Water Depth	76m	42m	46m	94m	73m
Distance to shore	72km	24km	23km	41km	67km
Hydrocarbon type	MDO Group II				
Total spill volume (m^3) / Release rate (m^3/hr)	280 m^3 / 46.7 m^3/hr				220 m^3 / 36.7 m^3/hr
Volume basis	AMSA's guideline for indicative maximum credible spill volumes for other, nonoil tanker, vessel collision (AMSA 2015) is the volume of the largest fuel tank. The loss of a full tank is most likely an overestimate as hydrostatic pressure would limit the release and pumping of oil in a ruptured tank to another tank could also restrict the amount lost. Based on the type of support vessel usually in service, the largest fuel tank volume of 280 m^3 has been used to undertake the impact assessment. The Halibut scenario was based on a pipeline repair vessel with a slightly smaller tank (220 m^3).				
Release duration	6 hours				
Modelled duration	30 days				
MDO Characteristics					
Density	829 kg/m^3 @ 15˚C				

API	37.6
Dynamic Viscosity	4.0 cP @ 25°C
Pour Point	-14 ºC
Oil Property Category	Group II (light persistent oil)
Boiling point (ºC)	
Volatile (<180°C)	6.0 %
Semi-volatile (180 – 265 °C)	34.6 %
Low volatility (265 – 380 °C)	54.4 %
Residual (>380 °C)	5.0 %

7.5.2.2 Modelling Outputs – Weathering and Fate

Marine diesel contains 95% light hydrocarbons (or non-persistent constituents) that are likely to evaporate when available to the atmosphere. The remaining 5% is composed of heavy hydrocarbons (or persistent compounds) that may persist on the sea-surface for extended times.

It is important to note that the viscosity of marine diesel does not change significantly over time and hence has a strong tendency to physically entrain into the upper water column as oil droplets in the presence of waves, where it is subjected to microbial biodegradation (decay) but can refloat to the surface if wave energies abate.

On release to the marine environment, diesel is predicted to be distributed over time into the following components:

- surface;
- water column, consisting of:
- entrained (non-dissolved oil droplets that are physically entrained by wave action) and;
- dissolved (principally the aromatic hydrocarbons);
- evaporated;
- stranded on shoreline; and
- decayed (microbial biodegradation).

Of these components, surface hydrocarbons, dissolved aromatics and oil stranded on shorelines have the most significant impact.

Figure 7-2, Figure 7-3, Figure 7-4 and Figure 7-5 present the fate and weathering graph for modelling of an MDO release at the worst of the four of the modelled locations taking into account

- the largest sweep are of oil on the sea surface
- the largest volume of shoreline loading
- the longest length of shoreline contacted
- the minimum time before exposure to nearshore waters

For the WKF and KPA releases no shoreline contact was predicted so the deterministic trajectory that had the largest swept area of oil on the sea surface of 10 g/m^2 (actionable oil) was considered the 'worst' simulation and selected for weathering and fate analysis.

Figure 7-2 presents the fates and weathering graph for the corresponding single spill trajectory for WKF. At the conclusion of the simulation period, approximately 68% spilled oil was lost to the atmosphere through evaporation. Approximately 17% of the MDO was predicted to have decayed by the end of the simulation, while approximately 15% was predicted to remain within the water column.

Figure 7-5 presents the fates and weathering graph for the 'worst' KPA single spill trajectory. At the conclusion of the simulation period, approximately 89% spilled oil was lost to the atmosphere through evaporation, approximately 5% of the MDO was predicted to have decayed, while approximately 5% was predicted to remain within the water column.

Figure 7-3 presents the fates and weathering graph for the PCA 'worst' single spill trajectory; the deterministic trajectory that had the largest volume of shoreline loading. At the conclusion of the simulation period, approximately 53% spilled oil was lost to the atmosphere through evaporation. Approximately 22% of the MDO was predicted to have decayed by the end of the simulation, while approximately 17% was predicted to remain within the water column and 8% is predicted to arrive ashore.

The deterministic trajectory for BTA MDO modelling that resulted in the largest volume of shoreline loading, the longest length of shoreline contacted above 100 g/m^2 (actionable shoreline oil) and the minimum time before exposure to immediate nearshore waters by visible oil was identified as the 'worst' simulation and was selected for weathering and fate analysis. Figure 7-4 presents the fates and weathering graph for the BTA 'worst' single spill trajectory. At the conclusion of the simulation period, approximately 67% spilled oil was lost to the atmosphere through evaporation, approximately 14% of the MDO was predicted to have decayed, while approximately 12% was predicted to remain within the water column and 8% is predicted to arrive ashore.

The figures clearly show that evaporation is the dominant process contributing for the removal of MDO from the sea surface. Volatile and semi-volatile components of the oil are predicted to evaporate within first 24 hours, with the remaining oil tending to remain within the wave-mixed layer of the water column (3-10 m deep, depending on the conditions).

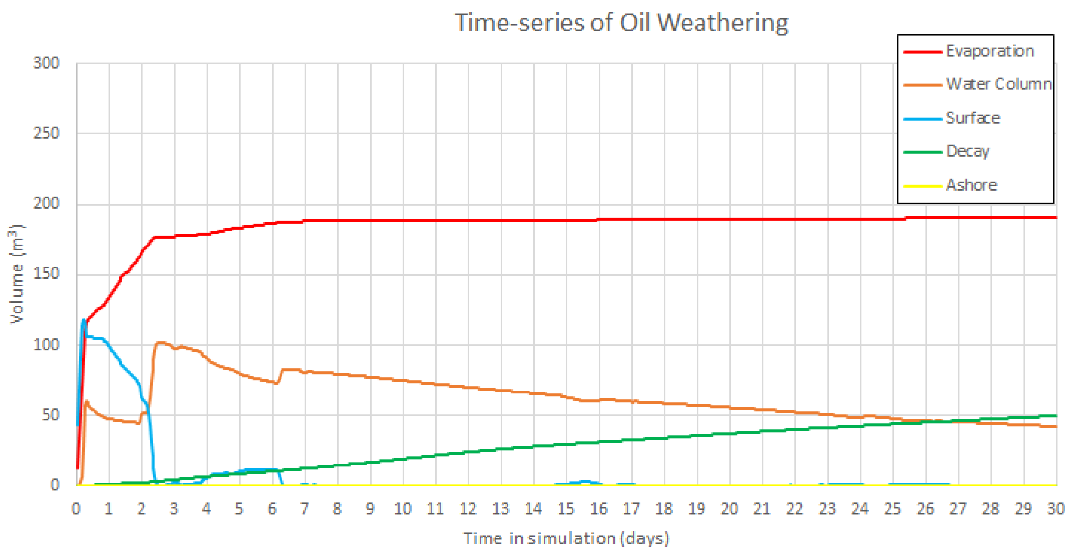

Figure 7-2 Predicted weathering of MDO for the single spill trajectory at WKF with the largest sea surface swept area

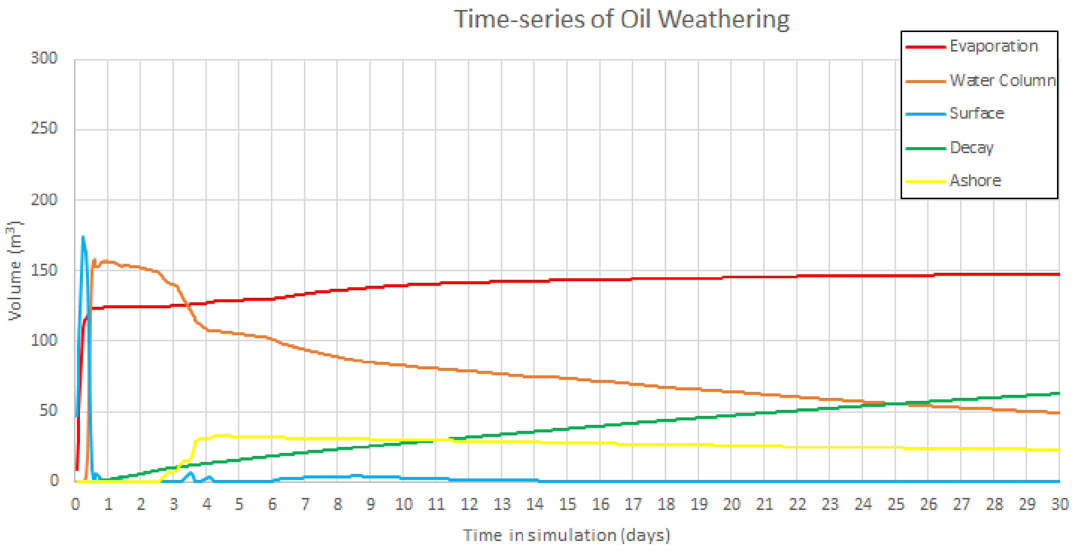

Figure 7-3 Predicted weathering of MDO for the single spill trajectory at PCA with the largest oil volume ashore.

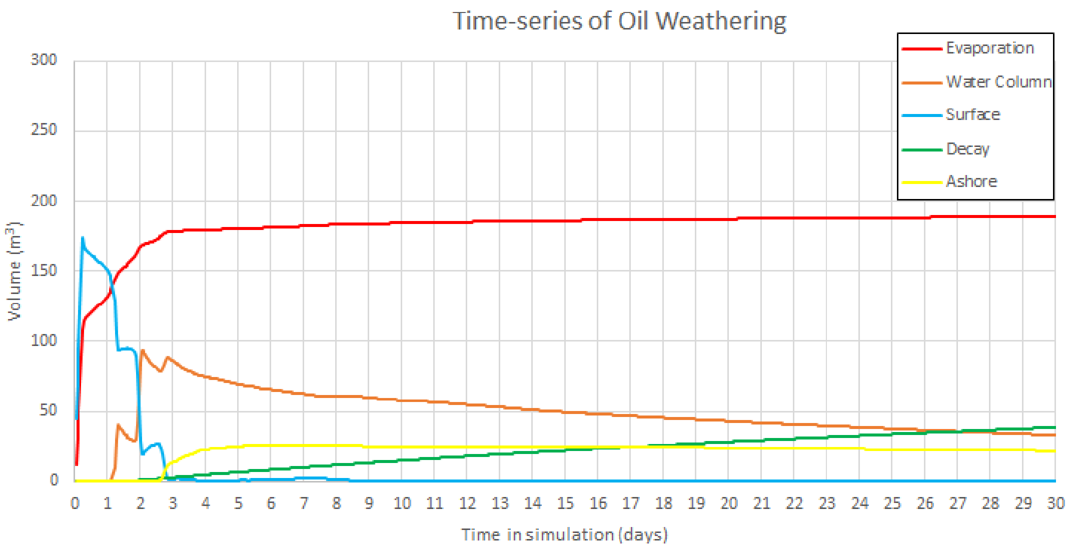

Figure 7-4 Predicted weathering of MDO for the single spill trajectory at BTA with the largest oil volume ashore, longest length of shoreline contacted above the moderate threshold and the minimum time before exposure to immediate nearshore waters by visible oil

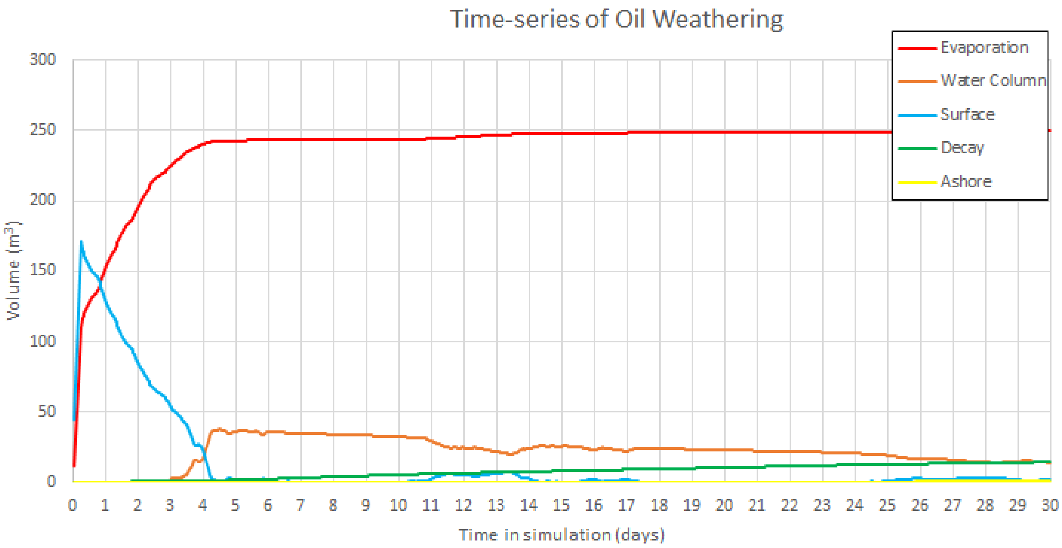

Figure 7-5 Predicted weathering of MDO for the single spill trajectory at KPA with the largest sea surface swept area

7.5.2.3 Modelling Outputs – Stochastic

Oil spill modelling predicts the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, as a result of any spill. This is known as the Potentially Exposed Area (PEA) and is used for planning purposes to ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the EP.

Modelling is also used to inform specific impact assessments by understanding the location and extent of oil at concentrations likely to result in environmental consequences. There is no agreed exposure level below which environmental impacts will not occur, so outputs should not be interpreted as a boundary. However, mapping areas which could be moderately impacted by a spill is a useful tool for impact or consequence assessment.

The extent of potential moderate hydrocarbon exposure is described in Table 7-11. Other environmental sensitivities outside of the moderately exposed area but within the PEA are identified in Table 7-12.

Table 7-11 Environmental sensitivities with potential moderate exposure from an MDO release

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)				
		LOC at West Kingfish (WKF)	**LOC at Perch (PCA)**	**LOC at Barracouta (BTA)**	**LOC at Kipper (KPA)**	**LOC at Halibut (HLA)**
Surface Exposure	Moderate 10 g/m^2	Maximum distance from release site is approx. 15 km in an ENE direction. The zone of moderate exposure overlaps the following BIAs (92% probability): Birds • Black-browed Albatross - Foraging • Buller's Albatross - Foraging • Campbell Albatross - Foraging • Common Diving-petrel - Foraging • Indian Yellow-nosed Albatross - Foraging • Short-tailed Shearwater - Foraging • Shy Albatross - Foraging • Wandering Albatross – Foraging Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Distribution • Does not extend into State waters or contact any National Parks and Reserves	Maximum distance from the release site is 24 km in a north easterly direction. The zone of moderate exposure overlaps the following foraging BIAs (99% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Short-tailed Shearwater • Shy Albatross • Wandering Albatross Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Breeding & Distribution • Does not extend into State waters or contact any National Parks and Reserves	Maximum distance from the release site is 33 km in a south westerly direction. The zone of moderate exposure overlaps the following foraging BIAs (100% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross • Short-tailed Shearwater (34% probability) Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Breeding & Distribution. • Does not extend into State waters or contact any National Parks and Reserves	Maximum distance from the release site is 17 km in an easterly direction. The zone of moderate exposure overlaps the following foraging BIAs (up to 97% probability): Birds • Antipodean Albatross - Foraging • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross • White-faced Storm-petrel Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Distribution. Upwelling East of Eden also has 97% probability of exposure. Does not extend into State waters or contact any National Parks and Reserves	Maximum distance from the release site is ~16 km in an ENE direction. The zone of moderate exposure overlaps the following foraging BIAs (74% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Distribution. Upwelling East of Eden has 1% probability of exposure. Does not extend into State waters or contact any National Parks and Reserves
	High 50 g/m^2	Maximum distance from release site is approx. 5 km in a westerly direction. The zone of moderate exposure overlaps the following BIAs (10% probability): Birds • Black-browed Albatross - Foraging • Buller's Albatross - Foraging • Campbell Albatross - Foraging • Common Diving-petrel - Foraging • Indian Yellow-nosed Albatross - Foraging • Short-tailed Shearwater - Foraging • Shy Albatross - Foraging • Wandering Albatross – Foraging Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark - Distribution	Maximum distance from the release site is 1 km in a south westerly direction. The zone of moderate exposure overlaps the following foraging BIAs (6% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Short-tailed Shearwater • Shy Albatross • Wandering Albatross Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Breeding & Distribution	Maximum distance from the release site is 10 km in an ENE direction. The zone of moderate exposure overlaps the following foraging BIAs (25% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Breeding & Distribution	Maximum distance from the release site is 2 km in a NNE direction. The zone of moderate exposure overlaps the following foraging BIAs (up to 13% probability): Birds • Antipodean Albatross - Foraging • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Distribution.	Maximum distance from the release site is 3 km in an easterly direction. The zone of moderate exposure overlaps the following foraging BIAs (8% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross Marine mammals • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Distribution.

