the OA (refer to Figure 2-2). Given the presence of natural reef and hard substrate areas around Wilson Promontory (outside of the OA) and the potential for transfer operations to be undertaken in this sheltered water area, this was considered to represent a 'worst case' location to assess the risk of the spread of IMS as a result of Campaign #1 activities.

This Section of the EP discusses the methodology and conclusions of these studies in relation to IMS and HMOs, Section 7.3 addresses range-expanding native species. Where 'IMS study' is stated, this is in reference to the first study undertaken for activities within the OA (Cmth Waters). The second study is referred to as the 'Victorian State Waters IMS study' and is discussed in Section 7.4.3.2.3.

All HMOs were assessed to be highly unlikely to be present on the platform jackets and were thus excluded from further assessment (Biofouling Solutions, 2026a).

7.4.2 Risks of introduction or spread of Invasive Marine Species

The introduction or spread of IMS within the OA through vessel biofouling, ballast water discharge or the transport of removed infrastructure has the potential to result in:

- change in ecosystem dynamics
- changes in the functions, interests or activities of other users.

7.4.3 Risk assessment

7.4.3.1 Consequence evaluation

IMS are likely to have little or no natural competition or predators, thus potentially outcompeting native species for food or space, preying on native species, or changing the nature of the environment. Once established, some pests can be difficult to eradicate (Hewitt, et al., 2004) and therefore there is the potential for a long term or persistent change in habitat structure. It has been found that highly disturbed environments (such as marinas) are more susceptible to colonisation than open-water environments, where the number of dilutions and the degree of dispersal are high (Paulay, Kirkendale, Lambert, & Meyer, 2002).

The benthic habitat within the OA is characterised by a soft sediment and shell/rubble seabed, infauna communities, and sparse epibiotic communities (typically sponges). The South-east Marine Region profile also identifies 'shelf rocky reefs and hard substrates' as a KEF within this region, due to the high productivity and aggregations of marine life associated with these seabed features. These areas are located throughout the South-east marine region in water depths from the sub tidal zone up to the continental shelf break (which generally occurs between approximately 150m – 220m) – but have not been mapped.

The southwestern corner of the OA, which is a sheltered water location where transfer of removed infrastructure from the HLV to a barge or HTV may occur, is adjacent to Victorian State waters where Seal Islands and Wilsons Promontory have extensive subtidal reef habitat. Parks Victoria provided feedback during relevant person consultation for this EP that a key concern relating to National Parks adjacent to the OA such as Wilsons Promontory was the transport of marine pests as a result of Campaign #1 activities. There are also nearshore reefs located along the northern boundary of the OA. Given the predominant habitat preference for the majority of the IMS identified in Table 7-25, these shallower water environments are considered to be more conducive to the establishment of IMS and impacts as a result of this establishment and hence have driven the consequence assessment of this risk assessment.

Marine pest species can also deplete fishing grounds and aquaculture stock, with between 10% and 40% of Australia's fishing industry being potentially vulnerable to marine pest incursion. For example, the introduction of the northern Pacific seastar (*Asterias amurensis*) in Victorian and Tasmanian waters was linked to a decline in scallop fisheries (Dommisse & Hough, 2004). Similarly, the New Zealand screw shell thought to have been introduced on dry ballast or through the live oyster trade, may threaten other mollusc species, including scallops. The New Zealand screw shell can densely blanket the seafloor with live and dead shells, and faecal pellets and therefore also smother other seafloor species (ABC, 2000). Marine pests can also damage marine and industrial infrastructure, such as encrusting jetties and marinas or blocking industrial water intake pipes. By building up on vessel hulls, they can slow the vessels down and increase fuel consumption.

The IMS studies undertaken identified a set of marine species that, based on the impacts they have caused internationally and/or are able to cause in Australian waters, have been identified as high-risk organisms by the Commonwealth and/or State governments and whose transfer and introduction into Commonwealth or State/Territory waters is prohibited by law (Biofouling Solutions, 2026a). These include marine species listed on:

- *The Australian Priority Marine Pest List* (DAFF, 2025a)
- *The National Priority List of Exotic Environmental Pets, Weeds and Disease* (DAFF, 2025b)
- listed as 'noxious' under Section 75 of the *Fisheries Act 1995* (Vic)
- selected other non-indigenous species that are not included in the lists above but have been considered as high-priority pests in the past and of which there are established populations in eastern Victoria and/or northern Tasmania.

Surveys undertaken by DEECA and Esso, as well as a review of scientific and technical literature was also used to identify potential IMS which may be present around BBMT and Corner Inlet for consideration in the assessment of the risk of the spread of IMS from BBMT to the OA.

The species assessed in detail in the IMS study (Biofouling Solutions, 2026a) and the Victorian State Waters IMS study (Biofouling Solutions, 2026b) and the potential environmental consequences of these species are described in Table 7-20.

Table 7-20 Review of environmental impacts of studied IMS (adapted from (Biofouling Solutions, 2026b)

Species	Type	Worst case environmental impacts (OA and adjacent areas)
Codium fragile spp. Fragile Dead mans fingers	alga	Very low to low; minor impacts on rocky reefs and seagrass
Undaria pinnatifida Japanese seaweed	alga	Very low to low; no consistent impacts observed in other invaded locations
Arcuatula senhousia Asian date mussel	mussel	Very low to moderate; may form mats in soft-sediments and seagrass
Maoricolpus roseus New Zealand screw shell	gastropod	Very low to high; potential for dense populations displacing native macroinvertebrates in soft-sediment habitats
Magallana gigas Pacific oyster	oyster	Very low to moderate; competition and displacement in intertidal/shallow rocky habitats
Sabella spallanzanii Mediterranean fanworm	worm	Very low to moderate; competition in soft sediments, low reef impacts
Carcinus maenas European shore crab	crab	Very low to low; long established in Australia with no consistent local impacts
Hemigrapsus sanguineus Asian shore crab	crab	Very low to moderate; predation/competition in saltmarsh and rocky reefs
Asterias amurensis Northern Pacific seastar	Sea star	Very low to moderate; predation on bivalves and benthic species
Acanthogobius flavimanus Yellow fin goby	fish	Very low to moderate; competition/predation on estuarine fish
Tridentiger trigonocephalus Chameleon goby	fish	Very low to low; limited to artificial structures
Spartina anglica Cordgrass	grass	Very low; absence of suitable saltmarsh habitat in or adjacent to OA
Grateloupia turuturu Devils tongue weed	alga	Low; no significant adverse impacts documented
Petalonia binghamiae Brown macroalgae	alga	Very low; favours enriched estuaries, unlikely in exposed habitats

The IMS study concluded the following in relation to the ecological consequences if any of the IMS assessed were to establish within, or adjacent to the OA as a result of the Campaign #1 activities (Biofouling Solutions, 2026a);

- if the IMS examined were to become established within the OA and nearby shallow-water environments, they will likely persist for years
- given the high-energy offshore and wave-exposed nearshore environments, and the presence of diverse existing biological assemblages, IMS are considered to remain relatively localised and cause minor to moderate ecological change
- examples provided in the IMS study that that confirm this pattern include A. *amurensis* and *M. gigas,* which are both widely distributed IMS that have caused considerable impacts in some invaded locations around Australia. However, both only reach high abundance in sheltered environments and areas of high food concentrations, such as in estuaries and embayments, and around aquaculture facilities and developed coastlines. In contrast, they occur at low densities in more exposed environments where propagules are dispersed more widely and critical resources more limited (Biofouling Solutions, 2026a)

If an IMS was introduced to the OA or spread as a result of Campaign #1 activities or the ongoing management of partially removed facilities, and if it did colonise an area, it is expected that any colony would remain relatively localised and cause minor to moderate impacts to the habitats in and adjacent to the OA. Therefore, the consequence has been assessed as:

- **Consequence Level III**.

7.4.3.2 Likelihood evaluation

7.4.3.2.1 INTRODUCTION OF IMS TO THE OPERATIONAL AREA

Vessels may pose a risk of introducing IMS to the OA through ballast water and hull biofouling.

The introduction of IMS is recognised globally as a threat to marine biodiversity, and the IMO has developed guidelines (IMO, 2023) for managing biofouling and ballast water. Commonwealth, State and Territory authorities also regulate the risk of IMS from biofouling and ballast water. Vessels operating in Australia are required to meet these requirements, and vessels meeting these requirements pose a much lower risk of harbouring IMS or releasing IMS into the environment.

In accordance with the Australian biofouling management requirements, Campaign #1 vessels arriving from beyond Australia and entering the Australian territorial sea will report biofouling management actions prior to arrival through the mandatory pre-arrival report, which is reported through Department of Agriculture, Fisheries and Forestry Maritime and Aircraft Reporting System. The vessels will be cleared by DAFF by either an inspection onboard conducted by a biosecurity officer at the first port of entry or by DAFF granting clearance based on pre-agreed entry requirements.

Compliance with regulatory requirements for the management of biofouling and ballast water and ensuring all vessels are assessed as posing a low biofouling risk through an IMS risk assessment in accordance with national guidelines will significantly reduce the likelihood of the introduction of an IMS into Bass Strait.

Given these requirements must be met, it is considered **Likelihood Category D** (very unlikely) that IMS would be introduced to the OA via the Campaign #1 activities or the ongoing management of partially removed facilities.

7.4.3.2.2 SPREAD OF IMS WITHIN THE OPERATIONAL AREA OR TO ADJACENT AREAS

As outlined in Section 7.4.1 above, an IMS study was undertaken to assess the likelihood of the Campaign #1 activities resulting in the spread of IMS within the OA or to adjacent areas. This IMS study has informed the likelihood assessment described in the following Sections.

IDENTIFICATION OF POTENTIAL IMS

As discussed above, the IMS study identified a list of marine species that have been identified as high risk organisms. The IMS study also identified two marine HMOs that are the causal agents of disease for valuable natural fishery and aquaculture species and that have been detected in Victoria, Tasmania, or South Australia. These are (Biofouling Solutions, 2026a):

- the abalone/haliotid herpesvirus, the causal agent for abalone viral ganglioneuritis been observed in Victoria in farmed and wild abalone. In Tasmania, the virus but not the disease has been detected in wild

abalone populations. However, the disease has been observed in Tasmanian abalone holding and aquaculture facilities. Abalone can occur as part of biofouling assemblages on artificial infrastructure

- ostreid herpes virus, the causal agent for Pacific oyster mortality syndrome, can result in dramatic losses of farmed oysters and several bivalve species are thought to be potential hosts or reservoirs. The first Australian case of Pacific oyster mortality syndrome was recorded in 2010 in New South Wales. Later outbreaks occurred in Tasmania (2016) and South Australia (2018). Oysters are common biofouling species and often dominant components of assemblages fouling artificial infrastructure.

MECHANISMS FOR THE SPREAD OF IMS

IMS could be spread as a result of the Campaign #1 activities via the following mechanisms:

- the potential presence of IMS/HMOs within marine growth on jackets targeted for removal. An estimate of the likelihood of IMS/HMO presence was determined based on multiple lines of evidence. Marine growth which is present on the jacket structures will be discharged to the sea during the Campaign #1 activities - refer to Section 6.12.
- The settlement onto and then release of organisms or fragments from vessel hulls during the return transit of vessels to the OA following offloading of the removed structures at BBMT
- Campaign #1 vessels taking part in the lifting and transfer of jackets will need to take on and/or discharge ballast water during the decommissioning activities

LIKELIHOOD OF IMS BEING PRESENT ON THE JACKET STRUCTURES

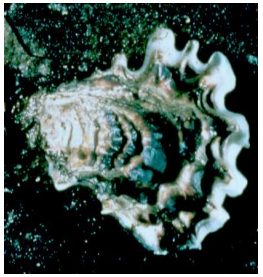
The IMS study drew on multiple lines of evidence to undertake an assessment of the likelihood of the identified IMS and HMOs being present on the jacket sections to be removed during Campaign #1, including:

- hydrodynamic modelling and literature on propagule dispersal in Bass Strait and surrounding regions to assess the potential for the arrival of IMS or HMOs via ocean currents
- archived Automatic Identification System (AIS) data on vessel movements and port call histories between 2022 - 2024 to assess the potential for historical arrival of target species via vessel biofouling and ballast water discharge
- review of visual survey data collected on and around the platforms during Environmental Survey 1 (Summer) and Environmental Survey 2 (Winter) during 2021-2022
- review of extensive ROV footage (over 500 videos) from structural surveys undertaken at the Campaign #1 facilities by Esso during the period 2020-2024 by an experienced biosecurity scientist and IMS inspector. Footage from all Campaign #1 facilities was reviewed as part of this exercise and included examinations of all major structure types (i.e. jacket legs, risers, J-Tubes, well conductors and guides, skimmer piles, utility services infrastructure (e.g. sanitary water overboard, firewater services, service water conductors), caissons, tank piles and members, anodes, joints, welds, nodes, rows, tripods, and PCA and DPA gravity bases. Footage from platforms not targeted for removal was also undertaken to build a broader understanding of potential IMS (or RES) presence across the Bass Strait assets and examination of high resolution still images of fenders removed from FTA in early 2025 (large structures with visible biofouling) was carried out.

The analysis focused on the area from the waterline to approximately 15m depth, which is the range where most of the target IMS would be expected to be encountered given their habitat preferences and usual depth distribution. However, as some species may occur at greater depths, numerous recordings were also examined that covered jacket legs and other structures down to the seabed. The quality of video footage was generally very good for all platforms except PCA, where due to insufficient lighting, it was not possible to identify certain species based on colour alone and inspection was based on other common morphological characteristics such as size, shape, appendages or other physical features (Biofouling Solutions, 2026a). The IMS inspector concluded with confidence that had the IMS species identified for consideration in the studies been present on the platform infrastructure, they would have been detected during the review of the over 500 ROV video recordings. The exceptions to this were the smaller and more cryptic IMS - *A. senhousia, H. sanguineus, A. flavimanus* and *T. trigonocephalus*. As a result, these species were assigned a conservative one step increase in likelihood of being present on the facilities to acknowledge this uncertainty.

IMS that were assessed via consideration of all of the lines of evidence above to be **Likelihood Category E** (very highly unlikely) to be present on the Campaign #1 facilities were then excluded from further assessment on the basis they:

- are biologically unable to reach the platform by ocean currents and/or
- are highly unlikely to have been transported there by vessel movements and/or
- have highly restricted established populations in southeast Australia, and
- were not detected during IMS-focused inspections of extensive survey footage from the facilities.

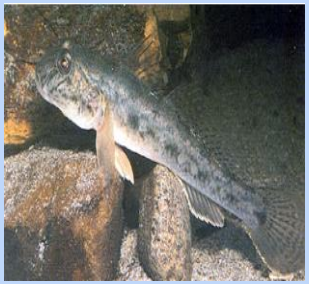


Neither of the two HMOs identified were carried forward for assessment as they were assessed to be **Likelihood Category E** (very highly unlikely) to be present on the facilities.

The assessed likelihoods of IMS species (that were taken forward for assessment) to be present on the jacket structures based on the multiple lines of evidence considered in the IMS study are provided in Table 7-25.

Table 7-21 Likelihood of species being present on Campaign #1 facilities (Biofouling Solutions, 2026a)

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
Codium fragile spp. fragile	Green alga 	Typically inhabits sheltered rocky shores and subtidal zones. Depth range: 0m – 15m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. • Arrival at facility locations theoretically possible via ocean currents or vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface area is occupied by jewel anemone and most of the remainder by sponges. While algae can grow on top of other organisms, jewel anemone possess venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers to colonisation and establishment on jacket structures exist.
Undaria pinnatifida	Japanese seaweed 	Usually found in sheltered, rocky areas. Depth range: Can be found to a depth of up to 25 m, but most common in subtidal habitats from 1-8 m depth.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. • Arrival at facility locations theoretically possible via vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface area is occupied by jewel anemone and most of the



Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
				remainder by sponges. This leaves very little space available for other species, particularly for self-sustaining populations able to survive long-term. While many algae and sessile invertebrates can grow on top of other organisms, jewel anemone possess venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers to colonisation and establishment on jacket structures exist
Arcuatula senhousia	Asian date mussel 	Normally found in muddy estuaries and bays, burrowing into the mud or sitting on top of it. Depth range: has been found from intertidal to subtidal habitats (to a depth of 20 m).	**Likelihood Category C** (unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage, however small size and cryptic nature makes this more uncertain. Hence a conservative one step increase in likelihood was made to acknowledge this uncertainty. • Arrival at facility locations theoretically possible via ocean currents or vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface area is occupied by jewel anemone and most of the remainder by sponges. This leaves very little space available for other species, particularly for self-sustaining populations able to survive long-term. While many algae and sessile invertebrates can grow on top of other organisms, jewel anemone possess

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
				venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers to colonisation and establishment on jacket structures exist.
Maoricolpus roseus	New Zealand screw shell 	Inhabits a wide range of substrates, from soft sediments to rock pools Depth range: 0 - 200m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. • Arrival at facility locations theoretically possible via ocean currents or vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • Barriers to colonisation and establishment on jacket structures exist. *M.roseus* predominantly lives within sandy and muddy substrates. It is not likely therefore the vertical jacket structures provide suitable habitat for establishment of this species.
Magallana gigas	Pacific oyster 	Usually attach to rocks, but can also be found in muddy or sandy areas, usually attached to shell fragments or small rocks. Depth range: 0 – 3m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. Mussels were identified, but the presence of *M.gigas* was ruled out following consultation with a recognised molluscan specialist. • Arrival at facility locations theoretically possible via ocean currents or vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
				area is occupied by jewel anemone and most of the remainder by sponges. This leaves very little space available for other species, particularly for self-sustaining populations able to survive long-term. While many algae and sessile invertebrates can grow on top of other organisms, jewel anemone possess venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers to colonisation and establishment on jacket structures exist.
Sabella spallanzanii	Mediterranean fanworm 	Generally found in shallow subtidal areas preferring harbours and embayments sheltered from direct wave action. Depth range: 1 – 30m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. • Arrival at facility locations theoretically possible via ocean currents or vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface area is occupied by jewel anemone and most of the remainder by sponges. This leaves very little space available for other species, particularly for self-sustaining populations able to survive long-term. While many algae and sessile invertebrates can grow on top of other organisms, jewel anemone possess venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
				to colonisation and establishment on jacket structures exist.
Carcinus maenas	European shore crab 	Sheltered estuaries and bays within the intertidal zone. Depth range: Found up to depth of 60 m, however crab numbers are greatly reduced past 20 m, and most adults are found around 6-7 m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. • Arrival at facility locations possible via ocean currents or vessels. • Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface area is occupied by jewel anemone and most of the remainder by sponges. This leaves very little space available for other species, particularly for self-sustaining populations able to survive long-term. While many algae and sessile invertebrates can grow on top of other organisms, jewel anemone possess venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers to colonisation and establishment on jacket structures exist.

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
Hemigrapsus sanguineus	Asian shore crab 	Intertidal, more rarely subtidal, rocky shores. Depth range: 0 – 0.4m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage, however small size and cryptic nature makes this more uncertain. Hence a conservative one step increase in likelihood was made to acknowledge this uncertainty • Arrival at facility locations possible via ocean currents or vessels. • Have small and isolated resident populations around mainland Australia and/or Tasmania, hence propagule pressure limited. • ROV surveys undertaken during Environmental Survey 1 (2021) and Environmental Survey 2 (2022) indicate that greater than 95% of the jacket surface area is occupied by jewel anemone and most of the remainder by sponges. This leaves very little space available for other species, particularly for self-sustaining populations able to survive long-term. While many algae and sessile invertebrates can grow on top of other organisms, jewel anemone possess venomous defense structures and hence likely minimise the potential for multi storey groups of organisms on the jacket structures. Hence barriers to colonisation and establishment on jacket structures exist.
Asterias amurensis	Northern Pacific seastar	Typically found in shallow waters particularly within estuaries and on mud, sand, silt or	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage. • Arrival at facility locations possible via ocean currents or vessels.

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
		rocky sheltered areas of intertidal zones - but has been observed in a range of habitats including rocky reefs and bedrock. Depth range: in its native Japan has been recorded at a depth of 200m. In Australia, is found in shallower (<25m) soft sediment habitats and reefs.		• Have extensive and widespread resident populations around mainland Australia and/or Tasmania. • Barriers to colonisation and establishment on jacket structures exist. Sea stars (including A. amurensis) are voracious predators that can be abundant on vertical structures where prey – in particular shellfish - is abundant. The dominance of jewel anemones and sponges (both non-preferred diet for sea stars) and the very limited presence of shellfish observed on the jacket structures suggest that the platform jackets/substructures do not represent a good habitat for predatory sea stars.
Acanthogobius flavimanus	Yellow fin goby 	Bottom dwelling fish that is found in riverine and estuarine areas. Mostly found on muddy substrata, but it does occur on clean sandy areas. Depth range: Up to 14 m.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage, however small size and cryptic nature makes this more uncertain. Hence a conservative one step increase in likelihood made to acknowledge this uncertainty • Arrival at facility locations possible via ocean currents or vessels. • Have small and isolated resident populations around mainland Australia and/or Tasmania, hence propagule pressure limited. • Barriers to colonisation and establishment on jacket structures exist. A.flavimanus is a benthic (bottom)

Species	Common Name	Habitat Preference (NIMPIS, 2026)	Likelihood of presence on jackets	Basis
				fish species which inhabits muddy and sandy bottoms and has a sedentary lifestyle. It is not likely therefore that the vertical jacket structures provide suitable habitat for establishment of this species.
Tridentiger trigonocephalus	Chameleon goby 	Commonly found in estuaries and rocky reef areas - prefers complex structures, often inhabiting mussel and oyster beds and artificial structures in ports and harbours. Depth range: Not described.	**Likelihood Category D** (very unlikely)	• Not identified during environmental surveys on facilities. • Not detected during IMS review of ROV footage, however small size and cryptic nature makes this more uncertain. Hence a conservative one step increase in likelihood was made to acknowledge this uncertainty. • Arrival at facility locations possible via ocean currents or vessels. • Have small and isolated resident populations around mainland Australia and/or Tasmania, hence propagule pressure limited. • Barriers to colonisation and establishment on jacket structures exist. *T.trigonocephalus* prefers estuarine mudflats, tidal creeks, and shallow bays with soft substrates. It is not likely therefore that the vertical jacket structures provide suitable habitat for establishment of this species.

LIKELIHOOD OF THE RELEASE AND ESTABLISHMENT OF IMS WITHIN THE OA - TRANSPORT AND TRANSFER OF JACKETS

As described in Section 6.12, marine growth which is present on the jacket structures will be lost to the marine environment during removal, transport and transfer activities. Although the likelihood of IMS being present on the jacket structures to be removed and transported has been assessed as unlikely or very unlikely (dependant on the species), the likelihood of IMS being spread within the OA or to adjacent areas, if they were in fact present within this marine growth discharge, was also assessed in the IMS Study.

The survival of IMS following their removal from the sea is influenced by physical variables such as air temperature and humidity and exposure to sunlight, wind and abrasion/disturbance (Biofouling Solutions, 2026a).

At the removal locations, the marine growth released during lifting will be discharged to the location from where it was sourced. As such there is not a risk of spread of IMS associated with this activity.

During transport activities, marine growth will be discharged to the marine environment due to the 'overhang' of the jacket sections when being transported on the JLS of the HTV. The PCA, DPA and WTA jackets will be fully inboard while transported on the HTV, hence the release of marine growth during this period will be less. Marine growth will be aggregated on the deck of the HTV and returned to the sea as close as practicable to the next removal location (refer to Table 6-63). The planned return to sea of some biofouling material is considered to represent a very low risk as many organisms will no longer be viable (having been exposed to air for periods of several days), and the material will be returned to a location similar to that where it originated. It is estimated that the jacket structures will have been exposed to the air for periods of between two and ten days between their removal and departure from the transfer area (Biofouling Solutions, 2026a). The activities will also be undertaken during the spring/summer period hence desiccation rates will be increased due to the higher air temperatures and survival periods reduced.

Most mobile organisms will depart or drop off the jackets within one day of their removal from the sea. Consequently, should they be present on the jacket structures, mobile IMS such as M. *roseus, C. maenas, H. sanguineus, A. amurensis, A. flavimanus,* and *T. trigonocephalus* are likely to vacate the jackets during removal transport or transfer operations (Biofouling Solutions, 2026a) and may be viable when they enter the water.

Sessile IMS such as (*C. fragile spp. tomentosoides, U. pinnatifida, A. senhousia, M. gigas or S. spallanzanii)* if present would be expected to slough off the jackets due to gravity, vibration or abrasion and may be viable when they enter the water.

There is very limited hard substrate within the OA, however natural reefs occur adjacent to the OA and at the primary transfer location (refer to Figure 3-7). The likelihood of the survival and establishment of IMS which require hard substrate (such as *C. fragile spp. fragile, G. turuturu, M. gigas, C. maenas, H. sanguineus, A. flavimanus, and T. trigonocephalus*) was determined as **Likelihood Category C** (unlikely). This was based on the conservative assumption made in the IMS study that if these IMS were released at a distance of less than 10km of natural reefs within or adjacent to the OA, these IMS could conceivably survive and become established – but the probability of this is difficult to determine (Biofouling Solutions, 2026a).

The likelihood of the survival and establishment of IMS which are known to occur in soft sediment habitats (such as *A. senhousia, M. roseus, S. spallanzanii , C. maenas, A. amurensis, A. flavimanus,* and *T. trigonocephalus) was* also assessed as **Likelihood Category C** (unlikely) due to the presence of extensive soft sediments in the OA.

For mobile IMS (such as *C. maenas, H. sanguineus, A. flavimanus, and T. trigonocephalus)* survival and establishment likelihood is only relevant for the initial 24 hours following removal of jackets, during which all mobile organisms are expected to depart the structures.

The overall likelihood of the transport and transfer of removed jacket sections causing the spread of IMS within the OA is the product of:

- the likelihood of the IMS being present on the jackets and
- the likelihood of survival and local establishment of the IMS assuming they are present on the jackets and released during the Campaign #1 activities.

Hence the IMS study concluded that the overall likelihood that the Campaign #1 activities will cause the spread of each of the 11 IMS assessed within the OA via the release of marine growth from the removed jacket structures was **Likelihood Category E** (very highly unlikely)**.**

LIKELIHOOD OF THE RELEASE AND ESTABLISHMENT OF IMS WITHIN THE OA - BALLAST WATER DISCHARGE

Campaign #1 vessels will be equipped with ballast water systems and will take on and discharge ballast during removal, transport and transfer operations. The HLV in particular has the ability to rapidly ballast and de-ballast to allow weight distribution during loading of large structures in the dynamic offshore environment.

Due to the unpredictability of wave, wind, and swell conditions all movements between the removal locations and transfer locations (both directions) may involve some uptake and/or discharge of ballast water. The likelihood that ballast water operations will spread IMS within the OA is the outcome of the following conditional factors:

- the likelihood of each species occurring on the jackets (refer to Table 7-21)
- the likelihood of larvae, spores, fragments, or individuals being released into the water surrounding the platforms during lifting of topsides or jackets
- the likelihood of this material being taken up with ballast water
- the likelihood of larvae, spores, fragments, or individuals surviving and establishing at the release site.

The IMS study assessed that it was **Likelihood Category E** (very highly unlikely) that the uptake and discharge of ballast water within the OA during Campaign #1 would result in the spread of the 11 IMS considered during the study (refer to Table 7-21). This was based on the combined outcome of their very low likelihood of being present on the jackets (and hence being taken up with ballast water) and their likelihood of becoming established if they were released in ballast water within the OA.

7.4.3.2.3 INTRODUCTION OF IMS TO THE OA VIA TRANSIT OF BARGES/HTV FROM BBMT

Following offloading of removed structures at BBMT, barges or HTVs will transit through Corner Inlet and back to the transfer area to collect additional jackets and topsides for offloading. Some IMS have been detected in Corner Inlet and hence the Victorian State Waters IMS Study assessed the potential risk of these vessels spreading IMS to the OA via biofouling, entanglement on vessel structure such as propellers or ballast water discharge. While the assessment focused on areas within the Victorian State Waters boundary – these areas are directly adjacent to the primary transfer area (refer to Figure 2-46), hence the results are considered to be applicable to informing the risk assessment undertaken in this section.

IDENTIFICATION OF POTENTIAL IMS

Surveys undertaken by DEECA and Esso, as well as a review of scientific and technical literature was undertaken to identify potential IMS which may be present around BBMT and Corner Inlet. These identified the following species which were considered in the Victorian State Waters IMS Study:

Table 7-22 IMS assessed for potential spread from BBMT to OA (Biofouling Solutions, 2026b)

Species	Common name	Habitat Preference	Details
Codium fragile spp. fragile	Dead mans fingers	Hard substrates	Has been present in Corner Inlet since 1995
Undaria pinnatifida	Japanese seaweed, wakame, Asian kelp	Hard substrates	Has been present in Victoria since 1996 – first detected in Corner Inlet in 2018.
Carcinus maenas	European shore crab	Soft and hard substrates	First recorded in Corner Inlet in the 1980s.
Spartina anglica	Cordgrass	Saltmarsh and the coastal fringe	First reported in Corner Inlet in the 1920s. Not a marine species, but can be spread via fragment and seed transport by ocean currents.

Species	Common name	Habitat Preference	Details
Grateloupia turuturu	Devils tongue weed	Rocky substrates	Detected in Corner Inlet in 2021. No reports of this species causing adverse environmental impacts in Australia to date.
Petalonia binghamiae	Brown macroalgae	Rocky substrates	Not included in any priority lists by Commonwealth or State agencies. Documented in Corner Inlet in 2024 and included to ensure all non indigenous marine species known from Corner Inlet were assessed.

LIKELIHOOD OF THE SPREAD OF IMS FROM BBMT TO THE OA – VESSEL BIOFOULING

The likelihood of the spread of IMS from BBMT to the OA (specifically the primary transfer area) via biofouling of vessels transiting from BBMT to the OA was determined via consideration of the following events (Biofouling Solutions, 2026b):

- **Presence of the IMS at BBMT**: As comprehensive information regarding the distribution and abundance of the IMS reported from Corner Inlet was not available, the conservative assumption was made that all IMS reported from BBMT are locally established and highly likely to be present during the offloading activities at BBMT (these species are *Spartina anglica*, *Codium fragile, Carcinus maenas and Petalonia binghamiae)*. IMS that have not been reported at BBMT, but have been reported from other areas of Corner Inlet were assumed to be locally established, but less likely to be present during the offloading activities (these species are *Undaria pinnatifida* and *Grateloupia turuturu)*.
- **Settlement or entrainment on vessel hulls**: Biofouling of vessels develops via the settlement of larvae or spores onto susceptible hull surfaces, which can only occur within the spawning or recruitment period of a species (which is seasonal). Hence a determination of the likelihood of IMS settlement onto barge or HTV vessel hulls during offloading activities at BBMT was undertaken based on whether the offloading activities occur within the spawning season of each species and on the expected period barges/HTVs are expected to remain alongside BBMT. It was also assumed that the vessels would have some proportion of areas that are susceptible to biofouling – in the absence of detailed information on antifouling coating and cleaning history of the barges/HTV that will be used to transport the jacket structures. The likelihood for spread via entanglement was assessed by studying the life history and morphology of the IMS species.
- **Release from vessel hulls**: Sessile biofouling organisms that have colonised a vessel hull via larvae or spore settlement are usually unable to self release. Introduction to new areas instead occurs vias the release of propagules by reproductively active individuals. Hence these individuals need to have reached sexual maturity, which for most marine invertebrates and algae occurs within weeks to months following settlement. Given the period between the barges or HTV departing BBMT and arriving at the OA (days), it is not considered that propagule release would occur as part of this activity, however this may be applicable to later in the Campaign #1 timeframe, which is estimated to take place between September and February. Mobile organisms will be able to self release from vessel hulls.
- **Survival and establishment**: Estimation of the likelihood that any IMS released from vessels within the OA (at the primary transfer area) will survive and become established considered the availability of local suitable habitat such as shallow reef and sources of mortality for individuals or propagules.

Based on their respective spawning seasons, it was assumed that spores and larvae of the following species may be present in the water column at BBMT during the decommissioning Campaign #1 activities- *Codium fragile,*

Grateloupia turuturu, Undaria pinnatifida, Carcinus maenas and Petalonia binghamiae and the expected docking period for HTVs or barges at BBMT (approximately 3 days) would be sufficient to allow settlement on vessel underwater surfaces that are susceptive to biofouling. However given the small population sizes of the IMS species studied, the abundance of propagules and drifting individuals is considered to be low – translating to a low likelihood of settlement for each species.

Reproductive maturity and propagule release can occur within the timeframe of the Campaign #1 activities, but this was assessed as unlikely to occur and given the presence of hard substrate at the transfer location, survival and local establishment of all IMS is considered to be possible – but unlikely.

For all species studied, the integration of the assessed likelihoods of the four individual events occurring resulted in an overall likelihood of the spread of IMS from BBMT to the OA (primary transfer area) via biofouling of vessels or entanglement to be assessed as **Likelihood Category E** (very highly unlikely).

LIKELIHOOD OF THE SPREAD OF IMS FROM BBMT TO THE OA – BALLAST WATER DISCHARGE

As per Section 7.4.3.2.2, it was assumed that all vessels (including HTVs and barges) may uptake and discharge ballast water during the loading and unloading of removed structures. The risk of this pathway resulting in the spread of IMS from BBMT to the OA (the primary transfer area) was assessed considering the likelihood of the following events (Biofouling Solutions, 2026b);

- **The presence of the IMS at BBMT** : Refer to description in the biofouling assessment above.
- **Uptake with ballast water:** If IMS are present in the water column at BBMT they could be taken up with ballast water, either as individuals, fragments or propagules. The likelihood of uptake for each species was assessed by considering their propensity for fragmentation and their spawning seasons. In the absence of abundance data for the IMS which may be present at BBMT, it was conservatively assumed that there may be small quantitates of individuals, fragments or spores of the IMS studied in the water column at BBMT. The reproductive seasons of the IMS studied have overlap with the planned timing of the Campaign #1 activities. Hence there is the potential that if IMS are present they may be taken up within ballast water. Given the small local population sizes of IMS within Corner Inlet the abundance of propagules and drifting fragments is considered to be very low, resulting in a correspondingly low likelihood of uptake in ballast water
- **Release, survival and establishment:** If uptake of IMS into ballast water does occur, given the short transit times from BBMT to the primary transfer location, organisms or propagules may be released in a viable state. If uptake did occur, propagules or fragments released would need to reach suitable habitat, in sufficient numbers, and form self-sustaining populations. Hence survival and establishment was conservatively assessed as 'unlikely' to occur.

For all species studied, the integration of the assessed likelihoods of the four individual events occurring resulted in an overall likelihood of the spread of IMS from BBMT to the OA (primary transfer area) via vessel ballast water to be assessed as **Likelihood Category E** (very highly unlikely).

7.4.4 Demonstration of As Low As Reasonably Practicable

Table 7-23 Decision Context and justification

Decision Context
The causes resulting in an introduction of IMS from ballast water discharge or biofouling are well understood and well managed by national and international regulations and industry guidance. Esso is experienced in the implementation of industry requirements through their existing ongoing operations. The environmental consequence of the impacts resulting from the potential introduction or spread of IMS has been assessed as **Consequence Level III**. The risk of the introduction or spread of IMS has been assessed as **Risk Category 4**. The transport and transfer of large items of removed infrastructure is not a standard activity within Bass Strait, hence IMS studies were undertaken by biosecurity experts to inform this risk assessment. Some stakeholder interest has been noted with regard to the potential introduction or spread of IMS as a result of the Campaign #1 activities.

Decision Context
Given the non-standard activities, Esso believes **Decision Context B** should apply.

Table 7-24 Good practice controls

Good practice	Adopted	Control	Rationale
Australian Ballast Water Management Requirements, Version 8 (DAWE, 2020a)	Adopted – RSK4-CM1	Ballast uptake and discharge during Campaign #1 activities is managed in accordance with Australian ballast water management requirements.	The requirements describe the obligations on vessel operators with regard to the management of ballast water and sediments when operating in Australian seas and includes legislative requirements under the *Biosecurity Act 2015* (Cth) and the International Convention for the Control and Management of Ships' Ballast Water and Sediments 2004. This includes: • ensuring the vessel has a valid Ballast Water Management Plan and a valid Ballast Water Management Certificate • ensuring all ballast operations are recorded in a Ballast Water Record System • ensuring reporting obligations are met - via submission of a Ballast Water Report if required • obtaining a low risk exemption for Australian sourced ballast water discharge or managing the discharge in accordance with the requirements • managing ballast water in accordance with the approved ballast water management options outlined in the requirements. This control is based on legislative requirements under the *Biosecurity Act 2015* (Cth) and must be accepted. Control is feasible and standard practice.
Australian biofouling management requirements (Version 2) (DAFF, 2023)	Adopted – RSK4-CM2	Vessel biofouling risk is managed in accordance with Australian biofouling requirements.	Biofouling risk for vessels will be managed in accordance with the Australian biofouling management requirements detailed in the *Australian biofouling management requirements Version 2* (DAFF, 2023) and the *2023 Guidelines for the control and management of ships' biofouling to minimize the transfer of invasive aquatic species* (IMO, 2023) for Campaign #1 vessels mobilising from beyond Australia. Risks associated with vessel biofouling and imported equipment will be assessed and mitigation measures documented in support of meeting the biosecurity clearance requirements for entering Australian waters. In accordance with the Australian biofouling management requirements, Campaign #1vessels arriving from beyond Australia and entering the

Good practice	Adopted	Control	Rationale
			Australian territorial sea will report biofouling management actions prior to arrival through the mandatory pre-arrival report, which is reported through Department of Agriculture, Fisheries and Forestry Maritime and Aircraft Reporting System. The vessels will be cleared by DAFF by either an inspection onboard conducted by a biosecurity officer at the first port of entry or by DAFF granting clearance based on pre-agreed entry requirements. The vessels will receive a Biosecurity Status Document confirming the vessel has an approved biosecurity status. This control is based on legislative requirements under the *Biosecurity Act 2015* (Cth) and must be accepted. Control is feasible and standard practice.
Compliance with the *Australian National Biofouling Management Guidance for the Petroleum Production and Exploration Industry* (Marine Pest Sectoral Committee, 2009).	Adopted – RSK4-CM3	A risk based management approach is applied for vessels being mobilised to the OA from international and domestic locations.	The risk of introducing to or spreading IMS within the OA is reduced by implementing proactive biofouling management options recommended under the *National biofouling management guidelines for the petroleum production and exploration industry* (Marine Pest Sectoral Committee, 2009).
Cleaning of immersible equipment such as ROVs or wire cutters.	Adopted – RSK4-CM4	All immersible retrievable equipment cleaned and/or inspected in prior to commencement of removal activities.	Management of submersible equipment will be in accordance with the *National biofouling management guidelines for the petroleum production and exploration industry* (Marine Pest Sectoral Committee, 2009).

Table 7-25 Engineering risk assessment

Control measure	Benefit	Cost/feasibility	Adopted
Use of freshwater ballast.	By using freshwater ballast, the likelihood of introducing or spreading IMS can be reduced. However, because the likelihood is already assessed as very highly unlikely, there is limited environmental benefit associated with	Costs associated with this measure are high, and disproportionate to the benefit.	Not adopted

Control measure	Benefit	Cost/feasibility	Adopted
	implementing this measure.		
Inspect and clean all vessels.	By dry docking and cleaning all wetted surfaces on all vessels the likelihood of IMS introduction is reduced.	The risk already has a low likelihood so the substantial cost (and time required) to inspect and clean all vessels outweighs the environmental benefit. The *Pioneering Spirit* HLV is too large to dry dock. The biofouling risk associated with this vessel will be managed in accordance with the Australian biofouling management requirements and in consultation with the Department of Agriculture, Fisheries and Forestry prior to its entry into Australia.	Not adopted
Use only vessels that are currently operating in Bass Strait .	By only using vessels that are currently operating in Bass Strait, the likelihood of introducing an IMS to the OA is reduced.	This control is not feasible given the requirement for specialist vessels to undertake the removal activities. These vessels are not currently available in Bass Strait.	Not adopted
Bulk removal of all marine growth at removal locations prior to transport.	Removed marine growth remains at original location, hence eliminating the risk of spread of IMS within the OA. Parks Victoria suggested a potential mitigation of removal if possible and minimising anything falling off during removal and transit.	Removal of all marine growth at the removal locations is not considered feasible due to the restricted access to structural members which are internally positioned within each jacket; difficulty working within the splash zone and other more complex safety considerations associated with extensive marine growth removal based on the nature and scale of the entire upper jacket sections.	Not adopted
Treatment of marine growth with biocides.	Marine growth mortality to eliminate the risk of spread of IMS within the OA.	Treatment can only be facilitated once jackets are lifted. The jacket size and lack of access make the application of biocide unfeasible. Application also has safety challenges due to the size of the jackets.	Not adopted
Suspension of jackets out of water at removal location for prolonged periods of time.	Allows desiccation of marine growth and minimises the risk of IMS being spread to other areas of the OA.	Safe lifting of a live load such as this will be completed under a strict weather window and requires jackets to remain suspended for the shortest achievable time. Remaining offshore with a load on slings is not an acceptable safe practice globally.	Not adopted
Visually inspect the jacket structures for IMS after lifting and prior to transport	Parks Victoria suggested this potential mitigation measure during relevant	The IMS study incorporated the review of over 500 videos of ROV footage taken during the period of 2020 - 2024 of the jacket structures by an experienced	Not adopted

Control measure	Benefit	Cost/feasibility	Adopted
and remove IMS if seen.	person consultations for this EP.	biosecurity expert. ROV footage collected during Environmental Survey 1 (Summer) and Environmental Survey 2 (Winter) was analysed by marine ecologists and selected footage also viewed by an experienced biosecurity expert. No IMS were identified. Given the long period of time the jacket structures have been in the marine environment, the marine ecosystem present on the jackets is considered to be stable and the risk of IMS colonising the jackets in the period between the collection of the ROV footage and the removal activities is low. Visually inspecting the jacket structures again prior to transport is not considered to provide an appreciable reduction in the risk of the spread of IMS, which has been assessed as **Risk Category 4** (the lowest risk). Visual inspection of the entirety of the jacket once lifted and sea fastened is also not feasible due to the extensive surface which would need to be inspected, resulting in the requirement for the jackets to remain suspended for a long period of time and the HLV to remain at the removal locations for an extended period. Safety issues and accessibility issues due to the size of the jackets would also preclude these visual inspection operations. Hence this control has not been adopted.	
Minimise the amount of marine growth falling off during **removal** of structures	Parks Victoria suggested this potential mitigation measure during relevant person consultations for this EP.	It is considered the majority of marine growth loss to sea will occur when the jacket is cut and lifted, hence will remain at the location where the jacket was removed from. Given the size of the jacket sections to be cut and lifted, potential actions to contain or minimise the amount of marine growth lost during activities at the removal locations are not practicable. Given the marine growth is falling within the location from which it was taken from, the release of marine growth at the removal locations does not pose a risk of IMS spread.	Not adopted

Control measure	Benefit	Cost/feasibility	Adopted
Minimise the amount of marine growth falling off during **transport** of structures	Parks Victoria suggested this potential mitigation measure during relevant person consultations for this EP.	During transport of structures from removal locations to the transfer location: The structures will be transported from the removal locations to the transfer location either on the deck of the HLV (if the 5000 tonne crane is used to lift the jacket sections) or on the HLV JLS (refer to Section 2.8.1and 2.8.2). Minimisation of marine growth falling to the sea from the jacket sections transported on the JLS, which overhang the HLV, is not technically feasible for the reasons outlined in Section 6.12.1. However minimisation of the amount of marine growth released to the marine environment along the transport route will be undertaken by aggregating any fallen marine growth on the HLV deck where this is safe and practicable to do so, and returning this to the sea at the next removal location (as per control measure RSK4-CM5 in Table 7-27). During transport of structures from the OA to the onshore reception centre at BBMT: As depicted in Figure 6-4, during transport from the sheltered water transfer location to BBMT via a HTV (or barges which are not shown in Figure 6-4), jacket sections will be loaded longitudinally. This alignment minimises the 'overhang' of the jacket sections from the side of the vessels, hence limiting the loss of marine growth to the environment during transit from the transfer location to BBMT. Marine growth that collects on the deck of the barges/HTV during transit from the transfer area to BBMT will be collected, where safe to do so, and taken onshore for composting or disposal in accordance with EPA Victoria regulations. Residual marine growth that cannot be collected will be washed off the deck to ensure a safe working environment for crew.	Adopted RSK4-CM5 RSK4-CM6 RSK4-CM7
Avoidance of Key Ecological Features – i.e. hard substrate	Minimises the chance of an IMS establishing and	KEFs located in the OA are depicted in Figure 3-7. There are two KEFs that occur in the OA:	Not adopted

Control measure	Benefit	Cost/feasibility	Adopted
and shelf rocky reefs as defined in the South-east marine regional profile (DoE, 2015a) which are present in the OA - during **transit** activities	impacting habitat values associated with the KEF.	• the Upwelling East of Eden which is located to the far east of the OA. The location of this feature in relation to the facilities to be removed means it is very unlikely transit activities will occur within or near this KEF. • a KEF referred to as 'shelf rocky reefs and hard substrate' which is referenced in the South-east marine regional profile (DoE, 2015a), but not mapped. Locations where hard substrate and rocky reefs which are considered to fall within the definition of this KEF are depicted in Figure 3-7, based on literature, publicly available data and Esso offshore environmental survey results. No other KEFs are present in the OA. The FTA SPJ is located within the area known as South-east reef (which meets the definition of the shelf rocky reefs/hard substrate KEF) while CBA and HLA are located immediately adjacent. Hence avoidance of this feature during transit of the FTA jacket is not feasible. Avoiding transit over South-east reef is also not practicable for CBA and HLA as this would result in the need for the HLV to transit via a protracted, indirect route to the transfer location with a jacket onboard. Marine growth released during transit within the South-east reef is likely to be alive, given the short timeframe from removal of the jacket and transit through this feature. However given the proximity of the jackets to this feature (in the case of FTA within the mapped extent), it is unlikely this will result in any appreciable impacts to the habitat within the KEF as a result of the risk of the spread of IMS, as if these are present on the jacket to be released, it is likely the species already exist at this location. While known areas which meet the definition of hard substrate and rocky	

Control measure	Benefit	Cost/feasibility	Adopted
		reefs KEF are depicted in Figure 3-7, other areas of hard substrate/rocky which have not been mapped may also be present within the OA. The discharge of marine growth during transit to the transfer area is expected to be spread over a wide area as the HLV travels and will be widely dispersed in the marine environment. The IMS study undertaken concluded that the likelihood of any IMS being present on the jacket structures is Likelihood Category C (unlikely) or Likelihood Category D (very unlikely). The study also concluded that the establishment of an IMS within or adjacent to the OA, (which would require a number of conditions to be met, with each successive stage becoming more and more unlikely) is Likelihood Category E (very highly unlikely). Jacket sections will either be fully inboard or be placed on a HTV or barge longitudinally for transport from the transfer location to the boundary of the OA (and onward to BBMT) – refer to RSK4-CM6. This minimises the loss of marine growth to the environment during this activity. Avoidance of all hard substrate areas which meet the definition of the shelf rocky reefs and hard substrates KEF in the OA would require an extensive exercise of seabed surveying across the OA to identify and map all areas of hard substrate for inclusion into vessel systems and/or the use of 'real time' methods during the execution campaign to identify hard substrate as the HLV is in transit. As the risk of the spread of IMS has been assessed as a Risk Category 4, the avoidance of KEFs (in particular the shelf rocky reef/hard substrate KEF) during transit activities undertaken in the OA is not considered to result in a reduction to the risk of the spread of IMS that would outweigh the cost, practicality and schedule implications resulting from implementing this control. Hence it has not been adopted.	

Control measure	Benefit	Cost/feasibility	Adopted
Avoidance of Key Ecological Features -i.e. hard substrate and shelf rocky reefs as defined in the South-east marine regional profile (DoE, 2015a) which are present in the OA - during **transfer** activities	Minimises the chance of an IMS establishing and impacting habitat values associated with the KEF.	Mapped areas of hard substrate and rocky reefs which meet the definition of the 'hard substrate and rocky reef KEF' are present within the proposed primary transfer area (refer to Figure 6-5). The IMS study undertaken has concluded that the likelihood of any IMS being present on the jacket structures is Likelihood Category C (unlikely) or Likelihood Category D (very unlikely). Even in the very unlikely event an IMS is present in the marine growth discharged, mobile species are predicted to depart or drop off within 1 day of removal from the sea (Biofouling Solutions, 2026a), hence they are very unlikely to still be present on jacket structures when they arrive at the primary transfer location. The rate of release of marine growth is expected to be highest during removal activities at the facility locations and then decrease during transit and transfer. The marine growth will be exposed to air for periods between 2 and 10 days prior to their departure from the transfer area and hence organisms will have desiccated considerably and may form a leathery layer from which gradual but highly reduced release will occur (Biofouling Solutions, 2026a). Avoidance of the mapped areas of hard substrate and rocky reefs in the primary transfer area will restrict the HLV from selecting the most appropriate location based on the conditions, to undertake transfers safely and efficiently. The HLV size, coupled with the HTV/barge and support vessel spread present during transfer operations makes avoidance of all hard substrate (mapped or unmapped)in the primary transfer area impractical. In order to avoid the mapped areas of hard substrate located in the east and west of the primary transfer area transfer (refer to Figure 3-7) may (depending on weather conditions) need to occur closer to sensitive environments in and around Corner Inlet (refer to Figure 2-46) in preference to the southern end of the primary transfer area which is more exposed.	Not adopted

Control measure	Benefit	Cost/feasibility	Adopted
		The risk of the Campaign #1 activities spreading IMS within or adjacent to the OA has been assessed as Risk Category 4. The study undertaken to assess these risks included consideration of the presence of hard substrate areas in and adjacent to the OA. As a result implementation of this measure is not considered to result in a reduction of the risk of the spread of IMS which would outweigh the practicality and schedule implications resulting from implementing this measure, hence it has not been adopted.	
The use of pre activity surveys or vessel equipment to identify hard substrate or rocky reef areas, which would fall within the definition of the KEF as defined in the South-east marine regional profile (DoE, 2015a).	Allows identification of areas considered to fall within the definition of the shelf rocky reefs and hard substate KEF, for avoidance during transit and transfer/mode change activities.	As discussed above, the avoidance of areas which may fall within the definition of the shelf rocky reefs and hard substrate KEF during transit or transfer operations has not been adopted. The implementation of this measure is not considered to result in a reduction of the risk of the spread of IMS which would outweigh the resulting practicality and schedule implications. In particular, the implementation of 'real time' identification methods and subsequent avoidance of hard substrate will impact the ability for the removals work to be completed, with no material change to the IMS risk. The HLV size and weight with structures onboard also restrict the ability of the vessel to pivot and change location to avoid hard substrate areas - if identified in real time during transit. The adoption of measures such as pre activity surveys or the use of vessel equipment to identify potential unmapped areas of hard substrate and rocky reefs, which may fall within the definition of the KEF for avoidance is not proposed for the Campaign #1 activities, given the practicality considerations and the fact that avoidance of such areas is not proposed.	Not adopted
Deploying settlement arrays at multiple depths and undertaking both visual identification and eDNA analysis	This measure was suggested for consideration by DAFF during relevant person consultation - noting this was raised in the context of	The deployment and analysis of settlement arrays for visual and eDNA analysis is a methodology to detect the presence or absence of species such as IMS in the water at specific locations.	Not adopted. eDNA analysis has been considered

Control measure	Benefit	Cost/feasibility	Adopted
of settlement plates for IMS surveillance.	the proposed end states for the lower jacket sections (during consultation for the SPJ End State EP which was submitted in 2022 and subsequently withdrawn). These techniques are not controls which would prevent or minimise the introduction or spread of IMS as a result of the Campaign #1 activities, but surveillance methods which could identify the potential presence or absence of IMS and provide information for liaison with relevant agencies.	Settlement arrays are simple structures that provide extra surfaces for organisms and propagules to settle on, that are then collected and examined by marine pest experts. Environmental DNA (eDNA) is an analysis technique used to collect shed DNA from organisms and potentially allow the identification of species present in an area from samples of seawater or marine growth. These surveys require substantial logistical planning, design and cost to execute, particularly in large areas that are not adjacent to platforms such as the primary transfer areas and must be timed to cover the reproductive/settlement period of target species (typically spring/summer) and provide adequate deployment time to allow for settlement (typically 3-6 months). The settlement arrays would be difficult to deploy and keep in place in the high energy environment of Bass Strait, unless substantial engineering was undertaken to devise methods to keep them from being destroyed or entangled in the platform structures or other emergency features. Multiple deployments/surveys would need to be undertaken – with pre surveys undertaken to establish a baseline for post Campaign #1 surveys. eDNA metabarcoding has limitations including the current availability of 'libraries' of confirmed species DNA, which are used to identify species and eliminate 'false positives' where native species that share the same sequence variant are incorrectly identified as IMS. Collection of water samples for eDNA analysis during removal activities at the platform locations is not feasible, due to the exclusion zones in place around the vessel during this safety critical operation. Given the lower assessed risk of the Campaign #1 activities resulting in the introduction or spread of IMS, the effort practicality and value of implementing these surveillance measures for the Campaign #1 execution activities is not considered to be	in RSK4-CM8

Control measure	Benefit	Cost/feasibility	Adopted
		proportionate to the risk, hence this has not been adopted. The use of molecular DNA based analysis methods to assist in the identification of any potential IMS specimens collected which are unable to be identified by morphology alone has been proposed as part of control measure RSK4-CM8. Esso is evaluating both settlement plates and eDNA analysis as potential methods for IMS surveillance as part of a broader environmental monitoring plan being considered for the wider Gippsland Basin decommissioning program (as described in Sections 1.1 and 1.3). This monitoring plan will be described in future EPs as it relates to the activity being proposed.	
Obtain photographs of any potential IMS (where accessible and safe to do so) for review/identification by a biosecurity expert.	This measure was discussed with GLaWAC during relevant person consultation. Provides information to facilitate reporting in accordance with the reporting requirements outlined in Table 8-7 of this EP.	This measure is feasible. Photographs will be taken (where this is safe and in accessible areas) of any potential IMS observed within marine growth falling on the deck of the HLV or HTV/barges and passed on to an IMS subject matter expert for identification. Observations will be undertaken as marine growth is being aggregated or collected by deck crew – who will receive training as to the appearance of potential IMS. A specific frequency of observations is not able to be defined, as this will depend on the frequency of marine growth aggregation or collection, which will be dictated by the amount of marine growth falling on the deck of the HTV or HTV/barges. If safe and practical to do so, specimens will be collected, preserved and sent ashore for morphological and anatomical identification by a taxonomic expert. If identification of the species can be achieved by this method, molecular DNA based analysis may then be undertaken to assist in species identification, in consultation with an IMS subject matter expert. Attempts will also be made to undertake observations, photographs and collection of specimens on marine growth which falls off the jackets once the structures are offloaded at the ORC	Adopted RSK4-CM8

Control measure	Benefit	Cost/feasibility	Adopted
		and placed in a laydown area - where this is safe and practicable - as access to the structures will be restricted. It is estimated that decomposition of the marine growth will occur most rapidly in the first 30 days following load in of the jacket structures- hence after this period, it is not considered observations will be able to discern any species in the decomposed remains and this will be of little value. In the event a positive identification is made, or suspected, reporting will be undertaken in accordance with the requirements outlined in Table 8-7.	

7.4.5 Demonstration of acceptability

Table 7-26 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 4** (the lowest category) and therefore considered acceptable.
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent A study has been undertaken in conjunction with third party experts to reduce the uncertainty regarding the potential risks of the introduction or translocation of IMS as a result of the Campaign #1 activities. It is not considered that there is significant scientific uncertainty associated with this aspect.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or	✓	Not inconsistent The risk of introduction or spread of IMS as a result of Campaign #1 activities has been assessed as **Risk Category 4** (the lowest category). Hence this is not considered to impact the health, diversity and productivity of

Factor	Demonstration criteria	Criteria met	Rationale
	enhanced for the benefit of future generations.		the environment and preclude the use and benefit of the area for future generations.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent The risk of introduction or spread of IMS as a result of Campaign #1 activities has been assessed as **Risk Category 4** (the lowest category). Hence this is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The requirements of the International Convention for the Control and Management of Ships' Ballast Water and Sediments 2004have been adopted. The following legislative and other requirements are considered relevant as they apply to the implementation of the BWM Convention in Australia: • *Biosecurity Act 2015* (Cth) • *Protection of the Sea (Harmful Anti-fouling Systems) Act 2006* (Cth) • Marine Order 98 (Marine pollution – anti-fouling systems) 2013. Australian BWM requirements (DAWE, 2020a) will be adhered to and measures for managing ballast water discharges in this document are incorporated in the controls. Biofouling risk is assessed, and mitigated, in accordance with the *National biofouling management guidelines for the petroleum production and exploration industry* (Marine Pest Sectoral Committee, 2009).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify

Factor	Demonstration criteria	Criteria met	Rationale
			and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	• Feedback from the Department of Agriculture, Fisheries and Forestry . has been reflected in the risk assessment. Feedback from Parks Victoria was provided in relation to nearshore National Parks such as Wilsons Promontory and potential mitigation measures. This has been considered and addressed in the risk assessment. • Feedback from GLAWaC has been incorporated into the risk assessment.

7.4.6 EPOs, control measures, EPSs and measurement criteria

Table 7-27 EPOs, control measures. EPSs and measurement criteria – Introduction or translocation of IMS

EPO	Control measure	EPS	Measurement criteria
RSK4-EPO1: No introduction to, or spread of, IMS within the OA as a result of Campaign #1 activities.	RSK4-CM1: Ballast uptake and discharge during Campaign #1 activities is managed in accordance with Australian ballast water management requirements.	RSK4-EPS1.1: Campaign #1 vessel ballast water to be managed in accordance with the requirements of the *Australian Ballast Water Management Requirements Version 8* (DAWE, 2020a).	RSK4-MC1.1.1: Valid Ballast Water Management Plan present on the vessel. RSK4-MC1.1.2: Valid International Ballast Water Management Certificate present on the vessel. RSK4-MC1.1.3: Complete and accurate vessel ballast water record system is in place on the vessel. RSK4-MC1.1.4: Biosecurity Status Document (issued via the Maritime and Aircraft Reporting System) showing an approved ballast status (for vessels arriving from beyond Australia or a low risk exemption or evidence of compliant ballast water management through a domestic ballast water risk assessment (for domestic trading vessels).

EPO	Control measure	EPS	Measurement criteria
	RSK4-CM2: Vessel biofouling risk is managed in accordance with Australian biofouling requirements.	RSK4-EPS2.1: Campaign #1 vessels sourced from international waters which enter Australian Territorial seas (12nm limit) prior to entering the OA will apply the Australian biofouling management requirements Version 2 (DAFF, 2023), including: • implementation of an effective biofouling management plan and record book • vessel cleaned of all biofouling within 30 days prior to arriving in Australian Territory, or implementation of an alternative biofouling management method pre-approved by the department.	RSK4-MC2.1.1: Biosecurity Status Document (issued via the Maritime and Aircraft Reporting System) showing a low risk or approved biofouling/biosecurity status.
	RSK4-CM3: A risk based management approach is applied for vessels being mobilised to the OA.	RSK4-EPS3.1: Campaign #1 vessels from international locations or sourced from Australian domestic locations, will comply with the Australian National Biofouling Management Guidance for the Petroleum Production and Exploration Industry (Marine Pest Sectoral Committee, 2009), including: • completion of an IMS risk assessment, which includes evidence that demonstrates the vessel has a current biofouling management plan and	RSK4-MC3.1.1: Documented IMS risk assessment confirms vessel poses low risk of introducing IMS prior to commencing work in the OA.

EPO	Control measure	EPS	Measurement criteria
		biofouling record book and/or implementation of mitigation measures to reduce risk • only vessels classified as a low-level risk can enter the OA.	
	RSK4-CM4: All immersible retrievable equipment cleaned and/or inspected prior to commencement of removal activities.	RSK4-EPS4.1: All immersible retrievable equipment has been cleaned and/or inspected in accordance with *National biofouling management guidelines for the petroleum production and exploration industry* (Marine Pest Sectoral Committee, 2009) prior to commencement of removal activities.	RSK4-MC4.1.1: Records document cleaning and/or inspection of immersible retrievable equipment.
	RSK4-CM5: Marine growth which falls on the deck of the HLV will be returned to the sea as close as practicable to the next removal location.	RSK4-EPS5.1: Marine growth that falls on the HLV vessel deck in accessible areas is aggregated and held onboard prior to returning to sea as close as practicable to the next removal location. Marine growth originating from the PCA/DPA monopods is only returned to the PCA/DPA removal location or will be transferred onshore for disposal. No marine growth originating from other facilities is returned to the PCA/DPA locations.	RSK4-MC5.1.1: Standard Operating Procedure as referenced within Allseas EMP and PCA and DPA lift plan. RSK-MC5.1.2: Marine growth management/discharge log.
	RSK4-CM6: Jacket structures will either be fully inboard or placed onto	RSK4-EPS6.1: Inboarding or longitudinal placement of removed jacket sections on HTVs/barges has been undertaken to minimise the potential for marine	RSK4-MC6.1.1: Transfer procedures include the requirement for jacket structures to be placed longitudinally.

EPO	Control measure	EPS	Measurement criteria
	HTVs or barges longitudinally (lengthways) to ensure there is minimal overhang of the structures outside of the vessel.	growth to drop to the marine environment during transit from the transfer location to BBMT.	RSK4-MC6.1.2: Jacket grillage on HTVs/barges installed (as built) for inboarding or longitudinal placement.
	RSK4-CM7: Marine growth that falls on HTVs/barges during transit from the transfer area to BBMT will be collected, where safe to do so, and taken onshore.	RSK4-EPS7.1: Marine growth that collects on the deck of the barges/HTV during transit from the transfer area to BBMT will be collected, where safe to do so, and taken onshore for composting or disposal in accordance with EPA Victoria regulations. Residual marine growth that cannot be collected will be washed off the deck to ensure a safe working environment for vessel crew.	RSK4 -MC7.1.1: Marine growth management/discharge log. RSK4 -MC7.1.2: Waste disposal records demonstrate waste was transferred onshore and disposed of in accordance with regulatory requirements.
RSK4-EPO2: In the event an IMS is identified, or suspected, notifications to the appropriate external parties are undertaken.	RSK4-CM8: Photographs of any potential IMS will be taken and provided to an IMS subject matter expert for review. Specimens will be collected to assist with identification (where it is safe, accessible and practicable to do so).	RSK4-EPS8.1: Photographs are taken of any potential IMS observed on or within marine growth which falls or is aggregated in accessible areas of the HLV or HTV or within one month of the jacket structure being loaded in at BBMT (if safe and accessible). Photographs are provided to an IMS subject matter expert for review. RSK4-EPS8.2: If a specimen of the photographed potential IMS can safely and practically be collected, the specimen is preserved and transported onshore for further identification. RSK4-EPS8.3: If identification cannot be achieved by	RSK4-MC8.1.1: Marine growth management/discharge log includes the requirement to take photographs/collect specimens of suspected IMS (if this safe, accessible and practical). RSK4-MC8.1.2: Training records of relevant crew members, which demonstrate training was provided in the identification of potential IMS and the requirement to obtain photographs/specimens if observed and safe, accessible and practical. RSK4–MC8.1.3: Records of any photographs taken/specimens collected/molecular analysis undertaken (if required) and results reviewed by an IMS subject matter expert. RSK4-MC8.1.4: In the event an IMS is positively identified, or suspected, records of reporting to relevant parties in accordance with Table 8-7.

EPO	Control measure	EPS	Measurement criteria
		morphological/anatomical analysis by a taxonomic expert, further techniques such as molecular, DNA-based analysis may be undertaken to assist with identification of the specimen, if required following consultation with an IMS subject matter expert. RSK4-EPS8.4: In the event an IMS is positively identified, or suspected, following review by an IMS subject matter expert, reporting to the appropriate external parties will be undertaken in accordance with the processes outlined in Table 8-7.	

7.4.7 Residual risk ranking

Table 7-28 Residual risk ranking outcome

Scenario	Consequence Level	Likelihood Category	Risk Category
Introduction of IMS to the OA (vessel biofouling and ballast water discharge)	III	D	4
Spread of IMS within the OA via jacket structures	III	E	4
Spread of IMS within the OA via ballast water discharge	III	E	4
Spread of IMS from BBMT to the OA via vessel biofouling	III	E	4
Spread of IMS from BBMT to the OA via vessel ballast discharge	III	E	4

7.5 Accidental release – Dropped objects

7.5.1 Causes of dropped objects

Dropped objects may be released by accidently dropping any objects not permanently fixed to the vessels (such as small tools and cargo loads such as bulk containers) off a vessel, or during ROV operations, due to human error, equipment failure or adverse weather. During the lifting, transport or transfer of the removed infrastructure there is also the remote possibility of larger dropped objects such as a topside module, strut or a jacket section. This event would require many layers of controls to fail concurrently and given the lifting methods, planning during the engineering phase of the project and removals preparation work undertaken is considered very highly unlikely. All of the structures will be assessed as structurally sound for lifting prior to any removals commencing.

Activities undertaken to prevent dropped objects during lifting, transport and transfer operations within the OA are described in Section 2.11.

7.5.2 Risks of dropped objects

The accidental release of dropped objects has the potential to result in:

- change in habitat – seabed disturbance
- change in water quality
- physical damage to underwater cultural or heritage sites.

The risk of dropped objects is applicable to the facility removal locations, the transit route and the transfer area.

The Department of Defence advised during relevant person consultation for this EP that unexploded ordnances may be present on and in the sea floor within the OA and that Esso must, therefore, inform itself as to the risks associated with conducting activities in the area (for example, the detonation of unexploded ordnances). This potential risk has been considered in response to this feedback.

This risk assessment has considered two scenarios as the consequence and likelihood for these scenarios will be different:

- Scenario 1 – A removed structure (jacket section, topside or strut) is dropped during lifting, transit or transfer activities.
- Scenario 2 – Any other smaller object is dropped during lifting, transit or transfer activities.

7.5.3 Risk assessment

7.5.3.1 Change in habitat

In the event of an accidental dropped object or structure from either the vessels, during ROV operations, or lifting operations, effects will be limited to localised physical disturbance to benthic communities arising from equipment sinking to the seabed and/or dragging across the seabed.

Any environmental impact caused by damage to small areas of seabed and associated communities would be mitigated by ubiquitous distribution of similar habitat in the region.

Severity of impact to benthic communities is affected by density of biota, sensitivity of biota to disturbance and recovery potential of benthic communities. Physical disturbance to the seabed from a dropped load would be limited to the footprint of the object and temporary in nature if the item was retrieved and longer term if irretrievable. Both are likely to pose minor environmental risk as the seabed within the OA is largely sandy sediment with benthic assemblages (predominantly polychaetes (worms), crustaceans and molluscs) and not particularly susceptible to physical disturbance.

Any lost materials such as batteries and so forth, would settle on the seafloor if dropped overboard. Over time, this may result in the leaching of chemicals to the seabed resulting in a small area of substrate becoming toxic and unsuitable for colonisation by benthic fauna. Given the low release volumes, it is expected that only very small areas of benthic habitat would be affected.

Considering the possible footprint of a smaller dropped object (against the total area of similar habitat within the Bass Strait region) it is highly unlikely that a dropped object would have an effect on any benthic community other than a minor and localised one resulting in a consequence level of:

- **Consequence Level IV**.

For larger objects such as topsides and jackets, sediment disturbance and short term, localised turbidity and associated benthic smothering would be anticipated at the site where the structure was dropped. Loose items on the topsides will be secured prior to lifting and transport, however in the event of a topside being dropped these items may be damaged and become debris on the seabed. Smaller items within the topsides may also be dislodged and become marine debris with the potential to wash ashore, depending on the location of the event and prevailing weather/sea conditions. This may entail shoreline cleanup activities and response actions such as the deployment of booms around the location to contain the spread of any debris. Marine debris can pose a threat to marine species such as birds, turtles and seals and is assessed further in Section 7.6.

While the environmental consequences to habitats in the event of a loss of a larger object such as a structure, strut or topsides are expected to be localised and medium term, if this event was to occur it would result in widespread national and international media coverage. As a result, in accordance with the determination of consequence methodology presented in Table 5-7, the consequence level has been assessed as:

- **Consequence Level I**.

7.5.3.2 Change in water quality

Within the removal locations, the pipelines associated with the Campaign #1 facilities will be flushed prior to facility removal operations and will not be 'live' or contain bulk hydrocarbons. As described in Section 6.8, after cleaning of the pipelines is completed, they are filled with water treated with inhibitor. It is expected that only small concentrations of oily residues will remain in the pipelines, with an estimated OIW content of <30ppm. Hence the potential consequence in the event a large dropped object caused damage to subsea infrastructure at the removal locations would be restricted to a release of water with low concentrations of residual hydrocarbons. This release would be rapidly dispersed in the marine environment.

The facility topside systems will also be de-inventoried and flushed prior to removal operations commencing (refer to Section 2.5) to minimise the presence of hydrocarbons and residual chemicals prior to lifting and transport. For removal operations platforms will be non-operational and, following the flushing of topside systems, the presence of hazardous and non-hazardous substances in the topsides will be minimal and any residual fluids would rapidly disperse in the marine environment.

The discharge of the small volumes of residual fluids which will be present in the jacket internal structures (ODSPs, CDSPs, JLSTs, and flooded jacket members) will occur when the jackets are lifted as assessed in Section 6.9. As a result there will be minimal residual fluids in the jackets during transport and transfer operations.

Potential impacts to water quality, if a large structure was to be dropped and remain on the seabed until recovery, are expected to be localised and short term, given the minimal volume of residual fluid within topside facilities. If this very highly unlikely event was to occur however, it is likely this would result in widespread national and international media coverage. As a result, in accordance with the determination of consequence methodology presented in Table 5-7, the consequence level has been assessed as:

- **Consequence Level I**.

Impacts from a chemical release during crane transfer of bulk containers – with the maximum volume based upon the loss of an intermediate bulk container containing 1m^3 of chemicals – would be minimal, due to the small potential volumes released, and the fact that spilled chemicals will rapidly evaporate, disperse, and weather. In the open ocean environment, the spilled liquids would be rapidly dispersed and diluted to concentrations at which they are non-toxic resulting in a:

- **Consequence Level IV**.

7.5.3.3 Physical damage to underwater cultural or heritage sites

The values and sensitivities within the OA are described in Table 3-2 of this EP. A number of historic shipwreck sites are located within the OA, which are protected under the *Underwater Cultural Heritage Act 2018* (Cth). The location of these shipwrecks is depicted in Figure 3-8.

If a removed structure was dropped on or adjacent to a shipwreck the result may be physical impact to the remains and impacts upon the cultural and historic values of the site. If this was to occur, this is likely to result in widespread media coverage and regulatory action, hence this has been assessed as a:

- **Consequence Level I**.

If a smaller item was dropped onto or adjacent to a shipwreck, physical damage may occur, but this would be less significant and would be dependent on the size of the object. The consequence to the cultural and historic value of the site has been assessed for this scenario as a:

- **Consequence Level III**.

7.5.3.4 Unexploded ordnances

Mine fields were laid in Australian waters during World War II. Post-war minefields were swept to remove mines and to make marine waters safe for maritime activities and these areas have been used safely by shipping for many years. Due to the lapse of time, navigation through the areas identified as those which may contain unexploded ordnances is now considered no more dangerous than from any other of the usual hazards to navigation. However, there is a remote risk that mines may still remain, having failed to respond to orthodox sweeping methods. Therefore, a risk still exists with regard to anchoring, fishing or any form of submarine or seabed activity (AHO, 2015).

There are three areas identified in Bass Strait by the Department of Defence as areas that may contain unexploded ordnances. Two of these areas occur partially within the OA (refer to Figure 3-31). These areas are all categorised as 'other' according to the Unexploded Ordnance Site Information website (Australian Department of Defence, 2025) which means:

> *"Defence records confirm that the area was used for military training but do not confirm that the site was used for live firing. UXO [unexploded ordnances] or explosive ordnance fragments/components have not been recovered from the site. Defence opinion is that it would be inappropriate to assess as either slight, substantial or remote. These sites have been included for general information purposes only. Defence makes no recommendations in regards to this category."*

As a result of the very highly unlikely assessed likelihood of a removed structure being dropped, combined with the remote risk that unexploded ordnances may remain on the seabed in the areas within the OA, the risk of a removed structure being dropped onto an unexploded ordnance during the Campaign #1 activities is not considered credible and has not been assessed further.

If a smaller item was dropped onto an unexploded ordnance physical damage may occur to the vessel which in a worst-case event could result in a spill of fuel to sea, but this would be dependent on the nature of the ordnance. if this event was to occur it would likely result in widespread national and international media coverage. As a result, in accordance with the determination of consequence methodology presented in Table 5-7, the consequence level has been assessed as:

- **Consequence Level I**.

The likelihood of Scenario 1 occurring has been as **Likelihood Category E** (very highly unlikely). The likelihood of Scenario 2 (loss of a smaller object) has been assessed as **Likelihood Category C** (unlikely).

7.5.4 Demonstration of As Low As Reasonably Practicable

Table 7-29 Decision Context and justification

Decision Context
The use of cranes and other lifting equipment to handle equipment and materials offshore is well practiced. There is a good understanding of potential dropped object sources, and the control measures required to manage these. Personnel safety risks as well as environmental risks with lifting and transfer operations mean that these activities are well managed. The removal of large structures as part of decommissioning campaigns, while a non-standard activity in Bass Strait, is well practiced internationally and the contractor who will undertake the removals has demonstrated experience with safely removing offshore structures significantly larger than those in Bass Strait. The environmental consequence of the impacts resulting from potential dropped objects has been assessed as **Consequence Level I** (removed structure) or **Consequence Level IV** (other dropped object).

Decision Context
The risk of potential dropped objects during Campaign #1 activities has been assessed as **Risk Category 3** (removed structure) and **Risk Category 4** (other dropped object). Stakeholders asked what will be done to address the risk of structurally derived dropped objects. Esso noted that all facilities undergo preparation works to remove or secure loose items to minimise potential losses and the single lift approach minimises the cutting and potential to inadvertently create loose or unstable items. Hence, Esso believes **Decision Context B** should apply.

Table 7-30 Good practice controls

Good practice	Adopted	Control	Rationale
HLV and CSV lifting procedures.	Adopted – RSK5-CM1	Specific lifting plans and procedures developed and implemented for each lifting and transfer operation.	Lifting plans and procedures are standard practice to minimise safety and environmental risks associated with lifting operations. Reduces the likelihood of a dropped object.
Crane handling and transfer procedures.	Adopted – RSK5-CM6	Crane handling and transfer procedures are in place.	The API Recommended Practice 2D are industry-developed requirements which provide guidance in the development of operating and maintenance procedures for use in the safe operation of cranes on fixed or floating offshore platforms. Relevant vessels certify that the deck cranes and accessory gear are compliant with API Recommended Practice 2D.
Cargo Securing Manual for each vessel.	Adopted – RSK5-CM5	All cargo securely fastened or stored during transport in accordance with approved Cargo Securing Manual to prevent loss to sea.	It is required practice that procedures are in place to ensure that cargo is securely fastened onboard vessels during transport activities.
Inspection and maintenance of lifting system via a Preventative Management System (PMS).	Adopted – RSK5-CM2	Visual inspection of lifting gear is undertaken regularly in line with the PMS by a qualified competent person. Lifting gear is inspected regularly in line with the PMS.	It is industry good practice that a PMS is in place to ensure that the lifting gear continues to operate at the required standard.
OPEP.	Adopted – RSK5-CM10	OPEP is in place to mitigate any impacts to the environment as a result of a dropped object.	Under the Environment Regulations, NOPSEMA require that the petroleum activity have an accepted OPEP in place before commencing the activity. In the event of the release of residual fluids from a dropped object such as cargo or a topsides structure the OPEP would be implemented. The

Good practice	Adopted	Control	Rationale
			OPEP also contains response actions in the event shoreline cleanup is required.

Table 7-31 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
Sea fastening requirements for structures accepted as fit for purpose prior to transport of the removed structures to the transfer area, and prior to departure from the transfer area (on a barge or HTV).	Ensure structures are securely fastened to the HLV, CSV, HTV or barge in accordance with and hence reduces the likelihood of dropped objects during removal, transit and transfer operations.	Sea fastening requirements are designed by HLV contractor and approved by a Marine Warranty Surveyor to ensure they are fit for purpose in relation to the industry specifications, transport duration, design conditions and risk.	Adopted – RSK5-CM3
Transfer operations will not be undertaken within a 100m radius of a shipwreck protected under the *Underwater Cultural Heritage Act 2018* (Cth).	Eliminates the risk of impacts as result of a dropped object to the heritage and cultural values of the shipwrecks identified in the OA – noting there are no shipwrecks within the facility removal locations.	Feasible and the benefits outweigh any associated cost with administering and communicating the avoidance areas.	Adopted – RSK5-CM7
Transfer operations will not be undertaken over 'live' (operational), underwater infrastructure marked on navigational charts such as cables, pipelines, wellheads etc.	Eliminates the risk of impacts to the environment as a result of a dropped object during transfer operations.	Feasible and the benefits outweigh any associated cost with administering and communicating the avoidance areas.	Adopted- RSK5-CM9
The HLV or CSV, when transporting a jacket or topsides will not transit within 100m of a shipwreck protected under the *Underwater*	Eliminates the risk of impacts to the heritage and cultural values of shipwrecks identified in the OA as result of a dropped object during transit.	Feasible and the benefits outweigh any associated cost with administering and communicating the avoidance areas.	Adopted RSK5 – CM8

Control measures	Benefit	Cost/feasibility	Adopted
Cultural Heritage Act 2018 (Cth).			
The HLV or CSV, when transporting a jacket or topsides will not transit over 'live' (operational) underwater infrastructure marked on navigational charts such as cables, pipelines, wellheads etc.	Eliminates the risk of impacts to the environment as a result of a dropped object during transit in the OA.	Not feasible. While avoidance of transit over live Esso operated infrastructure in the OA is considered feasible, a number of third party operated cables and underwater infrastructure intersects the OA and transit over this infrastructure cannot be avoided. Controls during transit operations, as outlined in Section 7.5.6 will be in place to ensure the risk of a dropped object are reduced to ALARP.	Not adopted.
Dead weight support.	The installation of dead weight supports reduces the likelihood of dropped objects by ensuring structures on facilities are kept in place during lifting and transit. Dead weight supports may include the use of pins, pipe hooks, shackles, chains, clamps to provide vertical or lateral support.	Industry standard engineering approach to support lift safety and dropped objects prevention.	Adopted–RSK5-CM4
Avoid transit or transfer within the areas identified by the Department of Defence as potentially containing unexploded ordnances.	Eliminate the risk associated with a dropped object impacting an unexploded ordnance.	The two areas within the OA which have been identified as potentially containing unexploded ordnances are categorised as 'other' according to the Unexploded Ordnance Site Information website (Australian Department of Defence, 2025). The Department of Defence does not make any recommendations as to actions that should, or should not, be undertaken in these areas. Defence records confirm that the area was used for military training but do not confirm that the site was used for live firing. Unexploded ordnances or explosive ordnance fragments/components have not been recovered from the areas. Hence the presence of unexploded ordnances in the areas within the OA is not confirmed and the risk of these occurring is considered to be remote. In addition, given the very low risk of a dropped object occurring during transfer and transit activities, this control will not result in a reduction in risk that would	Not adopted

Control measures	Benefit	Cost/feasibility	Adopted
		outweigh the cost and logistical impacts of the avoidance of these areas.	
Dropped objects will be recovered during Campaign #1 or recorded for removal as part of the wider Bass Strait decommissioning program.	Recovery of a dropped object does not change the likelihood of a dropped object but may reduce the environmental consequence.	Feasible.	Adopted – RSK5-CM11
If a removed structure (topside, jacket section or strut) cannot be recovered during Campaign #1, a recovery plan will be developed, including a timeframe for recovering the structure as soon as practicable.	Recovery of the structure as soon as practicable does not change the likelihood of a dropped object but may reduce the environmental consequence.	Recovery considerations will include consideration of the location and water depth of the structure, the risk to personnel and the availability of suitable equipment for recovery.	Adopted – RSK5-CM12

7.5.5 Demonstration of acceptability

Table 7-32 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 4 and 4** (the lowest category) and therefore considered acceptable.
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used	✓	Not inconsistent. The risks associated with dropped objects were assessed as having the potential to result in a residual **Risk Category 4** thus are not considered

Factor	Demonstration criteria	Criteria met	Rationale
	as a reason for postponing measures to prevent environmental degradation.		as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The risk of dropped objects is unlikely to result in a detrimental effect on the overall population of any of the species assessed and will not impact upon the environment such that future generations cannot meet their needs.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The proposed activities outlined in this EP align with the requirements of the OPGGS Act: • Section 280(2) – No interference with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the exercise of the rights conferred by titles granted • Schedule 3 (occupational health and safety) of the OPGGS Act and Safety Regulations – Require the operator of each offshore facility to prepare a Safety Case for submission to NOPSEMA including assessment and controls to manage significant risks associated with dropped objects. Activities at a facility must be conducted in accordance with a Safety Case that has been accepted by NOPSEMA. The requirements of SOLAS Chapters VI and VII, in relation to a Cargo

Factor	Demonstration criteria	Criteria met	Rationale
			Securing Manual, have also been adopted. *The requirements of the Underwater Cultural Heritage Act 2018* (Cth), in particular that the Act requires no adverse impact to UCH have been taken into consideration in the impact assessment.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objectives to clearly define and communicate OI requirements to contractors and to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	Stakeholders asked what will be done to address the risk of structurally derived dropped objects. Esso noted that all facilities undergo preparation works to remove or secure loose items to minimise potential losses and the single lift approach minimises the cutting and potential to inadvertently create loose or unstable items. No

Factor	Demonstration criteria	Criteria met	Rationale
			objections or further questions were asked.

7.5.6 EPOs, control measures, EPSs and measurement criteria

Table 7-33 EPOs, control measures, EPSs and measurement criteria – Dropped objects

EPO	Control measure	EPS	Measurement criteria
RSK5-EPO1: No dropped objects as a result of facility removal, transport or transfer operations.	RSK5-CM1: Specific lifting plans and procedures developed and implemented.	RSK5-EPS1.1: A specific lifting procedure/plan is developed and implemented for critical lifting and transfer operations.	RSK5-MC1.1.1: Lift Procedure/Plan for each critical lift and transfer undertaken, including verification sign offs at critical steps.
	RSK5-CM2: Visual inspection of lifting gear is undertaken regularly in line with the PMS.	RSK5-EPS2.1: Visual inspection of lifting gear is undertaken regularly in line with the PMS by a qualified competent person. Lifting gear is also inspected in accordance with class survey requirements, ensuring compliance with statutory and classification society standards.	RSK5-MC2.1.1: Inspection of PMS records and equipment register verifies that inspections have been conducted to schedule.
	RSK5-CM3: Sea fastening requirements for structures accepted as fit for purpose.	RSK5-EPS3.1: Securing requirements for removed structures (topsides, jackets and struts) are accepted as fit for purpose by the Campaign 1 Marine Warranty Surveyor prior to transport to the transfer area, and prior to departure from the transfer area.	RSK5-MC3.1.1: Approval of sea fastening design by Marine Warranty Surveyor. RSK5-MC3.1.2: Confirmation that a competent person has verified that the installed sea fastening complies with the Marine Warranty approved design.
	RSK5-CM4: Dead weight support.	RSK5-EPS4.1: Dead weight supports are in place to ensure structures on facilities are kept in place during lifting and transit and do not become dropped objects.	RSK5-MC4.1.1: Where required, design reports available for dead weight supports. RSK5-MC4.1.2: Confirmation that a competent person has verified that the installed support complies with the approved design.
	RSK5-CM5: All cargo securely fastened or stored during transport.	RSK5-EPS5.1: All cargo securely fastened or stored during transport in accordance with approved Cargo Securing Manual to prevent loss to sea.	RSK5-MC5.1.1: A completed pre-departure inspection checklist verifies that cargo is securely sea-fastened.

EPO	Control measure	EPS	Measurement criteria
	RSK5-CM6: Crane handling and transfer procedures are in place.	RSK5-EPS6.1: A crane handling and transfer manual is in place and implemented by competent crane operators.	RSK5-MC6.1.1: Verification of training records of crane operators. RSK5-MC6.1.2: Approved crane handling and transfer manual.
RSK5-EPO2: In the event of a dropped object, no adverse impacts to shipwrecks protected under the *Underwater Cultural Heritage Act 2018* (Cth)	RSK5-CM7: Transfer operations will not be undertaken within a 100m radius of a shipwreck protected under the Underwater Cultural Heritage Act 2018 (Cth).	RSK5-EPS7.1: Transfer operations are not undertaken within a 100m radius of a shipwreck protected under the *Underwater Cultural Heritage Act 2018* (Cth).	RSK5-MC7.1.1: Transfer location selection decision criteria (refer to Section 2.8.2) includes avoidance of known shipwreck locations. RSK5-MC7.1.2: Records show transfers were not made within a 100m radius of a shipwreck protected under the *Underwater Cultural Heritage Act 2018* (Cth).
	RSK5–CM8: The HLV or CSV, when transporting a jacket or topsides, will not transit within 100m of a shipwreck protected under the *Underwater Cultural Heritage Act 2018* (Cth).	RSK5- EPS 8.1 Transit operations are not undertaken within a 100m radius of a shipwreck protected under the *Underwater Cultural Heritage Act 2018* (Cth).	RSK-MC 8.1.1: Helmsman display as updated with the locations of shipwrecks protected under the *Underwater Cultural Heritage Act 2018* (Cth).
RSK5-EPO3: In the event of a dropped object, no impact to underwater infrastructure that results in an environmental incident.	RSK5-CM9: Transfer operations will not be undertaken over underwater infrastructure marked on navigational charts such as cables, pipelines, wellheads etc.	RSK5-EPS9.1: Transfer operations are undertaken in accordance with transfer location decision criteria, which stipulates the transfer area must be clear of underwater infrastructure as marked on navigational charts.	RSK5-MC9.1.1: Transfer location selection decision criteria (refer to Section 2.8.2) includes avoidance of underwater infrastructure as marked on navigational maps. RSK5-MC9.1.2: Records show transfer location decision criteria was followed and transfers were not undertaken over underwater infrastructure as marked on navigational charts.
RSK5-EPO4: In the event of a dropped object, mitigation measures and recovery are	RSK5-CM10: OPEP is in place to mitigate any impacts to the environment as a result of a dropped object.	RSK5-EPS10.1: OPEP is in place to response to an incident such as a dropped structure (topsides) that may result in a release of residual fluids to sea or the	RSK5-MC10.1.1: Test records confirm that emergency response capability has been maintained in accordance with that described in the ERP and the OPEP. RSK5-MC10.1.2: Records confirm that emergency response activities have been

EPO	Control measure	EPS	Measurement criteria
undertaken as soon as practicable.		requirement for cleanup activities.	implemented in accordance with the OPEP. RSK5-MC10.1.3: Records or other documented evidence of implementation and maintenance of OPEP, including training/drills where required.
	RSK5-CM11: Dropped objects will be recovered during Campaign #1 or recorded for removal as part of the wider Bass Strait decommissioning program.	RSK5-EPS11.1: Dropped objects are removed prior to the end of Campaign #1.	RSK5-MC11.1.1: The Campaign #1 temporary storage register confirms dropped objects are recorded and removed.
		RSK5-EPS11.2: If any dropped objects are not removed during Campaign #1 these are documented for future removal.	RSK5-MC11.2.1: Esso Subsea Material Register is updated following Campaign #1 for dropped objects that have not been removed.
	RSK5-CM12: If a removed structure (topside, jacket section or strut) is dropped and cannot be recovered during Campaign #1, a recovery plan will be developed.	RSK5-EPS12.1: If a large dropped object such as a removed structure (topside, jacket section or strut) cannot be recovered during Campaign #1, a recovery plan will be developed, including a timeframe for recovering the structure as soon as practicable.	RSK5-MC12.1.1: Recovery plan which includes: • methodology for removal • timeframe for removal • any required controls for the interim period prior to removal to reduce environmental impacts to ALARP and acceptable.

7.5.7 Residual risk ranking

Given the extensive preparation and planning, coupled with the many layers of controls in place to ensure the safety of the removal operations, the likelihood of the loss of a structure such as a topside or jacket during removal, transport and transfer operation is considered **Likelihood Category E** (very highly unlikely)**.**

The likelihood of a smaller dropped object from a vessel has been assessed as **Likelihood Category D** (very unlikely).

Table 7-34 Residual risk ranking outcome – Dropped objects

Scenario	Consequence Level	Likelihood Category	Risk Category
Removed structure (topside, jacket or strut)	I	E	3
Other dropped objects	IV	D	4

7.6 Accidental release – Solid waste

7.6.1 Causes of accidental release of waste

The handling and storage of materials and waste on board Campaign #1 vessels has the potential for accidental discharge of materials and waste. The single lift approach to decommissioning maintains maximum structural

integrity of the topsides and jackets during lifting and transport. Measures taken to prepare the structures for decommissioning (cleaning and removal/securing of loose items, sealing equipment and items that may contain hazardous material where appropriate reduces the potential for items to be lost. Accidental release of solid waste materials to sea from the decommissioned structures themselves is hence considered unlikely. Risks associated with any potential dropped objects are assessed separately in Section 7.4.6.

Wastes associated with vessel operations include small items such as consumable personal protective equipment and packaging. These small items are more likely to be accidently released if not properly secured. All Campaign #1 vessels will use separate clearly identified cans, drums, boxes, bags, or other containers for storage of any small quantities of vessel operations derived wastes to be off loaded for onshore disposal.

Vessel waste management procedures will be in place to address the following topics:

- compliance requirements
- waste identification and classification
- waste registration and reporting
- waste storage and separation
- signage, labelling and placarding
- waste inspections
- waste handling
- waste transportation
- communication and training.

The following example vessel wastes will be transported to shore, but have the potential to be accidentally dropped or released overboard:

- paper and cardboard
- wooden pallets
- metal, aluminium, cans
- glass
- plastics.

The following example hazardous materials may be generated using consumable products and will be transported to shore, but may be accidentally dropped or released overboard:

- hydrocarbons, hydraulic oils and lubricants
- hydrocarbon-contaminated materials (e.g. oily rags, oil filters)
- batteries
- contaminated personal protective equipment.