Surface Exposure	Low 1 g/m^2	Maximum 67 km from release location in a north easterly direction. The BIAs listed as being affected by moderate exposure (described in Table 7-11), have a 100% probability of low surface exposure. In addition, the white-faced storm petrel foraging BIA has an 8% probability of low surface exposure. There is a 5% chance of low surface exposure at Upwelling East of Eden KEF.	Maximum 75 km from release location in an ENE direction. BIAs affected by moderate exposure (described in Table 7-11), will also be affected (100%) by low surface exposure. Victorian waters are predicted to be exposed at 3% probability.	Maximum 74 km from release location. In addition to the BIAs affected by moderate exposure (described in Table 7-11), low surface exposure may occur within the Upwelling East of Eden KEF (13%). Victorian waters are predicted to be exposed at 6% probability, with a 1% probability of exposure of Ninety Mile Beach Marine Park.	Maximum 161 km from release location in an ENE direction. All BIAs affected by moderate exposure (described in Table 7-11), have a 100% probability of being exposed to low levels of surface exposure. In addition, the following BIAs may be exposed: Humpback Whale – Foraging (1%) Wedge-tailed Shearwater – Foraging (1%) Upwelling East of Eden has 100% probability of exposure. Other KEFs, state waters or coastal receptors are not predicted to be exposed.	Maximum ~40 km from release location in a southerly direction. All BIAs affected by moderate exposure (described in Table 7-11), have a 100% probability of being exposed to low levels of surface exposure. In addition, the following BIAs may be exposed: Wedge-tailed Shearwater – Foraging (1%) Upwelling East of Eden has 12% probability of exposure. Other KEFs, state waters or coastal receptors are not predicted to be exposed.
Shoreline Exposure	Low 10g/m^2	No shoreline contact is predicted.	There is a 2% probability of shoreline contact. The minimum time for visible oil to shore 28 hours; maximum volume ashore 28.1 m^3. Wellington and Woodside Beach are predicted to be the first shoreline receptors, after 28 hours. Maximum 24 km of shoreline contacted.	Probability of shoreline contact: 4%. The minimum time for visible oil to shore ~2 days; maximum volume of oil ashore was 25.1 m^3. Wellington, Ocean Grange and Seaspray are predicted to be the first shoreline receptors, after ~2 days (<4% probability). Maximum 16 km of shoreline contacted.	No shoreline contact is predicted.	No shoreline contact is predicted.
In-water (dissolved) Exposure	Low 10ppb instantaneous	Exposure will be confined to the surface 10m of the water column. 0-10m water depth Foraging seabirds, Pygmy Blue Whale and Southern Right whale, Indo-Pacific/Spotted Bottlenose Dolphin, Grey nurse shark and	Narrow zone of water column exposure predicted to extend approximately 40 km from the spill location in north easterly and south westerly directions. Exposure will be confined to the surface 10m of the water column.	Small area less than 5 km in diameter located approx. 40 km north east of the release location. Exposure will be confined to the surface 10 m of the water column. Small area less than 5 km in diameter	Narrow zone of water column exposure predicted to extend approximately 20 km from the spill location in north easterly and south westerly directions. Exposure will be confined to the surface 10 m of the water column.	Confined to the surface 10 m of the water column. 0-10m water depth Foraging seabirds, Pygmy Blue Whale and Southern Right whale, White Shark BIA that occur in close proximity to release location

		LOC at West Kingfish (WKF)	LOC at Perch (PCA)	LOC at Barracouta (BTA)	LOC at Kipper (KPA)	LOC at Halibut (HLA)
		White Shark BIA that occur in close proximity to release location have less than 6% probability of being exposed at low instantaneous dissolved hydrocarbon threshold. Upwelling East of Eden KEF may be exposed at low threshold (1%). Exposure not predicted to extend into Victorian, NSW or Tasmanian State Waters.	0-10m water depth Foraging seabirds, Pygmy Blue Whale and Southern Right whale, Indo-Pacific/Spotted Bottlenose Dolphin, Grey nurse shark and White Shark BIA that occur in close proximity to LOC location have less than 3% probability of being exposed at low instantaneous dissolved hydrocarbon threshold. Exposure not predicted to extend into Victorian, NSW or Tasmanian State Waters.	located approx. 40 km NE of the release location. 0-10m water depth Low probability of foraging seabirds, and other nearby BIAs being exposed by low threshold instantaneous dissolved hydrocarbons (1%). No exposure to Victorian, NSW or Tasmanian State Waters.	0-10m water depth Foraging seabirds, Pygmy Blue Whale and Southern Right whale, White Shark BIA that occur in close proximity to release location have less than 2% probability of being exposed at low instantaneous dissolved hydrocarbon threshold. Upwelling East of Eden KEF may be exposed at low threshold (2%). Exposure not predicted to extend into Victorian, NSW or Tasmanian State Waters.	have up to 13% probability of being exposed at low instantaneous dissolved hydrocarbon threshold. Upwelling East of Eden KEF may be exposed at low threshold (29%). Exposure not predicted to extend into Victorian, NSW or Tasmanian State Waters.
In-water (entrained) Exposure	Low 10ppb instantaneous	Exposure will be confined to the surface 10m of the water column. 0-10m water depth: In-water entrained hydrocarbon at the low threshold extends along the southern Australian coast from the Bass Strait Islands, Tasmania to Ulladulla, NSW. The probability of contact with the nearshore waters of various terrestrial National Parks and Reserves ranges from approximately 10% at Croajingolong, to less than 6% at Cape Conran, Mimosa Rocks and Bournda Entrained hydrocarbon at the low threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 20% and 15% respectively and contact Point Hicks, and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans Marine Park (NSW) Entrained hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 7% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. Other receptors predicted to be contacted by entrained oil at the low threshold - With probabilities of 20 - 50% are: • Albatross, shearwater and petrel foraging BIAs; • Little penguin foraging BIA; • Pygmy blue whale distribution and foraging BIAs; • Southern right whale migration BIA; • Indo-Pacific spotted bottlenose dolphin breeding BIA; • White shark foraging and distribution BIAs;	Exposure will be confined to the surface 10m of the water column. 0-10m water depth In-water entrained hydrocarbon at the low threshold extends along the southern Australian coast from Wilsons Promontory, Victoria to Jervis Bay, NSW. The probability of contact with the nearshore waters of various terrestrial National Parks and Reserves ranges from approximately 30% at Croajingolong, 15% at Cape Conran, 10% at Mimosa Rocks and Bournda, to less than 5% at Gippsland Lakes and Wilsons Promontory. Entrained hydrocarbon at the low threshold is predicted to encroach upon Victorian, and NSW state waters with likelihoods of 50% and 30% respectively and contact Point Hicks, Ninety Mile Beach and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans Marine Park (NSW) Entrained hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 5% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. Other receptors predicted to be contacted by entrained oil at the low threshold - With probabilities of 20 - 50% are: • Albatross, shearwater and petrel foraging BIAs; • Little penguin foraging BIA; • Pygmy blue whale distribution and foraging BIAs; • Southern right whale migration BIA; • Humpback whale foraging BIA;	Exposure will be confined to the surface 10m of the water column. 0-10m water depth In-water entrained hydrocarbon at the low threshold extends along the southern Australian coast from Wilsons Promontory, Victoria to Tathra, NSW. The probability of contact with the nearshore waters of various terrestrial National Parks and Reserves ranges from approximately 30% at Croajingolong, 15% at Cape Conran to less than 10% at Mimosa Rocks, Bournda, Gippsland Lakes and Wilsons Promontory. Entrained hydrocarbon at the low threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 50% and 20% respectively and contact Point Hicks, Ninety Mile Beach and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans Marine Park (NSW) Entrained hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 4% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. Other receptors predicted to be contacted by entrained oil at the low threshold - With probabilities of 20 - 50% are: • Albatross, shearwater and petrel foraging BIAs; • Little penguin foraging BIA; • Pygmy blue whale distribution and foraging BIAs; • Southern right whale migration BIA; • Humpback whale foraging BIA; • Indo-Pacific spotted bottlenose dolphin breeding BIA;	Exposure will be confined to the surface 10m of the water column. 0-10m water depth In-water entrained hydrocarbon at the low threshold extends along the southern Australian coast from Marlo, Victoria to Ulladulla, NSW. The probability of contact with the nearshore waters of various terrestrial National Parks and Reserves ranges from approximately 10% at Croajingolong to less than 5% at Cape Conran and Eurobodalla. Entrained hydrocarbon at the low threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 21% and 19% respectively and contact Point Hicks and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans Marine Park (NSW). Entrained hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 4% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups. Other receptors predicted to be contacted by entrained oil at the low threshold - With probabilities of 20 - 35% are: • Albatross, shearwater and petrel foraging BIAs; • Little penguin foraging BIA; • Pygmy blue whale distribution and foraging BIAs; • Southern right whale migration BIA; • Humpback whale foraging BIA; • Spotted bottlenose dolphin breeding BIA; • White shark distribution and foraging BIAs;	Exposure will be confined to the surface 10m of the water column. 0-10m water depth In-water entrained hydrocarbon at the low threshold extends along the southern Australian coast from Wilsons Promontory, Victoria to Tathra, NSW. The probability of contact with the nearshore waters of various terrestrial National Parks and Reserves ranges from approximately 15% at Croajingolong, to approximately 10% at Bournda, to less than 5% at Cape Conran, Gippsland Lakes and Wilsons Promontory. Entrained hydrocarbon at the low threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 20% and 15% respectively and contact Point Hicks, Wilsons Promontory and Cape Howe Marine National Parks and Beware Reef Marine Sanctuary. Entrained hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 6% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. Other receptors predicted to be contacted by entrained oil at the low threshold - With probabilities of 30 - 85% are: • Albatross, shearwater and petrel foraging BIAs; • Pygmy blue whale distribution and foraging BIAs; • Southern right whale migration BIA; • Humpback whale foraging BIA; • White shark foraging and distribution BIAs; • KEF: Upwelling East of Eden

7.5.3 Risk Assessment

An accidental release of marine diesel has the potential to result in the following impacts:

- Change in water quality;
- Change in habitat.

As a result of change in water quality and / or habitat, further impacts may occur which include:

- Injury / mortality to fauna;
- Change in fauna behaviour
- Change to the function, interests or activities of other users.

Receptors that could be affected by a LOC (Vessels) are identified in Table 7-13.

Table 7-13 Receptors potentially impacted by a LOC from a vessels

Impacts	Water quality	Plankton	Fish	Birds	Marine reptiles	Marine mammals	Coastal habitats and communities	KEFS	National Parks and Reserves	Cultural – Indigenous and Historic	Commercial Fisheries	Tourism and Recreation
Change in water quality	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Change in habitat							✓	✓	✓			
Injury / mortality to fauna		✓	✓	✓	✓	✓	✓					
Changes to the functions, interests or activities of other users										✓	✓	✓

7.5.3.1 Consequence Evaluation

Consequence evaluation of potentially exposed receptors in the event of a LOC from a vessel is described below.

Table 7-14 Risks of surface, shoreline and in-water hydrocarbon exposure from marine diesel spill

Receptor	Impact of MDO exposure	Exposure risk assessment
Water quality	A release of marine diesel has the potential to result in a change i.e. decline in water quality. However a significant proportion (~97.%) of MDO consists of volatile components which evaporate within the first 24 hours so water quality impacts are limited. Degraded water quality will potentially impact all the receptors identified in Table 7-13. These impacts are discussed individually within other sections.	Modelling predicts that a change in water quality will be restricted to surface exposure, with limited in water (dissolved) exposure predicted (i.e. no exposure above the moderate threshold). The area of surface exposure for an individual release event will be small, with maximum distance from the release site of surface exposure at the low threshold predicted to be 72 km. The consequences to water quality are assessed as **Level IV**.
Plankton	Plankton are found in nearshore and open waters beneath the surface in the water column. These organisms migrate vertically through the water column to feed in surface waters at night (NRDA, 2012). As they move close to the sea surface it is possible that they may be exposed to both surface hydrocarbons but to a greater extent, hydrocarbons dissolved or entrained in the water column	There is no predicted exposure above the moderate in-water (dissolved) threshold. The consequences to plankton are assessed as **Level IV**.
Fish	Fish can be exposed to oil through a variety of pathways, including: direct dermal contact (e.g. swimming through oil); ingestion (e.g. directly or via oil-affected prey/foods); and inhalation (e.g. elevated dissolved contaminant concentrations in water passing over the gills). <u>Surface oil</u> Since fish and sharks do not generally break the sea surface, the exposure of surface hydrocarbons to fish and shark species are unlikely to occur. Near the sea surface, fish are able to detect and avoid contact with surface slicks meaning fish mortalities rarely occur in the event of a hydrocarbon spill in open waters (Volkman *et a*l., 2004). As a result, wide-ranging pelagic fish of the open ocean generally are not highly susceptible to impacts from surface hydrocarbons. Adult fish kills reported after oil spills occur mainly to shallow water, near-shore benthic species (Volkman *et al*., 2004). Following the Deep Water Horizon incident, it was suggested that whale sharks may be vulnerable to oiling of gills if exposed to the oil. The tendency of whale sharks to feed close to surface waters will increase the likelihood of exposure to surface slicks and elevated hydrocarbon concentrations beneath slicks. <u>In-water oil</u> Exposure to hydrocarbons entrained or dissolved in the water column can be toxic to fishes. Studies have shown a range of impacts including changes in abundance, decreased size, inhibited swimming ability, changes to oxygen consumption and respiration, changes to reproduction, immune system responses, DNA damage, visible skin and organ lesions, and increased parasitism. However, many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Pelagic free-swimming fish and sharks are unlikely to suffer long-term damage from oil spill exposure because dissolved/entrained hydrocarbons in water are not expected to be sufficient to cause harm. Pelagic species are also generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in surface layers only. Fish are most vulnerable to hydrocarbon discharges during their embryonic, larval and juvenile life stages. Oil exposure may result in decreased spawning success and abnormal larval development. Impacts on eggs and larvae entrained in the upper water column are not expected to be significant given the temporary period of water quality impairment, and the limited areal extent of a spill. As egg/larvae dispersal is widely distributed in the upper layers of the water column it is expected that current induced drift will rapidly replace any oil affected populations.	NOAA (2013) and ITOPF (2011) state that marine diesel spills in open water are so rapidly diluted that fish kills are rarely observed. The predicted impact from surface oiling on fish is considered to be negligible at a population level. Pelagic free-swimming fish and sharks are unlikely to suffer either acute or chronic effects from oil spill exposure because dissolved/entrained hydrocarbons in the water column are predicted to be below thresholds at which impacts might occur and their mobile, transitory characteristics reduce the risk of prolonged exposure. The consequences to fish are assessed as **Level IV**.
Birds	Seabirds and shorebirds are sensitive to the impacts of oiling, with their vulnerability arising from the fact that they cross the air - water interface to feed, while their shoreline habitats may also be oiled (Hook *et al*., 2016). Species that raft together in large flocks on the sea surface are particularly at risk (ITOPF, 2011). <u>Surface oil</u> Birds foraging at sea have the potential to directly interact with oil on the sea surface some considerable distance from breeding sites in the course of normal foraging activities. Seabird species most at risk include those that readily rest on the sea surface (e.g. shearwaters) and surface plunging species (e.g. terns, boobies). As seabirds are a top order predator, any impact on other marine life (e.g. pelagic fish) may disrupt and limit food supply both for the maintenance of adults and the provisioning of young. For seabirds, direct contact with hydrocarbons can foul feathers, which may subsequently result in hypothermia due to a reduction in the ability of the bird to thermo-regulate and impair water-proofing. A bird suffering from cold, exhaustion and a loss of buoyancy may also dehydrate, drown or starve (DSEWPAC, 2011). Increased heat loss as a result of a loss of water-proofing results in an increased metabolism of food reserves in the body, which is not countered by a corresponding increase in food intake, may lead to emaciation (DSEWPAC, 2011). The greatest vulnerability in this case occurs when birds are feeding or resting at the sea surface (Peakall *et al.,* 1987). In a review of 45 actual marine spills, there was no correlation between the numbers of bird deaths and the volume of the spill (Burger, 1993).	Several threatened, migratory and/or listed marine species may occur in the area exposed to moderate to high surface thresholds. There are foraging BIA's for some species of petrels and albatrosses throughout the exposed area. However, there are no breeding BIAs within this area. Seabirds rafting, resting, diving or feeding at sea have the potential to come into contact with surface oil, ranging from moderate to high exposure. Given the extensive ocean foraging habitat available to species such as albatross and petrel, the small area and temporary nature of MDO on the sea surface makes it unlikely that a spill will limit their ability to forage for unaffected prey. When first released, the MDO has higher toxicity due to the presence of volatile components. Individual birds making contact close to the spill source at the time of the spill may suffer impacts however it is unlikely that a large number of birds will be affected. As such, acute or chronic toxicity impacts (death or long-term poor health) to small numbers of birds are possible, however this is not considered significant at a population level. The maximum length of shoreline predicted to be exposed to shoreline loading of hydrocarbons that may have biological impacts to birds (>100 g/m^2) is 14 km. This section of coastline comprises mostly wide sandy beaches that provides habitat for shorebird species such as Hooded plovers and terns and nesting habitat for seabird species. MDO is unlikely to persist on the surface of sandy beaches because it quickly penetrates porous sediments (NOAA, 2013). This behaviour limits the duration of exposure to fauna on the shoreline. Shorebirds foraging for food in intertidal areas or along the high tide mark and splash zone may encounter weathered hydrocarbons that may be brought back to nests.

Receptor	Impact of MDO exposure	Exposure risk assessment
	Penguins may be especially vulnerable to oil because they spend a high portion of their time in the water and readily lose insulation and buoyancy if their feathers are oiled (Hook *et al*., 2016). The Iron Baron vessel spill (325 tonnes of bunker fuel in Tasmania in 1995) is estimated to have resulted in the death of up to 20,000 penguins (Hook *et al*., 2016). Shoreline oil Shorebirds are likely to be exposed to oil when it directly impacts the intertidal zone and onshore due to their feeding habitats. Foraging shorebirds will be at potential risk of both direct impacts through contamination of individual birds (e.g. fouling of feathers) and indirect impacts (e.g. fouling and/or a reduction in prey items) (Clarke, 2010). Birds that are coated in oil can also suffer from damage to external tissues, including skin and eyes, as well as internal tissue irritation in their lungs and stomachs Breeding birds (both seabirds and shorebirds) may be exposed to oil via direct contact or the contamination of the breeding habitat (e.g. shores of islands) (Clarke, 2010). Bird eggs may subsequently be damaged if an oiled adult sits on the nest.	Hydrocarbon entering the sandy nests of Hooded plovers, terns or other bird species is likely to percolate through the sand and not accumulate in the feathers of adults or young. Toxicity effects from ingestion of contaminated prey caught in the intertidal zone or from direct exposure, or transport back to, are unlikely, as the volatile components are likely to have flashed off prior to stranding (minimum stranding times range from 2 days). The populations of seabird and shorebird species have a wide geographic range, meaning that impacts to individuals or a population at one location will not necessarily extend to populations at other un-impacted locations. Consequently, the potential consequence of risks to seabirds and shorebirds from a vessel collision event are considered to be **Level III**, to account for a species of local importance being affected.
Marine Reptiles	Marine turtles are vulnerable to the effects of oil at all life stages; eggs, hatchlings, juveniles, and adults. Oil exposure affects different turtle life stages in different ways; and each turtle life stage frequents a habitat with varied potential to be impacted during an oil spill. Several aspects of turtle biology and behaviour place them at particular risk, including a lack of avoidance, indiscriminate feeding in convergence zones, and large pre-dive inhalations. Marine turtles can be exposed to oil externally (e.g. swimming through oil slicks) or internally (e.g. swallowing the oil, consuming oil affected prey, or inhaling of volatile oil related compounds). Marine reptiles can therefore be affected by surface and shoreline exposure. Surface oil Effects of oil on turtles include increased egg mortality and developmental defects; direct mortality due to oiling in hatchlings, juveniles, and adults; and negative impacts to the skin, blood, digestive and immune systems, and salt glands. Oil can enter cavities such as the eyes, nostrils, or mouth; and oil covering their bodies may interfere with breathing because they inhale large volumes of air to dive. Experiments on physiological and clinical pathological effects of hydrocarbons on loggerhead turtles (~15–18 months old) showed that the turtles' major physiological systems were adversely affected by both chronic and acute exposures (96 hour exposure to a 0.05 cm layer of South Louisiana crude oil versus 0.5 cm for 48 hours) (Lutcavage *et al.* 1995). Recovery from the sloughing skin and mucosa took up to 21 days, increasing the turtle's susceptibility to infection or other diseases, such as fibropapilloma (Lutcavage *et al*. 1995). Records of oiled wildlife during spills rarely include marine turtles, even from areas where they are known to be relatively abundant (Short, 2011). An exception to this was the large number of marine turtles collected (613 dead and 536 live) during the Deep Water Horizon (DWH) incident in the Gulf of Mexico (GoM), although many of these animals did not show any sign of oil exposure (NOAA, 2013). Of the dead turtles found, 3.4% were visibly oiled and 85% of the live turtles found were oiled (NOAA, 2013). Of the captured animals, 88% of the live turtles were later released, suggesting that oiling does not inevitably lead to mortality. Shoreline oil Turtles may experience oiling impacts on nesting beaches and eggs through chemical exposures resulting in decreased survival to hatching and developmental defects in hatchlings. Adult females crossing an oiled beach could cause external oiling of the skin and carapace; nothing that most oil is deposited at the high-tide line, and most turtles nest well above this level. Studies on freshwater snapping turtles showed uptake of PAHs from contaminated nest sediments, but no impacts on hatching success or juvenile health following exposure of eggs to dispersed weathered light crude (Rowe *et* al., 2009). However, other studies found evidence that exposure of freshwater turtle embryos to PAHs results in deformities (Bell *et a*l., 2006, Van Meter *et al*., 2006). Turtle hatchlings may be more vulnerable to smothering as they emerge from the nests and make their way over the intertidal area to the water (AMSA, 2015). Hatchlings that contact oil residues while crossing a beach can exhibit a range of effects including impaired movement and bodily functions (Shigenaka, 2003). Hatchlings sticky with oily residues may also have more difficulty crawling and swimming, rendering them more vulnerable to predation. It should be noted that the threat and relative impacts of an unplanned discharge on some marine reptile species are considered less damaging than other stressors. Report cards produced on protected marine reptiles in Australia generally ranked oil pollution as either 'not of concern' or 'of less concern' depending on the marine region (DSEWPaC 2012a).	Marine turtles, or their habitat, may occur in the area potentially exposed to marine diesel at moderate - high concentrations, however they are not noted to reside or aggregate in significant numbers, and there are no recognised BIAs or critical habitats in the region. There are no turtle nesting beaches along the Gippsland coastline, so impacts to turtles from shoreline oiling will not occur. Although the effects of MDO on marine reptiles, specifically turtles can be severe, the low density of turtles expected in the region (due to lack of BIA or aggregations) suggests that few, if any, individuals would be affected. Consequently, the potential impacts to marine reptiles are considered to be **Consequence Level IV**.
Marine Mammals (Pinnipeds)	Pinnipeds are directly at risk from impacts associated with the exposure to surface, shoreline and in-water hydrocarbons. Surface oil Pinnipeds are vulnerable to sea surface exposures in particular given they spend much of their time on or near the surface of the water, as they need to surface every few minutes to breathe, and regularly haul out on to beaches. Pinnipeds are also sensitive as they will stay near established colonies and haul-out areas, meaning they are less likely	Seals are known to occur within the area exposed to moderate-high surface threshold. However, these areas are not identified as critical habitat and there are no identified BIAs for seals in the region. There is no predicted oil stranding along shorelines known to be used by Australian or New Zealand fur-seals as breeding or haul-out sites. As such, it is unlikely that oiling of seals will occur on shorelines.

Receptor	Impact of MDO exposure	Exposure risk assessment
	to practise avoidance behaviours. This is corroborated by Geraci and St. Aubins (1988) who suggest seals, sea-lions and fur-seals have been observed swimming in oil slicks during a number of documented spills. As a result of exposure to surface oils, pinnipeds, with their relatively large, protruding eyes are particularly vulnerable to effects such as irritation to mucous membranes that surround the eyes and line the oral cavity, respiratory surfaces, and anal and urogenital orifices. Hook *et al* (2016) reports that seals appear not to be very sensitive to contact with oil, but instead to the toxic impacts from the inhalation of volatile components. For some pinnipeds, fur is an effective thermal barrier because it traps air and repels water. Petroleum stuck to fur reduces its insulative value by removing natural oils that waterproof the pelage. Consequently, the rate of heat transfer through fur seal pelts can double after oiling (Geraci & St.Aubin, 1988), adding an energetic burden to the animal. Kooyman *et al* (1976) suggest that in fact, fouling of approximately one-third of the body surface resulted in 50% greater heat loss in fur seals immersed in water at various temperatures. Fur-seals are particularly vulnerable due to the likelihood of oil adhering to fur. Heavy oil coating and tar deposits on fur-seals may result in reduced swimming ability and lack of mobility out of the water. <u>In-water oil</u> Ingested hydrocarbons can irritate or destroy epithelial cells that line the stomach and intestine, thereby affecting motility, digestion and absorption. However, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison *et al*., 1986). Volkman *et al* (1994) report that benzene and naphthalene ingested by seals is quickly absorbed into the blood through the gut, causing acute stress, with damage to the liver considered likely. If ingested in large volumes, hydrocarbons may not be completely metabolised, which may result in death. <u>Shoreline oil</u> Breeding colonies (used to birth and nurse until pups are weaned) are particularly sensitive to hydrocarbon spills (Higgins & Gass, 1993). ITOPF (2011) report that species that rely on fur to regulate their body temperature (such as fur-seals) are the most vulnerable to oil as the animals may die from hypothermia or overheating, depending on the season, if the fur becomes matted with oil. It is reported that most pinnipeds scratch themselves vigorously with their flippers and do not lick or groom themselves, so are less likely to ingest oil from skin surfaces (Geraci & St. Aubin, 1988). However, mothers trying to clean an oiled pup may ingest oil. The Long Term Environmental Impact and Recovery report for the Iron Barren oil spill concluded that “The number of pups born at Tenth Island in 1995 was reduced when compared to previous years. There was a strong relationship between the productivity of the seal colonies and the proximity of the islands to the oil spill wherein the islands close to the spill showed reduced pup production and those islands more distant to the oil spill did not” (Tasmanian SMPC, 1999). Pinnipeds are further at risk because they appear to rely on scent to establish a mother-pup bond (Sandegren, 1970; Fogden, 1971), and consequently oil-coated pups may not be recognisable to their mothers. This is only theorised, with studies and research indicating interaction between mothers and oiled pups were normal (Davis and Anderson, 1976; Davies, 1949; Shaughnessy & Chapman, 1984). Australian sea-lions have 'naturally poor recovery abilities' due to 'unusual reproductive biology and life history' (TSSC, 2005). Due to the extreme philopatry of females and limited dispersal of males between breeding colonies, the removal of only a few individuals annually may increase the likelihood of decline and potentially lead to the extinction of some of the smaller colonies.	Although the characteristics of MDO reduce the risk of hyperthermia from oiling, other effects of surface and in-water MDO on pinnipeds can be severe. Long term impacts at a population level are considered unlikely however the consequence is assessed as **Level III.**
Marine Mammals (Cetaceans)	Whales and dolphins can be exposed to the chemicals in oil through: • Internal exposure by consuming oil or contaminated prey; • Inhaling volatile oil compounds when surfacing to breathe; • External exposure, by swimming in oil and having oil directly on the skin and body; and • Maternal transfer of contaminants to embryos (NRDA, 2012). <u>Surface oil</u> Unlike with pinnipeds (see above), oil would not be expected to adhere well to the surface of cetacean skin due to the lack of hairs and the frequent sloughing of skin cells (Engelhardt 1983, Helm *et al*. 2015). In addition, oil should not readily penetrate cetacean skin due to tight intercellular bridges and thick epidermis (O'Hara & O'Shea 2001). Nevertheless, cetaceans can be exposed to oil through direct contact with the eyes, mouth (ingestion), and airways (inhalation), potentially leading to inflammation and lung congestion (Geraci & St. Aubin 1990). Helm *et al.* (2015) suggested that inhalation of toxic compounds associated with fresh oil was of greater concern than absorption through the skin and ingestion. The inhalation of oil droplets, vapours and fumes is a distinct possibility if	Several threatened, migratory and/or listed cetacean species may traverse the MDO spill plume. The distribution and foraging BIA for the Pygmy blue whale and the migration BIA for the Southern right whale may be exposed to surface concentrations at moderate-high thresholds. Biological effects of physical contact with areas of moderate concentrations of MDO at the sea surface are unlikely to lead to any long-term consequences. In the unlikely event of an MDO spill, the environmental impact would be limited to a relatively short period following the release and would need to coincide migration to result in exposure of a large number of individuals. The highly mobile nature of cetacean species means that such exposure is not anticipated to result in long term population viability effects and the resultant impact is assessed as **Consequence Level III.**

Receptor	Impact of MDO exposure	Exposure risk assessment
	whales or dolphins surface in slicks to breathe. Exposure to hydrocarbons in this way could damage mucous membranes, damage airways or even cause death. Cetaceans may incidentally draw seawater and floating oil, into their lungs by breathing in splashed droplets or liquid that has collected near the blowhole just prior to inhalation. Aspiration of liquid oil can cause physical injuries to the respiratory tract by irritating tissues/membranes and can also lead to absorption of toxicants into the blood, as in inhalation exposure (Takeshita *et al*., 2017). French-McCay (2016) proposed exposure to oil concentrations of 10 g/m^{2}could result in mortality to marine mammals. Evidence suggests that many cetacean species are unlikely to detect and avoid spilled oil (Matkin *et al*. 2008). There are numerous examples where cetaceans have appeared to incidentally come into contact with oil and/or not demonstrated any obvious avoidance behaviour. Following the Exxon Valdez oil spill, Matkin *et al*. (2008) reported killer whales in slicks of oil as early as 24 hours after the spill and evidence presented by Aichinger Dias *et al.* (2017) showed that following the DWH oil spill cetaceans in the GoM came into direct contact with both oil and sheen by swimming through them. Although in the GoM it was observed that cetaceans were able to detect the thick and dark-coloured patches of oil, detection of the lighter substances may have been more difficult. Photographs of dolphins with oil on their bodies showed that oil can adhere to and persist on cetacean skin, and contrary to suggestions from previous studies, direct contact with oil and resultant exposure to toxic compounds is of concern (Aichinger Dias *et al*., 2017). <u>In water (dissolved and entrained) oil</u> The physical impacts from ingested hydrocarbon with subsequent lethal or sub-lethal impacts are applicable to both dissolved and entrained oil. However, the susceptibility of cetaceans varies with feeding habits. Baleen whales (such as Blue, Southern right and Humpback whales) are not particularly susceptible to ingestion of oil in the water column as they feed by skimming the surface. Oil may stick to the baleen while they 'filter feed' near slicks. Toothed whales and dolphins may be susceptible to ingestion of dissolved and entrained oil as they gulp feed at depth. As highly mobile species, in general it is very unlikely that these animals will be constantly exposed to concentrations of hydrocarbons in the water column for continuous durations (e.g., >96 hours) that would lead to chronic effects. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013). Ingestion of oil may however result in acute nausea and vomiting and aspiration of oily vomitus into the lungs. Research conducted in the GoM linked aspiration pneumonia, lung abscesses, and pulmonary infections in dolphins to exposure to DWH oil (Venn-Watson *et al*., 2015a cited in Takeshita *et al.,* 2017) Some whales, particularly those with coastal migration and reproduction, display strong site fidelity to specific resting, breeding and feeding habitats, as well as to their migratory paths and this may override any tendency for cetaceans to avoid the noxious presence of hydrocarbons. The Southern right whale exhibits varying degrees of site fidelity, with the majority of females and calves returning to the same birthing location, while some also travel long distances between breeding grounds within a season (DSEWPAC, 2012c). If spilled oil reaches these biologically important habitats, the pollution may disrupt natural behaviours, displace animals, reduce foraging or reproductive success rates and increase mortality. Takeshita *et al.* (2017) concluded that the range of adverse health effects and increased mortality/reproductive failure observed in cetacean populations throughout the GoM since the DWH oil spill are consistent with the range of exposure scenarios. If sufficiently high numbers of animals are impacted, the greater population may experience reduced recovery and survival rates. The restitution time for cetaceans affected at a population level is assumed to be long term, i.e. 40 years, based on consensus on recovery times for marine mammals following the DWH incident (Bock *et. al*., 2018).	
Coastal Habitat – Shoreline (Sandy)	Sandy beaches provide potential foraging and breeding habitat for numerous bird, marine turtle and pinniped species. These activities primarily occur above the high tide line, with exception of haul outs. Note, most of the oil on a sandy shore will be concentrated at, and below, the high tide mark. Sandy beaches are also inhabited by a diverse assemblage (although not always abundant) of infauna (including nematodes, copepods and polychaetes); and macroinvertebrates (e.g. crustaceans). Because the sand retains oil, such animals may be killed if oil penetrates into the sediments. Long-term depletion of sediment fauna could have an adverse effect on birds or fish that use tidal flats as feeding grounds (IPIECA, 1999). Depth of penetration in sandy sediment is influenced by: • Particle size. Penetration is not generally as great on mud as on coarser sediments. • Oil viscosity. Viscous oils and mousse (water-in-oil emulsion) tend to penetrate less deeply than low-viscosity oils such as light crudes or diesel oil. • Drainage. If sediments are poorly drained (as is often the case with tidal flats remote from creeks or channels), the water content may prevent the oil from penetrating into the sediment. In contrast, oil may reach depths greater than one metre in coarse well-drained sediments. • Animal burrows and root pores. Penetration into fine sediments is increased if there are burrows of animals such as worms, or pores left where plant roots have decayed.	The maximum length of coastline potentially at risk from stranded oil at the moderate threshold is 14 km. This coastline is dominated by wide sandy beaches. With the shortest time to shoreline accumulation at the moderate threshold being 3 days the MDO will have partially weathered. The shoreline loadings may result in acute toxicity, and mortality, of invertebrate communities, especially as the MDO will easily penetrate into sandy sediments. However, tidal action is expected to lead to rapid weathering of any hydrocarbons in the intertidal area and the populations of these communities would be likely to rapidly recover. The impact of MDO coming ashore on sandy beaches is considered to have a **Consequence Level III.**