7.6.2 Risk of accidental releases of waste

The potential environmental impacts associated with the accidental release of waste are:

- injury/mortality to fauna
- change in habitat.

7.6.2.1 Injury/mortality to fauna

Discharged overboard, wastes can cause injury or death to marine fauna or seabirds through ingestion or entanglement (e.g. plastics caught around the necks of seals or ingested by seabirds, fish or cetaceans). Marine debris has been identified as a threat to several marine mammals (e.g. whales, dolphins, seals), marine reptiles, seabirds and fish in relevant conservation advice and recovery plans.

Recognition of the problem of plastic and microplastic debris in the marine environment is a key aspect of the National Plastics Plan (DAWE, 2021). The *National Plastics Plan 2021* (DAWE, 2021) also supports action to address marine plastic debris, including the implementation of the *Threat Abatement Plan for the impacts of marine debris on vertebrate wildlife of Australia's coasts and oceans* (DoEE, 2018) which identifies EPBC Act listed species for which there are scientifically documented adverse impacts resulting from marine debris.

The threatened or migratory fauna species identified as impacted by marine debris and have known BIAs that overlap the OA include whales (PBW and SRW) and albatross (antipodean, Buller's, Indian yellow-nosed and wandering) (DoEE, 2018). The CMPBW, NRPSRW and *Wildlife Conservation Plan for Seabirds* (DAWE, 2020b)

identified marine debris as a threat to the relevant species. The number of any of these species likely to be exposed to accidental releases of waste is very low.

Threats to marine organisms were considered primarily mechanical, including entanglement and ingestion of small plastic pieces. However, more recent research has demonstrated microplastic ingestion across a range of marine species (Cole, Lindeque, Halsband, & Galloway, 2011), suggesting the potential for more complex and poorly understood impacts on marine ecosystems (DoEE, 2018).

The patterns of reports of entanglement in and ingestion of plastic debris by wildlife in Australian waters are likely to be influenced by factors such as the size and distribution of populations, foraging areas, migration patterns, diets, proximity of species to urban centres, changes in fisheries equipment and practices, weather patterns, and ocean currents, as well as the frequency of monitoring and/or observation of wildlife. Species dominating existing entanglement and ingestion records are turtles and humpback whales. Australian pelicans and a number of cormorant species are also frequently reported (Ceccarelli, 2009).

7.6.2.2 Change in habitat

Hazardous wastes released to the sea can cause pollution and contamination, with either direct or indirect effects on marine organisms. For example, chemical residues (depending on the volumes released) can impact on marine life from plankton to pelagic fish communities, causing physiological damage through ingestion or absorption through the skin. Impacts from a minor accidental release would be limited to the immediate area surrounding the release, prior to the dilution of the chemical with the surrounding seawater. In an open ocean environment such as the OA, it is expected that any release would be rapidly diluted and dispersed, and thus temporary and localised.

Solid hazardous wastes, such as paint cans containing paint residue, batteries and so forth, would settle on the seabed if dropped overboard. Over time, this may result in the leaching of hazardous materials to the seabed, which is likely to result in a small area of substrate becoming toxic and unsuitable for colonisation by benthic fauna. The benthic habitats of the area are broadly similar to those elsewhere in the region, so impacts to very localised areas of seabed will not result in the long-term loss of benthic habitat or species diversity or abundance.

Stakeholders were interested in understanding what measures will be taken to ensure waste is appropriately handled and disposed of. Esso noted vessel operators will implement waste procedures and will comply with Australian was regulations and standards. No objections or further questions were asked.

The environmental consequence of an accidental release of solid waste is assessed as **Consequence Level IV.**

The likelihood of such an event occurring has been assessed as **Likelihood Category D** (very unlikely).

7.6.3 Demonstration of As Low As Reasonably Practicable

Table 7-35 Decision Context and justification

Decision Context
The risk of accidental release of waste is well regulated via various treaties and legislation, both nationally and internationally, which specify industry best practice control measures. These are well understood and implemented by the industry. There is little uncertainty associated with the potential environmental impacts of this risk. The environmental consequence of the impacts resulting from the accidental release of waste has been assessed as **Consequence Level IV**. The risk of the accidental release of waste has been assessed as **Risk Category 4**. No objections were raised by relevant persons during consultations for Campaign #1 with regard to the risk of accidental release of waste. Hence, Esso believes **Decision Context A** should apply.

Table 7-36 Good practice controls

Good practice	Adopted	Control	Rationale
MARPOL Annex V Prevention of Pollution by Garbage from Ships.	Adopted – RSK6-CM1	Compliance with MARPOL Annex V and associated Marine Order 95 (Marine pollution prevention — garbage)	The vast majority of commercial ships are built to and surveyed for compliance with the standards set by classification societies. The role of vessel classification and classification societies has been recognised by the IMO across many critical areas including the 1988 Protocol to the International Convention on Load Lines and the MARPOL. A vessel built in accordance with the applicable Rules of an IACS member society may be assigned a class designation relevant to the IMO Rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex V Regulations for the Prevention of Pollution by Garbage from Ships specifically requires vessels (as appropriate to class) to have a garbage management plan and garbage record book in place and implemented.

Table 7-37 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
N/A	N/A	N/A	N/A

7.6.4 Demonstration of acceptability

Table 7-38 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 4** (the lowest category) and therefore considered acceptable.
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.

Factor	Demonstration criteria	Criteria met	Rationale
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having the potential to result in a **Consequence Level IV** thus are not considered as having the potential to result in serious or irreversible environmental damage.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The risk associated with accidental release of waste is unlikely to result in a detrimental effect on upon the environment such that future generations cannot meet their needs.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The proposed activities outlined in this EP align with the requirements of the OPGGS Act: • Section 280(2) – no interference with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the exercise of the rights conferred by titles granted. The requirements of SOLAS Chapters VI and VII, in relation to a Cargo Securing Manual, have also been adopted. Marine debris (including entanglement) is a recognised threat to the species in the following conservation management plans and advice. The proposed controls are consistent with conservation/management actions in: • CMPBW • NRPSRW • *Recovery Plan for Marine Turtles in Australia 2017-2027* (DoEE, 2017) • *Conservation Advice for Leatherback Turtles* (DEWHA, 2008a)

Factor	Demonstration criteria	Criteria met	Rationale
			• Conservation Advice for Rhincodon typus (whale shark) (TSSC, 2015c) • *National Plastics Plan* (DAWE, 2021) • Threat Abatement Plan for impacts of marine debris on vertebrate wildlife of Australia's coasts and oceans (DoEE, 2018) • *Wildlife Conservation Plan for Seabirds* (DAWE, 2020b). General vessel derived releases are covered under: • *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Cth).
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objectives to clearly define and communicate OI requirements to contractors and to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	No relevant person concerns have been raised concerning the accidental release of waste.

7.6.5 EPOs, control measures, EPSs and measurement criteria

Table 7-39 EPOs, control measures, EPSs and measurement criteria – Accidental release of solid waste

EPO	Control measure	EPS	Measurement criteria
RSK6-EPO1: No unplanned release of solid waste to the marine environment.	RSK6-CM1: Compliance with MARPOL Annex V and associated Marine Order 95 (Marine pollution prevention — garbage)	RSK6-EPS1.1: Campaign #1 vessels are compliant with MARPOL Annex V and associated Marine Order 95 (Marine pollution prevention — garbage) requirements as appropriate to vessel class.	RSK6-MC1.1.1: Vessel maintains a garbage record book. RSK6-MC1.1.2: Garbage management plan current and implemented.

7.6.6 Residual risk ranking

Table 7-40 Residual risk ranking outcome

Consequence Level	Likelihood Category	Risk Category
IV	D	4

7.7 Accidental release – Accidental release of hazardous or non-hazardous substances

7.7.1 Causes of accidental release of hazardous or non-hazardous substances

Hazardous and non-hazardous materials that could be accidentally released to the environment include fuels, hydraulic fluids, chemicals and grouting spread from spills or LOC from Campaign #1 vessels (including ROVs) or from the platforms during removal, transport and transfer from the *Pioneering Spirit* HLV or CSV onto barges or a HTV. Hazardous chemicals can also be found in some fire-fighting foams that may be released to the marine environment if used.

Most of the hazardous substances present on Campaign #1 vessels are used for the adequate operation of plant and equipment required to complete final preparation of topsides before lifting operations, as well as operation of plant and equipment onboard Campaign #1 vessels. These substances are standard across the shipping industry and includes gear oil, engine oil and hydraulic oil, and may also include thermal oil. Quantities of these products that are carried by vessels are low and vary from vessel to vessel. Similarly, residual quantities remaining in equipment on the platform topsides are expected to be small.

In addition, decommissioning activity vessels will be carrying MGO that will be used to power propellers, thrusters and other equipment during decommissioning activities. This type of oil represents the largest volumes of any hazardous substances within the vessels. Risks associated to MGO from accidental release due to rupture of a fuel tank are described and assessed in Section 7.8 of this EP.

For removal operations platforms will be non-operational and, following the flushing of topside systems, the presence of hazardous and non-hazardous substances in the topsides will be minimal. Temporary diesel generators will be installed at the platforms for final topside removal preparations by Allseas. As a result, diesel has been identified as a source for potential accidental release.

It is also noted that there is a risk of formation of pyrophoric material inside the skimmer piles in the form of iron sulphide (FeS). This compound may be formed due to the presence of sulphate reducing bacteria.

Causes of accidental releases of hazardous and non-hazardous substances during decommissioning activities may include:

- inadequate storage or handling of hazardous or non-hazardous substances
- failure or mechanical breakdown of equipment that use, store or transfer hazardous or non-hazardous materials
- failure to align valves correctly during transfer of hazardous or non-hazardous substances to tanks, or during transfer from vessels to platforms, such as grouting
- overfilling of chemicals or fuel bulk storage tanks
- spontaneous reaction from potential small quantities of residual pyrophoric material remaining inside the skimmer piles if it is exposed to air and it is dry
- use of non- approved fire-fighting foams.

Accidental release of hydraulic fluids can occur from both hydraulic line failure and failure or breakdown of equipment onboard vessels and ROVs. These events are associated with small volume spill events.

An accidental release of fuel into the sea may occur during bunkering operations due to failure of equipment or from a human error. Bunkering of vessels during the Campaign #1 activities will generally be conducted at port facilities, with Barry Beach Marine Terminal being the preferred location. However, due to the operational constraints of the *Pioneering Spirit,* vessel-to-vessel bunkering at sea is the only feasible option. For this vessel it is expected that bunkering will occur only once during the duration of Campaign #1 activities. While smaller support vessels, such as tugs, are planned to refuel at Barry Beach Marine Terminal or at a port nearby, provisions will remain in place to allow for bunkering at sea in exceptional or unforeseen circumstances where port refuelling is not a practical or viable option.

In addition, accidental release of diesel may occur from equipment located on the topsides that is required to complete final preparations for removal before lifting operations including that associated to temporary generators installed in the topsides. Release may be due to human error or leaks from equipment or storage containers.

The environmental risks associated with a loss of marine fuel from a vessel collision are assessed in Section 7.8.

On the risk of accidental release of grout, during installation of lifting points to prepare the platforms for removal an arrangement is required for lifting of KFA and KFB topsides that involves the installation of prefabricated grouted lifting points at designated locations around nominated deck legs within these two platforms. The grouted lifting points consist of two half shells clamped together to become a single lifting point. Section 2.7 describes this activity in more detail. Accidental release of grout may potentially occur due to failure of equipment or from human error during the grout transfer operations from the vessel to the platform.

On the risk of potential presence of pyrophoric material inside the skimmer piles, a pyrophoric reaction could result in a quick and spontaneous release of white smoke to the atmosphere. A pyrophoric reaction may only occur if:

- pyrophoric material has formed inside the piles, and there is residual material remaining after cleaning activities of the piles are completed
- once the facility is lifted from the water, the pyrophoric material that may remain inside the structure is exposed to air and dries out.

On the risk of release of material containing PFOS, IMO has listed some fire-fighting foams as prohibited on vessels from 1 January 2026. This prohibition is enacted via the *Navigation Act 2012* (Cth). Additionally, the Australian Government has listed PFOS, PFOA and PFHxS on the Industrial Chemicals Environmental Management Register (Schedule 7), which sets standards in relation to prohibiting their import, export, manufacture, use and disposal, applicable to offshore platforms that is in effect since 1 July 2025. As a result, all vessels that will take part in decommissioning operations will comply with relevant legislation and IMO requirements on these substances

7.7.2 Risks of loss of containment of hazardous or non-hazardous substances

A minor LOC has the potential to result in:

- change in water quality
- change in habitat
- injury/mortality to fauna
- change to the function, interest or activities of other users

- change in air quality.

Small spills of chemicals or stored fuel that could occur from failure of storage tanks/containers or from accidental release during handling of substances in the vessels are expected to be contained within the vessel and will not flow overboard into the sea. Vessels have Shipboard Oil Pollution Emergency Plans (SOPEPs) in place to manage this type of spill events.

The volume of hydraulic fluids potentially released into the sea from an accidental spill is estimated to be small. For instance, a ROV underwater hydraulic line failure is estimated to result in a maximum spill volume of 20L.

Potential spills from vessel to vessel pumping activities of substances associated to bunkering may be accidentally released into the sea. For bunkering operations, it is suggested that the maximum credible spill volume from a refuelling incident with continuous supervision is approximately the transfer rate over 15 minutes (AMSA, 2015). Assuming failure of dry-break couplings and based on the largest typical transfer rate in the order of 300m^3/hour, this equates to an instantaneous spill of approximately 75m^3.

Potential spills from vessel to platform pumping activities of substances associated to transfer of grout may be accidentally released into the sea. Estimated volume of grout slurry per lifting point is approximately 2m^3. In an unplanned release scenario, it is expected that grout slurry released from a single lifting point installation operation would be <1t.

The volume of diesel that will be present at the topsides for operation of temporary generators is estimated to be a maximum of 2.5m^3 at any one time, which is inclusive of an allowance of spare diesel drums available for refuelling of the generator. Standard preventative and containment measures will be in place to manage the risk from accidental diesel spills at the topsides and prevent potential release to the sea. To this end, equipment will be in good working conditions and temporary diesel generators and fuel storage area will either have a dedicated drip tray or appropriate bunding to contain and manage any accidental spill. It has been estimated that the potential volume of hazardous or non-hazardous materials that could accidentally be released into the ocean is small. Small open sea hydrocarbon spills result in similar short-term impacts as that of a large hydrocarbon release (Brussaard, et al., 2016). The characteristics of open sea waters is a significant mitigating factor in dispersing small oil spills, such that, no definitive evidence of long-term effects on marine fauna has been identified (Dicks, 1998).

Considering the small volumes of chemicals or hydrocarbons associated with this type of event together with the control measures in place, the consequence of a LOC of hazardous substances into the sea is assessed as **Consequence Level IV.**

The likelihood of such an event occurring is considered to be **Likelihood Category D** (very unlikely).

For the risk of accidental emissions to air from a pyrophoric reaction within the skimmer piles, it is noted that a pyrophoric reaction may occur when the FeS material is exposed to air and is dry. A cleaning process of the ODSPs and CDSPs will be implemented during facility preparation activities (covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) scope) that aims for the reduction in the volume and concentration of fluids that may be present in these systems to the maximum extent practicable, including potential pyrophoric material that may be have formed and remain within these structures after the cleaning process is completed. Even so, if there is presence of remaining concentrations of pyrophoric material, it is expected that internal walls of the piles are wet, eliminating one of the conditions required for a pyrophoric rection to take place.

As a result, the presence and availability of iron sulphides that may be present within the skimmer piles after the cleaning process is completed is expected to be minimal, and material is expected to be wet. Hence the likelihood of such an event occurring is assessed as **Likelihood Category E** (very highly unlikely).

7.7.3 Demonstration of As Low As Reasonably Practicable

Table 7-41 Decision Context and justification

Decision Context
The transfer, storage and handling of fuels and chemicals offshore are commonly practised activities. Similarly, grouting operations for installation of lifting points is a well-established operation that the vessel contractor is familiar with, including implementation of this method in previous decommissioning projects that Allseas has

Decision Context
completed. There is a good understanding of potential spill sources, and the control measures required to manage these. There is some uncertainty associated with skimmer piles regarding the potential risk of pyrophoric material that may be attached to the internal walls of these piles and that could create instant (short duration) atmospheric emissions because of a pyrophoric reaction that may occur during transport. However, the likelihood of the event occurring has been assessed as very highly unlikely. The environmental consequence of the impacts resulting from the accidental release of hazardous or non-hazardous substances has been assessed as **Consequence Level IV**. The risk of the accidental release of hazardous or non-hazardous substances has been assessed as **Risk Category 4**. No issues, objections or claims were raised by relevant persons during the relevant persons consultations process for this campaign with regard to the accident release of hazardous substances. Esso believes **Decision Context B** should apply.

Table 7-42 Good practice controls

Good practice	Adopted	Control	Rationale
Confirm vessels are compliant with applicable requirements.	Adopted – RSK7-CM1	Compliance with IMO/Industrial Chemicals Environmental Management Standard.	Compliance with the relevant legislation ensures that PFOS containing fire-fighting foams are not used on Campaign #1 facilities or vessels.
Discharge of least environmentally hazardous chemical.	Adopted – RSK7-CM15	*Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013).	This risk control practice requires that chemicals intended for discharge must be approved prior to use. This practice assesses chemicals that have the potential to be discharged to the environment (i.e. not household chemicals) to ensure the lowest toxicity, most biodegradable and least accumulative chemicals are selected which meet the technical requirements of the application.
Comply with MARPOL Annex I – Chapter 2.	Adopted – RSK7-CM2 and RSK7-CM11	Class certificate – oil pollution.	Under MARPOL – Annex I requirements, any ship of 400 gross tonnage or above is required to hold an International Oil Pollution Prevention Certificate.
Comply with Esso and relevant contractor occupational health, safety and environment procedures. OIMS System 6: Management or Work and Equipment.	Adopted – RSK7-CM3	Job Safety Analysis and Permit to Work.	Job Safety Analysis and Permit to Work controls reflect industry good practice adopted to ensure the safety of personnel on board all vessels servicing and supporting offshore facilities, and to reduce the risks associated with such operations Third-party providers are selected based on defined performance expectations aligned with regulatory and operational requirements. Their

Good practice	Adopted	Control	Rationale
OIMS System 8: Selecting and Engaging with Third Party Providers.			performance is actively monitored, and accountability is maintained through structured oversight to ensure compliance and continuous improvement.
Use of equipment fit for purpose.	Adopted – RSK7-CM4	Design and certification of hoses.	Hose certification reflects industry good practice adopted to ensure the safety of personnel on board all vessels servicing and supporting offshore facilities, and to reduce the risks to the environment associated with such operations.
Preventative maintenance.	Adopted – RSK7-CM5	Preventative maintenance program.	It is industry good practice that a preventative maintenance program is in place to ensure that equipment is in good working condition, including hoses inspection and replacement when degraded.
ROV condition check.	Adopted – RSK7-CM6	International Marine Contractors Association (IMCA) audit – ROV.	It is industry practice to obtain an IMCA survey report prior to charter of an ROV to support marine activities. An IMCA audit is a verification tool which states the ROV condition and operational readiness as per IMCA guidelines.
Comply with MARPOL Annex I – Chapter 5.	Adopted – RSK7-CM7and RSK7-CM12	SOPEP	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the IMO across many critical areas including the SOLAS, the 1988 Protocol to the International Convention on Load Lines and MARPOL. A vessel built in accordance with the applicable Rules of an IACS member society may be assigned a class designation relevant to the IMO Rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require that a Shipboard Marine Pollution Emergency Plan (or equivalent, according to class) is in place. MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require that a SOPEP (or equivalent, according to class) is in place.

Good practice	Adopted	Control	Rationale
			To prepare for a spill event, the SOPEP details: • response equipment available to control a spill event • review cycle to ensure that the SOPEP is kept up to date • testing requirements, including the frequency and nature of these tests. In the event of a spill, the SOPEP details: • reporting requirements and a list of authorities to be contacted • activities to be undertaken to reduce or control the release • procedures and point of contact on the ship for coordinating with local and national authorities.

Table 7-43 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
EMP – Vessel contractor.	Reduces the risk of incidents that could result in spill of hazardous and non-hazardous substances.	Vessel contractor will develop and implement an EMP that aligns and complies with the requirements contained in this EP. It also provides information and measures on how to manage hazardous and non-hazardous materials to prevent and reduce the risk of unplanned releases. The vessel EMP includes a requirement to comply with relevant regulations, including Marine Orders 91 and 93.	Adopted – RSK7-CM8 and RSK7-CM13
Procedures for grouting operations.	Following a documented procedure reduces the risk of accidental release of grout.	Vessel contractor will develop and implement a grouting procedure for grouting operations. The procedure will include (but is not limited to), the following considerations to minimise the risk of accidental release: • grouting operations to be conducted by trained personnel only • consideration on pre-start checks of equipment and lines, and maintenance/certifications of equipment where required.	Adopted – RSK7-CM9 and RSK7-CM14
Verification of completion of de-inventory and cleaning works were completed per facility preparation	Verification that de-inventory and cleaning activities have been completed per facility preparation scope of works	Verification of completion of facility preparation works and outcomes achieved is a practical measure that could be implemented. Verification of results from facility preparation activities allows for elimination or significant reduction of uncertainty, and provides the	Adopted – RSK7-CM10

Control measures	Benefit	Cost/feasibility	Adopted
works scope under the *Bass Strait Environment Plan (AUGO-EV-EMM-012)*.	allows for reduction in the uncertainty of presence of materials/substances within the piles that may remain present in these systems and that may pose a risk.	operator with the opportunity to adapt in advance where/if required	

7.7.4 Demonstration of acceptability

Table 7-44 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 4** (the lowest category) and therefore considered acceptable.
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. The activities were evaluated as having a very unlikely probability of occurrence. Best industry practice and controls will be implemented to minimise potential occurrence of unplanned events. Esso considers the precautionary principle has been applied.
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The assessment undertaken for the accidental release – LOC of hazardous or non-hazardous substances has concluded that potential environmental impacts would be short term and localised in nature. Best industry practices and other controls are in place to further reduce the probability of occurrence of an unplanned release Any impacts as a result of an unplanned release hazardous or non-hazardous substances will not impact the health,

Factor	Demonstration criteria	Criteria met	Rationale
			diversity and productivity of the environment in such a manner that future generations may be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent. The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The requirements of MARPOL Annex I have been adopted. The following legislative and other requirements are considered relevant as they apply to the implementation of MARPOL in Australia: • *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Cth) • *Navigation Act 2012* (Cth) – Chapter 4 (Prevention of Pollution) • Marine Order 91 (Marine pollution prevention – oil) • Marine Order 93 (Marine pollution prevention – noxious liquid substances) 2016.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"*
	Meets ExxonMobil Environmental Standards.	✓	The controls proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements

Factor	Demonstration criteria	Criteria met	Rationale
			• OIMS System 8: Selecting and Engaging with Third Party Providers objectives to clearly define and communicate OI requirements to contractors and to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	No relevant person concerns have been raised concerning the accidental release of hazardous substances.

7.7.5 EPOs, control measures, EPSs and measurement criteria

Table 7-45 EPOs, control measures, EPSs and measurement criteria – Accidental release of hazardous or non-hazardous substances

EPO	Control measure	EPS	Measurement criteria
RSK7-EPO1: No unplanned release of hazardous or non-hazardous substances.	RSK7-CM1: Compliance with IMO/Industrial Chemicals Environmental Management Standard.	RSK7-EPS1.1: Campaign #1 vessels are compliant with IMO/IChEMS.	RSK7-MC1.1.1: Evidence of alert (raised for each vessel) related to prohibitions applicable to firefighting foams. RSK7-MC1.1.2: Vessel specific chemicals register that includes firefighting equipment present onboard. RSK7-MC1.1.3: Records of inspection/audit of firefighting equipment onboard the vessels.
	RSK7-CM2: Class certificate – oil pollution.	RSK7-EPS2.1: Campaign #1 vessels are compliant with MARPOL Annex I and MARPOL Annex V and associated Marine Order 91 (Marine Pollution Prevention – Oil) as applicable to vessel class.	RSK7-MC2.1.1: Vessel maintains an International Oil Pollution Prevention Certificate.
	RSK7-CM3: Job Safety Analysis and Permit to Work.	RSK7-EPS3.1: Application of relevant Esso and contractor procedures.	RSK7-MC3.1.1: Records of application of work safety procedures (JSAs, last minute checks). RSK7-MC3.1.2: Records of third-party performance compliance checks/inspections by Esso.

7.7.6 Residual risk ranking

Table 7-46 Residual risk ranking outcome

Consequence Level	Likelihood Category	Risk Category
IV	D	4

7.8 Accidental release – Loss of containment refined oils (marine gas oil)

7.8.1 Causes of loss of containment of refined oils

A full range of potential oil pollution scenarios were identified based on the type of activities and operations that will be undertaken during Campaign #1. Prior to commencement of Campaign #1 activities, that are covered under

this EP, facility preparation activities will have been completed including but not limited to P&A of wells, and flushing of topsides equipment and pipelines. These facility preparation activities prior to Campaign #1 are covered under the *Bass Strait Environment Plan* (AUGO-EV-EMM-012). As a result, platforms within the scope of the Campaign #1 EP will be non-operational, wells P&A'd, and associated pipelines adequately flushed/purged and isolated, with no risk of unplanned oil release from these sources (refer to Sections 6.7 to 6.10 for a description of planned discharges from pipelines and other systems).

Decommissioning activities will require operation of specialised vessels, and as such, potential source of a worst-case oil pollution event during Campaign #1 would originate from an unplanned release/LOC of oil from a vessel. Detailed description of a worst-case vessel oil release scenario is discussed in this Section. Additional potential unplanned oil pollution sources associated with Campaign #1 activities are described in Section 7.7.

The HLV and other vessels such as CSVs will use MGO to power its engines during decommissioning activities. As a result, there will be significant volumes of this type of fuel stored within each vessel. Other smaller vessels that are part of the marine spread for Campaign #1 operations such as supply vessels, tugs or HTVs may use MGO or alternatively MDO. These two types of fuels are part of the same oil group (Group II – light persistent oil. Scenarios identified in which a worst-case release of MGO from an unplanned event may occur are:

- LOC resulting from a collision between HLV and a platform during preparation for or while conducting lifting operations at the facilities locations, that results in fuel tank rupture and MGO loss
- LOC resulting from a collision between the HLV with third-party vessels nearby the platforms or commercial shipping lines with presence of large third-party vessels such as cargo ships, tankers and large passenger ships, which in a collision event, may damage the HLV to an extent where the outer layer of ballast water tanks are breached and the internal fuel tanks of the vessel are also breached, resulting in potential tank rupture and MGO loss
- LOC from rupture of tank of a support vessel during transfer operations due to collision with other vessels. Based on the operational conditions that will be in place during transfer operations, including presence and traffic of small third-party vessels in the area, unplanned release of oil from smaller vessels such as a support vessel at or nearby the area where these transfer operations will take place is considered credible, however highly unlikely to eventuate.

The scenarios described above have been used as the basis for spill modelling and subsequent identification and assessment of risks from an unplanned release of oil from a vessel (refer to Sections 7.8.2 and 7.8.3).

For the purpose of identification of worst-case oil spill scenarios for Campaign #1 activities, risk mitigation factors such as the following were not considered:

- procedures in place by the vessel contractor for operations
- existing shipping exclusion zone (also known as the ATBA) currently in place around operating oil and gas facilities in the Gippsland Basin for vessels larger than 200 gross tonnes
- Traffic Separation Schemes implemented in the area which regulates vessel traffic flow to enhance safety of navigation around the ATBA by separating shipping into one-direction lanes for vessels heading north-eastwards and those heading south-westwards
- the 500m exclusion zone that will be required around Campaign #1 vessels during decommissioning activities
- the speed at which vessels will transit, which may prevent collision between ships or significantly reduce the force of the impact minimising the likelihood of tank breaches
- Notices to Mariners that will be issued prior to HLV operations in the Gippsland Basin.

As a result, the potential release of MGO for the worst-case scenarios identified is considered an extremely unlikely event that provides a significantly conservative approach to assess potential impacts from an unplanned oil spill event during execution of Campaign #1.

Unplanned oil spill from a vessel drift or powered grounding scenario is considered not credible given the lack of emergent features within the OA, the water depth at which Campaign #1 vessels will operate, and the type of DP system installed in the HLV (DP Class 3). The design basis of a DP3 Class system is to allow vessel to stay on location in the worst failure mode defined by IMO, which includes fire or flooding of an engine room, a switchgear room, or any other active or passive component of the system causing similar serious effect (Janson, 1998). DP3 Class system is the most comprehensive DP system offering the highest level of protection, safety and reliability,

and it is aimed to prevent loss of position from any single failure, including a completely burnt fire division or flooded watertight compartment as described above.

Location, specific type of activity underway, and design of vessels are some of the factors that need to be considered when determining the potential risk of unplanned oil spills from vessels. From a HLV perspective the following is considered when conducting transfer operations:

- transfer operations will be conducted in areas that are located away from shipping lines frequently used by large vessels such as cargo, tankers, container or cruise ships. Instead, predominant vessel traffic in the area where transfer operations are likely to take place is limited to smaller craft such as fishing boats and other vessels engaged in recreational activities, which transit at lower speeds and have more manoeuvrability. In addition, the HLV will be mainly stationary during transfer operations, further reducing potential of collision with the HLV by third-party vessels
- the HLV has a design configuration that follows the principle of a double-hulled vessel, protecting the fuel in internal storage tanks that are located at least two layers of steelwork in from the exterior of the vessel that is exposed to external contact with other vessels. In the extremely unlikely collision event scenario between the HLV and these smaller craft, it is not considered feasible that the smaller vessels will have the necessary impact energy that would penetrate the HLV outer hull, penetrate the ballast water tanks in the first layer of the vessel from outside, and reach and puncture internal fuel tanks located in the second layer from the outside, behind the ballast water tanks.
- During simultaneous operations at a transfer location involving the HLV and other vessels such as CSVs, HTVs, tugs, barges or other support vessels, consideration is again given to the location of the fuel tanks in the Pioneering Spirit. The only fuel tanks in the HLV that are relatively close to the vessel's side shell are all located on starboard side, midship of the HLV. These tanks are 3 metres inboard from the external side shell, and in the second layer of the vessel from the outer shell, mirroring a double-hull configuration. In addition to the distance between the outer hull and the fuel tanks shell, the HLV has strengthening members installed in the structure separating the outer hull from the fuel tanks, and it also has a reinforced ice impact area protecting the zone where these tanks are located. This design provides the HLV with further protection against impact that is in addition to the double-hull configuration.
- It is also noted that the general configuration of the HLV, including location of the JLS and the TLS, results in the need for other vessels involved in the transfer operations to be positioned at very specific areas of the HLV. These locations where the other vessels must be positioned are at least 150 metres away from the starboard side tanks.
- In addition to the geometrical and structural physical boundaries that prevent a HLV tank to be ruptured, and the location of other vessels nearby the HLV involved in the transfer operations relative to the location of the fuel tanks located at starboard side, it is also considered that these other vessels will not have a significant impact energy that could break into the HLV double-hull structure and through the ice impact protection and strengthening members in the very unlikely scenario of a collision, as the speed at which vessels involved in the transfer operation are sailing within this location is very slow.
- Approaching of a barge or a HTV towards the HLV is conducted by using at least two tugs as guide boats, which provides further assurance that movement of the HTV or barge is controlled at all times.
- in contrast to the activity of lifting a topside or jacket at the platform location, the HLV will not be connected to an external fixed structure during transfer operations. This eliminates the risk of collision of the HLV vessel with a fixed structure (platform) from unforeseen situations (i.e. unforeseen adverse metocean conditions) when conducting transfer operations
- accidental drop of these structures on deck that could result in penetration of the deck and then further breach and rupture of fuel tanks is considered not credible as:
    - transfer operations of topsides and jackets from the HLV onto HTVs or barges is a safety-critical operation with detailed planning, engineering, and weather assessment completed prior to removal operations commence. These vessels will approach the HLV in a controlled fashion taking into consideration weather and operational conditions and will tie-up to the HLV in a set configuration to enable the transfer to be undertaken
    - when transferring jackets from the HLV using the JLS onto a HTV or barge, the jacket itself is located outboard of the HLV and does not project over the HLV deck during this operation. The physical distance from the JLS to the nearest HLV fuel tank during transfer operations is more than 110m

- when transferring topsides from the HLV using the TLS onto a HTV or barge, the topside is carried and set down within the bows of the twin hulls and does not project over the HLV deck at any stage. The physical distance from the TLS to the nearest HLV fuel tank during transfer operations is more than 60m. The combination of physically transferring these structures outboard the HLV decks and physical distance from the operations pose an extremely low level of risk of dropped objects to the HLV resulting in fuel tank breach
- other smaller structures will be transferred from the HLV to HTV or barges using the aft port side crane. The physical distance from the aft port crane to the nearest HLV fuel tank during transfer is more than 60m. It should be noted that the fuel tanks are located beneath the accommodation/super structure of the vessel where lifts are restricted to.

Based on the above, a potential HLV unplanned oil spill during transfer operations from a ruptured fuel tank due to vessel collision or dropped objects is considered a not credible scenario. Campaign #1 vessels that will conduct the operations for decommissioning of facilities will rely entirely on Group II fuel (i.e. MGO), however, there may be minimal residual volumes of HFO present in the vessels. The residual volume of HFO is the result of remaining content of this type of fuel that was used by the vessels during previous projects or for long distance transit purposes. Before commencing Campaign #1 activities, the vessel operator will ensure HFO contained in the vessel is minimised, and MGO will be the fuel type to be used for decommissioning operations. It is possible that residues of HFO sitting at the bottom of the tanks may not be fully removed by the vessel fuel transfer systems utilised for this purpose. As a result, it is expected that minimal residual volumes of this fuel will be present in the vessels. The estimated maximum residual volume to be present in a single tank for the *Pioneering Spirit* is up to approximately 80m^3. Any fuel tanks containing residual volumes of HFO in the HLV are located behind a double hull, and ballast water tanks, which act as additional barriers of protection. Given the combination of residual volume of fuel in these tanks, the level of barriers to the external environment and the extreme unlikelihood of a collision event with enough energy to breach these tanks, the scenario of HFO spill from a collision event is assessed as not credible.

7.8.2 Spill modelling

To understand the potential consequences of a worst-case unplanned release of oil associated with vessel operations during Campaign #1 activities as described in Section 7.8.1, the following was considered for the purpose of impacts and risk assessment:

- for worst-case scenario associated to the HLV unplanned release, Esso commissioned RPS to undertake spill modelling of potential MGO loss from the occurrence of the worst-case scenario (refer to Appendix H-1), described in Section 7.8.1 as *"Loss of containment resulting from a collision between HLV and platforms during preparation to or while conducting lifting operations at the facilities locations, that results in tank rupture and MGO loss'*, and *'Loss of containment resulting from a collision between HLV with third-party commercial (merchant) vessels nearby the platforms or commercial shipping lines with presence of large third-party vessels… resulting in potential tank rupture and MGO loss"*. Further information is presented in Sections 7.8.2.1 to 7.8.2.3 of this EP
- for the worst-case scenario associated with the support vessel unplanned release during transfer operations, Esso commissioned RPS to undertake spill modelling of potential MGO loss from the occurrence of the worst-case scenario (refer to Appendix H-2), described in Section 7.8.1 as *"LOC from rupture of tank of a support vessel during transfer operations due to collision with other vessels"*
- for an adequate identification and assessment of potential risk from an oil spill during transfer operations, the representative transfer locations chosen for the model are those that can be established as the most environmental sensitive locations within the OA, namely the area located towards the western end of the OA in proximity to State waters near Wilsons Promontory and Corner Inlet. The location selected for modelling of the spill scenario at the representative Transfer Location A (see Appendix H-2) also includes consideration of limitations for transfer operations such as water depth. Figure 2-46 shown in section 2.8.4 of this EP provides a visual representation of areas where transfer operations could be conducted. Location of fuel release modelled for Transfer Location A is deemed to be in proximity to the area closest to Corner Inlet where simultaneous operations between Pioneering Spirit and support vessels may occur. In addition, as described in the Emergency Preparedness and Response plan (EPR) developed for the Decommissioning – Campaign#1 project, additional precautionary measures have been put in place to ensure there is a robust response plan in place in the event a very highly unlikely spill incident occurs at a location within Commonwealth Waters but in proximity to the Corner Inlet area. These precautionary measures includes an assessment of environmental sensitivities or protected matters for the full extension

of the Corner Inlet area (even though the EMBA only covers the area of Corner inlet located towards the east of this sensitive receptor) and development of additional Tactical Response Plans (TRP) – despite the shoreline loading thresholds and probability required for development of such TRPs not being met (refer to Decommissioning – Campaign1 Emergency Response Plan).

Both reports shown in Appendix H-1 and Appendix H-2 used the same methodology approach, including:

- current and wind dataset was generated whereby current included the combined influence of three-dimensional large scale ocean currents and tidal currents
- a three-dimensional oil spill model was used to simulate the drift, spread, weathering and fate of the spilled oil
- each scenario modelling was conducted using a stochastic approach involving 100 randomly selected spill single trajectory simulations
- where applicable, deterministic runs were also assessed and presented
- a description of floating, shoreline and in-water thresholds including:
    - floating (sea surface) oil exposure thresholds
    - shoreline accumulation (contact) thresholds
    - in-water exposure thresholds (dissolved and entrained).

Based on the outcomes of the modelling reports, it is determined that the potential extent of a worst-case spill from the LOC from a support vessel during transfer operations is mostly within the extent of the spill resulting from a worst-case release scenario from the HLV, with the exception of a portion towards the eastern end of Corner Inlet, which may be reached by entrained hydrocarbons in the event of a release of MGO during transfer operations as described in Section 7.8.1. Therefore, results from both RPS reports (refer to Appendix H-1 and Appendix H-2) are used as the basis to inform and assess potential impacts and risks from an unplanned release of LOC from a vessel, and to establish required controls.

7.8.2.1 Modelling methodology

Esso commissioned RPS to undertake stochastic and deterministic modelling of potential LOC of MGO from the HLV at representative locations adjacent to where platforms are located (refer to Appendix H-1) and from a support vessel at representative transfer locations (refer to Appendix H-2). These locations were selected to be representative of the potential impacts from the unlikely event of a MGO release from the HLV and from a support vessel as described in Section 7.8.1. The spill modelling inputs and parameters are summarised in Table 7-47.

The worst-case spill scenarios modelled were completed with the intent of providing an understanding of a conservative outer envelope of the potential area of exposure to a spill. The modelling didn't consider any applicable controls, such as legislative requirements and/or guidelines in place to prevent vessel collisions, or standard vessel operational procedures to prevent and manage scenarios where oil is released, increasing the conservative nature of the modelling completed to represent a highly unlikely oil spill event during decommissioning activities.

Table 7-47 HLV MGO spill modelling inputs for Campaign #1

Parameter	Details	
Vessel	**HLV**	**Support vessel**
Number of spill simulations	100	
Period of the year (season)	Annual analysis	
Hydrocarbon type	MGO (Group II type fuel)	
Total spill volume	1165m^3	280m^3

Parameter	Details						
Volume basis	Based on the design of the Allseas *Pioneering Spirit*, it is noted that there are no fuel tanks located directly next to the outer hull. All the fuel tanks in the *Pioneering Spirit* are located behind ballast water tanks. This configuration prevents the direct exposure of fuel tanks to impacts from collision events, and it follows the same principle as a double-hulled vessel configuration. Based on the protection provided to the fuel tanks by the design of the vessel, and following AMSA's guideline for indicative maximum credible spill volumes from collision for vessels that are protected by a double-hull, (AMSA, 2015) , the volume used for the spill modelling (MGO) and the risk assessment is 1165m^3. The loss of fuel from a ruptured tank is influenced by the location of the rupture and the hydrostatic pressure, which would limit the release into the ocean; also, pumping of fuel from the affected tank into other tanks in the vessel that have not been compromised could also restrict the amount of fuel lost.			Release from largest fuel tank from a support vessel, following AMSA's guideline for indicative maximum credible spill volumes from vessels due to a collision event (AMSA, 2015).			
Release locations	DPA 38° 29' 14"S, 147° 22' 39"E	WTA 38° 14' 24"S, 147° 52' 25"E	FTA 38° 24' 26"S, 148° 16' 41"E	KFA 38° 35' 47"S, 148° 08' 41"E	FLA 38° 18' 40"S, 148° 26' 22"E	TLA 38° 52' 46"S, 146° 44' 38"E	TLB 39° 1' 49"S, 146° 35' 15"E
Location basis	The locations chosen for modelling were selected to provide representative information and coverage for potential vessel spill scenarios within the OA during decommissioning activities.						
Release duration	12 hours			6 hours			
Modelled duration	30 days						
MGO characteristics:							
Density	829.1kg/m^3@25˚C						
API gravity	37.6						

Parameter	Details			
Dynamic viscosity	4.0cP @25°C			
Pour point	-14°C			
Oil property category	Group II (light persistent oil)			
Boiling point	Volatile (<180°C) 6.0%	Semi-volatile (180–265°C) 34.6%	Low volatility (265–38 °C) 54.4%	Residual (>380°C) 5.0%

7.8.2.2 Modelling outputs – Weathering and fate

MGO contains approximately 95% of volatile and semi-volatile hydrocarbons (or non-persistent to light-persistent constituents) that are likely to evaporate when available to the atmosphere. The remaining 5% is composed of heavy hydrocarbons (or persistent compounds) that may persist on the sea-surface for extended times.

It is important to note that the viscosity of MGO does not change significantly over time and hence has a strong tendency to physically entrain into the upper water column as oil droplets in the presence of waves, where it is subjected to microbial degradation (decay) but can re-float to the surface if wave energies abate.

Figure 7-1 to Figure 7-7 shows the predicted oil fate and weathering corresponding to a single spill trajectory at each of the modelled locations, representing the largest swept area of floating oil above 10g/m^2. Results indicates that for the oil exposed to the surface, evaporation is the main weathering process taking place immediately after the release occurs. Between the first and second day after the release, the entrainment process presents a sharp and rapid increase followed then by a steadier decrease over the remaining 28 eight days of the model.

At the conclusion of the spill simulation period (30 days), between 44% (at KFA and FLA) and 52% (at DPA) of the spilled oil was lost to the atmosphere through evaporation, between 30% (at DPA) and 40% (at FTA and FLA) of the MGO was predicted to have decayed, whilst between 14% and 18% was predicted to remain entrained within the water column.

7.8.2.3 Modelling outputs – Stochastic

Oil spill modelling predicts the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, because of any spill. This is known as the spill EMBA and is used for planning purposes to

ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the EP.

Modelling is also used to inform specific impact assessments by understanding the location and extent of oil at concentrations likely to result in environmental consequences. There is no agreed exposure level below which environmental impacts will not occur; therefore, outputs should not be interpreted as a boundary. However, mapping areas that could be moderately impacted by a spill is a useful tool for impact consequence assessment. Exposure values defined in this EP for risk assessment of an unplanned release from a vessel collision are based on NOPSEMA's *Environment bulletin - Oil spill modelling (April 2019)* (NOPSEMA, 2019b) and are described in Table 7-48.

Table 7-48 Exposure values

Parameter	Exposure value		Description
Sea surface exposure (floating oil)	Low	1g/m^2	Approximates range of socio-economic effects and establishes planning area for scientific monitoring.
	Moderate	10g/m^2	Approximates lower limit for harmful exposures to birds and marine mammals.
	High	50g/m^2	Approximates surface oil slick and informs response planning.
Shoreline exposure	Low	10g/m^2	Predicts potential for some socio-economic impact.
	Moderate	100g/m^2	Loading predicts area likely to require clean-up effort.
	High	1000g/m^2	Loading predicts area likely to require intensive clean-up effort.
In-water (dissolved) exposure	Low	10ppb	Establishes planning area for scientific monitoring based on potential for exceedance of water quality triggers.
	Medium	50ppb	Approximates potential toxic effects, particularly sublethal effects to sensitive species.
	High	400ppb	Approximates toxic effects including lethal effects to sensitive species.
In-water (entrained) exposure	Low	10ppb	Approximates toxic effects including lethal effects to sensitive species.
	High	100ppb	Approximates toxic effects including lethal effects to sensitive species.

The environmental sensitivities within this area are described from Table 7-49 to Table 7-55, based on results for the worst-case release from HLV at five representative locations near the platforms, and the worst-case release from a support vessel at two representative transfer locations, modelled for a MGO spill.

Table 7-49 Vessel collision DPA - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure	Moderate (10g/m^2)	Maximum distance from release location is approximately 31.4km in a northeast direction. The zone of moderate exposure overlaps several

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. The spill does not extend into State waters or contact any marine parks at this threshold, and it doesn't overlap with KEFs.
	High (50g/m^2)	Maximum distance from release location is approximately 20.2km in a southwest direction. There is an 87% probability that the zone of high exposure will overlap with several albatrosses and the common diving petrel foraging BIAs, PBW foraging BIA, SRW migration BIA and the white shark breeding BIA.
Shoreline exposure	Moderate (100g/m^2)	The maximum length of the shoreline accumulation at moderate threshold is 13km. The highest predicted probabilities of moderate shoreline exposure were at East Gippsland (33%) and Point Hicks (32%), with the minimum predicted time before shoreline accumulation at these locations as 3.88 days.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0m - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (11%) at the moderate threshold was predicted to overlap with several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. There is a 1% probability of water column exposure in the Upwelling East of Eden KEF and 1% probability of overlap with State waters (Victoria). There is no probability of exposure indicated for marine national parks. The probability of water column exposure in State waters (Victoria) is 1%, and there was no probability of exposure indicated for marine national parks.

Table 7-50 Vessel collision WTA - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure (floating oil)	Moderate (10g/m^2)	Maximum distance from release location is approximately 31.5km in a northeast direction. The zone of moderate exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. There is a 2% probability of floating oil within the moderate threshold to reach the Upwelling East of Eden KEF, and the spill do not extend into State waters or marine parks at this threshold.
	High (50g/m^2)	Maximum distance from release location is approximately 19.1km in a northeast direction. There is a 75% probability that the zone of high exposure will overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA.

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Shoreline exposure	Moderate (100g/m^2)	The maximum length of the shoreline accumulation at moderate threshold is 11km. The highest predicted probabilities of moderate shoreline exposure were at East Gippsland (20%) and Point Hicks (15%), with the minimum predicted time before shoreline accumulation at these locations as 3.96 days and 4.54 days respectively.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (15%) at the moderate threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. There is a 2% probability of water column exposure in the Upwelling East of Eden KEF and 1% probability of overlap with State waters (Victoria). There is no probability of exposure indicated for marine national parks.

Table 7-51 Vessel collision FTA - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure (floating oil)	Moderate (10g/m^2)	Maximum distance from release location is approximately 46km in a southwest direction. The zone of moderate exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. There is a 1% probability of floating oil within the moderate threshold to reach the Upwelling East of Eden KEF, and the spill do not extend into State waters or marine parks at this threshold.
	High (50g/m^2)	Maximum distance from release location is approximately 19.1km in a northeast direction. There is a 69% probability that the zone of high exposure will overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area.
Shoreline exposure	Moderate (100g/m^2)	The maximum length of the shoreline accumulation at moderate threshold is 2km. The highest predicted probabilities of moderate shoreline exposure were at Bega Valley (3%) and Montague Island (1%), with the minimum predicted time before shoreline accumulation at these locations as 9.42 days and 11.42 days respectively.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (23%) at the moderate threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area.

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		There is a 2% probability of water column exposure in the Upwelling East of Eden KEF, and there is no probability of exposure indicated for State waters or marine national parks.

Table 7-52 Vessel collision KFA - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure (floating oil)	Moderate (10g/m^2)	Maximum distance from release location is approximately 48.9km in a southwest direction. The zone of moderate exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. Modelling results indicate no overlapping of floating oil at the moderate threshold with KEFs, marine national parks or State waters.
	High (50g/m^2)	Maximum distance from release location is approximately 16.6km in a southwest direction. There is a 78% probability that the zone of high exposure will overlap with several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area.
Shoreline exposure	Moderate (100g/m^2)	The maximum length of the shoreline accumulation at moderate threshold is 5km. There is a probability of moderate shoreline exposure at Montague Island (2%), with the minimum predicted time before shoreline accumulation at this location as 6.42 days.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (17%) at the moderate threshold was predicted to overlap with several albatrosses foraging BIAs, the common diving petrel and short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. There is a 1% probability of water column exposure in the Upwelling East of Eden KEF, and there is no probability of exposure indicated for State waters or marine national parks.

Table 7-53 Vessel collision FLA - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure (floating oil)	Moderate (10g/m^2)	Maximum distance from release location is approximately 39.2km in a south-southwest direction. The zone of moderate exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. In addition, the Upwelling East of Eden KEF also overlaps with floating oil at the moderate threshold.

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		On the other hand, modelling results indicate no overlapping of floating oil at the moderate threshold with marine national parks or State waters.
	High (50g/m^2)	Maximum distance from release location is approximately 18.5km in a south-southwest direction. There is a 67% probability that the zone of high exposure will overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA, the white shark known distribution area, and the Upwelling East of Eden KEF.
Shoreline exposure	Moderate (100g/m^2)	The maximum length of the shoreline accumulation at moderate threshold is 9km. There is a probability of moderate shoreline exposure at Bega Valley (3%), with the minimum predicted time before shoreline accumulation at this location as 10.32 days.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (24%) at the moderate threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. In the same way, there is a 24% probability of water column exposure in the Upwelling East of Eden KEF. Modelling results indicate there is no probability of exposure for State waters or marine national parks at the moderate threshold.

Table 7-54 Vessel collision TLA - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure (floating oil)	Moderate (10g/m^2)	Maximum distance from release location is approximately 10.8km in an east - northeast direction. The zone of moderate exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the Short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. There is a 4% probability of exposure at Seal Islands and a 42% probability of floating oil reaching State waters (Victoria). The spill does not extend into marine parks at this threshold.
	High (50g/m^2)	Maximum distance from release location is approximately 4.4km in a southwest direction. There is a 26% probability that the zone of high exposure will overlap with several albatrosses, the common diving petrel and the Short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA, and the white shark breeding BIA.
Shoreline exposure	Moderate (100g/m^2)	The maximum length of the shoreline accumulation at moderate threshold is 5.3km. The maximum probability of moderate shoreline exposure is at Seal Islands (20%) with the minimum predicted time before shoreline accumulation at this location as 0.24 days (5.76 hours). Probability for

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		shoreline exposure at East Gippsland and Point Hicks is 19%. The minimum predicted time before shoreline accumulation at these two locations is 7.68 days.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0m - 10m depth from the surface. For this scenario, modelling results indicate there is no probability of exposure to dissolved hydrocarbons at or above moderate thresholds.

Table 7-55 Vessel collision TLB - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Sea surface exposure (floating oil)	Moderate ($10g/m^2$)	Maximum distance from release location is approximately 10km in a southwest direction. The zone of moderate exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration and breeding BIAs and the white shark breeding and foraging BIAs. There is a 3% probability of floating oil exposure at the Beagle Marine Park, and 15% probability for State waters (Victoria).
	High ($50g/m^2$)	Maximum distance from release location is approximately 5.7km in a southwest direction. There is a 21% probability that the zone of high exposure will overlap with several albatrosses, the common diving petrel and the short-tailed shearwater BIAs, the PBW foraging BIA, SRW migration BIA, and the white shark breeding and foraging BIAs.
Shoreline exposure	Moderate ($100g/m^2$)	The maximum length of the shoreline accumulation at moderate threshold is 7.1km. The maximum probability of moderate shoreline exposure is at Seal Islands (26%) with the minimum predicted time before shoreline accumulation at this location as 0.72 days (17.28 hours). Probability for shoreline exposure at East Gippsland and at Point Hicks is 13%, with a minimum predicted time before shoreline accumulation at these two locations as 16.16 days.
In-water (dissolved) exposure	Moderate (50ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0m - 10m depth from the surface. For this scenario, modelling results indicate there is no probability of exposure to dissolved hydrocarbons at or above moderate thresholds.

Other features from the five locations modelled that are outside of the mapped (moderately exposed) area that are within the EMBA are outlined in Table 7-56 to Table 7-62.

Table 7-56 DPA vessel collision - MGO modelling output summary

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure	Low ($1g/m^2$)	Zone of low exposure extends approximately 200km from release location in a predominately east-northeast direction. The zone of low exposure overlaps several albatrosses foraging BIAs, the common diving petrel and the short-

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
(floating oil)		tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. In addition, there is an 8% probability of overlap with the Upwelling East of Eden KEF, a 2% and 1% probability of overlap with the Ninety Miles Beach and the Point Hicks Marine National Parks respectively, and a 6% probability of overlap with State waters (Victoria). Due to the fate and weathering process predicted for MGO, sea surface exposure (maximum residence) is estimated to be 2.46 days after the release.
Shoreline exposure	Low ($10g/m^2$)	The maximum length of the shoreline accumulation is 99km. The highest probability for shoreline exposure is at East Gippsland (58%) followed by Point Hicks (51%), with the minimum predicted time before shoreline accumulation at these locations as 3.17 days.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (47%) at the low threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. Similarly, there is probability of water column exposure in the Upwelling East of Eden KEF (7%), the Point Hicks and Cape Howe Marine National Parks (2% and 1% respectively) and with State waters (4% for Victoria and 1% for New South Wales).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the coastal area near Cape Paterson, Victoria to the southeast of Ulladulla, New South Wales. Exposure to entrained hydrocarbons at the low threshold overlaps with several albatrosses foraging BIAs, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration and breeding BIAs and the white shark breeding BIA. Probability of entrained hydrocarbons contact with nearshore waters areas ranges from 1% at Pyramid Island and Eurobodalla to 49% at East Gippsland. Entrained hydrocarbons contact probability with the shorelines of various terrestrial national parks and reserves ranges from approximately 1% at Eurobodalla, Answer Island, Kanowna Island and Skull rock, to 53% at East Gippsland. Entrained hydrocarbon at the low threshold could also potentially overlap with other receptors, including the following: • Beagle and the East Gippsland AMPs, with likelihoods of 13% and 4% respectively • Kent Group National Park, with a likelihood of 2% • Cape Howe, Ninety Mile Beach, Points Hick and Wilsons Promontory Marine National Parks, with likelihoods of 28%, 8%, 56% and 3% respectively • Upwelling East of Eden (72%), Shelf rocky Reefs (7%), Canyons of the Eastern Continental Slope (2%) and Big Horseshoe Canyon (1%)

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		• State waters in Victoria (57%), New South Wales (25%) and Tasmania (12%).

Table 7-57 WTA vessel collision - MGO modelling output of other features outside the mapped area

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure (floating oil)	Low (1g/m^2)	Zone of low exposure extends approximately 240km from release location in a predominately east-northeast direction. The zone of low exposure overlaps several albatrosses, petrels and shearwaters foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. In addition, there is a 36% probability of overlap with the Upwelling East of Eden KEF, a 1% probability of overlap with the Point Hicks Marine National Park, and a 1% probability of overlap with State waters (Victoria). Due to the fate and weathering process predicted for MGO, sea surface exposure (maximum residence) is estimated to be less than one day after the release.
Shoreline exposure	Low (10g/m^2)	The maximum length of the shoreline accumulation is 54km. The highest probability for shoreline exposure is at East Gippsland (41%) followed by Point Hicks (30%), with the minimum predicted time before shoreline accumulation at these locations as 3.21days and 3.41 days respectively.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (55%) at the low threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. Similarly, there is probability of water column exposure in the Upwelling East of Eden KEF (17%), the Point Hicks and Cape Howe Marine National Parks (4% and 2% respectively) and with State waters (5% for Victoria and 2% for New South Wales).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the coastal area near Wilsons Promontory in Victoria and the Kent Group islands, to the southeast of Ulladulla, New South Wales. Exposure to entrained hydrocarbons at the low threshold overlaps with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. Entrained hydrocarbons contact probability with nearshore waters areas ranges from 1% at Pyramid Island and Eurobodalla to 49% at East Gippsland. Entrained hydrocarbon at the low threshold could also potentially overlap with other receptors, including the following: • Beagle and the East Gippsland AMPs, with likelihoods of 12% and 7% respectively • Kent Group national park (4%) • Cape Howe and Point Hicks, with likelihoods of 38% and 61% respectively

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		• Upwelling East of Eden (78%), Shelf rocky Reefs (7%), Big Horseshoe Canyon (4%) and Canyons of the Eastern Continental Slope (4%). • State waters in Victoria (64%), New South Wales (33%) and Tasmania (12%).

Table 7-58 FTA vessel collision - MGO modelling output of other features outside the mapped area

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure (floating oil)	Low ($1g/m^2$)	Zone of low exposure extends approximately 108km from release location in a predominately east-northeast direction. The zone of low exposure overlaps several albatrosses, petrels and the shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. In addition, there is a 21% probability of overlap with the Upwelling East of Eden KEF. The spill does not extend into State waters or marine parks at this threshold. Due to the fate and weathering process predicted for MGO, sea surface exposure (maximum residence) is estimated to be less than one day after the release.
Shoreline exposure	Low ($10g/m^2$)	The maximum length of the shoreline accumulation is 31km. The highest probability for shoreline exposure is at Bega Valley (13%) followed by Montague Island (8%), with the minimum predicted time before shoreline accumulation at these locations as 6.58 days and 5.33 days respectively.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (52%) at the low threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. Similarly, there is probability of water column exposure in the Upwelling East of Eden KEF (19%), the Cape Howe Marine National Park (1%) and with State waters in Victoria and New South Wales (2% each).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the coastal area near the Kent Group islands and Flinders Island in Tasmania, to the south of Ulladulla, New South Wales. There is a 98% probability of exposure with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. The entrained hydrocarbons contact probability with nearshore water areas ranges from 2% at Craggy Island to 10% at Bega Valley. Entrained hydrocarbon at the low threshold could also potentially overlap with other receptors, including the following: • Beagle (5%), East Gippsland (5%) and Flinders (2%) AMPs • Kent Group National Park (5%) • Cape Howe and Point Hicks, with likelihoods of 16% and 11% respectively

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		• Upwelling East of Eden (71%), Big Horseshoe Canyon (12%), Shelf rocky Reefs (3%) and Canyons of the Eastern Continental Slope (2%). • State waters in Victoria (18%), New South Wales (13%) and Tasmania (5%).

Table 7-59 KFA vessel collision - MGO modelling output of other features outside the mapped area

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure (floating oil)	Low (1g/m^2)	Zone of low exposure extends approximately 71km from release location in a predominately northeast direction. The zone of low exposure overlaps several albatrosses, petrels and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. In addition, there is a 4% probability of overlap with the Upwelling East of Eden KEF. The spill does not extend into State waters or marine parks at this threshold. Due to the fate and weathering process predicted for MGO, sea surface exposure (maximum residence) is estimated to be approximately 1.33 days after the release.
Shoreline exposure	Low (10g/m^2)	The maximum length of the shoreline accumulation is 45km. The highest probability for shoreline exposure is at Montague Island (7%) followed by Bega Valley (5%), with the minimum predicted time before shoreline accumulation at these locations as 6.04 days and 14.71 days respectively.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (72%) at the low threshold was predicted to overlap with several albatrosses, common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. Similarly, there is probability of water column exposure in the Upwelling East of Eden KEF (8%), the Kent Group National Parks (1%) and with State waters (1% for Victoria, New South Wales and Tasmania).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the coastal area near Wilsons Promontory in Victoria and Flinders Island (Tasmania), to the north of Tuross Heads, New South Wales. Exposure to entrained hydrocarbons at the low threshold overlaps with several albatrosses, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. The entrained hydrocarbons contact probability with nearshore water areas ranges from 1% at Pyramid Island to 6% at Bega Valley, Craggy Island and Montague Island. Entrained hydrocarbon at the low threshold could also potentially overlap other receptors, including the following: • Beagle, East Gippsland and Flinders AMPs, with likelihoods of 13%, 5% and 2% respectively

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		• Kent Group National Park (11%) • Cape Howe and Point Hicks, with likelihoods of 11% and 5% respectively • Upwelling East of Eden (49%), Big Horseshoe Canyon (11%) and Shelf Rocky Reefs (5%) • State waters in Victoria (11%), New South Wales (12%) and Tasmania (11%).

Table 7-60 FLA vessel collision - MGO modelling output of other features outside the mapped area

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure (floating oil)	Low ($1g/m^2$)	Zone of low exposure extends approximately 180km from release location in a predominately east-northeast direction. The zone of low exposure overlaps several albatrosses, petrels and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. In addition, there is a 100% probability of overlap with the Upwelling East of Eden KEF. The spill does not extend into State waters or marine parks at this threshold. Due to the fate and weathering process predicted for MGO, sea surface exposure (maximum residence) is estimated to be approximately 1.13 days after the release.
Shoreline exposure	Low ($10g/m^2$)	The maximum length of the shoreline accumulation is 41km. The highest probability for shoreline exposure is at Bega Valley (8%) followed by East Gippsland (7%), with the minimum predicted time before shoreline accumulation at these locations as 5.63 days and 7.92 days respectively.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0 - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (68%) at the low threshold was predicted to overlap with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. Similarly, there is probability of water column exposure in the Upwelling East of Eden KEF (68%), the East Gippsland Marine Park (1%) and with State waters (1% for Victoria and New South Wales).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the coastal area near Kent Group islands and Flinders Island (Tasmania), to the north of Tuross Heads, New South Wales. There is a 96% probability of exposure with several albatrosses and the common diving petrel foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark known distribution area. The entrained hydrocarbons contact probability with nearshore waters areas ranges from 1% at Pyramids Island and Inner Sister and Outer Sister islands to 11% at Bega Valley. Entrained hydrocarbon at the low threshold could also potentially overlap other receptors, including the following:

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		• Flinders, Beagle, East Gippsland and Freycinet AMPs, with likelihoods of 8%, 6%, 5% and 2% respectively • Kent Group National Park (4%) • Cape Howe and Point Hicks, with likelihoods of 17% and 11% respectively • Upwelling East of Eden (96%), Big Horseshoe Canyon (18%), Shelf Rocky Reefs (4%), Canyons of the Eastern Continental Slope (3%) and the Seamounts South and East of Tasmania (1%) • State waters in Victoria (18%), New South Wales (14%) and Tasmania (6%).

Table 7-61 TLA vessel collision - MGO modelling output of other features outside the mapped area

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure (floating oil)	Low (1g/m^2)	Zone of low exposure extends approximately 21.2km from release location in a predominately southwest direction. The zone of low exposure overlaps several albatrosses, the common diving petrel and the Short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. There is a 67% and a 20% probability of exposure at State waters (Victoria) and Seal Islands respectively, and a 1% probability of exposure at the white shark foraging BIA.
Shoreline exposure	Low (10g/m^2)	The maximum length of the shoreline accumulation is 30.3km. The highest probability for shoreline exposure is at Seal Islands (47%) followed by East Gippsland (44%), with the minimum predicted time before shoreline accumulation at these locations as 0.18 days (4.32 hours) and 5.35 days respectively.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0m - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (16%) at the low threshold was predicted to overlap with several albatrosses, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark breeding BIA. There is probability of water column exposure at Seal Islands (1%) and with State waters in Victoria (7%).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the coastal area towards the southwest of Wilsons Promontory in Victoria, to the northeast of Eden in New South Wales. Modelling results also indicate entrained hydrocarbons at the low threshold may extend into the eastern end of Corner Inlet. There is a 100% probability of exposure with several albatrosses, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW BIA and the white shark breeding BIA. There is also an 80%, 75% and 14% probability of exposure at the white shark foraging BIA, the southern right whale breeding BIA, and the little penguin foraging BIA. Entrained hydrocarbons contact probability with nearshore waters areas ranges from 2% at Skull Rock to75% at Seal Islands.

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		Entrained hydrocarbon at the low threshold is also predicted to overlap other receptors, including the following: • Beagle (24%) AMP • Wilsons Promontory (18%) • Corner Inlet (13%) • Point Hicks (43%), Ninety Mile Beach (3%) and Cape Howe (10%) marine national parks • Upwelling East of Eden (49%) • State waters in Victoria (100%), Tasmania (16%) and New South Wales (7%).

Table 7-62 TLB vessel collision - MGO modelling output of other features outside the mapped area

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
Surface exposure (floating oil)	Low ($1g/m^2$)	Zone of low exposure extends approximately 15km from release location in a predominately southwest direction. The zone of low exposure overlaps several albatrosses, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration and breeding BIAs and the white shark breeding and foraging BIAs. There is a 9% probability of exposure at Beagle Marine Park, 5% probability at Wilsons Promontory and 4% at Seal Islands There is also an 33% probability of floating oil reaching State waters (Victoria).
Shoreline exposure	Low ($10g/m^2$)	The maximum length of the shoreline accumulation is 30.9km. The highest probability for shoreline exposure is at Seal Islands (68%) followed by East Gippsland (32%) and Point Hicks (31%), with the minimum predicted time before shoreline accumulation at these locations as 0.36 days (8.64 hours) at Seal Islands and 8.47 days at other two locations.
In-water (dissolved) exposure	Low (10ppb instantaneous)	Analysis of potential for in-water exposure in the water column between 0m - 10m depth from the surface. The greatest probability of dissolved hydrocarbon exposure (14%) at the low threshold was predicted to overlap with several albatrosses, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark foraging and breeding BIAs. There is probability of water column exposure at Seal Islands (1%) at State waters in Victoria (2%).
In-water (entrained) exposure	Low (10ppb instantaneous)	In-water entrained hydrocarbon at the low threshold extends along the southeastern Australian coast, from the waters south from Cape Paterson (Victoria) to the coastal waters southeast of Eden, New South Wales. Modelling results also indicate entrained hydrocarbons at the low threshold may extend into the northeast end of Corner Inlet There is a 100% probability of exposure with several albatrosses, the common diving petrel and the short-tailed shearwater foraging BIAs, the PBW foraging BIA, SRW migration BIA and the white shark foraging and breeding BIAs. There is also a 78% and 8% probability of exposure at the southern right whale breeding BIA and the little penguin foraging BIA.

Model parameter	Exposure value	Stochastic modelling (based on 100 annualised spill trajectories)
		Entrained hydrocarbons contact probability with nearshore waters areas ranges from 1% at Bega Valley and Curtis Island to 88% at Seal Islands. Entrained hydrocarbon at the low threshold is also predicted to overlap other receptors, including the following: • Beagle (76%) AMPs • Wilsons Promontory (47%) • Corner Inlet (6%) • Point Hicks (25%), and Cape Howe (3%) marine national parks. • Upwelling East of Eden (27%), • State waters in Victoria (100%), Tasmania (39%) and New South Wales (3%).

7.8.3 Risks of loss of containment of refined oils

An accidental release of MGO has the potential to result in the following impacts:

- injury/mortality to fauna
- change in habitat
- change in water quality
- change to the function, interest or activities of other users.

Table 7-63 outlines the impact assessment for MGO spill.

This risk assessment is based on the outcomes from the vessel release scenarios described in Section 7.8.2. These spill modelling results provide a conservative approach to identifying the outer envelope of the potential area of exposure in the unlikely event of a MGO spill event. Key considerations of the input data used include:

- source of the potential oil spill
- representative locations where potential spill could occur and proximity to environmental sensitive receptors
- characteristics of the spill (i.e. type of oil, volume, etc.)
- stochastic (non-deterministic) modelling methodology: 100 hundred single trajectory simulations/runs for each scenario modelled. Each simulation/run had the same spill information (location, volume, duration, composition), but had random start times/dates to ensure that each spill simulation/run was subject to a unique set of wind and current conditions, and at different seasons
- exposure values selected for risk assessment are conservative and follow precautionary principle approach. These values are in line with standard practices and follows the advice from *Environment bulletin - Oil spill modelling (April 2019)* (NOPSEMA, 2019b).

Spill modelling results indicate that if an oil release event was to occur during transfer operations, entrained hydrocarbons at the low threshold may partially extend into Corner Inlet. However, and following the precautionary principle, risk assessment described below includes consideration of Corner Inlet in its entirety.

Table 7-63 Consequence Assessment

Receptor	Impact of MGO exposure	Exposure risk assessment
Benthic Habitats: Bare substrate, seagrass, subtidal rocky reef, macroalgae, corals	**Bare substrate** While this receptor represents the 'bare sand' areas offshore, it does provide habitat for benthic invertebrates (both infauna and macroinvertebrates). Unconsolidated mixed and particulate sediments are likely to be dominated by burrowing fauna (e.g. annelid worms, molluscs, echinoderms, crustaceans, cnidarians). Many of the organisms that live in these habitats are habitat modifiers (e.g. through burrows or shell production), stabilising and/or oxygenating the sediments around them, and providing additional ecological niches for colonisation by other fauna – increasing local biodiversity. Deep water benthic invertebrates are usually protected from oiling by the buoyant nature of hydrocarbons, although the depth of oil penetration is dependent on turbulence in the water column. Hydrocarbons can also reach the benthos through the settlement of oiled particles such as faeces, dead plankton or inorganic sand particles (Jewett, Dean, Smith, & Blanchard, 1999). **Seagrass** The predominant benthic habitat in the Gippsland Basin is bare substrate. However, there are known areas of seagrass within Victorian waters, including Corner Inlet and Lakes Entrance. Seagrasses most often grow in sediments in intertidal and shallow subtidal waters where there is sufficient light and are common in sheltered coastal areas such as bays, lees of islands and fringing coastal reefs. As such, they may be exposed to both surface and subsurface hydrocarbons. Submerged vegetation in nearshore areas can be exposed to oil by direct contact (i.e. smothering) and by uptake by rhizomes through contaminated sediments. Exposure also can take place via uptake of hydrocarbons through plant membranes. In addition, seeds may be affected by contact with oil contained within sediments (NRDA, 2012).When seagrass leaves are exposed to petroleum oil, sub-lethal quantities of the soluble fraction can be	**Bare substrate** Based on the nature of the potential worst-case spill event (vessel collision), release of oil would occur at or close to the water surface and dissolved hydrocarbon is expected to be present mostly within the upper water column section between 0 - 10m from the water surface. As a result, there is no expected direct exposure of the substrate to hydrocarbons from a spill event during execution of Campaign #1 activities, including removal operations at the facilities, vessel transit and transfer operations. **Seagrass** There is no predicted exposure at or above the moderate dissolved hydrocarbons threshold and moderate surface (floating) oil thresholds at known seagrass areas such as Corner Inlet and Lakes Entrance. However, there is a very low probability (2%) of entrained hydrocarbon exposure at high thresholds within Corner Inlet, which may result in negative effects to this sensitive habitat. **Macroalgae** Suitable hard substrate for macroalgal beds occur in areas such as Gabo Island and within the Bemm River Estuary. In addition, the Giant Kelp Ecological Community is currently limited to Tasmanian coastal waters. There is no predicted exposure at or above the moderate surface (floating) oil, moderate dissolved hydrocarbons, or high entrained hydrocarbons thresholds at these locations, resulting in no impact to this receptor. **Corals** Corals are not a common habitat type in the Gippsland Basin, however solitary soft corals may occur where suitable hard substrate, such as rocky reef or man-made structures, is present. Corals have been recorded at Kent Group Islands and Wilsons

Receptor	Impact of MGO exposure	Exposure risk assessment
	incorporated into the tissue, causing a reduction in tolerance to other stress factors (Zieman, Macko, & Mills, 1984). The toxic components of petroleum oils are thought to be the polycyclic aromatic hydrocarbons (PAH), which are lipophilic and therefore able to pass through lipid membranes and tend to accumulate in the thylakoid membranes of chloroplasts (Ren, Huang, McConkey, Dixon, & Greenberg, 1994). As such, the susceptibility of seagrasses to hydrocarbon spills will depend largely on distribution. Deeper communities will be protected from oiling under all but the most extreme weather conditions. Shallow seagrasses are more likely to be affected by dispersed oil droplets or, in the case of emergent seagrasses, direct oiling. Theoretically, intertidal seagrass communities would be the most susceptible because the leaves and rhizomes may both be affected. **Subtidal rocky reefs** Nearshore and offshore subtidal reef habitats are dominated by seaweeds, mobile invertebrates and fish. Potential impacts to sensitive receptors related to these reefs are discussed in the appropriate sections. It was observed that the release of large quantities of fuel oil during the grounding of the Iron Baron did not substantially affect populations of subtidal reef associated organisms (Edgar & Barrett, 1995). **Macroalgae** Macroalgae are most often limited to growing on intertidal and subtidal rocky substrata in shallow waters to 10m depth. As such, they may be exposed to subsurface and entrained and dissolved hydrocarbons, however, are susceptible to surface hydrocarbon exposure more so in intertidal habitats as opposed to subtidal habitats. Reported toxic responses to oils have included a variety of physiological changes to enzyme systems, photosynthesis, respiration, and nucleic acid synthesis (Lewis & Pryor, 2013). Despite the well-established pool of literature on macroalgae exposure to petroleum oils, very few investigations	Promontory. None of these two locations are subject to potential exposure to concentrations of oil at or above the moderate threshold for dissolved hydrocarbons and high threshold for entrained hydrocarbons. Benthic species are not expected to come into direct contact with hydrocarbons in the immediate vicinity of the release locations. Benthos may be affected through indirect contact with oil via deposition of oiled particles (i.e. faeces, inorganic sand particles, dead plankton), however their habitat is widespread throughout Bass Strait and population level impacts are not anticipated. Recent studies have shown that infaunal taxa are similar across the Bass Strait but the contribution of each to the assemblage varies. Where hard substrate or points of attachment (facilities) are present, colonisation by epifauna occurs mostly in the form of sessile, invertebrate, filter feeders. The effects are expected to be localised and temporary. Invertebrates of value have been identified to include squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone). Filter-feeding, sessile benthic invertebrates such as sponges, bryozoans, scallops, abalone and hydroids may be exposed to sub-lethal impacts, however population level impacts are considered unlikely. The consequence on benthic habitats is assessed as **Consequence Level II** (Potential localised medium term, significant adverse effects).

Receptor	Impact of MGO exposure	Exposure risk assessment
	have reported effects on species that are common in Australian waters (Lewis & Pryor, 2013). Smothering, fouling and asphyxiation are some of the physical effects that have been documented from oil contamination in marine plants (Blumer, 1971) (Cintron, Lugo, Marinez, Cintron, & Encarnacion, 1981). In macroalgae, oil can act as a physical barrier for the diffusion of CO_2 across cell walls (O'Brien & Dixon, 1976). The effect of hydrocarbons however is largely dependent on the degree of direct exposure and how much of the hydrocarbon adheres to algae, which will vary depending on the oils physical state and relative 'stickiness'. The morphological features of macroalgae, such as the presence of a mucilage layer or the presence of fine 'hairs' will influence the amount of hydrocarbon that will adhere to the algae. A review of field studies conducted after spill events (Connell, Miller, & Farrington, 1981) indicated a high degree of variability in the level of impact, but in all instances, the algae appeared to be able to recover rapidly from even very heavy oiling. The rapid recovery of algae was attributed to the fact that for most algae, new growth is produced from near the base of the plant while the distal parts (which would be exposed to the oil contamination) are continually lost. Other studies have indicated that oiled kelp beds had a 90% recovery within three to four years of impact, however full recovery to pre-spill diversity may not occur for long periods after the spill (French-McCay D. P., 2004). Intertidal macroalgal beds are more prone to oil spills than subtidal beds because although the mucous coating prevents oil adherence, oil that is trapped in the upper canopy can increase the persistence of the oil, which impacts upon site-attached species. Additionally, when oil sticks to dry fronds on the shore, they can become overweight and break as a result of wave action (IPIECA, 2005). The toxicity of hydrocarbons to macroalgae varies for the different macroalgal life stages, with water-soluble hydrocarbons more toxic to macroalgae (O'Brien & Dixon, 1976). Toxic effect concentrations for hydrocarbons and algae have varied greatly among species and studies, ranging 2 - 10,000,000ppb (Lewis & Pryor, 2013). The sensitivity of	

Receptor	Impact of MGO exposure	Exposure risk assessment
	gametes, larva and zygote stages however have all proven more responsive to petroleum oil exposure than adult growth stages (Lewis & Pryor, 2013). Macrophytes, including macroalgae, require light to photosynthesise. So, in addition to the potential impacts from direct smothering or exposure to entrained and dissolved hydrocarbons, the presence of entrained hydrocarbon within the water column can affect light qualities and the ability of macrophytes to photosynthesise. Exposure to in-water hydrocarbons poses the greatest threat to sensitive macroalgal assemblages, specifically the Giant Kelp Forests TEC, that grow on rocky reefs from the seafloor ≥8m below sea level. This TEC is located within Tasmanian coastal waters. Substrate on which this TEC may occur is also found in Victoria along the west coast of Wilsons Promontory and from Sydenham Inlet to Gabo Island (DSEWPAC, 2012a). **Corals** Corals are most often located in shallow and intertidal regions, where there is the potential for exposure to surface and in-water hydrocarbons. Experimental studies and field observations indicate all coral species are sensitive to the effects of oil, although there are considerable differences in the degree of tolerance between species. Differences in sensitivities may be due to the ease with which oil adheres to the coral structures, the degree of mucous production and self-cleaning, or simply different physiological tolerances. Direct contact of coral by hydrocarbons may impair respiration due to smothering (IPIECA, 2004). Coral gametes or larvae in the surface layer where they are exposed to the slick may also be fouled (Epstein, Bak, & Rinkevich, 2000). Physical oiling of coral tissue can cause a decline in metabolic rate and may cause varying degrees of tissue decomposition and death (Negri & Heyward, 2000). Oil may also cling to certain types of sediment causing oil to sink to the seafloor, covering corals in oiled sediment.	

Receptor	Impact of MGO exposure	Exposure risk assessment
	Where corals come into direct contact with surface exposures (i.e., intertidal/shallow areas), they are more susceptible due to physical presence, than toxicity associated with dissolved oil components within the water column which, in some cases, may be more toxic than the floating surface slicks (Volkman, Miller, Revill, & Connell, 1994). A range of impacts is reported to result from toxicity including partial mortality of colonies, reduced growth rates, bleaching and reduced photosynthesis. Laboratory and field studies have demonstrated that branching corals appear to have a higher susceptibility to hydrocarbon exposure than massive corals or corals with large polyps. Chronic effects of oil exposure have been consistently noted in corals and, ultimately, can kill the entire colony. Chronic impacts include histological, biochemical, behavioural, reproductive and developmental effects. Field studies of chronically polluted areas and manipulative studies in which corals are artificially exposed to oil show that some coral species tolerate oil better than other species (NOAA, 2010). Reproductive stages of corals have been found to be more sensitive to oil toxicity. Fertilisation of coral species has been observed to be completely blocked in Acropora tenuis at concentrations of fuel oil dispersed with Ardox 6120 of 0.15ppm (Harrison, 1999), with significant reductions in fertilisation of *A.millepora* and *A. valida* at concentrations between 580 and 5800ppb, in addition to developmental abnormalities and reduced survival of coral larvae at similar concentrations. Lower concentrations of less than 100ppb crude oil were observed to inhibit larval metamorphosis in A. millepora (Negri & Heyward, 2000). Studies undertaken after the *Montara* incident included diver surveys to assess the status of Ashmore, Cartier and Seringapatam coral reefs. These found that other than a region-wide coral bleaching event caused by thermal stress (i.e. caused by sea water exceeding 32°C), the condition of the reefs was consistent with previous surveys, suggesting that any effects of hydrocarbons reaching these reefs was minor, transitory or sub-lethal and not detectable (Heyward, Moore, Radford, & Colquhoun, 2010). This is	

Receptor	Impact of MGO exposure	Exposure risk assessment
	despite AMSA observations of surface slicks or sheen nears these shallow reefs during the spill (Heyward, Moore, Radford, & Colquhoun, 2010). Surveys in 2011 indicated that the corals exhibiting bleaching in 2010 had largely survived and recovered (Heyward, et al., 2012), indicating that potential exposure to hydrocarbons while in an already stressed state did not have any impact on the healthy recovery of the coral.	
Plankton	Plankton are found in nearshore and open waters beneath the surface in the water column. These organisms migrate vertically through the water column to feed in surface waters at night (NRDA, 2012). As they move close to the sea surface it is possible that they may be exposed to floating hydrocarbons, but plankton also has the potential to be directly affected by in-water hydrocarbons as a result of toxicity effects. Phytoplankton are typically not sensitive to the impacts of oil, though they do accumulate it rapidly (Hook, Batley, Holloway, Irving, & Ross, 2016) due to their small size and high surface area to volume ratio. Oil can affect the rate of photosynthesis and inhibit growth in phytoplankton, depending on the concentration range. For example, photosynthesis is stimulated by low concentrations of oil in the water column (10 – 30ppb) but becomes progressively inhibited above 50ppb. Conversely, photosynthesis can be stimulated below 100ppb for exposure to weathered oil (González, et al., 2009). In addition, the potential for effects to photosynthesis (i.e. temporary suppression of primary production) from shading caused by continuous surface slicks may have implications for consumers of phytoplankton (Hook, Batley, Holloway, Irving, & Ross, 2016), though a prolonged surface coverage over an extensive area would be required. During the DWH oil spill it was observed that plankton and other surface material were found to be sinking at rates of more than 10 times the normal level. It was hypothesised that the weathered spilled oil catalysed clumping of organic particles (Schrope, 2013). It is currently unclear as to whether this effect was caused by the chemical characteristics of the weathered oil, or a bacterial effect.	Plankton are likely to be exposed to floating (surface) oil above the moderate exposure threshold within a zone up to an approximately maximum distance of 49km in length from the spill location (at KFA) extending parallel to the Gippsland coastline. Maximum probability of exposure to levels above the moderate threshold for dissolved hydrocarbons is 35% within the Twofold Shelf Bioregion. There is also a low probability of exposure to moderate levels of dissolved hydrocarbons at the Upwelling East of Eden, where significant episodic phytoplankton blooms occur. This intermittent bloom events forms the basis to support a productive food chain, from zooplankton up to large marine fauna such as whales. Plankton are at their highest concentrations below surface waters (e.g. 60m water depth for phytoplankton during the day) and undertake a vertical migration which would likely reduce their potential for (and duration of) exposure to dissolved hydrocarbons in the surface layer of the water column (0 - 10m below the surface). There is a low probability of an oil spill during Campaign #1 activities to significantly impact plankton. As a conservative approach, and recognising potential, however unlikely, effects on the food web, consequence on plankton is therefore predicted to have a **Consequence Level III.**

Receptor	Impact of MGO exposure	Exposure risk assessment
	Zooplankton (microscopic animals such as rotifers, copepods and krill that feed on phytoplankton) are vulnerable to hydrocarbons (Hook, Batley, Holloway, Irving, & Ross, 2016). Water column organisms that come into contact with oil risk exposure through ingestion, inhalation and dermal contact (NRDA, 2012), which can cause immediate mortality or declines in egg production and hatching rates along with a decline in swimming speeds (Hook, Batley, Holloway, Irving, & Ross, 2016). Plankton are abundant in the upper layers of the water column and is the basis of the marine food web, so an oil spill in any one location is unlikely to have long-lasting impacts on plankton populations at a regional level. Reproduction by survivors or dispersion from unaffected areas (via sea surface currents) is likely to rapidly replenish losses (Abbriano, et al., 2011). Plankton have life cycles based on rapid reproduction with levels of high productivity. It is also in the nature of plankton to be dispersive. Oil spill field observations show minimal or transient effects on plankton (Abbriano, et al., 2011). Once background water quality is re-established, plankton takes weeks to months to recover (ITOPF, 2011). Plankton found in open waters of the exposure zone is expected to be widely represented within waters of the wider Bass Strait region and across all waters in the southeastern offshore region, which aids in the re-establishment of communities.	
Fish, sharks and rays	Fish can be exposed to oil through a variety of pathways including: direct dermal contact (e.g. swimming through oil); ingestion (e.g. directly or via oil-affected prey/foods); and inhalation (e.g. elevated dissolved contaminant concentrations in water passing over the gills). Fish are considered vulnerable to oil spills because they inhabit areas coincident with oil exploration and production and those areas that may be subsequently impacted by an oil spill; including coral reefs, seagrasses, nearshore areas, deep offshore areas, pelagic habitats and demersal habitats (Moore & Dwyer, 1974) (Gundlach & Hayes, 1978). Of the potential toxicants, monoaromatic and PAH are regarded as the most toxic to fish. **Surface oil**	The potential MGO release locations are located both in open ocean waters and in waters closer to shore. The zone of moderate surface oil and high entrained hydrocarbons is predicted to extend within these areas. Exposure to dissolved hydrocarbons at or above moderate thresholds is not predicted in areas closer to coastal waters. Shallow inshore fish species including various syngnathids (seahorses, pipefish, pipehorses and seadragons) are less likely to be able to move away from surface or in-water oil and therefore may be exposed to elevated levels or for longer periods. However, their habitats are widespread, and any impacts are expected to be

Receptor	Impact of MGO exposure	Exposure risk assessment
	Since fish and sharks do not often break the sea surface, the exposure of surface hydrocarbons to fish and shark species are unlikely to occur. Near the sea surface, fish are able to detect and avoid contact with surface slicks meaning fish mortalities rarely occur in the event of a hydrocarbon spill in open waters (Volkman, et al., 2009). As a result, wide-ranging pelagic fish of the open ocean are not highly susceptible to impacts from surface hydrocarbons. Adult fish kills reported after oil spills occur mainly to shallow water, near-shore benthic species (Volkman, et al., 2009). Following the Deep-Water Horizon (DWH) incident, it was suggested that whale sharks may be vulnerable to oiling of gills if exposed to the oil. The tendency of whale sharks to feed close to surface waters will increase the likelihood of exposure to surface slicks and elevated hydrocarbon concentrations beneath slicks. **In-water oil** Exposure to hydrocarbons entrained or dissolved in the water column can be toxic to fish. Studies have shown a range of impacts including changes in abundance, decreased size, inhibited swimming ability, changes to oxygen consumption and respiration, changes to reproduction, immune system responses, DNA damage, visible skin and organ lesions, and increased parasitism. However, many fish species can metabolize toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Pelagic free-swimming fish and sharks are unlikely to suffer long-term damage from oil spill exposure because dissolved/entrained hydrocarbons in water are not expected to be sufficient to cause harm. Pelagic species are also highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in surface layers only. Fish are most vulnerable to hydrocarbon discharges during their embryonic, larval and juvenile life stages. Oil exposure may result in decreased spawning success and abnormal larval development. Impacts on eggs and larvae entrained in the upper water column are not expected to be significant given the temporary period of water quality impairment, and the limited	localised and at individual organism levels rather than population levels. Although pelagic fish species may be exposed to moderate levels of dissolved oil, their mobile and transitory characteristics reduce the risk of prolonged exposure. Large-scale population level effects following a LOC on fish species, abundances or assemblage composition would be unlikely due to the wide geographical distribution of many fish in Bass Strait and the potential for rapid re-colonisation. Deep water demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in upper layers of the water column only. There is potential for exposure to moderate thresholds of dissolved hydrocarbons at the white shark foraging and reproduction BIAs and the SRW migration and reproduction BIAs, while the high exposure to entrained hydrocarbons will contact these same BIAs for white sharks, but also the grey nurse shark foraging and migration BIAs. Pelagic species of shark are at greatest risk of being exposed to oil following a LOC given their wide foraging areas and risks of consuming contaminated prey. Juvenile white sharks appear to aggregate in Corner Inlet and Ninety Mile Beach, and philopatric characteristics means they may return to the place of birth to breed even if habitats are contaminated. This species is widely distributed and thus unlikely to suffer ecologically important declines in abundance. The consequences to fish and sharks are assessed as **Consequence Level II,** taking into consideration the potential impacts to threatened species such as the white shark and the larval or juvenile stages of the Australian grayling.

Receptor	Impact of MGO exposure	Exposure risk assessment
	areal extent of a spill. As egg/larvae dispersal is widely distributed in the upper layers of the water column it is expected that current induced drift will rapidly replace any oil affected populations.	
Marine reptiles – Turtles	Marine turtles are vulnerable to the effects of oil at all life stages; eggs, hatchlings, juveniles, and adults. Oil exposure affects different turtle life stages in different ways; and each turtle life stage frequents a habitat with varied potential to be impacted during an oil spill. Several aspects of turtle biology and behaviour place them at particular risk, including a lack of avoidance, indiscriminate feeding in convergence zones, and large pre-dive inhalations. Marine turtles can be exposed to oil externally (e.g. swimming through oil slicks) or internally (e.g. swallowing the oil, consuming oil affected prey, or inhaling of volatile oil related compounds). **Surface oil** Effects of oil on turtles include increased egg mortality and developmental defects; direct mortality due to oiling in hatchlings, juveniles, and adults; and negative impacts to the skin, blood, digestive and immune systems, and salt glands. Oil can enter cavities such as the eyes, nostrils, or mouth; and oil covering their bodies may interfere with breathing because they inhale large volumes of air to dive. Experiments on physiological and clinical pathological effects of hydrocarbons on loggerhead turtles (approximately 15 - 18 months old) showed that the turtles' major physiological systems were adversely affected by both chronic and acute exposures (96 hour exposure to a 0.05cm layer of South Louisiana crude oil versus 0.5cm for 48 hours) (Lutcavage, Lutz, Bossart, & Hudson, 1995). Recovery from the sloughing skin and mucosa took up to 21 days, increasing the turtle's susceptibility to infection or other diseases, such as fibro papilloma (Lutcavage, Lutz, Bossart, & Hudson, 1995). Records of oiled wildlife during spills rarely include marine turtles, even from areas where they are known to be relatively abundant (Short, 2011). An	While marine turtles are known to occur in the area potentially exposed to MGO at moderate concentrations for surface and dissolved hydrocarbons, and high concentrations for entrained hydrocarbons, they do not reside or aggregate in significant numbers within the Gippsland Basin, and there are no recognised BIAs in the region. There is also probability of shoreline exposure at locations across the Gippsland coastline from a MGO release event. However, there are no turtle nesting beaches along the Gippsland coastline, therefore impacts to turtles from shoreline oiling is considered inconsequential. The low density of turtles expected in the region (due to lack of BIA or aggregations) suggests that few, if any, individuals would be affected in the event of a spill, rather than having an effect at a population level. The consequence on marine reptiles is considered to be **Consequence Level III.**

Receptor	Impact of MGO exposure	Exposure risk assessment
	exception to this was the large number of marine turtles collected (613 dead and 536 live) during the DWH incident in the Gulf of Mexico (GoM), although many of these animals did not show any sign of oil exposure (Montagna, Baguley, Cooksey, & Hyland, 2013). Of the dead turtles found, 3.4% were visibly oiled and 85% of the live turtles found were oiled (Montagna, Baguley, Cooksey, & Hyland, 2013). Of the captured animals, 88% of the live turtles were later released, suggesting that oiling does not inevitably lead to mortality. **Shoreline oil** Turtles may experience oiling impacts on nesting beaches and eggs through chemical exposures resulting in decreased survival to hatching and developmental defects in hatchlings. Adult females crossing an oiled beach could cause external oiling of the skin and carapace, noting that most oil is deposited at the high-tide line, and most turtles nest well above this level. Studies on freshwater snapping turtles showed uptake of PAH from contaminated nest sediments, but no impacts on hatching success or juvenile health following exposure of eggs to dispersed weathered light crude (Rowe, Mitchelmore, & Baker, 2009). However, other studies found evidence that exposure of freshwater turtle embryos to PAH results in deformities (Bell, Spotila, & Congdon, 2006) (Van Meter, Spotila, & Avery, 2006). Turtle hatchlings may be more vulnerable to smothering as they emerge from the nests and make their way over the intertidal area to the water. Hatchlings that contact oil residues while crossing a beach can exhibit a range of effects including impaired movement and bodily functions (Milton, Lutz, & Shigenaka, 2003). Hatchlings sticky with oily residues may also have more difficulty crawling and swimming, rendering them more vulnerable to predation. It should be noted that the threat and relative impacts of an unplanned discharge on some marine reptile species are considered less damaging than other stressors. Report cards produced on protected marine reptiles in Australia ranked oil pollution as either 'not of concern' or 'of less concern' depending on the marine region (DSEWPAC, 2012b).	