Receptor	Impact of MDO exposure	Exposure risk assessment
	A 100 g/m^2 threshold (considered a 'stain' or 'film', and equivalent to 0.1 mm thickness) is assumed as the lethal threshold for invertebrates on hard substrates and sediments (mud, silt, sand, gravel) in intertidal habitats. A threshold of 100 g/m^2 oil thickness would be enough to coat an animal and likely impact its survival and reproductive capacity (French-McCay, 2009). Based on this, areas of heavy oiling would likely result in acute toxicity, and death, of many invertebrate communities, especially where oil penetrates into sediments through animal burrows (IPIECA, 1999). However, these communities would be likely to rapidly recover (recruitment from unaffected individuals and recruitment from nearby areas) as oil is removed from the environment. Following the Sea Empress spill (in west Wales, 1996) many amphipods (sandhoppers), cockles and razor shells were killed. There were mass strandings on many beaches of both intertidal species (such as cockles) and shallow sub-tidal species. Similar mass strandings occurred after the Amoco Cadiz spill (in Brittany, France, 1978) (IPIECA, 1999). Following the Sea Empress spill, populations of mud snails recovered within a few months but some amphipod populations had not returned to normal after one year. Opportunists such as some species of worm may actually show a dramatic short-term increase following an oil spill (IPIECA, 1999). In March 2014, small volumes of crude oil from an unidentified source (confirmed to not be offshore oil and gas production facilities) washed up along a 7-km section of sandy beach on the Victorian Gippsland coast as small (a few millimetres thick) granular balls (Gippsland Times, 2014). AMSA (2014) reported that no impacts were observed over the course of two months following the incident. As a result of the DWH incident, oil washed up on sandy beaches of the Alabama coastline. The natural movement of sand and water through the beach system continually transformed and re-distributed oil within the beach system, and 18 months after the event, mobile remnant oil remained in various states of weathering buried at different depths in the beaches (Hayworth *et al*., 2011). There is also evidence that submerged oil mats (SOM) exist just offshore of the Alabama beaches (ranging in thickness from a few millimetres to several centimetres), which has resulted in the regular washing up of tar balls onto sandy beaches. These SOMs may serve as long-term sources of remnant oil to the beach ecosystem (Hayworth *et al*., 2011). Long-term changes to the beach ecosystem as a result of stranded oil are unknown. Other results from beach sampling undertaken at Dapuhin Island, Alabama, in May (pre-impact) and September 2011 (post-impact) found a large shift in the diversity and abundance of microbial species (e.g., nematodes, annelids, arthropods, polychaetes, protists, fungi, algae and bacteria). Post-spill, sampling indicated that species composition was almost exclusively dominated by a few species of fungi. DNA analyses revealed that the 'before' and 'after' communities at the same sites weren't closely related to each other (Bik *et al*., 2012). Similar studies found that oil deposited on the beaches caused a shift in the community structure toward a hydrocarbonoclastic consortium (petroleum hydrocarbon degrading microorganisms) (Lamendella *et al*., 2014).	
KEFs	Potential impacts to sensitive receptors related to the Upwelling East of Eden, such as plankton and other marine fauna, are discussed in the appropriate sections above.	The zone of moderate sea surface MDO exposure intersects the westernmost portion of the KEF: Upwelling East of Eden. While a spill would not affect the upwelling itself, if the spill occurs at the time of an upwelling event, it may result in krill being exposed to in-water MDO. However no in-water exposure is predicted above levels at which impacts are expected to occur. The consequence is assessed as **Level IV**.
National Parks and Reserves	Potential impacts to sensitive receptors related to the shoreline of the Gippsland Lakes Coastal Park, such as sandy beaches and birds, are discussed in the appropriate sections above.	Part of the coast bordering the Gippsland Lakes Coastal Park is within the zone of moderate shoreline exposure. The consequence to Gippsland Lakes Coastal Park is assessed as localised and short term, and ranked as **Consequence Level III.**
Commercial fisheries	Commercial fishing has the potential to be impacted through exclusion zones associated with the spill, the spill response and subsequent reduction in fishing effort. Exclusion zones may impede access to commercial fishing areas, for a short period of time, and nets and lines may become oiled. The impacts to commercial fishing from a public perception perspective however, may be much more significant and longer term than the spill itself. Fishing areas may be closed for fishing for shorter or longer periods because of the risks of the catch being tainted by oil. Concentrations of petroleum contaminants in fish and crustacean and mollusc tissues could pose a significant potential for adverse human health effects, and until these products from nearshore fisheries have been cleared by the health authorities, they could be restricted for sale and human consumption. Indirectly, the fisheries sector will suffer a heavy loss if consumers are either stopped from using or unwilling to buy fish and shellfish from the region affected by the spill. Impacts to fish stocks have the potential for reduction in profits for commercial fisheries, and exclusion zones exclude fishing effort. Davis *et al* (2002) report detectable tainting of fish flesh after a 24-hour exposure at crude concentrations of 0.1 ppm, marine fuel oil concentrations of 0.33 ppm and diesel concentrations of 0.25 ppm. The Montara spill (as the most recent [2009] example of a large hydrocarbon spill in Australian waters) occurred over an area fished by the Northern Demersal Scalefish Managed Fishery (with 11 licences held by 7 operators), with goldband snapper, red emperor, saddletail snapper and yellow spotted rockcod being the key species fished (PTTEP, 2013). As a precautionary measure, the WA Department of Fisheries advised the commercial fishing fleet to avoid fishing in oil-affected waters. Testing of fish caught in areas of visible oil slick (November 2009) found that there were no detectable	Several commercial fisheries may operate within the area potentially exposed in the event of a LOC and a temporary fisheries closure may be put in place. Oil may foul the hulls of fishing vessels and associated equipment, such as gill nets. A temporary fisheries closure, combined with oil tainting of target species (actual or perceived), may lead to financial losses to fisheries and economic losses for individual licence holders. Due to the rapid weathering of the MDO in the high energy Bass Strait environment it is unlikely that an exclusion zone would be established, consequently, the potential impacts to commercial fisheries from an MDO LOC are considered to be **Consequence Level III** (based on public impact consequence considerations as per Esso Risk Matrix Application Guide, 2018).

Receptor	Impact of MDO exposure	Exposure risk assessment
	petroleum hydrocarbons in fish muscle samples, suggesting fish were safe for human consumption. In the short-term, fish had metabolised petroleum hydrocarbons. Limited ill effects were detected in a small number of individual fish only (PTTEP, 2013). No consistent effects of exposure on fish health could be detected within two weeks following the end of the well release. Follow up sampling in areas affected by the spill during 2010 and 2011 (PTTEP, 2013) found negligible ongoing environmental impacts from the spill. Since testing began in the month after the DWH blowout in the Gulf of Mexico (GoM) (2010), levels of oil contamination residue in seafood consistently tested 100 to 1,000 times lower than safety thresholds established by the USA FDA, and every sample tested was found to be far below the FDA's safety threshold for dispersant compounds (BP, 2015). FDA testing of oysters found oil contamination residues to be 10 to 100 times below safety thresholds (BP, 2014). Sampling data shows that post-spill fish populations in the GoM since 2011 were generally consistent with pre-spill ranges and for many shellfish species, commercial landings in the GoM in 2011 were comparable to pre-spill levels. In 2012, shrimp (prawn) and blue crab landings were within 2.0% of 2007-09 landings. Recreational fishing harvests in 2011, 2012 and 2013 exceeded landings from 2007-09 (BP, 2014).	
Cultural – Indigenous and Historic	Visible sheen has the potential to reduce the visual amenity of cultural heritage sites such as indigenous or historic (e.g. shipwreck) protected areas.	Oil sheen is predicted to encroach upon nearshore waters in the vicinity of the Gunai Kurnai Native Title Determination Area and a number of historic shipwrecks. However, given the relatively short duration, and limited extent of predicted exposure the consequence level is considered **Level IV** (based on public impact consequence considerations as per Esso Risk Matrix Application Guide, 2018).
Tourism and Recreation	Refer to sections on fish, cetaceans and sandy shorelines above.	Tourism and recreation are also linked to the presence of marine fauna (e.g. whales), particular habitats and locations for swimming or recreational fishing. The modelling predicts a low probability of visible oil extending into Victorian waters (including Ninety Mile Beach MNP) and to the sandy shoreline along Ninety Mile Beach (including Gippsland Lakes Coastal Park). Short-term impacts to nature-based tourism and other human uses of beaches (and nearshore waters) may occur as a result of temporary beach closures to protect human health or due to perceptions of a polluted environment that is not desirable to visit. However, given the relatively short duration, and limited extent of predicted shoreline contact the consequence level is considered **Level III** (based on public impact consequence considerations as per Esso Risk Matrix Application Guide, 2018).

7.5.3.2 Likelihood Evaluation

Based on industry data, vessel collisions are considered rare (37 collisions reported from a total of 1200 marine incidents in Australian waters between 2005 and 2012). As most vessel collisions involve the loss of containment of a forward tank, which are generally double-lined and smaller than other tanks, the loss of the maximum volume used in the scenario above is unlikely.

Considering the inherent low likelihood of a collision occurring, the safeguards in place and enactment of the SMPEP and OPEP, and the rapid weathering of MDO, the probability of the impacts described above occurring is considered **Very Highly Unlikely (E)**.

7.5.4 Risk Ranking

Consequence	Likelihood	Risk Ranking
III	E	4

7.5.5 Controls

Good Practice	Adopted	Control	Rationale
Support vessel approach protocols	✓	**CM27**: Support vessel approach procedure	Support vessel approach procedure outlines the required 500 m approach and DP operational checklists complete to ensure safe approach to the platforms.
Structured operational limits criteria for dynamic positioning (DP) operations and vessel SIMOPS	✓	**CM28**: ASOG / CAMO procedures	The application of ASOG / CAMO risk management tools is industry best practice for DP operations. CAMO describes how to configure the vessels DP system and ASOG sets out the operational, environmental and equipment performance limits and procedures considered necessary for safe DP operations whilst carrying out a specific activity, including SIMOPS.
DP Class 2	✓	**CM27**: Support vessel DP system	DP Class 2 (redundancy so that no single fault in an active system will cause the system to fail) is the industry standard where loss of position keeping capability may cause personnel injury, pollution or damage with large economic consequences.
Shipboard Marine Pollution Emergency Plan (SMPEP)	✓	**CM20:** SMPEP	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the International Maritime Organisation (IMO) across many critical areas including the International Convention for the Safety of Life at Sea, (SOLAS), the 1988 Protocol to the International Convention on Load Lines and the International Convention for the Prevention of Pollution from Ships (MARPOL). A vessel built in accordance with the applicable Rules of an IACS Member society may be assigned a class designation relevant to the IMO rules, on satisfactory completion of the relevant classification society surveys. For ships in service, the society carries out routine scheduled surveys to verify that the ship remains in compliance with those Rules. Should any defects that may

Good Practice	Adopted	Control	Rationale
			affect class become apparent, or damages be sustained between the relevant surveys, the owner is required to inform the society concerned without delay. MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require that a SMPEP (or equivalent, according to class) is in place. To prepare for a spill event, the SMPEP details: • response equipment available to control a spill event • review cycle to ensure that the SMPEP is kept up to date • testing requirements, including the frequency and nature of these tests. In the event of a spill, the SMPEP details: • reporting requirements and a list of authorities to be contacted • activities to be undertaken to control the release • procedures for coordinating with local authorities.

7.5.6 Demonstration of ALARP

ALARP Decision Context and Justification	**Decision Context A** Operating vessels is common practice for activities such as fuel transfer, provision of cargo, and reverse logistical support. These activities are well regulated with associated control measures, well understood, and are implemented across the offshore industry. Although there is the potential for impacts of consequence Level III from a vessel collision, spill source volumes are limited in size, the environmental impact of MDO is well understood, a credible spill volume has been modelled and a very conservative threshold has been selected to define the PEA, so there is limited uncertainty associated with this event. During stakeholder engagement, no questions were raised regarding the acceptability of the risk of this event. Esso believes **ALARP Decision Context A** should apply.

7.5.7 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Risk Assessment Process for Unplanned Events	The risk ranking is lower than Category 1	✓	The risk ranking is Category 4 (the lowest category) and therefore considered acceptable.
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
	Activity does not have the potential to result in serious	✓	The activities were evaluated as having the potential to result in a Level III

Factor	Demonstration Criteria	Criteria Met	Rationale
	or irreversible environmental damage.		consequence thus are not considered as having the potential to result in serious or irreversible environmental damage.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	The proposed activities align with the requirements of the: • Navigation Act 2012 – Chapter 6 (Safety of Navigation) Part 6 deals with safe navigation including provisions about reporting of movement of vessels. The requirements of MARPOL Annex I has been adopted. The following legislative and other requirements are considered relevant as they apply to the implementation of MARPOL in Australia: • Protection of the Sea (Prevention of Pollution from Ships) Act 1983. • Navigation Act 2012 – Chapter 4 (Prevention of Pollution). • Marine Order 91 (Marine pollution prevention – oil) 2014
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"
	Meets ExxonMobil Environmental Standards	✓	There is no standard related to a LOC of marine diesel but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed activities meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; • OIMS System 8-1 objective to clearly define and communicate operations integrity requirements to contractors; and • OIMS System 10-2 objectives to document, resource and communicate emergency response plans, and conduct training, exercises and/or drills to determine the adequacy of the plans.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised concerning the risk of a LOC resulting from vessel collision.

7.6 Accidental Release – LOC from pipeline

7.6.1 Causes of Accidental Release – LOC from pipeline

Loss of containment from a pipeline could occur due to a variety of mechanisms varying from a pinhole leak through to a rupture. Details of different release scenarios have been described in Table 7-15.

7.6.2 Spill Modelling

Spill modelling was prepared for the worst case discharge scenarios to establish the extent of possible environmental impact (RPS, 2020). The spill modelling was prepared based on the parameters described in Table 7-23. The modelling was based on 100 spill simulations and annual analysis (i.e. over all seasons).

7.6.2.1 Discharge Scenarios and Modelling Inputs

Table 7-15 Selection of worst case discharge scenario - LOC from pipeline

Process	Description
Identify potential discharge scenarios	Loss of containment from a pipeline could occur due to a variety of mechanisms. Release scenarios from a pipeline are highly dependent on the size of the hole in the pipeline. Pipeline discharge scenarios could vary from a pinhole leak, a minor hole to a full rupture. Pinhole leaks could be caused through: • Corrosion Minor holes could be caused by: • Corrosion • Dropped objects • Anchor drag A full rupture could be caused by: • Failure of an unsupported span • Anchor drag on an unprotected section of pipeline. Vessel collision with platform that results in loss of containment from pipeline risers. A collision of a vessel with a riser could occur on facilities where oil risers that are external to the jacket and are located on the same side that vessel transfers occur (east side). On all of these facilities, pipeline risers are protected by a riser guard. The facilities where this is the case are: • Marlin Complex at Marlin A: MLA300 (300mm oil) • Marlin Complex at Marlin A: TNA200 (200mm oil) • Snapper: SNA250 (250mm oil)
Identification of potential pollutants	Bass Strait Operations include up to 600km of pipelines which contain a mixture of hydrocarbons, produced water and production chemicals. In general, pipelines are classified as “oil” or “gas” by their liquid content. As part of Bass Strait Offshore Operations there are eight pipelines which cross shore. The contents of these pipelines is as follows:

License	Name	DN (mm)	From	Contents	Contents	Status
VIC/PL4	BTA-Shore	150	Barracouta	Oil	Condensate from BTA.	In Service
VIC/PL5	HLA-VS1	600	Halibut	Oil	The HLA600 Pipeline contains liquids (condensate and crude) from a number of platforms in the HLA pipeline network.	In Service

<table>
<tr><th>Process</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><td></td><td></td><td></td><td></td><td></td><td>Contents of the HLA pipeline includes liquid products from 11 different facilities (BMB, BMA, WKF, FTA, CBA, HLA, WTN, FLA, TNA, WTA, SNA)</td><td></td></tr>
<tr><td>VIC/PL21</td><td>PCA-Shore</td><td>300</td><td>Perch</td><td>Oil</td><td>The PCA to shore pipeline has been suspended and filled with inhibited seawater.</td><td>Suspended</td></tr>
<tr><td>VIC/PL1</td><td>BTA-Shore</td><td>450</td><td>Barracouta</td><td>Gas</td><td>Gas from BTA. Gas from the BTW project will be fed into this pipeline once operations commence.</td><td>In Service</td></tr>
<tr><td>VIC/PL2</td><td>MLA-Shore</td><td>500</td><td>Marlin</td><td>Gas</td><td>Gas from TNA, WTN, FLA and MLA</td><td>In Service</td></tr>
<tr><td>VIC/PL13</td><td>SNA-Shore</td><td>600</td><td>Snapper</td><td>Gas</td><td>Gas from SNA</td><td>In Service</td></tr>
<tr><td>VIC/PL32</td><td>BMA-VS3</td><td>350</td><td>Bream A</td><td>Gas</td><td>Gas from BMA</td><td>In Service</td></tr>
<tr><td>n/a (secondary pipeline)</td><td>Shore-PCA</td><td>100</td><td>Shore</td><td>Gas lift</td><td>Inhibited seawater</td><td>Suspended</td></tr>
</table>
A loss of containment from a gas filled pipeline is considered to be of a lower consequence than from an oil pipeline as the product will disperse into the marine environment quickly. This assessment considers a release from an oil pipeline as the worst case.
</td></tr>
<tr><td>Determine characteristics of the discharge scenario (including calculation of potential spill volumes)</td><td>
A spill from a pipeline could happen at any location. In order to understand potential impacts to sensitive shoreline receptors, for the purposes of this worst case discharge scenario, it is assumed that the discharge occurs close to shore (at 3NM). Loss of containment at a pipeline riser on a platform would be further from shore than 3NM (as the closet platform is 23km (~12NM) from shore.
A pipeline discharge scenario could happen subsea but could also happen at surface where the pipeline reaches the platform (via a riser).
Loss of containment from a pipeline could occur due to a variety of mechanisms with volumes released highly dependent on the size of the hole.
Pinhole leak: Generally pinhole leaks release at a low rate. Release time can vary dependent on when the leak is identified and how it is repaired. Volumes of pinhole leaks have been estimated at up to 10kL
Minor hole (1 – 3 mm): Leaks from a minor hole are highly dependent on the size of the hole. The volume of release from a minor leak with a hole up to 3mm is approximately 400kL.
Full Rupture: Full rupture of a pipeline assumes a large hole and partial loss of contents from the pipeline up to a point of isolation. Taking into account distance between isolation points and diameter of the pipeline, the largest volume of oil pipelines is:

HLA – Shore: 20,300 kL
WKF – HLA: 5,500 kL
BMA – WKF: 3,600 kL

This release scenario does not assume loss full loss of inventory due to emergency de-pressuring of the pipeline and reaching subsea pressure equilibrium.
</td></tr>
<tr><td>Determine likelihood of the</td><td>Accidental release due to a pipeline pinhole leak has occurred within Esso Bass Strait Operations in the past 10 years. This scenario is considered likely (classified as likelihood A).</td></tr>
</table>

Process	Description
discharge scenario	Minor hole has not occurred within Esso Bass Strait Operations in the past 10 years but has occurred within the industry. This scenario is considered very unlikely (classified as likelihood D). A rupture of a pipeline has never occurred within Esso Bass Strait Operations and is not a common occurrence in the industry. It is considered very highly unlikely (classified as likelihood E).
Selection of worst case scenario	Although the likelihood of a pipeline leak is high, a preliminary assessment of impacts from a spill of this volume suggest it would have minor environmental impacts. Despite the very highly unlikely likelihood of occurrence, the impacts from a rupture would be considerably greater. Hence, the worst case pipeline scenario has been determined to be a rupture of the pipeline with the largest volume of oil, at a location close to shore.