Receptor	Impact of MGO exposure	Exposure risk assessment
Birds	Seabirds and shorebirds are sensitive to the impacts of oiling, with their vulnerability arising from the fact that they cross the air – water interface to feed, while their shoreline habitats may also be oiled (Hook, Batley, Holloway, Irving, & Ross, 2016). Species that raft together in large flocks on the sea surface are particularly at risk (ITOPF, 2011). **Surface oil** Birds foraging at sea have the potential to directly interact with oil on the sea surface at a considerable distance from breeding sites in the course of normal foraging activities. Seabird species most at risk include those that readily rest on the sea surface (e.g. shearwaters) and surface plunging species (e.g. terns, boobies). As seabirds are a top order predator, any impact on other marine life (e.g. pelagic fish) may disrupt and limit food supply both for the maintenance of adults and the provisioning of young. For seabirds, direct contact with hydrocarbons can foul feathers, which may subsequently result in hypothermia due to a reduction in the ability of the bird to thermo-regulate and impair waterproofing. A bird suffering from cold, exhaustion and a loss of buoyancy may also dehydrate, drown or starve (DSEWPAC, 2011). Increased heat loss as a result of a loss of water-proofing results in an increased metabolism of food reserves in the body, which is not countered by a corresponding increase in food intake, may lead to emaciation (DSEWPAC, 2011). The greatest vulnerability in this case occurs when birds are feeding or resting at the sea surface (Peakall, Wells, & Mackay, 1987). In a review of 45 actual marine spills, there was no correlation between the numbers of bird deaths and the volume of the spill (Burger A. E., 1993). Penguins may be especially vulnerable to oil because they spend a high portion of their time in the water and readily lose insulation and buoyancy if their feathers are oiled (Hook, Batley, Holloway, Irving, & Ross, 2016). The Iron Baron vessel spill (325MT of bunker fuel in Tasmania in 1995) is estimated to have resulted in the death of up to 20,000 penguins (Hook, Batley, Holloway, Irving, & Ross, 2016).	A number of threatened, migratory and/or listed marine species may occur in the area exposed to moderate-high surface thresholds. There are foraging BIAs for some species of petrels, albatrosses and shearwaters throughout the EMBA. However, there are no breeding BIAs within the area potentially affected by MGO spill at levels within moderate threshold for surface and dissolved hydrocarbons, and high thresholds for entrained hydrocarbons. Seabirds rafting, resting, diving or feeding at sea have the potential to come into contact with surface oil, ranging from moderate to high exposure. As such, acute or chronic toxicity impacts (death or long-term poor health) to seabirds are possible. Most species tend to forage on their own, though large feeding flocks will gather at rich or passing food sources. The maximum distance surface (floating) oil is predicted to reach at concentrations that may have biological impacts to birds is approximately 49km. Shorebirds are not likely to be significantly affected by in-water concentrations of hydrocarbons due to their limited exposure time in the water column. Because there is a mostly low probability for the zone of in-water moderate exposure (dissolved hydrocarbons) and high exposure (entrained hydrocarbons) to extend into nearshore waters, foraging shorebirds may be indirectly impacted by the loss of invertebrate prey. Foraging BIAs for several species of albatrosses, the common diving petrel, the white-faced storm petrel and the short-tailed shearwater overlap with shorelines along the Gippsland coast where oil is predicted to accumulate at concentrations within the moderate threshold. Shorebirds foraging in intertidal areas or along the high tide mark and splash zone, or nesting in coastal areas particularly close to the high-water mark are most at risk of exposure effect. The maximum length of shoreline predicted to be

Receptor	Impact of MGO exposure	Exposure risk assessment
	Shoreline oil Shorebirds are likely to be exposed to oil when it directly impacts the intertidal zone and onshore due to their feeding habitats. Foraging shorebirds will be at potential risk of both direct impacts through contamination of individual birds (e.g. fouling of feathers) and indirect impacts (e.g. fouling and/or a reduction in prey items) (Clarke & Herrod, 2016). Birds that are coated in oil can also suffer from damage to external tissues, including skin and eyes, as well as internal tissue irritation in their lungs and stomachs. Breeding birds (both seabirds and shorebirds) may be exposed to oil via direct contact or the contamination of the breeding habitat (e.g. shores of islands) (Clarke & Herrod, 2016). Bird eggs may subsequently be damaged if an oiled adult sits on the nest. Fresh crude was shown to be more toxic than weathered crude, which had a medial lethal dose of 21.3mgs/egg. Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos. Toxic effects on birds may result where oil is ingested as the bird attempts to preen its feathers, or via consumption of oil-affected prey. Whether this toxicity ultimately results in mortality will depend on the amount consumed and other factors relating to the health and sensitivity of the particular bird species. The threshold thickness of oil that could impart a lethal dose to an individual wildlife species is 10µm (approximately 10g/m^2) (Engelhardt, Petroleum effects on marine mammals, 1983) (Clark, 1984) (Battelle Memorial Institute, 1988) (Jenssen, 1994). A layer 25µm thick would be harmful for most birds that contact the slick (Scholten, et al., 1996).	exposed to moderate thresholds of hydrocarbons is approximately 13km. The populations of both seabird and shorebird species have a wide geographic range, meaning that impacts to individuals at one location will not necessarily extend to populations at other un-impacted locations. Given the extensive ocean foraging habitat available to species such as albatrosses and petrels, the relatively small affected area, the weathering characteristics of MGO, and the temporary nature of oil at levels that can result in harmful exposures to birds on the sea surface makes it unlikely that a spill will limit their ability to forage for unaffected prey. When first released, MGO has higher toxicity due to the presence of volatile components. Individual birds making contact close to the spill source at the time of the spill may be exposed to more significant potential impacts; however, it is unlikely that a large number of birds will be affected. As such, acute or chronic toxicity impacts (death or long-term poor health) to small numbers of birds are possible, however this is not considered significant at a population level. The Little penguin is not considered at risk globally, but some colonies are at risk on a regional scale (Cannell, et al., 2016) and declines in the status of this species have been reported from Tasmania (Stevenson & Woehler, 2007). The little penguin foraging BIA located around the Gabo Island area has a maximum probability of 2% of exposure to shoreline accumulation within the moderate threshold. No impact is expected to other little penguin foraging BIAs located within the Bass Strait from an unlikely MGO release event. Consequently, the potential consequence of risks to seabirds and shorebirds from a LOC are considered to be **Consequence Level II**, taking into consideration the particular vulnerability of shorebirds

Receptor	Impact of MGO exposure	Exposure risk assessment
		such as the hooded plover, which nest along the beaches and dunes of the Gippsland coast.
Marine mammals (pinnipeds)	Pinnipeds are directly at risk from impacts associated with the exposure to surface, shoreline and in-water hydrocarbons. **Sea surface oil** Pinnipeds are vulnerable to sea surface exposures in particular given they spend much of their time on or near the surface of the water, as they need to surface every few minutes to breathe and regularly haul out on to beaches. Pinnipeds are also sensitive as they will stay near established colonies and haul out areas, meaning they are less likely to practise avoidance behaviours. Seals, sea lions and fur seals have been observed swimming in oil slicks during a number of documented spills (Battelle Memorial Institute, 1988). As a result of exposure to surface oils, pinnipeds, with their relatively large, protruding eyes are particularly vulnerable to effects such as irritation to mucous membranes that surround the eyes and line the oral cavity, respiratory surfaces, and anal and urogenital orifices. Seals appear not to be very sensitive to contact with oil, but instead to the toxic impacts from the inhalation of volatile components (Hook, Batley, Holloway, Irving, & Ross, 2016). For some pinnipeds, fur is an effective thermal barrier because it traps air and repels water. Petroleum stuck to fur reduces its insulative value by removing natural oils that waterproof the pelage. Consequently, the rate of heat transfer through fur seal pelts can double after oiling (Battelle Memorial Institute, 1988), adding an energetic burden to the animal. It is suggested (Kooyman, Gentry, & McAllister, 1976) that in fact, fouling of approximately one-third of the body surface resulted in 50% greater heat loss in fur seals immersed in water at various temperatures. Fur seals are particularly vulnerable due to the likelihood of oil adhering to fur. Heavy oil coating and tar deposits on fur seals may result in reduced swimming ability and lack of mobility out of the water.	Both the New Zealand fur seal (*Arctocephalus forsteri*) and the Australian fur seal (*Arctocephalus pusillus doriferus*) are listed marine species with habitat and breeding sites known to occur in areas potentially exposed to in-water and shoreline oil above harmful exposure thresholds. These areas are not identified as critical habitat and there are no identified BIAs for fur seals in the region. Both the Australian and New Zealand fur seals are at risk to surface oil while at sea and to shoreline accumulated oil at haul out sites or rookeries. The direct effect to pups from exposure to shoreline oil at ≥100 g/m^2 could result in mortality, while indirect effects could be negative behavioural changes associated with the smell of shoreline oil or contamination of prey. The Australian fur seal is vulnerable to a population decline following a LOC because breeding locations are restricted to the islands of Bass Strait. It is predicted that Rag Island (located in the Seal Islands Group), a breeding location to which recently Australian fur seal expanded to, may be exposed to surface oil, accumulated shoreline oil, and in-water oil at concentrations that are likely to be harmful. The largest Australian fur seals breeding colonies, located in Seal Rocks and Lady Julia Percy, will not be affected by a potential oil spill during C#1. These species are particularly vulnerable to oil because oil is believed to adhere more readily to their coats. Such oiling can have significant effects to their function if foraging in areas with fresh oil. In addition, fur seals are known to aggregate around offshore oil and gas facilities where, in the event of a release, exposure to fresh oil would occur. The consequence of a LOC on pinnipeds is assessed as **Consequence Level II.**

Receptor	Impact of MGO exposure	Exposure risk assessment
	In-water oil Ingested hydrocarbons can irritate or destroy epithelial cells that line the stomach and intestine, thereby affecting motility, digestion and absorption. However, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982) (Addison & Brodie, 1984) (Addison, Brodie, Edwards, & Sadler, 1986). Benzene and naphthalene ingested by seals is quickly absorbed into the blood through the gut, causing acute stress, with damage to the liver considered likely. If ingested in large volumes, hydrocarbons may not be completely metabolized, which may result in death (Volkman, Miller, Revill, & Connell, 1994). **Shoreline oil** Breeding colonies (used to birth and nurse until pups are weaned) are particularly sensitive to hydrocarbon spills (Higgins & Gass, 1993). ITOPF (2011) report that species that rely on fur to regulate their body temperature (such as fur seals) are the most vulnerable to oil as the animals may die from hypothermia or overheating, depending on the season, if the fur becomes matted with oil. It is reported that most pinnipeds scratch themselves vigorously with their flippers and do not lick or groom themselves, so are less likely to ingest oil from skin surfaces (Battelle Memorial Institute, 1988). However, mothers trying to clean an oiled pup may ingest oil. The Long Term Environmental Impact and Recovery report for the Iron Barren oil spill concluded that *"The number of pups born at Tenth Island in 1995 was reduced when compared to previous years. There was a strong relationship between the productivity of the seal colonies and the proximity of the islands to the oil spill wherein the islands close to the spill showed reduced pup production and those islands more distant to the oil spill did not"* (Tasmania State Marine Pollution Committee, 1999). Pinnipeds are further at risk because they appear to rely on scent to establish a mother-pup bond (Sandegren, 1970) (Fogden, 1971), and consequently oil-coated pups may not be recognisable to their mothers. This is only theorised, with studies and research indicating interaction	

Receptor	Impact of MGO exposure	Exposure risk assessment
	between mothers and oiled pups were normal (Davis & Anderson, 1976) (Davies, 1949) (Shaughnessy & Chapman, 1984). Australian sea lions are endemic to Australia, found only in South Australia and Western Australia (DSEWPAC, 2013b). Australian sea-lions have 'naturally poor recovery abilities' due to unusual reproductive biology and life history (DSEWPAC, 2013b). Due to the extreme philopatry of females and limited dispersal of males between breeding colonies, the removal of only a few individuals annually may increase the likelihood of decline and potentially lead to the extinction of some of the smaller colonies	
Marine mammals (cetaceans)	Whales and dolphins can be exposed to the chemicals in oil through: • internal exposure by consuming oil or contaminated prey • inhaling liquid oil droplets and/or volatile oil compounds when surfacing to breathe • external exposure, by swimming in oil and having oil directly on the skin and body • maternal transfer of contaminants to embryos (NRDA, 2012). **Surface oil** Unlike with pinnipeds, oil would not be expected to adhere well to the surface of cetacean skin due to the lack of hairs and the frequent sloughing of skin cells (Engelhardt, 1983) (Helm, et al., 2014). In addition, oil should not readily penetrate cetacean skin due to tight intercellular bridges and thick epidermis (O'Hara & O'Shea, 2001). However, photographs of dolphins with oil on their bodies after the DWH oil spill showed that oil can adhere to and persist on cetacean skin, and contrary to suggestions from previous studies, direct contact with oil and resultant exposure to toxic compounds is of concern (Aichinger Dias, et al., 2017). Cetaceans can be exposed to oil through direct contact with the eyes, mouth (ingestion), and airways (inhalation), potentially leading to inflammation and lung congestion (Battelle Memorial Institute, 1988). Helm et al. (2014) suggested that inhalation of toxic compounds associated with fresh oil was of greater concern than absorption through the skin and	Several threatened, migratory and/or listed cetacean species may traverse the spill plume. Foraging BIA for the PBW and the migration BIA for the SRW are likely to be exposed to surface and in-water concentrations above the moderate exposure threshold for floating oil and dissolved hydrocarbons, and high threshold for entrained hydrocarbons. In addition, there is a probability of exposure of the SRW reproduction BIA to high thresholds of entrained hydrocarbons The foraging BIA for the Humpback whale and breeding BIA for the Indo-Pacific bottlenose dolphin (which extends northwards into New South Wales from the Victorian border) have a low probability to overlap the zone of moderate dissolved hydrocarbon (maximum 5%) and the zone of high entrained hydrocarbon (maximum 7%). It is plausible that individual whales could encounter surface oil above the moderate to high exposure threshold in the immediate vicinity of the release location, but the release would need to coincide with pod migration or foraging for a greater number of individuals to be present in the plume. Sightings of blue whales in the Gippsland Basin are reasonably rare (Bannister, Kemper, & Warneke, 1996). It is difficult to predict with certainty if a spill would lead to levels of mortality or reproductive

Receptor	Impact of MGO exposure	Exposure risk assessment
	ingestion. The inhalation of oil droplets, vapours and fumes is a distinct possibility if whales or dolphins surface in slicks to breathe. Exposure to hydrocarbons in this way could damage mucous membranes, damage airways or even cause death. Cetaceans may incidentally draw seawater and floating oil, into their lungs by breathing in splashed droplets or liquid that has collected near the blowhole just prior to inhalation. Aspiration of liquid oil can cause physical injuries to the respiratory tract by irritating tissues/membranes and can also lead to absorption of toxicants into the blood, as in inhalation exposure (Takeshita, et al., 2017). French-McCay (2016) proposed exposure to oil concentrations of 10g/m^2 could result in mortality to marine mammals (French-McCay D. , 2016). Evidence suggests that many cetacean species are unlikely to detect and avoid spilled oil (Matkin et al. 2008). There are numerous examples where cetaceans have appeared to incidentally come into contact with oil and/or not demonstrated any obvious avoidance behaviour. Following the Exxon *Valdez* oil spill, Matkin et al. (2008) reported killer whales in slicks of oil as early as 24 hours after the spill, and evidence presented by Aichinger Dias et al. (2017) showed that following the DWH oil spill cetaceans in the GoM came into direct contact with both oil and sheen by swimming through them. Although in the GoM it was observed that cetaceans were able to detect the thick and dark-coloured patches of oil, detection of the lighter substances may have been more difficult. **In-water oil** The physical impacts from ingested hydrocarbon with subsequent lethal or sub-lethal impacts are applicable to both dissolved and entrained oil. However, the susceptibility of cetaceans varies with feeding habits. Baleen whales (such as blue, SRW and humpback whales) are not particularly susceptible to ingestion of oil in the water column as they feed by skimming the surface. Oil may stick to the baleen while they filter feed near slicks. Toothed whales and dolphins may be susceptible to ingestion of dissolved and entrained oil as they gulp feed at depth. As highly mobile species, in general it is very unlikely that these animals will be constantly exposed to concentrations of hydrocarbons in the water column for continuous	depression that would manifest in terms of a population-level response. The highly mobile and transitory nature of cetacean species in Bass Strait means that exposure to moderate to high levels of surface oil (in the vicinity of the release location) or moderate levels of in-water hydrocarbon is not anticipated to result in long term population viability effects. In addition, a release of MGO is expected to be of a short to medium duration. Nevertheless, taking into account that the populations of some whale species remain small relative to pre-whaling days and are thought to have a multi-decadal recovery time, mortality of even a small number of adults and or calves as result of oiling could inhibit or retard species recovery. Also, considering the sensitivity of species potentially exposed, which include a number of marine mammals that are listed as threatened and the presence of established BIAs in the area that may be affected by an oil release that overlaps with the EMBA, the consequence of an MGO spill on marine mammals is assessed as **Consequence Level II.**

Receptor	Impact of MGO exposure	Exposure risk assessment
	durations (e.g. >96 hours) that would lead to chronic effects. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball & Truskewycz, 2013). Ingestion of oil may however result in acute nausea and vomiting and aspiration of oily vomitus into the lungs. Research conducted in the GoM linked aspiration pneumonia, lung abscesses, and pulmonary infections in dolphins to exposure to DWH oil (Takeshita, et al., 2017). Some whales, particularly those with coastal migration and reproduction, display strong site fidelity to specific resting, breeding and feeding habitats, as well as to their migratory paths and this may override any tendency for cetaceans to avoid the noxious presence of hydrocarbons. The SRW exhibits varying degrees of site fidelity, with the majority of females and calves returning to the same birthing location, while some also travel long distances between breeding grounds within a season (DCCEEW, 2024f). If spilled oil reaches these biologically important habitats, the pollution may disrupt natural behaviours, displace animals, reduce foraging or reproductive success rates and increase mortality. It was concluded that the range of adverse health effects and increased mortality/reproductive failure observed in cetacean populations throughout the GoM since the DWH oil spill are consistent with the range of exposure scenarios (Takeshita, et al., 2017). If sufficiently high numbers of animals are impacted, the greater population may experience reduced recovery and survival rates. The restitution time for cetaceans affected at a population level is assumed to be long term, i.e. 40 years, based on consensus on recovery times for marine mammals following the DWH incident (Bock, et al., 2018).	
Coastal environment– Sandy shoreline, inter-tidal flats,	**Sandy shorelines and inter-tidal flats** Sandy beaches provide potential foraging and breeding habitat for numerous bird, marine turtle and pinniped species. These activities primarily occur above the high tide line, with exception of haul outs. Note, most of	There are different types of shorelines found along the Gippsland and southern New South Wales coast and offshore islands, however this coastline is dominated by wide sandy beaches with

Receptor	Impact of MGO exposure	Exposure risk assessment
rocky shoreline, mangroves and saltmarsh	the oil on a sandy shore will be concentrated at, and below, the high tide mark. Sandy beaches are also inhabited by a diverse assemblage (although not always abundant) of infauna (including nematodes, copepods and polychaetes) and macroinvertebrates (e.g. crustaceans). Because the sand retains oil, such animals may be killed if oil penetrates into the sediments. Long term depletion of sediment fauna could have an adverse effect on birds or fish that use tidal flats as feeding grounds (IPIECA, 1999). Depth of penetration in sandy sediment is influenced by: • Particle size - Penetration is not as high on mud as on coarser sediments • Oil viscosity - Viscous oils and mousse (water-in-oil emulsion) tend to penetrate less deeply than low-viscosity oils such as light crudes or diesel oil • Drainage - If sediments are poorly drained (as is often the case with tidal flats remote from creeks or channels), the water content may prevent the oil from penetrating into the sediment. In contrast, oil may reach depths greater than one metre in coarse well-drained sediments • Animal burrows and root pores - Penetration into fine sediments is increased if there are burrows of animals such as worms, or pores left where plant roots have decayed. A 100g/m^2 threshold (considered a stain or film, and equivalent to 0.1mm thickness) is assumed as the lethal threshold for invertebrates on hard substrates and sediments (mud, silt, sand, gravel) in intertidal habitats. A 100g/m^2 oil concentration would be enough to coat an animal and likely impact its survival and reproductive capacity (French-McCay D. P., 2004). Based on this, areas of heavy oiling would likely result in acute toxicity, and death, of many invertebrate communities, especially where oil penetrates into sediments through animal burrows (IPIECA, 1999). However, these communities would be likely to rapidly recover (recruitment from unaffected individuals and recruitment from nearby areas) as oil is removed from the environment.	intermittent rocky shores, and salt marshes and isolated mangroves within tidal estuaries, coastal lakes and bays. Modelling results indicates that level of probability to shoreline exposure is influenced, among other factors, by the location where the spill may occur. For release scenarios closer to shore, shoreline exposure is greater, with a maximum length of shoreline exposed to oil at the moderate and high thresholds of 13km and 3km respectively. The shoreline loadings may result in acute toxicity, and mortality of many invertebrate communities, especially for light oil such as MGO which will easily penetrate into sandy sediments. However, tidal action is expected to lead to rapid weathering of any hydrocarbons in the intertidal area and in rocky shorelines, and the populations of these communities would be likely to rapidly recover. Impacts on intertidal communities are short term unless acute exposure to fresh product causes high mortality. The effect of a LOC on individual shorelines will depend on the type of shoreline, aspect and whether they are high or low energy shores. Shoreline recovery studies link restitution times to oil type, climate and shoreline type, and results range depending on the receptors monitored and level of clean up. Mangroves are highly productive habitats, serve as nursery habitat, and support a great diversity of plants and animals. Saltmarshes are important benthic primary producers and provide habitat for other species, thus the loss of salt marshes could have long-lasting indirect effects on other organisms (Environmental Protection Authority, 2016). In Victoria, mangroves are known to occur within sheltered bays or inlets such as Lakes Entrance and Corner Inlet. Similarly, saltmarshes are also known to occur near Corner Inlet, Lakes Entrance and towards the west coast of Wilsons Promontory. Based on the modelling results, there is no probability of exposure

Receptor	Impact of MGO exposure	Exposure risk assessment
	Following the *Sea Empress* spill (in west Wales, 1996) many amphipods (sandhoppers), cockles and razor shells were killed. There were mass strandings on many beaches of both intertidal species (such as cockles) and shallow sub-tidal species. Similar mass strandings occurred after the Amoco *Cadiz* spill (in Brittany, France, 1978) (IPIECA, 1999). Following the *Sea Empress* spill, populations of mud snails recovered within a few months, but some amphipod populations had not returned to normal after one year. Opportunists such as some species of worm may actually show a dramatic short-term increase following an oil spill (IPIECA, 1999). In March 2014, small volumes of crude oil from an unidentified source (confirmed to not be offshore oil and gas production facilities) washed up along a 7km section of sandy beach on the Victorian Gippsland coast as small (a few millimetres thick) granular balls (Gippsland Times and Maffra Spectator, 2014). AMSA (2014) reported that no impacts were observed over the course of two months following the incident. As a result of the DWH spill, oil washed up on sandy beaches of the Alabama coastline. The natural movement of sand and water through the beach system continually transformed and re-distributed oil within the beach system, and 18 months after the event, mobile remnant oil remained in various states of weathering buried at different depths in the beaches (Hayworth, Clement, & Valentine, 2011). There is also evidence that submerged oil mats exist just offshore of the Alabama beaches (ranging in thickness from a few millimetres to several centimetres), which has resulted in the regular washing up of tar balls onto sandy beaches. These submerged oil mats may serve as long-term sources of remnant oil to the beach ecosystem (Hayworth, Clement, & Valentine, 2011). Long-term changes to the beach ecosystem as a result of stranded oil are unknown. Other results from beach sampling undertaken at Dauphin Island, Alabama, in May (pre-impact) and September 2011 (post-impact) found a large shift in the diversity and abundance of microbial species (e.g. nematodes, annelids, arthropods, polychaetes, protists, fungi, algae and bacteria). Post-spill, sampling indicated that species composition was almost exclusively dominated by a few species of fungi. DNA analyses revealed that the before	to moderate concentrations of surface oil and dissolved hydrocarbons at these sensitive locations. However, there is a low probability of exposure to entrained hydrocarbons at high thresholds. The effect of a LOC on individual shorelines will depend on the type of shoreline, aspect and whether they are high or low energy shores. Shoreline recovery studies link restitution times to oil type, climate and shoreline type, and results range depending on the receptors monitored and level of clean up. As a result, the consequence of MGO accumulating on coastal environments is assessed as **Consequence Level II.**

Receptor	Impact of MGO exposure	Exposure risk assessment
	and after communities at the same sites weren't closely related to each other (Bik, Halanych, Sharma, & Thomas, 2012). Similar studies found that oil deposited on the beaches caused a shift in the community structure toward a hydrocarbonoclastic consortium (petroleum hydrocarbon degrading microorganisms) (Lamendella, et al., 2014). **Rocky shorelines** Rocky shores encompass a wide variety of habitats. Exposure to the sun and wave energy are key factors in determining the types of plants and animals that inhabit the rocky shores. The persistence of oil is largely governed by the same forces (IOGP, 2016). Rock surfaces exposed to strong wave action are typically dominated by barnacles and limpets that are firmly attached and if oil strands on those surfaces it may result in mortality of the affected animals but is unlikely to persist. Sheltered rocky shores in estuaries or inlets are typically dominated by macroalgae (seaweed) with various invertebrates living on or under the algae. Oil deposited in these habitats may not be washed off so quickly and recovery from impacts may take longer. **Mangroves and salt marshes** Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (Commonwealth of Australia, 2016). The effects of surface hydrocarbons on mangroves include damage by smothering of lenticels (mangrove breathing pores) on pneumatophores or aerial prop roots, or the lower trunk; or by the loss of leaves (defoliation) due to chemical burning. It is also known that mangroves take up hydrocarbons from contact with leaves, roots or sediments, and it is suspected that this uptake causes defoliation through leaf damage and tree death (Wardrop, Butler, & Johnson, 1987). In-water entrained and dissolved hydrocarbons may affect mangrove communities directly through root uptake of toxic contaminants or indirectly due to effects on benthic infauna leading to reduced rates of bioturbation and subsequent oxygen stress on the plants root systems. Observed thresholds for effects are likely to vary depending on the health of the system, the hydrocarbon spilled and the environmental conditions; however,	

Receptor	Impact of MGO exposure	Exposure risk assessment
	observations (Lin & Mendelssohn, 1996) demonstrated that more than 1kg/m^2 of oil during the growing season would be required to affect salt marsh or mangrove plants significantly. Subtropical and temperate coastal salt marsh (otherwise referred to as coastal salt marsh) is listed as a TEC. This TEC is usually associated with sandy/muddy shores of estuaries and embayments along low wave energy coastlines. The physical environment for the TEC is coastal areas under regular or intermittent tidal influence, with salt marsh being the key vegetation type – that being salt-tolerant grasses, herbs, sedges, rushes and shrubs generally less than 50cm high (DSEWPAC, 2013c). Salt marshes occur in sheltered conditions, commonly in the strandline zone, and the vegetation offers a large surface area for oil absorption and trapping. Additionally, many salt marsh grasses, which can be dominant over large areas, have corrugated leaf surfaces which increase their holding capacity. Evidence from case histories and experiments shows that the damage resulting from oiling is very variable – as are recovery times. Lighter, more penetrating oils are more likely to cause acute toxic damage than heavy or weathered oils. In areas of light to moderate oiling where oil is mainly on perennial vegetation with little penetration of sediment, the shoots of the plants may be killed, but recovery can take place from the underground systems. Good recovery commonly occurs within one to two years. Where thick deposits of viscous oil or mousse accumulate on the marsh surface, vegetation is likely to be killed by smothering and recovery delayed because persistent deposits inhibit recolonisation.	
Wetlands	Most wetlands of international importance i.e. Ramsar wetlands have a reduced risk of receiving oil following a LOC event at a release location outside these areas because they have no, or very narrow and/or seasonal, connections to the sea. If surface oil was to enter a Ramsar site, the level of effect would be dependent on the type of receptors exposed to oil and the proportion of the site exposed to oil as well as the nature of the oil (fresh versus weathered).	Floating oil and dissolved hydrocarbons at or above the moderate threshold are not predicted to reach the Gippsland Lakes or the Corner Inlet Ramsar sites. Maximum probability of exposure to low and high thresholds of in-water (entrained) hydrocarbons in the Corner Inlet Ramsar wetland is 15% and 2% respectively.

Receptor	Impact of MGO exposure	Exposure risk assessment
	Sensitive receptors found in Ramsar sites connected to the sea could include mangroves, salt marshes, fish, shorebirds and seabirds. The consequences of oil exposure to these specific receptors have been described individually in the Sections above.	Considering the higher sensitivity of the receptor (Ramsar site), the consequence is assessed as **Consequence Level II.**
National parks and reserves	Potential impacts to sensitive receptors related to the shorelines of the terrestrial parks, such as coastal habitats and birds, and the waters of the marine parks, such as benthic habitats, fish, cetaceans and pinnipeds, are discussed in the appropriate Sections above. Impacts on tourism and recreation from degraded aesthetic values and water quality or restricted access to the coast and recreational locales within the parks due to clean up efforts are discussed below	Floating oil and dissolved hydrocarbons at or above the moderate threshold are not predicted to reach national parks or reserves. There is the potential for exposure above the high threshold for in-water (entrained) hydrocarbons at Wilsons Promontory (8%), Point Hicks (11%), and Cape Howe (7%). Taking into consideration the potential impacts to the receptors within the terrestrial and marine parks and reserves, the overall consequence is assessed as **Consequence Level II.**
AMPs	AMPs vary in their conservation objectives and specific values, but all are designed to conserve fauna, habitats and water quality over the long term. AMPs support populations of threatened seabird, marine mammal and fish species. A temporary deterioration of water quality could have negative effects on organisms, such as plankton, seabirds, marine mammals and fisheries resources which in turn affect the values of those parks. These impacts are discussed individually within other Sections of this table.	Dissolved hydrocarbons at or above the moderate threshold are not predicted to reach AMPs. However, there is a potential for the zone of high exposure to entrained hydrocarbons to overlap with the Beagle and the East Gippsland AMPs. There is also a3% probability of exposure of the Beagle AMP to floating oil at the moderate threshold. Taking into consideration the potential impacts to the receptors within the AMP and the sensitivity of the area, the overall consequence is assessed as **Consequence Level II.**
KEFs	KEFs are underwater features and hence are not at direct risk from floating surface oil or shoreline accumulated oil. Deepwater geological features, such as the Big Horseshoe Canyon and canyons on the Eastern Continental Slope will not be impacted directly by oil. However, biological values associated with KEFs such as the Upwelling East of Eden and shelf rocky reefs may be at risk from oil. Potential impacts to sensitive receptors related to the KEF Upwelling East of Eden such as plankton and cetaceans are discussed in the appropriate Sections above.	Based on modelling results, exposure to concentrations at or above the moderate floating oil and the in-water (dissolved) thresholds intersects only the KEF Upwelling East of Eden. While a spill would not affect the upwelling itself, if the spill occurs at the time of an upwelling event, it may result in plankton, krill and other fauna being exposed to in-water phase hydrocarbons. Large marine mammals feeding at this time may suffer from reduced availability of prey however these impacts are expected to be localised and temporary.

Receptor	Impact of MGO exposure	Exposure risk assessment
		The consequence is assessed as **Consequence Level III.**
Cultural – Indigenous and historic wrecks	Visible sheen or oil stranded on the shoreline has the potential to reduce the visual or cultural (including activities such as camping, rituals and ceremonies) amenity of cultural heritage sites or IPAs sys. Impacts from oil exposure are unlikely for submerged shipwrecks.	Depending on the location of the release, there is a probability that MGO release will result in accumulation at shoreline or exposure to floating oil within the low-level thresholds in the vicinity of the Gunaikurnai Native Title Determination Area. However, the effect from oil spill is expected to be of a short to medium duration. The consequence is considered **Consequence Level III.**
Commercial fisheries	Commercial fishing has the potential to be impacted through exclusion zones associated with the spill, the spill response and subsequent reduction in fishing effort. Exclusion zones may impede access to commercial fishing areas for a short period of time, and nets and lines may become oiled. The impacts to commercial fishing from a public perception perspective, however, may be more significant and longer term than the spill itself. Fishing areas may be closed for fishing for shorter or longer periods because of the risks of the catch being tainted by oil. Concentrations of oil contaminants in fish and crustacean and mollusc tissues could pose a significant potential adverse risk to human health, and until these products from nearshore fisheries have been cleared by the health authorities, they could be restricted for sale and human consumption. Indirectly, the fisheries sector will suffer losses if consumers are either stopped from using or unwilling to buy fish and shellfish from the region affected by the spill. Impacts to fish stocks have the potential for reduction in profits for commercial fisheries. Detectable tainting of fish flesh occurs after a 24-hour exposure at crude concentrations of 0.1ppm, marine fuel oil concentrations of 0.33ppm and diesel concentrations of 0.25ppm (Davis, Moffat, & Shepherd, 2002). The *Montara* spill (as the most recent [2009] example of a large hydrocarbon spill in Australian waters) occurred over an area fished by the Northern Demersal Scalefish Managed Fishery (with 11 licences held by seven operators), with goldband snapper, red emperor, saddletail snapper and yellow spotted rockcod being the key species fished (PTTEP, 2013). As	Several commercial fisheries may operate within the area potentially exposed to an MGO plume and a temporary fisheries closure may be put in place. A temporary fisheries closure, combined with oil tainting of target species (actual or perceived), may lead to financial losses to fisheries and economic losses for individual licence holders. In addition, oil may foul the hulls of fishing vessels and associated equipment, such as gill nets, resulting in additional costs from cleaning and maintenance, or replacement of affected tools and equipment. The 2023 fishery status reports (Butler, et al., 2024) present information on maximum area fished and fishing intensity from Commonwealth fisheries. Based on the data provided in this report, the fisheries most active during 2022 in the area potentially exposed to hydrocarbons from an MGO spill, and therefore potentially most at risk of socioeconomic impact from reduced market confidence, are the SESSF, especially the CTS (for both the otter-board trawl and the Danish-seine). The Victorian Scallop Fishery extends 20nm from the high tide water mark of the entire Victorian coastline (excluding bays and inlets where commercial scallop fishing is prohibited). Highest fishing effort is concentrated in the eastern waters of the State, with most vessels launching from Lakes Entrance and Port Welshpool. However, there is limited data publicly available on the

Receptor	Impact of MGO exposure	Exposure risk assessment
	a precautionary measure, the Western Australia Department of Fisheries advised the commercial fishing fleet to avoid fishing in oil-affected waters. Testing of fish caught in areas of visible oil slick (November 2009) found that there were no detectable petroleum hydrocarbons in fish muscle samples, suggesting fish were safe for human consumption. In the short-term, fish had metabolized petroleum hydrocarbons. Limited ill effects were detected in a small number of individual fish only (PTTEP, 2013). No consistent effects of exposure on fish health could be detected within two weeks following the end of the well release. Follow up sampling in areas affected by the spill during 2010 and 2011 (PTTEP, 2013) found negligible ongoing environmental impacts from the spill. Since testing began in the month after the DWH blowout in the GoM (2010), levels of oil contamination residue in seafood consistently tested 100 to 1000 times lower than safety thresholds established by the USA FDA, and every sample tested was found to be far below the USA FDA's safety threshold for dispersant compounds (BP, 2015). The USA FDA testing of oysters found oil contamination residues to be 10 - 100 times below safety thresholds (BP, 2015). Sampling data shows that post-spill fish populations in the GoM since 2011 were consistent with pre-spill ranges and for many shellfish species, commercial landings in the GoM in 2011 were comparable to pre-spill levels. In 2012, shrimp (prawn) and blue crab landings were within 2.0% of 2007 - 2009 landings. Recreational fishing harvests in 2011, 2012 and 2013 exceeded landings from 2007 - 2009 (BP, 2015).	location and extent of this fishery and other fisheries that operate within Victorian waters. Western Port, Port Phillip Bay, Corner Inlet/Nooramunga and Gippsland Lakes are some examples of bay and inlet fisheries in Victoria, with Corner Inlet regarded as the largest commercial bay and inlet fishery. These areas also used for recreational fishing. However, it is noted that commercial fishing using the netting technique has been phased out from these areas. A temporary fisheries closure and the flow on losses from the lack of income derived from these fisheries based on reduced market confidence, together with the potential for extended media coverage (potentially greater than three months) has the possibility of exceeding medium community disruption (>100 – 1000 people) such as reduced employment (in fisheries service industries and the seafood supply chain). The flow on losses from the lack of income derived from these fisheries are likely to have short-term socio-economic consequences in local communities or the region, such as reduced employment in fisheries service industries which may include, but are not limited to tackle and bait supplies, fuel, marine mechanical services and accommodation among others. The potential economic impacts to commercial fisheries from a LOC are considered to be **Consequence Level I.**
Recreation and tourism	Refer to Sections on fish, cetaceans, birds, benthic and coastal habitats, wetlands, national parks and reserves, and AMPs described above.	Tourism and recreation are linked to the presence of marine fauna (e.g. whales), particular habitats and locations for swimming, leisure (such as sandy beaches) or recreational fishing. It is noted that VFA (2022) estimated that recreational fishing activities in Victoria contributes close to three billion dollars annually to the economy, and that this activity in Corner Inlet provides a significant contribution to the economy locally and regionally. Depending on the location of the MGO release, the modelling predicts probability of floating oil at concentrations within the low

Receptor	Impact of MGO exposure	Exposure risk assessment
		threshold (1g/m^2), as well as probability of shoreline accumulation at the low thresholds in areas used for recreation and leisure such as Corner Inlet, the eastern end of Wilsons Promontory, and some sandy beaches within the Wellington Shire and East Gippsland. Short to medium-term impacts to nature-based tourism and other human uses of beaches (and nearshore waters) may occur as a result of temporary beach closures including wider impacts due to perceptions of a polluted environment that is not desirable to visit. With respect to human health, post-*Macondo* oil spill (April 2010) studies in December found of 17,000 water samples, none exceeded US Environmental Protection Agency benchmarks for protection of human health (Operational Science Advisory Team, 2011) and a year later residual oil in nearshore and sandy shoreline areas was highly weathered and concentrations of constituents of concern were below levels of concern for human health (Operational Science Advisory Team, 2011). Alaska's tourism economy took approximately two years to recover from the Exxon Valdez (BOEM, 2017). Similarly, the Eastern Research Group (2014) reported that while the DWH spill had had a significant impact on several areas of tourism in the short term and had wide-ranging impacts across the GoM, the tourism economy has rebounded to pre-spill levels within four years. The extent of potential impacts to tourism and recreation depends on when and where the spill occurs, and the total volume of oil released during the event. Following the precautionary principle and considering the range of activities and locations, and the modelled impacts of the spill, the potential for reduced amenity of areas used by coastal tourists and recreational visitors, temporary health implications and possible closures, the consequence is considered as **Consequence Level I.**

The likelihood of such an event occurring is considered to be **Likelihood Category E** (very highly unlikely).

7.8.4 Demonstration of As Low As Reasonably Practicable

Table 7-64 Decision Context and justification

Decision Context
Vessel operations for decommissioning of offshore facilities and infrastructure is common and well-established practice worldwide. These activities are well regulated with associated control measures, well understood, and are implemented across the offshore industry. Although there is the potential for significant environmental impacts from a LOC of MGO from a vessel, the spill source volumes are restricted in size and limited to the volume of fuel that is inside the affected/ruptured fuel tank, the environmental impact of MGO is well understood, a credible spill volume has been modelled and a very conservative threshold has been selected to define the EMBA. As a result, there is limited uncertainty associated with this event. The highest environmental consequence to receptors resulting from the loss of containment of MGO from a vessel has been assessed as **Consequence Level I**. The risk of the loss of containment of MGO from a vessel has been assessed as **Risk Category 3**. No issues, objections or claims were raised by relevant persons during the consultation process with regard to the risk of LOC resulting from a vessel collision. However, a precautionary approach is required due to the potential consequence level of a spill event. Hence, Esso believes **Decision Context B** should apply.

Table 7-65 Good practice controls

Good practice	Adopted	Control	Rationale
Comply with MARPOL Annex I – Chapter 2.	Adopted – RSK8-CM1 and RSK8-CM10	Class certificate – oil pollution.	Under MARPOL – Annex I requirements, any ship of 400 gross tonnage or above is required to hold an International Oil Pollution Prevention Certificate.
Comply with Section 572C of the OPGGS Act.	Adopted – RSK8-CM2 and RSK8-CM11	OPEP and OSMP.	Under the Environment Regulations, NOPSEMA require that the petroleum activity have an accepted OPEP in place before commencing the activity. In the event of a vessel collision the OPEP will be implemented. The guidance note *Oil Pollution Risk Management* (NOPSEMA, 2025g) also indicates, that based on obligations set out in Section 572C of the OPGGS Act, the OPEP must include adequate arrangements for responding to and monitoring oil pollution (described in this EP as the OSMP). Esso's OSMP details the arrangements and capability in place for: • operational monitoring of a hydrocarbon spill to inform response activities

Good practice	Adopted	Control	Rationale
			• scientific monitoring of environmental impacts of the spill and response activities. Operational monitoring will allow adequate information to be provided to aid decision making to ensure response activities are timely, safe, and appropriate. Scientific monitoring will identify if potentially longer-term remediation activities are required.
Comply with MARPOL Annex I – Chapter 5.	Adopted – RSK8-CM3 and RSK8-CM12	SOPEP.	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the IMO across many critical areas including the SOLAS, the 1988 Protocol to the International Convention on Load Lines and MARPOL. A vessel built in accordance with the applicable Rules of an IACS member society may be assigned a class designation relevant to the IMO Rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require that a SOPEP (or equivalent, according to class) is in place. To prepare for a spill event, the SOPEP details: • response equipment available to control a spill event • review cycle to ensure that the SOPEP is kept up to date • testing requirements, including the frequency and nature of these tests. In the event of a spill, the SOPEP details: • reporting requirements and a list of authorities to be contacted • activities to be undertaken to reduce or control the release • procedures and point of contact on the ship for coordinating shipboard action with local and national authorities.

Good practice	Adopted	Control	Rationale
Comply with the OPGGS (Safety) Regulations 2024	Adopted – RSK8-CM5	Implementation of a safety case for each facility * *For Campaign #1 purposes, facility refers to the Pioneering Spirit HLV and the Fortitude CSV	NOPSEMA requires that the facility (namely the *Pioneering Spirit* HLV and *Fortitude* CSV) has an accepted Safety Case in place before commencing the activity. A Safety Case for these vessels will be sent to NOPSEMA for assessment. HLV and CSV operations will only be allowed if the Safety Case has been accepted by the regulator. The key elements of the Safety Case that function to reduce the likelihood of LOC include: • training • qualifications • maintenance (of HLV/CSV equipment) • MOC • emergency response • performance monitoring.

Table 7-66 Engineering risk assessment

Control measures	Benefit	Cost/feasibility	Adopted
Do not undertake the activity.	Eliminates spill potential	Not feasible General Direction 817 indicates Esso must complete all preparatory decommissioning activities and commence the topside dismantling campaign as soon as reasonably practicable, and no later than 30 September 2027, associated with facilities listed in Schedule 3 of the Direction.	Not adopted.
Implementation of ASOG and Critical Activity Mode Operation for Campaign #1 operations.	ASOG and Critical Activity Mode Operation are decision support tools that provide a higher level of confidence for safe vessel operations with a risk management approach. Critical Activity Mode Operation describes how to configure the vessels DP system including power generation and distribution, propulsion and position reference systems. ASOG sets out the operational, environmental and equipment performance limits considered necessary for safe DP operations while carrying out a specific activity.	The application of ASOG/Critical Activity Mode Operation risk management tools is industry best practice for DP operations. Critical Activity Operation describes how to configure the vessels DP system and ASOG sets out the operational, environmental and equipment performance limits considered necessary for safe DP operations while carrying out a specific activity.	Adopted – RSK8-CM4

Control measures	Benefit	Cost/feasibility	Adopted
CSV and HLV approach protocols.	Reduces the risk of incidents that could result in spill of oil into the marine environment.	Procedures will be clearly defined to manage the very low approach speeds for approaching the platforms to be removed by the HLV and the CSV.	Adopted - RSK8-CM6
Lifting and transfer operations procedures.	Reduces the risk of incidents that could result in spill of oil into the marine environment.	Procedures will be clearly defined to manage lifting operations and transfer operations from the HLV onto HTVs or barges.	Adopted – RSK8-CM7
Support/supply vessel approach protocols.	Reduces the risk of incidents that could result in spill of oil into the marine environment.	Procedures will be clearly defined to manage SIMOPS, including approach of supply vessels to other Campaign #1 vessels.	Adopted – RSK8-CM8
CSVs and HLV must be DP Class 2 or 3.	Reduces the risk from single faults in the system that affect the ability of the vessel to maintain station, minimising the incidents that may result in a vessel oil spill.	• DP Class 2/3 (redundancy so that no single fault in an active system will cause the system to fail) is the industry standard where loss of position keeping capability may cause personnel injury, pollution or damage with large economic consequences • CSVs operating during Campaign #1 may be DP2 or DP3. The HLV is a DP3 class vessel, further reducing the possibility of system failure due to a single fault.	Adopted – RSK8-CM9

7.8.5 Demonstration of acceptability

Table 7-67 Demonstration of acceptability test

Factor	Demonstration criteria	Criteria met	Rationale
Risk assessment process for unplanned events	The risk ranking is lower than **Risk Category 1**.	✓	The risk ranking is **Risk Category 3** and therefore considered acceptable.

Factor	Demonstration criteria	Criteria met	Rationale
Principles of ESD	a) The integration principle – decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations.	✓	Not inconsistent. Planning for Bass Strait decommissioning and decision making as to the most appropriate strategies and methods has incorporated contemplation of both short and long term economic, environmental, social and equitable considerations.
	b) The precautionary principle - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	✓	Not inconsistent. Unplanned release of oil into the water is a very highly unlikely event, however with potential for significant consequences on the environment. Esso has adopted industry best practice for assessing the risk and has management measures in place to reduce the risk to ALARP. This includes: • a conservative oil spill modelling was conducted to inform potential risk, sensitive receptors and response capabilities and measures • oil spill modelling was based on a worst-case scenario that is representative of specific vessel operations for Campaign #1 • Esso considered and applied requirements and advice from legislation, publications and industry guidelines on risk assessment, prevention and mitigation measures, and preparedness and response in the very highly unlikely event of an oil spill during Campaign #1 • Esso will implement measures and controls to manage the potential risk of an unplanned oil release, including best industry standards and practices, and engineering and design • vessels conducting activities for Campaign #1 will comply with regulatory requirements, including those that are specific to oil pollution and emergency preparedness.

Factor	Demonstration criteria	Criteria met	Rationale
	c) The intergenerational principle - the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	✓	Not inconsistent. The assessment undertaken for the accidental release – LOC of refined oils – has concluded that environmental impacts will be short term in nature. Best industry practices and other controls are in place to further reduce the probability of occurrence of an unplanned release. Any impacts as a result of an unplanned release of fuel will not impact the health, diversity and productivity of the environment in such a manner that future generations may be impacted.
	d) The biodiversity principle - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making	✓	Not inconsistent. The potential impact associated with this aspect is limited to a moderate short-term impact. It is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and other requirements	Legislative and other requirements have been identified and met.	✓	The proposed activities align with the requirements of the: • *Navigation Act 2012* (Cth) – Chapter 6 (Safety of Navigation) Part 6 deals with safe navigation including provisions about reporting of movement of vessels. The requirements of MARPOL Annex I has been adopted. The following legislative and other requirements are considered relevant as they apply to the implementation of MARPOL in Australia: • *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Cth) • *Navigation Act 2012* (Cth) – Chapter 4 (Prevention of Pollution) • Marine Order 91 (Marine pollution prevention – oil). The proposed activities align with the requirements of the OPGGS Act: • Schedule 3 (occupational health and safety) of the OPGGS Act and Safety Regulations require the

Factor	Demonstration criteria	Criteria met	Rationale
			operator of each offshore facility to prepare a Safety Case for submission to NOPSEMA. Activities at a facility must be conducted in accordance with a Safety Case that has been accepted by NOPSEMA.
Internal context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to *"comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".*
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to a LOC of MGO but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil OIMS Objectives.	✓	Proposed activities meet: • OIMS System 6: Regulatory Compliance and Sustainability Management objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements • OIMS System 8: Selecting and Engaging with Third Party Providers objectives to clearly define and communicate OI requirements to contractors and to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner • OIMS System 10: Managing Community Risk objective to anticipate community concerns and develop response plans, as appropriate • OIMS System 10: Emergency Preparedness and Response objectives to document, resource and communicate emergency response plans,

Factor	Demonstration criteria	Criteria met	Rationale
			and conduct training, exercises and/or drills to determine the adequacy of the plans.
External context	Concerns of relevant persons have been considered/addressed through the consultation process.	✓	No relevant person concerns have been raised concerning the risk of LOC resulting from a vessel collision.

7.8.6 EPOs, control measures, EPSs and measurement criteria

Table 7-68 EPOs, control measures, EPSs and measurement criteria – Loss of containment - refined oils

EPO	Control measure	EPS	Measurement criteria
RSK8-EPO1: No unplanned release of refined oils from rupture of vessel fuel tanks.	RSK8-CM1: Class certificate – oil pollution.	RSK8-EPS1.1: Campaign #1 vessels are compliant with MARPOL Annex I and MARPOL Annex V and associated Marine Order 91 (Marine Pollution Prevention – Oil) as applicable to vessel class.	RSK8-MC1.1.1: Vessel maintains an International Oil Pollution Prevention Certificate. RSK8-MC1.1.2: Classed approved Shipboard Oil Pollution Emergency Plan.
	RSK8-CM2: OPEP and OSMP.	RSK8-EPS2.1: An OPEP, inclusive of an OSMP, is in place for Campaign #1 operations.	RSK8-MC2.1.1: OPEP developed for Campaign #1 activities. RSK8-MC2.1.2: Implementation of OPEP (i.e. records of planned and executed emergency drills).
	RSK8-CM3: SOPEP.	RSK8-EPS3.1: Campaign #1 vessels comply with MARPOL Annex I – Chapter 5.	RSK8-MC3.1.1: SOPEP developed for each vessel that takes part of Campaign #1 activities. RSK8-MC3.1.2: Implementation of SOPEP (i.e. records of planned and executed emergency drills).
	RSK8-CM4: Implementation of ASOG and Critical Activity Mode Operation for Campaign #1 operations.	RSK8-EPS4.1: ASOG/Critical Activity Mode Operation risk management is applied during Campaign #1 activities.	RSK8-MC4.1.1: Records/evidence of ASOG and Critical Activity Mode Operation.
	RSK8-CM5: Implementation of a safety case for each facility * *For Campaign #1 purposes, facility refers to the Pioneering Spirit HLV and the Fortitude CSV	RSK8-EPS5.1: Safety case in place for the HLV (*Pioneering Spirit*) and the CSV (*Fortitude*).	RSK8-MC5.1.1: NOPSEMA approved Safety Cases for the HLV and the CSV.

EPO	Control measure	EPS	Measurement criteria
			RSK8-MC5.1.2: Record of Safety Case implementation checks undertaken prior to mobilisation.
	RSK8-CM6: CSV and HLV approach protocols.	RSK8-EPS6.1: Approach protocols to platforms in place for the CSV and HLV.	RSK8-MC6.1.1: Approach protocols to platforms developed for Campaign #1 activities. RSK8-MC6.1.2: Implementation of approach protocols (i.e. PSZ entry).
	RSK8-CM7: Lifting and transfer operations procedures.	RSK8-EPS7.1: Lifting and transfer operations procedures in place for the CSV and HLV.	RSK8-MC7.1.1: Records/evidence of: • procedures for lifting and transfer operations developed for Campaign #1 activities. • implementation of lifting and transfer operations procedures.
	RSK8-CM8: Support/supply vessel approach protocols.	RSK8-EPS8.1: Support/supply vessel approach protocols.	RSK8-MC8.1.1: Records/evidence of: • approach protocols for support and supply vessel operations developed for Campaign #1 activities implementation of approach protocols (i.e. PSZ entry)
	RSK8-CM9: CSVs and HLV must be DP Class 2 or 3.	RSK8-EPS9.1: CSVs are certified as DP Class 2 or Class 3.	RSK8-MC9.1.1: Current DP class certificate. RSK8-MC9.1.2: Failure Modes and Effects Analysis.
		RSK8-EPS9.2: HLV is certified as DP class 3.	RSK8-MC9.2.1: Current DP class certificate. RSK8-MC9.2.2: Failure Modes and Effects Analysis.
RSK8-EPO2: Minimise and control oil spilled from vessels in the	RSK8-CM10: Class certificate – oil pollution.	RSK8-EPS10.1: Campaign #1 vessels are compliant with MARPOL Annex I and MARPOL Annex V and associated Marine Order 91 (Marine Pollution	RSK8-MC10.1.1: Vessel maintains an International Oil Pollution Prevention Certificate.

EPO	Control measure	EPS	Measurement criteria
event of an unplanned release of oil due to rupture of a vessel fuel tank.		Prevention – Oil) as applicable to vessel class.	RSK8-MC10.1.2: Classed approved Shipboard Oil Pollution Emergency Plan.
	RSK8-CM11: OPEP and OSMP.	RSK8-EPS11.1: An OPEP, inclusive of an OSMP, is in place for Campaign #1 operations.	RSK8-MC11.1.1: OPEP developed for Campaign #1 activities. RSK8-MC11.1.2: Implementation of OPEP (i.e. records of planned and executed emergency drills).
	RSK8-CM12: SOPEP.	RSK8-EPS12.1: Campaign #1 vessels comply with MARPOL Annex I – Chapter 5.	RSK8-MC12.1.1: SOPEP developed for each vessel that takes part of Campaign #1 activities. RSK8-MC12.1.2: Implementation of SOPEP (i.e. records of planned and executed emergency drills).

7.8.7 Residual risk ranking

The impact assessment described in Table 7-63 presents different consequence level results that are specific to the type of receptor assessed. To determine the residual risk ranking, the highest consequence level assessed (assigned to wetlands, AMPs, commercial fisheries and the recreation and tourism receptors) will be considered for the risk ranking definition, as presented in Table 7-69 .

Table 7-69 Residual risk ranking outcome

Consequence Level	Likelihood Category	Risk Category
I	E	3

8 Implementation strategy

Regulation 22(1) of the Environment Regulations requires that an implementation strategy must be included in an EP. The implementation strategy must contain a description of the Environmental Management System for the activity (per Regulation 22(2)), including specific measures to be used to ensure that, for the duration of this EP, and until such time as the relevant petroleum titles are surrendered:

- the environmental impacts and risks of the activity continue to be identified and reduced to a level that is ALARP
- control measures detailed in the EP are effective in reducing the environmental impacts and risks of the activity to ALARP and an acceptable level
- EPOs and EPSs set out in the EP are being met.

The Environmental Management System for this EP is ExxonMobil's OIMS. Lloyd's Register Quality Assurance Inc. has assessed OIMS and concluded that it is consistent with the intent and meets the requirements of ISO 14001:2015 *Environmental management systems - Requirements with guidance for use*.

8.1 ExxonMobil's framework

As a wholly owned subsidiary of ExxonMobil Australia Pty Ltd, Esso complies with the Exxon Mobil Corporation Standards of Business Conduct, which require the Company to conduct business in a manner that is compatible with the environmental, social and economic needs of the communities in which it operates. These Standards also aim to protect the safety and health of employees, those involved in operations, and members of the public.

In addition to the Standards, Esso manages its operations in accordance with a structured and disciplined risk management framework known as OIMS.

8.1.1 Standards of Business Conduct

The Standards of Business Conduct form the framework by which ExxonMobil and its subsidiaries operate around the globe and provide employees with the principles and an understanding of ExxonMobil standards.

The Standards of Business Conduct include the following foundation policies:

- Ethics Policy
- Conflicts of Interest Policy
- Corporate Assets Policy
- Directorships Policy
- Gifts and Entertainment Policy
- Anti-Corruption Policy
- Political Activities Policy
- International Operations Policy
- Antitrust Policy
- Health Policy
- Environment Policy
- Safety Policy
- Product Safety Policy
- Customer Relations and Product Quality Policy
- Alcohol and Drug Use Policy
- Equal Employment Opportunity Policy
- Equal Employment Opportunity Policy (modified for application in the United States)
- Harassment in the Workplace Policy
- Harassment in the Workplace Policy (modified for application in the United States).

The Standards of Business Conduct can be accessed via the following link: https://corporate.exxonmobil.com/-/media/Global/Files/who-we-are/Standards-of-Business-Conduct_apr.pdf

This EP complies with the applicable Standards of Business Conduct, in particular, the Environment Policy which states:

Environment Policy

It is Exxon Mobil Corporation's policy to conduct its business in a manner that is compatible with the balanced environmental and economic needs of the communities in which it operates. The Corporation is committed to continuous efforts to improve environmental performance throughout its operations.

Accordingly, the Corporation's policy is to:

- Comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist
- Encourage concern and respect for the environment, emphasise every employee's responsibility in environmental performance, and foster appropriate operating practices and training
- Work with government and industry groups to foster timely development of effective environmental laws and regulations based on sound science and considering risks, costs, and benefits, including effects on energy and product supply
- Manage its business with the goal of preventing incidents and of controlling emissions and wastes to below harmful levels; design, operate, and maintain facilities to this end
- Respond quickly and effectively to incidents resulting from its operations, in cooperation with industry organisations and authorised government agencies
- Conduct and support research to improve understanding of the impact of its business on the environment, to improve methods of environmental protection, and to enhance its capability to make operations and products compatible with the environment
- Communicate with the public on environmental matters, and share its experience with others to facilitate improvements in industry performance
- Undertake appropriate reviews and evaluations of its operations to measure progress and to foster compliance with this policy.

8.1.2 Operations Integrity Management System

ExxonMobil's OIMS Framework establishes common worldwide expectations to address the risks inherent to the business. ExxonMobil uses the term OI to address all aspects of its business impacting personnel and process safety, security, health and environmental (SSHE) performance. The OIMS Framework includes 11 Elements, as shown in Figure 8-1. Each Element contains overarching Objectives, and a set of Expectations. The Corporate OIMS Framework can be found at: https://corporate.exxonmobil.com/-/media/global/files/risk-management-and-safety/oims-framework-brochure.pdf

The OIMS Framework also includes the characteristics of and processes for implementing OI Management Systems. Application of the OIMS Framework is required across the entire ExxonMobil enterprise, with a specific emphasis on design, construction and operations.

OIMS is applied by both Upstream and Global Projects to ensure that Corporate Expectations are met. The Global Projects OIMS Systems are described in Table 8-1. System 1: Leading, Managing and Driving Performance is the driver to ensure effectiveness of all 17 Systems. Each Global Projects System includes a description of the System objectives (including associated Corporate OIMS Expectations, where applicable) and scope, with listed processes, procedures, and verification mechanisms that meet those objectives.

The OIMS Management Committee has overall accountability for the implementation, execution, and continuous improvement of OIMS within Esso.

Key responsibilities of the OIMS Management Committee include:

- demonstrate commitment to OIMS through active and visible participation in OIMS implementation, execution and improvement
- ensure that Annual System Reviews are conducted
- review key OI performance indicators that show the status and effectiveness of OIMS implementation and execution
- periodically review OI incidents for learning and continuous improvements to OIMS.

Figure 8-1 OIMS framework

Table 8-1 Description of Global Projects OIMS Systems

Corporate OIMS Element	Global Projects OIMS System	
	Title	Linked Corporate OIMS Expectations
1 Leading, Managing and Driving Performance	Leading, Managing and Driving Performance	1.1-1.12, 2.2
2 Identifying, Assessing, Mitigating and Accepting Risk	Identifying, Assessing, Mitigating and Accepting Risk	1.4, 1.5, 2.1-2.3, 3.2, 4.2
3 Designing, Constructing and Preparing for Start Up	Quality Assurance and Pre-Startup Review	3.5, 3.6
	Project Management and Execution	3.1, 3.2
	Design and Construction Practices and Standards	3.3, 3.4, 3.7
4 Providing Information Needed for Construction, Operation and Maintenance	Information Needed for Construction, Operation, and Maintenance	4.1, 4.3
5 Selecting, Training, Engaging and Enabling People	Selecting, Training, Engaging and Enabling People	1.7, 5.1-5.4

Corporate OIMS Element	Global Projects OIMS System	
	Title	Linked Corporate OIMS Expectations

10 Preparing for Emergencies and Managing Potential Risk to the Community	Emergency Preparedness and Response	10.1
	Managing Community Risk	10.2, 2.1
11 Assessing and Driving Effectiveness	Assessing and Driving Effectiveness	1.11, 11.1-11.2

* Global Projects supports multiple Corporate OIMS Expectations.

Esso has determined the following OIMS Systems are required for the implementation of this EP:

- OIMS System 1: Leading, Managing and Driving Performance
- OIMS System 2: Identifying, Assessing, Mitigating and Accepting Risk
- OIMS System 3: Quality Assurance
- OIMS System 3: Project Management and Execution
- OIMS System 3: Design and Construction Practices and Standards
- OIMS System 4: Information Needed for Construction, Operation and Maintenance
- OIMS System 5: Selecting, Training, Engaging and Enabling People
- OIMS System 5: SSHE Behaviours and Human Performance
- OIMS System 6: Management of Work and Equipment
- OIMS System 6: Regulatory Compliance and Sustainability Management
- OIMS System 6: Critical Safeguard Management
- OIMS System 7: Managing Changes
- OIMS System 8: Selecting and Engaging Third Party Providers
- OIMS System 9: Learning from Project Activities and Incidents
- OIMS System 10: Emergency Preparedness and Response
- OIMS System 10: Managing Community Risk
- OIMS System 11: Assessing and Driving Effectiveness

8.2 OIMS System 1: Leading, Managing and Driving Performance

In accordance with OIMS System 1: Leading, Managing and Driving Performance, Esso has defined the roles and responsibilities relevant to this EP.

8.2.1 Roles and responsibilities

As required by Regulation 22(3) of the Environment Regulations, this Section sets out the roles and responsibilities of personnel in relation to the implementation, management and review of this EP.

An indicative organisational chart is provided in Figure 8-2, while Table 8-2 describes the responsibilities of key personnel involved in the activity.

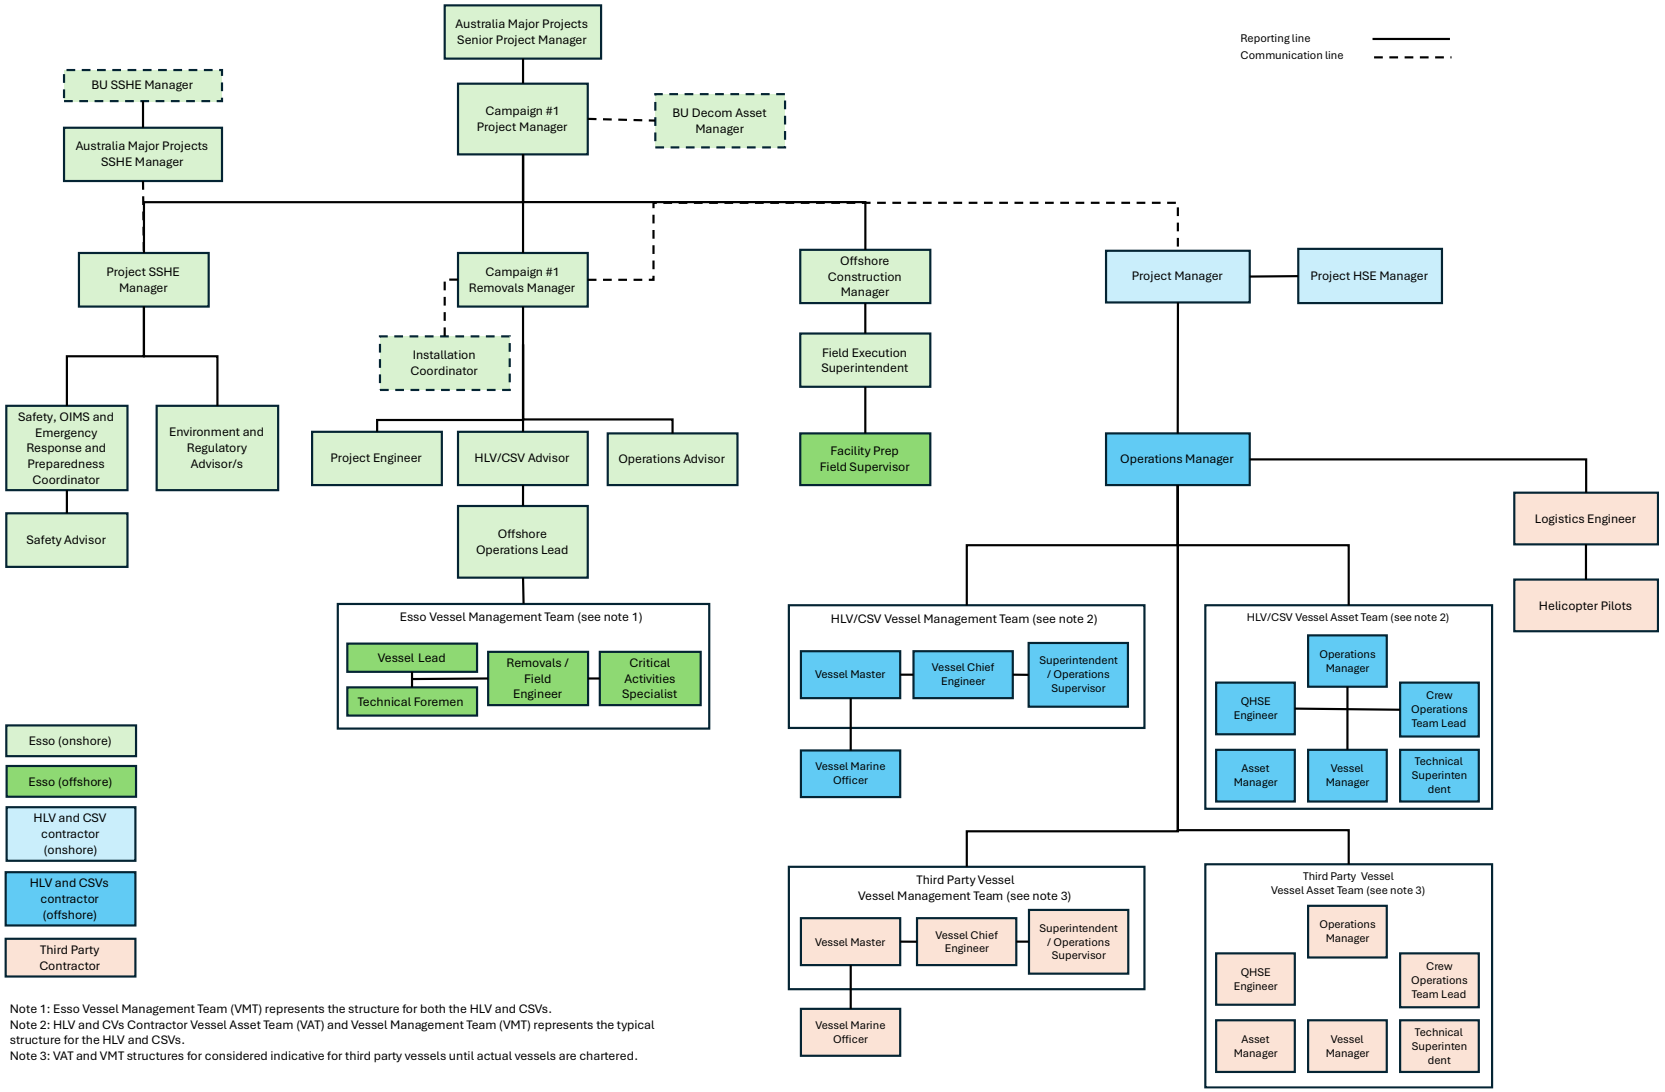

Figure 8-2 Activity-specific organisation chart for this EP

Table 8-2 Activity-specific key roles and responsibilities for this EP

Role	Responsibilities
Campaign #1 Project Manager	• Manages and stewards Campaign #1 decommissioning activities. • Ensures compliance with Company policies, standards and regulatory requirements.
Campaign #1 Removals Manager (Esso)	• Oversees day-to-day operations to ensure compliance with relevant environmental legislative requirements, commitments, conditions and procedures as provided in this EP. • Primary point of contact between Vessel Management Team (VMT) (based both onshore and offshore) and engineering, procurement and removals contractor. • Ensures campaign-related induction is delivered. • Ensures training matrix is fully implemented. • Ensures procedures are in place and used effectively for the safe and efficient work management during execution. • Ensures prompt follow-up action is initiated and completed after inspections/audits, incidents, and emergency drills. • Member of the Esso Emergency Response team. • Engaged in contract life cycle management • Reviews and approves environmental MOCs and provides support to the Environmental and Regulatory Advisor in the process.
Offshore Operations Lead (Esso)	• Provides guidance to Esso VMT to ensure procedural (including environmental) compliance during decommissioning activities, with support from the Environmental and Regulatory Advisor • Advises the Project Management team and VMT in incident response and case management. • Acts as primary interface with engineering, procurement and removals contractor with regard to vessel activities. • Monitors contractor performance (including environmental), with support from the Environmental and Regulatory Advisor. • Identifies where environmental MOC process may be triggered and provides support to Environmental and Regulatory Advisor as required. • Participates in daily communication between the Vessel Lead and Project Management team regarding environmental compliance. • Member of Esso Emergency Response team.
Vessel Lead (Esso)	• Member of the Esso VMT. • Primary interface with contractor VMT. • Manage Esso on-vessel personnel, which may include technical foremen, inspectors and Marine Warranty Surveyors. • Oversees all work activities and work programs ensuring work is undertaken in accordance with procedures, work instructions and in compliance with all legislative requirements and EP commitments. • Ensures vessel personnel understand their obligations with respect to the management of environmental risk • Provides oversight for on-vessel environmental performance and ensuring contractor environmental management systems are followed

Role	Responsibilities
	• Responsible for on-vessel incident response case management. • Ensure approved removal procedures are followed or MOC process is implemented as required. • Implement field surveillance plans. • Steward implementation of SSHE and emergency response plans. • Oversee Campaign #1/SSHE personnel on vessel. • Validate and endorse daily and other reports. • Monitor contractor performance and ensure environmental specifications are met and approved procedures are followed • Responsible for Esso reportable incident notifications.
Removals/Field Engineer (Esso)	• Member of the VMT. • Provide technical support as needed to the Esso VMT as required. • Promote environmental awareness and environmental performance. • Monitor work for alignment with the approved removal procedures. • Assist with environmental MOC process. • Steward Marine Warranty Surveyor activities. • Monitor offshore execution progress against the offshore integrated schedule. • Facilitate lessons learned, coordination of reporting, and supports field surveillance.
Critical Activities Specialist / Marine Warranty Surveyor (Esso)	• Provides support to Removal/Field Engineers. • Provide technical support as needed to VMT.
Technical Foreman (Esso)	• Member of the VMT. • Oversees offshore operations on 24-hour basis (via 12-hour shifts), communicating activities to the Vessel Lead. • Monitor and ensure environmental management systems are followed and ensure compliance with environmental specifications, procedures, and plans • Implement field surveillance plans. • Steward implementation of SSHE and emergency response plans. • Assist in the preparation of daily activity reports. • Monitor vessel condition/readiness. • Serve as day-to-day interface with contractor with a focus on safety and environmental aspects. • Provide safety and environmental monitoring/leadership/coaching as well as participate in safety meetings. • Participate, coach and assist contractor personnel in effective pre-task planning measures in Job Safety Analyses, and toolbox meetings. • Provide oversight of contractor's materials management/verification systems. • Monitor environmental compliance as required. • Assist in collection of all documentation offshore relating to the environmental aspects of Campaign #1 (i.e. equipment and personnel certifications, contractor daily reports, minutes of meetings, inspections and audits, accident/incident reports, near miss reports, survey reports, environmental MOC reports, and corrective action reports, as required).

Role	Responsibilities
	• Capture lessons learned during removal activities.
Project SSHE Manager	• Ensures all regulatory reporting requirements are met and reports to regulatory authorities as appropriate, including the reporting of environmental incidents. • Ensures Campaign #1 related induction is delivered. • Oversees the coordination of SSHE compliance audits and inspections. • Supports communication with regulators and government agencies.
Environmental and Regulatory Advisor (Esso)	• Acts as the Esso primary contact for environmental matters during execution of this EP including guidance on compliance queries, MOC and reporting. • Coordinates, monitors and reports compliance with EPOs and EPSs in accordance with the requirements of this EP. • Establishes and maintains processes to ensure that records relevant to this EP are defined and appropriately managed. • Prepares and supports contractor development of environmental/regulatory content for inductions and ensures that attendance records are maintained. • Provides guidance to Esso VMT in their role in environmental procedural and compliance monitoring during decommissioning activities. • Responsible for planning and coordinating Esso EP compliance audits and inspections. • Supports incident investigations as required. • Completes monthly incident reporting to NOPSEMA. • Completes annual and/or end of activity environmental performance reporting (as delegated by Project SSHE Manager). • Completes environmental MOCs as applicable to this EP. • Completes chemical discharge assessment. • Supports monitoring of contractor performance and ensures environmental specifications are met and approved procedures and plans are followed • Ensures IMS risk assessment is completed as appropriate prior to vessels commencing activities.
Helicopter Pilots (Contractor/Esso)	• Implements cetacean interaction management actions consistent with Part 8 Division 8.1 of the EPBC Regulations.
Project Manager (Contractor)	• Overall responsibility to ensure that the requirements of the EP are conducted, communicated and understood with all parties involved in the preparation and execution of the onshore and offshore works. • Ensure contractor and subcontractors are compliant with the Campaign #1 environmental requirements. • Ensure all contractor personnel are competent to perform the work they have been assigned and trained in environmental compliance obligations as applicable.
Vessel Master (Contractor)	• Member of the contractor VMT.

Role	Responsibilities
	• Overall responsibility for vessel operations and environmental performance. • Monitor the implementation of the environmental management controls during removal activities as part of daily inspection rounds. • Ensures environmental controls for the vessel are adequately resourced. • Ensures environmental equipment and resources are readily available. • Ensures vessel personnel are trained, competent and drilled in emergency response processes for the vessel. • Ensure all chemicals proposed to be discharged are communicated, assessed and approved prior to discharge. • Ensures all environmental incidents or non-conformances with EPOs and EPSs are reported in accordance with incident response and reporting procedures. • Ensures emergency drills are conducted as per the SOPEP schedule. • Ensures vessel personnel are appropriately qualified, trained and equipped for their roles on the vessel. • Ensures all vessel activities are in compliance with the requirements of this EP. • Ensures reporting of incidents are communicated with Esso VMT.
Vessel Chief Engineer (Contractor)	• Member of the contractor VMT. • Ensure an immediate and adequate response to any overboard spill (as per SOPEP requirements). • Ensure safe transfer of fuel, oil and sludge in bulk. • Ensure all equipment is maintained and operational as per planned maintenance requirements to avoid accidental discharges to water or air.
Project HSE Manager (Contractor)	• Provide Campaign #1 specific environmental instructions to the vessels, discipline engineers and subcontractors as applicable. • Perform environmental audits and inspections as applicable. • Oversee periodic environmental compliance reviews and ensure corrective actions from inspections are developed, tracked and closed out in a timely manner. • Monitor and steward close out of corrective actions identified during environmental monitoring or audits. • Ensure all project compliance requirements are managed, including those within this EP, and communicated to the Environmental and Regulatory Advisor (Esso) at agreed intervals. • Ensure relevant environmental and regulatory plans and procedures are approved and in place prior to mobilisation. • Ensure all vessels mobilised to site are compliant prior to works commencing. • Ensure contractor and subcontractor personnel understand their obligations with respect to the management of environmental risk. • Ensure contractor and subcontractor personnel undertake required training, and that all training records are maintained and communicated to Esso in agreed timeframes. • Verify that subcontractors meet environmental-related contractual obligations.

Role	Responsibilities
	• Develop and maintain an EMP which details EP obligations and requirements. • Track and report compliance with EPOs and EPSs in accordance with the requirements of this EP. • Manage change requests for the activity and ensure MOC documentation is submitted to the Environmental and Regulatory Advisor (Esso) for any scope changes in a timely manner. • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to Esso. • Verify that relevant environmental approvals for the activities exist prior to commencing activity.
Superintendent/Operations Supervisor (Contractor)	• Communicate HSE related issues (generic and project specific) in pre-shift and toolbox meetings to the relevant crew. • Identify the need for additional onboard work risk assessments and ensure compliance with Work Management systems. • Monitor the implementation of the environmental management controls during the decommissioning activities as part of daily inspection rounds. • Communicate the HSE expectations, including project specific expectations. • Report on HSE performance, including environmental monitoring. • Report anomalies to the Vessel Master and investigate incidents for adequate corrective and preventive actions.
Vessel Marine Officers (Contractor)	• Ensures compliance with all applicable navigational safety standards and regulations. • Conducts emergency drills. • Supervises vessel crew to ensure they are fit for duty and undertaking work only within their area of qualification and training. • Monitors, reports and takes appropriate action to remedy any vessel or equipment defects that may impact on safety and environmental performance of the vessel. • Maintains logs of emissions and discharges in accordance with MARPOL regulations. • Reports to the Vessel Master. • Reports all incidents and near-misses to the Vessel Master .

8.3 OIMS System 2: Identifying, Assessing, Mitigating and Accepting Risk

Implementation of OIMS System 2: Identifying, Assessing, Mitigating and Accepting Risk is achieved in relation to this EP through the processes outlined in Sections 5, 6 and 7. These Sections detail the identification, evaluation and management of safeguards to ensure risks are reduced to ALARP. Compliance with EPOs and EPSs, controls and measurement criteria are provided in Sections 6 and 7, and summarised in Appendix K.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, OIMS System 8: Selecting and Engaging with Third Party Providers oversight applies (refer to Section 8.14).

8.4 OIMS System 3: Quality Assurance and Pre-Start Up Review

Implementation of OIMS System 3: Quality Assurance and Pre-Start Up Review, where relevant, ensures that the controls and safeguards outlined in Sections 6 and 7 of this EP, and summarised in Appendix K, are verified to meet environmental objectives during execution.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, OIMS System 8: Selecting and Engaging with Third Party Providers oversight applies (refer to Section 8.14).

8.5 OIMS System 3: Project Management and Execution

Implementation of the OIMS System 3: Project Management and Execution ensures that risks associated with decommissioning activities are effectively managed through structured processes and controls. Within ExxonMobil, the ExxonMobil Capital Project Management System is the corporate system that provides guidance and ensures best practices are applied, on a scalable basis, when developing and executing capital projects. Although largely based on the ExxonMobil Capital Project Management System, a bespoke Decommissioning Project Management System framework for Campaign #1 has been developed. The Decommissioning Project Management System provides a structured process for development, reviews and decision making to achieve stated project objectives.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, OIMS System 8: Selecting and Engaging with Third Party Providers oversight applies (refer to Section 8.14).

8.6 OIMS System 3: Design and Construction Practices and Standards

OIMS System 3: Design and Construction Practices and Standards ensures that the design and construction of new or modified facilities comply with approved standards. For the decommissioning activities included in this EP, the relevant Centre of Expertise Decommissioning Specifications, which integrate applicable international Standards, along with recognised industry best practices, will be applied.

OIMS System 3: Design and Construction Practices and Standards also ensures that any new design practices or standards are thoroughly reviewed and evaluated for project applicability. Deviations from established industry decommissioning standards or practices will be reviewed by Esso prior to implementation and will undergo a MOC where considered appropriate.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, OIMS System 8: Selecting and Engaging with Third Party Providers oversight applies (refer to Section 8.14).

8.7 OIMS System 4: Information Needed for Construction, Operation, and Maintenance

In accordance with OIMS System 4: Information Needed for Construction, Operation, and Maintenance, Esso implements processes for the identification of integrity critical documents and drawings, as well as making provisions for these to be accessible, accurate and appropriately safeguarded. In the context of this System integrity critical information is the general term used to refer to both integrity critical documentation and pertinent records.

For decommissioning activities, the Digital Decommissioning Management Tool serves as the primary tool to manage, track and transfer relevant documentation and drawings. The Digital Decommissioning Management Tool ensures that decommissioning and disposal critical information is organised and appropriately transferred between Esso and contractors.

Processes are also established to ensure that records pertinent to this EP are defined and appropriately maintained.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, OIMS System 8: Selecting and Engaging with Third Party Providers oversight applies (refer to Section 8.14).

8.8 OIMS System 5: Selecting, Engaging and Enabling People

In accordance with OIMS System 5: Selecting, Engaging and Enabling People, Esso has processes in place to ensure that personnel and contractors are selected, trained and competent to meet the requirements of specific positions and roles. These processes align with the Regulation 22(4) of the Environment Regulations requirement that the implementation strategy details for ensuring that employee and contractors working on, or in connection with, the activity are aware of their responsibilities in relation to the EP, including during emergencies or potential emergencies.

8.8.1 Operations Integrity key positions

Key positions that could have a significant impact on OI must meet job specific requirements and maintain competency in their roles consistent with the Environment Policy and OIMS System 5: Selecting, Engaging and Enabling People. Personnel in these roles are subject to verification of training and experience relevant to their responsibilities.

The extent of initial, ongoing, and refresher training is determined by OI related training requirements and any identified competency or experience gaps, as documented in a training plan.

Learning management systems are used for competency tracking, e-learning, training, scheduling and tracking of re-qualification requirements. Training progress is reviewed periodically by an individual's Supervisor. Any new training requirements are completed per the training plan. Training programs specific to this EP are detailed in Section 8.8.2.

Job-specific OIMS requirements are defined and communicated to third parties during the contracting process. Third-party service providers are required to maintain training files for their personnel. The processes for third-party training and competency are evaluated as part of the contractor selection and management process, refer to OIMS System 8: Selecting and Engaging with Third Party Providers in Section 8.14.

8.8.2 Personnel training

In accordance with OIMS System 5: Selecting, Engaging and Enabling People, Esso has identified required training programs, specific to this EP, that will be implemented for Esso personnel, contractors and third parties.

8.8.2.1 Environmental induction

All personnel involved in activities related to this EP will undergo environmental awareness training as part of their induction, prior to the activities commencing. The level of induction provided will be appropriate to each individual's role and may include environmental familiarisation, where applicable.

The environmental awareness component of the induction includes:

- environmental regulatory requirements
- description of the environmental sensitivities and conservation values of the OA and surrounding waters
- roles and environmental responsibilities of key positions as defined in this EP
- overview of cetacean interaction management actions consistent with Part 8 Division 8.1 of the EPBC Regulations
- overview of waste management requirements
- chemical discharge assessment and approval process requirements
- overview of housekeeping and spill prevention
- procedures for reporting reportable and recordable environmental incidents
- overview of emergency response and spill management procedures.

The Removals Manager and Project SSHE Manager are responsible for ensuring personnel complete the required induction prior to the commencement of activities. All induction attendees will sign an attendance sheet to confirm their participation in, and understanding of, the induction which will be retained by the Esso Environmental and Regulatory Advisor or member of the Project SSHE team.

8.8.2.2 Marine Mammal Observers

Where MMOs are required for the activity they will be trained and experienced in whale identification and behaviour, distance estimation, and be capable of making accurate identifications and observations of whales in Australian waters per *EPBC Act Policy Statement 2.1 - Interaction between offshore seismic exploration and whales* (DEWHA, 2008b). This standard is applied in the absence of there being any definitive qualifications stipulated in Australia for MMOs.

Bridge crew and watchkeepers will also receive whale observation and species identification training to provide additional observation support to MMOs.

8.8.2.2.1 OIL SPILL RESPONSE

In accordance with Regulation 22(4) of the Environment Regulations, this implementation strategy describes the processes by which Esso ensures personnel have the appropriate competencies and training to undertake their roles and responsibilities in emergency situations. Roles and responsibilities will be defined in an emergency response bridging document prior to the commencement of this activity.

Appropriate training will be made available to specific personnel required to undertake a role in oil spill response. Personnel with an oil spill response role will undertake incident management training including Incident Command System (ICS) and oil spill response specific training, as defined by their role and in accordance with the roles' training plan. The training program has been designed to meet the PMA08 Chemical, Hydrocarbons and Refining training standard and includes the courses and topics as outlined in Table 8-3.

Table 8-3 Oil spill response training

Training/course	Delivered by	Training description
ICS 100/200 training	ExxonMobil (Esso) WebCAT CBT	ICS 100/200 training consists of computer-based training which addresses fundamental principles of the ICS including key roles and functions.
ICS 300 training	Various accredited organisations	ICS 300 training is instructor led training that expands upon the information covered in the ICS 100/200 course.
Australian Marine Oil Spill Centre (AMOSC) Core Group training	AMOSC	Training and competence must be completed and maintained in accordance with the AMOSC Core Group agreement. IMO 1/2/3 must be revalidated every three years and aerial observer must be revalidated every two years. Core Group Members must also participate in a Core Group Workshop every two years.
IMO I – Oil Spill Response Operations	Registered Training Organisation AMOSC	Designed for all personnel who may be called upon to act as an oil spill first responder and to participate in an oil spill clean-up.
IMO II – Oil Spill Response Management (or equivalent)	Registered Training Organisation AMOSC	Designed for personnel who require the knowledge and skills to support the management and coordination of oil spill response activities.
IMO III – Command and Control (or equivalent)	Registered Training Organisation AMOSC	Required for personnel identified to fulfil a Tier 2/3 Incident Commander role.
Aerial observers course	Registered Training Organisation AMOSC	The course includes theory and practical activities including:

Training/course	Delivered by	Training description
		• basic hydrocarbon theory and its relevance to aerial surveillance • basic understanding of how to work in an aviation crew environment • how to effectively plan and coordinate an aerial surveillance flight • how to carry out the plotting and recording of oil spill information • how to present oil spill information back through the Esso Incident Management Team in a clear and coherent manner.
Emergency Support Group (ESG) training (COURSE 509100)	ExxonMobil (Esso) WebCAT CBT	The ESG course is used to train ESG members in the ESG process as well as provide an overview of ExxonMobil's emergency response structure. This is a computer-based training which combines theory and a number of simulation exercises. Course objectives are to: • increase awareness of the ExxonMobil emergency response system and the underpinning principles • assist in achieving a consistent approach to the ESG response process across the Corporation • familiarise participants with roles and responsibilities within the ESG and the interface with other responders and stakeholders • provide an opportunity for participants to practice roles • improve ESG leadership and communication skills • build the confidence of participants in responding as a team and individually • enhance ExxonMobil's commitment to a consistent approach to emergency response.
Incident management training (PMAOMIR322)	Registered Training Organisation ERGT Australia	Course objectives are to: • collect and analyse data during an incident • record and report information during an incident • review incident response information and recommend process improvements.
Incident management training (PMAOMIR418)	Registered Training Organisation ERGT Australia	Course objectives are to: • assess the situation and determine priorities • manage incident control centre • liaise with internal management and support structures • ensure communications systems are effective • conclude and review incident activities.

8.8.2.3 Oil spill response roles

Esso Incident Management team members are selected based on skills and experience. Nominations are reviewed by the OIMS System 10: Emergency Preparedness and Response System Lead (to ensure training and competency requirements have been met or appropriate management measures have been put in place) and approved by the

Asset Manager. A road map of emergency preparedness and response required competencies is assigned to the new incumbent. A training plan is put in place and the OIMS System 5: Selecting, Training, Engaging and Enabling People mitigation approval process applies.

The selection of the Environmental Unit Lead is based on relevant experience as an Environmental and Regulatory Advisor, with experience and/or training in the implementation of scientific monitoring. Minimum requirements include involvement in drills and spill exercises and management of marine monitoring programmes. In addition, the minimum requirement includes a relevant tertiary degree in engineering, environmental science, environmental management or similar.

Esso also allocates members to an ESG, which provide strategic support in the event of an oil spill or other emergency event and contributes personnel to ExxonMobil's Regional Response team (RRT). The ExxonMobil RRT includes personnel with experience and/or training in oiled wildlife response. These personnel are able to provide above-field support to an oiled wildlife response through development of response plans and coordination of specialist resources.

Selected ExxonMobil personnel have been identified as members of the AMOSC Core Group and may be called upon to respond under the AMOSC Plan and National Plan arrangements.

8.8.2.4 Role-specific competencies and training

Mandatory competencies and training provided to specific personnel required to undertake a role in oil spill response are outlined in Table 8-4.