The WCS scenario for the loss of hydrocarbon is a pipeline rupture resulting in the partial loss of inventory of the pipeline based on the following:

- A worst-case credible release duration of 12 hours.
- A release location at the Halibut to shore (HLA-VS1 600) pipeline, at a distance 3 nm from the shore.
- A subsea release in 40 m water depth.
- 18,980 kL of a representative light crude released.
    - As described in Table 7-15, the HLA pipeline is fed by a variety of different crudes. The composition of this pipeline could change on any given day dependent on which platforms are producing. Proportions or gas, oil and water can vary.
    - Given the varied composition of the HLA pipeline, a representative crude has been chosen.
        - CBA is expected to be the facility producing the highest volumes of crude over the next 5 years.
        - HLA crude has been chosen for modelling as the CBA facility produces from the HLA reservoir. See Appendix A for further details of Gippsland oil types.

Modelling of the release scenario indicated that 50% of the pipeline contents would be released in 24 hours before the pressure of the pipeline reaches equilibrium with the pressure of seawater at 40m depth. Modelling suggests that the release rate would reach zero however, in reality, small amounts of oil may be discharged as sea state interacts with the hole in the pipeline. These discharges would be intermittent and dependent on sea state.

For the purposes of spill trajectory modelling and to assist in informing spill response capability, it has been assumed that the remaining 50% of the volume is released at a constant rate of 106 m^3/day, over a period of 90 days based on the estimated time to repair the pipeline.

Table 7-16 LOC from a pipeline modelling inputs and parameters

Parameter	Details
Number of spill simulations	100
Period of the year (season)	Annual
Release location	HLA600 pipeline, 3NM from Shore
Coordinates (GDA94)	38° 01' 01" S

Parameter	Details			
	147° 44' 59" E			
Water Depth	40 m			
Hydrocarbon Type	Light crude			
Total spill volume	18,980 m^3			
Volume basis	Release volume calculated based on volume of pipeline sections over a total of 74,000m assuming that: Release occurs at the 3NM limit at 40m water depth. Inventory at depths greater than 40m will release, inventory at depths between 0-40m will remain in the pipeline			
Release duration	50% of volume released in 24hrs Remaining volume released at a constant rate over 90 days			
Duration basis	Modelling a starting pressure of 4500kPag and an atmospheric pressure of 400kpa resulted in 50% of the pipeline released in approximately 24hrs before reaching pressure equilibrium with atmospheric. At this point, modelling indicated release rate trending to zero. It has been assumed that the remaining 50% of the volume is released at a constant rate over 90 days, based on the estimated time to repair the pipeline.			
Modelled duration	110 days			
Hydrocarbon Characteristics	Density (@ 15oC)		0.8215 (g/ml)	
	API		40.6	
	Dynamic Viscosity		2.97 (cP) @ 15 ºC	
	Pour Point		0 ºC	
	Oil Property Category		Group II (Light persistent oil)	
Boiling Point (BP) ºC (RPS, 2020)	Volatile < 180 15.18%	Semi-volatile 180 – 265 25.59%	Low volatility 265 – 380 41.61%	Residual > 380 17.62%
Oil proxy justification	CBA 19 was temporarily plugged and not producing at the time of sampling. CBA A19 accesses the same Halibut reservoir as was sampled from the HLA platform.			

7.6.2.2 Modelling Outputs – Weathering and Fate

The properties of the oil used in the modelling of the LOC scenario is shown in Table 7-22. Halibut crude is classified as a Group II oil according to the International Tanker Owners Pollution Federation classifications (ITOPF, 2015).

On release to the marine environment, crude is predicted to be distributed over time into the following components:

- surface;
- water column, including
  - entrained (non-dissolved oil droplets that are physically entrained by wave action);
  - dissolved (principally the aromatic hydrocarbons);
- evaporated;
- stranded on shoreline and
- decayed (microbial biodegradation).

- Of these components, surface hydrocarbons and dissolved aromatics have the greatest impact on receptors.

Figure 7-6 presents the fate and weathering graph for the modelled crude release.

Halibut crude contains 17.6% by mass of hydrocarbon compounds that will not evaporate at atmospheric temperatures. These compounds will persist in the marine environment. The whole oil has a high wax content (approx. 24%), indicating that surface slicks of Halibut crude are likely to form waxy flakes in the environment as it weathers over time. Soluble, aromatic, hydrocarbons contribute approximately 23% by mass of the whole oil. Surface discharge will inhibit the process of dissolution, with compounds tending to evaporate from the water into the atmosphere (RPS, 2020).

Evaporation rates will increase with temperature, but in general, about 15.2% of the oil mass should evaporate within the first 12 hours (BP < 180°C); a further 25.6% should evaporate within the first 24 hours (180°C < BP < 265°C); and a further 41.6% should evaporate over several days (265°C < BP < 380°C).

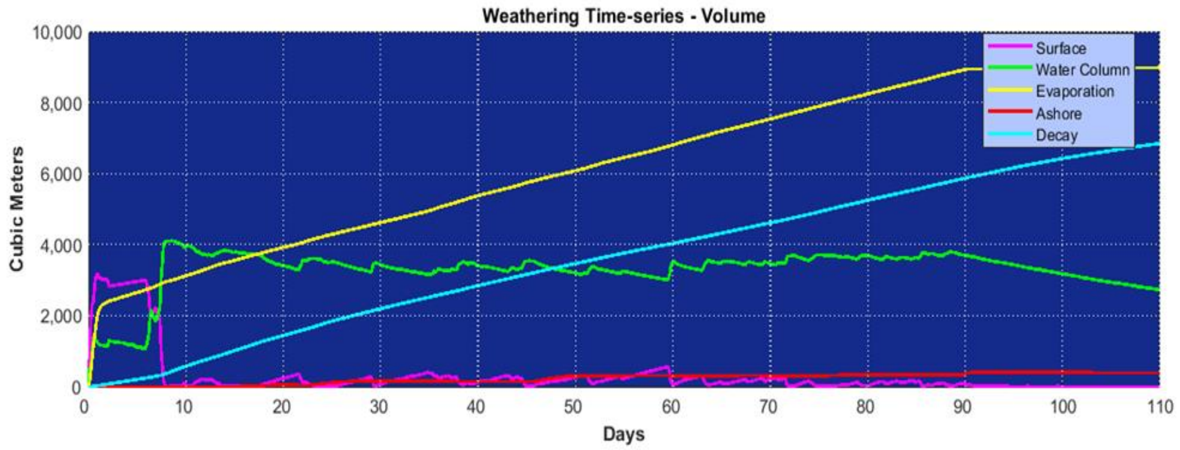

Figure 7-6 Predicted weathering and fates of Halibut crude from modelling the single spill trajectory with the largest area of floating surface oil from a 18980m³ LOC release from the HLA600 pipeline over 90 days, tracked for 110 days.

7.6.2.3 Modelling Outputs – Stochastic

As described in Section 7.2.1.1, oil spill modelling predicts that the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, as a result of any spill. The PEA (refer Section 5.1) is derived from this data and is used for planning purposes to ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the EP.

Modelling is also used to inform specific impact or consequence assessments by understanding the location and extent of oil at different concentrations. There is no agreed exposure level below which environmental impacts will not occur, therefore outputs should not be interpreted as a boundary. However, mapping areas which could be moderately impacted by a spill is a useful tool for impact or consequence assessment.

The environmental sensitivities within the moderate threshold area are described in Table 7-17. The sensitivities outside of the mapped (moderately exposed) area but within the PEA are shown in Table 7-18.

Table 7-17 Environmental sensitivities with potential for moderate hydrocarbon exposure from a LOC from a pipeline

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
Surface exposure	Moderate 10 g/m^2	Maximum distance from the release location was 343 km in a north easterly direction. The zone of moderate exposure overlaps the following BIAs: Birds • Antipodean Albatross – Foraging (5% probability) • Black Petrel – Foraging (2% probability • Black-browed Albatross – Foraging (87% probability) • Buller's Albatross - Foraging (79% probability) • Campbell Albatross –Foraging (87% probability) • Crested Tern – Foraging (2% probability) • Common Diving Petrel – Foraging (100% probability) • Flesh-footed Shearwater – Foraging (2% probability) • Great winged Petrel – Foraging (1% probability) • Indian Yellow-nosed Albatross – Foraging (87% probability) • Shy Albatross – Foraging (100% probability) • Short-tailed Shearwater – Foraging (10% probability) • Sooty Shearwater – Foraging (3% probability) • Wandering Albatross – Foraging (87% probability) • Wedge-tailed Shearwater – Foraging (3% probability) • White-capped Albatross – Foraging (1% probability) • White-faced Storm Petrel – Breeding / Foraging (1% / 18% probability) • Wilsons Storm Petrel – Migration (1% probability) • Little Penguin – Breeding (2% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging (100% probability) • Southern Right Whale – Migration (100% probability) • White Shark – Breeding & Distribution / Foraging (100 / 7% probability) • Grey Nurse Shark – Foraging / Migration (2% probability • Humpback whale – Foraging (3% probability) • Indo-Pacific/Spotted Bottlenose Dolphin – Breeding (2% probability) Upwelling East of Eden has 58% probability of exposure. Contact with Victorian waters is predicted with a probability of 100%, including Ninety Mile Beach and Point Hicks Marine National Parks. Contact with nearshore receptors ranges from 60% probability at Lakes Entrance to 16% at Ocean Grange and <3% at Sydenham Inlet and Seaspray. Contact with Gippsland Lakes Ramsar wetland is predicted with a probability of 29%. Contact with NSW waters is predicted with a probability of 2% including Batemans Marine Park. Contact with the nearshore receptor Eurobodalla is predicted at 2% probability.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
	High 100 g/m^2	Maximum distance from the release location was 7 km in a westerly direction. The zone of high exposure overlaps the following BIAs.(100% probability): Birds • Black-browed Albatross (57%) • Buller's Albatross (55%) • Campbell Albatross (57%) • Common Diving-Petrel • Indian Yellow-nosed Albatross (57%) • Shy Albatross • Wandering Albatross (57%) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark – Breeding & Distribution Upwelling East of Eden has 10% probability of exposure. Contact with Victorian waters is predicted with a probability of 100%. Contact with nearshore receptors ranges from 33% probability at Lakes Entrance to 6% at Ocean Grange and 1% at Seaspray. Although no Marine Parks are predicted to be contacted, contact with Gippsland Lakes Ramsar wetland is predicted with a probability of 2%.
Shoreline Exposure	Moderate 100 g/m^2	Shoreline contact at the moderate exposure threshold is predicted from Woodside Beach to Batemans Bay (NSW), with probabilities ranging from 1-2% at the outer edge of the contact zone to 100% in the Lakes Entrance / Ocean Grange area. Note: several National Parks and Reserves lie along this coastline including Gippsland Lakes, Lake Tyers, Cape Conran, Marlo, Croajingolong, Nadgee, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla. The minimum time before shoreline accumulation at the moderate threshold is approximately 6 hours (at Lakes Entrance). The maximum length of shoreline exposed is 115 km (average 49 km).
	High 1000 g/m^2	Shoreline contact at the high exposure threshold is most likely to occur in the Lakes Entrance / Ocean Grange area with a predicted probability of up to 92%. Probabilities range from 5 – 7% at the outer edge of the contact zone at Golden Beach and Lake Tyers Beach. The minimum time before shoreline accumulation at the high threshold is approximately 9 hours (at Lakes Entrance). The maximum length of shoreline exposed is 39 km (average 19 km).
In-water (dissolved) Exposure	Moderate 50ppb instantaneous	0-10m water depth The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to Victorian coastal receptors was 92% for East Gippsland, 32% for Wellington Shire (Ninety Mile Beach) and 20% for Gabo Island. Marine National Parks Cape Howe, Ninety Mile Beach and Point Hicks and Beware Reef Marine Sanctuary were also predicted to be contacted with probabilities between 8% and 92%. Gippsland Lakes Ramsar wetland was predicted to be exposed with a probability of 38%. For NSW probabilities were 13% for southern NSW (Bega Valley), 3% for Eurobodalla and Montague Island and 2% for Shoal Haven. Batemans Marine Park was also predicted to be contacted with a probability of 4%.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		For the Tasmanian islands in Bass Strait the probabilities were 3% for Hogan Island Group, 1% for Curtis Island and 1% for the waters of the Kent Group National Park. The KEF: Upwelling East of Eden was predicted to be exposed to in-water dissolved hydrocarbons (above the moderate threshold) with a probability of 92%. KEF Shelf rocky reefs was also predicted to be exposed with a probability of 4%. AMPs Beagle, East Gippsland, Flinders, Freycinet, Lord Howe and Central Eastern were predicted to be exposed at between 3 and 1% likelihood. Additionally, several BIAs were predicted to be exposed at the low threshold within the 0-10 m surface layer: Birds • Antipodean Albatross – Foraging (64% probability) • Back Noddy – Foraging (1% probability • Black Petrel – Foraging (5% probability) • Black-browed Albatross – Foraging (72% probability) • Black-winged Petrel – Foraging (1% probability) • Buller's Albatross - Foraging (65% probability) • Campbell Albatross –Foraging (72% probability) • Common Noddy – Breeding / Foraging (1% probability) • Crested Tern – Breeding / Foraging (4% probability) • Common Diving-Petrel - Foraging (82% probability) • Flesh-footed Shearwater – Foraging (5% probability) • Great-winged Petrel – Foraging (2% probability) • Indian Yellow-nosed Albatross – Foraging (72% probability) • Shy Albatross – Foraging (92% probability) • Wandering Albatross – Foraging (72% probability) • Wedge-tailed Shearwater – Foraging (24% probability) • White-capped Albatross – Foraging (2% probability) • White-faced Storm Petrel – Breeding / Foraging (8% / 92% probability) • Wilsons Storm Petrel – Migration (2% probability) • Little Penguin – Breeding / Foraging (4% / 24% probability) • Northern Giant petrel – Foraging (2% probability) • Short tailed Shearwater – Foraging (17% probability) • Sooty Shearwater – Foraging (16% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging (92% probability) • Southern Right Whale – Migration (92% probability) • White Shark –Distribution & Foraging (92% probability) • Grey Nurse Shark – Foraging / Migration (17% probability • Humpback whale – Foraging (17% probability) • Indo-pacific/Spotted Bottlenose Dolphin – Breeding (18% probability)

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		10-20m water depth The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to Victorian coastal receptors was 39% for East Gippsland, 15% for Wellington Shire (Ninety Mile Beach) and 12% for Gabo Island. Marine National parks Cape Howe, Ninety Mile Beach and Point Hicks and Beware Reef Marine Sanctuary were also predicted to be contacted with probabilities between 8% and 92%. Gippsland Lakes Ramsar wetland was predicted to be contacted with a probability of 21%. For NSW probabilities were 7% for southern NSW (Bega Valley), 4% for Eurobodalla and Montague Island and 2% for Shoal Haven. Batemans and Jervis Bay Marine Parks were also predicted to be contacted with a probability of 4% and 1% respectively. The KEF: Upwelling East of Eden was predicted to be exposed to in-water dissolved hydrocarbons (above the moderate threshold) with a probability of 41%., KEFs Shelf rocky reefs (2%) and Canyons on the eastern continental shelf and Tasman front and eddy field (both1%) were also predicted to be exposed. AMPs East Gippsland, Beagle, Flinders and Jervis were predicted to be exposed at between 2 and 1% likelihood. Additionally, several BIAs were predicted to be exposed at the low threshold within the 10-20m water column layer: Birds • Antipodean Albatross – Foraging (27% probability) • Black petrel – Foraging (4% probability) • Black-browed Albatross – Foraging (31% probability) • Buller's Albatross - Foraging (29% probability) • Campbell Albatross –Foraging (31% probability) • Crested Tern – Breeding / Foraging (4% probability) • Common Diving-Petrel – Foraging (35% probability) • Flesh-footed Shearwater – Foraging 4% probability) • Great-winged Petrel – Foraging (1% probability) • Indian Yellow-nosed Albatross – Foraging (31% probability) • Shy Albatross – Foraging (41% probability) • Wandering Albatross – Foraging (31% probability) • Wedge-tailed Shearwater – Foraging (13% probability) • White-capped Albatross – Foraging (1% probability) • White-faced Storm Petrel – Breeding / Foraging (6% / 41% probability) • Wilsons Storm Petrel – Migration (1% probability) • Little Penguin – Breeding / Foraging (4% / 13% probability) • Northern Giant petrel – Foraging (1% probability) • Short tailed Shearwater – Foraging (10% probability) • Sooty Shearwater – Foraging (8% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging (41% probability) • Southern Right Whale – Migration (41% probability) • White Shark –Breeding / Distribution & Foraging (31% / 41% probability)

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		• Grey Nurse Shark – Foraging / Migration (7% probability • Humpback whale – Foraging / Migration (11% / 1% probability) • Indo-pacific/Spotted Bottlenose Dolphin – Breeding (9% probability) 20-30m water depth For this water depth the pattern of contact was very similar but with considerably reduced likelihoods. Contact with coastal receptors and Marine Parks in Victoria was predicted at less than 5% probability and in NSW less than 2%. The highest likelihood of contact with any BIA was 8% for several seabird foraging BIAs.

Table 7-18 Environmental sensitivities outside of the moderately exposed area but within the PEA from a LOC from a pipeline

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
Surface Exposure	Low 1 g/m^2	Maximum distance from the release location was 1331 km in an ENE direction. The zone of low exposure overlaps the following BIAs: Birds • Antipodean Albatross – Foraging (5% probability) • Black Petrel – Foraging (2% probability • Black-browed Albatross – Foraging (87% probability) • Buller's Albatross - Foraging (79% probability) • Campbell Albatross –Foraging (87% probability) • Crested Tern – Foraging (2% probability) • Common Diving-Petrel – Foraging (100% probability) • Flesh-footed Shearwater – Foraging (2% probability) • Great winged Petrel – Foraging (1% probability) • Indian Yellow-nosed Albatross – Foraging (87% probability) • Shy Albatross - Foraging (100% probability) • Short-tailed Shearwater – Foraging (10% probability) • Sooty Shearwater – Foraging (3% probability) • Wandering Albatross – Foraging (87% probability) • Wedge-tailed Shearwater – Foraging (3% probability) • White-capped Albatross – Foraging (1% probability) • White-faced Storm Petrel – Foraging (18% probability) • Wilsons Storm Petrel – Migration (1% probability) • Little Penguin – Breeding (2% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging (100% probability) • Southern Right Whale – Migration (100% probability) • White Shark – Breeding & Distribution / Foraging (100% / 7% probability)

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		• Grey Nurse Shark – Foraging / Migration (2% probability • Humpback whale – Foraging (3% probability) • Indo-Pacific/Spotted Bottlenose Dolphin – Breeding (2% probability) Upwelling East of Eden has 58% probability of exposure. Contact with Victorian waters is predicted with a probability of 100%, including Ninety Mile Beach and Point Hicks Marine National Parks. Contact with nearshore receptors ranges from 60% probability at Lakes Entrance to 16% at Ocean Grange and <3% at Sydenham Inlet and Seaspray. Contact with Gippsland Lakes Ramsar wetland is predicted with a probability of 29%. Contact with NSW waters is predicted with a probability of 2% including Batemans Marine Park. Contact with the nearshore receptor Eurobodalla is predicted at 2% probability.
Shoreline Exposure	Low 10g/m^2	Shoreline contact at the low exposure threshold is predicted from Woodside Beach to Batemans Bay (NSW), with probabilities ranging from 3% at the outer edge of the contact zone to 100% in the Lakes Entrance / Ocean Grange area. Note: several National Parks and Reserves lie along this coastline including Gippsland Lakes, Lake Tyers, Cape Conran, Marlo, Croajingolong, Nadgee, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla. The minimum time before shoreline accumulation at the low threshold is approximately 6 hours (at Lakes Entrance). The maximum length of shoreline exposed is 160 km (average 82 km).
In-water (dissolved) Exposure	Low 10ppb instantaneous	0-10m water depth The probability of in-water dissolved hydrocarbon exposure at the low threshold to Victorian nearshore receptors was 100% for East Gippsland, 73% for Wellington Shire (Ninety Mile Beach) and 78% for Gabo Island. Marine National Parks Cape Howe, Ninety Mile Beach, Wilsons Promontory and Point Hicks and Beware Reef Marine Sanctuary were also predicted to be contacted with probabilities up to 100%. Gippsland Lakes Ramsar wetland was predicted to be contacted at 89%. For NSW probabilities were 71% for southern NSW (Bega Valley), 17% Montague Island, 11% for Eurobodalla, 7% for Shoal Haven and 1-2% for Kiama, Sutherland Shire, Wollongong, Waverly, Woollahra and Lord Howe Island. Batemans, Jervis Bay and Lord Howe Island Marine Parks were also predicted to be contacted with probabilities up to 21%. For the Tasmanian islands in Bass Strait the probabilities were 6% for Hogan Island Group, 2% for Curtis Island and the waters of the Kent Group National Park and 1% for Moncoeur Islands. The KEF: Upwelling East of Eden was predicted to be exposed to in-water dissolved hydrocarbons (above the low threshold) with a probability of 100%., KEFs Shelf rocky reefs (21%), Canyons on the eastern continental shelf (14%), Lord Howe Seamount Chain, Tasmantid seamount chain, Seamounts south and east of Tasmania and Tasman front and eddy field (1-3%) were also predicted to be exposed. AMPs East Gippsland (17%), Beagle (8%), Flinders (5%) and Freycinet, Jervis, Lord Howe and Central Eastern (between 1 – 3%). Additionally, several BIAs were predicted to be exposed at the low threshold within the 0-10 m surface layer: Birds • Antipodean Albatross – Foraging (100% probability) • Back Noddy – Breeding / Foraging (1% probability • Black Petrel – Foraging (25% probability)

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		• Black-browed Albatross – Foraging (100% probability) • Black-winged Petrel – Breeding / Foraging (1% probability) • Buller's Albatross - Foraging (99% probability) • Campbell Albatross –Foraging (100% probability) • Common Noddy – Breeding / Foraging (1% probability) • Crested Tern – Breeding / Foraging (21% probability) • Common Diving-Petrel – Foraging (100% probability) • Flesh-footed Shearwater – Breeding / Foraging (1% / 25% probability) • Great-winged Petrel – Foraging (21% probability) • Indian Yellow-nosed Albatross – Foraging (100% probability) • Shy Albatross Petrel – Foraging (100% probability) • Wandering Albatross – Foraging (100% probability) • Wedge-tailed Shearwater – Breeding / Foraging (1% / 82% probability) • White-bellied Storm Petrel – Breeding / Foraging (1% probability) • White-capped Albatross – Foraging (21% probability) • White-faced Storm Petrel – Breeding / Foraging (37% / 100% probability) • Wilsons Storm Petrel – Migration (21% probability) • Kermadec Petrel – Foraging (1% probability) • Grey ternlet – Breeding / Foraging (1% probability) • Little Penguin – Breeding / Foraging (21% / 82% probability) • Little Shearwater – Breeding / Foraging (1% probability) • Masked Booby – Breeding / Foraging (1% probability) • Northern Giant petrel – Foraging (21% probability) • Providence Petrel – Breeding / Foraging (1% probability) • Red-tailed Tropicbird – Breeding / Foraging (1% probability) • Short tailed Shearwater – Foraging (61% probability) • Sooty Shearwater – Foraging (50% probability) • Sooty Tern – Foraging (1% probability) • Southern Giant Petrel – Foraging (21% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging (100% probability) • Southern Right Whale – Migration (100% probability) • White Shark – Breeding, Distribution & Foraging (100% probability) • Grey Nurse Shark – Foraging / Migration (58% / 54% probability • Humpback whale – Foraging / Migration (75% / 3% probability) • Indo-pacific/Spotted Bottlenose Dolphin – Breeding (77% probability) • 10-20m water depth The probability of in-water dissolved hydrocarbon exposure at the low threshold to Victorian nearshore receptors was 93% for East Gippsland, 57% for

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		Wellington Shire (Ninety Mile Beach) and 63% for Gabo Island. Marine National Parks Cape Howe, Ninety Mile Beach, Wilsons Promontory and Point Hicks and Beware Reef Marine Sanctuary were also predicted to be contacted with probabilities up to 92%. Gippsland Lakes Ramsar wetland was predicted to be contacted at 89%. For NSW probabilities were 40% for southern NSW (Bega Valley), 11% Montague Island, 9% for Eurobodalla, 5% for Shoal Haven and 1-2% for Kiama, Wollongong and Lord Howe Island. Batemans, Jervis Bay and Lord Howe Island Marine Parks were also predicted to be contacted with probabilities up to 15%. For the Tasmanian islands in Bass Strait the probabilities were 5% for Hogan Island Group, 2% for the Kent Group National Park and 1% for Moncoeur Islands, Rodondo Island and Curtis Island. The KEF: Upwelling East of Eden was predicted to be exposed to in-water dissolved hydrocarbons (above the low threshold) with a probability of 94%., KEFs Shelf rocky reefs (13%), Canyons on the eastern continental shelf (8%), Lord Howe Seamount Chain, Tasmantid seamount chain, Seamounts south and east of Tasmania and Tasman front and eddy field (1-2%) were also predicted to be exposed. AMPs East Gippsland (8%), Beagle (7%), Flinders (3%), Jervis and Freycinet, Lord Howe and Central Eastern (each 2%). Additionally, several BIAs were predicted to be exposed at the low threshold within the 10-20m water column layer: <u>Birds</u> • Antipodean Albatross – Foraging (87% probability) • Back Noddy – Breeding / Foraging (1% probability • Black Petrel – Foraging (18% probability) • Black-browed Albatross – Foraging (87% probability) • Black-winged Petrel – Breeding / Foraging (1% probability) • Buller's Albatross - Foraging (78% probability) • Campbell Albatross –Foraging (87% probability) • Common Noddy – Breeding / Foraging (1% probability) • Crested Tern – Breeding / Foraging (15% / 18% probability) • Common Diving-Petrel – Foraging (94% probability) • Flesh-footed Shearwater – Breeding / Foraging (1% / 18% probability) • Great-winged Petrel – Foraging (12% probability) • Indian Yellow-nosed Albatross – Foraging (87% probability) • Shy Albatross – Foraging (94% probability) • Wandering Albatross – Foraging (87% probability) • Wedge-tailed Shearwater – Breeding / Foraging (1% / 67% probability) • White-bellied Storm Petrel – Breeding / Foraging (1% probability)

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		• White-capped Albatross – Foraging (12% probability) • White-faced Storm Petrel – Breeding / Foraging (27% / 94% probability) • Wilsons Storm Petrel – Migration (12% probability) • Kermadec Petrel – Foraging (1% probability) • Grey ternlet – Breeding / Foraging (1% probability) • Little Penguin – Breeding / Foraging (17% / 67% probability) • Little Shearwater – Breeding / Foraging (1% probability) • Masked Booby – Breeding / Foraging (1% probability) • Northern Giant petrel – Foraging (12% probability) • Providence Petrel – Breeding / Foraging (1% probability) • Red-tailed Tropicbird – Breeding / Foraging (1% probability) • Short tailed Shearwater – Foraging (43% probability) • Sooty Shearwater – Foraging (34% probability) • Sooty Tern – Foraging (1% probability) • Southern Giant Petrel – Foraging (12% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging (94% probability) • Southern Right Whale – Migration (94% probability) • White Shark – Breeding / Distribution & Foraging (85% / 92% probability) • Grey Nurse Shark – Foraging / Migration (41% / 37% probability • Humpback whale – Foraging / Migration (48% / 2% probability) • Indo-pacific/Spotted Bottlenose Dolphin – Breeding (46% probability) 20-30m water depth For this water depth the pattern of contact was very similar but with considerably reduced likelihoods. Contact with coastal receptors and Marine Parks in Victoria was predicted at less than 15% probability and in NSW less than 10%. The highest likelihood of contact with any BIA was 30% for Pygmy Blue Whale distribution/foraging, Southern Right Whale migration, White Shark distribution/foraging and several seabird foraging BIAs.
In-water (entrained) Exposure	Low 10ppb instantaneous	0-10m water depth At the surface layer (0-10 m), the probability of low exposure to the KEF Upwelling East of Eden, and Cape Conran, Point Hicks, Cape Howe / Mallacoota, Croajingolong, Corringle, Lake Tyers Beach, Lakes Entrance, Marlo and Sydenham Inlet nearshore receptors was 100%. Contact with NSW waters was also predicted with 100% probability, including the nearshore receptors of Bega valley (southern NSW) and Eurobodalla. Contact with Tasmanian and Queensland waters was predicted with likelihoods of 26% and 1% respectively. Additionally, several BIAs were predicted to be exposed at the low threshold with probabilities of 100%: Indo-Pacific/Spotted Bottlenose Dolphin – breeding, Humpback whale – foraging, Grey nurse shark – foraging/migration, Little penguin – foraging, Pygmy blue whale – distribution and foraging, Southern right

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		whale – migration, White shark – breeding, foraging and distribution as well as several seabird foraging BIAs. Marine National Parks • Bunurong 3% • Cape Howe 100% • Corner Inlet 5% • Ninety Mile Beach 53% • Point Hicks 100% • Marine Parks • Wilsons Promontory 10% • Batemans 81% • Great Sandy 1% • Jervis Bay 44% • Lord Howe Island 12% • Moreton Bay 1% • Port Stephens - Great Lakes 7% • Solitary Islands 2% • Marine Sanctuaries • Beware Reef 100% Marine Parks and Reserves • Kent Group 21% • Booderee 33% • Corner Inlet Marine and Coastal Park 6% • Nooramunga Marine and Coastal Park 6% • Shallow Inlet Marine and Coastal Park 6% • Wilsons Promontory Marine Park 12% • Wilsons Promontory Marine Reserve 7% • Ramsar wetlands • Corner Inlet 7% • East Coast Cape Barren Island Lagoons 4% • Elizabeth and Middleton Reefs Marine National Nature Reserve 6% • Gippsland Lakes 100% • Hunter Estuary Wetlands 1% • Logan Lagoon 3% Contact with the AMPS East Gippsland (99%), Jervis (61%), Flinders (41%), Beagle (29%), Central Eastern (24%), Freycinet (18%), Hunter (10%), Apollo (5%) and Coral Sea, Gifford, Huon, Norfolk, Solitary Islands and South Tasman Rise (each 1-2%). 10-20m water depth

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)
		At the 10-20m layer the probability of low exposure to the KEF Upwelling East of Eden was 100%. Additionally, several BIAs were predicted to be exposed at the low threshold with probabilities of 100%: Indo-Pacific/Spotted Bottlenose Dolphin – breeding, Humpback whale – foraging, Grey nurse shark – foraging/migration, Little penguin – foraging, Pygmy blue whale – distribution and foraging, Southern right whale – migration, White shark – breeding, foraging and distribution as well as several seabird foraging BIAs. Contact with Victorian waters was predicted at 100% likelihood, the highest predicted likelihoods for nearshore receptors were 98% at East Gippsland and 76% at Gabo Island. Contact with NSW and Tasmanian waters was predicted with likelihoods of 66% and 9% respectively. <u>20-30m water depth</u> At this water depth the exposure pattern was very similar to that of the layers above but with reduced likelihoods. The highest likelihood of contact with any BIA was 92% for Pygmy Blue Whale distribution/foraging, Southern Right Whale migration, White Shark breeding/distribution and several seabird foraging BIAs.