Table 8-4 Mandatory competencies and training for oil spill response roles

Section	Role	Mandatory competencies and training
Command	Incident Commander	• Incident management training (PMAOMIR418). • IMO III – Command and Control training (for Level II/III incidents). • Participate in regular drills and exercises.
	Safety Officer	• Incident management training (PMAOMIR322). • IMO II – Oil Spill Management, or IMO III – Command and Control. • Experience in implementing safety management systems. • Participate in regular drills and exercises.
	Liaison Officer	• Incident management training (PMAOMIR322). • Participate in regular drills and exercises.
Planning	Planning Section Chief	• Incident management training (PMAOMIR322). • IMO II – Oil Spill Management, or IMO III – Command and Control. • Experience in fulfilling Planning Section Chief role. • Participate in regular drills and exercises.
	Environment Unit Lead*	• IMO II – Oil Spill Management. • Incident management training (PMAOMIR322). • Familiarity with the *Bass Strait Operational and Scientific Monitoring Program* (AUGO-EV-EPL-001) (OSMP) – Refer to Attachment 2. • Participate in regular drills and exercises.
Operations	Operations Section Chief	• Incident management training (PMAOMIR 322). • IMO II – Oil Spill Management.

Section	Role	Mandatory competencies and training
		• Experience in fulfilling Operations Section Chief role. • Participate in regular drills and exercises.
	Maritime Unit	• ICS 100/200. • Experience in marine operations. • Participate in regular drills and exercises.
	Aviation Unit	• ICS 100/200. • Participate in regular drills and exercises.
	Aerial Observer	• Oil Spill Response Fundamentals training. • Aerial Marine Fauna Observer training course.
Logistics	Section Chief	• Incident management training (PMAOMIR322). • IMO II – Oil Spill Management, or IMO III – Command and Control. • Experience in fulfilling Logistics Section Chief role. • Participate in regular drills and exercises.
Finance and Administration	Finance and Administration Section Chief	• ICS 100/200. • Participate in regular drills and exercises.
RRT	All RRT members and select Esso Incident Management team members	• Oil spill response training program (ExxonMobil University of Spill Management). • ICS 100/200. • Participate in RRT exercises/workshops. • Role-specific training, as required.
ESG	All ESG members	• ESG CBT training. • ESG induction conducted by Esso Emergency Preparedness and Response Advisors. • Participate in regular drills and exercises.
AMOSC Core Group	Management	• IMO I – Oil Spill Response Operations training. • IMO II Oil Spill Management or IMOIII Oil Spill Response Command and Control. • AMOSC Core Group Workshop.
	Operations	• IMO I – Oil Spill Response Operations. • AMOSC Core Group Workshop.
	Aerial observer	• Aerial marine fauna observer training course.

* When the Esso IMT is activated, the Environmental Unit Lead becomes responsible for managing implementation of the Bass Strait OSMP Modules, as directed by the Planning Section Chief.

Note: When PMAOMIR322 is completed, completion for ICS 100/200 is assigned. When PMAOMIR418 is completed, completion for PMAOMIR322is assigned. When IMOIII is completed, Completion for IMOII is assigned.

8.9 OIMS System 5: SSHE Behaviours and Human Performance

In accordance with OIMS System 5: SSHE Behaviours and Human Performance, Esso applies human performance principles to ensure personnel perform their work safely and effectively. This includes the development and practise of behaviour-based processes that include:

- observing, recognising, reporting, and mitigating hazards and at-risk conditions
- intervening to address at-risk behaviours with co-workers
- recording and analysing results to reduce future events and eliminate at-risk behaviours.

These principles are reinforced through inductions and training managed by Esso and the Engineering, Procurement and Removals contractor.

8.10 OIMS System 6: Management of Work and Equipment

Management of work and equipment at Esso-owned, managed or controlled sites are undertaken in a structured and controlled manner to reduce the risk of incidents, in accordance with OIMS System 6: Management of Work Equipment.

This System ensures a structure for managing the risks associated with the work to be performed and confirming that interfaces with the work activities are appropriately considered.

In relation to this EP, work activities are managed through implementation of the following Esso and contractor processes:

- work permits are executed to protect personnel, equipment, and the environment from risks
- controls are in place for the temporary disarming, deactivation, or unavailability of integrity critical equipment
- work interfaces are evaluated, and procedures are in place to manage identified risks, including hand-over and simultaneous operations.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, OIMS System 8: Selecting and Engaging with Third Party Providers oversight applies (refer to Section 8.14).

8.11 OIMS System 6: Regulatory Compliance and Sustainability Management

8.11.1 Regulatory Compliance

OIMS System 6: Regulatory Compliance and Sustainability Management is used to implement several mechanisms to identify new or amended requirements that may have an impact on this EP, including:

- engagement with government agencies and review of government publications of laws and regulations
- participation in government-sanctioned working committees
- active participation in industry organisations or cooperatives (e.g. Australian Energy Producers formerly APPEA)
- active participation in local or international trade organisations
- subscriptions to specialist consultants, commercial publications and government provided subscriptions (e.g. SAI Global, Environment Essentials, COMLAW).

If new, amended or existing requirements are identified, an assessment is undertaken as to their applicability and possible impact on Esso operations and the environment. Environmentally relevant changes could include:

- changes to existing legislation or introduction of new legislation
- changes to the existing environment including (but not limited to) fisheries, tourism and other commercial and recreational uses, and any changes to protective matter requirements
- changes to the requirements of an existing external approval (e.g. changes to conditions of environmental licences)
- new information or changes in information from research, stakeholders, legal and other requirements, and any other sources used to inform the EP

- changes or updates identified from incident investigations, emergency response activities or emergency response exercises.

Changes to legislation are screened by the Esso Regulatory Lead before being forwarded to an appropriate subject matter contact for their determination on applicability. As applicable this is communicated to the Environmental and Regulatory Advisor for this Project. A tracking list of emerging/amending regulations and associated current review status is maintained by Esso.

Relevant changes to protected matter are assessed on a periodic basis by an Esso Environmental and Regulatory Advisor, and incorporated into risk assessments, control measures, EPOs and EPSs and implementation strategy in the EP where required.

Changes identified by the Esso Regulatory Lead are reviewed and assessed in accordance with the process outlined in OIMS System 7: Managing Changes.

8.11.2 Environmental management

In accordance with Regulation 22(5) of the Environment Regulations the implementation strategy must provide for sufficient arrangements for monitoring, recording, audit, management of non-conformance and review of environmental performance and the implementation strategy to ensure that the EPOs and EPSs in the EP are being met. The majority of these requirements are met through the implementation of OIMS System 6: Regulatory Compliance and Sustainability Management, with the exception of recording (see OIMS System 4: Information Needed for Construction, Operation, and Maintenance) and management of non-conformance (see OIMS System 9: Learning from Project Activities and Incidents).

OIMS System 6: Regulatory Compliance and Sustainability Management addresses corporate requirements for environmental and regulatory management, including socioeconomic and community health aspects. This includes the fundamental requirement to develop EMPs which identify and assess all environmental aspects, impacts and risks associated with Esso's activities, facilities and ongoing operations. The EMPs must also describe how the impacts and risks are addressed and controlled. As such, this EP meets the OIMS System 6: Regulatory Compliance and Sustainability Management requirement for an EMP for the activities outlined in this EP.

In addition, OIMS System 6: Regulatory Compliance and Sustainability Management includes processes and procedures for managing environmental impacts as discussed in the following Sections.

8.11.2.1 Chemical discharge assessment process

Esso assesses all chemicals that are planned to be discharged in the OA, during the activities described in this EP. The *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) may be triggered by the MOC process or through premobilisation verification. Environmental assessment of a chemical that is planned to be discharged to the environment also requires assessment for safety and health suitability in accordance with the *Workplace Substances Manual* (AUGO-PO-WSM-MOHLINK).

Chemicals that are planned to be discharged into the marine environment must be screened per Esso's *Environmental Chemical Discharge Assessment Process* (AUGO-EV-PCE-013) to identify if the chemical is considered to be environmentally hazardous in the marine environment. The objective of this process is to promote the selection of chemicals with the highest biodegradability, and the lowest possible toxicity and bioaccumulation potential for use in operational activities and to reduce the potential environmental impact of a discharge or unplanned release to ALARP and acceptable levels without compromising the safety of personnel.

The procedure is designed in compliance with Australian and international standards that include:

- Industrial Chemicals Environmental Management Standard
- Australian Environmental Criteria for Persistent, Bioaccumulative and/or Toxic Chemicals
- Offshore Chemical Notification Scheme OCNS
- OSPAR Convention
- Centre for Environment, Fisheries and Aquaculture Science
- Minamata Convention on Mercury.

The OCNS is used as a basis for selecting environmentally acceptable chemicals in the Australian offshore petroleum industry. The OCNS manages chemical use and discharge by the UK and Netherlands offshore petroleum industries. The scheme is regulated in the UK by the Department for Energy Security and Net Zero

using scientific and environmental advice. Esso's chemical assessment process follows the principles outlined in the OCNS.

The OCNS uses the Harmonised Mandatory Control Scheme developed through the OSPAR Convention. This ranks chemical products according to Hazard Quotient, calculated using the Chemical Hazard and Risk Management (CHARM) model (Thatcher, et al., 2017). The CHARM model requires the biodegradation, bioaccumulation and toxicity data of the product to be provided.

Under the OSPAR Convention, organic-based compounds used in production, completion and workovers, drilling and cementing are subject to the CHARM model. The CHARM model calculates the ratio of the 'Predicted Effect Concentration' against the 'No Effect Concentration' expressed as a Hazard Quotient, which is then used to rank the product. The Hazard Quotient is converted to a colour banding to denote its environmental hazard, which is then published on the Definitive ranked lists of registered products (OCNS, 2022). Gold has the lowest hazard, followed by silver, white, blue, orange and purple (having the highest hazard).

Products not amenable to assessment under the CHARM model (i.e. inorganic substances, synthetic based muds, hydraulic fluids or chemicals used only in pipelines) are assigned an OCNS grouping A – E, with 'A' having the greatest potential environmental hazard and 'E' having the least. Products that only contain substances that pose little or no risk to the environment are given the OCNS 'E' grouping. Data used for the assessment includes toxicity, biodegradation and bioaccumulation. This is known as the non-CHARM model.

Chemicals that are hazardous to the marine environment are subject to substitution warnings under the Harmonised Mandatory Control Scheme. The UK follows and applies the OSPAR Convention harmonised pre-screening scheme and complies with the recommendation of Regulation (EC) No 1907/2006 of the European Parliament and of the Council of 18 December 2006 concerning the Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH), to replace chemical substances identified as candidates for substitution. These substances are flagged with a substitution warning on the product template and the Centre for Environment, Fisheries and Aquaculture Science encourages operators to select products without a substitution warning.

Only chemicals ranked under the OCNS rating system as 'gold' or 'silver' (CHARM) and 'E' or 'D' (non-CHARM) with no substitution warning will be approved for discharge without further assessment.

If a chemical is not on the OCNS list, has a substitution warning (or equivalent) or has limited ecotoxicity data available, then further assessment is required to determine if the chemical is suitable for discharge to the marine environment. This assessment can include:

- an examination of legislative requirements and thresholds
- details of the technical requirement for this product and review of any possible alternative chemicals
- assessment of impacts to the receiving environment from discharge in the relevant scenario
- consideration of additional restrictions or controls to the approval (e.g. timeframes for use, periodic reassessment)
- determine if any by-products could be generated as a result of how the product is used (i.e. through thermal or chemical decomposition) and what impact these by-products would have on the environment
- seeking guidance from toxicity experts
- whole effluent toxicity testing the chemical in the discharge to determine if the environmental impact is beyond the mixing zone, and/or
- completing chemical dispersion modelling in the local environment.

8.11.2.2 Invasive Marine Species risk assessment process

A biofouling risk assessment will be undertaken for vessels which will incorporate the requirements of the following IMS legislation, guidance and risk assessment processes:

- *Biosecurity Act 2015* (Cth)
- Biosecurity Regulation 2016 (Cth)
- *Australian biofouling management requirements Version 2* (DAFF, 2023).
- *Australian Ballast Water Management Requirements, Version 8* (DAFF, 2020)
- *National biofouling management guidelines for the petroleum production and exploration industry* (Marine Pest Sectoral Committee, 2009)
- *Reducing marine pest biosecurity risks through good practice biofouling management* (NOPSEMA, 2024f)

- *Guidance on mitigation of marine invasive species: Biofouling and ballast water* (IMCA, 2023)

8.11.3 Audit, inspection and assessments

8.11.3.1 Audits and Inspections - Vessel activities

A due-diligence audit for all vessels will be carried out prior to the work commencing to ensure all controls listed in the EP to achieve the EPSs and EPOs are ready to be implemented prior to the activities commencing and to verify that procedures and equipment for managing routine discharges and emissions are in place for the activities described in this EP.

The Esso team will audit contractor and subcontractor vessels in conjunction with appropriate contractor personnel. Third-party vessels will be audited by the contractor. Esso personnel may attend as required.

Throughout Campaign #1, monthly EP compliance checks of EPSs and EPOs will be conducted and verified by the Esso Environmental and Regulatory Advisor for review and as the basis for the monthly recordable incident report (OIMS System 9: Learning from Project Activities and Incidents).

Once mobilised, Allseas and their subcontractors will conduct HSE inspections at an agreed schedule, which will be provided to Esso for ongoing compliance monitoring. Esso personnel may attend as required.

8.11.3.2 Audits - Environment Plan compliance

Esso will undertake an annual compliance audit of the commitments contained in this EP and assess the effectiveness of the implementation strategy. Any non-compliance with this EP will be subject to investigation and follow-up action as detailed in Section 8.15.1.

Any opportunities for improvement or non-compliances noted will be communicated to all relevant personnel at the time of the audit to ensure adequate time to implement corrective actions. The findings and recommendations of inspections and audits will be documented and distributed to relevant personnel for comments, and any actions tracked until closed out.

Results from environmental inspections and audits will be summarised in the Campaign #1 specific EP environmental performance report(s) submitted to NOPSEMA annually.

8.11.4 Environmental performance review

Environmental performance assurance of the activity will be undertaken in a number of ways. Performance assurance is undertaken to ensure that:

- controls are implemented in accordance with EPSs to achieve the EPOs
- non-conformances and opportunities for improvement are identified
- environmental monitoring and reporting requirements are met.

8.11.4.1 Daily vessel calls

Daily vessel calls are undertaken to keep all personnel involved up to date with the activities that are planned for the day and allows for input from the management team to assist with work planning.

8.11.4.2 Toolbox meetings

Toolbox meetings are conducted at the beginning of each shift to plan for any events that are occurring during the shift. This allows for relevant permits and risk assessments to be undertaken and to make sure that personnel completing the tasks understand all the associated safety and environmental risks and required controls.

Environmental issues will also be addressed in regular HSE meetings. Vessel crew will participate in these meetings with the Esso Vessel Lead or delegate and Vessel Master in discussing HSE matters that have arisen during that day or week's operations, and upcoming issues to consider. Outcomes will be documented in HSE meeting minutes.

8.11.4.3 Completion of activity

The Campaign #1 decommissioning team conducts regular reviews of key performance indicators such as incident reports (including spills), regulatory compliance and types/volumes of waste disposed.

The Esso and contractor VMT on board the vessel meets periodically to review and assess environmental issues and initiatives. Personnel from the vessels, Esso and other contractors attend where possible.

At the completion of activities described in this EP, a lessons learned review and assessment will be conducted to determine:

- the effectiveness of control measures
- improvements in procedures or processes for future activities.

8.11.5 Monitoring of emissions and discharges

In accordance with Regulation 22(6) of the Environment Regulations, the implementation strategy must provide for sufficient monitoring of, and maintain quantitative records of, emissions and discharges (whether occurring during normal operations or otherwise), such that the record can be used to assess whether the EPOs and EPSs in the EP are being met.

For vessel-based activities, the Vessel Master is responsible for collecting all the data on emissions and discharges for energy, fuel and waste for the duration of Campaign #1, and reporting to the Esso Project team including the Removals Manager and Environmental and Regulatory Advisor.

A summary of these results will be reported in the EP environmental performance report submitted to NOPSEMA. Table 8-5 summarises the monitoring requirements for routine operations.

The process for managing environmental monitoring records is addressed through OIMS System 6: Regulatory Compliance and Sustainability Management.

Table 8-5 Summary of monitoring of emissions and discharges

Aspect	Monitoring	Frequency	Reporting
Ballast water uptake/discharge	Volume Location	Per event	End of activity environmental performance report
Planned grout discharge	Location Volume	Per event	End of grouting activity environmental performance report
Other planned discharges (e.g. waste food, bilge water)	Type of discharge Location Volume	Daily	End of activity environmental performance report
Planned atmospheric emissions	Type and volume of fuel consumption (per vessel and helicopter used during execution of Campaign #1 activities)	Daily	End of activity environmental performance report
Planned waste from removal of facilities	Type of waste Tonnes (for SPJs)	Per event	End of activity environmental performance report
Unplanned spill to sea	Chemical/oil type and volume	By incident event	Incident report End of activity environmental performance report
Unplanned release of waste to sea	Waste type	By incident event	Incident report

Aspect	Monitoring	Frequency	Reporting
			End of activity environmental performance report
Dropped object to sea	Object type	By incident event	Incident report End of activity environmental performance report

8.11.6 Reporting

Regulation 51 of the Environment Regulations requires the reporting of environmental performance of this EP.

Regulation 22(7) of the Environment Regulations states that the implementation strategy must:

- state when the titleholder will report to the Regulator in relation to the titleholder's environmental performance for the activity
- provide that the interval between reports will not be more than one year.

In addition to environmental performance reporting, Regulation 54 of the Environment Regulations requires notifying NOPSEMA of the start and end of activity and Regulation 46 requires notifications that all of the obligations under the EP have been completed.

The routine reporting requirements required for this EP are described in Table 8-6.

Table 8-6 Routine EP reporting requirements

Requirement	Timing	Contact
Submit an end of activity EP environmental performance report to NOPSEMA	The end of activity EP environmental performance report will be submitted to NOPSEMA within three months of the completion of Campaign #1 activities.	NOPSEMA – submissions@nopsema.gov.au
Notify NOPSEMA of the commencement date	At least 10 days prior to activity.	
Notify NOPSEMA of the completion date	Within 10 days of activity completion.	
Notification of EP completion	Within 10 days of activity finalisation and obligation completion.	

8.12 OIMS System 6: Critical Safeguard Management

OIMS System 6: Critical Safeguard Management ensures that environmental safeguards are in place, maintained and verified to prevent or mitigate risks associated with the activity.

Risks associated with this EP are identified are then managed through structured processes outlined in Sections 5, 6 and 7. These Sections detail the identification, evaluation and management of safeguards to ensure risks are reduced to ALARP. Compliance with EPOs and EPSs, including specific controls and measurement criteria is outlined in Sections 6 and 7, and summarised in Appendix K, to ensure EPOs are met.

Managers and supervisors oversee the ongoing effectiveness of safeguards, using leading and lagging indicators to track performance and ensure continued integrity.

8.13 OIMS System 7: Managing Changes

Esso has developed MOC tools and procedures to meet the requirements outlined in OIMS System 7: Managing Changes. Changes which could trigger the MOC process include:

- new activities, assets, equipment, processes or procedures proposed to be undertaken or implemented that have not been:
    - assessed for environmental impact or risk previously, in accordance with the relevant standard, or
    - authorised in the existing management plans, procedures, work instructions or maintenance plans.
- proposed changes to activities, assets, equipment, processes or procedures that have the potential to impact on the environment or interface with an environmental receptor
- changes to the existing environment including (but not limited to) fisheries, tourism and other commercial and recreational uses, and any changes to protected areas, plans or requirements for protected species
- changes to the requirements of an existing external approval (e.g. changes to conditions of environmental licences)
- new information or changes in information from research, stakeholders, legal and other requirements, and any other sources used to inform the EP
- changes or updates identified from audits, inspections and assessments, incident investigations, emergency response activities or emergency response exercises.

OIMS System 7: Managing Changes is a structured process, involving relevant engineers, technicians, operations and maintenance personnel and SSHE specialists to evaluate the potential consequences of the proposed change, and to seek the endorsement of all potentially impacted parties.

The MOC process requires a number of assessments which include technical, regulatory, safety and environmental assessments. A mandatory screening checklist is undertaken for all work being assessed under the MOC process to identify the potential for a change to, or increase in, environmental impacts or risks. MOCs which identify potential change to or increase in environmental impacts or risks during screening require completion of an environmental checklist. A mandatory regulatory checklist is also completed to identify if proposed activities will result in a change to the EP. Environmental and regulatory checklists are reviewed by the Esso Environmental and Regulatory Advisor and approved by the Campaign #1 Removals Manager and/or Project SSHE Manager.

The Esso Environmental and Regulatory Advisor reviews the MOC in accordance with Regulation 39 of the Environment Regulations. A revision of the EP will be required under Regulation 39 in the event that a proposed change:

- constitutes a new stage or significant modification, or
- introduces a significant new environmental impact or risk, or
- significantly increases an existing environmental impact or risk.

Minor changes, which do not trigger a resubmission under Regulation 39, may result in administrative updates to this EP which are documented in a change register.

Esso also has a comprehensive process to identify and amend new regulations which is described in OIMS System 6: Regulatory Compliance and Sustainability Management.

8.14 OIMS System 8: Selecting and Engaging with Third Party Providers

OIMS System 8: Selecting and Engaging with Third Party Services Providers provides a systematic approach for the selection of contractors and subsequent management of interfaces between Esso and contractors to ensure work is performed in a safe, secure, and environmentally sound manner. This System applies to all service contractors (including marine operations, crane services, provision of lifting equipment and aviation services) and suppliers of critical equipment.

8.14.1 Contractor selection and management

Esso's contractor selection and management processes support two different phases of a contract life cycle:

- the first phase includes requisitioning for contractor services, pre-qualifying contractors, selecting the contractor, and conducting pre-mobilisation activities associated with subsequent contractor interface management
- the second phase occurs during contract work execution and involves ongoing interface management between Esso and the contractor, as well as monitoring and stewardship activities to confirm that the contractor is meeting the OI requirements of the agreement.

The pre-qualification process includes review of recent contractor performance results, reviews of contractor SSHE programs, contractor training and competency and site visits to the contractor's facilities to validate reported performance results and evaluate a contractor's capability for effective work execution. Esso's SSHE Group participates in the pre-qualification screening and bid evaluation process including contractor site assessments, as required. OIMS System 8: Selecting and Engaging with Third Party Providers specifies that all contractors conducting activities with potential high SSHE impact must submit a SSHE execution plan or a bridging document for the scope of work. High SSHE impacts are activities which, if poorly executed, could cause significant safety or environmental impacts. These may include aviation, construction, subsea activities and vessels.

The contractor's SSHE execution plan is required to address areas including:

- communication of SSHE expectations and requirements to contractor crews and subcontractors
- compliance with relevant regulatory obligations (including EMPs, Safety Cases, relevant laws and regulations)
- reporting of leading and lagging indicators
- incident investigation and management processes
- other specific requirements as dictated by the scope of the assignment or local site characteristics.

8.14.2 Vessel Environmental Management System

The *Pioneering Spirit* and *Fortitude* or similar vessel, operated by Allseas, will be utilised to execute the activities described in this EP. Vessel operations will be conducted in accordance with Allseas Integrated Management System and the specific requirements of this EP. The system integrates internationally recognised standards including ISO 14001, ISO 45001 and the International Safety Management Code, ensuring compliance with ExxonMobil's environmental policies and regulatory obligations.

Regulatory compliance for Allseas vessels aligns with the legal obligations administered by the IMO. The IMO regulation establishes controls and protocols to ensure personnel safety, protection of the marine environment from vessel pollution, and fair treatment of all seafarers. Compliance with IMO requirements is enforced through flag state registration, certification and inspection processes, ensuring that vessels meet international safety and environment standards.

Bridging plans will be used to document the interface between Esso and contractor systems and processes. Any third-party vessels subcontracted by Allseas will adhere to either the Allseas Integrated Management System or an equivalent Environmental Management System.

8.14.3 Contractor performance monitoring

Esso develops performance monitoring plans for third parties prior to a contractor mobilising to a work site location.

The Campaign #1 Removals Manager is engaged in the contract life cycle management and the Project SSHE Team assists in the assessment and monitoring of contractor performance, as required. Providers of OIMS-critical services such as aviation, vessels and decommissioning activities, are subject to a quarterly performance review and annual performance assessment.

Performance reporting consists of documented reports and verbal communications appropriate to the impacts and risks involved with the services provided. Written reports can include:

- non-conformance reports
- SSHE performance statistics, including environmental incidents
- assessments on the adequacy of actions taken from performance gaps/incidents
- deficiencies with SSHE requirements and recommended corrective actions
- review of contractor SSHE inspections and findings.

Report findings and recommendations are reviewed with contractor management and follow-up actions implemented to address deficiencies.

8.15 OIMS System 9: Learning from Project Activities and Incidents

OIMS System 9: Learning from Project Activities and Incidents requires management of SSHE incidents including initial response and notifications, investigation and analysis, documentation, communication of lessons learned, corrective actions management and the analysis of trends. In the context of this System, incidents (including near misses) are related to:

- personnel safety
- process safety
- security
- occupational health
- regulatory conformance
- environmental
- equipment reliability (with SSHE consequences).

System 9: Learning from Project Activities and Incidents requires that:

- the incident is reported in accordance with incident management processes
- an investigation occurs, if triggered by an evaluation of actual or potential incident severity, and
- the incident is correctly documented, lessons learned are communicated, and corrective actions are followed up and tracked.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, contractor incident management systems will be in place. Bridging documents will be developed to define and document the interface between Esso and contractor incident management systems and processes.

All incidents, assessment findings, lessons learned, and follow up actions will be captured, tracked, and analysed and shared to support continuous improvement and effective information management.

8.15.1 Management of non-conformance

Investigations into environmental incidents, including EP non-compliances, are conducted in accordance with the Esso incident management system required by OIMS System 9: Learning from Project Activities and Incidents.

Notification, reporting and investigation of incidents achieves the following:

- ensures management, regulatory authorities and other appropriate personnel are notified of incidents and near misses on a timely basis
- enables sharing of learnings throughout the organisation to continuously improve SSHE systems
- identifies corrective actions to prevent re-occurrence including (if applicable) actions to re-establish the stated control measures, as outlined in this EP, in order to continue to reduce impacts and risks to ALARP and an acceptable level
- enables the analysis and trending of incident data to ensure appropriate focus on emerging issues.

Incidents are managed in accordance with the Incident Management Manual for Global Projects which describes the responsibilities and processes for all stages of incident management. Esso utilises the IMPACT incident database as the single, centralised tool for capturing data: tracking, sharing and analysing incidents, assessment findings, lessons learned and follow-up actions.

All Esso personnel are responsible for notifying their immediate supervisor of incidents, near misses and identified hazards, and for taking appropriate responses as part of their regular duties. Accountability for investigation lies with business line management. The Esso SSHE team is responsible for maintaining the reporting system, subject matter expert advice and investigation support.

The triggers and expected deliverables for investigations are based on incident severity (actual and potential) and are documented in the Incident Management Manual. The triggers for an investigation into an environmental incident are a significant spill to the environment, community complaint or regulatory reportable incident (see Table 8-7).

Corrective actions that address the root cause(s) of the incident are identified and implemented to prevent the recurrence of similar incidents. Corrective actions can be improvements to facilities, programs, processes or procedures that are identified to reduce the impact or risk and enhance the integrity of operations. Once corrective actions have been identified from incident reports (including audit and inspection reports), the implementation process is managed to completion via IMPACT. This ensures results are achieved and that the improvement is documented and sustained.

In instances where full control of a worksite is authorised to the contractor for the decommissioning activities described in this EP, the contractor will conduct investigations in accordance with their incident management system. Bridging documents will be developed to define and document the interface between Esso and contractor incident management systems and processes, ensuring compliance with incident notification, investigation, and reporting requirements.

8.15.2 Incident notification and reporting

The Environment Regulations define recordable incidents and reportable incidents and also describe reporting requirements for each type of incident.

The requirements for reporting environmental incidents to external agencies are listed in Table 8-7.

Table 8-7 External incident notification and reporting requirements

Requirement	Timing	Contact
Recordable incidents		
A recordable incident, for an activity, means a breach of an EPO or EPS, in the EP that applies to the activity that is not a reportable incident. The written report contains a record of all recordable incidents during that month including: • all material facts and circumstances concerning the incidents that the titleholder knows or is able, by reasonable search or enquiry, to find out • any action taken to avoid or mitigate any adverse environmental impacts of the recordable incidents • the action that has been taken, or is proposed to be taken, to prevent a similar incident occurring in the future. If no recordable incidents have occurred during any particular month, a recordable incident report is not required. The written report is to be provided using the *Monthly Environmental Incident Reports form* (NOPSEMA, 2025f).	Not later than 15 days after the end of each calendar month.	NOPSEMA – submissions@nopsema.gov.au Copy Joint Venture partner: Woodside Energy (Bass Strait) Pty Ltd – bass.strait@woodside.com.au
Reportable incidents		
Reportable incidents are those that have caused, or have the potential to cause moderate to significant environmental damage.	Verbally as soon as practicable to NOPSEMA and no later than two hours of the incident, or, if the reportable incident was not detected by the titleholder	NOPSEMA Incident Phone Line – 1300 674 472 Reportable incidents reports to be submitted to NOPSEMA via e-mail - submissions@nopsema.gov.au or via secure file transfer

Requirement	Timing	Contact
The definition of 'environment' in the Environment Regulations is broad and covers: a) ecosystems and their constituent parts, including people and communities b) natural and physical resources c) the qualities and characteristics of locations, places and areas d) the heritage value of places and includes the social, economic and cultural features of the matters mentioned in paragraphs (a), (b), (c) and (d), above. This includes, but is not limited to, those identified through the risk assessment process as having a consequence ranking of I or II, or at a minimum the following incidents: • uncontrolled release of hydrocarbon liquids or chemicals exceeding 80L into the marine environment • loss of a large structure (topside, jacket section, or strut) to the marine environment • death or injury of a EPBC Act listed species, associated with the petroleum activity The notification must contain: • all material facts and circumstances concerning the reportable incident that the titleholder knows or is able, by reasonable search or enquiry, to find out • any action taken to avoid or mitigate the adverse environmental impact of the reportable incident	at the time of the first occurrence – the time the titleholder becomes aware of the reportable incident. Written notification as soon as practicable to NOPSEMA (copy to National Offshore Petroleum Titles Authority and DEECA. Written report as soon as practicable to NOPSEMA but within three days after the first occurrence including specifying if a further written report will be provided (then copy to National Offshore Petroleum Titles Authority and DEECA within seven days). If a formal investigation is triggered, a further written report must be submitted within the period specified by NOPSEMA.	https://securefile.nopsema.gov.au/filedrop/submissions DEECA – Earth Resources Regulation – errchiefinspector@deeca.vic.gov.au Compliance Duty Officer - 0419 597 010 (24-hour) Department of Transport and Planning – marine.pollution@transport.vic.gov.au State Duty Officer – 0409 858 715 National Offshore Petroleum Titles Administrator – reporting@nopta.gov.au Copy Joint Venture partner: Woodside energy (Bass Strait) Pty Ltd – bass.strait@woodside.com

Requirement	Timing	Contact
• the corrective action that has been taken or is proposed to be taken to stop, control or remedy the reportable incident. Written notification must also include any action taken or proposed to be taken to prevent a similar incident occurring in the future.		
Other reporting requirements		
Mandatory MARPOL report about a pollution incident involving: • a discharge (or probable discharge) of oil or noxious liquid substances in excess of permitted MARPOL discharge levels, quantities or rates, for whatever reason, including those for the purpose of securing the safety of the ship or for saving life at sea • a discharge (or probable discharge) of harmful substances in packaged form, including those in freight containers, portable tanks, road and rail vehicles and shipborne barges. Report to include: • name of ship(s) involved • time, type and location of incident • quantity and type of harmful substance • assistance and salvage measures • any other relevant information.	Vessel Master to notify AMSA verbally without delay. If AMSA asks for a written MARPOL report this must be provided within 24 hours after AMSA asks for the report.	AMSA +61 02 6230 6811 or 1800 641 792 rccaus@amsa.gov.au

Requirement	Timing	Contact
Notification of any suspected or known marine pest is to be provided to DEECA and copied to DAFF, with the following information (if available): • Date and time of observation • Species details, if known, including numbers observed • Location – GPS coordinates if possible • Habitat (i.e. sandy seabed, hard substrate) • Water depth • Photographs or imagery, including close up and from different angles and with a reference item such as a coin to show size if possible.	Written notification as soon as practicable upon observing or becoming aware of the presence of a suspected/known marine pest.	DAFF – ccimpe@aff.gov. Report a pest | Marine Pests DEECA – marine.pests@agriculture.vic.gov.au or phone 136 186 or via online form: Report a marine pest sighting | Marine pests | Biosecurity | Agriculture Victoria Copy of notification to be sent to NOPSEMA – submissions@nopsema.gov.au Copy to Joint Venture partner Woodside Energy (Bass Strait Pty Ltd – bass.strait@woodside.com

Wildlife emergency	Immediately	DEECA Whale and Dolphin Emergency Hotline – 1300 136 017 Seals, Penguins or Marine Turtles 136 186 (Mon-Fri 8am to 6pm) Marine Response Unit – 1300 245 678 Esso Environmental and Regulatory Advisor to notify Joint Venture partner Woodside Energy (Bass Strait Pty Ltd – bass.strait@woodside.com

Requirement	Timing	Contact
Notification of activities affecting listed species or ecological communities in or on a Commonwealth area (specifically unintentional injury or death of a cetacean or listed threatened/migratory/marine species caused by, or suspected to have been caused by petroleum activity)	Within seven days	DCCEEW Environmental Compliance Hotline: 1800 110 395 environment.compliance@dcceew.gov.au Copy to Joint Venture partner Woodside Energy (Bass Strait Pty Ltd – bass.strait@woodside.com
Cetacean vessel strike	Within three days	DCCEEW Hotline: 1800 920 528 EPBC.Permits@dcceew.gov.au Esso Environmental and Regulatory Advisor to notify Joint Venture partner Woodside Energy (Bass Strait Pty Ltd – bass.strait@woodside.com
Notification of identification of any historic shipwreck, aircraft or other type of underwater cultural heritage	Within 21 days	Notification to be made to DCCEEW via the Australasian Underwater Cultural Heritage Database: SHIPWRECKS - Notification of discovery of an in-situ Historic Shipwreck or Relic Copy to Joint Venture partner Woodside Energy (Bass Strait Pty Ltd – bass.strait@woodside.com

8.16 OIMS System 10: Emergency Preparedness and Response

The process to prepare emergency preparedness and response plans, including procedures to prevent and mitigate potential environmental impacts associated with accidents and emergency situations, is addressed through OIMS System 10: Emergency Preparedness and Response.

Emergency response planning and preparedness is essential to ensure that, in the event of an incident, all necessary actions are taken for the protection of the public, the environment, Company personnel, assets and reputation.

The following considerations are made for the purposes of emergency response:

- for decommissioning activities described in this EP, Allseas is the Operator of the facility[8] and has legislative responsibilities for all vessel operations, including response to emergencies
- Esso is the operator for the Gippsland Basin Joint Venture (Esso and Woodside Energy (Bass Strait) Pty Ltd)
- for emergency purposes, both Esso and Allseas will have responsibilities for emergency response. Responsibilities are described in an emergency response bridging document, which will be developed and implemented together with Allseas prior to commencement of decommissioning activities.

Esso implements incident management based on the ICS. The ICS is a system designed to provide a consistent organisation to respond to emergency situations. Positions within the ICS are fixed and have specific functions, ensuring that all responders know what to do and where they report in the organisation structure. The ICS is based on the US National Incident Management System 2006 ICS Structure, with slight modifications for industry.

As mentioned, a Campaign #1 specific bridging ERP will be developed to support the existing emergency response documentation. It will describe the location specific arrangements for responding to emergencies including the role of helicopter and vessel support functions, extreme weather evacuation planning, medivac, regulatory liaison and reporting.

The bridging ERP will address local responses for decommissioning activities including appropriate support linkages to Esso's Australian and corporate-wide emergency preparedness and response network including in-country, regional and global ESGs. The bridging ERP also details how the Operator and Esso will interact in the event of an emergency. A Campaign #1 specific Contacts Directory listing all contact numbers will also be developed.

8.16.1 Oil Pollution Emergency Plan

In accordance with Regulation 22(8) and 22(12) of the Environment Regulations, the implementation strategy must include an OPEP and arrangements for testing the response arrangements within this EP.

Esso has an OPEP (see Appendix A of Attachment 2) in place for all its offshore assets and operations in Bass Strait that outlines how Level 1, 2 and 3 spills will be managed. In addition, Quick Reference Information specific to the activities of this EP, is included as Appendix D of the OPEP in Attachment 2. The Quick Reference Information summarises hydrocarbon properties, worst-case deterministic modelling, receptors at risk, relevant shoreline Tactical Response Plans, and recommended spill response strategies.

In addition, to fulfill its responsibilities to respond to emergencies, Allseas has vessel SOPEP(s) in place that provides the basis, resources and strategy required to immediately respond to a spill emergency.

Esso's OPEP is in place for management of oil spill events during Campaign #1 activities. The Esso-Allseas emergency preparedness and response bridging document will provide detail on the response process, including responsibilities, resources and response strategies to be implemented depending on the size and nature of the spill.

[8] For the purposes of Campaign #1, the facility is understood to be vessel(s) conducting the decommissioning activities within the scope of this EP.

8.16.2 Oil spill response needs and capability

In order to determine appropriate oil spill response strategies and capabilities, Esso has assessed spill risk, fate and weathering in the process of developing this EP. Deterministic modelling was utilised to identify potentially impacted receptors and anticipated oil loadings. Where modelling indicates surface or shoreline exposure above moderate thresholds, i.e. actionable quantities of oil, an assessment has been carried out to determine resource needs and availability.

MGO is a Group II oil that has a low viscosity and spreads rapidly on the sea surface to form thin sheens. Due to the rapid spread and weathering of MGO in open water environments, on-water containment and recovery may be viable but are unlikely to be effective. The use of chemical dispersants is not recommended practice for MGO. Based on results from modelling at various representative locations, the highest probability of shoreline contact at the moderate threshold from an MGO spill within the OA is predicted to be 98% (refer OPEP).

8.16.3 Testing of oil spill response arrangements

In accordance with Regulation 22(14) of the Environment Regulations and requirements of OIMS System 10: Emergency Preparedness and Response, the response arrangements within the OPEP and provisions described in the Esso-Allseas emergency response bridging document will be tested:

- prior to the commencement of the activity
- when they are significantly amended
- not later than 12 months after the most recent test, where applicable
- in accordance with the:
    - Campaign #1 EP - Specific schedule defined in the Esso - Allseas emergency response bridging document. Schedule described in Volume 4 of the *Bass Strait Environment Plan* (AUGO-EV-EMM-012) [Table 9-1] will be the basis for the development of the Decommissioning – Campaign #1 EP-specific schedule
    - annual Emergency Preparedness and Response Activity Plan.

The annual Emergency Preparedness and Response Activity Plan includes additional detail on the type of test, frequency, duration, and participants and is cross-referenced to preparedness and response performance standards which are to be tested, as detailed in the annual Emergency Preparedness and Response Plan, provided as Attachment 2.

Testing may be externally or internally facilitated. Tests will be documented, assessed against objectives and applicable performance standards and any corrective actions/recommendations arising from the tests will be managed in accordance with the *Emergency Preparedness and Response Programs Guide* (AUGO-PO-SRT-337). Emergency response training records will be maintained in accordance with OIMS System 10: Emergency Preparedness and Response.

Where changes are required to the OPEP, resulting from testing/exercise outcomes, altered contractual arrangements, corrective actions, routine information updates (e.g. contact detail change), or other items; the OIMS System 10: Emergency Preparedness and Response Administrator is responsible for ensuring changes are assessed against the revision criteria of Regulation 39 of the Environment Regulations and where necessary, this EP and/or the OPEP is submitted to NOPSEMA as a formal revision, in accordance with the MOC process (OIMS System 7: Managing Changes). For changes which do not trigger a formal revision, internal revisions to the OPEP will also be in accordance with the MOC process with any change justified.

8.17 OIMS System 10: Managing Community Risk

OIMS System 10: Managing Community and Risk, ensures that community related risks are identified, assessed, and managed through proactive engagement with relevant persons, including local communities, Indigenous groups and regulatory authorities. Community engagement and hazard awareness are key components of this process, ensuring that stakeholders are informed of potential community exposures, emergency preparedness measures and recommended response actions.

Section 4 of this EP outlines the applicable consultation and engagement standards and legislative requirements, including Esso's definition of relevant persons, describes Esso's consultation methodology and how this methodology has been applied to the scope of this EP.

It is noted that third-party operated sites, such as the Barry Beach Marine Terminal are stewarded under the operator's own systems and OIMS system do not apply.

8.18 OIMS System 11: Assessing and Driving Effectiveness

Formal assessment is regularly undertaken on the performance of the OIMS Systems to ensure that the Systems continue to be suitable, effective and are continuously improved. This is undertaken, at a minimum, on an annual basis in accordance with OIMS System 11: Leading, Managing and Driving Performance.

A.1 Description of the environment

In accordance with the Environment Regulations – Part 4, Division 2 'Contents of environment plan', Section 21(2), the Environment That May Be Affected (EMBA) by the activity is described in this Section, together with its values and sensitivities. The description of the EMBA is within Section 3.2 of the Environment Plan (EP). The EMBA is shown in Figure A-1.

The following explanation has been inserted on all the figures displaying the EMBA throughout this Appendix:

> *"The environment that may be affected (EMBA) illustrated in this map represents the combined modelling results of 100 individual hydrocarbon spill simulations from a loss of containment from a vessel at representative locations where key decommissioning activities will take place. The theoretical spill at each location simulates the release of 1165m^3 over 12 hours, with a simulation length of 30 days, and a release of 280m^3 over 6 hours, with a simulation length of 30 days, using annualised metocean conditions. Each spill simulation is subject to different wind and ocean currents at different times of the year. The 100 individual spill simulations for each scenario are then combined to identify the largest envelope in which a single spill is predicted to occur. The EMBA is not representative of a single spill; an individual spill would affect a significantly smaller area. The modelled EMBA is based on the lowest reportable hydrocarbon thresholds."*

The description of the environment is based on the conservative outer envelope defined by the potential exposure to low thresholds of hydrocarbons, that is referred as the EMBA for Campaign #1 activities (refer to Section 3.2 of the EP). However, and acknowledging that a section of this outer envelope extends partially into the east and northeast portion of Corner Inlet, the identification and description of sensitive receptors which included the search of environmental sensitivities using the Department of Climate Change, Energy, the Environment and Water (DCCEEW) Protected Matters Search Tool (PMST) (Appendix A and Appendix C), the environmental impact assessment (Section 6 of the EP), and the environmental risk assessment (Section 7 of the EP) consider Corner Inlet in its entirety regardless of some areas of this sensitive receptor being outside the EMBA. This conservative approach is aligned with the precautionary principle and follows best practice for environmental impact and risk assessment.

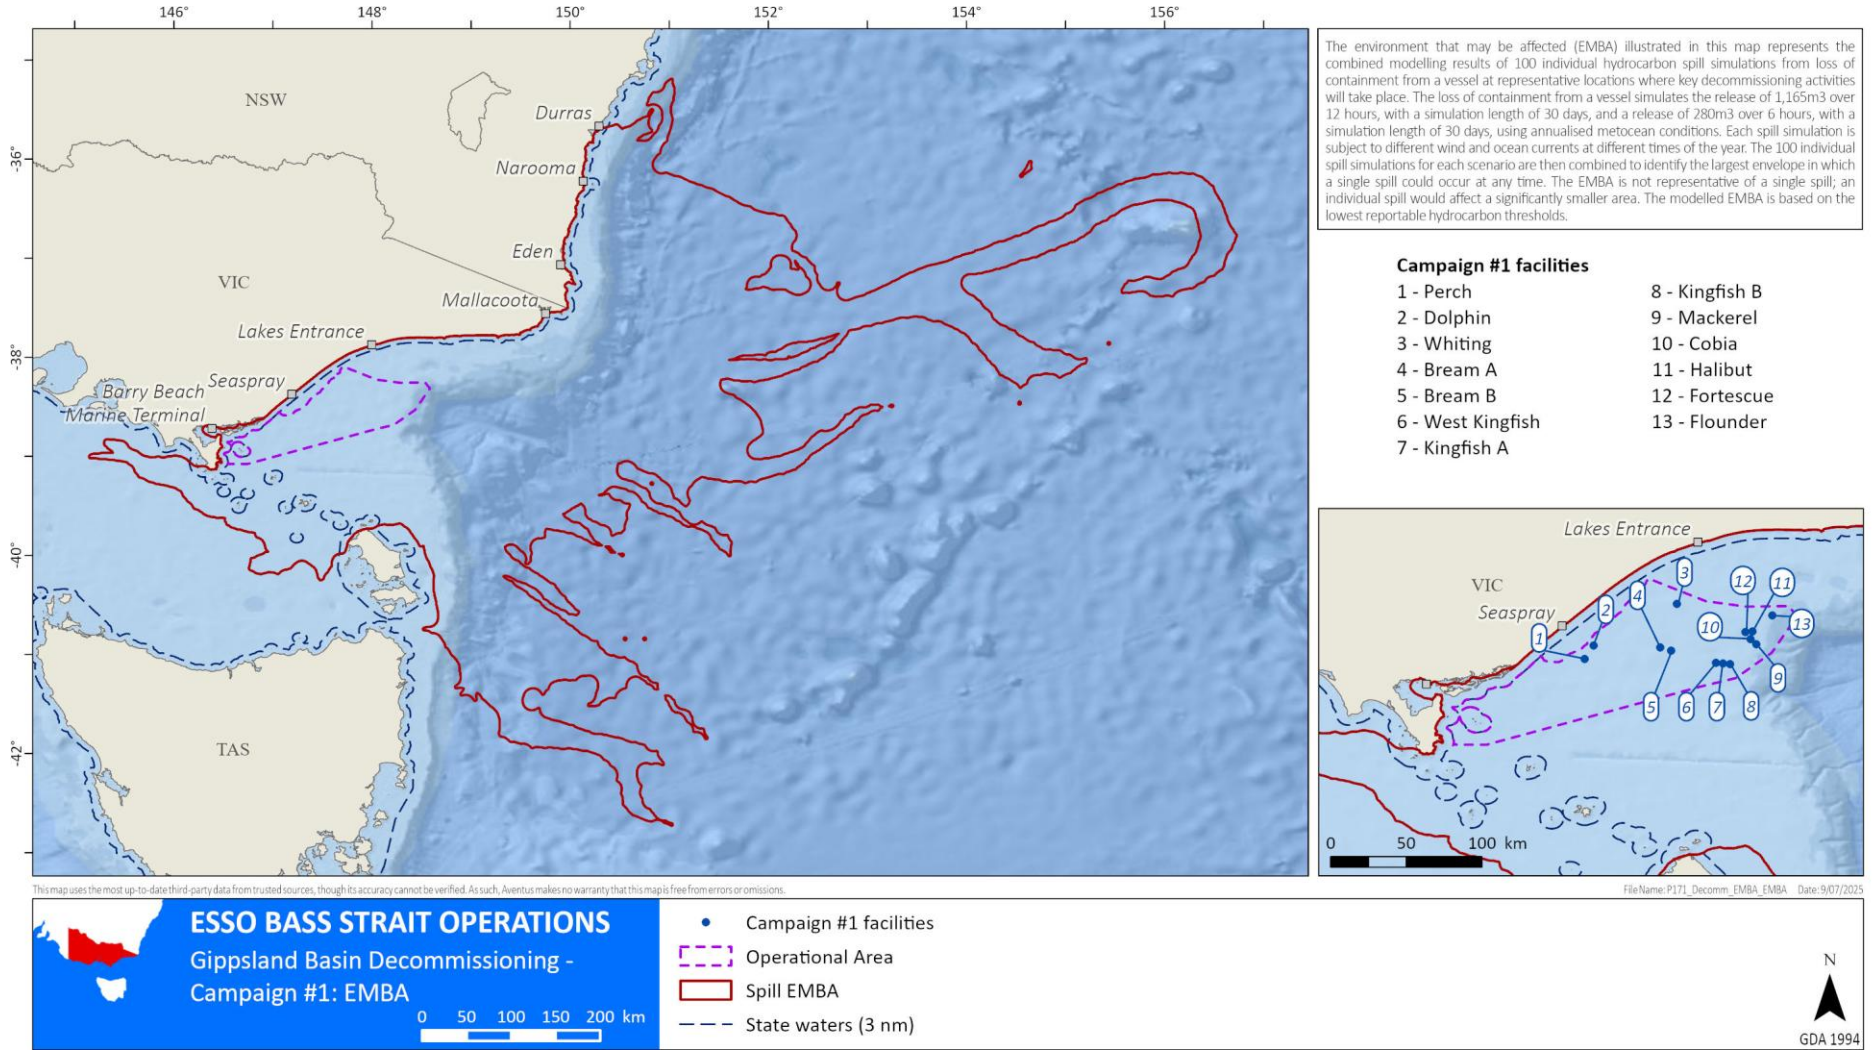

Figure A-1 Campaign #1 Execution EMBA

A.1.1 Conservation values and sensitivities

The conservation values and sensitivities found within the EMBA are described within this Section.

A.1.1.1 World heritage

World heritage is defined in Table 3-2 of the EP. There are no world heritage sites within the EMBA.

A.1.1.2 National heritage

National heritage is defined in Table 3-2 of the EP. There are no national heritage sites within the EMBA.

A.1.1.3 Commonwealth heritage

Commonwealth heritage places are defined in Table 3-2 of the EP. The Commonwealth heritage places identified within the PMST reports (Appendix D) are either outside the extent of the EMBA or are a terrestrial feature and hence have not been described.

A.1.1.4 Wetlands of International Importance

Wetlands of international importance (Convention on Wetlands of International Importance especially as Waterfowl Habitat (Ramsar) wetlands) are defined in Table 3-2 of the EP. Ramsar sites within or adjacent to the EMBA are described below and shown in Figure A-2.

A.1.1.4.1 Gippsland Lakes

The following information was extracted from the Australian Wetlands Database (DCCEEW, n.d.(a)).

The Gippsland Lakes Ramsar site, located in Victoria is a series of large, shallow, coastal lagoons approximately 70km in length and 10km wide, separated from the sea by sand dunes. The surface area of the lakes is approximately 364km^2 and the three main water bodies are Lake Wellington, Lake Victoria, and Lake King.

Gippsland Lakes provides important habitats, feeding areas, dispersal and migratory pathways, and spawning sites for numerous fish species that are directly and indirectly significant for commercial fisheries. Currently, parts of the Gippsland Lakes system are heavily used for commercial and recreational fisheries and boating activities, while the immediate hinterland has been developed for agricultural use, with limited residential and tourism purposes.

The bird diversity of the Ramsar wetland is high with 86 species of waterbirds being recorded including the nationally endangered Australasian bittern and nationally vulnerably Australian fairy tern and hooded plover.

The site meets six of the Ramsar criteria: 1, 2, 4, 5, 6 and 8.

The Gippsland Lakes is a good representation of a natural or near-natural wetland, characteristic of the biogeographical region. It forms one of the largest coastal lagoon systems in the Southeast Coast Drainage Division and contains a distinctive landscape of wetlands and flat coastal plains. The site supports a broad range of wetland types in close proximity to each other, including periodically and permanently inundated palustrine marshes, both shallow and deep lake features, lagoons with narrow inlets, and broad embayments.

The Ramsar site supports several nationally threatened wetland fauna species at various stages of their life cycle including two nationally threatened frog species (green and golden bell frogs and growling grass frogs), the Australian painted snipe, a vulnerable fish species (the Australian grayling) as well as one nationally threatened wetland-associated flora species, the swamp everlasting.

The site supports habitat and conditions that are important for critical life cycle stages of a variety of wetland-dependent fauna species. The permanence of the main lakes and the relatively regular flooding of the adjacent wetlands mean that this wetland is an important drought refuge for many water birds and other aquatic species, including as permanent refuges and breeding sites for two threatened frog species.

The Gippsland Lakes have been identified as being of outstanding importance for waterbirds, regularly supporting more than 20,000 waterfowl.

Waterbird species which are considered to have met the one per cent population threshold are: chestnut teal, fairy tern and little tern.

Gippsland Lakes is a recognised important recreational fishery and supports one of the largest fisheries of black bream in Victoria. In addition, the Gippsland Lakes supports over 230 species of fish including an abundance and diversity of native fish.

A.1.1.4.2 Corner Inlet

The following information was extracted from the Australian Wetlands Database (DCCEEW, n.d.(a)).

Corner Inlet is a 67,168ha wetland enclosed to the west and north by the South Gippsland coastline, in the southeast by a series of barrier islands and sandy spits lying end to end and separated by narrow entrances, and to the south by the hills of Wilsons Promontory. Corner Inlet includes the chain of barrier islands, multiple beach ridges, lagoons and swamps, tidal creeks, tidal deltas, and tidal washovers. The area contains the only extensive bed of broad-leafed seagrass in Victoria. The islands of Corner Inlet, although not rich in plant diversity, are of high biogeographical significance due to their geological history and connectivity to the mainland during ice ages. The islands also contain significant areas of saltmarsh and mangroves, both of which are communities of very limited distribution. These communities filter pollutants, stabilise sediments and protect the shoreline from erosion.

The site meets six of the Ramsar criteria: 1, 2, 4, 5, 6 and 8.

The inlet contains the most extensive intertidal mudflats in Victoria.

Corner Inlet provides breeding habitat for a variety of waterbirds, including several species listed as threatened at the State level and/or occurring in significant numbers and habitat for significant aggregations of waterbirds during post-breeding, and as a refuge during adverse environmental conditions.

Corner Inlet regularly supports well over 20,000 waterbirds including species such as the eastern curlew, curlew sandpiper, bar-tailed godwit, and double-banded plover.

The Corner Inlet Ramsar site has regularly supported more than one per cent of the population of the pied oystercatcher, sooty oystercatcher, pacific gull, fairy tern, red knot, red necked stint and chestnut teal.

Corner Inlet also supports the nationally critically endangered orange bellied parrot as well as several other threatened species, including the growling grass frog and Australian grayling. The Southern Right Whale (*Eubalaena australis*) (SRW), leatherback turtle, swift parrot and shy albatross have all also been recorded at the site.

The Ramsar site provides important habitats, feeding areas, dispersal and migratory pathways, and spawning sites for numerous fish species, including King George whiting, Australian salmon, greenback flounder, southern garfish, leatherjackets, short-finned eel and gummy shark.

Corner Inlet was used traditionally by Indigenous people, and many archaeological sites including scarred trees, burial sites, artefact scatters, shell middens and camps have been found.

Currently, the Ramsar site is used for biological conservation, ports with servicing facilities for offshore oil and gas exploration, commercial fishing, recreational fishing, and other recreational activities. Diving is popular around the numerous shipwreck sites in Corner Inlet and around the barrier islands.

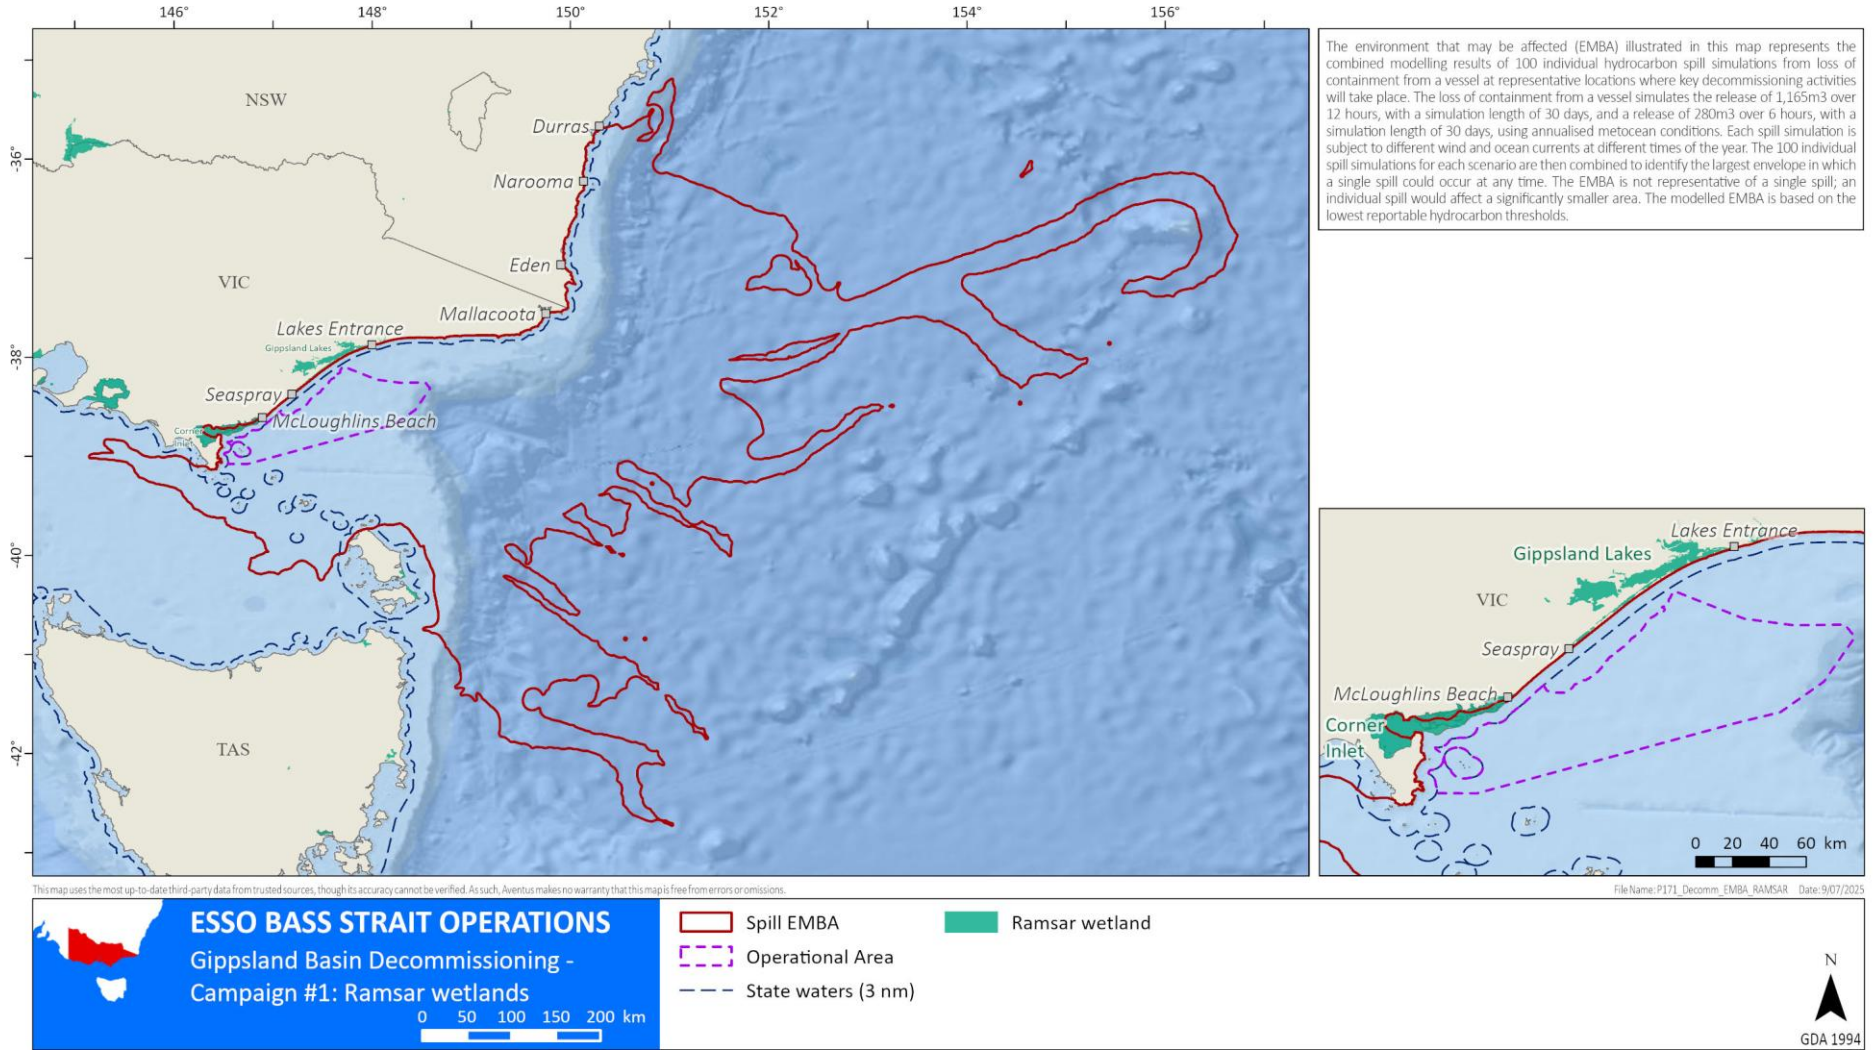

Figure A-2 Ramsar wetlands within or adjacent to the EMBA

A.1.1.5 Nationally Important Wetlands

Nationally Important Wetlands (NIWs) are defined in Table 3-2 of the EP. Table A-1 describes the NIWs identified within or adjacent to the EMBA and shown in Figure A-3.

Table A-1 NIWs within or adjacent to the EMBA

Wetland	Description
Victoria	
Benedore River	The Benedore River is located in East Gippsland in the Croajingolong National Park, with a catchment elevation that ranges from 210m (Above Sea Level (ASL)) at the headwaters to sea level at the river mouth. It flows naturally without artificial barriers through diverse geological zones - from sedimentary beach deposits, to non-marine sands, gravels, ironstone, and brown coal, and finally to sedimentary sandstone and mudstone - supporting *Environment Protection and Biodiversity Conservation Act 1999* (Cth) (EPBC Act) listed threatened fauna and being highly valued for recreational and scientific research purposes (DCCEEW, 2021).
Corner Inlet	Corner Inlet is located between Wilsons Promontory, Foster, and Woodside, covering an area of 67,168ha on the South East Coastal Plain at low elevations (0 – 10m ASL). It features the most southerly tidal mudflat system on mainland Australia, with a diverse geological setting comprising Quaternary marine, coastal, aeolian, lacustrine, and paludal sediments. The inlet is internationally (listed as a Ramsar site) and nationally significant for its geomorphology and high productivity, supporting unique flora and providing critical feeding grounds for a wide array of waterfowl and migratory wader species. It is also valued for recreation and scientific research (DCCEEW, 2021).
Ewing's Marsh (Morass)	Ewing's Marsh is a coastal wetland that formed in a long, narrow basin of Quaternary alluvium between an active 50km coastal barrier. It provides vital habitat for a diverse range of fauna, particularly water birds, and is valued for recreational use (DCCEEW, 2021).
Lake Bunga	Lake Bunga is a narrow freshwater lagoon in East Gippsland that forms part of the Gippsland Lakes Ramsar site. Fed by Bunga Creek and rarely open to the sea, the lake is valued for its geological, geomorphological, botanical and ornithological features (DCCEEW, 2021).
Lake King Wetlands	Lake King Wetlands consist of two large coastal lagoons with associated channels, saltmarshes, and brackish to fresh marshes in East Gippsland. The Lake King Wetlands are valued for their ecological, recreational, scientific, cultural, and landscape features, exemplifying a large coastal lagoon system. Within the wetlands, the internationally significant Mitchell River silt jetties and the state-recognised Tambo River Delta demonstrate remarkable geological and geomorphological processes, and Mullacky Swamp is noted for its special botanical significance (DCCEEW, 2021).
Mallacoota Inlet Wetlands	Mallacoota Inlet Wetlands comprise Mallacoota Inlet, Lake Barracoota and Howe Flat in East Gippsland. The wetlands are supplied with fresh water from Genoa River, Wallagaraugh River, Little River, Dowell River and several smaller streams, although sea water may enter via the shallow inlet entrance via tidal movement. The Mallacoota Inlet Wetlands provide a variety of wetland habitats ranging from estuarine to freshwater, deep inlet waters to sedgelands. It is also valued for recreational purposes (DCCEEW, 2021).
Sydenham Inlet Wetlands	Sydenham Inlet Wetlands, together with Tamboon Inlet, developed in an embayment between Pearl Point and Tamboon South headlands in East Gippsland. The Sydenham

Wetland	Description
	Inlet Wetlands include a variety of wetland types affected by fresh to saline water and provide a large area of estuarine habitat and support a high diversity of flora and fauna, including nesting and roosting sites. It is also valued for recreational purposes (DCCEEW, 2021).
Tamboon Inlet Wetlands	Tamboon Inlet Wetlands, together with Sydenham Inlet Wetlands, developed in an embayment between Pearl Point and Tamboon South headlands in East Gippsland. The Tamboon Inlet Wetlands have a variety of wetland types affected by fresh to saline water which support a diversity of flora and fauna and provides a large area of estuarine habitat. It is also valued for recreational purposes (DCCEEW, 2021).
Thurra River	The Thurra River wetland is located in East Gippsland with elevation ranging from 0 – 560m ASL. The river supports EPBC Act listed threatened fauna and flora species. It is also valued for recreational purposes (DCCEEW, 2021).
New South Wales	
Clyde River Estuary	The Clyde River Estuary is located on the south coastal plain from the tidal waters and intertidal wetlands of the Clyde River and Cullendulla Creek estuary upstream to Cyne Mallows in East Gippsland. Due to relatively large areas of mangrove, saltmarsh and seagrasses, it is a representative example of an estuarine wetland on the south coast. The estuary supports migratory birds and provides a nursery habitat for commercial fish species. It is also valued for cultural practices such as permanent camps and sustenance practices (DCCEEW, 2021).
Moruya River Estuary Saltmarshes	Moruya River Estuary Saltmarshes is located in the South East Corner bioregion with elevation ranging from 0 – 2m ASL. The salt marsh is part of a mature estuarine system that contains a number of extensive, modified salt and brackish marshes (DCCEEW, 2021).
Nadgee Lake and tributary wetlands	Nadgee Lake and tributary wetlands are located in the South East Corner bioregion. It is a relatively large intermittently closed and open coastal lake, although it is predominately closed to the ocean. The lake is supplied by large swamps and ephemeral creeks flowing from the Nadgee Range to the west. It is also valued for cultural practices and scientific research (DCCEEW, 2021).
Nargal Lake	Nargal Lake is one of the few dune-swale freshwater lakes in the bioregion. Lake waters are derived from a relatively small freshwater catchment. The swamp oak forest and sedgelands surround the lake, providing shelter, refuge and breeding sites for numerous bird species. It has cultural values and is identified as a site of significance to Aboriginal people (DCCEEW, 2021).
Nelson Lagoon	Nelson Lagoon is an intermittently closed and open barrier lagoon with several small, indented bays and a delta at the mouth of Nelson Creek. This lagoon features saltmarsh areas and an elevation of 0m ASL. It is also valued for recreational purposes (DCCEEW, 2021).
Tuross River Estuary	Tuross River Estuary is a complex delta estuary with many low islands and islets (>20), draining a major South East Corner bioregion river system and entering the sea adjoining a relatively long beach barrier. The estuary is valued for recreational (e.g. boating) and commercial (e.g. oyster farming and productive grazing) purposes. Cultural values include known middens and sites of Aboriginal sacred significance (DCCEEW, 2021).

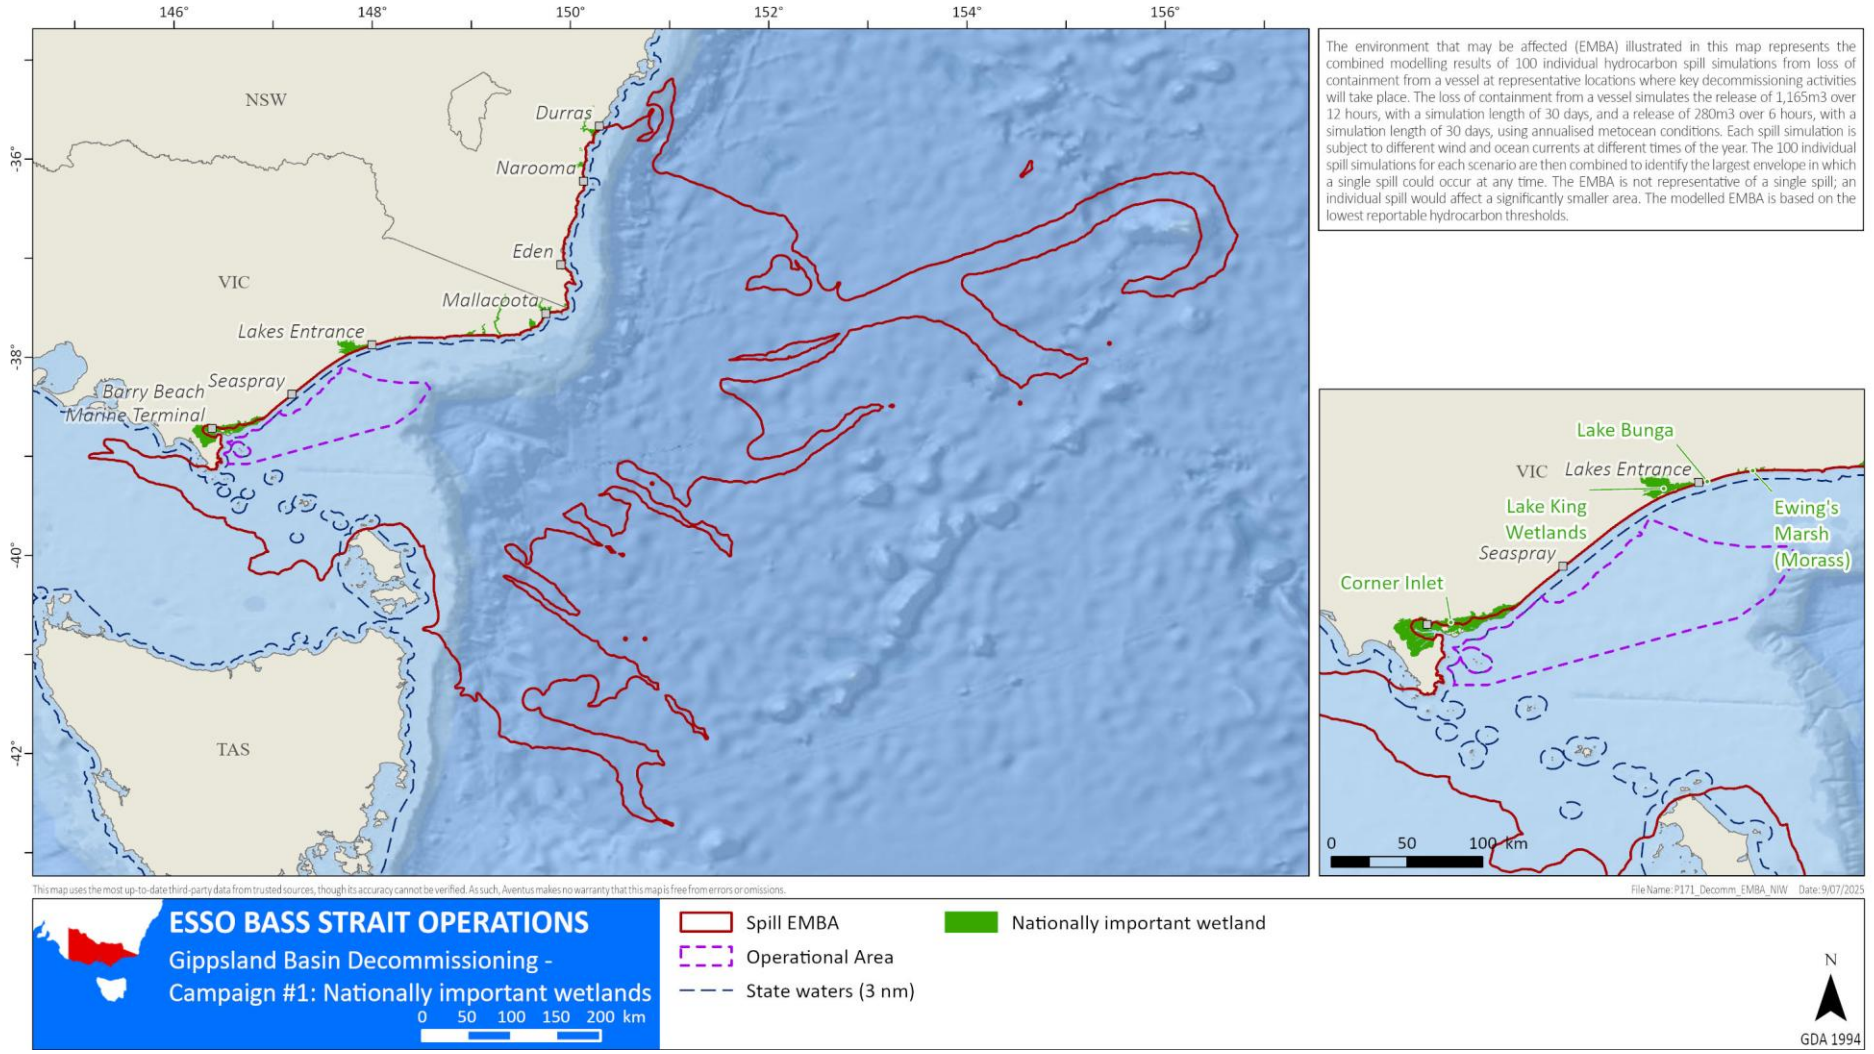

Figure A-3 NIWs within or adjacent to the EMBA

A.1.1.6 Threatened Ecological Communities

Threatened Ecological Communities (TECs) are defined in Table 3-2 of the EP. TECs within the EMBA are described below and shown in Figure A-4. Only TECs that are marine/coastal in nature have been described, a full list of TECs detected by the PMST report (refer to Appendix D of the EP).

A.1.1.6.1 Littoral Rainforest and Coastal Vine Thickets of Eastern Australia

This TEC is listed as critically endangered under the EPBC Act. This ecological community is a complex of rainforest and coastal vine thickets influenced by its proximity to the sea. It provides habitat for over 70 threatened plants and animals and provides important stepping-stones along the eastern Australian coast for various migratory and marine birds. The community also provides an important buffer to coastal erosion and wind damage (Commonwealth of Australia, 2019).

This ecological community occurs as a series of naturally disjunct and localised stands within 2km of the eastern coastline of Australia or adjacent to a large saltwater body, such as an estuary on a range of landforms including dunes and flats, headlands, and sea-cliffs, including offshore islands (Commonwealth of Australia, 2019).

This TEC has scattered and fragmented distribution from Princess Charlotte Bay, Queensland to East Gippsland in Victoria, including on estuarine and offshore islands. Sites that occur on the East Gippsland coast (including locations near Lakes Entrance, Marlo and Mallacoota) and communities found along the New South Wales southern coastline intersect with the EMBA.

A.1.1.6.2 Subtropical and Temperate Coastal Saltmarsh

This TEC is listed as vulnerable under the EPBC Act. The known distribution of this TEC includes the southern and eastern coasts of Australia where it occurs within a narrow margin in the subtropical and temperate climatic zones; and includes coastal saltmarsh occurring on islands within these climatic zones (DSEWPAC, 2013a).

The physical environment for the ecological community is coastal areas under regular or intermittent tidal influence. The community consists mainly of salt-tolerant (halophytes - grasses, herbs, sedges, rushes and shrubs) and non-vascular vegetation including epiphytic algae, diatoms and cyanobacterial. The ecological community is inhabited by a wide range of infaunal and epifaunal invertebrates, and temporary inhabitants such as prawns, fish and birds (and can often constitute important nursery habitat for fish and prawn species). The dominant marine residents are benthic invertebrates, including molluscs and crabs that rely on the sediments, vascular plants, and algae, as providers of food and habitat across the intertidal landscape (DSEWPAC, 2013a).

This community occurs sporadically along the Victorian coastline which intersects with the EMBA.

A.1.1.6.3 Giant Kelp Marine Forests of South East Australia

This TEC is listed as endangered under the EPBC Act. This ecological community was once common in the coastal waters of southeast Australia, including around Tasmania, across Bass Strait up to Victoria, eastern South Australia and southern New South Wales. However, after significant declines in recent decades, remnant fragments of Giant Kelp Marine Forest are now only found in Tasmania, where patches of giant kelp declined from 400ha in the late 1990s to less than 10ha by 2015 (DCCEEW, 2024a).

Giant kelp (*Macrocystis pyrifera*) plants are the foundation species of this TEC. Giant kelp is a large, brown algae that grows on rocky reefs from the seafloor 8m below MSL and deeper. Its fronds grow vertically toward the water surface, in cold temperate waters off southeast Australia. Their presence on a rocky reef adds vertical structure to the marine environment that creates significant habitat for marine fauna (DSEWPAC, 2012a). The kelp species itself is not protected. To be considered a Giant Kelp Marine Forest, the plants must form a closed or semi-closed canopy at or below the water's surface and grow at depths generally greater than 8m on a rocky substrate. Other components of this TEC include a large range of marine algae, reef associated fish and numerous invertebrates that shelter, feed, and reproduce within Giant Kelp Marine Forests (DSEWPAC, 2012a).

This TEC occurs sporadically along the Victorian and Tasmanian coastlines, intersecting with the EMBA.

A.1.1.6.4 Coastal Swamp Oak Forest of New South Wales and South East Queensland

This TEC is listed as endangered under the EPBC Act and occurs along South East Corner bioregion of New South Wales in coastal catchments, on coastal flats, floodplains, drainage lines, lake margins, wetlands and estuarine fringes where soils are at least occasionally saturated, water-logged or inundated. Coastal Swamp Oak *(Casuarina*

glauca) Forest is often found in association with other vegetation types such as coastal saltmarsh and mangroves (DoEE, 2018a).

The vegetation of the Coastal Swamp Oak Forest provides diverse habitat values and is a source of food for a wide range of fauna, particularly the crevices and hollows within older trees. Most fauna species that form a part of the Coastal Swamp Oak Forest also inhabit adjacent wetlands, grasslands, woodlands, and forests. Many fauna species within the ecological community are listed as threatened under State and/or Commonwealth legislation including small mammals, reptiles, invertebrates, amphibians, and birds (DoEE, 2018a).

This TEC intersects with the EMBA along the New South Wales coastline.

A.1.1.6.5 Assemblages of Species Associated with Open-coast Salt-wedge Estuaries of Western and Central Victoria

This TEC is listed as endangered under the EPBC Act and includes an assemblage of native plants, animals and micro-organisms associated with the dynamic salt-wedge estuary systems that occur within the temperate climate, microtidal regime, high wave energy coastline of western and central Victoria. This TEC is characterised by a core component of obligate estuarine taxa, with associated components of coastal, estuarine, brackish and freshwater taxa that may reside in the estuary for periods of time and/or utilise the estuary for specific purposes. Some assemblages of biota are dependent on the dynamics of salt-wedge estuaries for their existence, refuge, increased productivity, and reproductive success (TSSC, 2018).

The TEC currently encompasses 25 estuaries in the region defined by the border between South Australia and Victoria and the most southerly point of Wilsons Promontory (TSSC, 2018). Salt-wedge estuaries are typically ecosystems of high ecological value which are increasingly under threat. They contribute high levels of productivity to coastal and nearshore marine environments, and provide important refuge, nursery or breeding habitat for a wide range of invertebrates, fish and birds. This TEC intersects with the EMBA along the coastline near Wilsons Promontory.

A.1.1.6.6 Coastal Swamp Sclerophyll Forest of New South Wales and South East Queensland

This TEC is listed as endangered under the EPBC Act and includes the plants, animals and other organisms typically associated with forested palustrine wetlands, or swamp forests. This TEC is found in the temperate to subtropical coastal valleys between the Great Dividing Range and the coastline from near Gladstone in Queensland, through to the south coast of New South Wales (DAWE, 2021) where it intersects the EMBA. This TEC is present in low-lying coastal alluvial areas with minimal relief at elevations below 20m ASL but may occur occasionally up to 220m ASL (DAWE, 2021).

This TEC often has a layered canopy, dominated by melaleucas and/or eucalyptus robusta. This TEC supports a range of aquatic, ground dwelling and arboreal species.

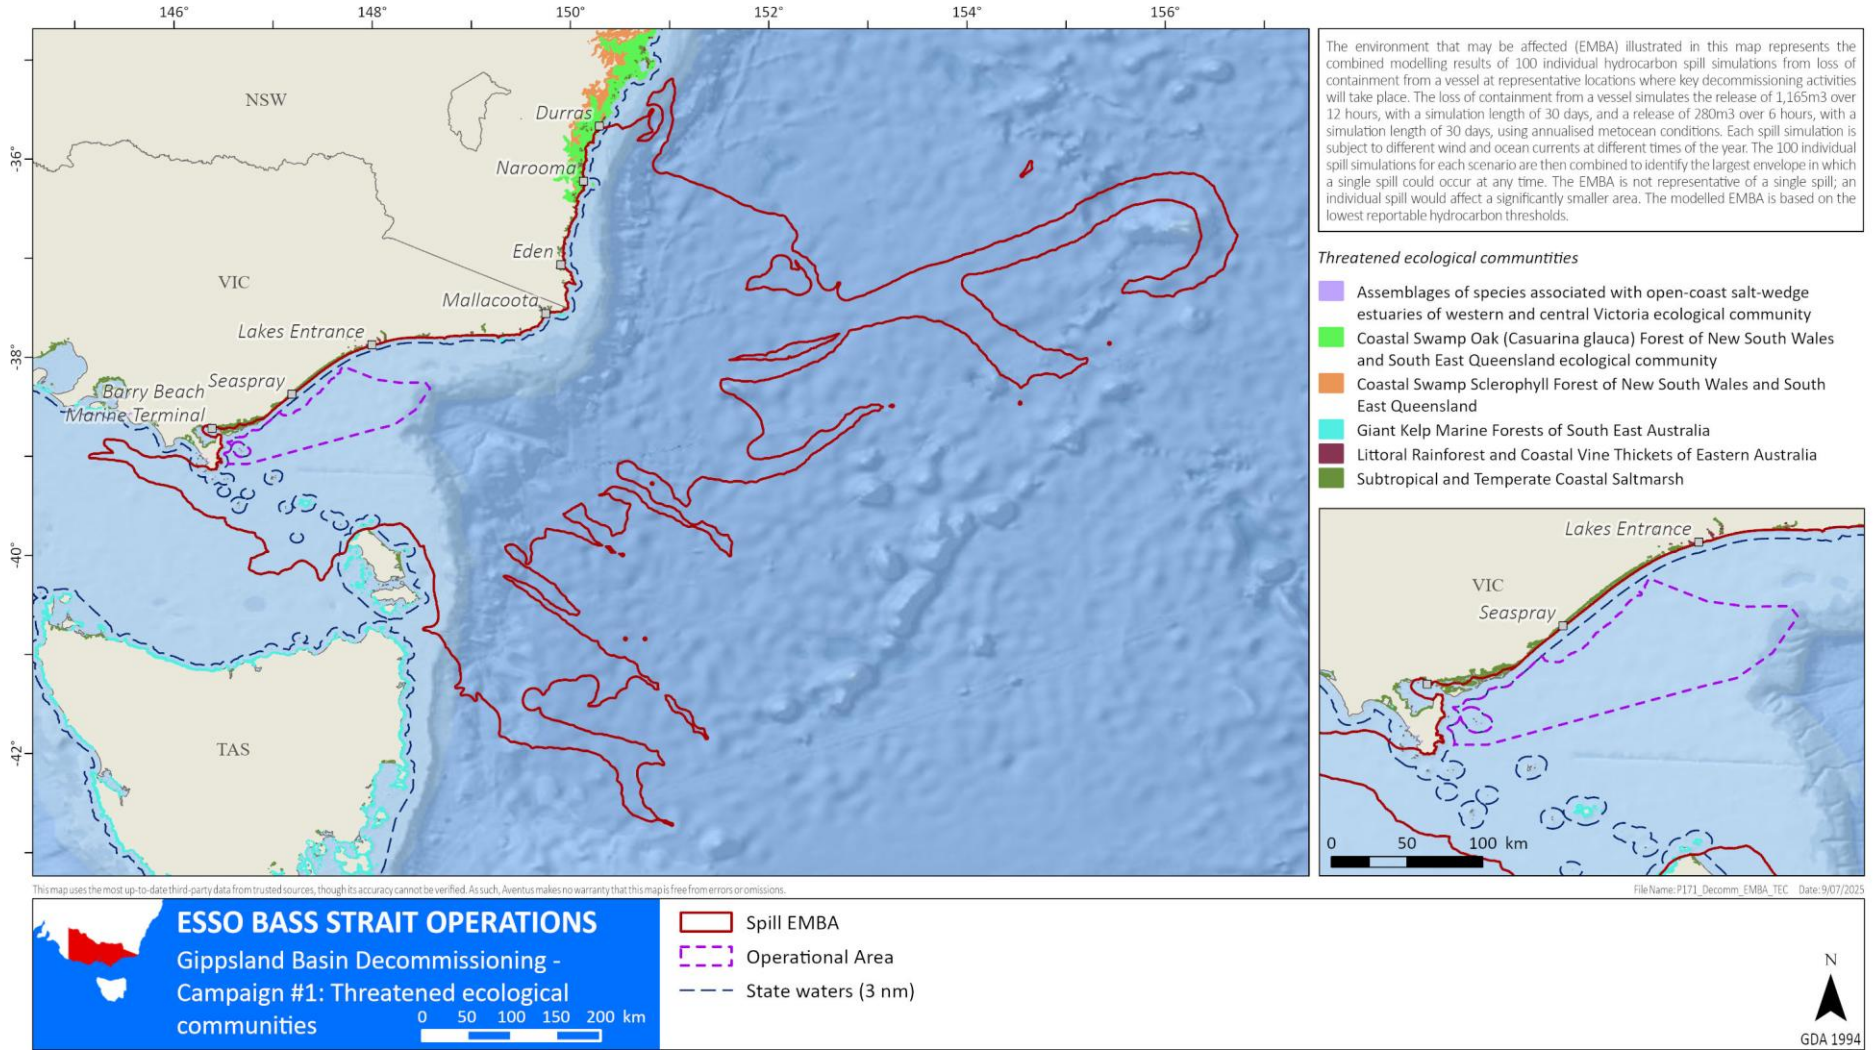

Figure A-4 TECs intersected by the EMBA

A.1.1.7 Australian Marine Parks

Australian Marine Parks (AMPs) are defined in Table 3-2 of the EP. AMPs within the EMBA are described below and shown in Figure A-5. The AMPs in the South-east Marine Parks Network, established between 1999 and 2007, were managed under the *South–east Commonwealth Marine Reserves Network management plan 2013–23* (Director of National Parks, 2013) which expired in 2023. As a result, the Director of National Parks prepared the *South-east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025) that sets out management of this network from 2025 to 2035. This management plan has been approved by the Minister for the Environment and Water and came into effect from the 13 February 2025.

The 2025 management plan (Director of National Parks, 2025) presents a description of the conservation values, which include natural, cultural, and socio-economic values. From the natural values perspective, this version reinforces the importance of values referenced in the superseded version, including the presence of Key Ecological Features (KEFs), Biologically Important Areas (BIAs) ecosystems and habitat or species that are particularly important due to their uniqueness, functional importance, vulnerability, biological productivity, diversity or ability to provide social and economic benefit. From a cultural and socio-economic perspective, the 2025 management plan (Director of National Parks, 2025) incorporates additional important values such as:

- 'Ancient land bridge', describing that areas now under the sea in the South-east Marine Parks Network were once part of the landscape used by First Nations people
- 'Culturally significant species', acknowledging that First Nations people have a cultural obligation to care for mutton birds, seals and whales and other marine animal resources as well as the interconnectivity between coastal and offshore marine environments
- 'Songlines and stories', acknowledging that First Nations people continue to honour ancient saltwater songlines, migrations, stories and ancestral connections (Director of National Parks, 2025).

A.1.1.7.1 East Gippsland Marine Park

The East Gippsland Marine Park is located off the northeast corner of Victoria and is 4137km^2. The full area of the marine park is designated as a Multiple Use Zone (IUCN VI) (Director of National Parks, 2025).

The marine park contains representative samples of an extensive network of canyons, the continental slope, and escarpments at water depths ranging from 604 - 5276m (Director of National Parks, 2025). The main seabed features include a dome-shaped plateau on the mid slope, two large box canyons and several large, tilted blocks.

The East Gippsland Marine Park is south-east of the New South Wales – Victorian border at Cape Howe. The park contains deepwater ecosystems extending from the upper slope to the abyssal plain. The main seabed features include a dome-shaped plateau on the mid slope, two large box canyons and several large, tilted blocks. The western section of the park intersects with the offshore edge of the Upwelling East of Eden, which is defined as a KEF, as it is an area of high productivity. The East Australian Current brings warm subtropical water from the north and forms large eddies around Cape Howe which interact with the varied seafloor terrain, causing upwelling of cooler waters. The mixing of cool and warm water creates phytoplankton blooms that support an abundance of zooplankton, fish, marine mammals and seabirds (Director of National Parks, 2025). Major conservation values identified within the *South–east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025) include:

- foraging BIAs including albatross species (including shy, black browed, Campbell, Indian yellow–nosed and wandering and Buller's), wedge-tailed shearwaters, white faced storm petrels and Pygmy Blue Whale (*Balaenoptera musculus brevicauda*) (PBWs)
- the lower slope (water depths ranging from 2500 - 3850m) supports diverse invertebrate fauna, including large red spiny king crab, squat lobsters, finned octopus, sea cucumbers, sea stars, sea spiders, shrimp, crinoids and sea whips, polychaetes and bivalves
- habitats, species and ecological communities associated with the Southeast Transition provincial bioregion
- the Upwelling East of Eden KEF
- social and economic benefits include commercial fishing.

A.1.1.7.2 Beagle Marine Park

Beagle Marine Park, in Bass Strait off Wilsons Promontory, surrounds Tasmania's Kent Group Marine Park and the Hogan and Curtis Island groups with a total area of 2928km^2. The park represents an area of shallow continental

shelf ecosystems in depths of about 46 - 77m and is designated as a Multiple Use Zone (IUCN VI) and a National Park Zone (IUCN II) (Director of National Parks, 2025), with areas of 2448km^2 and 479km^2 respectively (Director of National Parks, 2025).