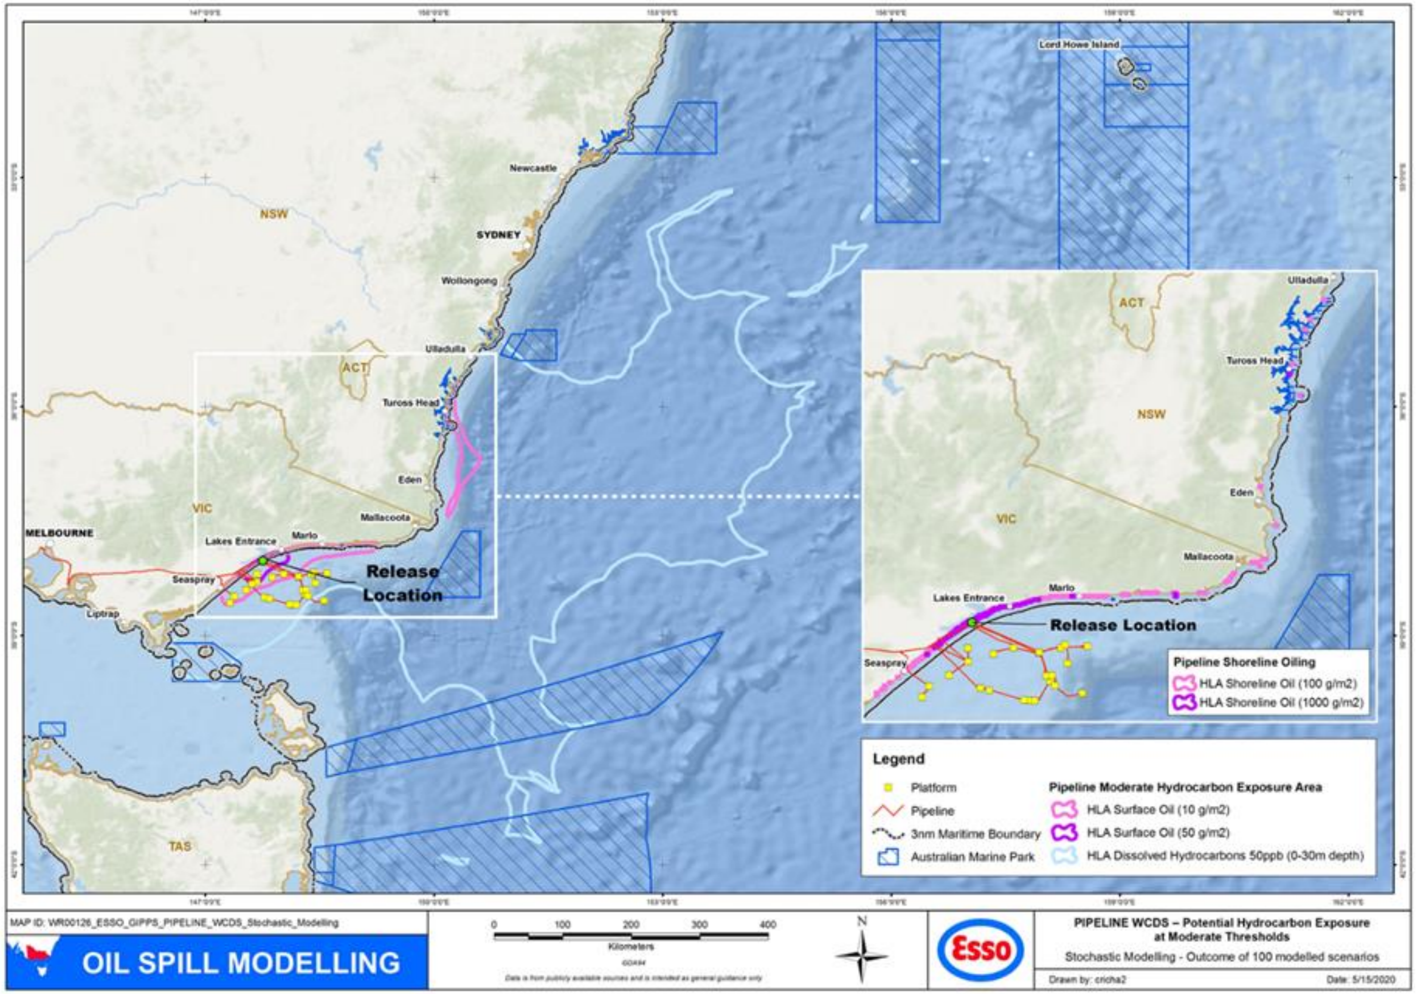

Figure 7-7 LOC stochastic modelling output for Pipeline WCDS. Hydrocarbon exposure at the moderate thresholds (Surface: 10 g/m^2, shoreline: 100 g/m^2, and In-water (dissolved): 50 ppb instantaneous)

7.6.3 Risk Assessment

An accidental release of reservoir hydrocarbons as a result from a loss of containment from a pipeline has the potential to result in the following impacts:

- Change in water quality;
- Change in habitat.

As a result of change in water quality and / or habitat, further impacts may occur which include:

- Injury / mortality to fauna;
- Change to the function, interests or activities of other users.

Receptors that could be affected by a loss of containment from a pipeline are identified in Table 7-19.

Table 7-19 Receptors potentially impacted by a LOC from a pipeline

7.6.3.1 Consequence Evaluation

Consequence evaluation of potentially exposed receptors in the event of a LOC from a pipeline are described in Table 7-20.

Table 7-20 Risk of surface, shoreline and in-water hydrocarbon exposure from loss of containment from a pipeline

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
Water quality	A release of reservoir hydrocarbons resulting from a pipeline LOC has the potential to result in a change i.e. decline in water quality. Degraded water quality will potentially impact all the receptors identified in Table 7-19. These impacts are discussed individually within other sections.	Modelling predicts that surface, shoreline and in-water (dissolved) exposure will occur as a result of a LOC. Figure 7-7, show the extent of potential impacts to water quality (at moderate thresholds). Due to the potentially persistent nature of the hydrocarbon and the potential area of impact, the consequences to water quality are assessed as **Level III.**
Benthic Habitats – Bare Substrate, Coral, Seagrass, Macroalgae, Subtidal Rocky Reef	**Bare Substrate** While this receptor represents the 'bare sand' areas offshore, it does provide habitat for benthic invertebrates (both infauna and macroinvertebrates). Unconsolidated mixed and particulate sediments are likely to be dominated by burrowing fauna (e.g. annelid worms, molluscs, echinoderms, crustaceans, cnidarians). Many of the organisms that live in these habitats are habitat modifiers (e.g. through burrows or shell production), stabilising and/or oxygenating the sediments around them, and providing additional ecological niches for colonisation by other fauna – increasing local biodiversity. Surveys undertaken after the Montara blowout found no obvious visual signs of major disturbance at Barracouta and Vulcan shoals (Heyward *et al.,* 2010), which occur about 20-30 m below the water line in otherwise deep waters (generally >150 m water depth). Later sampling indicated the presence of low-level severely degraded oil at some shoals, though in the absence of pre-impact data, this could not be directly linked to the Montara spill. Levels of hydrocarbons in the sediments were, in any case, several orders of magnitude lower than levels at which biological effects become possible (Heyward *et al.,* 2012; Gagnon & Rawson, 2011). Studies undertaken since the DWH incident have shown that fewer than 2% of the more than 8,000 sediment samples collected exceeded the US EPA sediment toxicity benchmark for aquatic life, and these were largely limited to the area close to the wellhead (BP, 2015). Acute or chronic exposure through contact and/or digestion can result in toxicological risks to invertebrates. However, the presence of an	Exposure to in-water hydrocarbons is restricted to 30m below the surface and therefore any potential impact to benthic habitats from in-water hydrocarbons will only occur in shallower nearshore waters. The zone of moderate exposure to dissolved hydrocarbons is predicted to extend into nearshore Tasmanian (i.e. Bass Strait islands), Victorian and southern NSW waters. The predominant benthic habitat in the Gippsland Basin is bare substrate. However, known areas of seagrass which may be exposed include at Lakes Entrance, Bemm River Estuary and Tamboon Inlet and numerous estuaries and inlets along the southern NSW coast. There is the potential that exposure could result in sub-lethal impacts, more so than lethal impacts, possibly because much of seagrasses' biomass is underground in their rhizomes (Zieman *et al*., 1984). Seagrass in this region is not considered a significant food source for marine fauna. Suitable hard substrate for macroalgal beds including the threatened 'Giant Kelp' (*Macrocystis pyrifera)* occur in areas such as around Gabo Island and within the Bemm River Estuary. Little is known about the effects of oil on *M. pyrifera,* but some studies (e.g. Edgar & Barrett 2000; Reed & Lewis 1994) suggest that this species, like other macroalgae, may be some of the least sensitive marine species to oil exposure. As described opposite, intertidal species of macroalgae are more prone to direct exposure than subtidal beds, however sub-lethal toxicity effects from in-water (dissolved) hydrocarbons may be observed. Corals are not a common habitat type in the Gippsland Basin however solitary soft corals may occur where suitable hard substrate, such as rocky reef or man-made structures, is present. Sub-lethal toxicity effects may result from direct contact with

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	exoskeleton (e.g. crustaceans) reduces the impact of hydrocarbon absorption through the surface membrane. Invertebrates with no exoskeleton and larval forms may be more prone to impacts. Exposure can induce changes in burrowing depth into the substrate (which can lead to higher predation rates on some species) and can limit the growth, recruitment and reproductive capacity of some marine invertebrates (Fukuyama et al,. 1998). Deep water benthic invertebrates are usually protected from oiling by the buoyant nature of hydrocarbons, although the depth of oil penetration is dependent on turbulence in the water column. Hydrocarbons can also reach the benthos through the settlement of oiled particles such as faeces, dead plankton or inorganic sand particles (Jewett *et al*., 1999). **Coral** Corals are generally located in shallow and intertidal regions, where there is the potential for exposure to surface and in-water hydrocarbons. Experimental studies and field observations indicate all coral species are sensitive to the effects of oil, although there are considerable differences in the degree of tolerance between species. Differences in sensitivities may be due to the ease with which oil adheres to the coral structures, the degree of mucous production and self cleaning, or simply different physiological tolerances. Direct contact of coral by hydrocarbons may impair respiration and also photosynthesis by symbiotic zooanthellae (IPIECA, 1992). Coral gametes or larvae in the surface layer where they are exposed to the slick may also be fouled (Epstein *et al.,* 2000). Physical oiling of coral tissue can cause a decline in metabolic rate and may cause varying degrees of tissue decomposition and death (Negri and Heyward, 2000). Oil may also cling to certain types of sediment causing oil to sink to the seafloor, covering corals in oiled sediment. Where corals come into direct contact with surface exposures (i.e., intertidal/shallow areas), they are more susceptible due to physical presence, than toxicity associated with dissolved oil components within the water column which, in some cases, may be more toxic than the floating surface slicks (Volkman *et al*., 1994). A range of impacts is	in-water hydrocarbons or indirectly through feeding on contaminated prey (plankton). Benthic species which come into direct contact with hydrocarbons in the immediate vicinity of the release location may be affected, however their habitat is widespread throughout Bass Strait and population level impacts are not anticipated. The benthic habitat of the OA (described in detail in Section 5.2.1.1) is predominantly featureless muddy, gravelly sand and no areas of rocky reef have been observed. Recent studies have shown that infaunal taxa are similar across the Bass Strait but the contribution of each to the assemblage varies Where hard substrate or points of attachment (facilities) are present, colonisation by epifauna occurs mostly in the form of sessile, invertebrate, filter feeders. The degree of colonisation varies between facilities however sponge beds have only been detected at Bream B. Benthic invertebrate species closer to shore may also be affected, although these effects will be localised and temporary. Invertebrates of value (i.e. target species, see Commercial Fisheries below) have been identified to include squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone). Filter-feeding, sessile benthic invertebrates such as sponges, bryozoans, scallops, abalone and hydroids may be exposed to sub-lethal impacts however population level impacts are considered unlikely. The consequence of a LOC on benthic habitats is assessed as **Level II.**

Effect Dimensions		Sensitivity Dimensions	
Duration	M	Irreplaceability	M-H
Size/Scale	M	Vulnerability	M
Intensity	M	Influence	M
M		M	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	reported to result from toxicity including partial mortality of colonies, reduced growth rates, bleaching and reduced photosynthesis. Laboratory and field studies have demonstrated that branching corals appear to have a higher susceptibility to hydrocarbon exposure than massive corals or corals with large polyps. Chronic effects of oil exposure have been consistently noted in corals and, ultimately, can kill the entire colony. Chronic impacts include histological, biochemical, behavioural, reproductive and developmental effects. Field studies of chronically polluted areas and manipulative studies in which corals are artificially exposed to oil show that some coral species tolerate oil better than other species (NOAA, 2010). Reproductive stages of corals have been found to be more sensitive to oil toxicity. Fertilisation of coral species has been observed to be completely blocked in *Acropora tenuis* at heavy fuel oil concentrations of 150 ppb (Harrison, 1999), with significant reductions in fertilisation of *A.millepora* and *A. valida* at concentrations between 580 and 5800 ppb, in addition to developmental abnormalities and reduced survival of coral larvae at similar concentrations. Lower concentrations of less than 100 ppb crude oil were observed to inhibit larval metamorphosis in *A. millepora* (Negri & Heyward, 2000). Studies undertaken after the Montara incident included diver surveys to assess the status of Ashmore, Cartier and Seringapatam coral reefs. These found that other than a region-wide coral bleaching event caused by thermal stress (i.e., caused by sea water exceeding 32°C), the condition of the reefs was consistent with previous surveys, suggesting that any effects of hydrocarbons reaching these reefs was minor, transitory or sub-lethal and not detectable (Heyward *et al*., 2010). This is despite AMSA observations of surface slicks or sheen nears these shallow reefs during the spill (Heyward *et al*., 2010). Surveys in 2011 indicated that the corals exhibiting bleaching in 2010 had largely survived and recovered (Heyward *et al.,* 2012), indicating that potential exposure to hydrocarbons while in an already stressed state did not have any impact on the healthy recovery of the coral. In addition, surveys undertaken after the Montara blowout on the plateau areas of Barracouta and Vulcan shoals (Heyward *et al.,* 2010), which occur about 20-30 m below the water line in otherwise deep waters	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	(generally >150 m water depth), and contain algae, hard coral and seagrass, found no obvious visual signs of major disturbance. **Macroalgae** Macroalgae are generally limited to growing on intertidal and subtidal rocky substrata in shallow waters to 10 m depth. As such, they may be exposed to subsurface and entrained and dissolved hydrocarbons, however are susceptible to surface hydrocarbon exposure more so in intertidal habitats as opposed to subtidal habitats. Reported toxic responses to oils have included a variety of physiological changes to enzyme systems, photosynthesis, respiration, and nucleic acid synthesis (Lewis & Pryor 2013). Despite the well-established pool of literature on macroalgae exposure to petroleum oils, very few investigations have reported effects on species that are common in Australian waters (Lewis & Pryor 2013). Smothering, fouling and asphyxiation are some of the physical effects that have been documented from oil contamination in marine plants (Blumer, 1971; Cintron *et al.*, 1981). In macroalgae, oil can act as a physical barrier for the diffusion of CO_2 across cell walls (O'Brien & Dixon, 1976). The effect of hydrocarbons however is largely dependent on the degree of direct exposure and how much of the hydrocarbon adheres to algae, which will vary depending on the oils physical state and relative 'stickiness'. The morphological features of macroalgae, such as the presence of a mucilage layer or the presence of fine 'hairs' will influence the amount of hydrocarbon that will adhere to the algae. A review of field studies conducted after spill events by Connell *et al*. (1981) indicated a high degree of variability in the level of impact, but in all instances, the algae appeared to be able to recover rapidly from even very heavy oiling. The rapid recovery of algae was attributed to the fact that for most algae, new growth is produced from near the base of the plant while the distal parts (which would be exposed to the oil contamination) are continually lost. Other studies have indicated that oiled kelp beds had a 90% recovery within 3-4 years of impact, however full recovery to pre-spill diversity may not occur for long periods after the spill (French-McCay, 2004). Intertidal macroalgal beds are more prone to oil spills than subtidal beds because although the mucous coating prevents oil adherence, oil that is trapped in the upper canopy can increase the persistence of the oil,	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	which impacts upon site-attached species. Additionally, when oil sticks to dry fronds on the shore, they can become overweight and break as a result of wave action (IPIECA, 1995). The toxicity of hydrocarbons to macroalgae varies for the different macroalgal life stages, with water-soluble hydrocarbons more toxic to macroalgae (O'Brien and Dixon, 1976). Toxic effect concentrations for hydrocarbons and algae have varied greatly among species and studies, ranging 2 - 10,000,000 ppb (Lewis & Pryor, 2013). The sensitivity of gametes, larva and zygote stages however have all proven more responsive to petroleum oil exposure than adult growth stages (Lewis & Pryor, 2013). Macrophytes, including macroalgae, require light to photosynthesise. So in addition to the potential impacts from direct smothering or exposure to entrained and dissolved hydrocarbons, the presence of entrained hydrocarbon within the water column can affect light qualities and the ability of macrophytes to photosynthesise. Exposure to in-water hydrocarbons poses the greatest threat to sensitive macroalgal assemblages, specifically the Giant Kelp Forests TEC, that grow on rocky reefs from the sea floor ≥8 m below sea level. The largest extent of this TEC is in Tasmanian coastal waters. Substrate on which this TEC may occur is also found in Victoria along the west coast of Wilson's Promontory and from Sydenham Inlet to Gabo Island (DSEWPaC 2012b). . **Seagrass** Seagrasses generally grow in sediments in intertidal and shallow subtidal waters where there is sufficient light, and are common in sheltered coastal areas such as bays, lees of islands and fringing coastal reefs. As such, they may be exposed to both surface and sub-surface hydrocarbons. Submerged vegetation in nearshore areas can be exposed to oil by direct contact (i.e., smothering) and by uptake by rhizomes through contaminated sediments. Exposure also can take place via uptake of hydrocarbons through plant membranes. In addition, seeds may be affected by contact with oil contained within sediments (NRDA, 2012). When seagrass leaves are exposed to petroleum oil, sub-lethal quantities of the soluble fraction can be incorporated into the tissue, causing a reduction in tolerance to other stress factors (Zieman *et al*.,	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	1984). The toxic components of petroleum oils are thought to be the PAH, which are lipophilic and therefore able to pass through lipid membranes and tend to accumulate in the thylakoid membranes of chloroplasts (Ren *et al*., 1994). As such, the susceptibility of seagrasses to hydrocarbon spills will depend largely on distribution. Deeper communities will be protected from oiling under all but the most extreme weather conditions. Shallow seagrasses are more likely to be affected by dispersed oil droplets or, in the case of emergent seagrasses, direct oiling. Theoretically, intertidal seagrass communities would be the most susceptible because the leaves and rhizomes may both be affected. **Subtidal rocky reefs** Nearshore and offshore subtidal reef habitats are dominated by seaweeds, mobile invertebrates and fish. Potential impacts to sensitive receptors related to these reefs discussed in the appropriate sections. It was observed that the release of large quantities of fuel oil during the grounding of the Iron Baron did not substantially affect populations of subtidal reef associated organisms (Edgar & Barrett, 1995)	
Plankton	Plankton are found in nearshore and open waters beneath the surface in the water column. These organisms migrate vertically through the water column to feed in surface waters at night (NRDA, 2012). As they move close to the sea surface it is possible that they may be exposed to floating hydrocarbons but plankton also has the potential to be directly affected by in-water hydrocarbons as a result of toxicity effects. Phytoplankton are typically not sensitive to the impacts of oil, though they do accumulate it rapidly (Hook *et al*., 2016) due to their small size and high surface area to volume ratio. Oil can affect the rate of photosynthesis and inhibit growth in phytoplankton, depending on the concentration range. For example, photosynthesis is stimulated by low concentrations of oil in the water column (10–30 ppb) but becomes progressively inhibited above 50 ppb. Conversely, photosynthesis can be stimulated below 100 ppb for exposure to weathered oil (González *et al*. 2009). In addition, the potential for effects to photosynthesis (i.e. temporary suppression of primary production) from shading caused by continuous surface slicks may have implications for consumers of phytoplankton (Hook *et al.,* 2016), though a prolonged surface coverage over an extensive area would be required. During the DWH oil spill it	Plankton are likely to be exposed to in-water (dissolved) hydrocarbons above the moderate exposure threshold, within a zone (up to approximately 500 km in width) extending parallel to the Gippsland and southern NSW coastline (for up to approximately 500 km from the release location). Plankton are at their highest concentrations below surface waters (e.g. 60 m water depth for phytoplankton during the day) and undertake a vertical migration which would likely reduce their potential for (and duration of) exposure to dissolved hydrocarbons in the surface layer of the water column. The impact to plankton is therefore predicted to be **Level III** with potential effects on the food web recognised.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	was observed that plankton and other surface material were found to be sinking at rates of more than 10 times the normal level. It was hypothesised that the weathered spilled oil catalysed clumping of organic particles (Schrope 2013). It is currently unclear as to whether this effect was caused by the chemical characteristics of the weathered oil, or a bacterial effect. Zooplankton (microscopic animals such as rotifers, copepods and krill that feed on phytoplankton) are vulnerable to hydrocarbons (Hook *et a*l., 2016). Water column organisms that come into contact with oil risk exposure through ingestion, inhalation and dermal contact (NRDA, 2012), which can cause immediate mortality or declines in egg production and hatching rates along with a decline in swimming speeds (Hook *et al*., 2016). Plankton are generally abundant in the upper layers of the water column and is the basis of the marine food web, so an oil spill in any one location is unlikely to have long-lasting impacts on plankton populations at a regional level. Reproduction by survivors or dispersion from unaffected areas (via sea surface currents) is likely to rapidly replenish losses (Abbriano et al. 2011). Plankton have life cycles based on rapid reproduction with levels of high productivity. It is also in the nature of plankton to be dispersive. Oil spill field observations show minimal or transient effects on plankton (Abbriano *et al.* 2011). Once background water quality is re-established, plankton takes weeks to months to recover (ITOPF, 2011). Plankton found in open waters of the exposure zone is expected to be widely represented within waters of the wider Bass Strait region and generally across all waters in the south eastern offshore region, which aids in the re-establishment of communities.	