Major conservation values identified within the *South–east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025) include:

- the seabed covers part of an ancient land bridge between Tasmania and Victoria and was used by First Nations people before it was submerged at the end of the last glacial period about 10,000 years ago. First Nations communities hold knowledge, oral traditions, stories and songlines that connect to the times of the land bridge that have been passed down through the generations, giving unique insights into the flooding of this Country
- between the Kent Group and Hogan Group of islands are mesophotic (middle-light) reefs that rise 2 - 5m above the seabed and are considered relict coastal dunes that formed on the ancient land bridge. These mesophotic reefs, a rare ecosystem within Bass Strait, support a sessile invertebrate assemblage comprised of bryozoans, hydroids and a high diversity of temperate sponges. Abundant and diverse fish communities are associated with these mesophotic reefs and are dominated by butterfly perch, barber perch, jackass morwong, common gurnard perch, Melbourne silverbelly, Degen's leatherjacket, and rosy wrasse. Aggregations of hundreds of predominantly female Port Jackson sharks have been observed in 2018 and 2024, indicating that these reef features are important for the species during winter foraging migrations to Bass Strait
- the shallower eastern section of the park is dominated by linear ridges less than 1m in height that extend several kilometres. These low-profile ridges are sometimes covered by shell hash and gravel that support a diverse sessile filter feeding invertebrate community dominated by bryozoans and sponges. The deeper, southwestern part of the park is sediment-dominated and contains extensive mobile dune fields less than 1m high with patches of doughboy scallops
- foraging BIAs for many seabirds, including albatross species (including the endangered shy albatross; the vulnerable black browed, Campbell, Indian yellow-nosed and wandering albatrosses; and Buller's albatross), white faced storm petrel, common diving petrel, short-tailed shearwater and little penguin. There are also BIAs for white sharks, SRWs and PBWs
- humpback whales and short-tailed shearwaters are culturally significant species
- the KEFs represented include the Shelf Rocky Reefs and hard substrate[1], including the mesophotic reefs between the Kent Group and Hogan Group of islands
- habitats, species and ecological communities associated with the Southeast Shelf Transition provincial bioregion and the Twofold Shelf and Flinders mesoscale bioregions
- the social and economic benefits include commercial fishing and shipping.

A.1.1.7.3 Flinders Marine Park

Flinders Marine Park is off the northeast tip of Tasmania near Flinders Island. The park extends from the mid-continental shelf eastwards to the outer limit of Australia's Exclusive Economic Zone and protects a range of ecosystems, including mesophotic (middle-light) reefs; rariphotic (rare light) reefs; shelf sediments; upper-, mid-, and lower-slope reefs and sediments; canyons; and seamounts. It covers a depth range from about 34m on the shallow continental shelf to abyssal depths of 5041m near the edge of the Exclusive Economic Zone. The park protects a range of ecosystems, including mesophotic reefs, rariphotic reefs, shelf sediments, upper–, mid–, and lower–slope reefs and sediments, canyons and seamounts. The park has a total area of 27,046km^2 and is recognised as a National Park Zone (IUCN II), a Multiple Use Zone (IUCN VI), and a Habitat Protection Zone (IUCN IV), each one covering areas of 15,024km^2, 1129km^2 and 10,892km^2 respectively (Director of National Parks, 2025).

[1] Currently not defined within the Australian Marine Spatial Information System or identified within the PMST reports (refer to Appendix D of the EP).

Major conservation values identified within the *South–east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025) include:

- the seabed covers part of an ancient land bridge between Tasmania and Victoria and was used by First Nations people before it was submerged at the end of the last glacial period about 10,000 years ago
- ecosystems, habitats and communities associated with the Tasmania Province, the Tasmanian Shelf Province, the Southeast Transition, the Southeast Shelf Transition
- diverse mesophotic reefs supporting a diverse benthic community of sponges, cnidarians, hydroids, gorgonian fans and soft corals
- the shelf break (water depths of approximately 120m) is largely sediment draped with few reef features, although midway along the shelf break are two canyon incisions with exposed reef, including cliffs up to 60m high. Fish communities associated with these features are dominated by reef ocean perch, jackass morwong and striped trumpeter
- the upper slope reefs and canyons support an abundance of rare black corals and octocorals and several species of conservation-dependent deepwater sharks, including the Harrisson's dogfish and southern dogfish
- foraging BIAs for many seabirds, including albatrosses (including the endangered shy albatross; the vulnerable antipodean, black browed, Campbell, Indian yellow-nosed and wandering albatrosses; and Buller's albatross), white faced storm petrel, common diving petrel and short-tailed shearwater. There are also BIAs for white sharks, SRWs and PBWs
- habitats, species and ecological communities associated with provincial bioregions - Southeast Transition, Southeast Shelf Transition and Tasmanian Shelf Province, and the Flinders and Freycinet mesoscale bioregions
- the KEF[1] represented include the Shelf Rocky Reefs and hard substrate, includes rariphotic reefs in the northwest of the marine park and east Tasmania subtropical convergence zone
- social and economic benefits include commercial fishing
- the proposed Tayaritja Sea Country Indigenous Protected Area (IPA) overlaps the western part of Flinder. This is the first proposed Sea Country IPA in the South-east Marine Park Network, extending from northeast Lutruwita/Tasmania over the submerged ancient land bridge and surrounds Tayaritja/Bass Strait Islands. The Tayaritja Sea Country IPA proposes to protect culturally and ecologically important habitats and species.

A.1.1.7.4 Jervis Marine Park

Jervis Marine Park is located about 20 km offshore, adjacent to the NSW Jervis Bay Marine Park and the Commonwealth Booderee National Park, comprising an area of 2473km^2 and covering a depth range from 120 - 5000m approximately. The park has Habitat Protection Zone (IUCN IV) and Special Purpose Zone (Trawl) (IUCN VI) (Director of National Parks, 2018).

Seafloor features represented in the reserve include abyssal-plain/deep ocean floor, canyons, shelf and slope. The reserve includes two KEFs, it is one of three shelf incising canyons occurring within the region (unique seafloor feature with ecological properties of regional significance) and Shelf Rocky Reefs.

Major conservation values are:

- ecosystems habitats and communities associated with the Central Eastern Province and Southeast Shelf Transition
- important foraging area for seabirds, grey nurse sharks and humpback whales
- KEFs, Canyons on the Eastern Continental Slope and Shelf Rocky Reefs
- contains one known historic shipwreck *HMAS Tattoo* (wrecked in 1939)
- Sea Country is valued for Indigenous cultural identity, health and wellbeing
- social and economic values include tourism, commercial fishing and recreation.

A.1.1.7.5 Freycinet Marine Park

The Freycinet Marine Park is located east of Tasmania, 6 - 12km offshore from the Freycinet Peninsula. It covers 57,941km^2, with depths from 40 – 5230m (Director of National Parks, 2025). The park protects a range of ecosystems, including mesophotic reefs; rariphotic reefs; shelf sediments; upper–, mid–, and lower–slope reefs and sediments; and seamounts. It has National Park (IUCN II), Recreational Use (IUCN IV), Multiple Use (IUCN VI),

and Habitat Protection (IUCN IV) zones, each one with areas covering 56,825 km^2, 323km^2, 725 km^2 and 68km^2 respectively (Director of National Parks, 2025).

Major conservation values identified within the *South–east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025) include:

- Joe's Reef is an isolated granite reef that rises approximately 20m above the surrounding seabed near the western boundary of the park. This structurally complex reef occurs in depths of 59 - 83m, so the top of the reef extends into the mesophotic rocky reef ecosystem. It is covered in a diverse invertebrate fauna of sponges, gorgonian fans, mushroom corals and rare but distinctive tree-forming black corals up to 3m tall. Associated fish assemblages are dominated by reef–associated species such as jackass morwong, ocean perch, butterfly perch, splendid perch, rosy wrasse and striped trumpeter
- in the northwest corner of the park there are lower profile, fragmented and isolated patch reefs in depths of approximately 80m. Associated fish assemblages are dominated by jackass morwong, barred grubfish, ocean perch and common gurnard perch. There are steep mudstone ledge/cliffs without significant reef complexity and the associated fish assemblages include relatively high abundances of jackass morwong, ocean perch and striped trumpeter. Sawtail catshark have also been observed at these shelf break reefs. Between 70 - 80m and 120 - 200m the habitat is primarily soft sediment with associated fish assemblages dominated by flathead and barred grubfish. Toothy flathead is the most common flathead species and is widely distributed across the shelf. Tiger flathead is found across the shelf to the shelf breaks but predominantly in the Multiple Use Zone and in lower numbers. Sand flathead is found in shallower shelf sites in the Multiple Use Zone
- much of the shelf between 80m and 120m has low profile dune-like ridge features and are likely consolidated relic glacial coastal dune features drowned by sea level rise following the last glacial period. These systems are intermediate between reef and soft sediment and are typically covered in a fine layer of sand or silt with emergent small sponges and bryozoan/hydroid turf matrix. Fish assemblages include jackass morwong, common gurnard perch, spikey dogfish, gummy shark and draughtboard shark
- foraging BIAs for seabirds, including albatrosses (including shy, antipodean, black browed, Campbell, Indian yellow–nosed, wandering and Buller's), white faced storm petrel, common diving petrel, soft plumaged petrel, and short-tailed shearwater. There are also BIAs for white sharks, PBWs and SRWs
- habitats, species, and ecological communities associated with provincial bioregions - Tasmania Province, Tasmanian Shelf Province, and Southeast Transition - and the Freycinet mesoscale bioregion
- the KEFs represented include:
    - Shelf Rocky Reefs and hard substrate, includes rariphotic reefs in the north-west of the park[1]
    - seamounts, east and south of Tasmania
    - east Tasmania subtropical convergence zone[1].
- social and economic benefits include commercial and recreational fishing, and scuba diving.

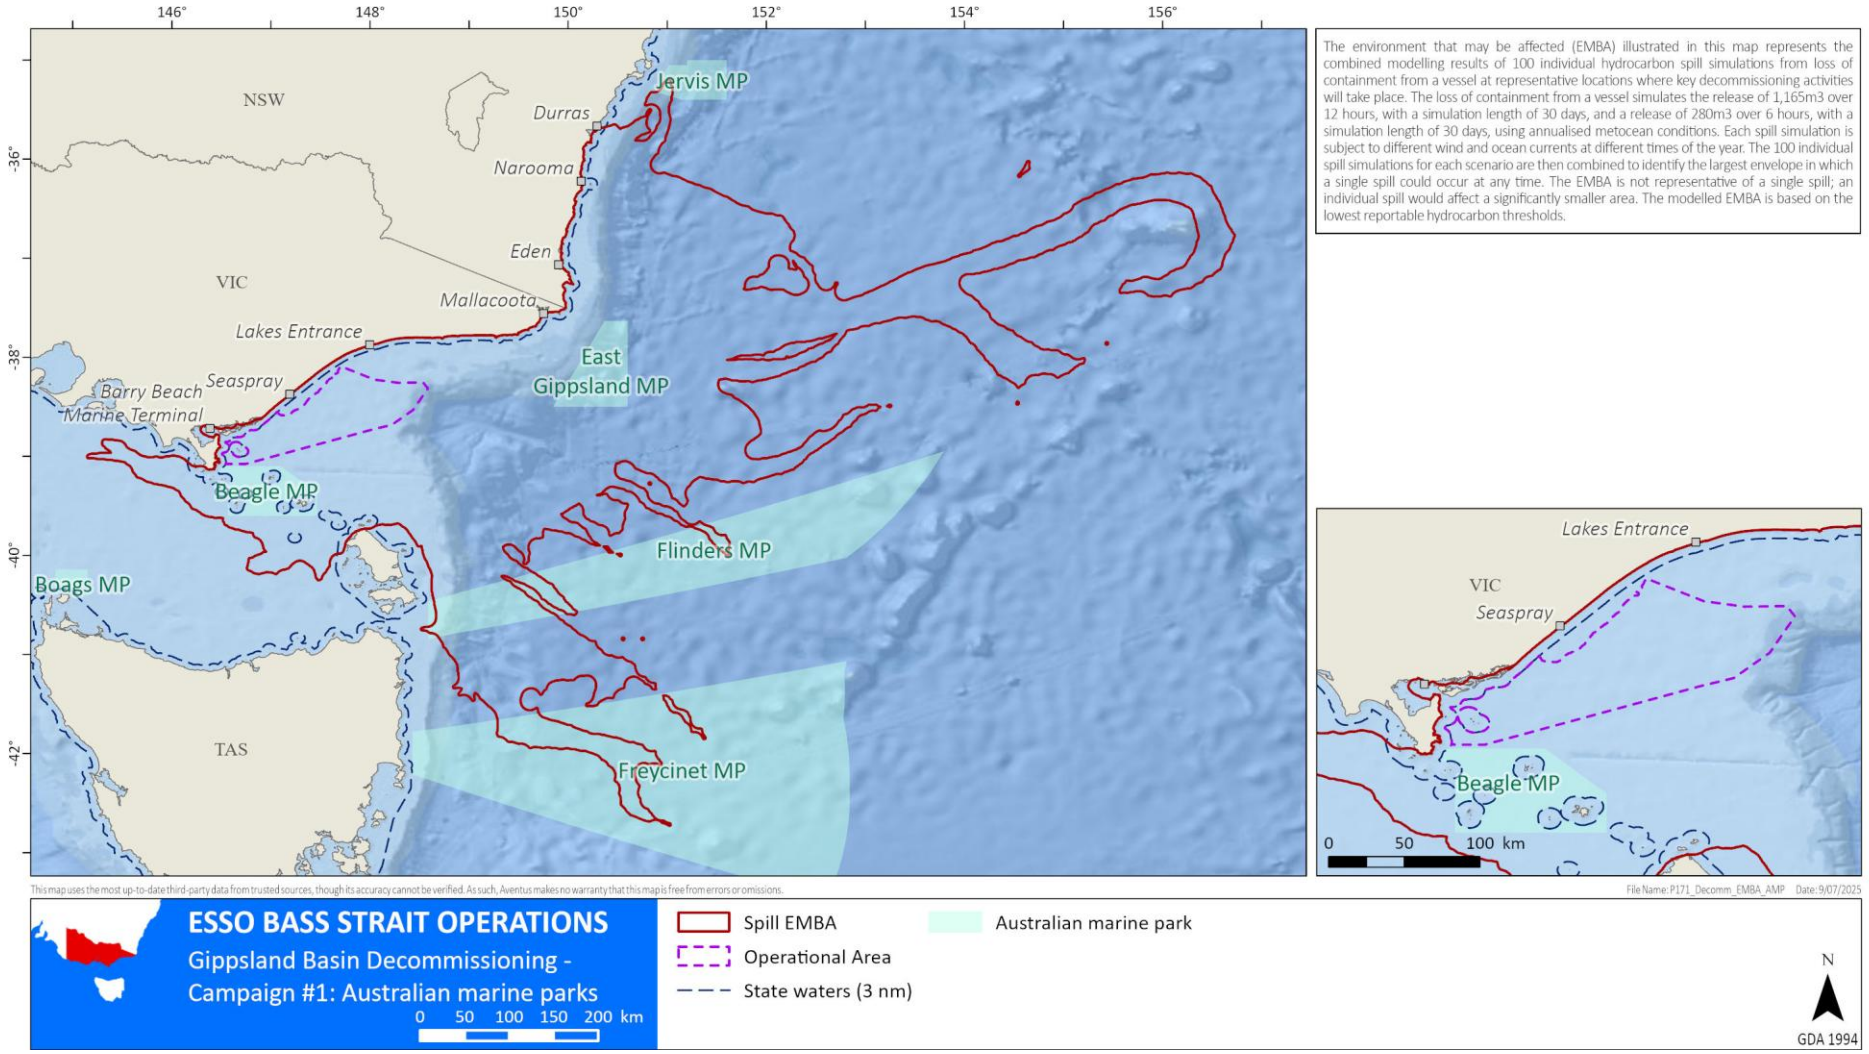

Figure A-5 AMPs intersected by the EMBA

A.1.1.8 Key Ecological Features

KEFs are defined in Table 3-2 of the EP. KEFs within the EMBA are described below and shown in Figure A-6.

A.1.1.8.1 Upwelling East of Eden (South–east Marine Region)

The Upwelling East of Eden is present along the eastern Victorian and southern New South Wales coasts and is defined as a KEF as it is an area of high productivity and aggregations of marine life (DCCEEW, n.d.(b)).

The East Australian Current brings warm subtropical water from the north and forms large eddies around Cape Howe which interact with the varied seafloor terrain, causing upwelling of cooler waters. The mixing of cool and warm water creates phytoplankton blooms that support an abundance of zooplankton, fish, marine mammals and seabirds (Director of National Parks, 2025). As a result, the upwelling supports regionally high primary productivity that supports fisheries and biodiversity, including top order predators, marine mammals, and seabirds.

This area is one of two feeding areas for blue whales (*Balaenoptera musculus*) and humpback whales, known to arrive when significant krill aggregations form. The area is also important for seals, other cetaceans, sharks, and seabirds (Director of National Parks, 2025).

A.1.1.8.2 Big Horseshoe Canyon (South–east Marine Region)

Big Horseshoe Canyon is defined as a KEF as it is an area of high productivity and aggregations of marine life. The KEF lies south of the coast of eastern Victoria. This feature is the eastern most arm of the Bass Canyon system (Director of National Parks, 2025).

The steep, rocky slopes of the Big Horseshoe Canyon provide hard substrate habitat for attached large epifauna. Sponges and other habitat forming species provide structural refuges for benthic fishes, including the commercially important pink ling (Director of National Parks, 2025).

The Big Horseshoe Canyon is the largest southeastern canyon sampled for benthic biodiversity (Williams, et al., 2009). It has a total area of 319km^2 in 1500m depth that supports a rich, abundant, filter-feeding benthic megafauna, and it is the only known temperate location of the stalked crinoid.

A.1.1.8.3 Shelf Rocky Reefs and Hard Substrates (Temperate East Marine Region and South-East Marine Region)

A search of the presence of this KEF within the EMBA using the Protected Matters Search Tool (PMST) identified the presence of shelf rocky reefs within the Temperate East Marine Region only. This KEF is considered a unique seafloor feature which is associated with ecological properties of regional significance (DCCEEW, n.d.(b)).

Shelf Rocky Reefs support a range of complex benthic habitats that, in turn, support diverse benthic communities. Along the continental shelf, south of the Great Barrier Reef, benthic communities on rock outcrops and boulder substrates shift from algae-dominated communities to those dominated by attached invertebrates, including dense populations of large sponges, with a mixed assemblage of moss animals and soft corals; this shift generally occurs at a depth of 45m (DSEWPAC, 2012b). Below wave-influenced areas, massive and branched growth forms of sponges are more prevalent, and sponge species richness and density generally increase with depth along the New South Wales coast.

Collectively, these invertebrates create a complex habitat-forming community that supports microorganisms and other invertebrates, such as crustaceans, molluscs, annelids, and echinoderms. These habitats also contribute to increased survival of juvenile fish by providing refuge from predation. Rocky reef habitats on Australia's east coast support a diverse assemblage of demersal fish, which show distinct patterns of association with shelf-reef habitats, e.g. jackass morwong, barracouta, orange-spotted catshark, eastern orange perch, butterfly perch and warehou are species that distinguish rocky reef habitats at depths greater than 45m from those of soft sediments (DCCEEW, n.d.(b)). Figure A-6 presents the location of this KEF based on the data available in the Marine bioregional plan for the Temperate East Marine Region (DSEWPAC, 2012b)

In addition to the outcome on the presence of shelf rocky reef obtained from the PMST this KEF is also present in the South-East Marine Region. The South-east marine region profile (DoE, 2015a) presents a combined description of shelf rocky reefs and hard substrates (also referred in that document as hard grounds), indicating they are areas where high productivity and aggregation of marine life could occur. Shelf rocky reefs and hard grounds are present in all areas of the continental shelf including Bass Strait, from the subtidal zone to the continental shelf break, which generally occurs in 50m to 150-220m depth. Shelf rocky reefs and hard grounds in the South-East Marine Region provide attachment sites for macroalgae and sessile invertebrates, increasing the structural diversity of shelf ecosystems, and provide habitat and shelter for fish (DoE, 2015a).

Similarly, the South-east Marine Parks Network Management Plan (Director of National Parks, 2025) identify the presence of shelf rocky reefs and hard substrates as one of the KEFs that can be encountered in some of the parks that are part of this network. More specifically, the marine parks within the South-east network that overlaps with the EMBA and where this KEF is reported to be present are:

- Beagle marine park: includes the mesophotic reefs between the Kent Group and the Hogan Island Group.
- Flinders marine park: includes the rariphotic reefs in the north-west of the park
- Freycinet marine park: includes the rariphotic reefs in the north-west of the park

None of the three marine parks mentioned above overlap with the operational area (OA) established for the Decommissioning - Campaign#1 project.

Although the South-east marine region profile (DoE, 2015a) and the South-east Marine Parks Network Management Plan (Director of National Parks, 2025) confirm the presence of the shelf rocky reef (and hard substrates) in this area, and provide a general indication of where this KEF may be present from the subtidal zone to the continental shelf break, this KEF has not been spatially defined and hence reef locations are not specifically known within this region.

Historical ROV surveys of platforms (based on Esso ROV inspection data from 2010, 2013 and 2014) have not detected variances in abundance of biota on the seabed surrounding the platforms that are within the scope of this EP, which may be indicative of hard substrates occurring.

The South-east Reef is mapped to exist in the VIC/L5 area and thought to possess some low-relief limestone reef features (Bax & Williams, 2001). The reef is situated in approximately 70 metres water depth, with the nearest SPJs to this feature being FTA, CBA and HLA (McLean, et al., 2022). In addition, Seamap (Seamap Australia, 2025), provides some information on presence of ecosystems such as mesophotic rocky reefs, shallow rocky reefs and rariphotic shell reefs that may be present within the depths at which the hard substrate and shelf rocky reef KEF may occur.

Figure A-6 of this EP presents the location of the hard substrate and shelf rocky reef KEF within the South-east region to the best of Esso's knowledge to date, based on the information available from government agencies, literature, and data acquired through ROV operations by Esso facilities within the Bass Strait.

A.1.1.8.4 Canyons on the Eastern Continental Slope (Temperate East Marine Region)

The Canyons on the Eastern Continental Slope are defined as a KEF as they are a unique seafloor feature with enhanced ecological functioning and integrity, and biodiversity, which apply to both its benthic and pelagic habitats (DSEWPAC, 2012b).

The Canyons on the Eastern Continental Slope lie off the coast of New South Wales. Canyon systems have a marked influence on the diversity and abundance of species through their combined effects of topography, geology, and localised currents, all of which funnel nutrients and sediments into the canyon. As such, these features are valued for their enhanced productivity and biological diversity properties. Canyons contribute to habitat diversity by providing a hard surface that offers anchoring points and vertical relief for filter feeder benthic species. Hard substrata support different species assemblages, particularly favouring large filter feeder–dominated benthic species (e.g. attached sponges and crinoids) that thrive in abundance in the enhanced current flow conditions. Large benthic animals such as sponges and feather stars are abundant, with particularly high diversity found in the upper slope regions (150 – 700m) (DSEWPAC, 2012b). A range of higher trophic level species, including crustaceans, echinoderms, bivalves, cephalopods and fish, are then attracted to these regions. Canyons, are therefore, significant contributors to overall biodiversity, particularly in terms of benthic organisms. Due to isolation, restricted dispersal, and connectivity, it is also expected this diversity encompasses a high degree of endemism, further contributing to the social and biological values of these communities (DCCEEW, n.d.(b)).

A.1.1.8.5 Seamounts South and East of Tasmania (South–east Marine Region)

The Seamounts South and East of Tasmania are defined as a KEF as they are an area of high productivity and aggregations of marine life (Director of National Parks, 2025).

These seamounts are a chain or cluster of seamounts rising from the abyssal plain, continental rise or plateau situated 200km or more from shore (east of Flinders Island to southeast of southern Tasmania). Seamounts with hard substrate summits and slopes provide attachment points for sessile invertebrates, while the soft sediments can be habitat for species that burrow into the sediments (Director of National Parks, 2025).

These seamounts create localised upwellings of nutrient rich waters from the seafloor. The hard substrate supports sessile invertebrates (DCCEEW, n.d.(b)).

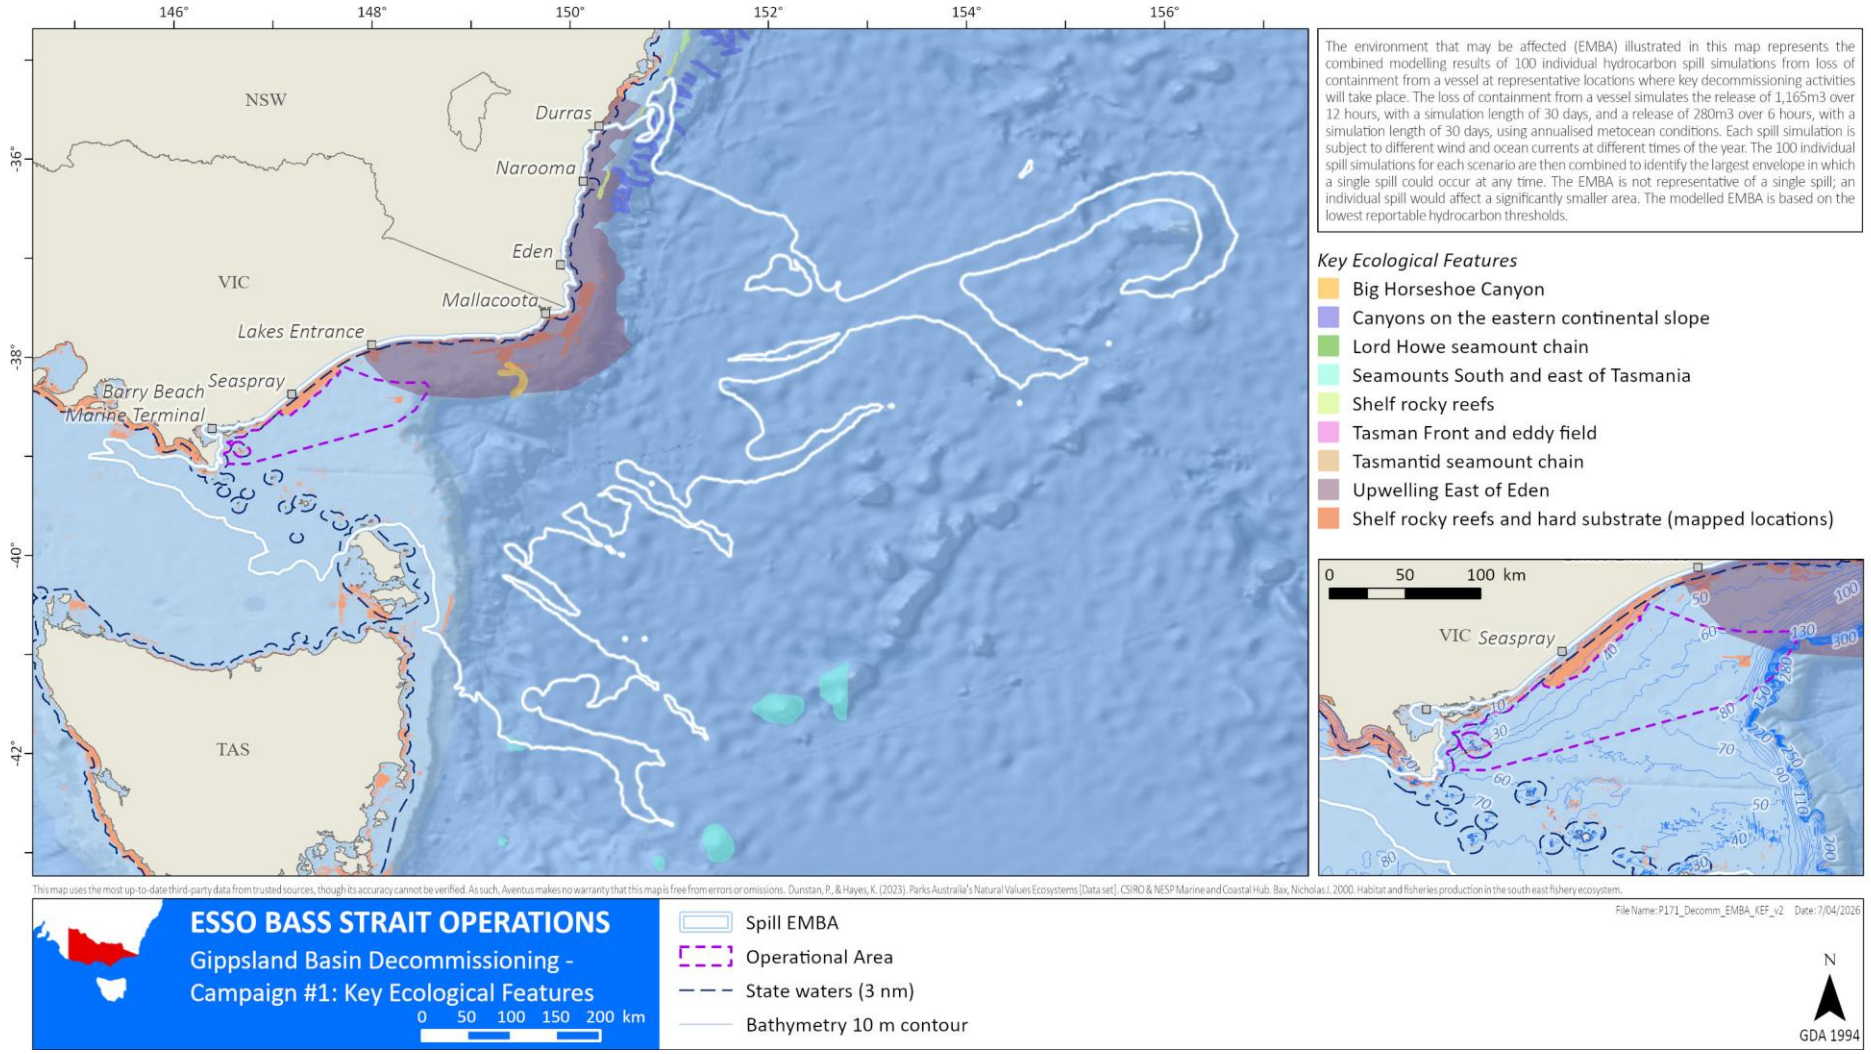

Figure A-6 KEFs intersected by the EMBA

A.1.1.9 Other protected areas

The National Reserve System is Australia's network of protected areas and is made up of Commonwealth, State and Territory reserves, Indigenous lands, and protected areas. National parks and reserves which include marine protected areas and terrestrial protected areas are declared under each individual state's legislation and are managed by State authorities.

This Section only lists the protected areas that are marine and/or coastal in nature that are intersected by the EMBA and that are spatially defined. A detailed list of other protected areas found within the EMBA can be seen in the PMST report (Appendix D of the EP). The marine/aquatic and coastal protected areas in relation to each state are mapped in Figure A-7, Figure A-8 and Figure A-9.

A.1.1.9.1 Marine/aquatic protected areas

Table A-2 lists and describes the marine/aquatic protected areas within the EMBA.

Table A-2 Marine/aquatic protected areas within the EMBA

Name	Description
Victoria (see Figure A-7)	
Beware Reef Marine Sanctuary	The Beware Reef Marine Sanctuary is a State marine protected area, Category II (IUCN), located approximately 5km southeast of Cape Conran, comprising of a granite outcrop covering an area of 220ha and extending approximately 500m from the edge of the exposed reef. It rises from a depth of approximately 30m and is exposed at low tide, providing a resting area for Australian fur seals (Victorian National Parks Association, 2016). The reef is covered by outcrops of bull kelp (*Durvillaea sp.*) and supports a range of marine life, including seahorses and leafy sea dragons (Parks Victoria, n.d.(a)). Beware Reef is a popular location for recreational divers and the remains of numerous shipwrecks can be encountered in the sanctuary.
Cape Howe Marine National Park	The Cape Howe Marine National Park is situated in the far east of Victoria alongside the border with New South Wales. The habitats found in the park include kelp forests, granite and sandstone reefs, sandy beaches and soft sediments. The marine life of the area is particularly diverse because species of both warm and cool areas can reside here. Whales pass by Cape Howe on their migration from Antarctica and are sometimes followed by a pod of orcas. Little penguins also forage at the rook on Gabo Island (Parks Victoria, n.d.(b)).
Corner Inlet Marine and Coastal Park	Corner Inlet Marine National Park is located north and east of Wilsons Promontory adjacent to the southern shores of Corner Inlet and covers an area of 1550ha. The national park protects large areas of seagrass including the only extensive *Posidonia australis* meadow in southern Australia. Amongst the seagrass over 300 marine invertebrates live including crabs, seastars, sea snails, squid and many fish including pipefish, stingrays, flathead, whiting and flounder. The seagrass and surrounding marshes are particularly important for international migratory birds such as the eastern curlew (Parks Victoria, n.d.(c)). The area has been listed as part of the Corner Inlet Ramsar site.
Ninety Mile Beach Marine National Park	Ninety Mile Beach Marine National Park is located 30km south of Sale and adjacent to Gippsland Lakes Coastal Park and covers 5km of coastline. The huge subtidal sandy expanses characteristic of the area exhibit particularly high species diversity including tube building worms, small molluscs and many tiny crustaceans. Many pelagic fish species feed on the benthos, and young great white sharks have also been observed feeding in the area (Parks Victoria, n.d.(d)).

Name	Description
Nooramunga Marine and Coastal Park	Nooramunga Marine and Coastal Park covers an area of 30,170ha in Corner Inlet. The park consists of shallow marine waters, intertidal mudflats and a series of over 40 sand islands. The park, along with the Corner Inlet Marine and Coastal Park to its west, contains the largest stands of white mangrove and saltmarsh areas in Victoria. The saltmarshes are dominated by beaded glasswort (*Sarcocornia quinqueflora*) and shrubby glasswort (*Tecticornia arbuscula*). Seagrass meadows also occur throughout the park. Seaward of the mangroves are extensive areas of intertidal mud and sand flats. An immense range of marine plants and invertebrates can be found here that provide food for the thousands of migratory wading birds that arrive each year from their Northern Hemisphere breeding grounds. The seagrass meadows provide habitat to over 300 marine invertebrates, including a range of large crabs, seastars, sea snails, iridescent squid and many fish including pipefish, stingarees, flathead, whiting and flounder. Finfish such as snapper, King George whiting, flathead, garfish and salmon are caught by recreational fishers. Thirty-two migratory wader species have been recorded in the park.
Point Hicks Marine National Park	The Point Hicks Marine National Park is located alongside Croajingolong National Park, East Gippsland. Many creatures found here are not found further west because the water is too cold, for example the large black sea urchin. The park is approximately 4000ha in area, with fauna including intertidal and shallow subtidal invertebrates, diverse sessile invertebrates living on subtidal reefs, kelps and small algae, and a high diversity of reef fish. In addition to the subtidal reef, the marine environment around Point Hicks includes intertidal rock operational areas and offshore sands (Parks Victoria, n.d.(e)). Point Hicks Marine National Park is also a popular location for recreational divers. Remains of two shipwrecks can be encountered in the park.
Wilsons Promontory Marine National Park, Marine Park and Marine Reserve	Wilsons Promontory Marine National Park is Victoria's largest marine protected area at 15,604ha, is located around the southern tip of Wilsons Promontory, is classified as Category II (IUCN), and the Parks Victoria level of protection is established as 'Marine A' (refer to Appendix A of the *Wilsons Promontory Conservation Action Plan for parks and reserves managed by Parks Victoria* (Parks Victoria, 2017)). Wilsons Promontory Marine Park is located along the western and eastern coastlines of Wilsons Promontory. The southern end of the western section limits with the marine national park, whilst the southern end of the eastern section limits with an area of the marine reserve. The marine park also covers the Shellback Island, Norman Island, and Rabbit Island (Parks Victoria, 2006). Extension of the park is 5566ha and it is classified as Category IV (IUCN), and the Parks Victoria level of protection is established as 'Marine B' (Parks Victoria, 2017). Wilsons Promontory Marine Reserve is divided into two separate areas: one area to the west of Wilsons Promontory, covering the Glennie Group of islands; the second area covers a small section of the eastern coastline of Wilsons Promontory, between Refuge Cove to the north and Cape Wellington to the south (Parks Victoria, 2006). Extension of the reserve is 627ha and is classified as Category IV (IUCN), and the Parks Victoria level of protection is established as 'D' (Parks Victoria, 2017). The Wilsons Promontory Marine Park and Wilsons Promontory Marine Reserve complement the Wilsons Promontory Marine National Park system and protect other important values within this area. These three systems fall under the same planning area, covering a total of 22,075ha, and are governed under the *Wilsons Promontory*

Name	Description
	Marine National Park and Wilsons Promontory Marine Park Management Plan (Parks Victoria, 2006) implemented by Parks Victoria. There is a diversity of marine life including octopus, sharks and rays. It is a popular location for recreational divers particularly around the sponge gardens. The offshore islands, including Anser Island, support many colonies of fur seals and oceanic birds such as little penguins, fairy prions, silver gulls and Pacific gulls (Parks Victoria, 2017). Wilsons Promontory National Park is a popular tourist destination due to its coastal scenery and diverse natural environments. Tourist activities include walking, camping, sightseeing, viewing wildlife, fishing, boating, diving, sea kayaking and surfing. The park is important for its range of plants and animals, including many threatened species including the New Holland mouse, ground parrot and white-bellied sea eagle. Coastal features include expansive intertidal mudflats, sandy beaches and sheltered coves interrupted by prominent headlands and granite cliffs in the south, backed by coastal dunes and swamps. The avifauna recorded for Wilsons Promontory includes around half of all Victorian bird species. Significant species of migratory wading birds feed on the tidal mudflats of Corner Inlet within and adjoining the park. The offshore islands have breeding and roosting sites for sea birds, including a large number of short-tailed shearwaters (Parks Victoria, 2017). Natural values of significance of the Wilsons Promontory Marine Protected Areas include but are not limited to: • abundant and diverse marine flora and fauna, including hundreds of fish species and invertebrates such as sponges, ascidians, sea whips and bryozoans • 126 species of marine flora and fauna at, or presumed to be at, their eastern or western distributional limits • important breeding populations of several seabird species, Australian fur seals and New Zealand fur seals, including one of the largest Australian fur seal breeding populations in the State • important habitat for several threatened shorebird species, including species listed under international migratory bird agreements • part of a nationally significant area for the recovery of great white shark populations. Four marine conservation assets have been identified in the Wilsons Promontory Park Landscape, including the 'Coastal (including islands)' asset. This asset, and all marine habitats, are in very good condition (Parks Victoria, 2017). The *Wilsons Promontory Conservation Action Plan for parks and reserves managed by Parks Victoria* (Parks Victoria, 2017) establishes that Australian and New Zealand fur seals are of particular importance, as they breed on some islands within the park, they play a pivotal role as marine apex predators and, along with seabirds, are an important vector for the transfer of marine nutrients to the terrestrial ecosystems of the islands and are of importance for ecotourism operators. As such, fur seal breeding populations (Australian and New Zealand fur seals) have been identified as one of the three nested assets within the more general 'Coastal (including islands)' asset. Kanowna Island hosts one of the four largest breeding population of fur seals in Victoria, and the current extent of the breeding population is expanding and now also occurring at Rag Island (Parks Victoria, 2017), which is part of the group of islands that are located within the Seal Islands Wildlife Reserve. Conservation outcome for the 'Coastal (including islands)' asset of the Wilsons Promontory Marine National Park includes, that over the 15 years to 2031, suitable conditions for fur seals haul-out and breeding are maintained (Parks Victoria, 2017).

Name	Description
Tasmania (see Figure A-8)	
Kent Group National Park	The Kent Group National Park includes is Tasmania's northernmost national park and comprises six islands and islets of the Kent Group (Erith, Dover, Deal, North East Isle, South West Isle and Judgement Rocks). Surrounding the largest of the islands, the Kent Group Marine Reserve covers 29,000ha of marine habitat including deep and shallow reefs as well as extensive sponge beds (State of Tasmania, 2009). The waters around the Kent Group include the southernmost strongholds of several fish species including the violet roughy, mosaic leatherjacket and Wilson's weedfish, and the southern limit of distribution of Maori wrasse, one spot puller and Bank's shovelnose. The Kent Group Marine Reserve is made up of a sanctuary zone which is a 'no take' zone, and a habitat protection zone which allows for lower impact fishing (e.g. abalone and rock lobster fishing, hand line fishing). The North East Isle is a 32.62ha unpopulated granite island with a peak elevation of 125m above sea level. Recorded breeding seabird and wader species include little penguin, short-tailed shearwater, fairy prior, common diving petrel, Pacific gull and sooty oystercatcher (Brothers, Pemberton, Pryor, & Halley, 2001).
New South Wales (see Figure A-9)	
Batemans Marine Park	The Batemans Marine Park was established in 2006 and covers approximately 85,000ha, extending from the north end of Murramarang Beach near Bawley Point to Wallaga Lake in the south. It includes all of the seabed and waters from the mean high-water mark on the coast to 3nm offshore, Including all estuaries, creeks, rivers and lakes (except Nargal Lake) to the limit of tidal influence. Scuba diving, snorkelling, beach going, whale, seal and other wildlife watching, fishing, swimming, surfing, and boating are all popular pastimes at this park. The park covers a range of habitats, including continental shelf seafloor along with sponge gardens, beaches, rocky shores, kelp beds, coralline algal banks, rocky reefs, islands, seagrass, mangroves, and estuarine habitats. The Montague Island Nature Reserve, within the marine park, is a breeding and nesting place for over 40,000 sea birds including shearwaters, little penguins, crested terns and silver gulls and is a haul out site for Australian and New Zealand fur seals. Both Montague Island and the Tollgate Islands (also within the park) are aggregation sites for grey nurse sharks (DPI (NSW), 2018).

A.1.1.9.2 Coastal protected areas

This Section lists the coastal protected areas that are within the EMBA.

- Victoria (see Figure A-7):
  - Anser Island Reference Area
  - Bemm, Goolengook, Arte and Errinundra Rivers
  - Cape Conran Coastal Park
    - This park extends from Sydenham Inlet in the east to Point Ricardo near Marlo. The park includes ocean beaches and is a popular park for water activities - swimming, diving, boating, fishing and rock pooling. Many birds feed on the nectar rich plants of the heathlands and banksia woodlands including the threatened ground parrot (*Pezoporus wallicus wallicus*). Lizards and large lace monitors are common around Cape Conran (Parks Victoria, n.d.(f)).
  - Cape Howe Wilderness Zone
  - Croajingolong National Park

- The Croajingolong National Park follows the far-eastern coastline of Victoria for 100km and was previously classified as a UNESCO World Biosphere Reserve. However, in 2020, this National Park was voluntarily withdrawn as a Biosphere Reserve (DCCEEW, 2022a). Over 1000 species of native plants have been recorded in the park including 90 species of orchids. The park also contains areas of cool temperate and warm temperate rainforest, eucalypt forest and coastal heathland. Of the 52 mammal species recorded in the park, arboreal mammals, such as possums, gliders and bats are common. Seals, whales, and dolphins occur in coastal waters adjacent to the park. The islands and ocean beaches attract migratory seabirds and waders, the wetlands are habitat for a diversity of waterfowl and the coastal woodlands are favoured habitat for birds of prey; the Nadgee Lake and tributary wetlands are a recognised NIW. Significant populations of reptiles and amphibians also occur within the park. The park's secluded coastal camping locations make it popular for beach walks, bird watching, boating and fishing (Parks Victoria, n.d.(g)).

- East Gippsland Coastal streams
- Ewing Morass Natural Features Reserve
- Gippsland Lakes Coastal Park
  - The Gippsland Lakes are a group of large coastal lagoons in eastern Victoria, separated from the sea by sand dunes and fringed on the seaward side by Ninety Mile Beach. The main lakes - Wellington, Victoria and King cover an area of 340km^2 and have a shoreline of 320km. The lakes are fed by a number of river systems. The largest of the rivers are the Latrobe River and the Avon River (flowing into Lake Wellington), and the Mitchell River, Nicholson River and Tambo River (flowing into Lake King). The system is linked to the sea by an artificial entrance near the eastern end, opened in 1889, where the town of Lakes Entrance is now situated (Parks Victoria, n.d.(h)) (Parks Victoria, n.d.(i)).
- Jack Smith Lake W.R Natural Features Reserve
- Lake Tyers S.P. State Park
  - Ewing Morass Wildlife Reserve and Lake Tyers State Park are located along Pettmans Beach, approximately 20km east of Lakes Entrance. It is an extensive sandy beach, frequented by campers and fishers. The area is highly significant to Gunaikurnai Traditional Owners due to its Aboriginal cultural heritage (Parks Victoria, n.d.(j)).
- Mount Vereker Creek Natural Catchment
- Rame Head Remote and Natural Area
- Sandpatch Wilderness Zone
- Seal Islands W.R. Nature Conservation Reserve
  - Seal Island Wildlife Reserve is part of the parks and reserves within the Wilsons Promontory Park Landscape that is managed by Parks Victoria. The extension of the reserve is 36ha and it is classified as Category IV (IUCN), and the Parks Victoria level of protection is established as 'D' level (Parks Victoria, 2017). General description of the natural values and conservation assets, which include information on fur seals, is presented in Table A-2 in the Wilsons Promontory Marine National Park section.
- Snowy River
- Southern Wilsons Promontory Remote and Natural Area
- Vereker Creek Reference Area
- Wilsons Promontory National Park
- Wilsons Promontory Islands Remote and Natural Area
- Wilsons Promontory Wilderness Zone

- Tasmania (see Figure A-8):
  - Bass Pyramid Nature Reserve
  - Blyth Point Conservation Area
  - Cone Islet Conservation Area
  - Craggy Island Conservation Area

- Curtis Island Nature Reserve
    - Curtis Island, part of the Curtis Group, is a granite island with an area of 150ha lying in northern Bass Strait between the Furneaux Group and Wilsons Promontory. Curtis Island is a nature reserve and supports up to 390,000 breeding pairs of short-tailed shearwaters. Other recorded breeding seabird and wader species include little penguin, fairy prion, Pacific gull and sooty oystercatcher. Other islands in the Curtis Group are Cone Islet, Sugarloaf Rock and Devils Tower. Devils Tower comprises two small granite islands with a combined area of 4.77ha. It is a nature reserve and recorded breeding seabird species include short-tailed shearwater, fairy prion and common diving-petrel. The island is also used as a regular haul-out site for Australian fur seals (Brothers, Pemberton, Pryor, & Halley, 2001).
- Devils Tower Nature Reserve – see description above.
- East Moncoeur Island Conservation Area
    - West Moncoeur Island and East Moncoeur Island are part of Tasmania's Rodondo Group lying in northern Bass Strait south of Wilsons Promontory. The islands are granite islands ringed by steep cliffs. Recorded breeding seabird and wader species include little penguin, short-tailed shearwater, fairy prion, common diving petrel, Pacific gull and sooty oystercatcher. Both islands are considered important breeding sites for seabirds (Brothers, Pemberton, Pryor, & Halley, 2001). West Moncoeur Island holds an important breeding colony of Australian fur seals and is a nature reserve (Coastcare, 2000).
- Hogan Group Conservation Area
    - Hogan Island, the largest island in the Hogan Group, is a 232ha granite island located in northern Bass Strait between the Furneaux Group and Wilsons Promontory. Recorded breeding seabird and wader species include little penguin, short-tailed shearwater, Pacific gull, silver gull and sooty oystercatcher (Brothers, Pemberton, Pryor, & Halley, 2001). Other islets of the group include: Twin, Long, Round, East, Boundary (or North East) islets, and Seal Rock.
- Jacksons Cove Conservation Area
- Mount Tanner Nature Recreation Area
- North East Islet Nature Reserve
- North East River Game Reserve
- Rodondo Island Nature Reserve
- Sentinel Island Conservation Area
- Sister Islands Conservation Area
- Sugarloaf Rock Conservation Area
- West Moncoeur Island Nature Reserve
    - West Moncoeur Island and East Moncoeur Island are part of Tasmania's Rodondo Group lying in northern Bass Strait south of Wilsons Promontory. The islands are granite islands ringed by steep cliffs. Recorded breeding seabird and wader species include little penguin, short-tailed shearwater, fairy prion, common diving petrel, Pacific gull and sooty oystercatcher. Both islands are considered important breeding sites for seabirds (Brothers, Pemberton, Pryor, & Halley, 2001). West Moncoeur Island holds an important breeding colony of Australian fur seals and is a nature reserve (Coastcare, 2000).
- Wright Rock Nature Reserve

- New South Wales (see Figure A-9):
    - Ben Boyd National Park
    - Biamanga National Park
    - Bournda National Park
        - Bournda has been a special place for the Dhurga and Yuin people for thousands of years and its name means ‘place of tea tree and kangaroos’. The estuarine wetlands provide roosting and feeding areas for a large variety of waders and waterfowl including threatened species such as little tern, hooded plover and pied oystercatcher (NPWS, n.d.(a)).

- Broulee Island Nature Reserve
    - Broulee Island Nature Reserve is located on the south coast of New South Wales and covers the entire 43ha of Broulee Island to mean high water mark. Broulee Island Nature Reserve contains a vegetation succession from mangroves on the shoreline rock platforms to an open forest dominated by southern mahogany on the plateau. The shoreline and adjacent waters are utilised by a number of seabird species, none of which are known to breed on Broulee Island; these include shearwaters, cormorants, gulls (NPWS, 2008).
- Eurobodalla National Park
    - Eurobodalla National Park contains a range of aquatic environments including lagoons, lakes, estuaries, sheltered and wild beaches that protect a wide variety of plants and animals. The park provides an important habitat for a wide variety of birds with 131 bird species having been recorded in the park. Estuaries and headlands are important over-wintering areas for migratory birds, including 17 species of waders, and the hooded plover and little tern nest on the sand islands, sand spits and dunes. Water based activities such as boating, fishing and swimming are all popular in the park (NPWS, n.d.(b)).
- Mimosa Rocks National Park
    - Mimosa Rocks National Park takes its name from the Paddle Steamer *Mimosa* that wrecked in 1863 after running aground on rocks at the northern end of the park. The rocks of the park have distinctive castle-like features that are the result of geological folds, faults and intrusions. The park provides important habitat for many migratory birds, including hooded plovers and pied oystercatchers that nest along the coastline. The bar tailed godwit rests briefly here in summer months during its migration from Alaska to New Zealand. The park is popular for fishing, surfing, snorkelling and birdwatching. From May to November, the headlands are excellent whale watching vantage points (NPWS, n.d.(c)).
- Montague Island Nature Reserve
    - The Montague Island Nature Reserve, within the Batemans Marine Park, is a breeding and nesting place for over 40,000 sea birds including shearwaters, little penguins, crested terns and silver gulls and is a haul out site for Australian and New Zealand fur seals. Both Montague Island and the Tollgate Islands (also within the park) are aggregation sites for grey nurse sharks.
- Murramarang National Park
    - Murramurang National Park spans 44km of coastline on the New South Wales south coast and supports more than 90 species of bird including gannets, shearwaters, white-faced storm petrels, sooty oystercatchers and little penguins. The forest of spotted gums stretches right to the ocean (NPWS, n.d.(d)). The park includes four offshore Islands and encompasses Brush Island Nature Reserve, Belowla Island Nature Reserve and Tollgate Islands Nature Reserve.
- Nadgee Nature Reserve
- Tollgate Islands Nature Reserve

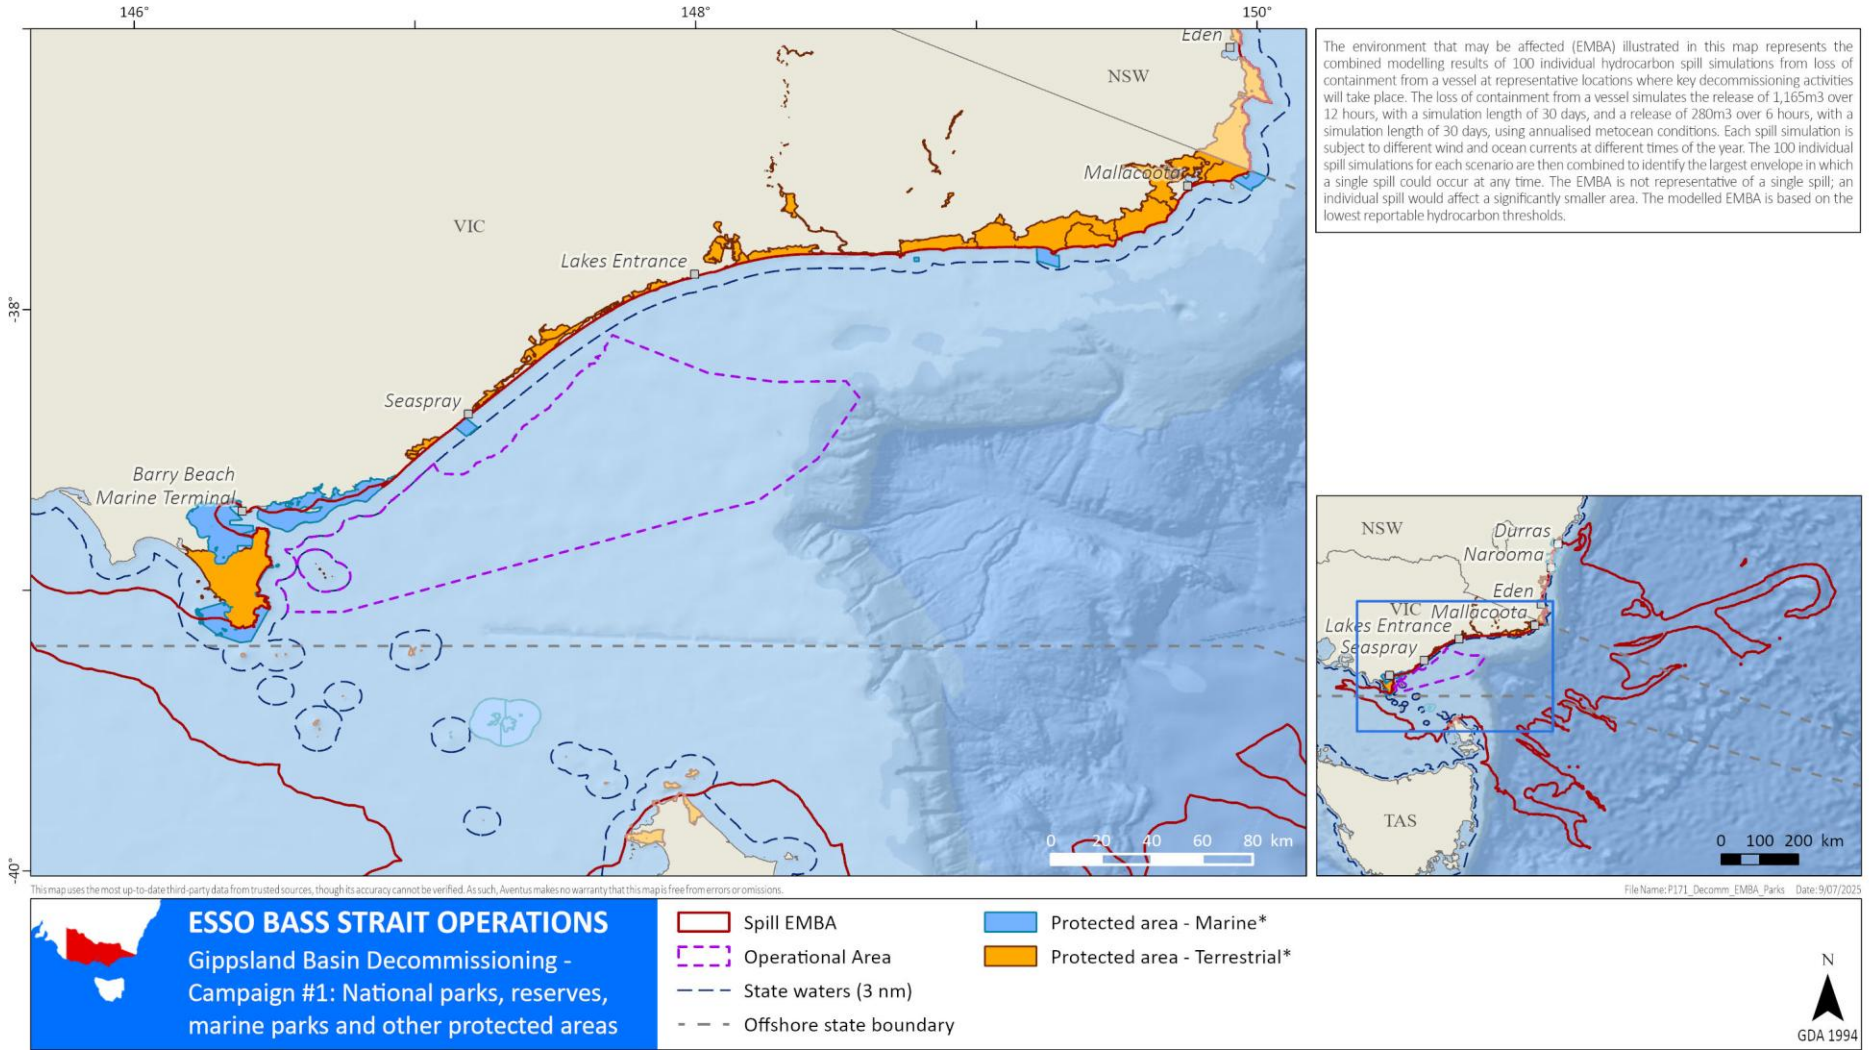

Figure A-7 Victorian protected areas intersected by the EMBA

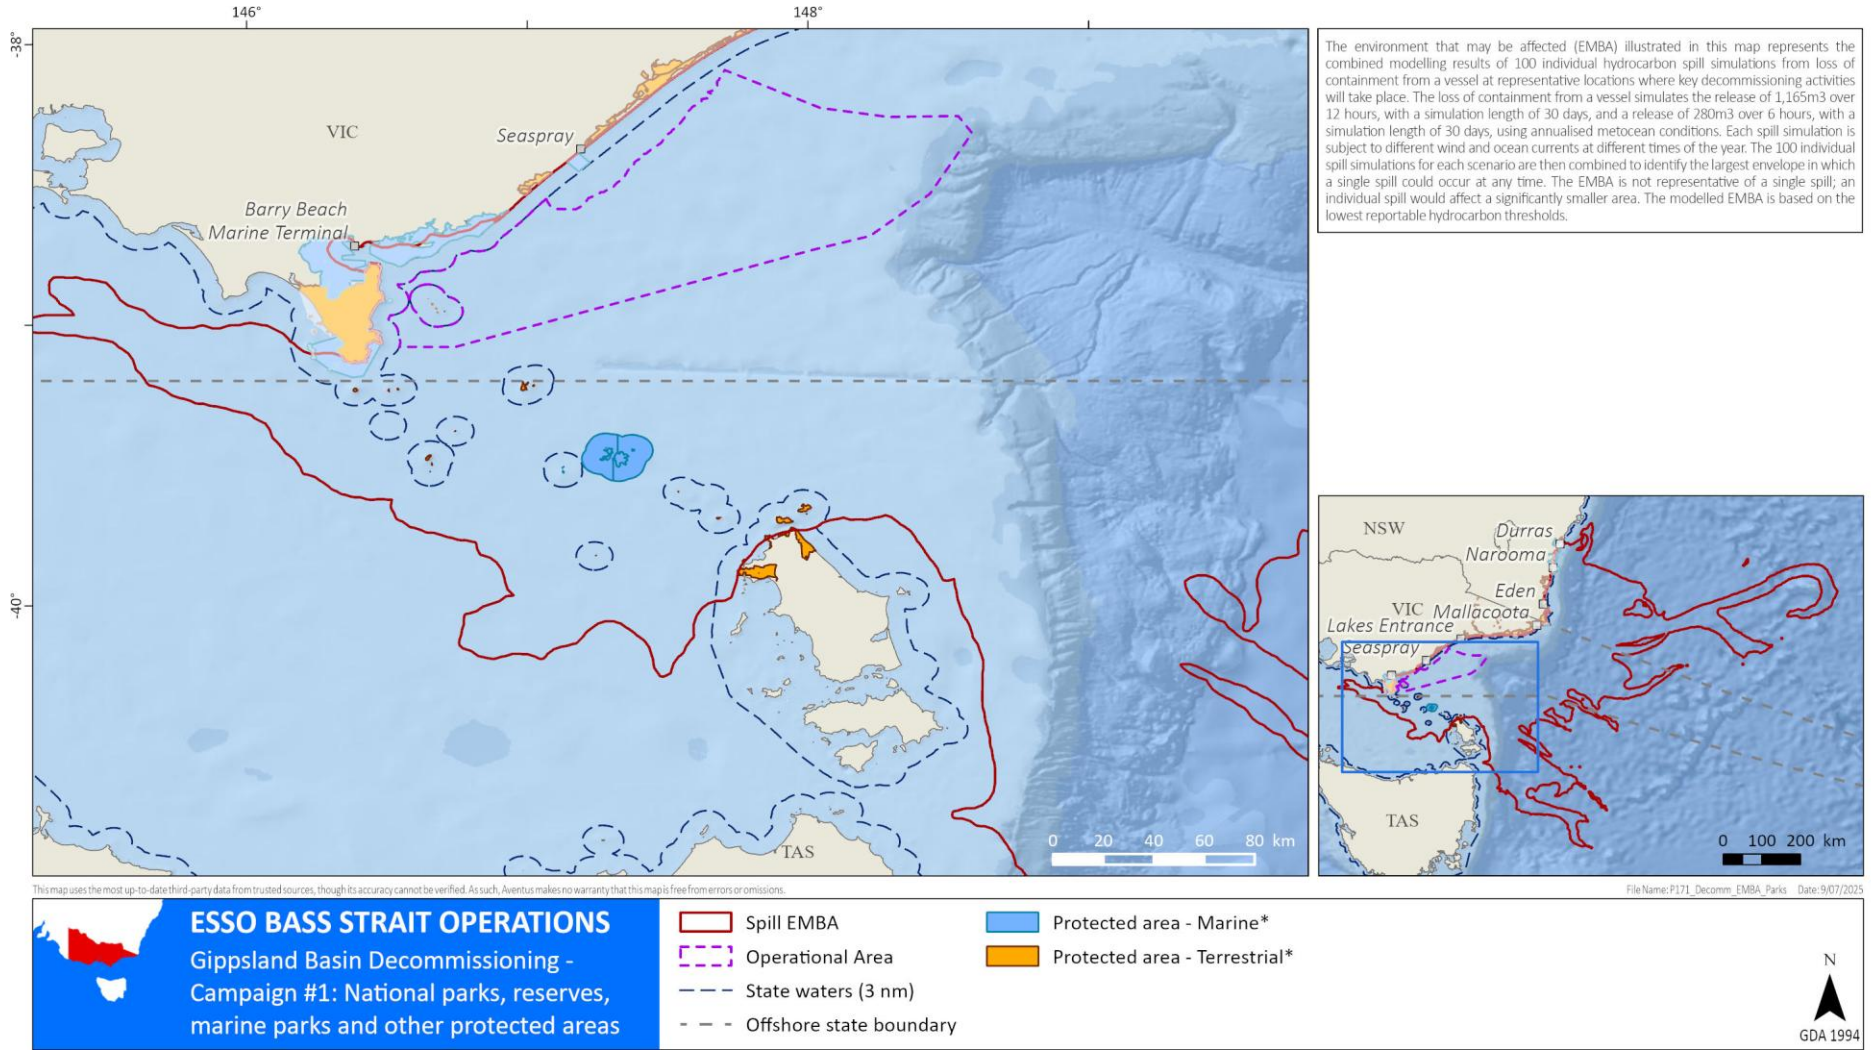

Figure A-8 Tasmanian protected areas intersected by the EMBA

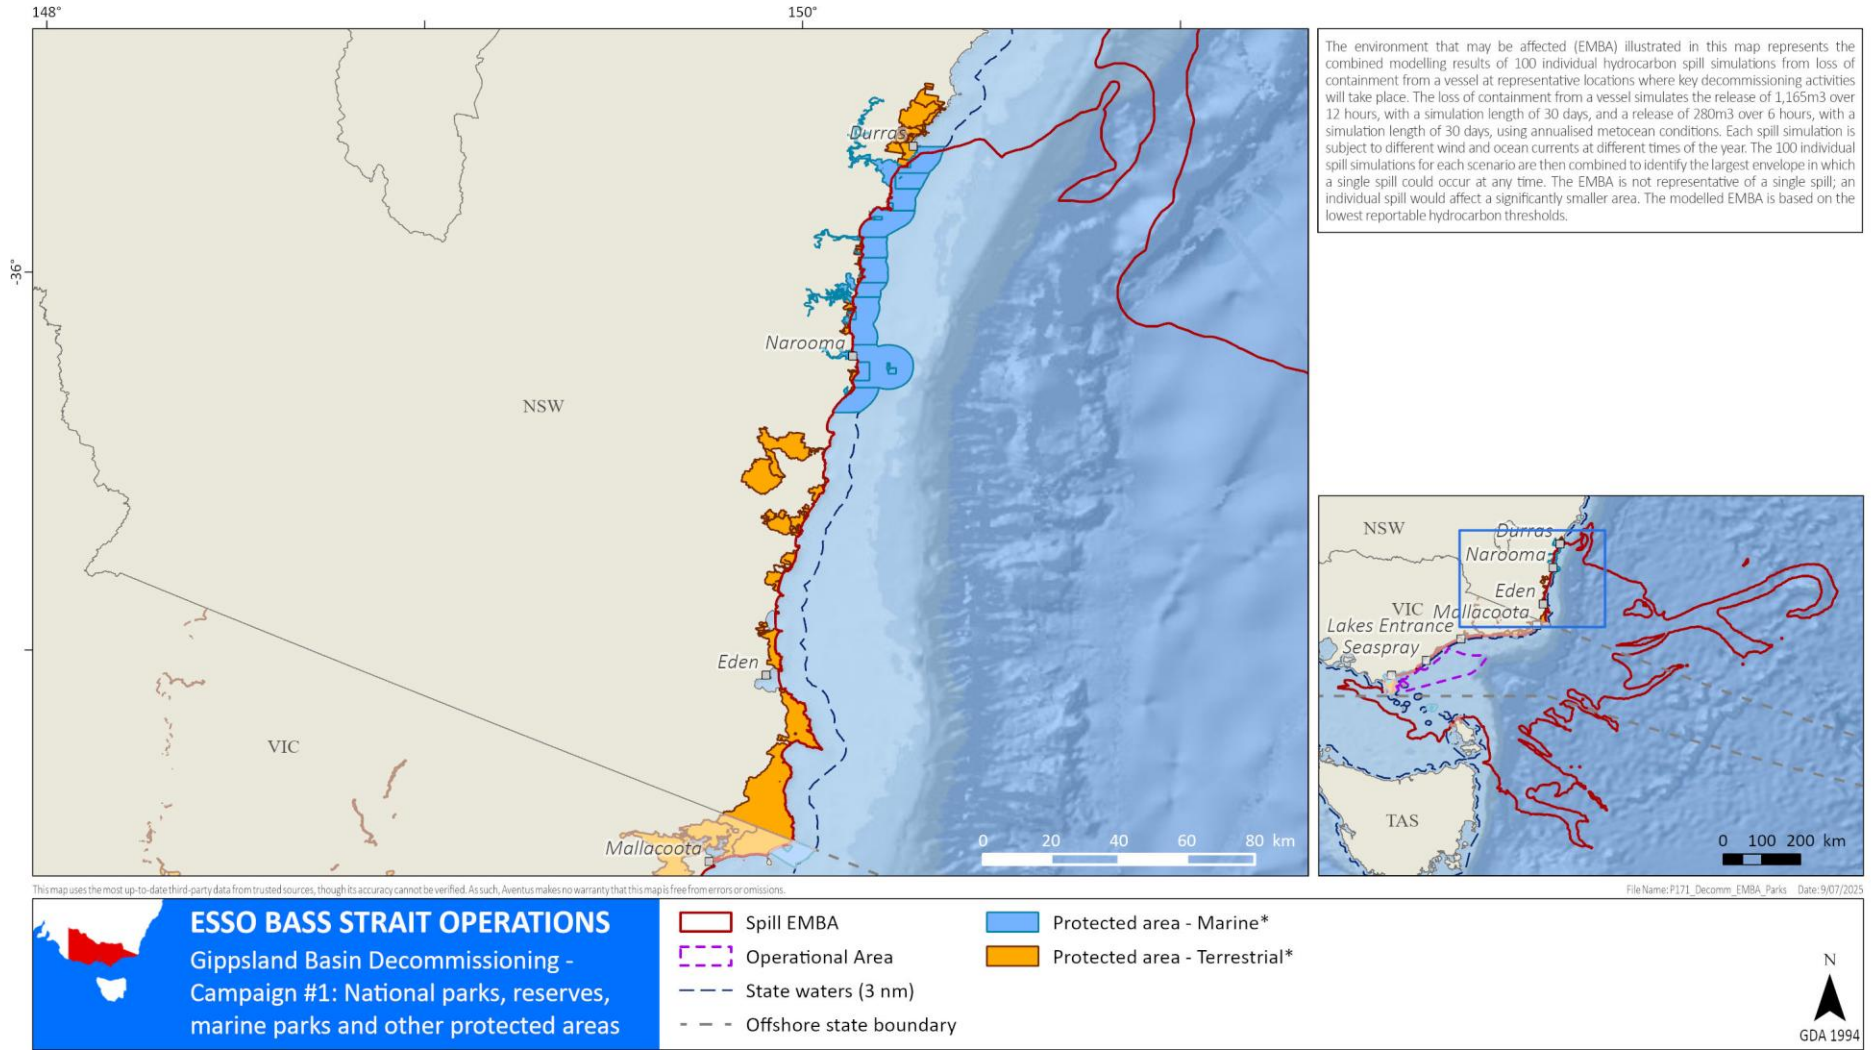

Figure A-9 New South Wales protected areas intersected by the EMBA

A.1.2 Regional context

The regional context of the EMBA is described in this Section.

A.1.2.1 Commonwealth marine regions

Six marine regions have been identified in Commonwealth waters around Australia. Australia has one of the largest marine jurisdictions of any nation in the world. Australian waters cover 14.7 million km^2, including waters around the external territories of Cocos (Keeling), Christmas, Heard and McDonald Islands as well as waters adjacent to Australia's Antarctic Territory.

The EMBA lies within two marine bioregions; the southeast marine region and the temperate east region, which are described below.

A.1.2.1.1 South-east Marine Region

The South-east Marine Region includes the Commonwealth waters of Bass Strait and those surrounding Macquarie Island in the Southern Ocean. The region spans approximately 1.6 million km^2, from the warm temperate waters in the north of the region, through the cool temperate waters around Tasmania, to the subantarctic Southern Ocean waters around Macquarie Island. The key conservation values of the South-east Marine Region are (DoE, 2015a):

- features eight KEFs with high biodiversity and productivity, including the East Tasmania subtropical convergence zone, Bass Strait Water Cascade, Upwelling East of Eden, seamounts south and east of Tasmania, shelf rocky reefs and hard substrates and Bonney Upwelling
- breeding and resting areas for SRW
- migration areas for blue, fin, sei, humpback whales and SRW
- foraging areas for Australian sea-lion, white shark, Harrisson's dogfish, killer and sei whales, Australasian gannet, fairy prion, black-faced cormorant, little penguin, crested tern, and several species of seal, penguin, albatross, petrel, shearwater and gulls
- wrecks of *MV City of Rayville*, *SS Cambridge* and ketch *Eliza Davies*
- 10 provincial bioregions and 17 seafloor types are represented in the network.

In 2013, the Director of National Parks issued the first management plan for the South-east Marine Parks Network of marine reserves (Director of National Parks, 2013), which expired in 2023. As a result, the Director of National Parks prepared the *South-east Marine Parks Network Management Plan 2025* (Director of National Parks, 2025) that sets out management of this network from 2025 to 2035. This management plan has been approved by the Minister for the Environment and Water and came into effect from the 13 February 2025.

The 2025 management plan presents a description of the conservation values, which include natural, cultural, and socio-economic values. From the natural values perspective, this version reinforces the importance of values referenced in the superseded version, including the presence of KEFs, BIAs ecosystems and habitat or species that are particularly important due to their uniqueness, functional importance, vulnerability, biological productivity, diversity or ability to provide social and economic benefit. From a cultural values perspective, the plan now in force incorporates additional important values such as:

- 'Ancient land bridge', describing that areas now under the sea in the South-east Marine Parks Network were once part of the landscape used by First Nations people
- 'Culturally significant species', acknowledging that cultural obligation to care for mutton birds, seals and whales and other marine animal resources as well as the interconnectivity between coastal and offshore marine environments
- 'Songlines and stories', acknowledging that First Nations people continue to honour ancient saltwater songlines, migrations, stories and ancestral connections (Director of National Parks, 2025).

Underwater cultural heritage (UCH), acknowledging that shipwrecks, sunken aircrafts and other kinds of underwater artefacts can be protected for their cultural heritage significance under the *Underwater Cultural Heritage Act 2018* (Cth) (UCH Act).

A.1.2.1.2 Temperate East Marine Region

The Temperate East Marine Region spans an area of approximately 1.4 million km^2 from the southern boundary of the Great Barrier Reef in Queensland to Bermagui in southern New South Wales. The key conservation values of the Temperate East Marine Region are (DSEWPAC, 2012b):

- features with high biodiversity and productivity such as the Canyons of the Eastern Continental Slope and Shelf Rocky Reefs
- nesting sites for listed seabirds on islands along the New South Wales coast, including Montague Island (short-tailed shearwater, sooty shearwater)
- breeding sites for little penguin, shearwater, Wilson's storm petrel, crested tern
- migration areas for humpback whale
- breeding sites for Indo-Pacific bottlenose dolphin
- foraging sites for several species of petrel, albatross, shearwater
- three provincial bioregions.

1.1.1 Provincial bioregions

Based on the *Integrated Marine and Coastal Regionalisation of Australia (IMCRA) v4.0 - Provincial Bioregions* (DCCEEW, 2023a), the EMBA is situated within the following provincial bioregions (see Figure A-10):

- Bass Strait Shelf Province
- Central Eastern Province
- Southeast Shelf Transition
- Southeast Transition
- Tasmania Province
- Tasmanian Shelf Province.

A.1.2.2 Mesoscale bioregions

Based on the *Integrated Marine and Coastal Regionalisation of Australia (IMCRA) v4.0 - Provincial Bioregions* (DCCEEW, 2023a), the EMBA is situated within the following mesoscale bioregions (Figure A-11):

- Batemans Shelf
- Central Bass Strait
- Central Victoria
- Flinders
- Freycinet
- Twofold Shelf.

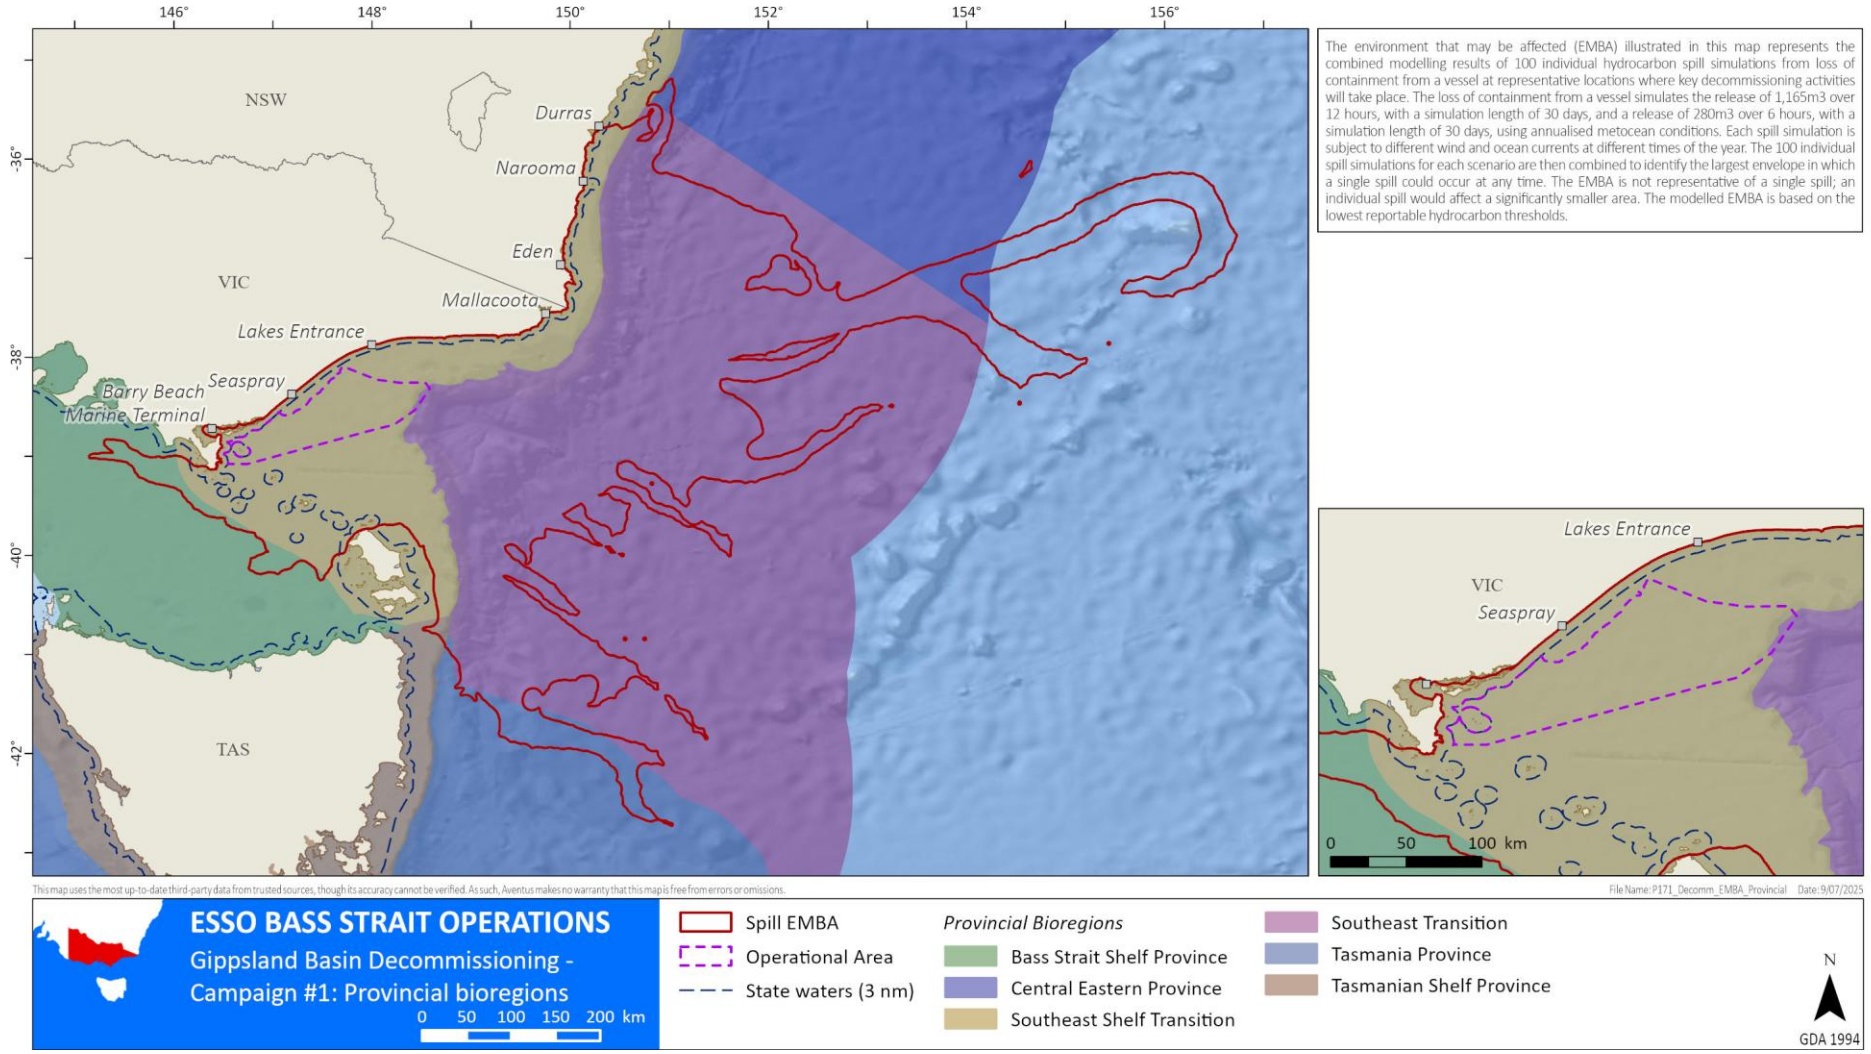

Figure A-10 Provincial bioregions within the EMBA

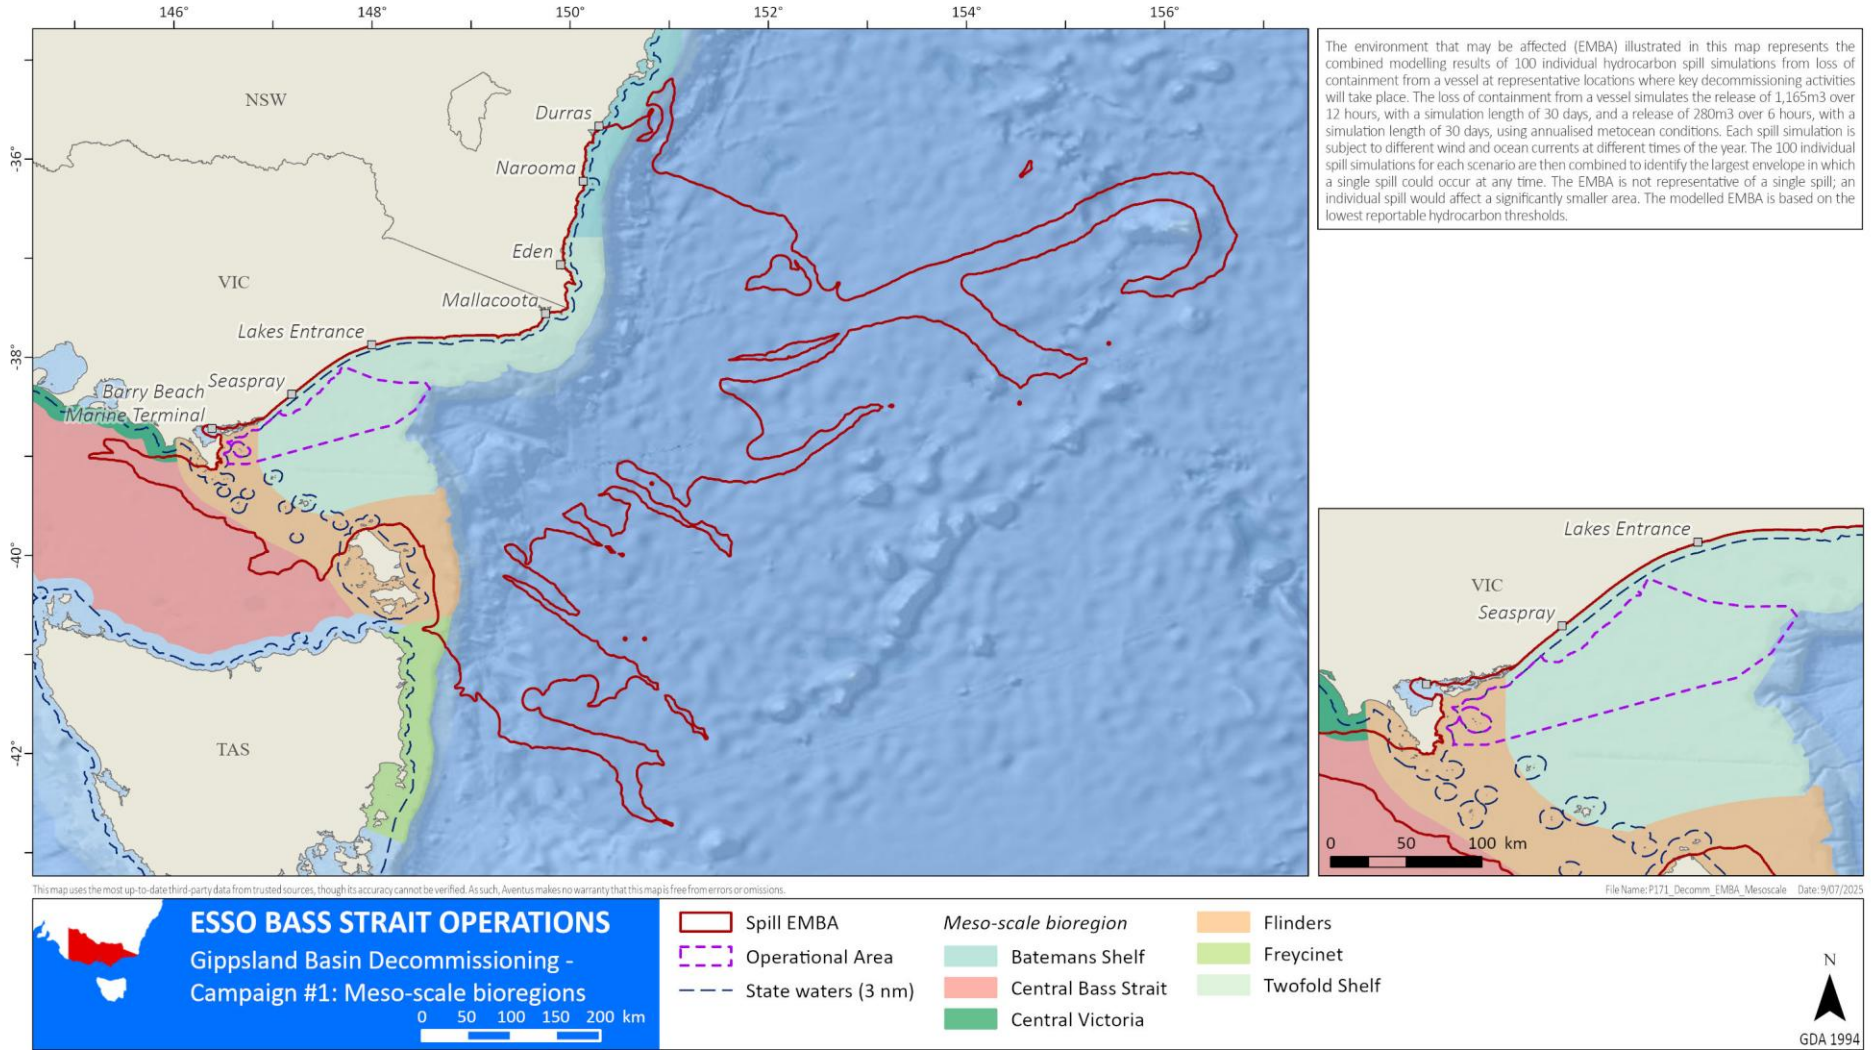

Figure A-11 Mesoscale bioregions within the EMBA

A.1.3 Physical environment

A.1.3.1 Climate and meteorology

Average mean monthly maximum temperatures from 1991 to 2020 in coastal Victoria – East Sale (closest weather station to where decommissioning – Campaign #1 activities will take place) range from 14.2°C in July to 26.1°C in January. In contrast, average mean minimum monthly temperatures for this same period range between 3.6°C in July to 13.6°C in January (BOM, 2025a). Offshore (on Hogan-Island in central Bass Strait), milder conditions occur with average maximum temperatures between 13°C to 21.8°C during July and January respectively, and an average minimum temperature range of 8.8°C in August to 15.3°C in February (BOM, 2025b).

Mean average monthly rainfall along the Gippsland coast (East Sale) ranges from 33.4mm in May (lowest 3.2mm in January 2009) to 62.2mm in November (highest 204.6mm in September 1993) (BOM, 2025a). Offshore (on Hogan Island in central Bass Strait) monthly rainfall ranges from 35.4mm in February (lowest 3.6mm for this same month in 2022) to 72.4mm in August (highest 164.8mm for this same month in 2013) (BOM, 2025b).

Mean wind speeds recorded at East Sale weather station in the period from 1991 to 2010 are in the range of 11.1 - 16.3km/hour during the morning and 17.1 - 24.2km/hour in the afternoon, with maximum gusts reaching an average of 152km/hour in December (BOM, 2025a). The wind direction is predominately westerly during winter, westerly and easterly during spring and autumn (when wind speeds are highest) and easterly during summer. Strong southeasterly winds can be generated by low pressure systems known as east coast lows. Although these occur relatively infrequently (once or twice per year), the longer fetch of these winds increases their potential for generating extreme wave conditions (BOM, 2025b).

There are three main and one minor types of storms which can generate severe wave conditions in Bass Strait (Esso, 1989) (Cardno, 2017) within the area where removal operations will take place:

- Southeast storms - Are generally associated with what has become known as an east-coast low. East-coast lows are generally associated with very strong east to southeast winds (speeds in excess of 80kn have been measured off the New South Wales coastline) and high rainfall. Southeast storms resulting from east-coast lows occur relatively infrequently (on average one to two per year), and not all travel far enough south to cause concern in Bass Strait. The waves they generate are however, unrestricted by fetch or water depth. As such they have the greatest potential for generating extreme wave conditions in eastern Bass Strait.
- Southwest storms - Occur relatively frequently (typically several severe storms per year). Due to fetch and depth limitation, it is unlikely that extreme design-wave conditions will occur during a southwest storm.
- South storms - Are generally associated with low-pressure systems in the western part of the Tasman Sea. During the peak of the storm the Tasman Sea lows generate very strong south southeast through to south southwest winds in Bass Strait. During storm development however, the wind can have a significant southeast or southwest component, depending on the origin of the low. Southerly storms occur at about the same frequency as southeast storms. Southerly storms are considered to have a greater potential than the southwest storms for generating extreme wave conditions.
- Small-scale Bass Strait lows - Can generate southeast, south, or southwest waves, depending on their origin and location. These storms can be quite severe (e.g. the January 1986 storm), but due to fetch limitations are unlikely to be the cause of extreme design-wave conditions.

A.1.3.2 Oceanography

A.1.3.2.1 Currents and tides

Currents in the Gippsland Basin are tide and wind driven. Tidal movements predominantly have a northeast–southwest orientation. Tidal flows come from the east and west during a rising (flood) tide, and flow out to the east and west during a falling (ebb) tide. Tidal streams are dominated by the lunar tidal constituent, which has a period of 12.4 hours. The main tidal components vary in phase by about three to four hours from east to west. Most of this phase change occurs between Lakes Entrance and Wilsons Promontory. Timing of the high tide, for example, can vary by up to three hours across this region. Tides in the area from Lakes Entrance to Gabo Island are, however, relatively weak in comparison to other areas of Bass Strait (Global Environmental Modelling System, 2005).

Bass Strait is characterised by shallow water and tidal currents. While there is a slow easterly flow of waters in Bass Strait, there is also a large anticlockwise circulation. The shallowness of the water means that these waters more rapidly warm in summer and cool in winter than other waters of the region.

Wind driven currents in Gippsland Basin can be caused by the direct influence of weather systems passing over Bass Strait (wind and pressure driven currents) and the indirect effects of weather systems passing over the Great Australian Bight (Global Environmental Modelling System, 2005).

The eastern parts of the region are strongly influenced by the East Australian Current that flows southward adjacent to the east coast of New South Wales, Victoria and Tasmania, carrying warm equatorial waters (refer to Figure A-12 and Figure A-13). The East Australian Current is up to 500m deep and 100km wide and is strongest in summer when it can flow at up to 5kn. In winter it flows at 2 – 3kn as the oceanographic and climatic drivers in the Coral Sea diminish. The East Australian Current tends to form ocean eddies that rotate around warm, central cores that can be up to 200km across and may persist for months. Eddies form more frequently off the south coast of New South Wales than other areas but are also common along the east coast of Tasmania. The eddies can cross the continental shelf, and when mixing with shelf break waters, create upwellings that form isolated areas of enhanced productivity 200 – 300km in diameter. Seasonal and transient upwellings are important ecological features of the region. The East Australian Current also affects sea surface temperatures on the eastern Tasmanian shelf, which can vary substantially among years depending on the relative influence of subtropical waters.

At the shelf break east of Bass Strait, nutrient-rich waters rise to the surface in winter as part of the processes of the Bass Strait Water Cascade, where the eastward flushing of the shallow waters that are more saline and slightly warmer than surrounding Tasman Sea waters form an undercurrent that cascades down the continental slope. The cascading water has a displacing effect causing nutrient rich waters to rise which in turn leads to increased primary productivity in those areas. The cascading water also concentrates nutrients, and some fish and whales are known to aggregate along its leading edge.

Further offshore, in the southeast, currents are driven by two parameters, the Sub-Antarctic Water movement, coming from the south, and the Bass Strait water movement from the west (Tomczak, 1985) (Gibbs, Arnott, Longmore, & Marchant, 1991). The presence of deepwater currents is documented in the *Blackback Oceanographic Measurement Program* (Lawson and Treloar Pty Ltd, 1996), *Prediction of Bass Strait Cascade Currents* (Treloar and Lawson Pty Ltd, 1998) and *Metocean Design Criteria for Bass Strait Fixed Platforms* (Esso, 1989).

Esso undertook a comprehensive current measurement program in the Blackback study area using seven current meters moored 3m above the seabed over a 12 month period (Lawson and Treloar Pty Ltd, 1996) to provide an understanding of the regional oceanography of the Bass Strait continental shelf and continental slope, particularly the relative importance of tidal, wind-driven and density-generated currents and the influence of regional topography on currents in the study area.

Tidal current analysis indicated general seabed current alignment normal to the bathymetry, at speeds of around 0.2 - 0.3m/s. The dominance of the bathymetry was most evident at the current meter sites located within a clearly defined valley.

Analysis of residual, non-tidal current vectors during significant storm periods has confirmed that wind driven currents are the strongest currents in the continental shelf areas but are of progressively lesser significance lower down the continental slope. The study has also provided evidence of flow of water from the continental shelf down the continental slope, conforming to the Bass Strait Water Cascade, as evidenced by high easterly currents and minimum vertical variation in temperature from the shelf to depths of 500m. Currents during these cascade flows were stronger than background tidal currents and were the strongest currents recorded lower down the continental slope.

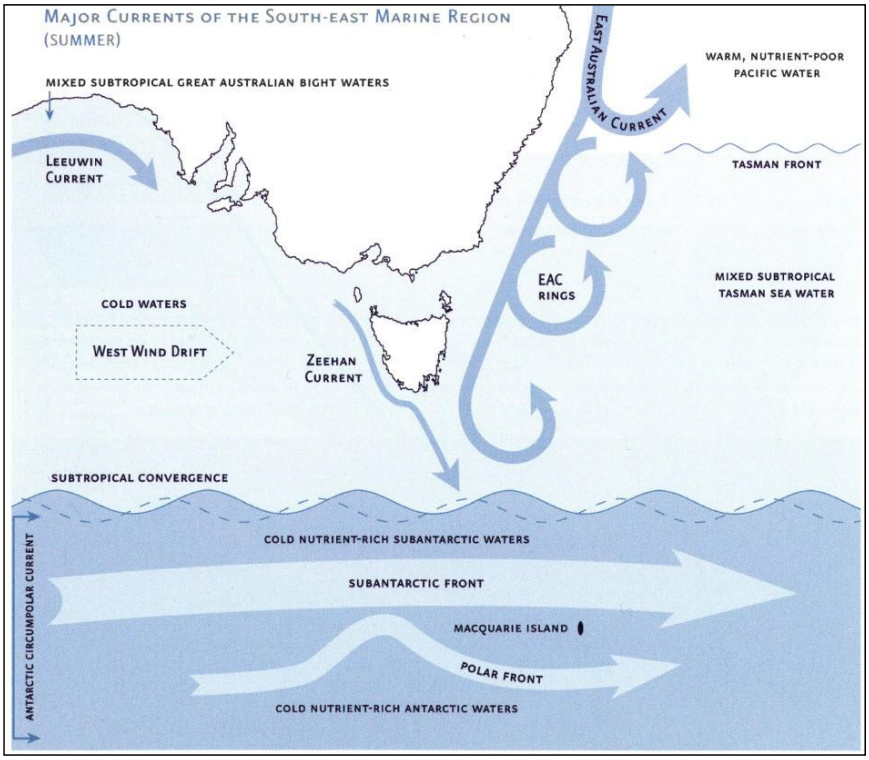

Figure A-12 Major ocean currents in southeastern Australian waters - Summer

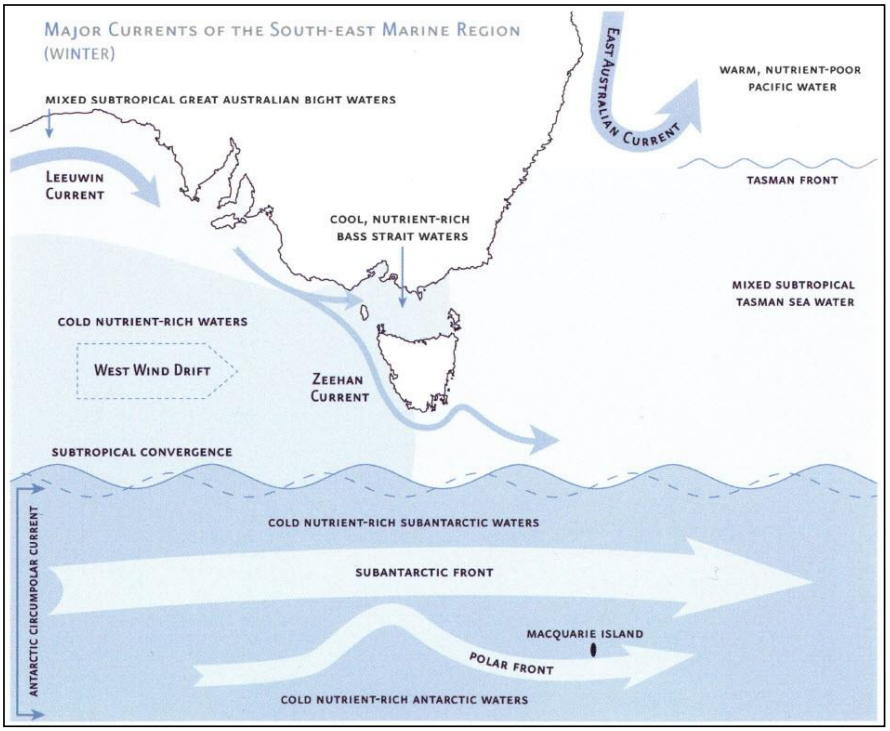

Figure A-13 Major ocean currents in southeastern Australian waters - Winter

A.1.3.2.2 Water temperatures and density stratification

Temperatures in the subsurface waters of Bass Strait range from about 13°C in August/September to 16°C in February/March. Surface temperatures can exceed 20°C at times in late summer due to the warmer waters of the East Australia Current entering the strait. Water temperatures within the EMBA are expected to follow this pattern (Jones I. S., 1980). The monthly sea temperature and salinity profiles of the water column within the area of study were obtained from the World Ocean Database 2018 (Boyer, et al., 2018) produced by the National

Oceanographic Data Centre (National Oceanic and Atmospheric Administration) and its co-located World Data Center for Oceanography.

Table A-3 shows the monthly average sea surface temperatures and salinity representative for offshore locations in deep waters (e.g. Whiting (WTA), Fortescue (FTA), Kingfish A (KFA) and Flounder (FLA)), as well as that representative for offshore locations in more shallow waters (e.g. Dolphin (DPA)). Monthly average sea surface temperatures were shown to range from 13°C (September) and 20.9°C (March) at deep waters, and from 12.4°C (September) and 19.9°C (February) in shallower waters. Salinity remained consistent throughout the year for both deep and shallower waters, ranging from 35.4 to 35.6psu (RPS, 2024).

Table A-3 Average monthly sea surface temperature and salinity nearby DPA, WTA, FTA, KFA and FLA locations within the 0 - 5m water depth

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
WTA, FTA, KFA and FLA (deep waters)												
Temperature (°C)	19.2	20.8	20.9	18.8	16.7	15.2	14.2	13.6	13.0	13.8	16.0	16.8
Salinity (psu)	35.5	35.5	35.5	35.5	35.5	35.5	35.5	35.4	35.4	35.4	35.4	35.4
DPA (shallower waters)												
Temperature (°C)	19.6	19.9	19.7	18.3	16	14.6	13.2	12.5	12.4	13.4	15.6	17.2
Salinity (psu)	35.5	35.5	35.5	35.5	35.6	35.6	35.5	35.4	35.4	35.4	35.4	35.4

Waters are generally well mixed, but surface warming sometimes causes weak stratification in calm summer conditions. During these times, mixing and interaction between varying water masses leads to variations in horizontal water temperature and a thermocline (temperature profile) develops. The thermocline acts as a low friction layer separating the wind driven motions of the upper well mixed layer from the bottom well mixed layer. As a result, upwelling of cold water on the northern shores of Bass Strait can occur (Jones I. S., 1980).

Information on density and temperature profiles of the deeper area of the Blackback field has been obtained (Lawson and Treloar Pty Ltd, 1996). Temperatures measured at the seabed confirmed a decrease in temperature with depth of measurement. The survey also showed a period (July to September) of uniformity of temperature at all measured depths, indicating flow down the continental slope (Bass Strait Water Cascade). The range of water temperatures observed at the seabed is from a maximum of 17°C at 93m to a minimum of 7°C at 480m. The minimum temperatures at depth were recorded in summer, possibly because of stronger stabilising stratification and absence of the cascade of relatively warmer water during winter.

A.1.3.2.3 Waves

Bass Strait is a high energy environment exposed to frequent storms and significant wave heights. High wave conditions are generally associated with strong west to southwest winds caused by the eastward passage of low-pressure systems across Bass Strait. Storms may occur several times a month resulting in wave heights of 3 - 4m or more. In severe cases, southwest storms can result in significant wave heights of greater than 6m (Jones I. S., 1980).

Extreme design wave conditions are associated with east coast low pressure systems. These can result in very strong east to southeast winds in eastern Bass Strait. *Metocean Design Criteria for Bass Strait fixed platforms* (Esso, 1989) gives a design significant wave height of 9.0m and a corresponding maximum wave height of 17.5m.

Wave data from the Kingfish B (KFB) weather station were analysed for the ten-year period from 1990 - 2000 (O'Grady & McInnes, 2010). Average significant wave heights at KFB were 1.97m, approximately 40% lower than those to the west of Bass Strait (Cape de Couedic and Cape Sorell) and approximately 10% higher than on the east coast at Eden. The highest significant wave height recorded was 4.79m. Wave periods at KFB are also lower by just over 30% compared to those to the west of Bass Strait and are about 10% lower than those at Eden. These differences are a result of the fetch-limited conditions that exist in Bass Strait where a portion of the long period waves from the Southern Ocean are blocked by Tasmania. Table A-4 shows the monthly mean, significant wave

height and 99th percentile values recorded at KFB for the period of 1990 - 2000 (O'Grady & McInnes, 2010). The analysis of the data showed that for waves at KFB, the highest wave events occur most frequently with westerly wind events and were usually associated with storm surge events (occurring 58% of the time) in northeastern Bass Strait. However, high wave events can also occur during easterly wind events when a weak or a negative surge from the southeast is present (occurring 31% of the time) (O'Grady & McInnes, 2010).

Table A-4 KFB wave data

Month	Mean wave height (m)	Wave height standard deviation	Wave height 99th percentile (m)	Peak wave period (sec)	Peak wave period standard deviation	Peak wave period 99th percentile (sec)	Number of observations
Jan	1.64	0.67	3.58	7.83	1.75	13.27	4832

A.1.3.2.4 Bathymetry

The seabed bathymetry across the region is highly variable. A significant portion of the EMBA lies within water past the continental shelf in depths range from 300 - 5000m (see Figure A-14). The bathymetry contours along the coast where the EMBA lies range from 10m to 300m deep (refer to Figure A-14).

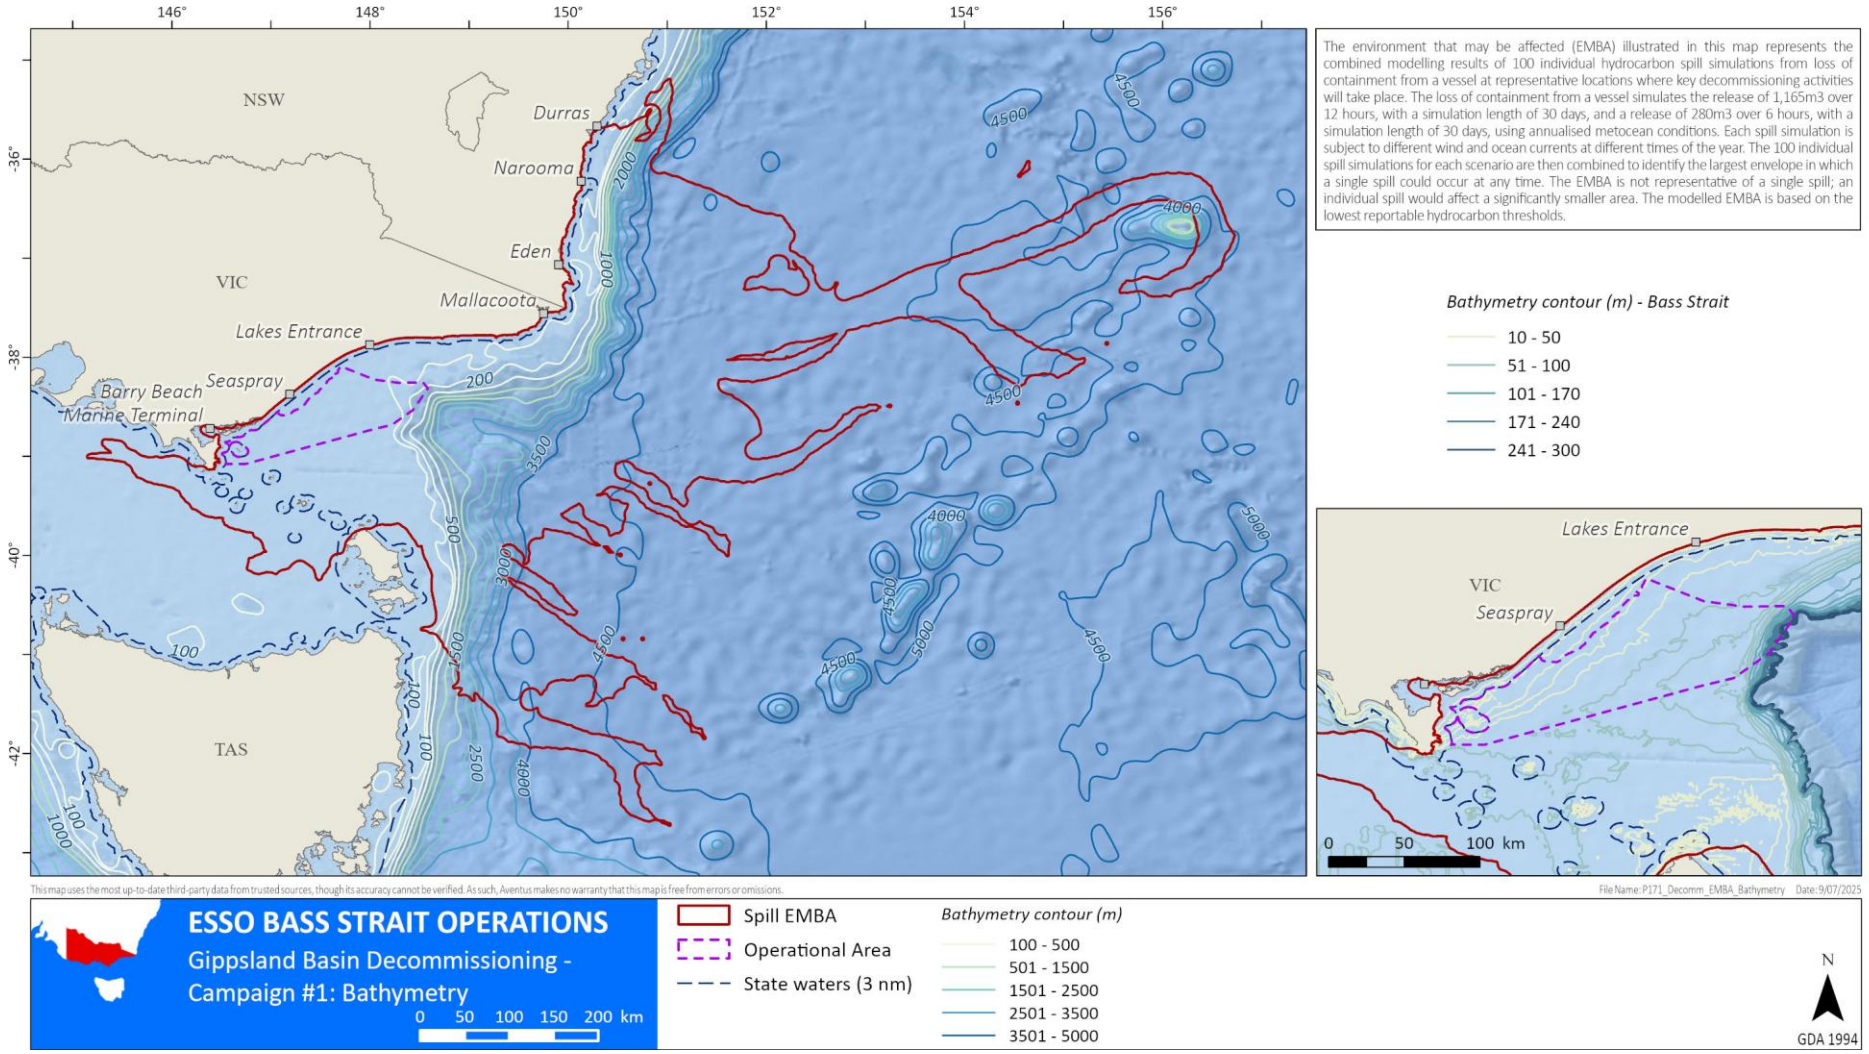

Figure A-14 Bathymetry within the EMBA

A.1.4 Biological environment

1.1.2 Benthic habitat

A.1.4.1.1 Bare substrate

The Gippsland Basin is composed of a series of massive sediment flats, interspersed with small patches of reef, bedrock and consolidated sediment. The sandy plains are only occasionally broken by low ribbons of reef; however, these reefs do not support the large brown seaweeds characteristic of many Victorian reefs, but instead are inhabited by resilient red seaweeds and encrusting animals that can survive the sandy environment (*Bass Strait Environment Plan* (AUGO-EV-EMM-012)). In the Gippsland Basin, seabed material is predominantly calcium carbonate comprised of calcarenite marls and marine shales (*Bass Strait Environment Plan* (AUGO-EV-EMM-012)). A study of the seascape of the southeastern Australian continental shelf conducted in 2001 found that 89% of the seabed was sediment flats/bare substrate with prominent hard grounds making up the remaining 11% of the seabed (Bax & Williams, 2001).

Maxon Consulting Inc, 2024 presents an assessment of information available from environmental surveys completed in the Gippsland Basin in 2021, 2022 and 2023, which included monitoring of locations adjacent to selected Esso offshore platforms and near-field and far-field reference locations. The assessment report indicates sediment categories are dominated by coarse-grained sands, however, increased mud and gravel size fractions co-occur at approximately 40 - 80m depth. The mid-depth shelf area is bordered by sandy sediments in the near-shore shallows (10 - 40m) and at depths greater to 80m towards the shelf break (Maxon Consulting Inc, 2024). The report also notes that results are remarkably consistent between monitoring completed by Esso versus AusSeabed samples collected a few kilometres apart, suggesting stable seabed conditions over several decades. Figure A-15 presents the sediment categories identified for the Gippsland Basin (Maxon Consulting Inc, 2024).

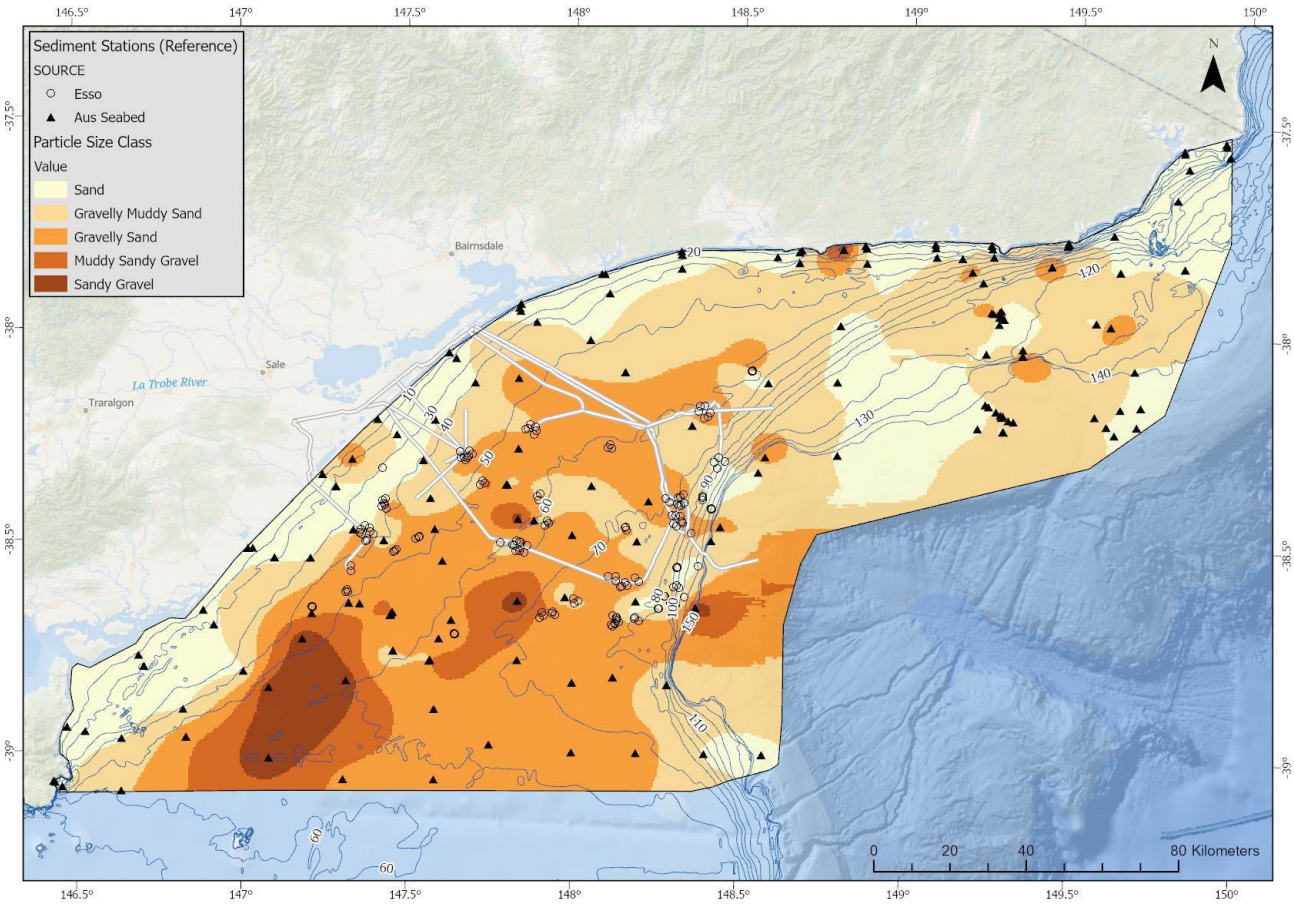

Figure A-15 Gippsland Basin surface sediment particle size descriptions based on Folk (1980). Data sourced from Geoscience Australia's marine sediments database and Esso far-field reference stations

The benthic fauna present on the soft sediment can be broadly divided into two groupings:

- the epibenthos which includes sessile species such as sponges and bryozoans, hydroids, ascidians, poriferans and mobile fauna including hermit crabs, sea stars and octopus
- the infauna which includes a diverse range of species such as amphipods, shrimps, bivalves, tubeworms, small crustaceans, nematodes, nemerteans, seapens, polychaetes and molluscs (Parry, Campbell, & Hobday, 1990).

Many of these species are burrowing organisms that cause moderate bioturbation (Edgar, 2001). Scientific surveys have shown that some shallow Victorian sandy environments have the highest levels of animal diversity in the sea ever recorded (Parks Victoria, n.d.(k)). In the area around the Ninety Mile Beach in East Gippsland more than 600 different marine animal species, many of them very small, have been found within an area of $10m^2$ (Parks Victoria, n.d.(k)). This high species richness was a major factor in the creation of a marine national park on the Ninety Mile Beach (Parks Victoria, n.d.(d)). The subtidal sand invertebrate fauna is dominated by small animals, mostly crustaceans, molluscs, echinoderms and polychaetes (Plummer, Morris, Blake, & Ball, 2003) (Bax & Williams, 2001).

The Maxon Consulting Inc report (2024) indicates that within the Gippsland Basin, biological communities generally are categorised into the inner shelf, outer shelf, and central shelf zones (Bax & Williams, 2001) (Passlow, O'Hara, Daniell, Beaman, & Twyford, 2006). This zonation is significantly influenced by sediment type, with the hard substrates of the inner shelf, supporting a higher diversity and abundance of epifaunal organisms (Lavering, 1994). From the inner shelf zone (circa. 10 – 50m depth) of east Gippsland, (Coleman, Gason, & Poore, 1997) identified polychaete worms, bivalve molluscs, and peracarid crustaceans as the dominant invertebrate macrofaunal groups. These taxa collectively accounted for 99% of all individuals and 98% of all species in their study. A Remotely Operated Vehicle (ROV) seabed survey conducted following drilling at the Snapper Operational Area (OA) in 2009 (Coffey Environments Pty Ltd, 2010) and a seabed monitoring program conducted near West Tuna in 1999 (URS Corporation, 2000) confirmed that polychaetes and crustaceans were the most abundant infaunal taxa present in the seabed sediments.

Passlow, O'Hara, Daniell, Beaman, & Twyford (2006) documented high diversity across various invertebrate groups on the Bass Strait shelf, including polychaetes, pycnogonids (sea spiders), brachiopods, decapods (e.g. crabs, crayfish, shrimps, prawns), isopods, echinoderms (e.g. sea stars, sea urchins), and gastropods (e.g. snails). Shallow basins within the shelf tend to support higher macrofaunal densities and species richness. These environments benefit from the accumulation of detrital food and less demanding physical conditions, which are likely to contribute to the enhanced biodiversity observed in these zones (Maxon Consulting Inc, 2024). Refer to Figure A-16 for information on macrofauna abundance and proportions of key phyla based on results from survey at the platform locations sampled.

Figure A-17 presents sampling locations for the monitoring program completed in 2021, 2022 and 2023, including those associated to platform locations and reference locations in the vicinity and further away from the platforms.

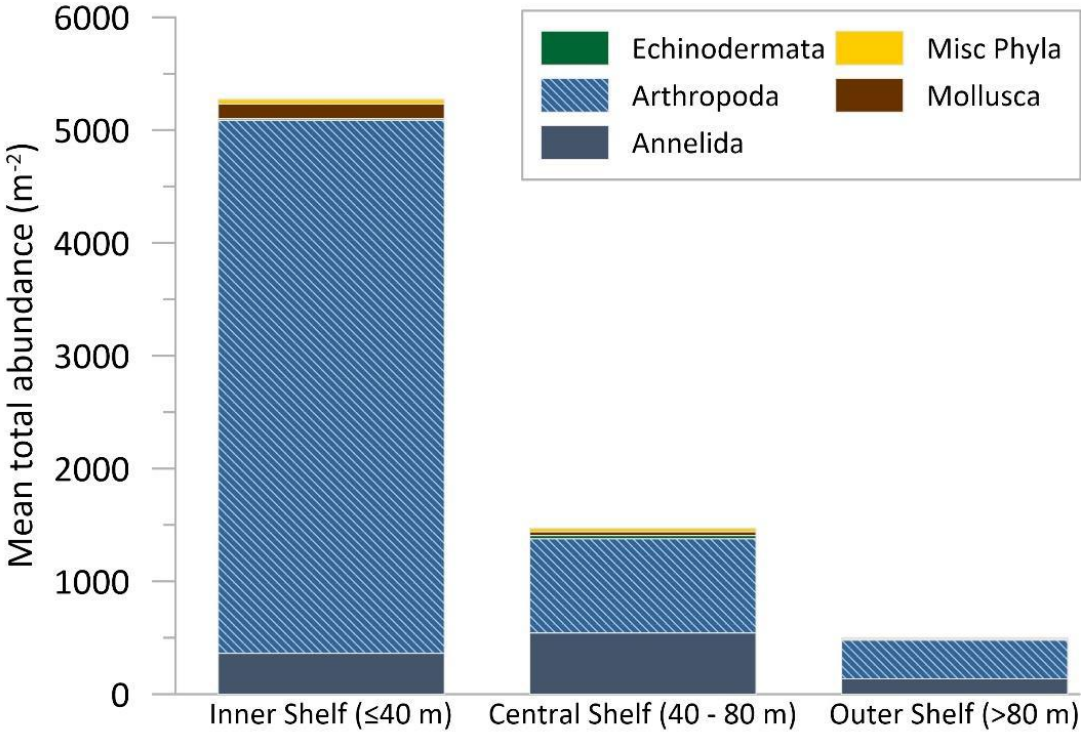

Figure A-16 Mean total macrofauna abundance

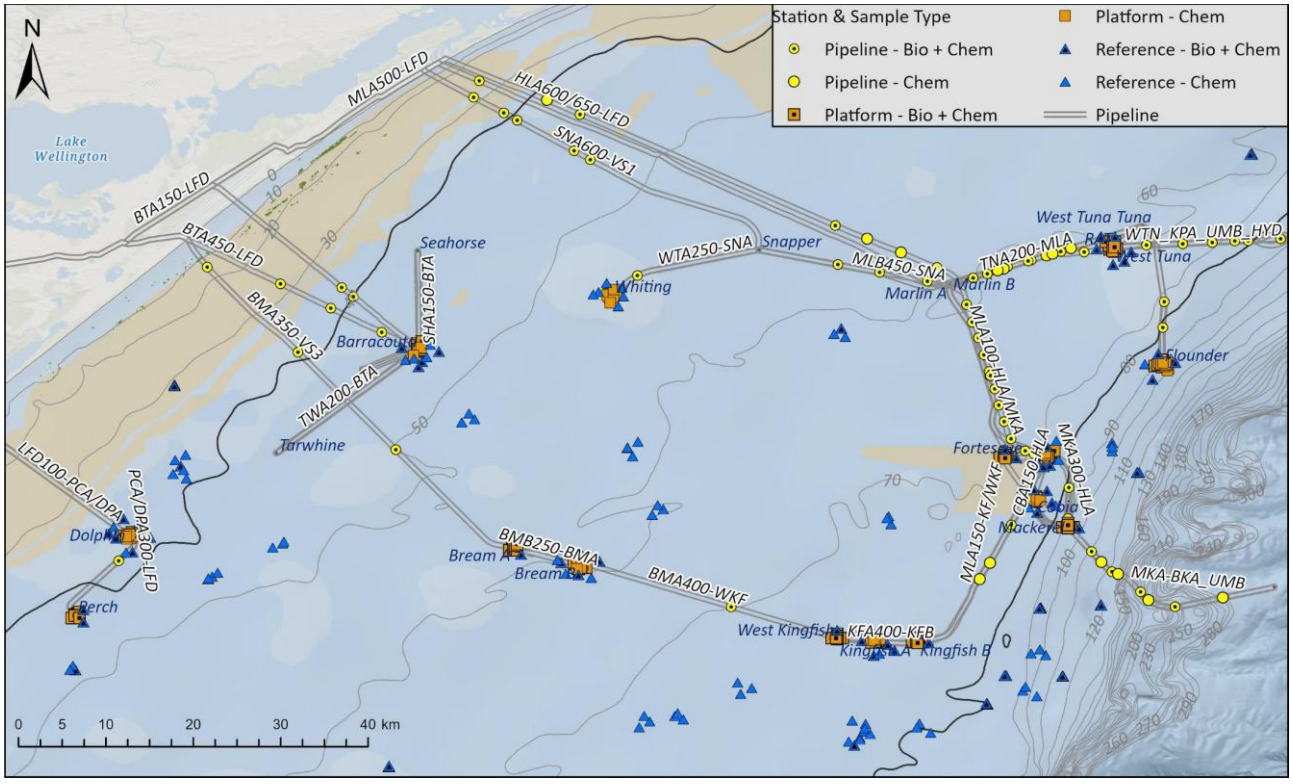

Figure A-17 Sediment survey locations

Analysis of results from surveys completed in 2021, 2022 and 2023 suggest that on a family level, the sampled macrofauna community was relatively rich, with many taxa, an evenly distributed fauna, and intermediate levels of dominance. This richness may, in part have resulted from the sampling of a number of areas with significant gravel/shell content mixed in with the sand, and some stations with considerably more fine sediment than others. This provides variety in the physical milieu that the organisms are exposed to, resulting in the presence of a large

number of taxa that occurred at only a few of the 335 sampled stations, noting that no taxon occurred at all stations (Maxon Consulting Inc, 2024).

The low proportion of mud-class sediments within the mix of bottom particles amplifies differences in community composition between areas where they are present and where they are absent, while also influencing the trophic structure of the associated fauna. Gravel patches promote the presence of deposit-feeding interstitial organisms, such as *Syllidae*, by trapping nutrients from overlying waters. In the predominantly sandy areas where water movement patterns ensure a steady or frequent supply of suspended nutrient particles, large groups of suspension feeders, such as the tube-building amphipod *Corophiidae*, gather to exploit these resources (Maxon Consulting Inc, 2024).

Furthermore, the Maxon Consulting Inc report (2024) indicates this heterogeneity, despite the appearance of a uniform habitat, can be highly pronounced, with stark contrasts between the predominantly sandy bottom and the intermittent gravelly-muddy patches. These microhabitat variations create distinct ecological niches that significantly influence benthic community dynamics. Richness of macrofauna is the result of such subtle physical disparity, and that diversity is very evident in this sampling. The number of family level taxa reported here exceeds those reported for similar nearby habitat (Gray, et al., 1997). Many of the taxa are uncommon, occurring only a few times in the stations sampled. That does not mean that they are rare, but that their populations are strongly adapted to specific microhabitats and their larvae only settle when conditions are right. While total abundance was highest in shallow depths of the inner shelf, heterogeneous sediments of the broad central shelf support communities that are more diverse and evenly distributed among taxa.

A.1.4.1.2 Seagrass

Seagrasses are marine flowering plants, with about 30 species found in Australian waters (Huisman, 2000). There is a distinction between tropical and temperate seagrasses, and the approximate latitude for the change occurs at Moreton Bay (southern Queensland). The dominant temperate species in the EMBA are *Amphibolis antarctica, Halophila australis, Heterozostera tasmanica*, *Posidonia australis and Zostera muelleri* (Kirkham, 1997). Seagrasses generally grow in sediments in intertidal and shallow subtidal waters where there is sufficient light and are common in sheltered coastal areas such as bays, lees of island and fringing coastal reefs (McLeay, Sorokin, Rogers, & Ward, 2003) (Rogers, et al., 2013) (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). Seagrass habitats occur worldwide, from arctic to tropical climates.

Seagrass meadows are important in trapping and stabilising sediments, as seagrass leaves baffle wave action and reduces water movement to the extent that fine suspended particles settle out and are trapped (Edyvane, 1998). Seagrass meadows also provide habitat and nursery grounds for juvenile fish and invertebrates, enhance biodiversity, and promote primary production (Huisman, 2000) (Rogers, et al., 2013) (Kirkham, 1997).

Known areas of seagrass within or adjacent to the EMBA include coastal waters Corner Inlet and Lakes Entrance, and numerous inlets and estuaries along the New South Wales coast (Butler, Lucieer, Walsh, Flukes, & Johnson, 2017). A review of information available through *CoastKit Victoria* (DEECA, 2023a) confirms the presence of seagrass within sections of Corner Inlet, the Nooramunga Marine and Coastal Park, Gippsland Lakes (mainly within Lake King), and the Sydenham Inlet. While seagrass meadows are present throughout this region, the proportion of seagrass habitat is not high compared to the rest of Australia, in particular with parts of South Australia and Western Australia (Kirkham, 1997).

A.1.4.1.3 Subtidal rocky reefs

This habitat occurs either as extensions of intertidal rocky shores or as isolated offshore reefs and is always submerged. The rocky reefs of southern Australia support a highly endemic marine flora and fauna. Subtidal rocky reefs are scattered along the Gippsland shore and make up approximately 11% of the southeastern Australian shelf (Bax & Williams, 2001).

This habitat consists of subtidal substrates composed primarily of limestone reefs and outcrops of sandstone and granite. The composition and characteristics of the substrate vary across the region based on its geologic origin and history. Fossiliferous limestone, as the name suggests, is composed of skeletons of dead animals, such as bivalve and bryozoan clasts. The skeletal elements are cemented together by a fine-grained calcareous matrix formed by a slow rate of sedimentation, suggesting that the process is continuing to (slowly) occur on the Gippsland Basin continental shelf (Bax & Williams, 2001). Known locations of this type of substrata are Howe Reef, Gabo Reef and Broken Reef.

Limestones usually form in large, tabular slabs of low relief (<2m), as is the case in Broken Reef, however they can also form as low-lying hard grounds that are bored and encrusted by benthic organisms. These are likely to form 'patches' or mosaics of hard substratum that show little (<20cm) or no vertical relief. Based on ROV video surveillance, the presence of South East Reef is not evident when comparing the abundance of biota around the Cobia platform versus other facilities (based on Esso ROV inspection data from 2010, 2013 and 2014). This may be due to the layer of sediment coverage over the hard substrate or the lack of extrusions/elevations.

Another form of the hard substrate is the coarse-grained, quartz rich sandstone. In Gippsland, sandstone, together with fossiliferous sandstone, occur as elongate, low relief slabs which crop out from soft sediments along the Gippsland coastline. While it has not been confirmed, this type of sandstone is also likely to be a common constituent of banks or reefs further offshore.

The inner shelf of the Gippsland coastline features localised higher relief (>10m) outcrops formed of distinctive irregular, hexagonally jointed, coarsely crystalline granite, or hard reefs. Granite reef areas include Point Hicks and New Zealand Star Banks. Figure A-18 shows the high level substrata distribution in southeast Australia (Bax & Williams, 2001).

Rocky reef habitats can support rich, diverse communities of attached epifauna (e.g. stalked crinoids, sponges, ascidians etc.) and associated algae and other fauna. Structures with a higher relief (reef or bank) several metres high can provide protection and food and attract diverse fish and invertebrate species (NOAA, 2010).

The substrata are only one factor which influences the presence of biological communities. The distribution of fish and invertebrate communities is also correlated with latitude, depth, temperature, and hydrology. Areas where the temperate and subtropical currents overlap have a different distribution of communities to places like Horseshoe Canyon, where upwelling occurs.

Other known areas of subtidal rocky reef include Bastion Point, Quarry Beach, Little Rame Head, Wingan Point, The Skerries Special Management Area, Petrel Point, Thurra River, Pearl Point, Yeerung River Estuary (intermittently open), Cape Conran (East Cape, Cowrie Bay, Flat Rocks), Point Ricardo and Ricardo Beach (all of which are within the EMBA).

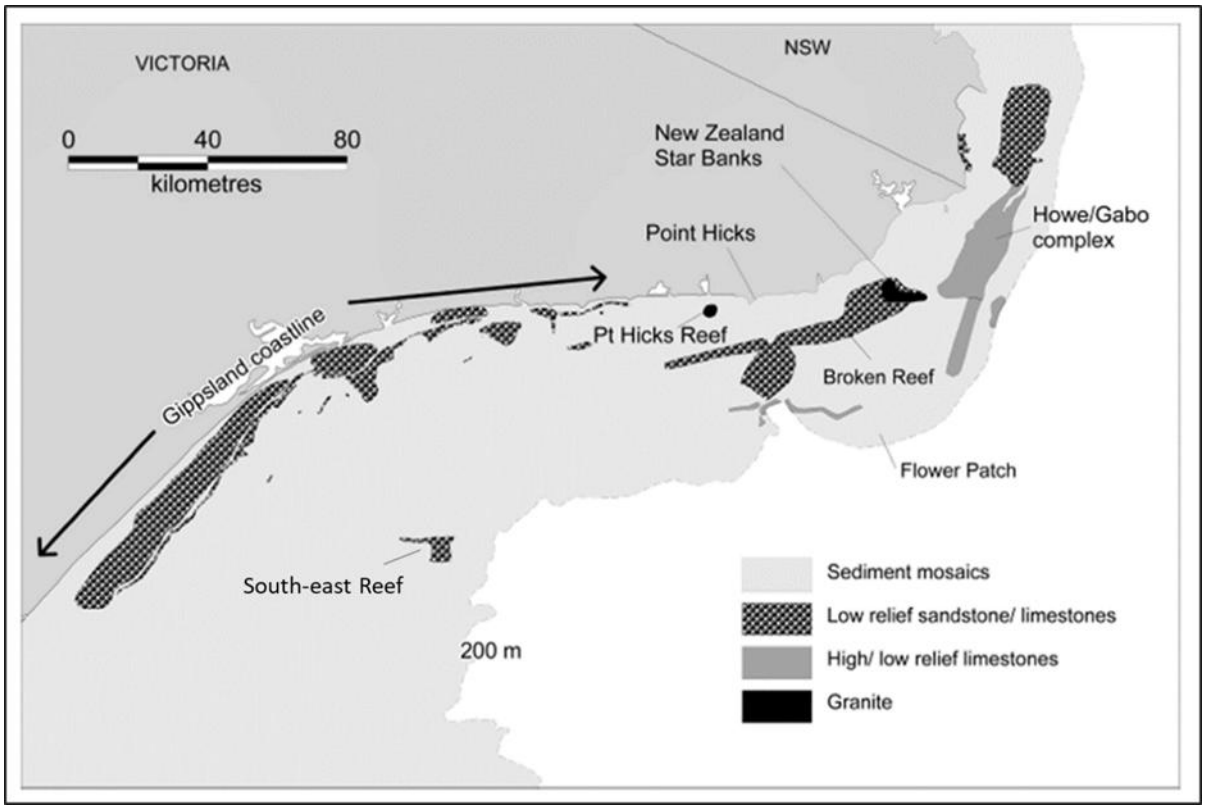

Figure A-18 Substrata on the southeastern Australian continental shelf (Bax & Williams, 2001)

A.1.4.1.4 Macroalgae

Macroalgae are multicellular marine algae, commonly known as seaweed. Macroalgae communities are generally found on intertidal and shallow subtidal rocky substrates as they require a surface to attach themselves to and can occur throughout Australian nearshore waters. Macroalgae are divided into three groups: brown algae (*Phaeophyceae),* red algae *(Rhodophyta*), and green algae (*Chlorophyta*).

Brown algae are typically the most visually dominant and form canopy layers (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). Macroalgae assemblages vary, but *Ecklonia radiata* and *Sargassum* sp. are typically common in deeper areas. The principal physical factors affecting the presence and growth of macroalgae include temperature, nutrients, water motion, light, salinity, substratum, sedimentation and pollution (Sanderson, 1997). Macroalgal systems are an important source of food and shelter for many ocean species, including in their unattached drift or wrack forms (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006).

Kelps are very large brown algae that grow on hard subtidal substrates in cold temperate regions. Kelps have a holdfast that attaches to the substrate, a stem-like or trunk-like stipe, and large, flattened, leaf-like blades called fronds. The Giant Kelp Marine Forests are classed as TECs. Refer to Section A.1.1.6.3 for information on Giant Kelp Marine Forests.

Known areas containing macroalgae within the EMBA include around Gabo Island and within the Bemm River estuary (Butler, Lucieer, Walsh, Flukes, & Johnson, 2017).

A.1.4.1.5 Coral

Corals are generally divided into two broad groups: the zooxanthellate (reef-building, hermatypic or hard) corals, which contain symbiotic microalgae (*Zooxanthellae* spp.) that enhance growth and allow the coral to secrete large amounts of calcium carbonate; and the azooxanthellate (ahermatypic or soft) corals, which are generally smaller and often solitary (Keable, 2007). Hard corals are generally found in shallower (<50m) waters, while soft corals are found at most depths, including in deeper waters throughout the continental shelf, slope and off-slope regions, to well below the limit of light penetration.

There are three factors that appear to drive the spawning of warm water corals a gradual rise in sea temperature (this triggers the gametes to mature), the lunar cycle, and the daylight cycle. As such, the timing of coral spawning events varies around Australia. Large spawning events for Great Barrier Reef corals typically occur four to five days after the full moon in October or November (and occasionally into December). Reproduction methods for cold water corals are not as well understood, but it is likely that some are still broadcast spawners (like their tropical counterparts), while others brood and release formed larvae (Roberts, Wheeler, Freiwald, & Carins, 2009).

While corals may not occur as a dominant habitat type within the Gippsland sector, their presence has been recorded within the region for example Kent Group Marine Reserve, Freycinet Marine Park, and around Wilsons Promontory, all of which are within the EMBA. Soft corals are typically present in deeper waters throughout the continental shelf, slope and off-slope regions, to well below the limit of light penetration.

A.1.4.1.6 Submarine canyons

Submarine canyons are abundant features along continental and oceanic island margins that connect continental shelves to deep ocean basins. Because of the physical complexity of canyon habitats, predictions concerning the effects of canyons on diversity are not straightforward since a variety of environmental and physical characteristics interact in canyon habitats. The most important driver affecting biodiversity and biomass/abundance patterns in canyons is organic matter input and is mostly related to coastal detrital inputs or pelagic productivity regimes (De Leo, Smith, Rowden, Bowden, & Clark, 2010).

Seafloor terrain and substrate heterogeneity account for the second most important driver of benthic biodiversity in submarine canyons. One of these factors, sediment grain size, can be considered as a super-parameter (Etter & Grassle, 1992) since it directly or indirectly reflects local physical energy and sedimentation patterns. At moderate rates of flow and sediment deposition, suspension and deposit feeding, macrobenthos can be enhanced in abundance and/or diversity in canyons (Vetter & Dayton, 1999), whereas at high rates of flow and sediment accumulation, canyon fauna can become impoverished, yielding low species richness and high dominance by a few tolerant species (Rowe, Polloni, & Haedrich, 1982) (Gage, Lamont, & Tyler, 1995) (Vetter & Dayton, 1999).

While some studies have reported levels of megafaunal biodiversity in canyons rivalling seamounts (Schlacher, et al., 2007), in other cases high disturbance rates (Rowe, Polloni, & Haedrich, 1982) and absence of stable habitat collection led to faunal impoverishment compared to adjacent slope environments (Vetter & Dayton, 1999).

Submarine canyons that intersect the EMBA are described in Section A.1.1.8, including the Big Horse Canyon and the Canyons on the Eastern Continental Slope (Geoscience Australia, n.d.).

A.1.4.2 Coastal environment

A range of shoreline types are represented along the coastal areas within the EMBA, including sandy shorelines, rocky shorelines, cliffs, intertidal flats, and saltmarsh (Griffin, Hazelwood, Nicholas, & Xu, 2012).

The coastline, from Wilsons Promontory in the west to Cape Howe in the east near the New South Wales border, consists mainly of steep sandy beaches and rocky outcrops.

The New South Wales coast consists of primarily rocky outcrops with sections of sandy beaches and rocky cliffs. The offshore islands in Bass Strait are characterised by steep cliffs and rocky shores. These shoreline types are also dominant along the north and east coast of Tasmania.

A.1.4.2.1 Sandy shorelines

This shoreline type has been defined as beaches dominated by sand-sized (0.063 - 2mm) particles and also includes mixed sandy beaches (i.e. sediments may include mud or gravel, but sand is the dominant particle size).

Sandy beaches are dynamic environments, naturally fluctuating in response to external forcing factors (e.g. waves, currents etc.). Sandy beaches can support a variety of infauna and provide nesting and/or foraging habitat to shorebirds, seabirds and pinnipeds. Sand particles vary in size, structure, and mineral content; this in turn affects the shape, colour, and inhabitants, of the beach.

This shoreline type is the most common along the entire Victorian coast, including popular locations within the EMBA such as Ninety Mile Beach, East Gippsland and Squeaky Beach, Wilsons Promontory.

A.1.4.2.2 Rocky shorelines

Sheltered rocky shores are characterised by a rocky substrate that can vary widely in permeability. This shoreline type has been defined as hard and soft rocky shores, including bedrock outcrops, platforms, low cliffs (less than 5m in height), and scarps. Depending on exposure, rocky shores can be host to a diverse range of flora and fauna, including barnacles, mussels, tube building worms, sea squirts (cunjevoi), sea anemones, sponges, sea snails, starfish, and algae. Australian fur seals are also known to use rocky shores for haul-out and/or breeding. Most animals on the intertidal rocky shores are herbivorous molluscs, grazing algae off rock surfaces.

This is a common shoreline type along the southern New South Wales coast, the islands of Bass Strait, and for smaller areas of Victoria's coast (e.g. Wilsons Promontory). Intertidal rocky shores occur at Bastion Point, Quarry Beach, Shipwreck Creek, Seal Cove, Little Rame Head, Sandpatch Point, Petrel Point, Thurra River, Clinton Rocks, Cloke Rock, Tamboon Inlet and Shelley Beach (all of which are within the EMBA in Victoria).

A.1.4.2.3 Sea cliffs

The intertidal zone is steep (>30° slope) and narrow with very little width. Sediment accumulations are uncommon because waves remove debris that has slumped from the eroding cliffs. There is strong vertical zonation of intertidal biological communities. Species density and diversity vary greatly, but barnacles, snails, mussels, polychaetes, and macroalgae can be abundant (NOAA, 2010).

This environment occurs behind Betka Beach and Secret Beach through to Little Rame Head, Sandpatch Point, Wingan Point, The Skerries, Rame Head, Petrel Point, Point Hicks, Clinton Rocks, Tamboon Inlet, Pearl Point, Cape Conran (Needle Rocks, Irvine Rocks, Quincy Rocks Salmon Rocks), and at Ricardo Point (all of which are within the EMBA in Victoria). This is a common shoreline type for the Furneaux Group in Bass Strait (within the EMBA in Tasmania).

A.1.4.2.4 Inter-tidal flats

This shoreline type has been defined as areas with predominantly mud-sized (<0.063mm) particles, and also includes mixed sediments (e.g. sands, shell or gravel), where the mud fraction is dominant. These areas are also exposed to high tidal variation, including tidal flats, and are often associated with mangrove or saltmarsh environments.

Sheltered intertidal flats are composed primarily of mud with minor amounts of sand and shell. They are usually present in calm-water habitats, sheltered from major wave activity, and frequently backed by marshes like estuaries or bays. The sediments are very soft and cannot support even light foot traffic in many areas. There can be large concentrations of bivalves, worms, and other invertebrates in the sediments. They are heavily used by birds for feeding (NOAA, 2010).

Sheltered intertidal flats occur at Corner Inlet and Nooramunga Marine and Coastal Parks. Bare sediment occurs at Mallacoota Inlet, Wingan Inlet, Sydenham Inlet - Bemm River and Mud Lake.

A.1.4.2.5 Mangroves

Along the Gippsland coast, mangroves can be found in Corner Inlet, Nooramunga Marine and Coastal Park and Cunninghame Arm at Lakes Entrance (Butler, Lucieer, Walsh, Flukes, & Johnson, 2017).

The roots and trunks are intertidal, with only the lowest leaves inundated by high tide. The width of the forest can range from one tree to many kilometres. The substrate can be sand, mud, leaf litter, or peat, often as a veneer over bedrock. Mangroves are highly productive, serve as nursery habitat, and support a great diversity and abundance of animal and plant species (NOAA, 2010).

A.1.4.2.6 Saltmarshes

Saltmarshes are terrestrial halophytic (salt-adapted) ecosystems that mostly occur in the upper-intertidal zone and are widespread along the coast of Victoria and New South Wales. They are typically dominated by dense stands of halophytic plants such as herbs, grasses, and low shrubs. Depending on location and inter-annual variations in rainfall and runoff, associated vegetation may include species tolerant or adapted to salt, brackish, or even tidal freshwater conditions. The diversity of saltmarsh plant species increases with increasing latitude (in contrast to mangroves). The vegetation in these environments is essential to the stability of the saltmarsh, as they trap and bind sediments. The sediments are generally sandy silts and clays and can often have high organic material content. Saltmarshes provide a habitat for a wide range of both marine and terrestrial fauna, including infauna and epifaunal invertebrates, fish, and birds (NOAA, 2010).

Saltmarshes are found along the coast throughout the EMBA, although are most extensive behind the sand dunes of Ninety Mile Beach, East Gippsland (Boon, et al., 2011).

Saltmarshes can be found behind Mallacoota Entrance to Lake Barracouta, Wingan Inlet, inside Cann River Estuary, Tamboon Inlet, Sydenham Inlet (Bemm River Estuary and Mud Lake), Dock Inlet, inside Snowy River Estuary, Lake Tyers Estuary, and inside Lakes Entrance - Gippsland Lakes Ramsar site (within the EMBA in Victoria). In southern New South Wales between Towradgi Creek about 40km north of the Victorian border there are approximately 12km^2 of saltmarsh spread over 62 estuaries (Daly, 2013), including areas of Tomaga River and Moruya River, Tuross Lake, Wapengo Lake, Bega River, and Wonboyn River (Creese, Glasby, West, & Gallen, 2009) (within the EMBA).

1.1.3 Plankton

Plankton species, including phytoplankton and zooplankton, are key components in oceanic food chains.

Phytoplankton are autotrophic planktonic organisms living within the photic zone that spend either part or all of their lifecycle drifting with the ocean currents. They are the start of the food chain in the ocean (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). Phytoplankton communities are largely comprised of protists, including green algae, diatoms, and dinoflagellates (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). There are three size classes of phytoplankton: microplankton (20 - 200µm), nanoplankton (2 - 20µm) and picoplankton (0.2 - 2µm). Diatoms and dinoflagellates are the most abundant of the micro and nanoplankton size classes and are generally responsible for the majority of oceanic primary production (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006). Phytoplankton are dependent on oceanographic processes (e.g. currents and vertical mixing), that supply nutrients needed for photosynthesis. Thus, phytoplankton biomass is typically variable (spatially and temporally) but greatest in areas of upwelling or shallow waters where nutrient levels are high. Seasonal variation in phytoplankton (via chlorophyll-a concentrations) has been demonstrated in Australian waters from the analysis for Moderate Resolution Imaging Spectro Radiometer (MODIS) Aqua sensor imagery (Figure A-19).

Phytoplankton biomass ranges across Bass Strait (integrated over 0 - 100m depth) from about 1.6µg/L chlorophyll from shallow waters to 0.1µg/L in deeper waters (Gibbs, Arnott, Longmore, & Marchant, 1991). Phytoplankton biomass rapidly drops off with water depth, to about 0.1µg/L below 100m, due to diminishing light penetration.

Zooplankton is the faunal component of plankton, comprised of small protozoa, crustaceans (such as krill) and the eggs and larvae from larger animals. More than 170 species of zooplankton have been recorded in eastern and central Bass Strait, but it has been found that seven dominant species make up 80% of individuals (*Bass Strait Environment Plan* (AUGO-EV-EMM-012)). Zooplankton biomass is higher in shallow waters of Bass Strait (16.1mg/m^3 dry weight off Mallacoota and 15.5mg/m^3 off Seaspray), dropping to between 1.2 - 2.1mg/m^3 further offshore (integrated over the top 50m of the water column), near the deepest regions of the eastern Great Australian Bight (Gibbs, Arnott, Longmore, & Marchant, 1991). As with phytoplankton, zooplankton biomass appears to be higher in the shallow waters of the shelf. Copepods dominate the species encountered (Chaloupka & Watson, 1982).

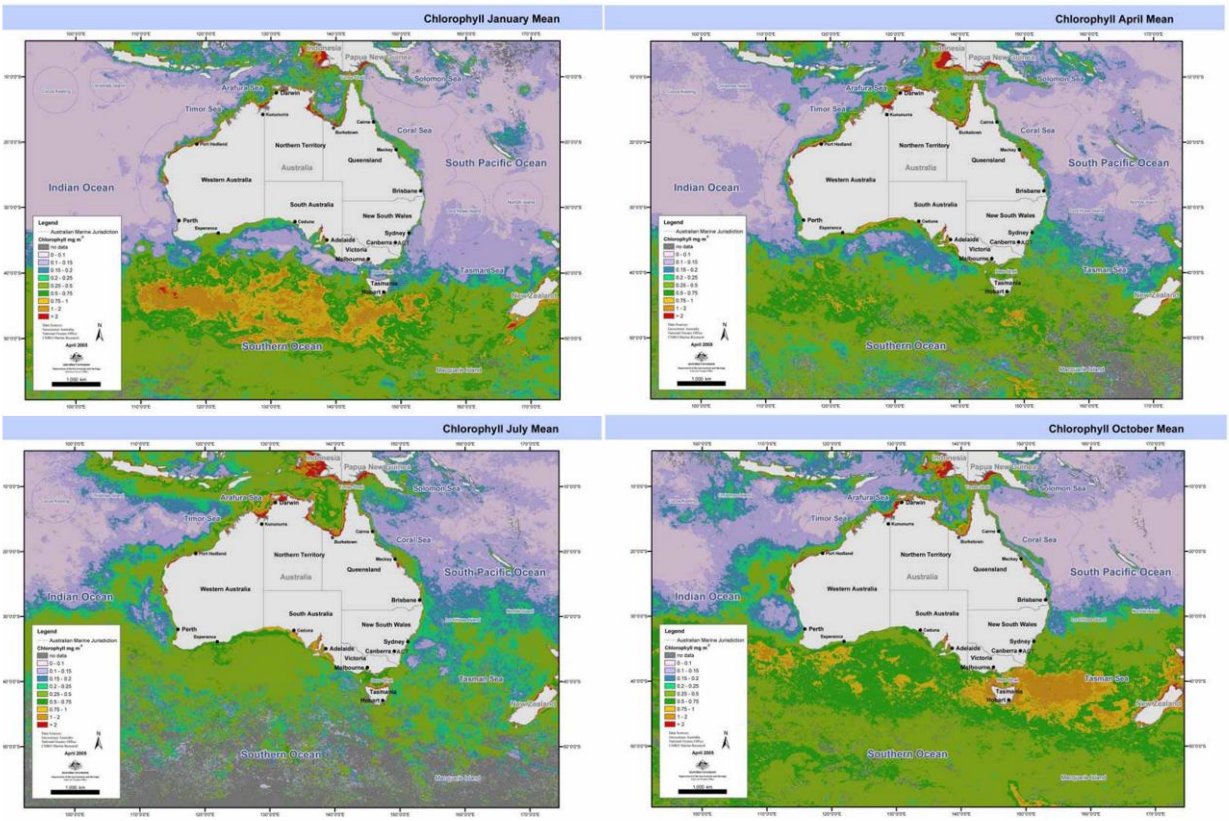

Figure A-19 Seasonal phytoplankton growth from MODIS ocean colour composites (McClatchie, Middleton, Pattiaratchi, Currie, & Kendrick, 2006)

A.1.4.3 Fish, sharks and rays

Fish species detected by the PMST within the EMBA are listed in Table B-1 and Table B-2 in Appendix B of the EP (see also Appendix D of the EP for the full PMST report for the EMBA). Only fish, sharks and ray species that are listed threatened species under the EPBC Act are discussed further. Appendix D lists the relevant threats to shark species that may occur within the EMBA, as identified by management plans, conservation advice and recovery plans. No relevant threats were identified for rays or fish.

It is estimated that there are over 500 species of fish found in the waters of Bass Strait, including a number of species of importance to commercial and recreational fisheries (Land Conservation Council , 1993). Fish species commercially fished within the EMBA are listed in Sections A.1.6.2, A.1.6.3, A.1.6.4, and A.1.6.5.

There are 52 fish species, including seven species of shark, listed as threatened under the EPBC Act with potential to occur within the EMBA (see Table B-2 in Appendix B). In total, 34 of the 52 fish species identified in the EPBC Act PMST (approximately 71%) are syngnathids, which includes seahorses, seadragon, pipehorse and pipefish. Sygnathidae are mostly benthic on coastal reefs, amongst marine algae, seagrass beds, or on sandy and rubble substrates and in caves and crevices. A few species are found offshore amongst floating *Sargassum* spp. algae (Bray, Seahorses, pipefishes, SYNGNATHIDAE, 2021) they can be found in waters less than 50m deep and are sometimes recorded in deeper offshore waters. It is likely that Syngnathidae species will occur in coastal reefs, marine algae, seagrass beds, sandy and rubble substrates and caves and crevices sites throughout the EMBA.

A.1.4.3.1 Black rockcod

The black rockcod (*Epinephelus daemelii*) is listed as vulnerable under the EPBC Act. The black rockcod is a large cod species distributed in warm temperate to temperate marine waters of southeastern Australia, from southern Queensland to Mallacoota in Victoria, and rarely south of this point (DSEWPAC, 2012c).

The species inhabits caves, gutters, and crevices generally to depths of 50m, with juveniles found inshore. Individuals are highly territorial and have small home ranges (DSEWPAC, 2012c). The black rockcod is a protogynous hermaphrodite, meaning it changes sex from female to male during its life cycle. The species has declined in number due to angling and spearfishing (DSEWPAC, 2012c). Given their known distribution, the black rockcod may occur in suitable habitat north of Mallacoota (Victoria) and is likely to occur toward the north end of the EMBA in New South Wales. The Elizabeth and Middleton Reefs Marine National Nature Reserve (outside the EMBA) supports an abundant population of black rockcod (DSEWPAC, 2012c).

A.1.4.3.2 Eastern dwarf galaxias

The eastern dwarf galaxias (*Galaxiella pusilla*) is listed as endangered under the EPBC Act. The species conservation status was upgraded from vulnerable to endangered in November 2023 due to its restricted geographic distribution, continuing habitat decline and population fragmentation (DCCEEW, 2023b).

Habitat suitable to the dwarf galaxias is slow flowing and still, shallow, permanent, and temporary freshwater habitats such as swamps, drains and the backwaters of streams and creeks, often (but not always) containing dense aquatic macrophytes and emergent plants (Saddlier, Jackson, & Hammer, 2010) (DELWP, 2015).

There are 46 rivers and wetlands that are listed in *Dwarf Galaxias Galaxiella pusilla [Action Statement No. 258]* (DELWP, 2015) as being important to the species, the only listed waterway within the EMBA is the Merriman Creek. Therefore, the eastern dwarf galaxias may be encountered in the EMBA if the Merriman Creek (Victoria) is open to the ocean at the time of the spill.

A.1.4.3.3 White's seahorse

The White's seahorse (*Hippocampus whitei*) is listed as endangered under the EPBC Act and is endemic to New South Wales and Queensland in eastern Australia (TSSC, 2020). It is also included as one of nine priority fish species in the *Threatened Species Action Plan 2022-2032* (DCCEEW, 2022b).

White's seahorse is a small (maximum length approximately 16cm), long snouted seahorse which is highly variable in colour with their colouration known to change depending on the habitat they are found in. The species is known to live in the wild for up to five to six years (TSSC, 2020).

The White's seahorse is known to occur in water depths between 1 - 15m and is known to occur in estuaries from Saint Georges Basin, New South Wales (towards the north end of the EMBA) to Hervey Bay, Queensland (outside of the EMBA). The White's seahorse is found utilising a wide range of habitat types (both natural and artificial). It prefers more complex habitats, believed to provide better protection and more available food resources (TSSC, 2020). The species displays strong site fidelity, with tagged males occurring on the same site for up to 56 months and females 49 months, with no seahorse ever recorded moving between sites. Individuals are not known to move far, as the largest distance a tagged animal was found to travel was only 70m (TSSC, 2020).

The major threat to the White's seahorse is loss of habitat across its range followed by cleaning of artificial habitats (protective swimming nets) within the Sydney region (TSSC, 2020). Due to the known habitat preferences of the White's seahorse, the species may be encountered in the EMBA within the coastal regions of New South Wales in proximity to Saint Georges Basin.

A.1.4.3.4 Orange roughy

The orange roughy (*Hoplostethus atlanticus*) was listed as Conservation Dependent under the EPBC Act in 2006, within Australian waters with most stocks reported to be well below 20% of estimated pre-fishing equilibrium biomass and closed to targeted fishing (DCCEEW, n.d.(b)).

The orange roughy is a commercially important demersal fish species that is found in ridge and slope waters 180 - 1800m deep (DCCEEW, n.d.(b)). Orange roughy are very long lived, very slow to mature and have low fertility relative to other bony fishes. Ageing studies show that they do not mature until their mid-20's to mid-30's and may live to 150 years of age.

Although widespread, orange roughy migrate hundreds of kilometres to form spawning aggregations over seamounts between June and August in the Southern Hemisphere (DCCEEW, n.d.(b)). They are synchronous spawners and form dense spawning and feeding aggregations. Recovery of the species is threatened by commercial trawl fishing. Given its habitat preferences, the orange roughy is likely to occur in deep waters of the EMBA.

A.1.4.3.5 Australian grayling

The Australian grayling (*Prototroctes maraena*) is listed as vulnerable under the EPBC Act. The Australian grayling is a dark brown to olive-green fish that is approximately 19cm in length. The species typically inhabits the coastal streams of New South Wales, Victoria, and Tasmania, migrating between streams and the ocean (Backhouse, Jackson, & O'Connor, 2008a). The species spends most of its life in freshwater (DEECA, 2023b), and migrates to lower reaches of rivers to spawn in autumn (Gomon & Bray, 2020), though timing is dependent on many variables including latitude and varying temperature regimes (Backhouse, Jackson, & O'Connor, 2008a), with increased stream flows also thought to initiate migration (DEECA, 2023b).

Threatening processes to this species include barriers to movement, river regulation, poor water quality, siltation, introduced fish, climate change, diseases, and fishing (Backhouse, Jackson, & O'Connor, 2008a). Several rivers intersected by the EMBA (at their mouths, when open) are listed as important locations for the species (DEECA, 2023b). The species may therefore be present in the EMBA in the relatively rare event that creek and river mouths are open, and the species is spawning.

A.1.4.3.6 Eastern gemfish

The eastern gemfish (*Rexea solandri*) is listed as Conservation Dependent under the EPBC Act. Gemfish are found throughout southern Australian temperate waters. In Australia, the eastern gemfish are distributed from Cape Moreton, southern Queensland, along the east coast to Bass Strait and the waters off Tasmania.

Eastern gemfish are mesopelagic and inhabit deeper continental shelf habitats and upper slope waters from 100 – 700m (down to 1254m) but are generally found in waters about 250 – 500m deep. Historical and ongoing commercial fishing is the highest threat to the eastern gemfish. This species is generally caught close to the seabed, but the fish are likely to move into mid-water at times, larvae occur in shallow to very shallow waters. Gemfish are carnivorous and feed close to the ocean floor on other fish, primarily *Macrouridae* (whiptails). Due to the deep-water distribution of this species, it is likely to be present with the eastern sections of the EMBA.

A.1.4.3.7 Blue warehou

The blue warehou (*Seriolella brama*) is listed as Conservation Dependent under the EPBC Act. The blue warehou is a bentho-pelagic species found in southern Australia where it inhabits continental shelf and slope waters. Adults can be found at depths from 50 - 300m. Blue warehou are schooling fish and usually aggregate close to the seabed and juveniles can sometimes be found schooling close to the surface in estuaries, often in association with jellyfish. This species is commercially important and formally managed under the *Blue warehou (Seriolella brama) Stock Rebuilding Strategy* (AFMA, 2022). Blue warehou is likely to occur in the EMBA.

A.1.4.3.8 Non-parasitic lamprey

As of March 2023, the non-parasitic lamprey (*Mordacia praecox*) also known as precocious lamprey, is listed as endangered under the EPBC Act (DCCEEW, 2023c). The species is listed in the PMST report as to be within the EMBA. However, unlike most parasitic lamprey species, the non-parasitic lamprey is entirely a freshwater species, completing its life cycle in rivers and never migrating to brackish or marine systems. Consequently, it is restricted to individual river basins. Within each river system, specimens of the non-parasitic lamprey have only been reported relatively close to the coast (<50km) (DCCEEW, 2023c). The species has been reported in far southern New South Wales from Wallagaraugh River on the New South Wales and Victoria border, and also at northern New South Wales and southeastern and central Queensland.

A.1.4.3.9 Grey nurse shark (east coast population)

The grey nurse shark (*Carcharius taurus*) (eastern population) is listed as critically endangered under the EPBC Act due to commercial fishing, spearfishing, and protective beach meshing (TSSC, 2001). The grey nurse shark is also included as one of nine priority fish species in the *Threatened Species Action Plan 2022-2032* (DCCEEW, 2022b).

The grey nurse shark was historically widespread in sub-tropical and warm temperate seas and previously recorded from all Australian states except Tasmania (TSSC, 2001). The species currently has a broad inshore

distribution throughout sub-tropical to cool temperate waters on the continental shelf, with separate east coast and west coast populations (DoE, 2014). The east coast population extends from central Queensland to southern New South Wales, occasionally as far south as the New South Wales/Victoria border (DoE, 2014), which coincides with the BIA for their migration and foraging (December to April) which is intercepted by the EMBA and shown in Figure A-20.

Preferred habitat for grey nurse sharks is inshore rocky reefs or islands, generally aggregating near the seabed in water depths of 10 - 40m in deep sandy or gravel filled gutters, or in rocky caves border (DoE, 2014). There are no known aggregation sites located off the Victorian coast border (DoE, 2014) however, the EMBA does intersect with the migration and foraging BIA (December to April) within the coastal waters towards the south of New South Wales (Figure A-20). Given the current distribution of the grey nurse shark and the known foraging and migration areas, the species is known to occur within the EMBA.

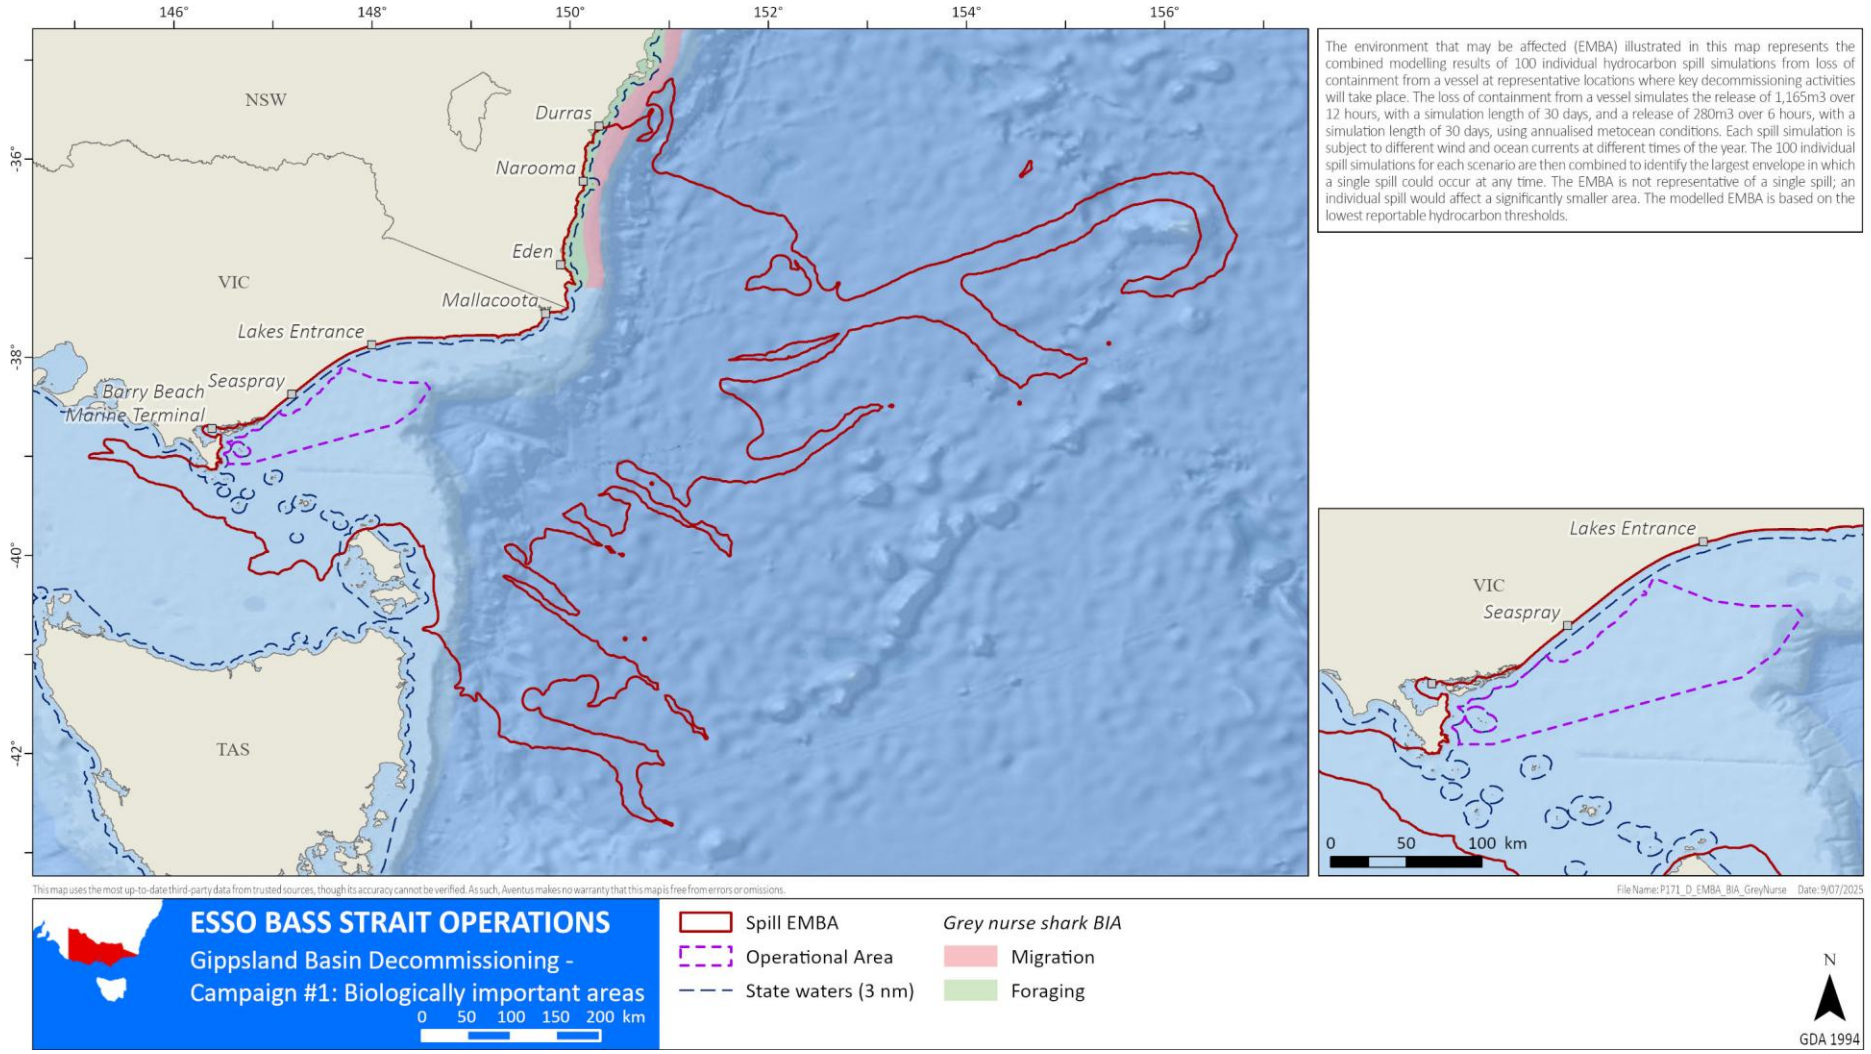

Figure A-20 Grey nurse shark BIAs intersected by the EMBA

A.1.4.3.10 Great white shark

The great white shark (*Carcharodon carcharias*) is listed as vulnerable under the EPBC Act. The great white shark is widely distributed and located throughout temperate and sub-tropical waters, with their known range in Australian waters including all coastal areas except the Northern Territory (DSEWPAC, 2013b). Studies of great white sharks indicate that they are usually solitary animals, largely transient and only temporarily resident (e.g. days to weeks) in areas it inhabits (DSE, 2003) (DSEWPAC, 2013b). However, individuals are known to return to feeding grounds on a seasonal basis (Klimley & Anderson, 1996).

The species moves seasonally along the south and east Australian coasts, moving northerly along the coast during autumn and winter and returning to southern Australian waters by early summer. Observations of adult sharks are more frequent around fur seal and sea lion colonies, including Wilsons Promontory and The Skerries (both within the EMBA and is also reflected by the foraging BIA (see Figure A-21) (DSE, 2003). The *Recovery Plan for the White Shark (Carcharodon carcharias)* (DSEWPAC, 2013b) indicates juvenile white sharks appear to congregate in certain key areas including the Corner Inlet-Ninety Mile Beach area. (Bray, 2023) indicates that Corner Inlet may be an important nursery area for the eastern population of great white sharks, mostly from mid-summer through to autumn. A breeding BIA covering the area from Wilsons Promontory to Lakes Entrance is intercepted by the EMBA. Likewise, a foraging BIA located in the Bass Strait between Wilsons Promontory and the Kent Group of islands, as well as an area nearby Mallacoota, are within the EMBA (Figure A-21).

Key threats to the species, as listed in the *Recovery Plan for the White Shark (Carcharodon carcharias)* (DSEWPAC, 2013b) and *Great White Shark Carcharodon carcharias [Action Statement No. 185]* (DSE, 2003) are mortality from targeted fishing, accidental fishing bycatch and illegal fishing, and mortality from shark control activities (such as beach meshing and drum lining), none of which will take place during the activity. Similarly, the activity will have no impact on the 10 objectives for protection listed in the plan. Given their transitory nature and the proximity of foraging areas, great white sharks are known to occur within the EMBA.

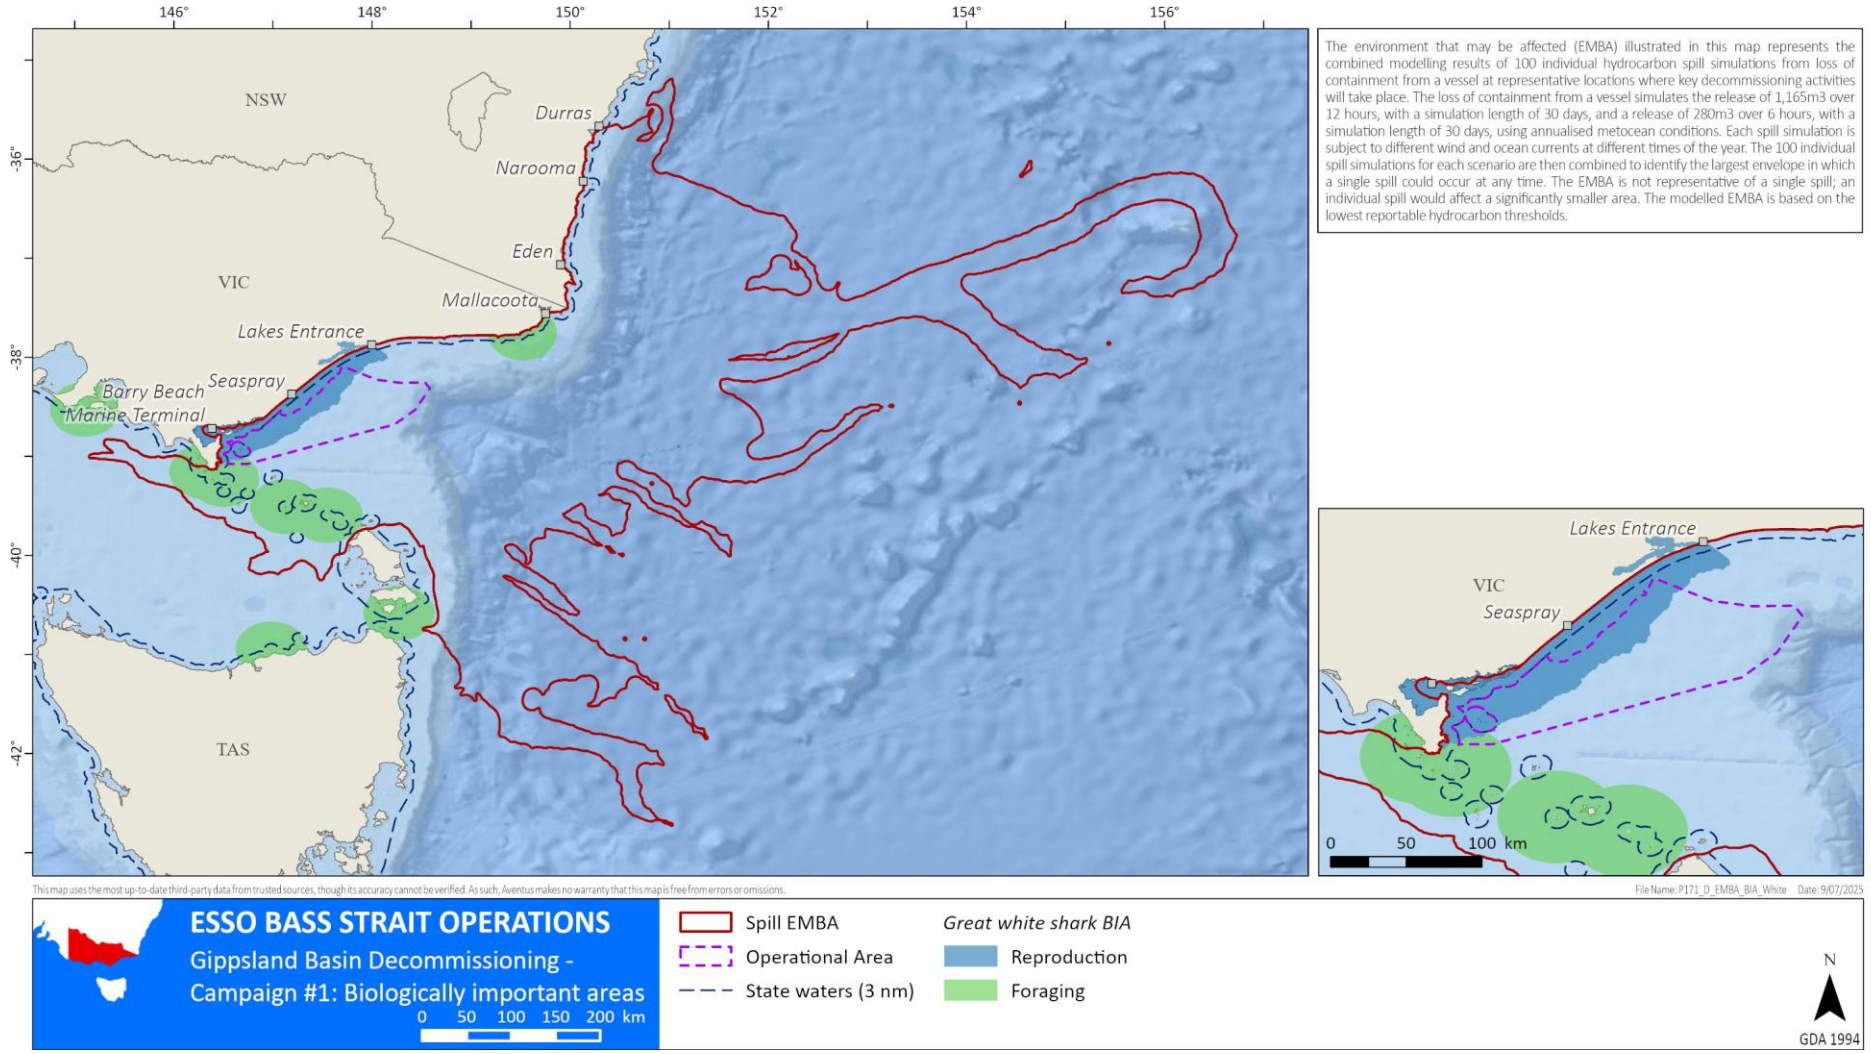

Figure A-21 Great white shark BIAs intersected by the EMBA

A.1.4.3.11 Harrisson's dogfish

Harrisson's dogfish (*Centrophorus harrissoni*) is listed as Conservation Dependent under the EPBC Act. In Australian waters, Harrisson's dogfish distribution extends off the Clarence River, New South Wales, to the South East Cape, Tasmania, and from Fraser Seamount, Queensland to Taupo Seamount, New South Wales (DCCEEW, n.d.(b)), preferring depths of 200 – 1050m.

The main threat to southern dogfish in Australian waters was population reduction caused by past fishing pressure in both State and Commonwealth-managed commercial fisheries operating on the upper-slope (TSSC, 2013a). Harrisson's dogfish populations are estimated to have declined by more than 90% in parts of their range off southern New South Wales and eastern Victoria. As a result, the species was listed under the EPBC Act as Conservation Dependent in June 2013. This species habitat preferences indicates that it is likely to occur in the EMBA.

A.1.4.3.12 Little gulper shark

The little gulper shark (*Centrophorus uyato*) is listed as Conservation Dependent under the EPBC Act. The little gulper shark is distributed along the continental slope of southern Australia from Forster (New South Wales) to Bunbury (Western Australia), including Tasmania, in depths of 200 - 700m, but usually in depths below 400m (DCCEEW, n.d.(b)).

Little gulper sharks undertake day-night migrations across their depth range from relatively deep daytime residence depths (1000m) to shallower nighttime feeding depths (to 200m). This species feeds mainly on fish, crustaceans and squid. It migrates up gullies on the continental slope to feed at night on mesopelagic fish that have migrated from deeper waters. The main threat to the little gulper shark in Australian waters is population reduction caused by past fishing pressure in both State and Commonwealth-managed commercial fisheries operating on the upper-slope (TSSC, 2013b). Species in genus *Centrophorus* are vulnerable to over-exploitation due to the fact that they are long-lived, late to mature and have small litters (DCCEEW, n.d.(b)). This species habitat preferences indicates that it is likely to occur in the EMBA.

A.1.4.3.13 Whale shark

The whale shark (*Rhincodon typus*) is listed as vulnerable under the EPBC Act and is the world's largest fish and one of the only three filter feeding shark species (TSSC, 2015a). They have a broad distribution in warm and tropical waters of the world, and in Australia are known only to occur on the west coast of Western Australia, with a feeding aggregation occurring off the Ningaloo Reef between March and July each year (TSSC, 2015a). Isolated records exist of whale sharks off New South Wales, Victoria and South Australia. Because this species is not known to migrate through Bass Strait, and the lack of known distribution in Victoria, Tasmania, and New South Wales, it is highly unlikely to occur within the EMBA.

A.1.4.3.14 Scalloped hammerhead

The scalloped hammerhead (*Sphyrna lewini*) is listed as Conservation Dependent under the EPBC Act. The scalloped hammerhead is a relatively large, fusiform-bodied, moderately slender shark with a circum-global distribution in tropical and sub-tropical waters. This species has a strong genetic population structuring across ocean basins as it rarely ventures into or across deep ocean waters but ranges quite widely over shallow coastal shelf waters (TSSC, 2024).

Within Australian waters the scalloped hammerhead extends from New South Wales (around Wollongong, where it is less abundant), around the north of the continent and then south into Western Australia. Due to the species distribution, the scalloped hammerhead may be encountered within the area of the EMBA that extends up to the area near Jervis Bay, New South Wales.

A.1.4.3.15 School shark

The school shark is listed as Conservation Dependent under the EPBC Act. The species is a widespread mainly coastal and bottom associated shark found in temperate areas over the continental shelf to about 800m on the continental slope (DCCEEW, n.d.(b)). Juveniles are often found in shallow, inshore bays of Victoria and Tasmania. School sharks also occur well offshore in the Tasman Sea. Although usually found near the bottom, the species ranges through the water column even into the pelagic zone (DCCEEW, n.d.(b)).

The species feeds on bony fishes (bottom-dwelling and pelagic species), squid and octopus. Small juveniles feed on crustaceans, polychaete worms, gastropods, and echinoderms. The species was fished throughout its range

and heavily exploited due to the excellent quality of its flesh for eating and its oil (DCCEEW, n.d.(b)). In addition, targeted fishing of juveniles and degradation of nearshore nursery sites has been linked to population declines (DCCEEW, n.d.(b)). The species is currently the focus of the *School Shark (Galeorhinus galeus) Stock Rebuilding Strategy* (AFMA, 2015), which aims to rebuild the species to 40% of its pre-exploitation levels within a biologically relevant timeline, by closing areas to protect pups and breeding age school sharks as well as preventing targeted fishing of the species. School sharks are likely to be present in the EMBA.

A.1.4.4 Cetaceans

Cetaceans are a widely distributed and diverse group of carnivorous, finned, aquatic marine mammals. They comprise whales, dolphins and porpoises. Cetaceans are generally found in the ocean but can also inhabit river systems.

Table B-4 in Appendix B of the EP lists the cetacean species within the EMBA. Table A-5 lists the relevant threats to cetacean species that may occur within the EMBA, as identified by management plans, conservation advice and recovery plans. Cetacean species that are listed as threatened or migratory under the EPBC Act or have known BIAs within the EMBA are discussed further.

There are several pelagic dolphins that may occur in the EMBA. The population size of these species is not known; however, none are considered to be rare. No specific conservation or listing advice exists and their distribution has not been specifically defined. All species feed on pelagic fish, squids, octopus, shrimps, and other marine fauna taken at depths exceeding 250m. The extent of occurrence is large in all cases, estimated to be greater than 20,000km^2. All are tropical to subtropical species (occasionally temperate) with distribution varying depending on water temperature and flow of warm currents.

A.1.4.4.1 Southern right whale

Two populations of SRW occur in Australia, the western and the eastern SRWs. While the geographical boundary between these two populations is unclear, for management purposes the western population includes Western Australia and South Australia waters west of Ceduna (South Australia), whereas the eastern population, comprises coastal waters of east of Ceduna (South Australia), Victoria, Tasmania, New South Wales and Queensland (DCCEEW, 2024b).

SRW predominantly occupy shallow, coastal areas where they calve and nurse their young on the Australian coast. The peak period of abundance is typically in late July and August, although there is within season variability that differs between females with calves and unaccompanied whales. Females accompanied by a calf generally occupy the calving ground for two to three months between June and September, whereas unaccompanied whales (males and females without a calf) are more variable in their occupancy of coastal areas throughout the reproductive season (DCCEEW, 2024b). Mapping of BIAs available via the Australian Marine Spatial Information System website (Geoscience Australia, n.d.) identifies two BIA that are overlapped by the EMBA (Figure A-22); reproduction (May to September) and migration (April to October). Similarly, the *National Recovery Plan for the Southern Right Whale* (DCCEEW, 2024b) includes mapping that indicates reproduction season for SRW ranging approximately from May to September (Figures 4 and 5 of the Recovery Plan), however this plan also makes reference to the reproduction season extending from May to October.

Known calving and aggregation grounds in the southeast region are Warrnambool, Port Fairy, Port Campbell and Portland in Victoria, and Encounter Bay, South Australia (Commonwealth of Australia, 2012). Calving itself usually occurs in very shallow (<10m depth) waters. Other population classes stay in the nursery grounds for shorter and variable periods of time; there is typically a lot of movement along the coast, and thus habitat connectivity is important for this species. The summer offshore distribution and migration routes of SRW largely is unknown but is known to include directly southern and western migration pathways but may include offshore habitat where mating (Mackay, et al., 2015).

According to the BIA Protocol (DCCEEW, 2023d) category definitions, reproduction BIAs are areas known or likely to be regularly or repeatedly used by individuals or aggregations of a species for reproduction or to provide refuge, or other advantage to young. Migration BIAs are areas known or likely to be regularly or repeatedly used by individuals or aggregations of a species for undertaking seasonal or other temporal movements which contribute to connectivity with other functionally important areas (DCCEEW, 2023d). Both BIAs are overlapped by the EMBA (Figure A-22). In addition, under Part 13, Section 270 of the EPBC Act, a Recovery Plan must identify the habitats that are critical to the survival of the species or community concerned (DCCEEW, 2024b). As such, the *National*

Recovery Plan for the Southern Right Whale (DCCEEW, 2024b) has established that 'habitat critical to the survival' of SRWs are all the reproductive BIAs across the species range, based on the following:

- they meet the species essential life cycle requirements for reproduction (e.g. mating, calving, and nursing) and reproduction is known to occur at that location
- there is a level of occupancy by individual breeding females at these locations of multiple days in any given year, and across multiple years, for long-term maintenance of the species
- they are critical for recovery of the SRW in terms of expanding habitat occupancy and contributing to the maintenance of genetic diversity as site fidelity may lead to small-scale genetic differences.

The *National Recovery Plan for the Southern Right Whale* (DCCEEW, 2024b) indicates that 'Critical Habitat', as defined under Section 207A of the EPBC Act, is different from 'habitat critical to the survival' and only applies to Commonwealth land and sea, and there is no such habitat identified or included in the Register of Critical Habitat. The Plan also confirms that there are no important cetacean habitat areas identified for SRW in the Australian Whale Sanctuary as defined under Section 228A of the EPBC Act (DCCEEW, 2024b).

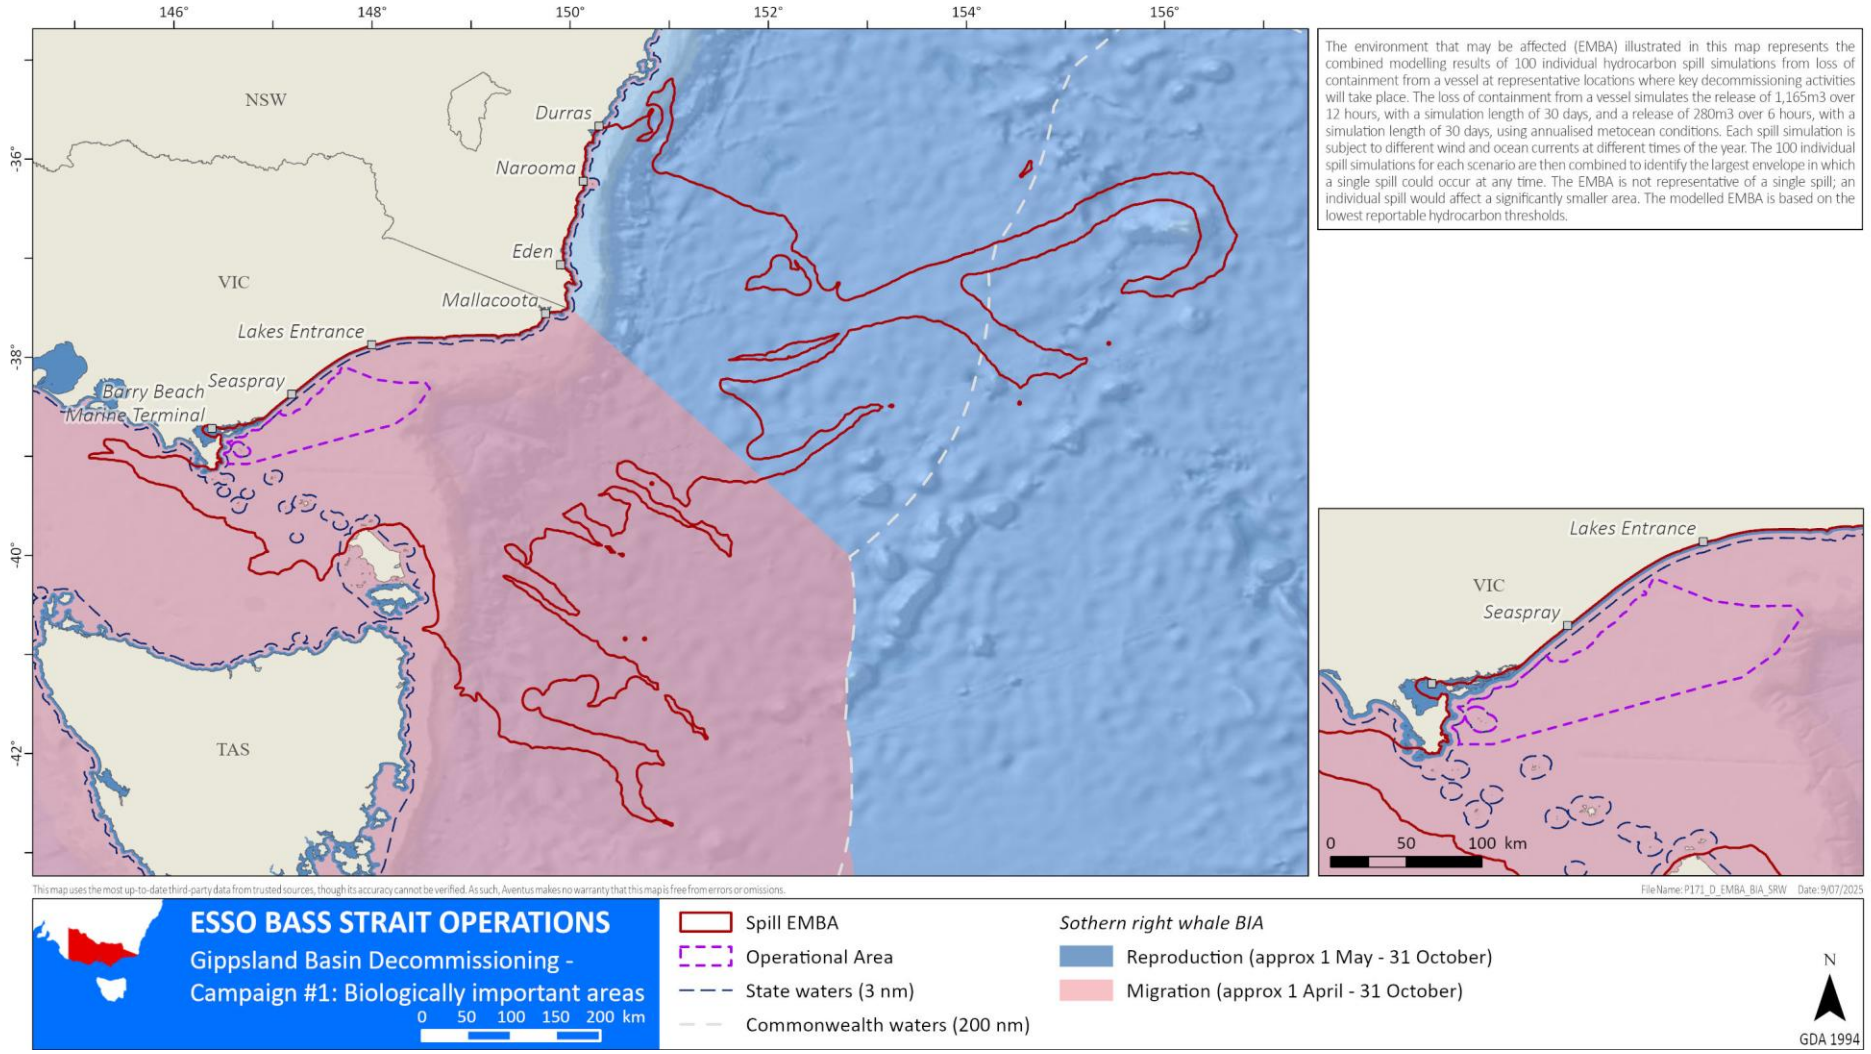

Figure A-22 SRW BIAs intersected by the EMBA

A.1.4.4.2 Blue whales

The blue whale (*Balaenoptera musculus*) has four subspecies, two of which occur within Australian waters, including the Antarctic blue whale (*B. m. intermedia*) and the PBW (*B. m. brevicauda*) (Rice 1998, in (Department of the Environment, 2023).

The PBW has five population groups, two of which are found in the Southern Hemisphere. Figure A-23 summarises the known and predicted ranges of the species and populations around Australia and New Zealand and their likely presence in Esso's areas of operation in eastern Bass Strait.

A.1.4.4.2.1 DISTRIBUTION

Long term passive acoustic recorders set by McCauley et al. (2018) found Antarctic blue whale calls along the entire southern Australian coast, while calls from the New Zealand PBW population occur predominantly eastward of Bass Strait and calls from the Indo-Australian PBW population were heard west of Bass Strait. The Indo-Australian PBW population wasn't recorded on the east Australian coast or east of Bass Strait and the New Zealand PBW population was always heard in the Bass Strait recordings, and only ever heard as far west as Portland in Victoria. The Antarctic blue whale was recorded at all sites south of 19°S (McCauley, Gavrilov, Jolliffe, Ward, & Gill, 2018).

Balcazar, et al. (2015) suggests that the Australian continent acts as a geographic boundary, separating Indo-Australian and New Zealand PBW acoustic populations at the junction of the Indian and Pacific Ocean basins. The distribution of PBW in the Australian region is illustrated in Figure A-24. There are few contemporary records of blue whales in the Gippsland region. However, recent scientific literature suggests that PBW populations are capable of travelling great distances far beyond their expected range (Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres, 2023). This concept that blue whales can extend beyond their current range is corroborated by Branch, et al. (2023), who modelled the predicted detection range for the Antarctic blue whale and PBW populations. Findings from Branch, et al. (2023) and Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres (2023) are discussed further within the population sub-headings in this Section.

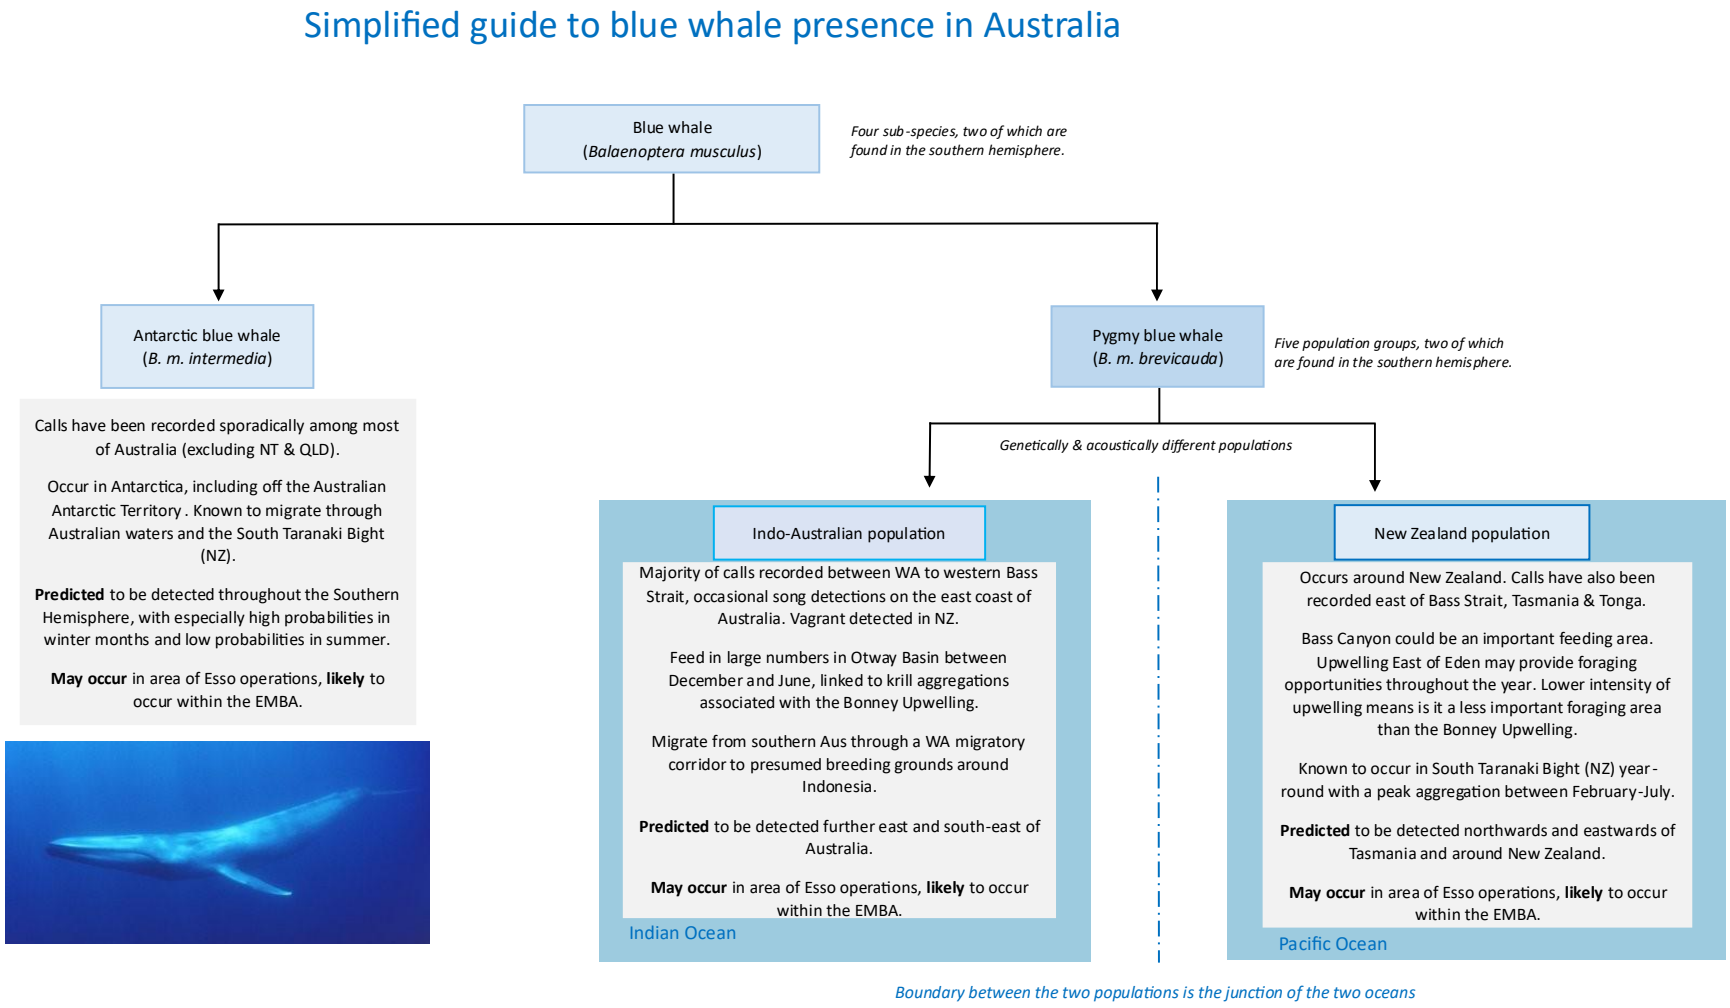

Figure A-23 Simplified guide to blue whale presence in Australia

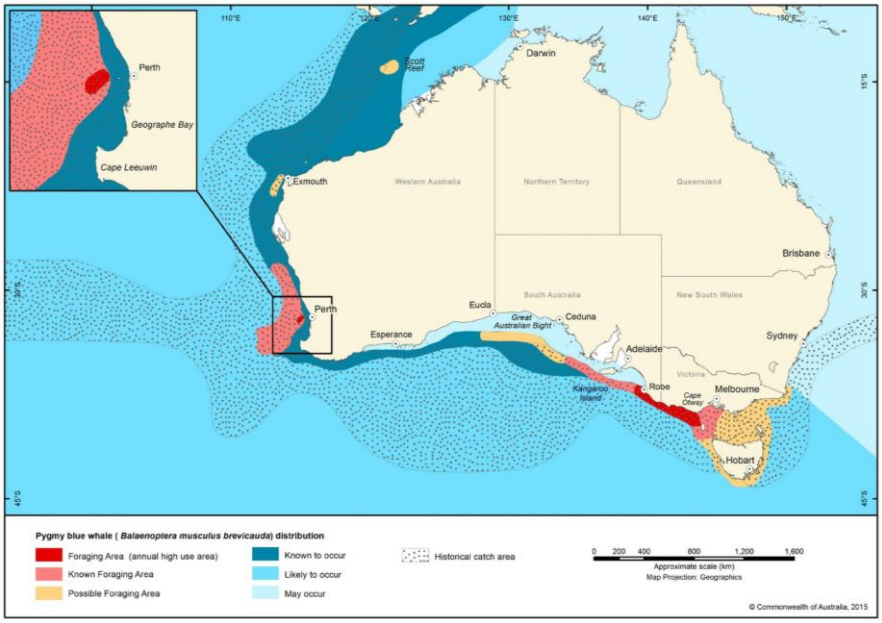

Figure A-24 Distribution and foraging areas for the PBW (Commonwealth of Australia, 2015)

A.1.4.4.2.2 DIET

Blue whales have the highest known prey requirements, consuming up to two tonnes of krill per day (Commonwealth of Australia, 2015). Krill is the key to understanding the ecology and behaviour of blue whales. Krill is sensitive to temperature and migrates vertically and horizontally to maintain optimal positioning with respect to nutrients, often being found along thermal fronts and thermoclines. Krill abundance in a given season may be linked to oceanographic conditions of the previous year. The krill species, *Nyctiphanes australis*, frequently swarm at or near the surface, making it easily available to foraging blue whales. It can also be found at depth, where blue whales must dive to search and consume it. Foraging is energetically expensive for blue whales, which must regularly find sufficient food to balance their enormous energy requirements (Gill P. , 2020). There are two important seasonal feeding aggregations areas known in Australia where large numbers of PBW have been recorded: the Bonney Upwelling KEF and adjacent waters off South Australia and Victoria (located approximately 230km west of the EMBA); and the Perth Canyon KEF and adjacent waters off Western Australia (located over 2800km west of the EMBA). Prominent surface upwelling commonly occurs west of Portland where the shelf is narrow (the Bonney Upwelling); whereas on the broader shelf between Portland and King Island, upwelling is usually subsurface, with cooler upwelled water beneath a warmer surface layer (Gill P. , 2020).

A.1.4.4.2.3 ANTARCTIC BLUE WHALE

The Antarctic blue whale subspecies consists of one or more populations that feed off Antarctica during summer, and limited evidence suggests that some proportion migrate to subtropical latitudes of the Pacific and Indian Ocean to breed. They have been acoustically detected off the west and north coasts of Tasmania predominately from May to December. Based on the seasonality of recordings, these areas possibly form part of their migratory route, breeding habitat or a combination of the two (Director of National Parks, 2025).

Results of continuous acoustic recordings that took place from January 2016 to February 2018 in the South Taranaki Bight in New Zealand (Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres, 2023) noted that the South Taranaki Bight could be a migratory corridor for the Antarctic blue whale. The Antarctic blue whale is predicted to remain consistently within the Southern Hemisphere, with especially high probabilities in winter months (May-August), and low probabilities in summer (December - March) (Branch, et al., 2023).

In light of the findings of Branch, et al. (2023) and Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres (2023), it is likely the Antarctic blue whale will be present within the EMBA.

A.1.4.4.2.4 INDO-AUSTRALIAN PYGMY BLUE WHALE

The distribution and migration patterns of Indo-Australian PBW are relatively well understood in areas further west of the EMBA. Satellite tagging of Indo-Australian PBW by Double et al. (2014) and Möller, et al.) (2020) has revealed that the Indo-Australian population migrates from southern Australian foraging grounds through a

Western Australian migratory corridor to (presumed) breeding grounds in waters around Indonesia. In July 2024, revised BIA spatial data became publicly available via the Australian Marine Spatial Information System website (Geoscience Australia, n.d.). Based on the revised BIA data, the EMBA overlaps with 31% of the foraging BIA for PBW (Figure A-25).

The time and location of the appearance of Indo-Australian PBW generally coincides with the upwelling of cold water in summer and autumn along the Bonney Upwelling and the associated aggregations of krill that they feed on (Gill & Morrice, Cetacean Observations. Blue Whale Compliance Aerial Surveys, 2003). The Bonney Upwelling generally starts in the eastern part of the Great Australian Bight in November or December and spreads eastwards to the Otway Basin around February as southward migration of the subtropical high-pressure cell creates upwelling favourable winds. Sighting data indicates that blue whales are seasonally distributed (Gill P. C., et al., 2011) (McCauley, Gavrilov, Jolliffe, Ward, & Gill, 2018).

Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres (2023) detected the Indo-Australian PBW song during a 10-day period in January 2017, implying a rare vagrant occurrence. The modelling predicts that the distribution of the Australian PBW is further westward of Western Australia, further south along the Great Australian Bight and Indian Ocean, south-eastward towards the Bass Strait and Tasmania and even as far as New Zealand (Branch, et al., 2023).

In light of the findings of Branch, et al. (2023) and Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres (2023), it is likely the Indo-Australian PBW will be present within the EMBA.

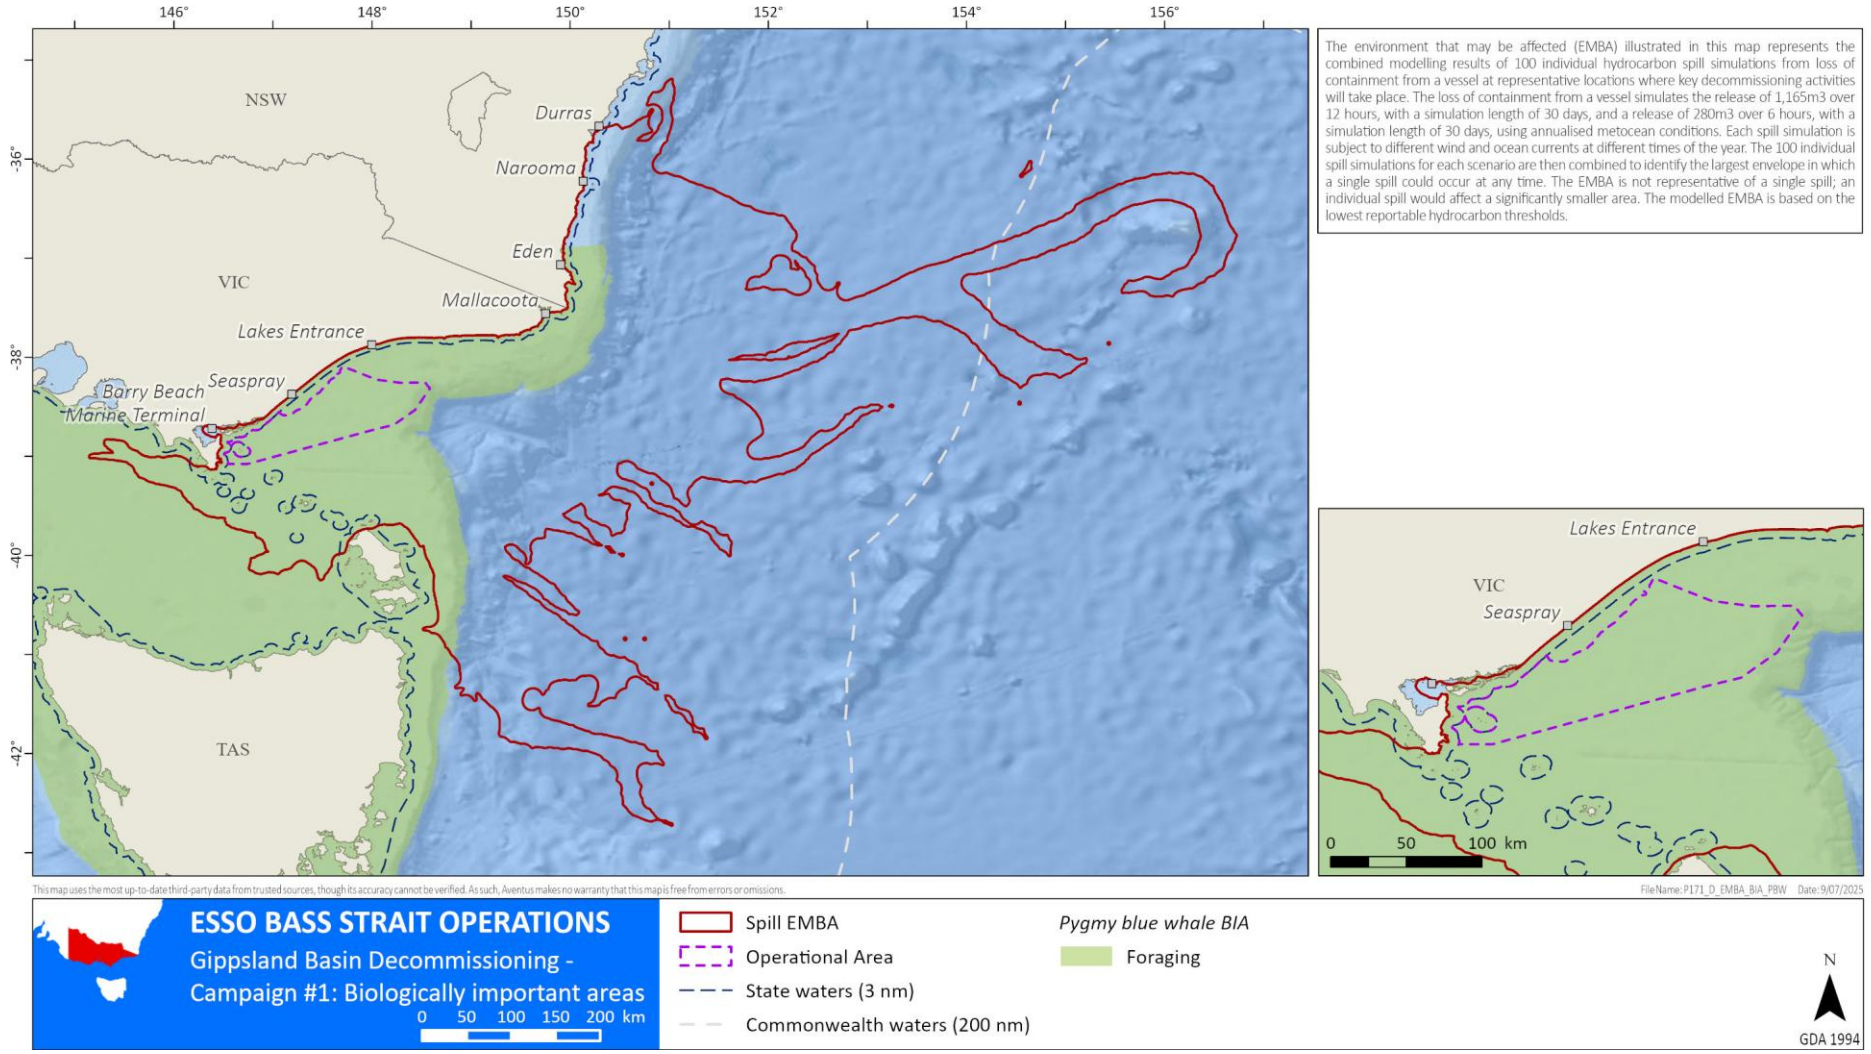

Figure A-25 PBW BIAs intersected by the EMBA

A.1.4.4.2.5 NEW ZEALAND PYGMY BLUE WHALE

Relatively little is known about New Zealand PBW. Antarctic blue whales are known to co-occur with PBW around New Zealand. Antarctic blue whale detections peaked during austral winter and spring, indicating that New Zealand, and the South Taranaki Bight in particular, is a migratory corridor for them. Some Antarctic blue whale calls were also detected during the breeding season (September and October). PBW calls were highly concentrated in the South Taranaki Bight, particularly between March and May, suggesting that an aggregation may occur here (Warren, McPherson, Giorli, Goetz, & Radford, 2021).

The Upwelling East of Eden KEF is located within the EMBA and is a recognised upwelling system. Upwelling influence areas were mapped between September and May (austral spring, summer and autumn) each year for a period of 14 years (Sept 2002 to May 2016) along 4500km of the south-eastern coast of Australia using monthly MODIS sea surface temperature data (Huang & Hua Wang, 2019).

The study confirmed that there were three seasonal/semi-seasonal upwelling centres: the Bonney Upwelling; the Kangaroo Island Upwelling; and the Eyre Peninsula Upwelling, in the western Victorian/South Australian coastal upwelling system. The New South Wales coastal upwelling system is a persistent/semi-persistent system occurring continuously from austral spring to autumn, although during mid to late autumn the upwelling may be either lacking or isolated and restricted to the coast. The intensity of the southern New South Wales/eastern Victorian upwelling system, centred on the Eden Upwelling, has a less distinct seasonal pattern (Figure A-26) (Huang & Hua Wang, 2019).

(Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres, 2023) states that despite extensive acoustic recordings in eastern Australia, Bass Strait and Tonga, the New Zealand population has rarely been being detected in these locations. The New Zealand PBW is anticipated to be distributed northwards and eastwards of Tasmania (including Bass Strait and the eastern coast of Australia), and around New Zealand (Branch, et al., 2023).

In light of the findings of (Barlow, Klinck, Ponirakis, Holt-Colberg, & Torres, 2023)and (Branch, et al., 2023), it is likely the New Zealand PBW is present within the EMBA.

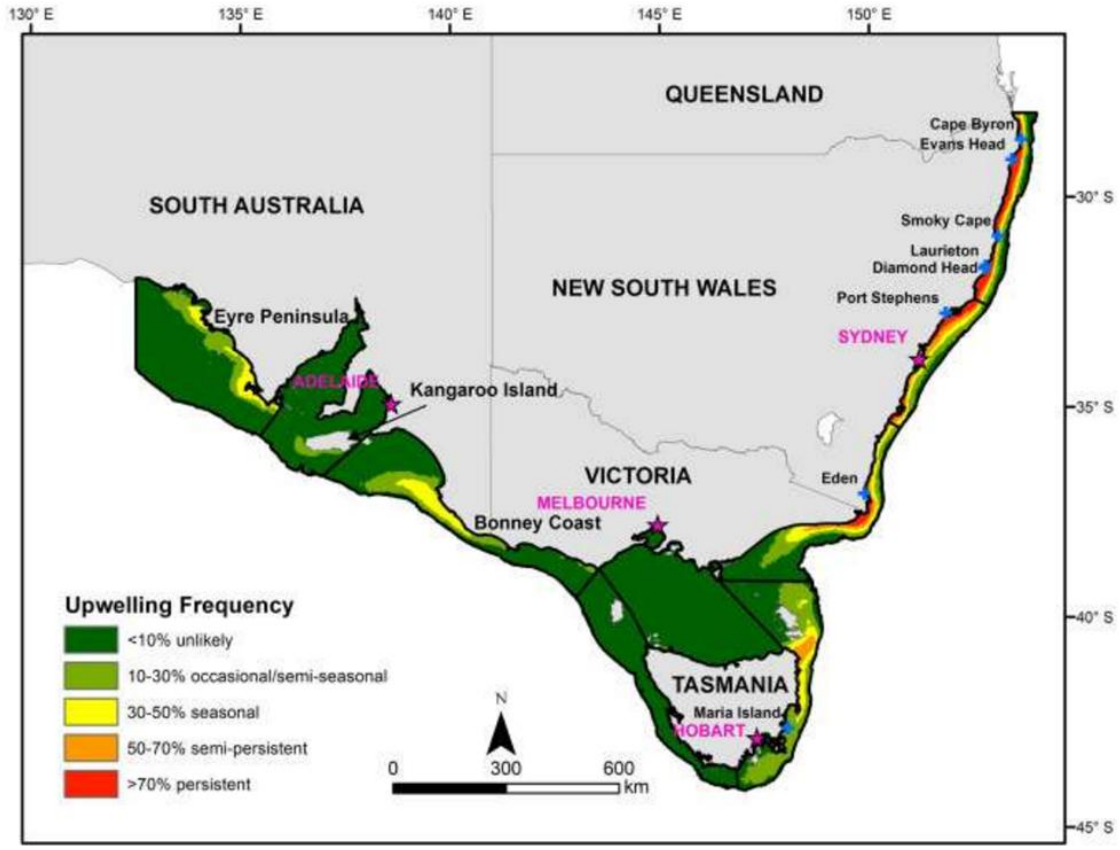

Figure A-26 Upwelling frequency (Huang & Hua Wang, 2019)

A.1.4.4.3 Humpback whales

Humpback whales (*Megaptera novaeangliae*) migrate annually along the eastern coast of Australia heading north to tropical calving grounds from May to August, and south to Southern Ocean feeding areas from August to November (Figure A-27). While the main migration route of this species is along the east coast of Australia along the continental shelf to the east of Bass Strait, some animals migrate through Bass Strait. Humpback whales do not feed, breed, or rest in Bass Strait and the Victorian coastal waters are not a key location for this whale species (Bannister, Kemper, & Warneke, 1996).

Most feeding grounds are south of Australian waters (TSSC, 2015b). A BIA for migration has been identified within the EMBA, along the east coast of Australia (Figure A-28). Humpback whales in the Southern Hemisphere primarily feed on Antarctic krill (*Euphausia superba*). While most feeding grounds are south of Australian waters, there are some feeding grounds that are regularly used on the southern migration in Australian coastal waters: off the coast of Eden in New South Wales, and east coast of Tasmania (TSSC, 2015b).

In late February 2022, the humpback whale was removed from the 'vulnerable' category and now holds no threatened status under the EPBC Act. The Department of Agriculture, Water and the Environment (DAWE) listing advice (TSSC, 2022) states that humpback whales have been recovering strongly for the past five decades, since their severe decline due to commercial whaling which ceased in 1963. However, they remain Matters of National Environmental Significance under the EPBC Act as a listed migratory species, and the species remains listed as a cetacean, where it is an offence to kill, injure, take, trade, keep, move, or interfere with a cetacean (TSSC, 2022).

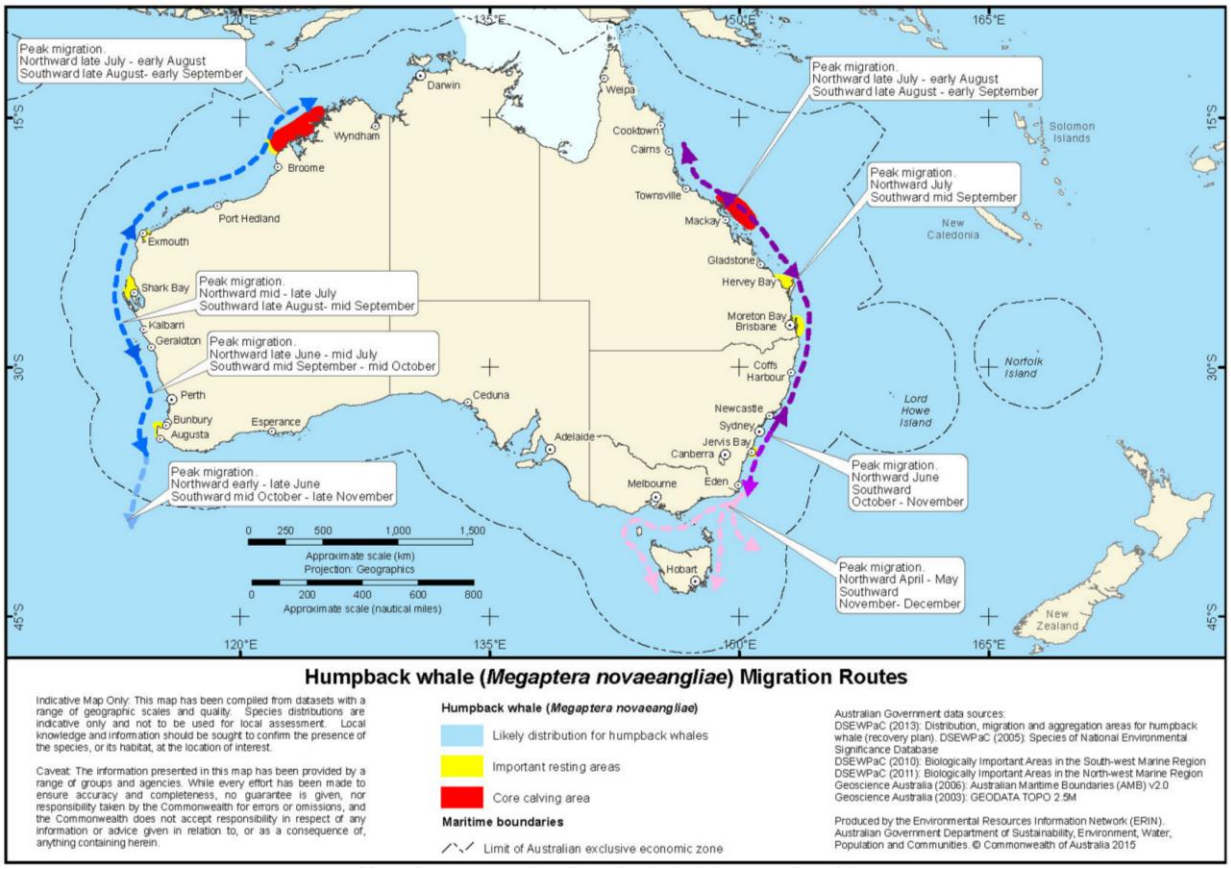

Figure A-27 Migration routes for humpback whales around Australia (TSSC, 2015b)

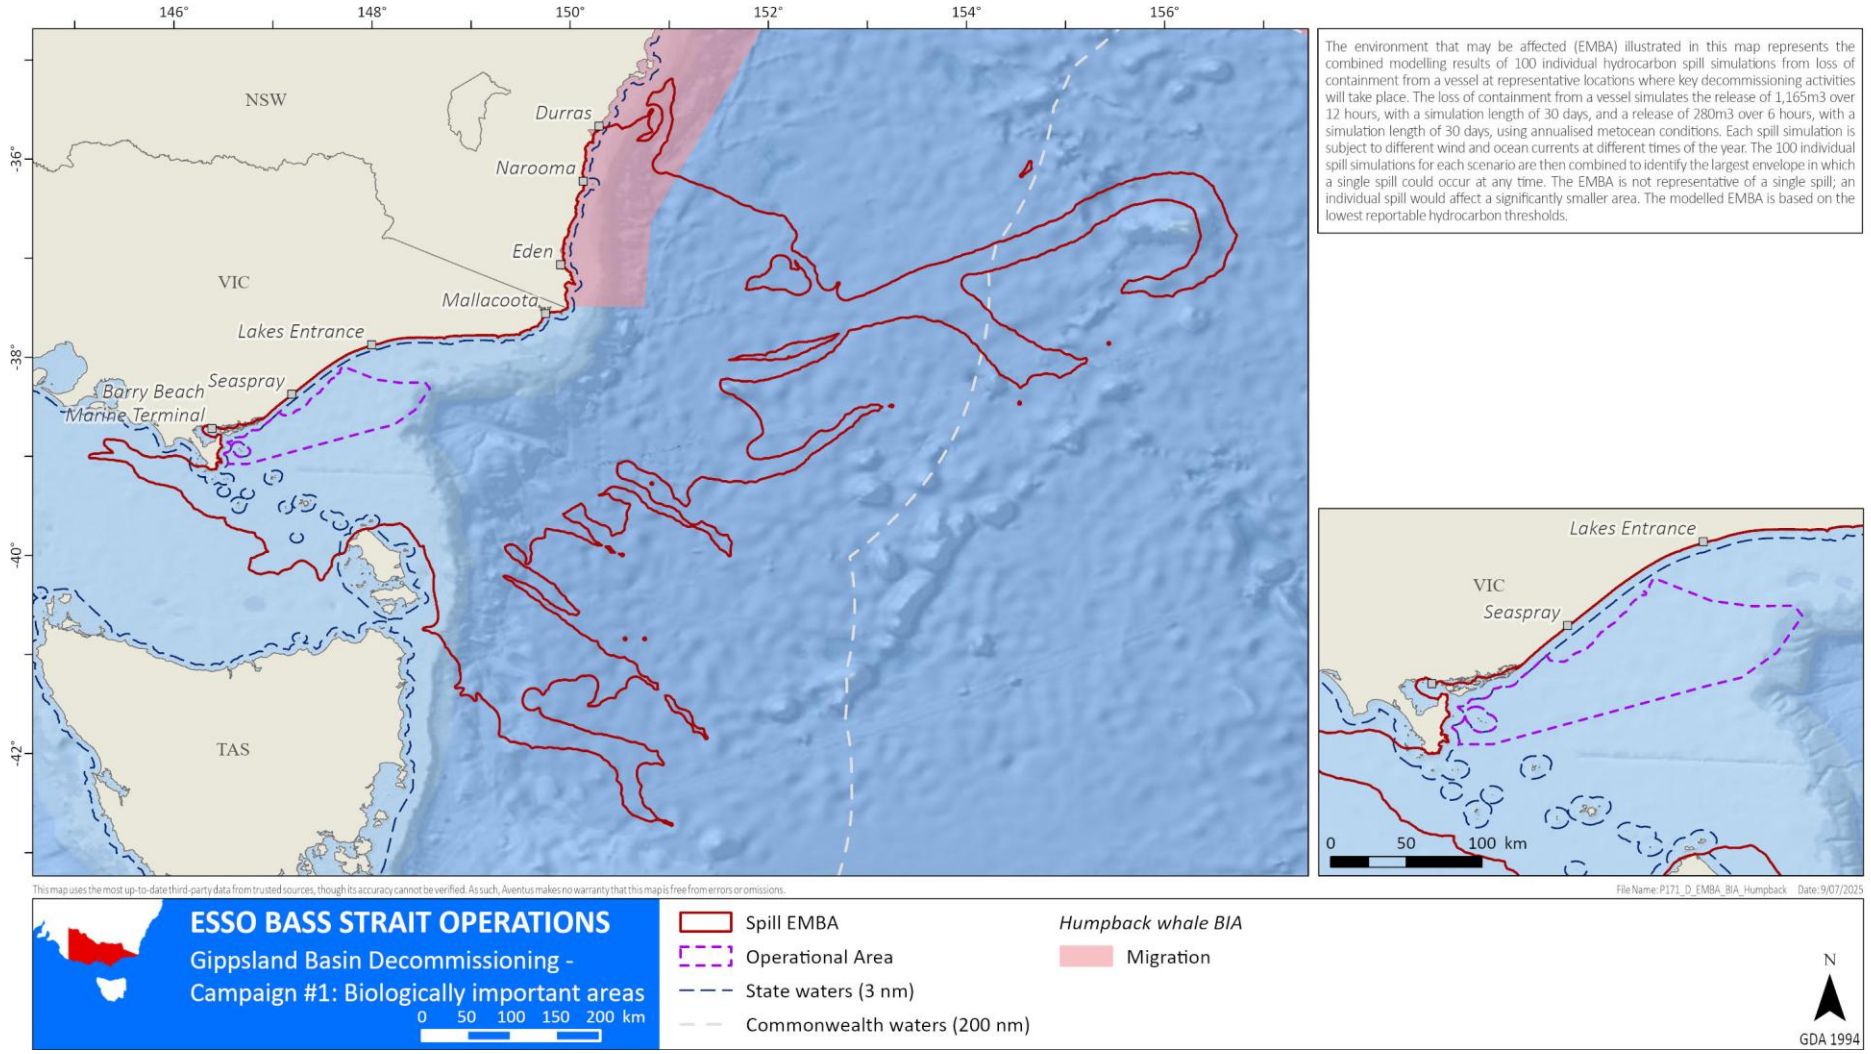

Figure A-28 Humpback whale BIAs intersected by the EMBA

A.1.4.4.4 Pygmy right whale

Records of pygmy right whales (*Caperea marginata*) in Australian waters are distributed between 32°S and 47°S but are not uniformly spread around the coast (DCCEEW, n.d.(b)). Areas of coastal upwelling events appear to be an important component regulating pygmy right whale distribution. Pygmy right whales have primarily been recorded in areas associated with upwellings and with high zooplankton abundance, which constitute their main prey. There is some evidence to indicate that the area south of 41°S is important for weaned pygmy right whales, possibly because of the higher prey abundance in these waters (DCCEEW, n.d.(b)).

A.1.4.4.5 Sperm whale

Sperm whales (*Physeter macrocephalus*) are the largest of the toothed whales and are generally found in pods of up to 50 individuals (DCCEEW, n.d.(b)). Sperm whales have a global distribution. They generally inhabit deeper oceanic waters with a water depth of 600m or more and are uncommon in waters less than 300m (DCCEEW, n.d.(b)). The PMST indicates that the species may occur within the EMBA. No BIAs for the species are recorded in the EMBA.

A.1.4.4.6 Antarctic minke whale

The Antarctic minke (*Balaenoptera bonaerensis*) whale is more robust than the other large baleen whales. The maximum length of Antarctic minke whales appears to be around 9.8m. Antarctic minke whales are not gregarious and tend to swim alone or in pairs, although large feeding groups of up to 400 individuals may form in higher latitudes (DCCEEW, n.d.(b)). Minke whales are known to be curious, often approaching boats from a distance.

Antarctic minke whales have been recorded in all Australian states except the Northern Territory. The paucity of records obscures the determination of the range of Antarctic minke whales along the Australian coast, although they are known to occur north to 21°S off the east coast. The distribution up the west coast of Australia is currently unknown. The current extent of occurrence for Antarctic minke whales is estimated to be greater than 20,000km^2 (based on the Australian Economic Exclusion Zone) (DCCEEW, n.d.(b)).

A.1.4.4.7 Bryde's whale

The Bryde's whale (*Balaenoptera edeni*) is restricted to tropical and temperate waters and has been recorded off all Australian states with exception of the Northern Territory (Bannister, Kemper, & Warneke, 1996). Bryde's whales can be found in both oceanic (500 - 1000m isobath) and inshore waters (<200m isobath) (DCCEEW, n.d.(b)). Population estimates are not available for Bryde's whales, globally or in Australia, and no migration patterns have been documented in Australian waters (DCCEEW, n.d.(b)). Bryde's whale is considered to be a fairly opportunistic feeder, and it appears that the coastal and offshore forms may be distinguished by their prey preferences, with the smaller coastal form feeding on schooling fishes, such as pilchard, anchovy, sardine, mackerel, herring and others. In contrast, the larger offshore form appears to feed on small crustaceans, such as euphausids, copepods, pelagic red crabs and cephalopods.

A.1.4.4.8 Sei whale

Sei whales (*Balaenoptera borealis*) have been infrequently recorded in Australian waters; however occasional sightings have been recorded off Tasmania, New South Wales, Queensland and within the Great Australian Bight (DCCEEW, n.d.(b)). Sei whales typically feed between the Antarctic and subtropical convergences, and their diet is planktonic crustacea, in particular copepods and amphipods. However, they have also been observed feeding on the continental shelf in the Bonney Upwelling region during November and May, suggesting the area may be used for opportunistic feeding (DCCEEW, n.d.(b)).

A.1.4.4.9 Fin whale

The distribution of fin whales (*Balaenoptera physalus*) in Australian waters is uncertain, but they have been recorded in Commonwealth waters off most States (the species is rarely found in inshore waters) (DCCEEW, n.d.(b)). Fin whales frequently lunge or skim feed, at or near the surface, feeding on planktonic crustacea, some fish and cephalopods (DCCEEW, n.d.(b)). Fin whales generally feed in high latitudes, however depending upon prey availability and locality, they may also feed in lower latitudes. Fin whales have been observed in waters off the Bonney Upwelling during November and May, suggesting the region may be used for opportunistic feeding (DCCEEW, n.d.(b)). Fin whales have also been detected acoustically south of Portland, Victoria (Erbe, McCauley, Gavrilov, Madhusudhana, & Verma, 2016).

Table A-5 lists the relevant threats (as identified by relevant management plans/listing advice/conservation advice) to threatened whale species that may occur within the EMBA.

Table A-5 Key threats to threatened whale species relevant to the activity

Common name	Recovery plan/conservation advice/management plan	Key threats (relevant to the activity)
Sei whale	*Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015c)	• Anthropogenic noise and acoustic disturbance. • Habitat degradation including pollution. • Pollution (persistent toxic pollutants). • Vessel strike.
Blue whale	*Conservation Management Plan for the Blue Whale* (Commonwealth of Australia, 2015)	• Noise interference. • Habitat modification from marine debris or chemical discharge. • Vessel strike.
Fin whale	*Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015d)	• Anthropogenic noise and acoustic disturbance. • Pollution (persistent toxic pollutants). • Vessel strike.
SRW	*National Recovery Plan for the Southern Right Whale* (DCCEEW, 2024b)	• Entanglement (marine debris). • Habitat modification. • Anthropogenic underwater noise (vessel noise). • Collision (vessel strike). • Pollution (chronic chemical pollution).

A.1.4.4.10 Killer whale

The killer whale (*Orcinus orca*) is the largest member of the dolphin family. The killer whale is thought to be the most cosmopolitan of all cetaceans and appear to be more common in cold, deep waters, though they have often been observed along the continental slope and shelf particularly near seal colonies (Bannister, Kemper, & Warneke, 1996). The killer whale is widely distributed from polar to equatorial regions and has been recorded in all Australian waters with concentrations around Tasmania. The only recognised key locality in Australia is Macquarie Island and Heard Island in the Southern Ocean (outside the EMBA) (Bannister, Kemper, & Warneke, 1996).

The habitat of killer whales includes oceanic, pelagic and neritic (relatively shallow waters over the continental shelf) regions, in both warm and cold waters (DCCEEW, n.d.(b)). The breeding season is variable, and the species moves seasonally to areas of food supply (Bannister, Kemper, & Warneke, 1996) (Morrice, 2004).

A.1.4.4.11 Dusky dolphin

The dusky dolphin (*Lagenorhynchus obscurus*) is rare in Australian waters and is primarily found from approximately 55°S to 26°S, though sometimes further north associated with cold currents. They are considered to be primarily an inshore species but can also be oceanic when cold currents are present (Gill & Wapstra, 2000).

Only 13 reports of the dusky dolphin have been made in Australia since 1828 (the very first described specimen of the species by French naturalists was from off the coast of Tasmania in 1826 and key locations are yet to be identified (Bannister, Kemper, & Warneke, 1996). The dusky dolphin occurs across southern Australia from Western Australia to Tasmania and there are confirmed sightings near Kangaroo Island, South Australia, and off Tasmania. No key localities or critical habitats in Australian waters have been identified (Bannister, Kemper, & Warneke, 1996).

A.1.4.4.12 Indian Ocean bottlenose dolphin

The Indian Ocean bottlenose dolphin (*Tursiops aduncus*) is distributed continuously around Australia (DCCEEW, n.d.(b)). The Indian Ocean bottlenose dolphin occurs mainly in riverine and shallow coastal waters (on the shelf or around oceanic islands) (DSEWPAC, 2012d). Known populations include Jervis Bay, Twofold Bay, and Port Phillip

Bay (DSEWPAC, 2012d) (only Twofold Bay is within the EMBA). Calving peaks occur in spring and summer or spring and autumn (DCCEEW, n.d.(b)). Gestation lasts approximately 12 months, so peak mating period coincides with peak calving period in each location (DCCEEW, n.d.(b)).

A BIA for breeding for the Indo-Pacific/spotted bottlenose dolphin has been identified within New South Wales coastal waters (within the EMBA) (Figure A-29) (DCCEEW, 2024c).

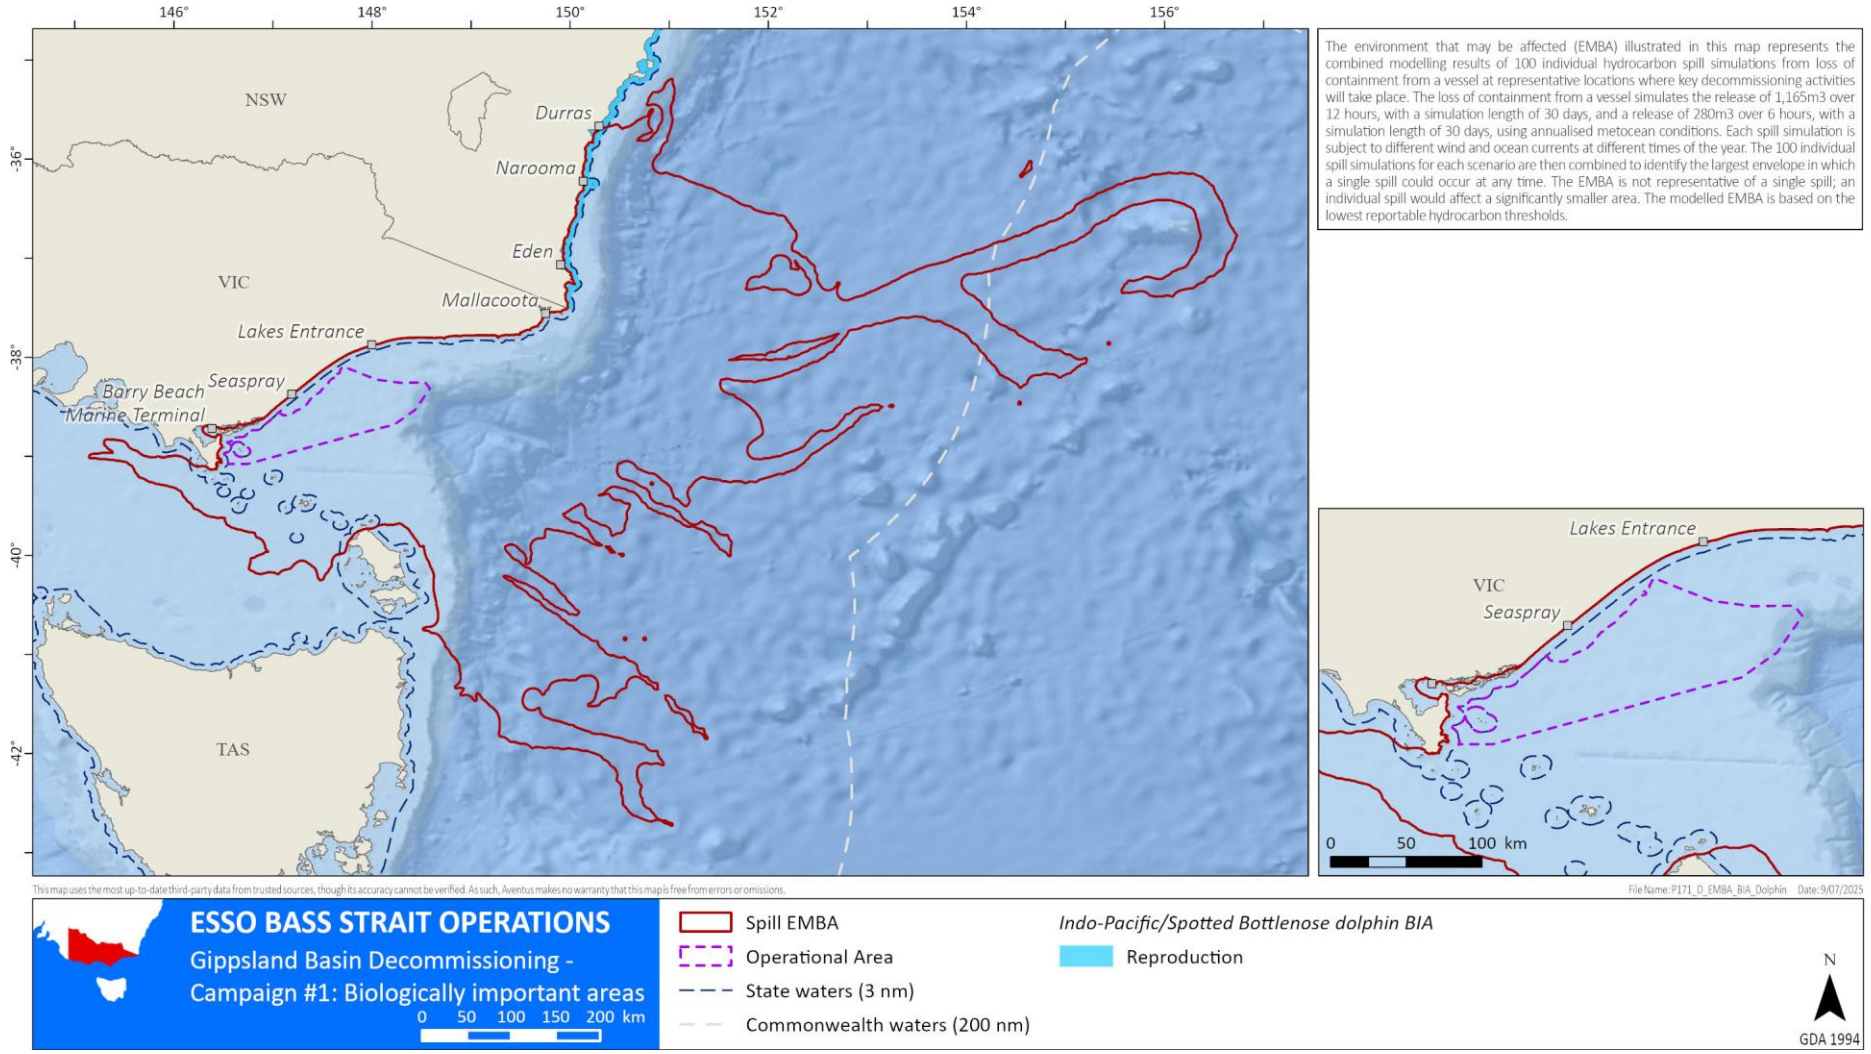

Figure A-29 Indo-Pacific/spotted bottlenose dolphin BIAs intersected by the EMBA

A.1.4.5 Pinnipeds

Two species of pinnipeds were detected by the PMST as potentially occurring in the EMBA. Neither of which are threatened or migratory. Both are described below.

A.1.4.5.1 Australian fur seal

Australian fur seals (*Arctocephalus pusillus*) are endemic to southeastern Australian waters and have a relatively restricted distribution around the rocky islands of Bass Strait (Figure A-30). The species has been recorded in the waters off South Australia, Victoria, Tasmania, and New South Wales (Kirkwood, Warneke, & Arnould, 2009), with an estimated population of 120,000 individuals (Kirkwood, et al., 2010).

There are 13 established breeding colonies of the Australian fur seal, including five colonies located in Victoria, seven located in Tasmania and one located on North Casuarina Island in South Australia (Kirkwood, et al., 2010). The largest of the established colonies occur at Seal Rocks adjacent Phillip Island (25.9% of the breeding population) and at Lady Julia Percy Island (25.5% of the breeding population), in Victoria. Both areas are located outside the EMBA.

Australian fur seal breeding colonies in Bass Strait that are within the EMBA, and estimated number of individuals at each location (Kirkwood, et al., 2010) are (Figure A-30):

- Rag Island (1500 Australian fur seals)
- Kanowna Island (15,000 Australian fur seals)
- The Skerries (14,000 Australian fur seals)
- Judgment Rock in the Kent Group of islands (13,000 Australian fur seals)
- West Moncoeur Island (1100 Australian fur seals)
- Wright Rocks (690 Australian fur seals).

Australian fur seal haul-out sites listed by Kirkwood, et al. (2010), and Parks Victoria (2023) that are within the EMBA (Figure A-30) include Gabo Island, East Island (in the Hogan Group), and Beware Reef.

Australian fur seals have a relatively restricted distribution around the islands of Bass Strait where it is the most common seal (Kirkwood, et al., 2006). Adult tagged seals have shown travel paths from Flinders Island to King Island presumably passing through central Bass Strait. Their preferred habitat, especially for breeding, is a rocky island with boulder or pebble beaches and gradually sloping rocky ledges.

During the summer months Australian fur seals are observed repeatedly travelling between northern Bass Strait islands and southern Tasmania waters following the Tasmanian east coast. Lactating female fur seals and some territorial males are restricted to foraging ranges within Bass Strait waters. Lactating female Australian fur seals forage primarily within the shallow continental shelf of Bass Strait.

Australian fur seals forage on benthos at depths of between 60 - 80m (Hume, Hindell, Pemberton, & Gales, 2003) (Arnould & Kirkwood, 2007) (Robinson, Gales, Terauds, & Greenwood, 2008) generally within 100 - 200km of the breeding colony for up to five days at a time (Hume, Hindell, Pemberton, & Gales, 2003). The lactation period lasts for between ten and eleven months and some females may nurse pups for up to three years (Arnould & Hindell, 2001).

Male Australian fur seals are bound to colonies during the breeding season from late October to late December. Outside the breeding season they forage up to several hundred kilometres and are away for long periods even up to nine days (Kirkwood, et al., 2006). The sexes generally forage in the same environment (Kirkwood, et al., 2006) this suggests that males target different prey than females as observed in similar New Zealand fur seals where males prey on larger fish and seabird species compared to females. Considering the locations of known breeding and haul-out sites within the EMBA, it is likely the species will be encountered.

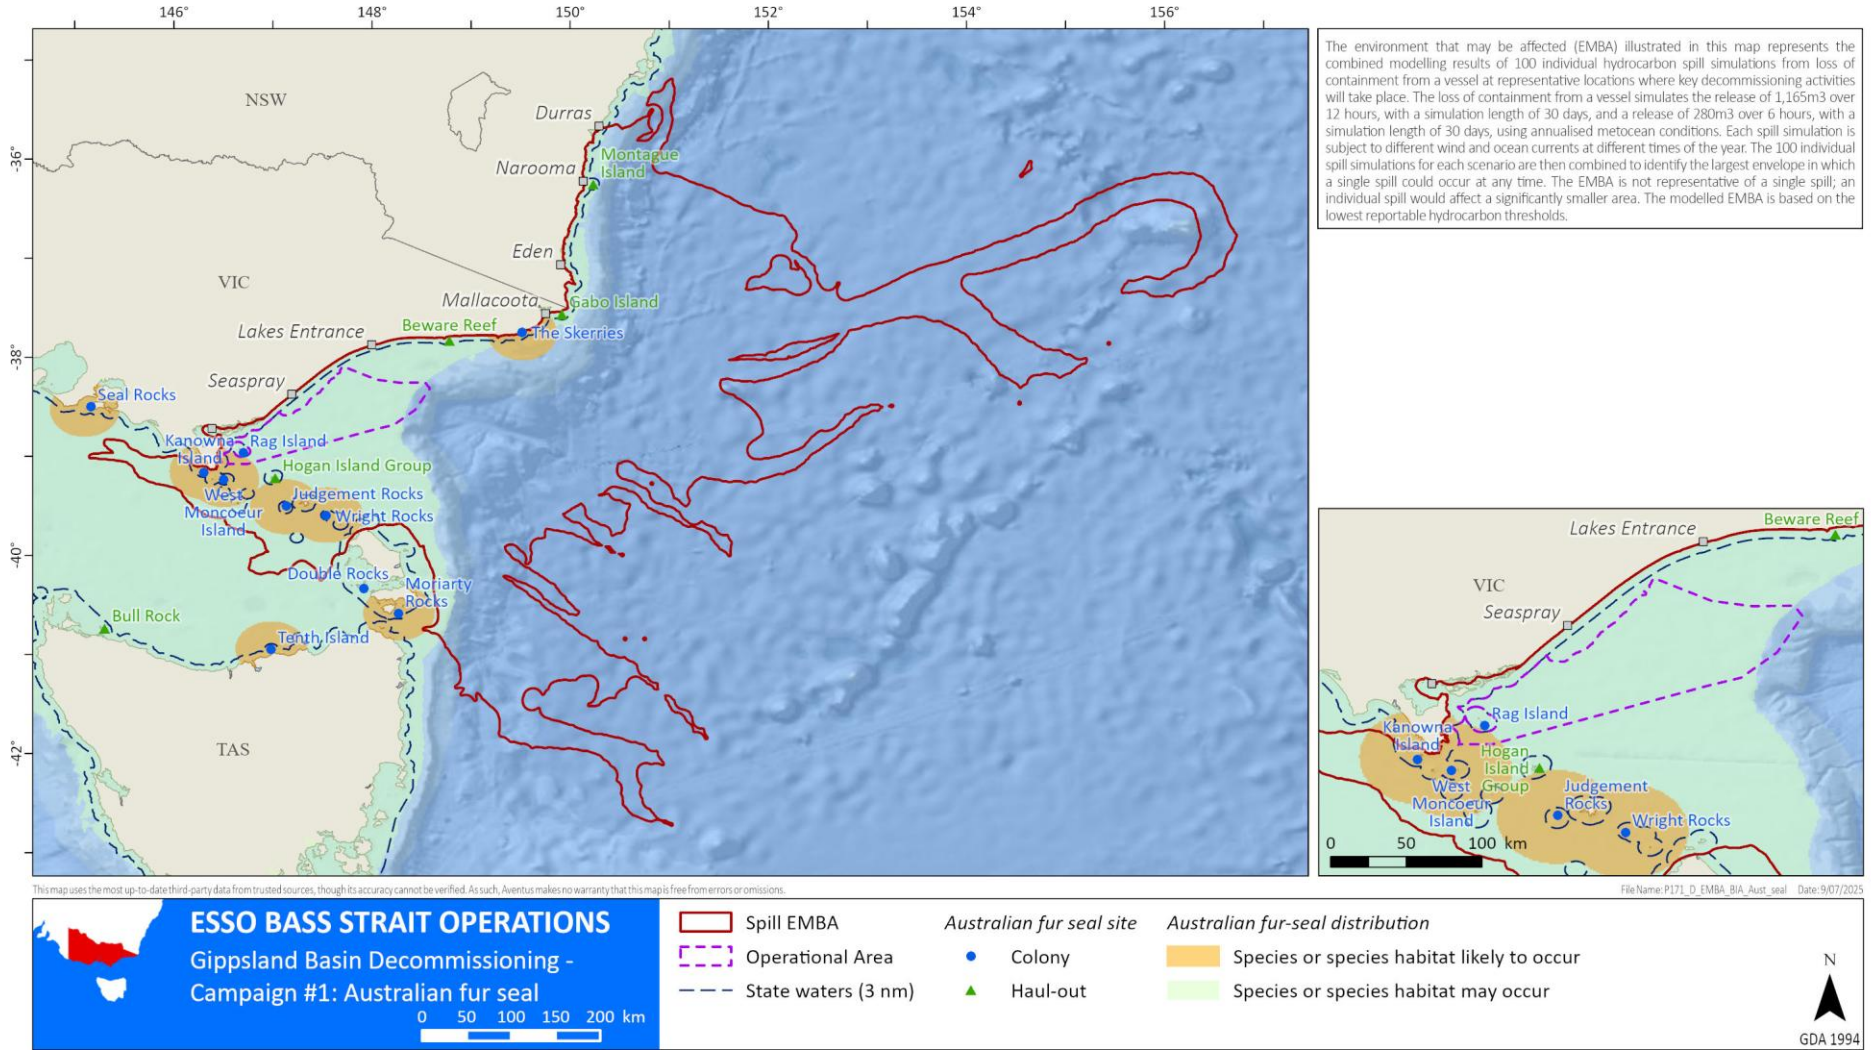

Figure A-30 Australian fur seal distribution, breeding colonies and haul-out sites within the EMBA

A.1.4.5.2 New Zealand fur seal

New Zealand fur seals (*Arctocephalus forsteri*) are mostly found in central South Australian waters (Kangaroo Island to south Eyre Peninsula), with 77% of their population found here (outside the EMBA) (Shaughnessy, 1999).

There are 51 known breeding sites for New Zealand fur seals in Australia, with most of these outside of Victoria (47 in South Australia and Western Australia) (Arnould & Kirkwood, 2007). (Kirkwood, Warneke, & Arnould, 2009) identified four breeding locations within Victoria, at Kanowna Island, off Wilsons Promontory, the Skerries (both located within the EMBA), and at the Lady Julia Percy Island and Cape Bridgewater (both located approximately 267km west of the EMBA) (Figure A-31).

During the summer period (November to January) the breeding sites are occupied by pups/young juveniles, whilst adult females alternate between the breeding sites and foraging at sea (Shaughnessy, 1999).

New Zealand fur seals feed on small pelagic fish, squid, and seabirds, including little penguins (Shaughnessy, 1999). Juvenile seals feed primarily in oceanic waters beyond the continental shelf; lactating females feed in mid-outer shelf waters (50 - 100km from the colony) and adult males forage in deeper waters.

In 2005 - 2006, New Zealand fur seal pup production at the 40 known Australian breeding colonies was estimated at 17,600 pups, equivalent to approximately 35,000 breeding females (Chilvers & Goldsworthy, 2015). The population has been slow to recover from the previous intense sealing operations from 1798 to 1820, partially as the species are slow reproducers, producing one pup per year when they reach sexual maturity at four years. Up to 15% of pups die before they reach two months of age, primarily because of fishing net and other marine debris entanglements. Chilvers & Goldsworthy (2015) estimates the total population of New Zealand fur seals within Australia is approximately 117,400 individuals, increasing to approximately 200,000 individuals when considering the population within New Zealand waters.

Haul-out sites in Bass Strait, as reported by Barton, Pope, & Howe (2012) and OSRA (2015) that are located within the EMBA include Beware Reef, Kanowna Island, the Hogan Islands Group and West Moncoeur Island.

There are no BIAs for the New Zealand fur seal in Bass Strait. Considering the locations of known breeding and haul out sites within the EMBA, it is likely the species will be encountered.

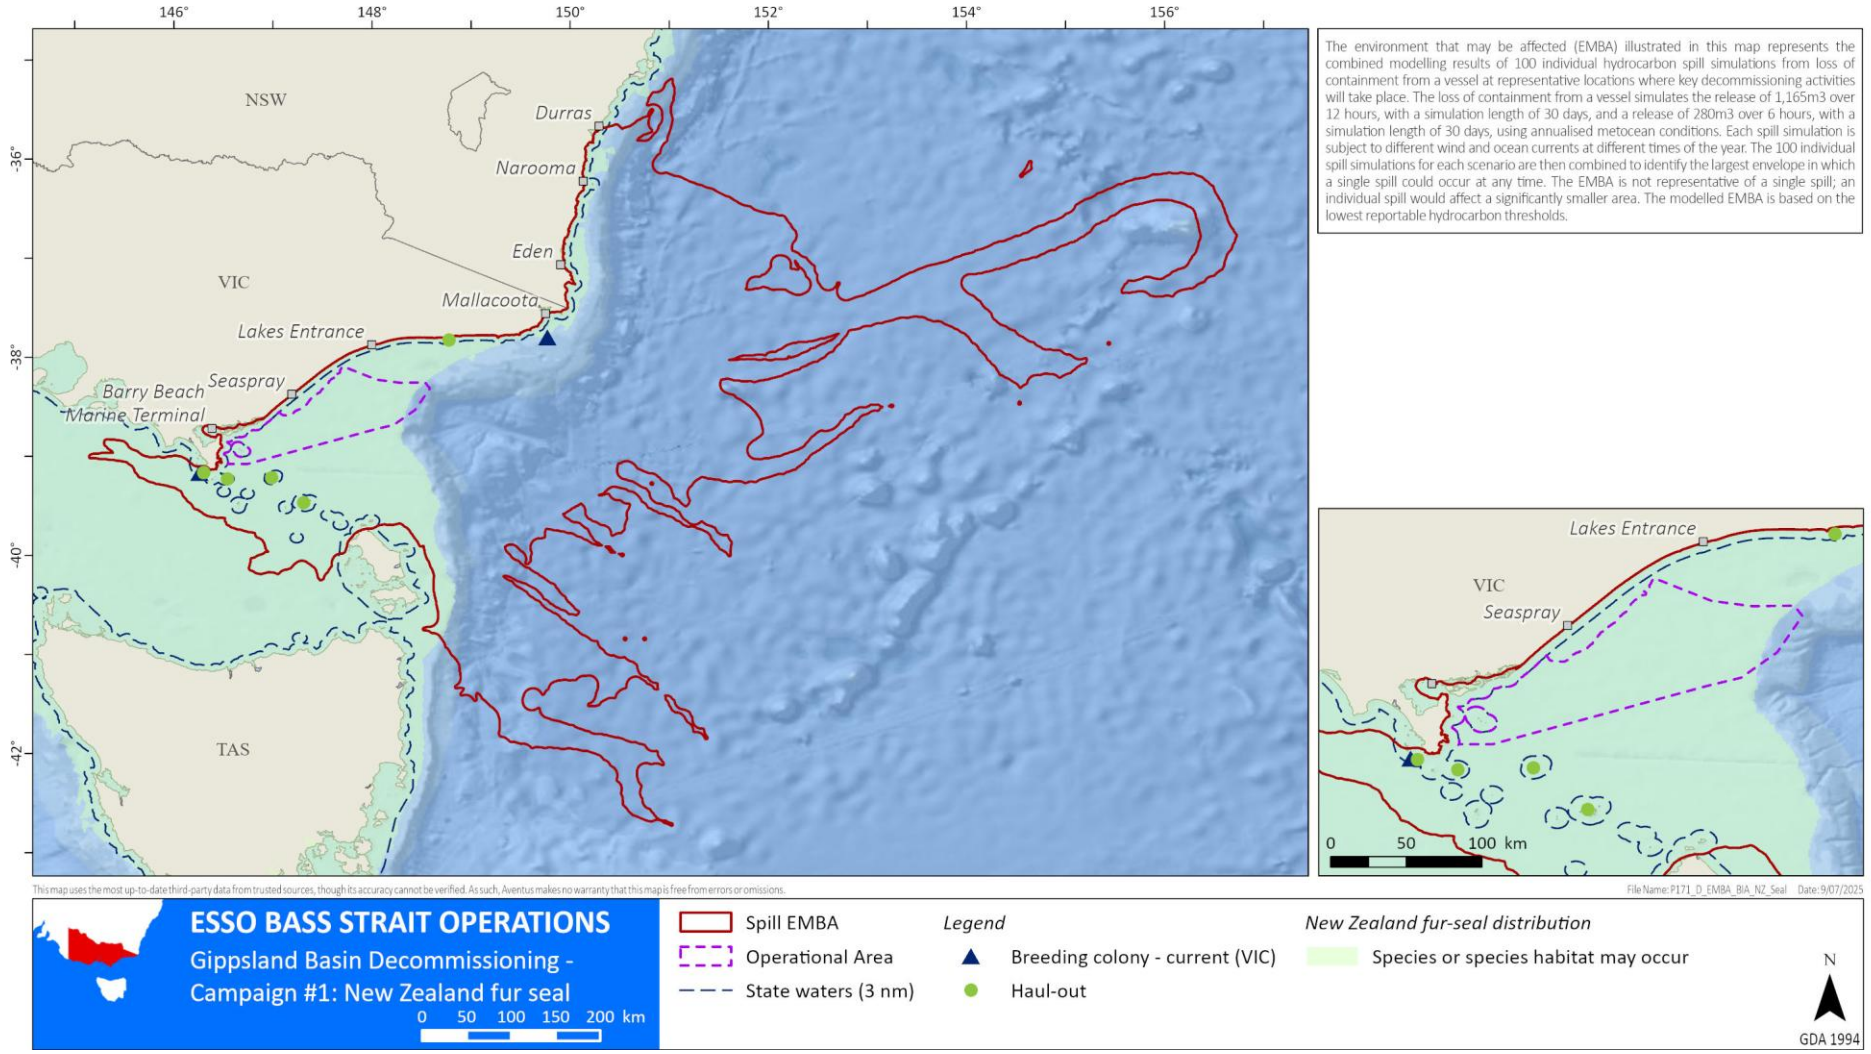

Figure A-31 New Zealand fur seal distribution, breeding colonies and haul-out sites within the EMBA

A.1.4.6 Turtles

Adult marine turtles spend the majority of their lives in the ocean, typically only coming onshore to nest. Females can lay (on average) between two and six clutches per season, with the period between clutches known as the internesting period. Female turtles typically remain close to the same nesting site during an internesting period. Egg incubation varies between species but is typically two months (DoEE, 2017). Hatchlings disperse into oceanic currents, and the juveniles will stay in pelagic waters until large enough to settle into coastal feeding habitats. Leatherback turtles are an exception to these general patterns, often exhibiting larger internesting zones, and travelling vast distances to forage rather than settling in a coastal habitat (DoEE, 2017). Flatback turtles also lack an oceanic phase and remain in the surface waters of the continental shelf.

There are five marine turtle species (or species habitat) that occur within the EMBA. All of which are described below. Table A-6 shows the key threats (as identified in the *Recovery Plan for Marine Turtles in Australia, 2017-2027)* (DoEE, 2017) relevant to the activity for threatened turtles that may occur within the EMBA.

Table A-6 Key threats to threatened turtle species relevant to the activity

Common name	Recovery plan	Key threats (relevant to the activity)
Loggerhead turtle	*Recovery Plan for Marine Turtles in Australia, 2017-2027* (DoEE, 2017)	• Marine debris. • Chemical discharge. • Light pollution. • Habitat modification. • Vessel disturbance. • Noise interference.
Green turtle		
Leatherback turtle		
Hawksbill turtle		
Flatback turtle		

Light pollution as a threat to marine turtles is also addressed by the *National Light Pollution Guidelines for Wildlife* (Commowealth of Australia, 2023).

A.1.4.6.1 Loggerhead turtle

The loggerhead turtle (*Caretta caretta*) has a global distribution throughout tropical, sub-tropical and temperate waters; and in Australia typically occurs in the waters of coral and rocky reefs, seagrass beds, or muddy bays throughout eastern, northern, and Western Australia (DCCEEW, n.d.(b)). Loggerhead turtles are carnivorous, feeding primarily on benthic invertebrates. While the species has a broad foraging range throughout Australian waters, nesting is known to occur (from two different genetic stocks) on sandy beaches on the central western and eastern coasts (DCCEEW, n.d.(b)). The eastern Australian population is smaller than the western Australian population; and has also undergone a decline from approximately 3500 nesting females in 1977, to approximately 500 nesting females in 2000 (DCCEEW, n.d.(b)). No nesting or internesting, critical habitat, or BIAs, have been identified for the loggerhead turtle within the EMBA.

A.1.4.6.2 Green turtle

Green turtles (*Chelonia mydas*) are found in tropical and subtropical waters throughout the world; usually occurring within the 20°C isotherms, although individuals can stray into temperate waters (DCCEEW, n.d.(b)). Within Australia, green turtles typically nest, forage and migrate across tropical northern Australia (DCCEEW, n.d.(b)). The total Australian population of green turtles is approximately 70,000 individuals, with approximately 8000 of these found in the southern Great Barrier Reef area. Adult green turtles consume mainly seagrass and algae, although they will occasionally eat mangroves, fish-egg cases, jellyfish, and sponges; juvenile green turtles are typically more carnivorous and will also consume plankton during their pelagic stage (DCCEEW, n.d.(b)). No nesting or internesting, critical habitat, or BIAs, have been identified for the green turtle within the EMBA.

A.1.4.6.3 Leatherback turtle

The leatherback turtle (*Dermochelys coriacea*) has the widest distribution of any marine turtle, occurring in tropical to sub-polar oceans (DEWHA, 2008). In Australia, the leatherback turtle has been recorded foraging in all Australian states, but no large nesting populations have been recorded (DEWHA, 2008). The leatherback turtle is a highly pelagic species, venturing close to shore mainly during the nesting season (DCCEEW, n.d.(b)). Adults feed

mainly on pelagic soft-bodied creatures such as jellyfish, tunicates, salps, squid (DCCEEW, n.d.(b)). No nesting or internesting, critical habitat, or BIAs, have been identified for the leatherback turtle within the EMBA.

A.1.4.6.4 Hawksbill turtle

The hawksbill turtle (*Eretmochelys imbricata*) is found in tropical, subtropical, and temperate waters all around the world (DCCEEW, n.d.(b)). Hawksbill turtles are omnivorous, feeding on sponges, hydroids, cephalopods (octopus and squid), gastropods (marine snails), cnidarians (jellyfish), seagrass and algae (DCCEEW, n.d.(b)). During their pelagic phase (while drifting on ocean currents), young hawksbill turtles will feed on plankton. Hawksbill turtles that forage on the Great Barrier Reef migrate to neighbouring countries including Papua New Guinea, Vanuatu, and the Solomon Islands; it is not known from which stock hawksbill turtles foraging in New South Wales originate (DCCEEW, n.d.(b)). No nesting or internesting, critical habitat, or BIAs, have been identified for the hawksbill turtle within the EMBA.

A.1.4.6.5 Flatback turtle

The flatback turtle (*Natator depressus*) is found in tropical waters of northern Australia and is one of only two species of sea turtle without a global distribution (DCCEEW, n.d.(b)). All known nesting locations for this species are within Australia (DCCEEW, n.d.(b)). Flatback turtles are primarily carnivorous, feeding on soft-bodied invertebrates; juveniles eat gastropod molluscs, squid, siphonophores. Limited data also indicate that cuttlefish, hydroids, soft corals, crinoids, molluscs and jellyfish may also form part of their diet (DCCEEW, n.d.(b)). No nesting or internesting, critical habitat, or BIAs, have been identified for the flatback turtle within the EMBA.

A.1.4.7 Birds

Birds in the marine environment can include both seabirds and shorebirds.

Seabirds refers to those species of bird whose regular habitat and food sources are derived from the ocean (both coastal and pelagic); seabirds include species such as pelicans, gannets, cormorants, albatrosses, and petrels. Seabirds spend much of their lives at sea in search of prey only to return for a short time to breed and raise chicks. Most species tend to forage on their own, though large feeding flocks will gather at rich or passing food sources. Squid, fish, and krill are common sources of food.

Shorebirds (sometimes referred to as wading birds) refers to those species of bird commonly found along sandy or rocky shorelines, mudflats, and shallow waters; shorebirds include such species as plovers and sandpipers. Shorebirds spend most of their time (nesting, feeding, and breeding) on the shoreline and don't swim.

The coast and neighbouring islands within the EMBA provide feeding and nesting habitats for many coastal and migratory bird species.

Table B-3 in Appendix B of the EP lists the EPBC Act listed threatened, migratory and marine bird species (or species habitat) (see Appendix D of the EP for the full PMST report). Many of the birds are also listed in the following international conventions that aim to protect the birds themselves and their habitat:

- Republic of Korea Migratory Birds Agreement 2006
- Agreement between the Government of Australia and the Government of the People's Republic of China for the Protection of Migratory Birds and their Environment 1986
- Convention on the Conservation of Migratory Species of Wild Animals (Bonn Convention) 1979
- Agreement between the Government of Australia and the Government of Japan for the Protection of Migratory Birds and Birds in Danger of Extinction and their Environment 1974
- Ramsar.

A.1.4.7.1 Albatrosses and petrels

Table B-3 in Appendix B of the EP lists the albatross and petrel species and EPBC Act listed status that have the potential to occur within the EMBA. BIAs for albatross and petrel species are shown in Figure A-32, Figure A-33, Figure A-34, Figure A-35 and Figure A-36.

Albatrosses and petrels are mostly surface capturing, pelagic predators that feed on live and dying prey. Their ability to dive varies across species and involves either surface plunge dives or shallow dives to catch prey (generally less than 15m deep). Both species are wide-ranging, opportunistic predators, individuals will forage singly and will then aggregate in larger numbers where there is a rich food source. They prefer to feed during the day or at night (often by moonlight) (Commonwealth of Australia, 2022).

Albatrosses and petrels have a diverse diet, depending on the availability of food, including cephalopods, crustaceans, cyclostomes, fish, and tunicates, although diet is not well known for several species. Both species have a tendency to follow fishing vessels. Competition for fishers discards and baited hooks can be intense with smaller birds subject to secondary attacks by other larger birds (Commonwealth of Australia, 2022).

Albatross and petrel species occurring in Australia's jurisdiction predominantly breed on remote, offshore islands in the higher latitudes, apart from the northern royal albatross (detected in the PMST) and westland petrel (not detected in the PMST) that breed on the south island of New Zealand (Commonwealth of Australia, 2022).

Albatrosses and petrels are extremely site faithful. The remote offshore islands (Table A-7) should be regarded as habitat that is potentially critical to the survival of albatrosses and petrels in Australia.

Table A-7 Albatross and petrel breeding site locations in Australia's jurisdiction

Site	Species	Approximate distance to the EMBA	Size (ha)
Albatross Island	Shy albatross	164km southwest	33
Mewstone	Shy albatross	460km southwest	13
Pedra Branca	Shy albatross	409km southwest	2.5
Macquarie Island	Black-browed albatross, grey-headed albatross, grey petrel, light-mantled albatross, wandering albatross, northern giant petrel, southern giant petrel	1443km southeast	13,000
Bishop and Clerk Islets	Black-browed albatross	1487km southeast	60
Heard Island	Black-browed albatross, light-mantled albatross, southern giant petrel	5496km southwest	36,800
McDonald Islands	Black-browed albatross, light-mantled albatross, southern giant petrel	5575km southwest	360
Giganteus Island	Southern giant petrel	5766km southwest	16
Hawker Island	Southern giant petrel	5112km southwest	190
Frazier Islands	Southern giant petrel	3690km southwest	60

A.1.4.7.2 Shearwaters

Table B-3 in Appendix B of the EP lists the shearwater species and EPBC Act listed status that have the potential to occur within the EMBA. Shearwaters represent the most abundant seabird in Australia they are typically pelagic, except during breeding seasons where they are found on remote islands or coastal headlands. Shearwaters are medium-size long-winged seabirds that are most common in temperate and cold waters. They spend most of their time foraging in the ocean and return to coastal cliffs and offshore islands only to breed. Shearwaters feed on fish, squid, cephalopod molluscs (squid, cuttlefish, nautilus and argonauts), crustaceans (barnacles and shrimp) and other soft-bodied pelagic prey. Food is usually taken by pursuit plunging, surface plunging or surface seizing (DCCEEW, n.d.(b)). Some shearwaters, such as the sooty and flesh footed, are transequatorial migrants and are widely distributed across the Pacific Ocean.

Known breeding locations for the sooty shearwater and wedge-tailed shearwater include oceanic islands in New South Wales (such as Solitary Island, Cabbage Tree Island, Muttonbird Island and Bird Island) (DCCEEW, n.d.(b)). Breeding season in southeastern Australia for shearwaters is typically over summer, late August/early September to May. Shearwater nests are usually in burrows or rock crevices. Due to their expansive ranges, it is likely that shearwaters may overfly, forage, breed or rest in the EMBA. BIAs for four shearwater species are shown in Figure A-36.

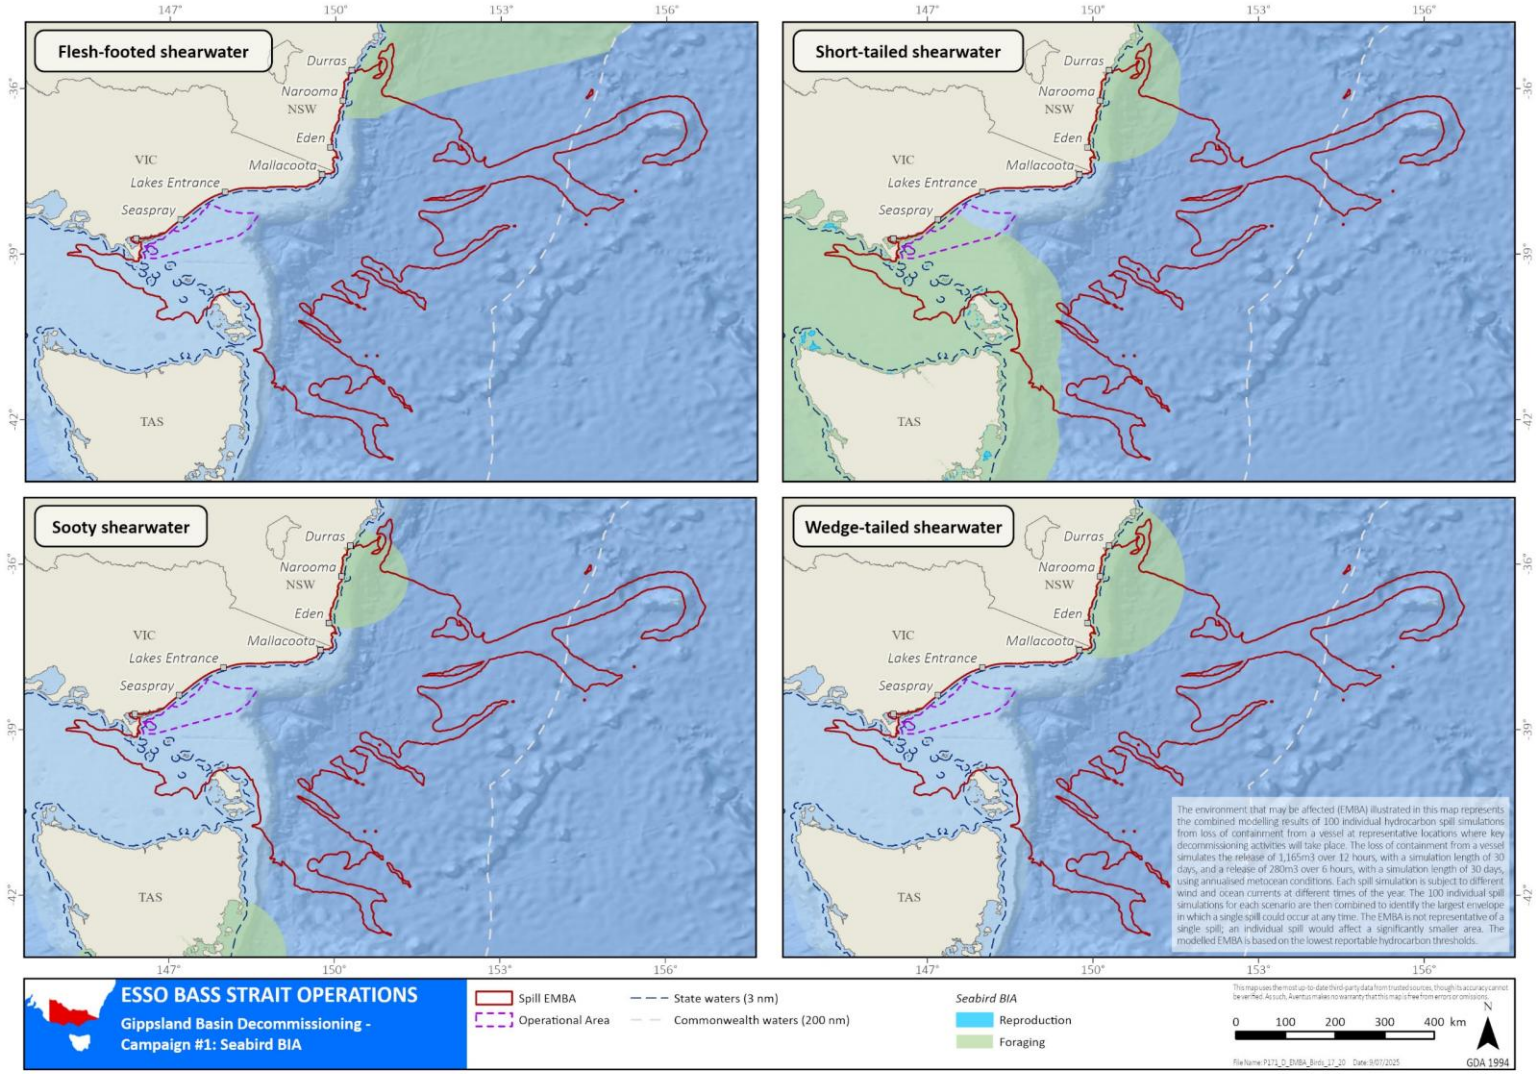

Figure A-36 BIAs for the flesh-footed, short-tailed, sooty and wedge-tailed shearwaters intersected by the EMBA

A.1.4.7.3 Other seabirds

Table B-3 in Appendix B of the EP lists the other seabird species and EPBC Act listed status that have the potential to occur within the EMBA and are described below:

- Fork-tailed swift (*Apus pacificus*) - A medium-sized bird that has a large global distribution and population, occurring throughout much of Australia. In Victoria, it is widespread but sparsely scattered, occurring over cliffs, beaches and sometimes well out to sea (Birdlife Australia, 2025). This species is almost exclusively aerial, feeding on insects in flight. As a migratory species, it arrives in Australia from September to October, leaving southern Australia from mid-April (Birdlife Australia, 2025). As a common species, the fork-tailed swift may fly over the EMBA from September to April.
- Fairy prion (*Pachyptila tutur*) - The most common prion found in southeast Australia. This species is found mainly offshore but may move inshore during stormy weather. Their diet primarily consists of krill but may include some fish and squid. Surface seizing and dipping are their primary feeding methods, but they can also surface plunge and use pattering (BirdLife International, n.d.).
- White-bellied sea eagle (*Haliaeetus leucogaster*) - Is distributed along the coastline in coastal lowlands with breeding sites from Queensland to Victoria in coastal habitats and terrestrial wetlands in temperate regions. The breeding season is from June to January with nests built in tall trees, bushes, cliffs, or rock outcrops. Breeding pairs are generally widely dispersed (Birdlife Australia, 2025). This species forages over open water (coastal and terrestrial) and feeds on fish, birds, reptiles, mammals, and crustaceans and normally launches into a glide to snatch its prey, usually with one foot, from the ground or water surface. This species is widespread and makes long-distance movements (Birdlife Australia, 2025) and is likely to be present along the adjacent coastline of the EMBA.
- Osprey (*Pandion haliaetus*) - A common, medium-sized raptor that is present around the entire Australian coastline, with the breeding range restricted to the north coast of Australia (including many offshore islands) and an isolated breeding population in South Australia (Birdlife Australia, 2025). Breeding occurs from April to February. Ospreys occur mostly in coastal areas but occasionally travel inland along waterways, where they feed on fish, molluscs, crustaceans, reptiles, birds, and mammals. They are mostly resident or sedentary around breeding territories, and forage more widely and make intermittent visits to their breeding grounds in the non-breeding season (Birdlife Australia, 2025). Due to their broad habitat, osprey is likely to be present in the coastal areas of the EMBA.
- Terns - Several EPBC Act listed tern species may occur within the EMBA. Terns are slender, lightly built birds with long, forked tails, narrow wings, long bills, and relatively short legs. Many of the tern species present along the southern Australian coastline are widespread and occupy beach, wetland, and grassland habitats. Terns rarely swim, they hunt for prey in flight, dipping to the water surface or plunge diving for prey (Flegg, 2002) usually within sight of land for fish, squid, jellyfish and sometimes crustaceans. Fairy terns feed by plunge diving on small baitfish in coastal waters, usually close to land (Birdlife Australia, 2025). The total number of Australian fairy terns is estimated to be 5000 mature individuals that utilise offshore, estuarine, lacustrine, wetland, beach, and spit habitats (DSEWPAC, 2011). The species nests above the high-water mark in clear view of the water and on sites where the substrate is sandy and the vegetation low and sparse (DSEWPAC, 2011). Fairy terns are threatened by predation from introduced mammals, disturbance by humans, dogs, and vehicles (DSEWPAC, 2011). BIA for the crested tern intercepted by the EMBA can be seen in Figure A-35.
- Noddies – One EPBC Act listed noddy species (common noddy; *Anous stolidus*) may occur within the EMBA. Noddies are part of the same family as terns. The common noddy is a tropical seabird with a worldwide distribution, occurring around isolated, bare, or vegetated, inshore, or oceanic islands or coral reefs with rocky cliffs or offshore stacks and coral or sand beaches (DAWE, 2020). Their diet consists predominantly of small fish as well as squid, pelagic molluscs, medusae and insects. No BIAs for noddy species are intercepted by the EMBA.
- Black-faced cormorant (*Phalacrocorax fuscescens*) - Is endemic to southern Australia (DAWE, 2020); and favours rocky coasts. The species feeds in coastal waters on a variety of fish, typically catching prey by pursuit diving. There are 40 significant breeding sites (defined as more than 10 breeding pairs) known for the species in southern Australia. Breeding usually occurs on rocky islands, but also on stacks, slopes, and sea cliffs in colonies of up to 2500 individuals (DAWE, 2020). A section of a foraging BIA for the black-faced cormorant towards the northwest corner of Flinders Island limits with the boundary of the EMBA, as shown in Figure A-37.

- Little penguin (*Eudyptula minor*) - A seabird that does not fly and is the smallest of the 17 penguin species in the world. Little penguins occur from Western Australia (Carnac Island) to New South Wales (Broughton Island) and Tasmania. Their distribution is not continuous, with sections of the southern coast of Australia lacking breeding colonies (DAWE, 2020). They are permanent residents of the coastal and offshore islands of parts of the Victorian and Tasmanian coast and Bass Strait islands, with the South-east Marine Region representing about 60% of the species known breeding population (Director of National Parks, 2025).

  Individuals exhibit strong site fidelity, returning to the same breeding colony each year to breed in the winter and spring months. While on land, penguins remain in burrows to rest, nest, and moult. Nest building (in sand dunes or in rock crevices) occurs from June to December, breeding occurs from August to October, egg laying occurs from August to December, chick raising occurs from August to March and moulting occurs between February and April (during which time they must remain on land).

  During winter, little penguins spend most of their time at sea, returning to the burrows to rest and attend to their burrows (DELWP, 2017). Little penguins dive on average between 10 - 30m in depth, with their preferred food sources being young barracouta, anchovies, red cod, warehou, pilchards and, squid (Phillip Island Nature Parks, n.d.). They forage mostly from dawn to an hour before dusk, returning to their burrows at dusk (Birdlife Australia, 2025). During the breeding season, little penguins forage within 5 - 25km of the coast, and at other times, foraging can occur up to 75km from the coast (Wiebkin, 2011).

  Based on Oil Spill Response Maps (OSRA, 2015), little penguin colonies in the Gippsland region that are within the EMBA are listed below and illustrated in Figure A-38:

  - Shellback Island (400 breeding pairs)
  - Norman Island (1000 breeding pairs)
  - Glennie Group Islands (3400 breeding pairs)
  - Anser Group of Islands (500 breeding pairs)
  - Wattle Island (400 breeding pairs)
  - Seal Island (1000 breeding pairs)
  - Notch Island (1000 breeding pairs)
  - Rag Island (400 breeding pairs)
  - Rabbit Island (8000 breeding pairs)
  - Rabbit Rock (200 breeding pairs)
  - Tullaberga Island (900 breeding pairs)
  - Gabo Island (35,000 breeding pairs) (50% of Victorian population).

  Other Bass Strait islands with known populations of little penguins within the EMBA are listed below and illustrated in Figure A-38:

  - Curtis Group (2000 individuals)
  - Hogan Group (10,000 individuals)
  - Furneaux Group (> 40,000 pairs).

  Additionally, Phillip Island (Victoria) supports 32,000 individuals and Betsy Island (Tasmania) has a population of 15,000 pairs. Both islands are outside of the EMBA.

  According to the New South Wales Government (2019) approximately 25,000 pairs of little penguins nest on islands off the coast of New South Wales. The largest colonies are on the following islands, all of which are within the EMBA can be seen in Figure A-38:

  - Montague Island
  - Tollgate Island
  - Brush Island.

  The only known mainland breeding colony in New South Wales is in a secluded cove in the Manly area of Sydney Harbour which is outside the EMBA (NSW Government, 2019).The BIAs for little penguins within the EMBA is presented in Figure A-38.

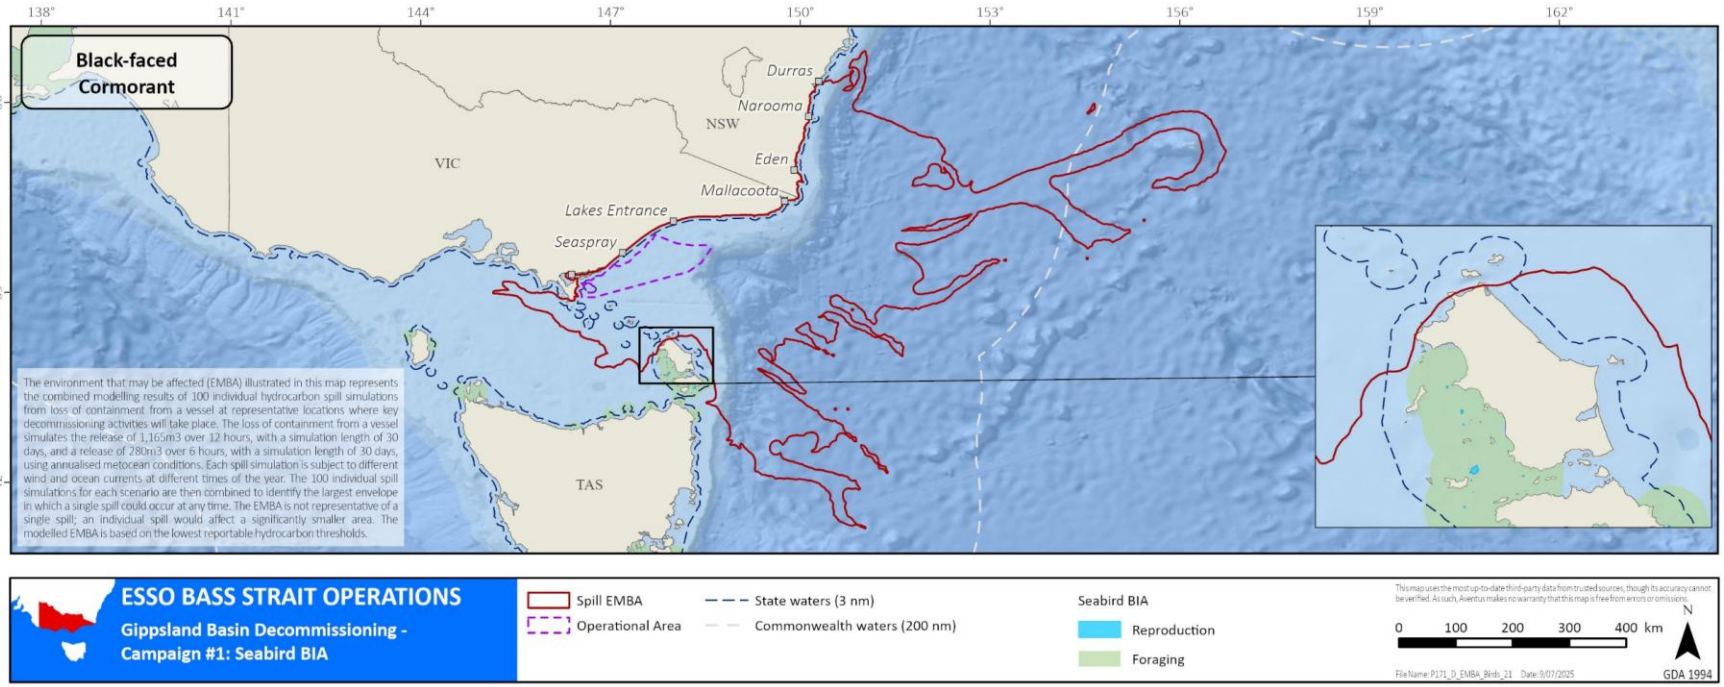

Figure A-37 BIAs for the black-faced cormorant proximal to the EMBA

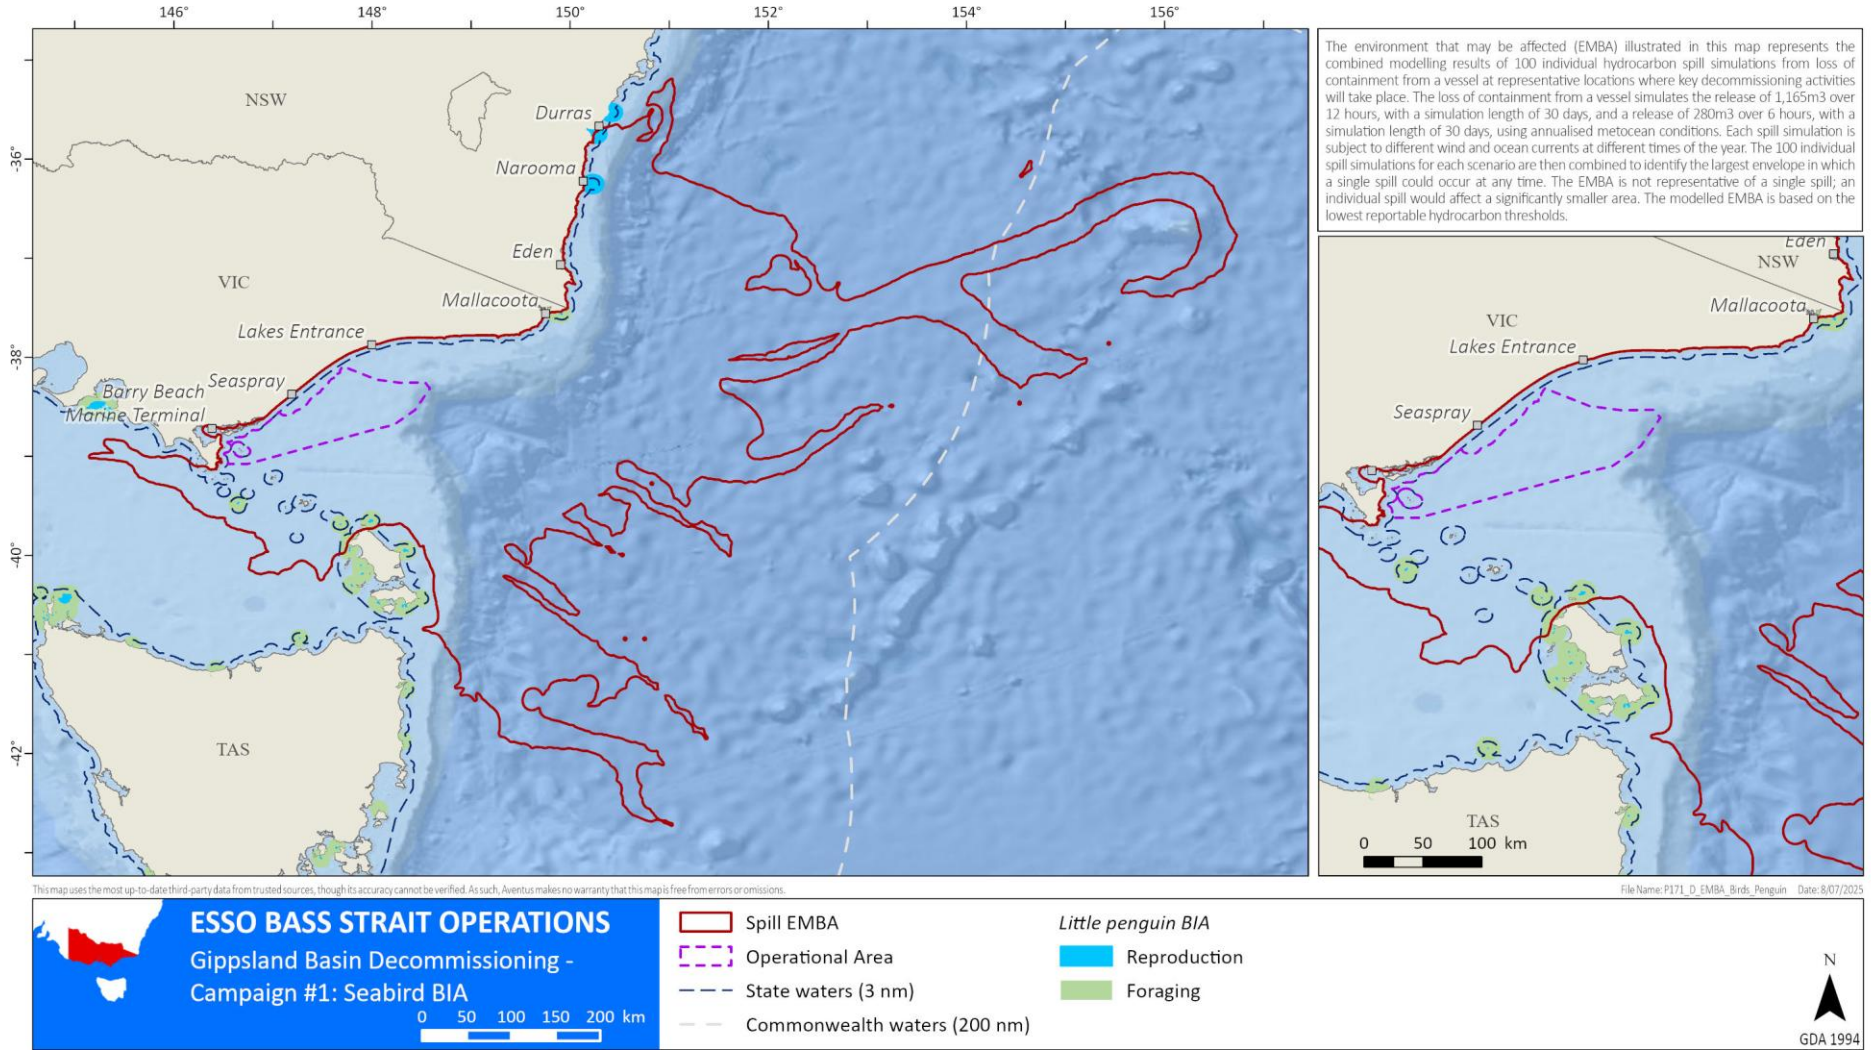

Figure A-38 Little penguin BIAs intersected by the EMBA

A.1.4.7.4 Orange-bellied parrot

The orange-bellied parrot (*Neophema chrysogaster*) breeds in Tasmania during summer, migrates north across the Bass Strait in autumn and over-winters on the mainland. Birds depart the mainland for Tasmania from September to November (Green, 1969). The southward migration is rapid (Stephenson, 1991), so there are few migration records. The northward migration across western Bass Strait is more prolonged (Higgins, 1999).

The parrot's breeding habitat is restricted to southwest Tasmania (outside of the EMBA) (see Figure A-39), where breeding occurs from November to mid-January mainly within 30km of the coast (Brown & Wilson, 1984). The species forage on the ground or in low vegetation (Brown & Wilson, 1980) (Brown & Wilson, 1984) (Loyn, Lane, Chandler, & Carr, 1986). During winter, on mainland Australia, orange-bellied parrots are found mostly within 3km of the coast. In Victoria, they mostly occur in sheltered coastal habitats, such as bays, lagoons and estuaries, or, rarely, saltworks. They are also found in low samphire herbland dominated by beaded glasswort (*Sarcocornia quinqueflora*), sea heath (*Frankenia pauciflora*) or sea-blite (*Suaeda australis*), and in taller shrubland dominated by shrubby glasswort (*Sclerostegia arbuscula*) (DELWP, 2016).

The range and migration route of the orange-bellied parrot are shown in Figure A-39.

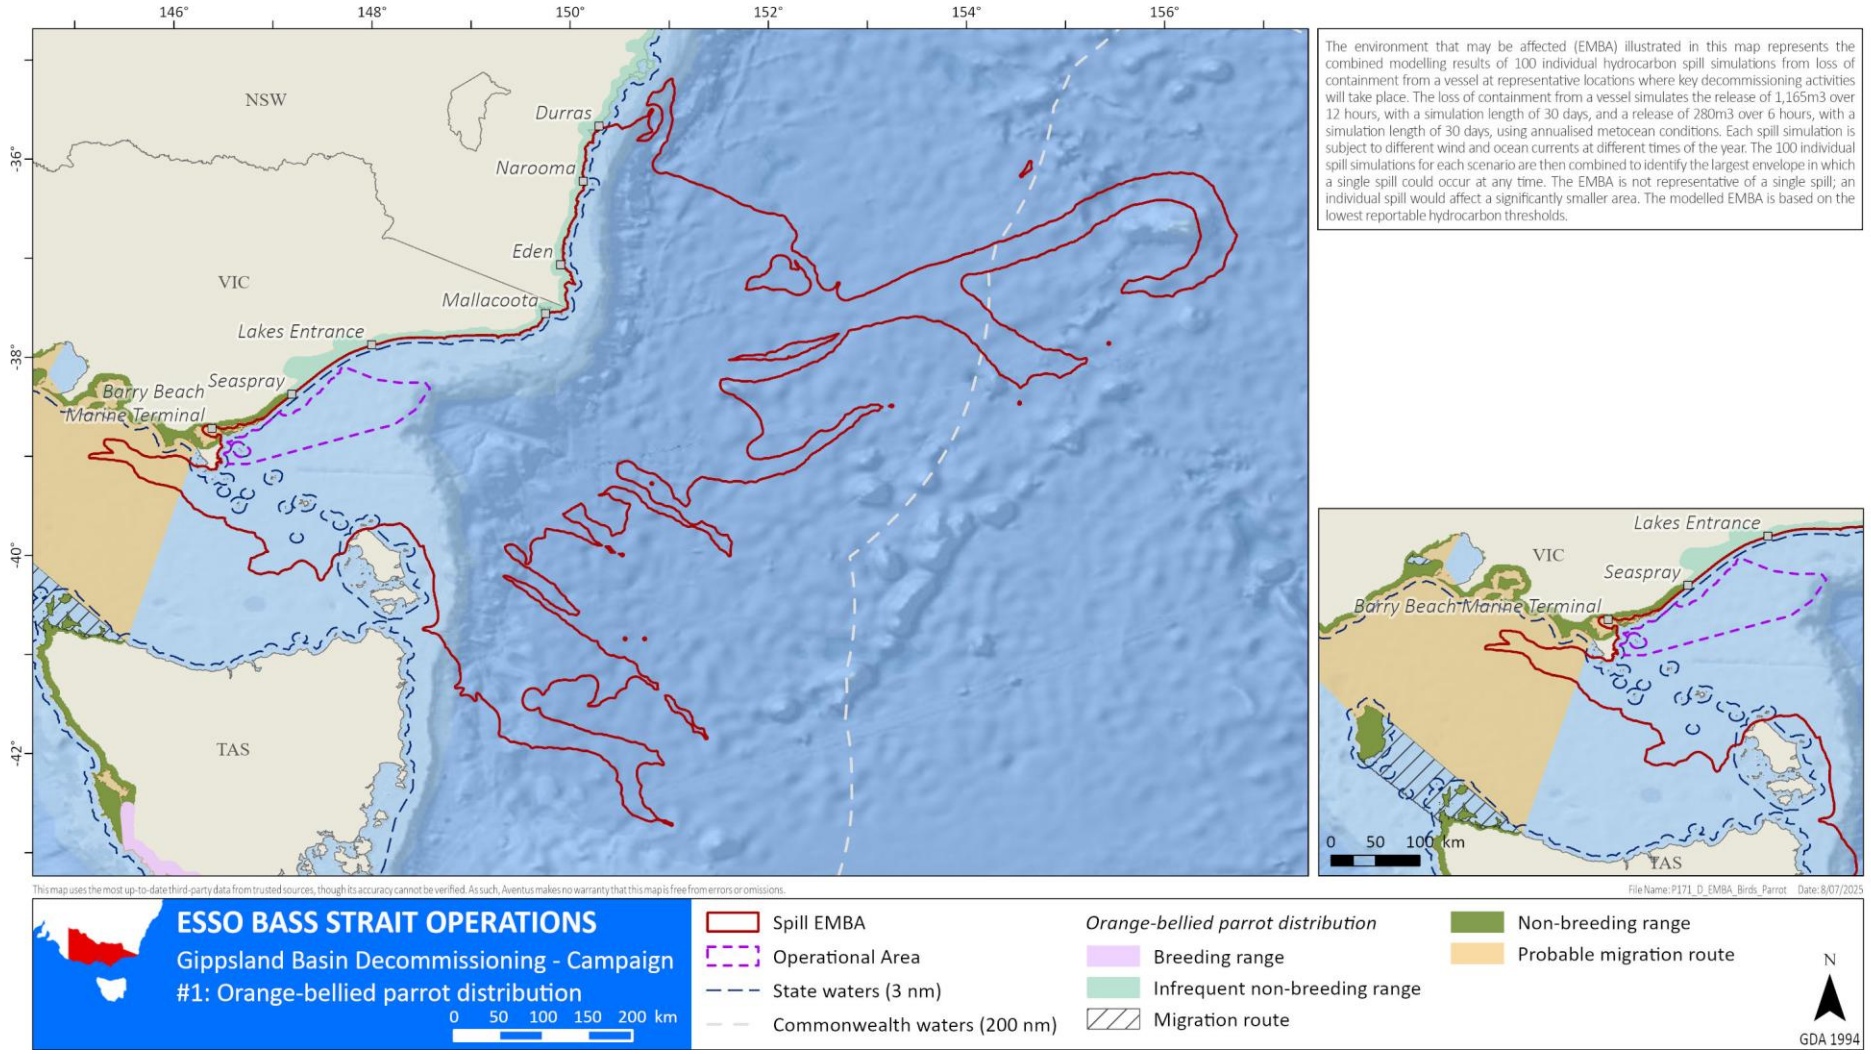

Figure A-39 The range and migration route of the orange-bellied parrot intersected by the EMBA

A.1.4.7.5 Shorebirds

Table B-3 in Appendix B of the EP lists the shorebird species and EPBC Act listed status and are described below:

- Plovers - There are several EPBC Act listed plovers that may occur within the EMBA. Plovers are medium sized wading birds that have wide-ranging coastal habitats comprising estuaries, bays, mangroves, damp grasslands, sandy beaches, sand dunes, mudflats, and lagoons (Flegg, 2002), with roosting also taking place on sand bars and spits. Plovers feed on a range of molluscs, worms, crustaceans, and insects. Plovers (with the exception of the hooded and red-capped lovers) breed in Asia and the Arctic region and are more likely to be present in Australia during summer, depending on the species. The hooded plover breeds in Australia and builds its nests in sandy oceanic beaches. The location of these nests presents the greatest threat to this species' population, as nests, eggs and chicks are vulnerable to predation and trampling (Birdlife Australia, 2025).
- Sandpipers - There are several EPBC Act listed sandpiper species that may occur within the EMBA sandpipers breed in Europe and Asia and migrate to Australia during the southern summer. Sandpipers are small wader species found in coastal and inland wetlands, particularly in muddy estuaries, feeding on small marine invertebrates. Up to 3000 sharp-tailed sandpiper and up to 1800 curlew sandpipers are known to congregate to feed at the Gippsland Lakes. Curlew sandpipers breed in Siberia and migrate to Australia, arriving around September each year (DCCEEW, 2023e). The species forages mainly on invertebrates, including worms, molluscs, crustaceans, and insects. Curlew sandpipers usually forage in water, near the shore or on bare wet mud at the edge of wetlands. The species is threatened by the sustained loss of intertidal mudflat habitat at key migration staging sites in the Yellow Sea (DCCEEW, 2023e).
- Snipes - There are four EPBC-Act listed snipe species that may occur within the EMBA. These snipe species (other than the Australian painted snipe, which is endemic to Australia) are present during the Southern Hemisphere summer (breeding in Asia and Russia in the Northern Hemisphere summer). They are medium-sized waders that roost among dense vegetation around the edge of wetlands during the day and feed at dusk, dawn and during the night on seeds, plants, worms, insects, and molluscs (Birdlife Australia, 2025). There are few records of the pin-tailed and Swinhoe's snipe in Victoria, while the Australian painted snipe is known to occur at Mallacoota Inlet (outside of the EMBA). The nest of the Australian painted snipe is usually a scrape in the ground lined with twigs and stalks of grass. The species is threatened by the loss and degradation of wetlands, through drainage and diversion of water for agriculture and reservoirs (Birdlife Australia, 2025). Snipes are likely to be present within the EMBA during the summer.
- Godwits - There are two EPBC Act listed godwit species that may occur within the EMBA. Godwits are large waders that are found around all coastal regions of Australia during the Southern Hemisphere summer (breeding in Europe during the Northern Hemisphere summer), though the largest numbers remain in northern Australia. Godwits are commonly found in sheltered bays, estuaries and lagoons with large intertidal mudflats or sandflats, or spits and banks of mud, sand, or shell-grit where they forage on intertidal mudflats or sandflats, in soft mud or shallow water and occasionally in shallow estuaries (Birdlife Australia, 2025). They have been recorded eating annelids, crustaceans, arachnids, fish eggs and spawn and tadpoles of frogs, and occasionally seeds. The Nooramunga Marine and Coastal Park (within the EMBA) has recorded the largest concentrations of bar tailed godwit in southeastern Australia. Godwits are likely to be present within the EMBA during the summer.
- Knots - The red and great knots are EPBC Act listed species that may occur within EMBA. Both the red and great knots have a coastal distribution around the entire Australian coastline when it is present during the Southern Hemisphere summer (breeding in eastern Siberia in the Northern Hemisphere summer). The red knot is a medium-sized wader that prefers sandy beach, tidal mudflats and estuary habitats, where they feed on bivalve molluscs, snails, worms and crustaceans (Birdlife Australia, 2025). Lake Reeve has supported the largest concentration (5000) of red knot recorded in Victoria.
- Curlews - Two curlews (eastern and little) are listed under the EPBC Act. Curlews are medium-sized migratory birds that breed in the far north of Siberia and winters in Australasia. The eastern curlew is the world's largest shorebird and is widespread in coastal regions in the northeast and south of Australia, including Tasmania. It is commonly found on intertidal mudflats and sandflats where it uses its long beak to pick the surface and probes for crabs. Curlews are also found on sheltered coasts, especially estuaries, mangrove swamps, bays, harbours, and lagoons (DCCEEW, 2023f). The eastern curlew is listed as endangered on the IUCN Red List. According to the East Asian-Australasian Flyway Partnership, Eastern

curlew numbers have declined by 81% in Australia over the past three decades. This led the Australian Government to class the birds as critically endangered, under the EPBC Act (Morrick, et al., 2021). In Victoria, the main strongholds are in Corner Inlet (within the EMBA) and Western Port Bay (outside the EMBA), with smaller populations in Port Phillip Bay and scattered elsewhere along the coast. Eastern curlews are found on islands in Bass Strait and along the northwest, northeast, east and southeast coasts of Tasmania. Historically, sightings have been recorded in Bass Strait and depending on the time of year, curlews may be present in the EMBA (DCCEEW, 2023e). The little curlew breeds in Siberia and is seen on passage through Mongolia, China, Japan, Indonesia and New Guinea. In Australia, the little curlew is a bird of coastal and inland plains of the north where it often occurs around wetlands and flooded ground. They often form large flocks, occasionally comprising thousands of birds and sometimes associate with other insectivorous migratory shorebirds.

Table A-8 lists a summary of the relevant threats to marine species that may occur within the EMBA, as identified by management plans, conservation advice and recovery plan.

Table A-8 Relevant key threats identified in recovery plans, conservation advice and management plans for species that occur within the OA and EMBA

Common name	Recovery plan/conservation advice/management plan	Key threats (relevant to the activity)
All		
All vertebrate	*Threat Abatement Plan for the impacts of marine debris on vertebrate wildlife of Australia's coasts and oceans* (DoEE, 2018b)	• Marine debris.
Sharks		
Whale shark	*Conservation Advice Rhincodon typus (whale shark)* (TSSC, 2015a)	• Habitat disruption from mineral exploration, production and transportation. • Marine debris. • Vessel disturbance.
Cetaceans, sirenia and pinnipeds		
Cetaceans and other marine megafauna	*National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna* (Commonwealth of Australia, 2017)	• Vessel strike.
Sei whale	*Conservation Advice Balaenoptera borealis (sei whale)* (TSSC, 2015c)	• Anthropogenic noise and acoustic disturbance. • Habitat degradation including pollution. • Pollution (persistent toxic pollutants). • Vessel strike.
Blue whale	*Conservation Management Plan for the Blue Whale* (Commonwealth of Australia, 2015)	• Noise interference. • Habitat modification from marine debris or chemical discharge. • Vessel strike.

Common name	Recovery plan/conservation advice/management plan	Key threats (relevant to the activity)
Fin whale	*Conservation Advice Balaenoptera physalus (fin whale)* (TSSC, 2015d)	• Anthropogenic noise and acoustic disturbance. • Pollution (persistent toxic pollutants). • Vessel strike.
SRW	*National Recovery Plan for the Southern Right Whale* (DCCEEW, 2024b)	• Entanglement (marine debris). • Habitat modification. • Anthropogenic underwater noise (vessel noise). • Collision (vessel strike). • Pollution (chronic chemical pollution).
Turtles		
All marine turtles (flatback, green, hawksbill, leatherback, loggerhead)	*National Light Pollution Guidelines for Wildlife* (Commowealth of Australia, 2023)	• Light pollution.
	Recovery Plan for Marine Turtles in Australia 2017-2027 (DoEE, 2017)	• Marine debris. • Chemical discharge. • Light pollution. • Habitat modification. • Vessel disturbance. • Noise interference.
Leatherback turtle	Approved Conservation Advice for Dermochelys coriacea (Leatherback Turtle) (DEWHA, 2008)	• Vessel strike. • Marine debris.
Birds		
All seabirds and shorebirds	*National Light Pollution Guidelines for Wildlife* (Commowealth of Australia, 2023)	• Light pollution.
Seabirds (refer to Table B-3 in Appendix B of the EP for a list of shorebirds within the EMBA)	*Wildlife Conservation Plan for Seabirds* (DAWE, 2020)	• Light pollution. • Climate change.
Shorebirds (refer to Table B-3 in Appendix B of the EP for a list of shorebirds within the EMBA)	*Wildlife Conservation Plan for Migratory Shorebirds* (DoE, 2015b)	• Pollution (marine debris, light, acute, chronic). • Climate variability and change.
Albatross and petrels (refer to Table B-3 in Appendix B of the EP	*National Recovery Plan for albatrosses and petrels (2022)* (Commonwealth of Australia, 2022)	• Marine pollution (fuel/oil spills, chemical contaminants/marine debris).

Common name	Recovery plan/conservation advice/management plan	Key threats (relevant to the activity)
for a list of albatross and petrel within the EMBA)		• Marine infrastructure interactions (including vessel collision and lighting).

A.1.4.8 Marine pests

It is widely recognised that marine pests can become invasive and cause significant impacts on economic, ecological, social and cultural values of marine environments. Impacts can include the introduction of new diseases, alteration of ecosystem processes and reduction of native biodiversity, causing major economic loss and disrupting human activities (Brusati & Grosholz, 2007).

A search on the Department of Agriculture, Fisheries and Forestry website (DAFF, 2024) and the National Introduced Marine Pest Information System website (Australian Government, 2025) indicates the following marine pests are found within waters of the EMBA:

Victoria:

- European shore crab (*Carcinus maenas*) – Prefers bays and estuaries but found on all types of shores at depths up to 60m, tolerates temperatures up to 30°C.
- Pacific oyster (*Crassostrea gigas*) – Found on hard substrate in intertidal and shallow subtidal areas in depths up to 3m, favours brackish waters in sheltered estuaries but tolerates a range of salinity and water quality and can occur offshore.
- Northern Pacific seastar (*Asterias amurensis*) - Found in bays, estuaries and reefs from high tide mark to 200m, in a range of habitats including seagrass, mussel beds, artificial structures, rock pools and rocky reefs.
- Asian date mussel (*Arcuatula senhousia*) – Normally found in muddy estuaries and bays, burrowing into the mud or sitting on top of it (Australian Government, 2022a).
- East Asian bivalve (*Theora lubrica*) – Lives in muddy sediments from the low tide mark to 50m, however it has been found at 100m. Adult species does not migrate. Adults slowly move to deeper water (Australian Government, 2020a).
- European clam or basket shell (*Varicorbula gibba*) – A shallow burrower that inhabits thick, muddy sand. It has the ability to attach to gravel and stones by a single byssal thread. The adult species does not migrate (Australian Government, 2023).
- Asian kelp (*Undaria pinnatifida*) – Usually found in sheltered, rocky areas. It is also found on structures and boats and is present in Tasmania and southern Victoria (Australian Government, 2022b).
- Dead man's finger (*Codium fragile* spp. *fragile*) – Found in a wide variety of areas, from very protected through to intermediately wave exposed in both intertidal and subtidal habitats. It grows profusely on any hard substrate including rocky reef, boulders, cobbles, shellfish, wharf pylons and marine farming equipment (Australian Government, 2022c).
- Devils tongue weed (*Grateloupia turuturu*) – Found attached to hard substrates in inshore waters within semi-exposed rocky intertidal pools or at shallow depths in sheltered waters. Generally found at or close to the waterline on vessels (Australian Government, 2022d).
- Rough seastar (*Astrostole scabra*) – Most commonly known from rocky bottoms, although it also occurs sub tidally on pebbles, reefs and hard clay. It is thought to prefer areas with turbulent water. Tasmanian records of this species range to 40m, however it has been found at a depth of 146m. The adult species does migrate. Organisms greater than 110mm in size appear to be found above 20m and individuals smaller than this are rarely found below 20m (possible offshore migration of smaller individuals) (Australian Government, 2020b).
- New Zealand screw shell (*Maoricolpus roseus*) – Prefers sand, mud or gravel in intertidal to subtidal areas, can be found in depths up to 30m.

New South Wales:

- European shore crab (*Carcinus maenas*) – Prefers bays and estuaries but found on all types of shores at depths up to 60m, tolerates temperatures up to 30°C.

- European fan worm (*Sabella spallanzanii*) - Attaches to hard surfaces, artificial structures, rocks, shells and seagrass on soft sediments, found in sheltered waters and depths up to 30m.
- New Zealand screw shell (*Maoricolpus roseus*) - Prefers sand, mud or gravel in intertidal to subtidal areas, can be found in depths up to 30m.
- Pacific oyster (*Magallana gigas*) – Found on hard substrate in intertidal and shallow subtidal areas in depths up to 3m, favours brackish waters in sheltered estuaries but tolerates a range of salinity and water quality and can occur offshore.
- Toxic dinoflagellate (*Alexandrium catenella/Alexandrium minutum/Alexandrium tamarense*) – Found in temperate to warm temperate coastal and estuarine waters, though occasionally reported in tropical waters. It is found to 20m depth in inshore waters, though may be found deeper offshore. Cysts found in bloom areas are associated with fine, organic rich estuarine and coastal sediments. Vegetative cell: species does migrate. Vertical migration in the water column (Australian Government, 2025).
- Dead man's finger (*Codium fragile* spp. *fragile*) – Found in a wide variety of areas, from very protected through to intermediately wave exposed in both intertidal and subtidal habitats. It grows profusely on any hard substrate including rocky reef, boulders, cobbles, shellfish, wharf pylons and marine farming equipment (Australian Government, 2022c).
- Colonial ascidian (*Botrylloides leachii*) – An encrusting species, growing on stones, shells, algae, seagrasses, other fouling species and man-made structures such as floats, ropes and aquaculture cages. It is found in the lower intertidal and shallow subtidal zones (Australian Government, 2022d).
- Bryozoan (*Bugula neritina*) – Grows well on pier piles, vessel hulls, buoys and similar submerged surfaces. They even grow heavily in ship's intake pipes and condenser chambers. In Australia, they occur primarily on artificial substrata. The adult species does not migrate (Australian Government, 2020c).
- Bryozoan (*Bugulina flabellata*) – Vertical, shaded, sub-littoral rock surfaces form substrata for this species. It has been recorded down to 35m (Australian Government, 2020d).
- Bryozoan (*Cryptosula pallasiana*) – Typical habitats include seagrasses, drift algae, oyster reef, artificial structures such as piers and breakwaters, man-made debris, rock, shells, ascidians, glass and vessel hulls. It has been reported from depths down to 35m (Australian Government, 2020e).
- Hydroid (*Obelia dichotoma*) – Found on a wide range of natural and man-made substrata. It appears to favour the blue mussel (*Mytilus edulis*) on which it grows in extensive colonies. It is also common on mussels and other invertebrate substrata and on port structures in temperate waters around the world. In Port Phillip Bay, it is found on cultured mussel farms (Australian Government, 2020f).
- Sponge isopod (*Paracerceis sculpta*) – Occurs throughout the intertidal zone, particularly associated with macroalgae, in sponges and under stones. It is also found amongst the fouling community on buoys, vessel hulls and other man-made structures. It lives in exposed areas and can withstand intense wave action (Australian Government, 2020g).

Tasmania:

- New Zealand screw shell (*Maoricolpus roseus*) - Prefers sand, mud or gravel in intertidal to subtidal areas, can be found in depths up to 30m.

In addition to the marine pests mentioned above Biofouling Solutions (2025) indicates that the long-spined sea urchin (*Centrostephanus rodgersii*), which is a native of New South Wales, has expanded its range into Victoria, Bass Strait, and Tasmania in response to warming sea surface temperature and the southern extension of the East Australian Current. *C. rodgersii* has caused significant urchin barrens in New South Wales and Tasmania, with impacts on ecologically and commercially important species such as abalone. It, too, has been reported from the southern tip of Wilsons Promontory and from reefs approximately 150km to the east of Corner Inlet, but it has not been observed on coastal reefs between these locations.

Other marine pests, described by Biofouling Solutions (2025), with known distribution in Victoria are listed below:

- Rice grass (*Spartina analica*)
- New Zealand screw shell (*Maoricolpus roseus*)
- New Zealand mussel (*Perna canaliculus*)
- Mediterranean fanworm (*Sabella spallanzanii*)
- Asian shore crab (*Hemigrapsus sanguineus*)
- Chameleon goby (*Tridentiger trigonocephalus*).

A.1.5 Cultural heritage values

Cultural heritage includes both tangible and intangible values, and the definition of cultural heritage has evolved in recent decades as non-tangible cultural heritage continues to develop. Non-tangible cultural heritage includes oral traditions, performing arts, social practices, rituals, festive events, knowledge, and practices concerning nature and the universe or the knowledge and skills to produce traditional crafts (UNESCO, n.d.). Tangible cultural heritage includes artefacts, monuments, a group of buildings and sites and museums that have a diversity of values including symbolic, historic, artistic, aesthetic, ethnological or anthropological, scientific, and social significance. Cultural heritage also captures natural heritage such as culturally significant landscapes (UNESCO, 2009).

This Section discusses Indigenous and maritime heritage. Refer to Sections A.1.1.1, A.1.1.2 and A.1.1.3 for World, National and Commonwealth heritage sites relevant to the EMBA.

A.1.5.1 Indigenous

Gunaikurnai is the name of the Indigenous group who have inhabited the Gippsland region for at least 18,000 years (Ramahyuck, 2017). Gunaikurnai Land and Waters Aboriginal Corporation (GLaWAC) (GLaWAC, 2025) describe their Country as:

> *"The land, the rivers and the ocean, the people, and the stories, the past and the future. All of it is connected. All of it is important to us. Country heals us and connects us to our ancestors, our culture, and our history".*

The Gunaikurnai people are recognised as Traditional Owners over approximately 1,330,000ha in Gippsland extending from west Gippsland near Warragul, east to the Snowy River, and north to the Great Dividing Range, and including 200m of offshore sea territory The Gunaikurnai people have interests and ancestral and historical connections to other places beyond this recognised area. Sea Country is considered to be equally important, with a huge diversity of marine life that supports rich tourism and fishing industries. Sea Country is discussed further in Section A.1.5.1.3.

A.1.5.1.1 Indigenous Protected Areas

IPAs are an essential component of Australia's National Reserve System, which is the network of formally recognised parks, reserves, and protected areas across Australia, designed to protect the nation's biodiversity. IPAs protect cultural heritage into the future, and provide employment, education, and training opportunities for Indigenous people in remote areas. The Gunaikurnai signed an agreement with the Federal Government in 2022 to start the process of establishing the Nanjit to Mallacoota Sea Country IPA consultation project, which extends from Nanjit, east of Wilsons Promontory, to Mallacoota, on the Victoria/New South Wales border. Another IPA consultation project that commenced in 2022 is the Tayaritja Sea Country IPA, which involves the preparation of a management plan for this proposed IPA. It extends from northeast Tasmania (Lutruwita) over the submerged ancient land bridge and surrounds Bass Strait Islands (Tayaritja), including the western portion of the Flinders Marine Park. There are also five established IPAs that occur nearby the EMBA, on and around Flinders Island to the southwest as seen in Figure A-40. They are all important rookeries for mutton birds and important cultural resources for Tasmanian Aboriginal people.

Figure A-40 IPAs nearby the EMBA

A.1.5.1.2 Indigenous Land Use Agreements

An Indigenous Land Use Agreement (ILUA) is a voluntary agreement between Native Title parties and other people or bodies about the use and management of areas of land and/or waters (NNTT, n.d.).

Registered ILUAs bind all native title holders to the terms of the agreement and also operate as a contract between the parties. A register of ILUAs is maintained by the Native Title Registrar. The register of ILUAs does not disclose the existence of any ILUA which overlaps with the OAs; however, the EMBA does overlap the areas of land and tidal waters (between the low water mark and the high-water mark) of the Gunaikurnai Settlement ILUA and Gunaikurnai and Icon Energy ILUA.

A.1.5.1.3 Sea Country

Country is the term often used by Indigenous people to describe the lands, waterways, and seas to which they are connected. The term contains complex ideas about law, place, custom, language, spiritual belief, cultural practice, material sustenance, family, and identity (AIATSIS, 2022). Sea Country, also known as Saltwater Country, is of particular importance for this activity, as the EMBA may extend into areas of known Sea Country.

Smyth and Isherwood (2016) describe Sea Country as all estuaries, beaches, bays, and marine areas collectively, within a traditional estate. Sea Country contains evidence of the ancient mystical events by which all geographic features, animals, plants, and people were created. Sea Country contains sacred sites and contains tracks (or song lines) along which mythological beings travelled during the creation period (Smyth & Isherwood, 2016). The sea, like the land, is integral to the identity of First Nations groups. Connection to Sea Country is accompanied by a complexity of cultural rights and responsibilities. Formal recognition of Sea Country rights lags considerably compared to land rights; this could be for a range of reasons including conflicting perspectives and opinions on traditional custodianship of land and how far it extends (Smyth & Isherwood, 2016). First Nations people see themselves as having responsibilities and rights across the land and sea boundaries that have been put in place over the last 200 years, this includes land that was once inundated by sea, and land that now lies beneath the sea (NOO, 2002a).

In April 2021, the Australian Government committed funding to the Sea Country IPA Program, under which grants will be provided to Indigenous organisations to expand existing IPAs and create new IPAs (DCCEEW, 2024d). The program seeks to increase the area of sea within IPAs in Australia. Ten Sea Country IPA consultation projects were announced in May 2022, including the:

- Nanjit to Mallacoota Sea Country IPA consultation project - Which extends from Corner Inlet to the Victoria/New South Wales border which overlaps with the coastal waters of the EMBA. GLaWAC has commenced steps to establish the Sea Country IPA and is currently conducting Sea Country Assessments, (GLaWAC, 2024) undertaking information gathering and is actively seeking engagement with Traditional Owners on how the IPA should be managed (GLaWAC, 2025). The proposed Sea Country IPA area is located in coastal waters along the eastern coast of Victoria from east of Wilsons Promontory to Mallacoota, including the Gippsland Lakes and estuaries around Mallacoota (within the EMBA).
- Tayaritja Sea Country IPA consultation project – Which is located in north-east Tasmanian waters - It will link existing island IPAs and other islands (refer to Figure A-40). The project area includes Ramsar wetlands and ecologically significant coastal habitats. IPA staff will rehabilitate, restore, monitor and evaluate ecologically significant marine ecosystems, helping to protect threatened marine animals and seabirds and over 120 plant species. The project includes implementation of a cultural burning program and a pest animal and weed management program aimed at maintaining healthy coastal ecosystems (DCCEW, 2024). The Tasmanian Aboriginal Centre is conducting actions towards the implementation of the proposed IPA such as consultation, development of a management plan, establishment of a Sea Country Ranger group and actions to support Sea Country management (Tasmanian Aboriginal Centre, 2025).

A.1.5.1.4 Native Title

Non-exclusive Native Title rights and interests that exist over land and water in the determination area include:

- rights of access
- rights to use and enjoy the land
- rights to take resources from the land for non-commercial purposes
- rights to protect and maintain sites of importance within the determination area
- rights to engage in certain activities on the land (including camping, cultural activities, rituals, ceremonies, meetings, gatherings, and teaching about the sites of significance within the determination area).

These rights do not confer exclusive rights of possession, use and enjoyment of the land or waters. Native Title does not exist in minerals, petroleum, or groundwater.

The Gunaikurnai people hold Native Title over much of Gippsland. The Native Title determination area (Tribunal file no. VCD2010/001) covers approximately 45,000ha and extends from west Gippsland near Warragul, east to the Snowy River, and north to the Great Dividing Range, (Figure A-41). It also includes 200m of offshore sea territory between Lakes Entrance and Marlo. The area includes ten parks and reserves that are jointly managed by the Victorian government and the Gunaikurnai people (NNTT, 2010). The Gunaikurnai people have occupied, used, and managed the coastal land and sea environment along the coastline adjacent to the EMBA for many thousands of years. These include areas that were dry land before the current sea level stabilised about 5000 years ago. During the last Ice Age, approximately 25,000 years ago, coastlines were on average 125m lower than the present day (Umwelt, 2022). The Gunaikurnai peoples cultural and spiritual connection with these landscapes continues, even where evidence of previous occupation now lies beneath the ocean (GLaWAC, 2015).

In the past, coastal wetlands were highly productive areas for hunter-gatherer people, having a variety of habitats and species, so the majority of archaeological sites in Victoria are found within 1km of the coast (Land Conservation Council , 1993). Along the Gippsland coast, stone artefacts that have been found were mostly made from silcrete and quartz from the hinterland. Middens on offshore islands indicate that in the past, Aboriginal people from the area now known as Wilsons Promontory were likely to have visited (Jones & Allen, 1979).

The Gunaikurnai people see no distinction between the land and the sea – it is all part of Country (GLaWAC, 2025). Sea Country can include parts of open ocean, beaches, land and freshwater on the coast. It encompasses all living things, beliefs, values, creation spirits and cultural obligations connected to an area (The University of Adelaide, n.d.). Water is of particular cultural significance to First Nations people as an integral part of songs, ceremonies, hunting and collecting, and other activities that bind people to their country and each other, including fishing (Smyth, Egan, & Kennett, 2018).

Coastal environments are an integrated cultural landscape/seascape that is conceptually very different from the broader Australian view of land and sea. Protecting this cultural heritage is a major concern for First Nations people (NOO, 2002a).

There are no Native Title determinations in New South Wales within the EMBA, however a Native Title Claimant Application was registered by the South Coast People (NSD1331/2017) for an area covering the New South Wales south coast from the south of Sydney to Eden, including the coastal waters (NNTT, 2018) (Figure A-41). Indigenous places along the southern New South Wales coast include Barlings Beach, Ten Pelican Lake BrouBarunguba Aboriginal Place, Mystery Bay Fish Trap, Merriman Island and Bermagui Waterhole (DCCEEW, 2025a).

There are no Native Title determinations in Tasmania, although there are areas of Indigenous cultural significance and IPAs nearby the EMBA, including Mt Chappell Island, Badger Island, Babel Island, Big Dog Island in the Ferneaux Group (NIAA, n.d.).

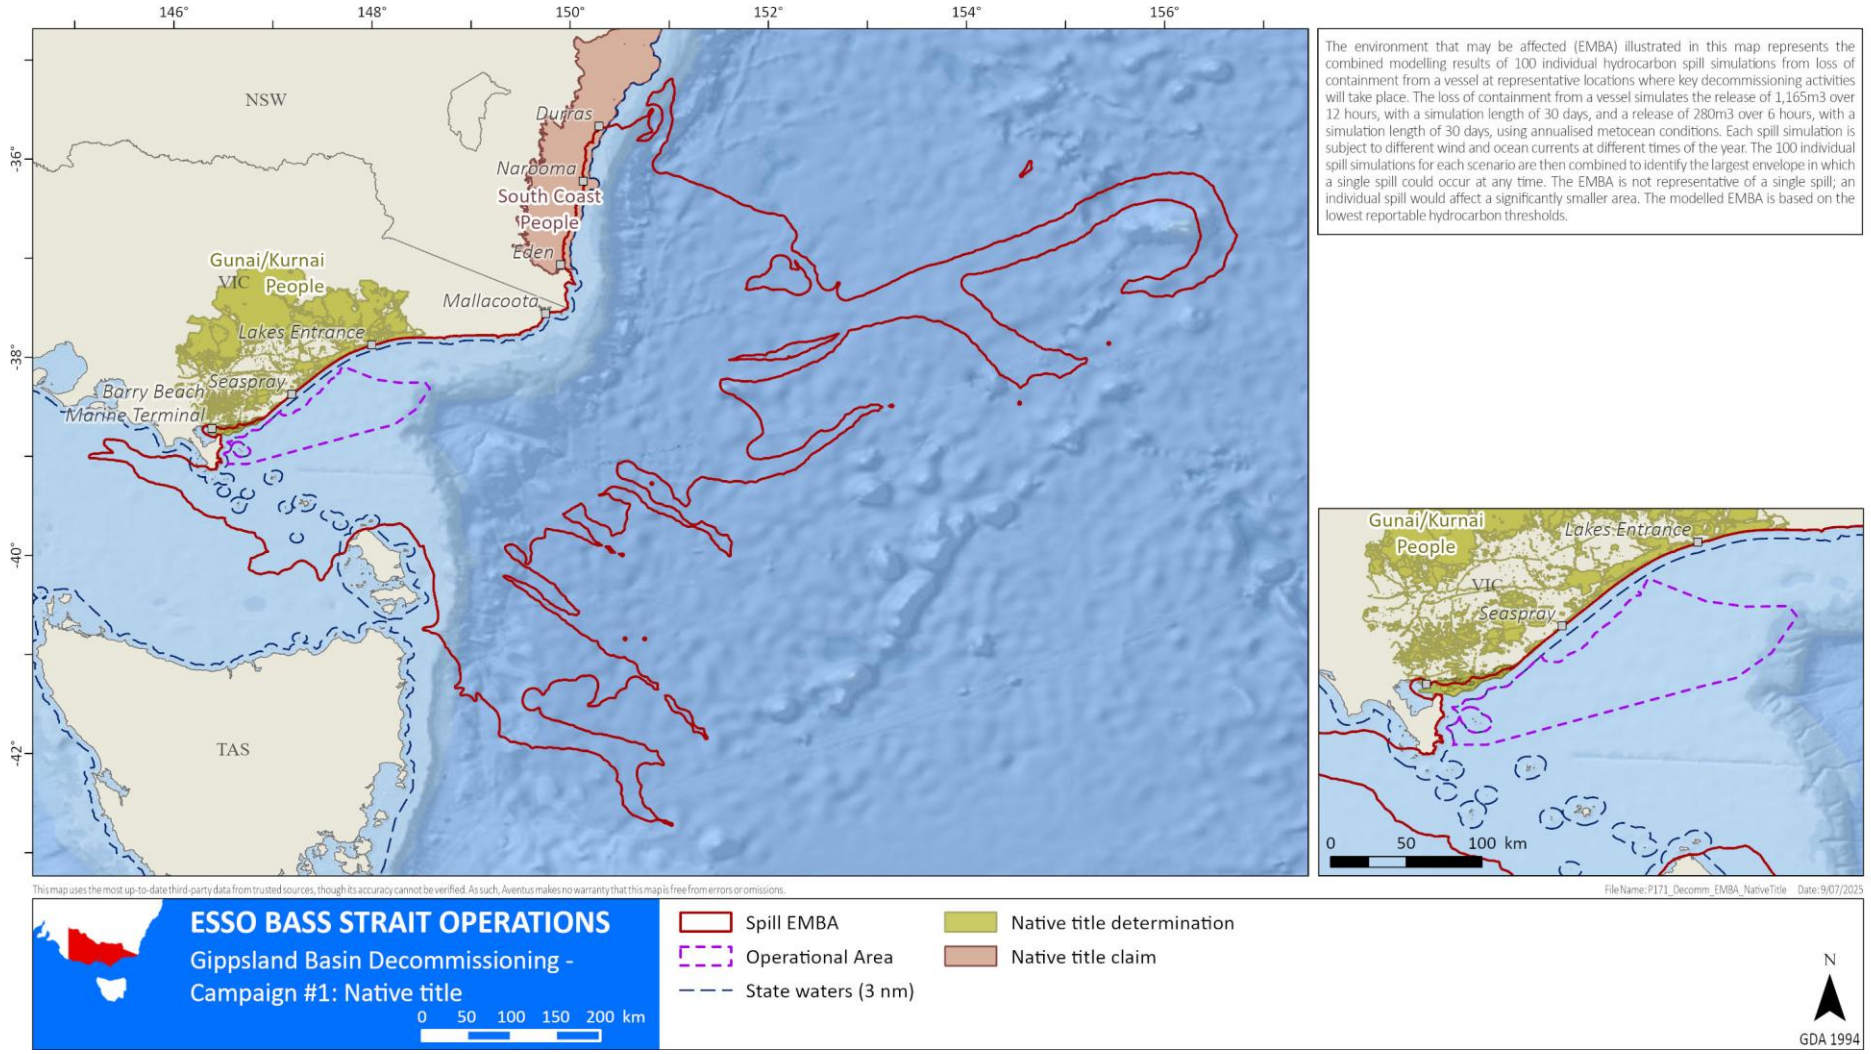

Figure A-41 Native Title claims and determinations intersected by the EMBA

A.1.5.2 Underwater cultural heritage

Shipwrecks, sunken aircraft and other types of UCH that have been underwater for more than 75 years old within Australian waters are protected under the UCH Act. Shipwrecks, sunken aircraft and other types of UCH that have been underwater for less than 75 years can be protected through an individual declaration by DCCEEW based on an assessment of heritage significance (DCCEEW, 2024e). A search of the Australasian Underwater Cultural Heritage Database (DCCEEW, 2025b) identified a large number of shipwrecks within the EMBA (refer to Figure A-42).

In addition to the general protection provided to UCH sites, the UCH Act also provides that an area containing protected UCH may be declared to be a Protected Zone. These zones may be established for a number of reasons including conservation, management or public safety considerations. There are 28 shipwrecks across Australia that have a Protected Zone in place (refer to Figure A-43) (DCCEEW, 2024e). There are no Protected Zones within the OA. The Protected Zones within the EMBA are listed below:

- *Clonmel (1841)* – Victoria (zone size: 50m radius)
- *SS Glenelg (1900)* – Victoria (zone size: 500m radius)
- *SS Federal (1901)* – Victoria (zone size: 800m radius)

Similarly, under the UCH Act, if a First Nations UCH site is discovered in Australian waters, it may be declared as protected under Section 19 of the UCH Act (DCCEEW, 2024e). There are no known First Nations UCH sites within the OA or EMBA.

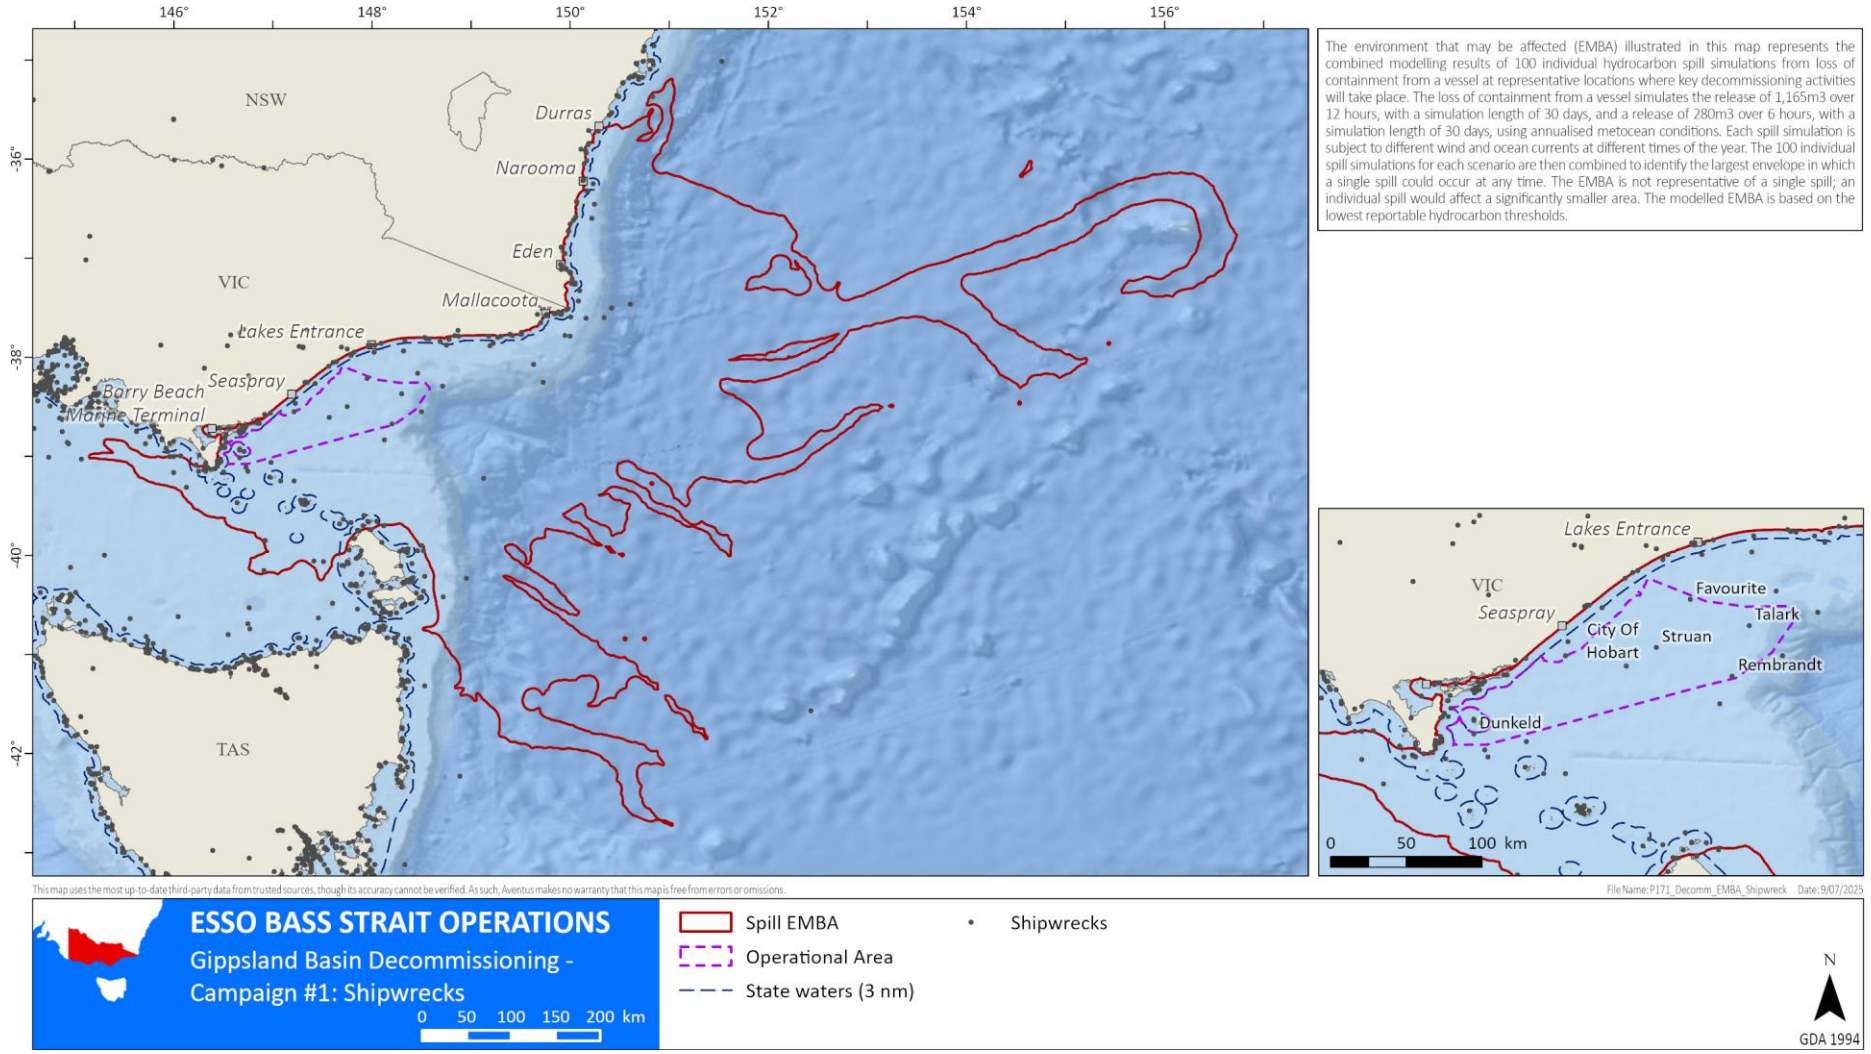

Figure A-42 Shipwrecks within the EMBA

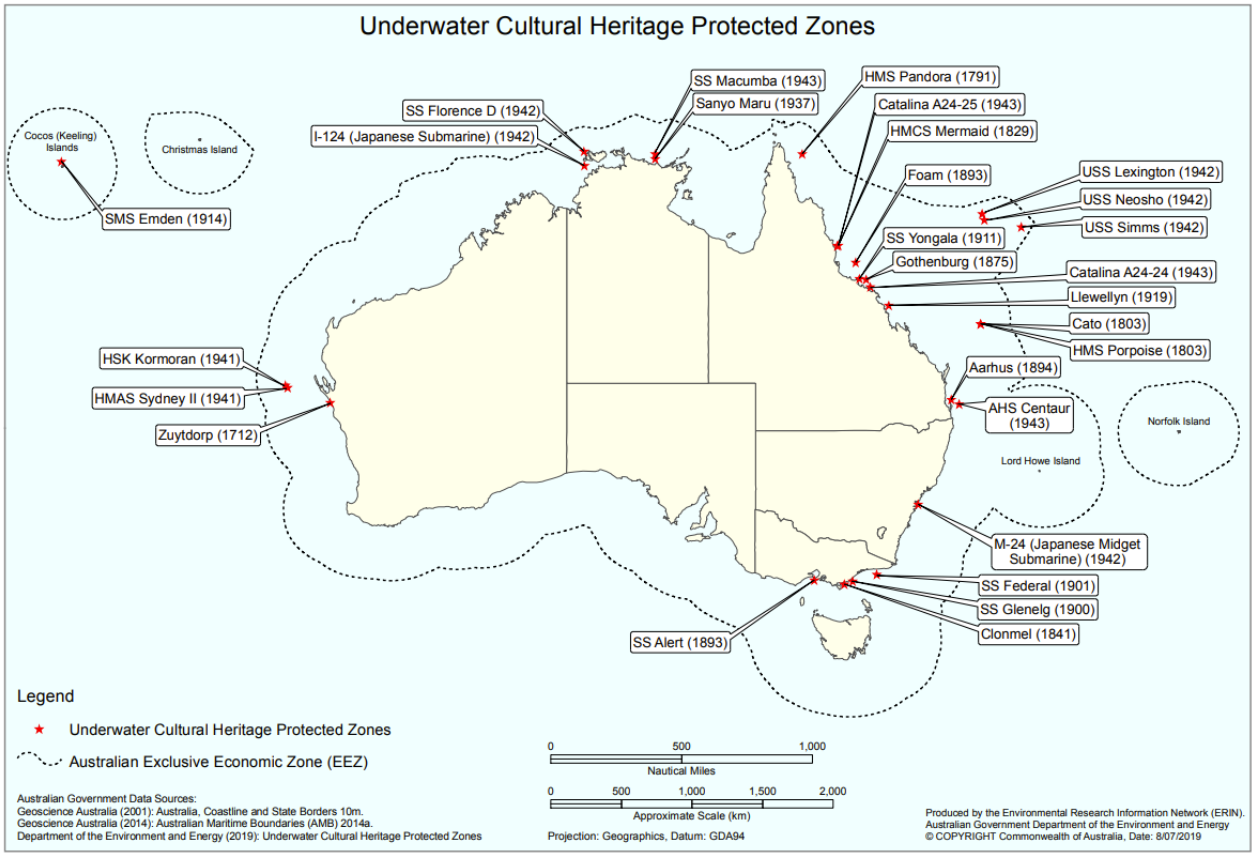

Figure A-43 Shipwreck Protected Zones within Australia (DCCEEW, 2024e)

A.1.6 Socio-economic environment

The social values of the environment can be defined in many ways and the relative importance of the values will vary depending on the perspective and interests of the people, groups or organisations affected (or otherwise). Social values, therefore, can be described in terms of conservation and biodiversity values, economic drivers, or cultural significance. This Section describes the values of the socio-economic and recreational activities in the EMBA.

A.1.6.1 Commercial fishing

Several Commonwealth, Victorian, Tasmanian and New South Wales commercial fisheries are licenced to operate in and around the EMBA. These are described in the following Sections.

A.1.6.2 Commonwealth fisheries

There are 22 Commonwealth fisheries that operate within Australian waters. Commonwealth fisheries are managed by the Australian Fisheries Management Authority under the *Fisheries Management Act 1991* (Cth). Their jurisdiction covers the area of ocean from 3nm from the coast out to the 200nm limit (the extent of the Australian Fishing Zone). Table A-9 summarises the Commonwealth fisheries with jurisdiction to fish within the EMBA based on the latest fishery status reports 2024 (Butler, et al., 2024).

Table A-9 Commonwealth fisheries within the EMBA

Commonwealth fishery	Target species	Description	Percentage overlap with the EMBA
Bass Strait Central Zone Scallop Fishery (BSCZSF)	Commercial scallop (*Pecten fumatus*)	The BSCZSF operates in the central area of Bass Strait between the Victorian and Tasmanian scallop fisheries (see below Sections). In 2023, fishing was permitted throughout the area of the fishery, except in four bed areas that were closed under the BSCZSF harvest strategy. Fishing intensity in 2023 was concentrated on western Bass Strait (Figure A-44). The 2023 fishing season attained a catch of 2063t valued at AUD$4.2M. Thirty-five fishing permits and nine fishing vessels were in active in 2023, and the primary landing ports were Beauty Point, Devonport, and Stanley (Tasmania); Apollo Bay, Lakes Entrance, Melbourne, Port Welshpool, Queenscliff, and San Remo (Victoria). Scallop dredges are the fishing method used in this fishery.	38.74%
Eastern Tuna and Billfish Fishery (ETBF)	Striped marlin (*Kajikia audax*), swordfish (*Xiphias gladius*), albacore (*Thunnus alalunga*), bigeye tuna (*Thunnus obesus*) and yellowfin tuna (*Thunnus albacares*)	The ETBF operates in the Exclusive Economic Zone and adjacent high seas, from Cape York Queensland to the Victoria – South Australian border, including waters around Tasmania and the high seas of the Pacific Ocean. Most of the catch in the fishery is taken with pelagic longlines, although a small quantity is taken using minor-line methods. The fishing intensity in 2023 was concentrated around the entire New South Wales coast and a significant portion of the Queensland coast. (Figure A-45). Catch for the 2023 fishing season was 4040t valued at $40.1M. There were 79 fishing permits for longline boat, with 34 active vessels, and 83 fishing permits for minor-line boat, with 12 active vessels. The primary landing ports are Bermagui, Coffs Harbour and Ulladulla (New South Wales), Cairns, Mooloolaba and Southport (Queensland).	5.17%
Small Pelagic Fishery (SPF)	Blue mackerel (*Scomber australasicus*), jack mackerel (*Trachurus declivis*), redbait (*Emmelichthys nitidus*) and Australian sardine (*Sardinops sagax*)	The SPF extends from southern Queensland to southern Western Australia. The fishery includes purse-seine and midwater trawl fishing methods. The maximum area fished for the 2023 - 2024 season was along the far eastern coast of Victoria and some areas along the New South Wales coast, as well as the eastern portion of the South Australia coast (Figure A-46). Catch for the 2023 - 2024 fishing season was 23,230t with no value assigned due to confidentiality. Twenty-eight fishing permits and a total of eight vessels (five vessels for purse seine fishing method and three vessels for midwater trawl fishing method) were active in the 2023 - 2024 fishing season, with the primary landing ports being Eden and Ulladulla (New South Wales).	5.53%

Commonwealth fishery	Target species	Description	Percentage overlap with the EMBA
Southern and Eastern Scalefish and Shark Fishery (SESSF)	See Commonwealth Trawl Sector (CTS), Scalefish Hook Sector (SHS), and the Gillnet Hook and Shark Hook	The SESSF is a multisector, multi-gear and multispecies fishery, targeting a variety of stocks. The management area covers almost half the area of the Australian Fishing Zone and spans both Commonwealth waters and the waters of several Australian States under Offshore Constitutional Settlement arrangements. Current management arrangements in the SESSF are structured around the following four primary sectors: • the CTS (overlaps with the EMBA) • the Gillnet, Hook and Trap Sector, which is comprised of the SHS, the Shark Gillnet and Shark Hook Sectors (SGSHS), and the Trap Sector (all of these overlap with the EMBA) • the East Coast Deepwater Trawl Sector (outside the EMBA) • the Great Australian Bight Trawl Sector (outside the EMBA). Refer to Figure A-47 for detail on the fishery management area and sub-areas covered by each sector that comprises the SESSF.	5.77%
SESSF CTS	The target species referenced here lists the main species within this sector, based on species catch data for the 2023 - 2024 fishing season. Blue grenadier (*Macruronus novaezelandiae*), tiger flathead (*Neoplatycephalus richardsoni*), orange roughy (*Hoplostethus atlanticus*), pink ling (*Genypterus blacodes*) and eastern school	The CTS extends south from Barrenjoey Point in northern New South Wales to east of Kangaroo Island, South Australia and is a major domestic source of fresh fish for the Sydney and Melbourne markets. The CTS predominantly uses demersal otter trawl and Danish-seine fishing methods. For the 2023 - 2024 season, otter trawl fishing intensity was saturated around eastern and western Victoria, southern New South Wales, eastern South Australia and along the coast of Tasmania (excluding the northern coast) (Figure A-48). Fishing intensity for the Danish-seine method was saturated around eastern Victoria (Figure A-49). Features and statistics for the CTS and the SHS are combined. During the 2023 - 2024 fishing season the sectors attained a total catch of 12,919t, however, at the time of the publication the value of the catch was not available. There were 24 trawl vessels and 18 Danish-seine active vessels during the 2023 - 2024 fishing season. Eden, Sydney and Ulladulla (New South Wales), Hobart (Tasmania), Lakes Entrance and Portland (Victoria) are the primary landing ports.	14.79%

Commonwealth fishery	Target species	Description	Percentage overlap with the EMBA
	whiting (*Sillago flindersi*)		
SESSF CTS and SHS	The target species referenced here lists the main species within this sector, based on species catch data for the 2023 - 2024 fishing season. Blue grenadier (*Macruronus novaezelandiae*), tiger flathead (*Neoplatycephalus richardsoni*), orange roughy (*Hoplostethus atlanticus*), pink ling (*Genypterus blacodes*) and eastern school whiting (*Sillago flindersi*)	The SHS extends around southeastern Australia to the border between South Australia and Western Australia (Figure A-50) and is a major domestic source of fresh fish for the Sydney and Melbourne markets. The SHS uses a variety of longline and dropline hook fishing methods, some of which are automated. The maximum area fished in the 2023 – 2024 occurred in eastern and western Victoria, along the eastern and central coast of South Australia, and along the coast of Tasmania (excluding the northern coast) (Figure A-50). See the CTS for the catch and value information during the 2023 - 2024 fishing season. There were 13 scalefish hook active vessels during the 2023 - 2024 fishing season. Eden, Sydney and Ulladulla (New South Wales), Hobart (Tasmania), Lakes Entrance and Portland (Victoria) are the primary landing ports.	6.12%
SESSF SGSHS	Gummy shark (*Mustelus antarcticus*), elephant fish (*Callorhincus millii*), sawshark (*Pristiophorus cirratus, P. nudipinnis)* and	Most fishing in the SGSHS using nets occurs in Bass Strait, while most fishing using hooks occurs off South Australia. The SGSHS uses demersal gillnet and demersal longline to target gummy shark (*Mustelus antarcticus*) although, sawsharks (*Pristiophorus cirratus and P. nudipinnis*) and elephant fish (*Callorhinchus milii*) are caught as byproducts. School shark was historically the primary target species in the fishery, but biomass was reduced below the limit reference point around 1990. Although overfished, school shark remains the second most economically important stock in the fishery.	8.70%

Commonwealth fishery	Target species	Description	Percentage overlap with the EMBA
	school shark (*Galeorhinus galeus*)	The Shark Gillnet Sector fishing intensity for 2023 - 2024 was saturated in central and eastern Victoria and northwest, northeast and east Tasmania (Figure A-51). The Shark Hook Sector maximum area fished in the 2023 - 2024 season included eastern and western Victoria, along the South Australia coast, and majority of the Tasmanian coast, with the highest fishing intensity presented in areas towards the southeast coast of South Australia (Figure A-51). During the 2023 - 2024 fishing season the SGSHS attained a total catch of 2116t, however, at the time of the publication the value of the catch was not available.	
Southern Bluefin Tuna Fishery (SBTF)	Southern bluefin tuna (*Thunnus maccoyii*)	The SBTF Fishery spans the Australian Fishing Zone. Young fish (one to four years of age) move from the spawning ground in the northeast Indian Ocean into the Exclusive Economic Zone and southwards along the Western Australian coast. Since 1992, most of the Australian catch has been taken by purse seine, targeting juvenile southern bluefin tuna (two to four years of age) in the Great Australian Bight. This catch is transferred to aquaculture farming operations off the coast of Port Lincoln, South Australia, where the fish are grown to a larger size to achieve higher market prices. The fishing methods used by the fishery include purse seine, pelagic longline and minor line. In the 2022 - 2023 season, the fishing intensity for the fishery was saturated along the southeastern coast of New South Wales and northeast corner of the coast of Victoria (Figure A-53). The 2022 - 2023 fishing season attained 6034t of catch valued at $32.57 million. There were 85 fishing permits holders at the start of the season with a total of 30 active vessels divided into 24 purse seine vessels and six longline vessels. The primary landing port is Port Lincoln, South Australia.	2.48%
Southern Squid Jig Fishery (SSJF)	Gould's squid (*Nototodarus gouldi*)	The SSJF is located off New South Wales, Victoria, Tasmania and South Australia, and in a small area of oceanic waters off southern Queensland. The fishery typically operates at night in continental shelf waters between depths of 60m and 120m using a single-method (jigging). The maximum area fished during the 2023 season was in western and eastern Victoria as well as along the north, northeast and eastern coast of Tasmania. In the 2023 fishing season, the highest fishing intensity occurred towards the western coast of Victoria and the eastern coast of Tasmania (Figure A-54).	6.84%

Commonwealth fishery	Target species	Description	Percentage overlap with the EMBA
		During the 2023 fishing season the SSJF had eight active vessels attaining 963t of catch valued at $4 million. The primary landing ports are Devonport, Triabunna (Tasmania), Portland, Apollo Bay, Port Fairy and Queenscliff[2] (Victoria).

The environment that may be affected (EMBA) illustrated in this map represents the combined modelling results of 100 individual hydrocarbon spill simulations from loss of containment from a vessel at representative locations where key decommissioning activities will take place. The loss of containment from a vessel simulates the release of 1,165m3 over 12 hours, with a simulation length of 30 days, and a release of 280m3 over 6 hours, with a simulation length of 30 days, using annualised metocean conditions. Each spill simulation is subject to different wind and ocean currents at different times of the year. The 100 individual spill simulations for each scenario are then combined to identify the largest envelope in which a single spill could occur at any time. The EMBA is not representative of a single spill; an individual spill would affect a significantly smaller area. The modelled EMBA is based on the lowest reportable hydrocarbon thresholds.

A.1.6.3 Victorian fisheries

Victorian-managed commercial fisheries with jurisdiction to fish in the waters of the EMBA are described in Table A-10.

Table A-10 Victorian managed fisheries within the EMBA

Victorian fishery	Target species	Description	Percentage overlap with the EMBA
Abalone Fishery (Figure A-55)	Blacklip abalone (*Haliotis rubra*) is the primary target, with greenlip abalone (*H. laevigata*) taken as a bycatch	The Abalone Fishery is one of Victoria's most valuable commercial fisheries that started in 1962. Almost all catch is exported to international markets, predominately in Asia. Abalone are caught along most of the Victorian coastline. Abalone are collected by divers (generally no greater than 30m deep) who use an iron bar to prise it from the rocks. The divers can stay under water for long periods by using hookah gear.	46.38%
Bait Fishery	Sandworm (*Nereis pelagica*), blood cockle (*Tegillarca granosa*), pipi (*Donax deltoides*), eastern king prawn (*Melicertus plebejus*), ghost shrimp (*Trypaea australiensis*), Australian anchovy (*Engraulis australis*)	The Victorian commercial Bait Fishery encompasses the harvest of fish and invertebrates including crustaceans and molluscs from coastal areas, bays, inlets, estuaries and inland streams and waterbodies for commercial purposes (Ingram, Conron, Hall, & Hamar, 2016).	N/A. This fishery is permitted but not active within the EMBA (SETFIA, 2022).
Bays and Inlet Fisheries (Figure A-56 and Figure A-57)	Multi-species fishery including King George whiting (*Sillaginodes punctatus*), black bream (*Acanthopagrus butcheri*) and various species of snapper, flathead, mullet, garfish, flounder, anchovies and pilchards	Victorian bay, inlet and estuarine finfish fisheries are multi-species, multi-method fisheries that are subject to multiple competing uses and are characterised by large fluctuations in fish abundance that are driven more often by both natural and human induced changes in aquatic habitat and environmental conditions, than by the direct effects of fishing. The larger bay and inlet fisheries include Western Port, Port Phillip Bay, Corner Inlet/Nooramunga and Gippsland Lakes, and both commercial and recreational fishing occurs at those areas. Commercial netting was phased out in Western Port (in 2009), Gippsland Lakes (in 2020) and Port Phillip (in 2022), (VFA, 2023). Corner Inlet and Gippsland Lakes are within the EMBA. In 2022, the *Corner Inlet Fishery Management Plan* (VFA, 2022) was declared for Corner Inlet fishery and it includes all marine waters inside the five main entrances from Bass	As these fisheries include several locations, no percentage is provided on overlap with the EMBA.

Victorian fishery	Target species	Description	Percentage overlap with the EMBA
		Strait: Port Welshpool Entrance, Port Albert Entrance, Kate Kearney Entrance, Shoal/Shallow Inlet Entrance, and McLoughlin's Beach Entrance. The Corner Inlet fishery is now Victoria's largest bay and inlet commercial fishery, typically providing around 230 - 350t of fresh seafood annually. Total landed commercial catch is worth around $3 million per annum in gross value of production (VFA, 2022). All commercial fishers in Corner Inlet are required to report any interactions with threatened, endangered and protected species. Interactions are defined as a fishing vessel, gear or operator coming into contact with a protected species, regardless of the outcome. The threatened, endangered and protected reporting records for Corner Inlet licence holders indicate a low number of interactions with protected species. Between 2015 and 2019, a total of 1214 interactions were reported, of which 1199 of the animals were returned to the water alive and 15 (approximately one per cent of interactions reported) were reported as injured or dead. Most reported incidences of threatened, endangered and protected interactions are from the seine netting method and mostly involve seahorses and pipefish, almost of all of which are released alive (VFA, 2022). For the Corner Inlet fishery, all forms of commercial and recreational fishing, including shellfish collection, are prohibited within the Corner Inlet Marine National Park boundaries. For the Gippsland Lakes fishery, commercial netting was phased out in 2020 (VFA 2023).	
Giant Crab Fishery (Figure A-58)	Giant crabs (*Pseudocarcinus gigas*)	The Giant Crab Fishery is a small, limited entry fishery affiliated with the Rock Lobster Fishery. Fishers target giant crabs using baited rock lobster pots.	46.35%
Pipi Fishery (Figure A-59)	Pipi (*Donax deltoides*)	The Pipi Fishery zone covers the entire Victorian coastline, excluding the intertidal zone of Port Phillip Bay, marine national parks, and sanctuaries where shellfish cannot be harvested. Pipis are found in habitats with high energy surf areas and sandy beaches. The known areas of harvestable quantities of pipi are beaches in Discovery Bay and surrounds in the west, and in Venus Bay and surrounds in the east.	55.43%

Victorian fishery	Target species	Description	Percentage overlap with the EMBA
Rock Lobster Fishery (Figure A-58)	Southern rock lobster (*Jasus edwardsii*)	The Rock Lobster Fishery is divided into two separately managed zones: eastern and western. The eastern zone extends west from the New South Wales border to Apollo Bay; the western zone extends from Apollo Bay west to the border with South Australia. The main ports in the eastern zone are Queenscliff, San Remo and Lakes Entrance. The Southern Rock Lobster Fishery is Victoria's second most profitable fishery after abalone. Southern rock lobsters are found to depths of 150m, with most of the catch coming from inshore waters less than 100m deep.	46.35%
Scallop Fishery (Figure A-60)	Commercial scallop (*Pecten fumatus*)	The Victorian Scallop Fishery extends 20nm from the high tide water mark of the entire Victorian coastline (excluding bays and inlets where commercial scallop fishing is prohibited). Highest fishing effort is concentrated in the eastern waters of the State, with most vessels launching from Lakes Entrance and Port Welshpool.	47.12%
Octopus Fishery (Figure A-61)	Primarily pale octopus (*Octopus pallidus)* however, maori octopus (*Macroctopus maorum)* and gloomy octopus (*Octopus tetricus*) may also be taken	The Octopus Fishery is the newest addition to the Victorian fisheries, commencing in 2020. The only area the fishery operates in is the eastern zone extending from Seaspray to the Victorian/New South Wales border and out to 20nm offshore, except for marine reserves. Octopus fishing in the central and western zones is less established and is being managed by the Victorian Fisheries Authority through exploratory, temporary permits.	46.94%
Wrasse Fishery (Figure A-62)	Primary: bluethroat wrasse (*Notolabrus tetricus*), purple wrasse (*N. fucicola*) Other: rosy wrasse (*Pseudolabrus psittaculus*), senator wrasse (*Pictilabrus laticlavius*), southern maori wrasse (*Ophthalmolepis lineolatus*)	The Wrasse Fishery is a commercial fishery that extends along the entire length of the Victorian coastline and out to 20nm offshore, except for marine reserves. Most wrasse is harvested by hook and line although commercial rock lobster fishers who also hold a commercial wrasse licence can keep those fish that they catch in their rock lobster pots.	46.74%