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td>Fish</td><td>Fish can be exposed to oil through a variety of pathways, including: direct dermal contact (e.g. swimming through oil); ingestion (e.g. directly or via oil-affected prey/foods); and inhalation (e.g. elevated dissolved contaminant concentrations in water passing over the gills). Fish are generally considered vulnerable to oil spills because they inhabit areas coincident with oil exploration and production and those areas that may be subsequently impacted by an oil spill; including coral reefs, seagrasses, nearshore areas, deep offshore areas, pelagic habitats and demersal habitats (Moore & Dwyer, 1974; Gundlach & Hayes, 1978). Of the potential toxicants, monocyclic and polycyclic aromatic hydrocarbons (MAHs and PAHs) are generally regarded as the most toxic to fish.

<u>Surface oil</u>

Since fish and sharks do not generally break the sea surface, the exposure of surface hydrocarbons to fish and shark species are unlikely to occur. Near the sea surface, fish are able to detect and avoid contact with surface slicks meaning fish mortalities rarely occur in the event of a hydrocarbon spill in open waters (Volkman et al., 2004). As a result, wide-ranging pelagic fish of the open ocean generally are not highly susceptible to impacts from surface hydrocarbons. Adult fish kills reported after oil spills occur mainly to shallow water, near-shore benthic species (Volkman et al., 2004). Following the DWH incident, it was suggested that Whale sharks may be vulnerable to oiling of gills if exposed to the oil. The tendency of Whale sharks to feed close to surface waters will increase the likelihood of exposure to surface slicks and elevated hydrocarbon concentrations beneath slicks.

<u>In-water oil</u>

Exposure to hydrocarbons entrained or dissolved in the water column can be toxic to fishes. Studies have shown a range of impacts including changes in abundance, decreased size, inhibited swimming ability, changes to oxygen consumption and respiration, changes to reproduction, immune system responses, DNA damage, visible skin and organ lesions, and increased parasitism. However, many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Pelagic species are also generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due</td><td>The release location is located in open waters however being only 3NM from shore floating oil is predicted to extend into shallower nearshore waters along the Ninety Mile Beach and eastwards towards Sydenham Inlet. Moderate surface exposure is predicted to cover a maximum area of approximately 100 km^2.The zone of moderate exposure to dissolved hydrocarbons is predicted to extend into nearshore Tasmanian (i.e. Bass Strait islands), Victorian and southern NSW waters.

Shallow inshore fish species including various syngnathids (seahorses, pipefish, pipehorses and seadragons) are less likely to be able to move away from surface or in-water oils and therefore may be exposed to elevated levels or for longer periods. Their habitats are typically widespread however any impacts are expected to be local on individual organism levels.

Although pelagic fish species may be exposed to moderate levels of dissolved oil their mobile, transitory characteristics reduce the risk of prolonged exposure. Large-scale population level effects following a LOC on fish species, abundances or assemblage composition would be unlikely due to the wide geographical distribution of many fish in Bass Strait and the potential for rapid re-colonisation, especially in the cases of widely distributed relatively common pelagic species. Deep water demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in upper layers (0 – 30 m) of the water column only.

The zone of moderate exposure to dissolved hydrocarbons may contact the White shark distribution and breeding BIAs and Grey nurse shark foraging and migration BIAs. Pelagic species of shark are at greatest risk of being exposed to oil following a LOC given their wide foraging areas and risks of consuming contaminated prey. White sharks are known to aggregate near Ninety Mile Beach and philopatric characteristics means they may return to the place of birth to breed even if habitats are contaminated. This species is widely distributed and thus unlikely to suffer ecologically important declines in abundance.

The consequences to fish and sharks are assessed as Level II, taking into consideration the potential impacts to threatened species such as the White and Grey nurse sharks.

<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>to their patterns of movement. Demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in surface layers only.

Fish are most vulnerable to hydrocarbon discharges during their embryonic, larval and juvenile life stages. Oil exposure may result in decreased spawning success and abnormal larval development. Impacts on eggs and larvae entrained in the upper water column are not expected to be significant given the temporary period of water quality impairment, and the limited areal extent of the spill. As egg/larvae dispersal is widely distributed in the upper layers of the water column it is expected that current induced drift will rapidly replace any oil affected populations.</td><td><table><tr><td>Intensity</td><td>M</td><td>Influence</td><td>M</td></tr><tr><td colspan="2">M</td><td colspan="2">M - H</td></tr></table></td></tr>
<tr><td>Birds</td><td>Seabirds and shorebirds are sensitive to the impacts of oiling, with their vulnerability arising from the fact that they cross the air-water interface to feed, while their shoreline habitats may also be oiled (Hook et al., 2016). Species that raft together in large flocks on the sea surface are particularly at risk (ITOPF, 2011).

<u>Sea surface oil</u>

Birds foraging at sea have the potential to directly interact with oil on the sea surface some considerable distance from breeding sites in the course of normal foraging activities. Seabird species most at risk include those that readily rest on the sea surface (e.g. shearwaters) and surface plunging species (e.g. terns, boobies). As seabirds are a top order predator, any impact on other marine life (e.g. pelagic fish) may disrupt and limit food supply both for the maintenance of adults and the provisioning of young.

For seabirds, direct contact with hydrocarbons can foul feathers, which may subsequently result in hypothermia due to a reduction in the ability of the bird to thermo-regulate and impair water-proofing. A bird suffering from cold, exhaustion and a loss of buoyancy may also dehydrate, drown or starve (DSEWPAC, 2011). Increased heat loss as a result of a loss of water-proofing results in an increased metabolism of food reserves in the body, which is not countered by a corresponding increase in food intake, may lead to emaciation (DSEWPAC, 2011). The greatest vulnerability in this case occurs when birds are feeding or</td><td>A number of listed threatened and/or migratory seabird species may occur in the area exposed above moderate surface thresholds. Moderate surface exposure is predicted to cover a maximum area of 100km^2. There are foraging BIA's for several species of petrels, shearwater and albatross, however, no breeding BIAs overlap with this exposed area.

Seabirds rafting, resting, diving or feeding at sea have the potential to come into contact with surface oil, ranging from moderate to high exposure, as such, acute or chronic toxicity impacts (death or long-term poor health) to seabirds are possible. Most species tend to forage on their own, though large feeding flocks will gather at rich or passing food sources.

The length of shoreline predicted to be exposed to shoreline loading of hydrocarbons that may have biological impacts to birds is approximately 115 km above the moderate threshold and 40 km above the high threshold. This section of coastline comprises mostly wide sandy beaches that provide nesting habitat for species such as Hooded plovers and terns or rocky islands and headlands that provide habitat for seabird colonies (such as Little penguin, petrels and albatrosses).

The Little penguin is not considered at risk globally, but some colonies are at risk on a regional scale (Cannell et al. 2016). and declines in the status of this species have been reported from Tasmania (Stevenson & Woehler 2007). Oil concentrations at the moderate to high threshold are predicted to accumulate on the shorelines of Gabo Island, which supports the world's largest Little penguin colony, The Skerries and Tasmanian Bass Strait islands such as Curtis Island</td></tr>
</table>

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>resting at the sea surface (Peakall et al., 1987). . In a review of 45 actual marine spills, there was no correlation between the numbers of bird deaths and the volume of the spill (Burger, 1993).

Penguins may be especially vulnerable to an oil spill because they do not fly and therefore spend a high proportion of their time in the water when away from resting and breeding locations and readily lose insulation and buoyancy if their feathers are oiled (Hook et al., 2016). This species also has strong attachment to its natal area (Colombelli-Négrel 2016) and consequently, birds are likely to retain a strong attachment to a site even if the site and adjacent waters are severely contaminated by oil. The Iron Baron vessel spill (325 tonnes of bunker fuel in Tasmania in 1995) is estimated to have resulted in the death of up to 20,000 penguins (Hook et al., 2016).

<u>Shoreline oil</u>

Shorebirds are likely to be exposed to oil when it directly impacts the intertidal zone and onshore due to their feeding habitats. Foraging shorebirds will be at potential risk of both direct impacts through contamination of individual birds (e.g. fouling of feathers) and indirect impacts (e.g. fouling and/or a reduction in prey items) (Clarke, 2010). Birds that are coated in oil can also suffer from damage to external tissues, including skin and eyes, as well as internal tissue irritation in their lungs and stomachs

Breeding birds (both seabirds and shorebirds) may be exposed to oil via direct contact or the contamination of the breeding habitat (e.g. shores of islands) (Clarke, 2010). Bird eggs may subsequently be damaged if an oiled adult sits on the nest. Fresh crude was shown to be more toxic than weathered crude, which had a medial lethal dose of 21.3 mg/egg. Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos.

Toxic effects on birds may result where oil is ingested as the bird attempts to preen its feathers, or via consumption of oil-affected prey. Whether this toxicity ultimately results in mortality will depend on the amount consumed and other factors relating to the health and sensitivity of the particular bird species.

Engelhardt (1983), Clark (1984), Geraci & St Aubin (1988) and Jenssen (1994) indicated that the threshold thickness of oil that could impart a</td><td>potentially impacting local populations. Under certain metocean conditions the zone of moderate surface exposure is predicted to overlap with the Little penguin breeding BIA.

There are many listed threatened and migratory shorebird species likely to occur in the area overlapping the extent of exposed shoreline. In the event of a LOC, these birds are potentially at risk of shoreline exposure. Birds are not likely to be significantly affected by in-water concentrations of hydrocarbons due to their limited exposure time in the water column. Shorebirds foraging in intertidal areas or along the high tide mark and splash zone, or nest in coastal areas particularly close to the high-water mark, are most at risk of exposure effects. Because the zone of moderate in-water exposure extends into nearshore waters foraging shorebirds may be indirectly impacted by the loss of invertebrate prey.

The populations of both seabird and shorebird species have a wide geographic range, meaning that impacts to individuals at one location will not necessarily extend to populations at other un-impacted locations.

Consequently, the potential consequence of risks to seabirds and shorebirds from a LOC are considered to be Level II.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	lethal dose to an individual wildlife species is 10 µm (~10 g/m^2). Scholten *et al*. (1996) indicates that a layer 25 µm thick would be harmful for most birds that contact the slick.	
Marine Reptiles - Turtles	Marine turtles are vulnerable to the effects of oil at all life stages; eggs, hatchlings, juveniles, and adults. Oil exposure affects different turtle life stages in different ways; and each turtle life stage frequents a habitat with varied potential to be impacted during an oil spill. Several aspects of turtle biology and behaviour place them at particular risk, including a lack of avoidance, indiscriminate feeding in convergence zones, and large pre-dive inhalations. Marine turtles can be exposed to oil externally (e.g. swimming through oil slicks) or internally (e.g. swallowing the oil, consuming oil affected prey, or inhaling of volatile oil related compounds). <u>Surface oil</u> Effects of oil on turtles include increased egg mortality and developmental defects; direct mortality due to oiling in hatchlings, juveniles, and adults; and negative impacts to the skin, blood, digestive and immune systems, and salt glands. Oil can enter cavities such as the eyes, nostrils, or mouth; and oil covering their bodies may interfere with breathing because they inhale large volumes of air to dive. Experiments on physiological and clinical pathological effects of hydrocarbons on loggerhead turtles (~15–18 months old) showed that the turtles' major physiological systems were adversely affected by both chronic and acute exposures (96 hour exposure to a 0.05 cm layer of South Louisiana crude oil versus 0.5 cm for 48 hours) (Lutcavage *et al*. 1995). Recovery from the sloughing skin and mucosa took up to 21 days, increasing the turtle's susceptibility to infection or other diseases, such as fibropapilloma (Lutcavage *et al*. 1995). Records of oiled wildlife during spills rarely include marine turtles, even from areas where they are known to be relatively abundant (Short, 2011). An exception to this was the large number of marine turtles collected (613 dead and 536 live) during the DWH incident in the GoM, although many of these animals did not show any sign of oil exposure (NOAA 2013). Of the dead turtles found, 3.4% were visibly oiled and 85% of the live turtles found were oiled (NOAA, 2013). Of the captured	While marine turtles, including threatened species, are known to occur in the area potentially exposed to hydrocarbons above surface and in-water (dissolved) moderate exposure thresholds, they are not noted to reside or aggregate in significant numbers, and there are no recognised BIAs in the region. There are no turtle nesting beaches along the Gippsland or southern NSW coastlines, so impacts to turtles from shoreline oiling will not occur. Although the effects of hydrocarbons on marine reptiles, specifically turtles can be severe, the low density of turtles expected in the region (due to lack of BIA or aggregations) suggests that a LOWC would affect individuals rather than population level. Consequently, the potential impacts to marine reptiles are considered to be **Consequence Level II**. Effect Dimensions / Sensitivity Dimensions: Duration: M — Irreplaceability: H Size/Scale: M — Vulnerability: H Intensity: M — Influence: H M — H

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	animals, 88% of the live turtles were later released, suggesting that oiling does not inevitably lead to mortality. Shoreline oil Turtles may experience oiling impacts on nesting beaches and eggs through chemical exposures resulting in decreased survival to hatching and developmental defects in hatchlings. Adult females crossing an oiled beach could cause external oiling of the skin and carapace; nothing that most oil is deposited at the high-tide line, and most turtles nest well above this level. Studies on freshwater snapping turtles showed uptake of PAHs from contaminated nest sediments, but no impacts on hatching success or juvenile health following exposure of eggs to dispersed weathered light crude (Rowe *et al.,* 2009). However, other studies found evidence that exposure of freshwater turtle embryos to PAHs results in deformities (Bell *et al*., 2006, Van Meter *et al.,* 2006). Turtle hatchlings may be more vulnerable to smothering as they emerge from the nests and make their way over the intertidal area to the water (AMSA, 2015). Hatchlings that contact oil residues while crossing a beach can exhibit a range of effects including impaired movement and bodily functions (Shigenaka, 2003). Hatchlings sticky with oily residues may also have more difficulty crawling and swimming, rendering them more vulnerable to predation. It should be noted that the threat and relative impacts of an unplanned discharge on some marine reptile species are considered less damaging than other stressors. Report cards produced on protected marine reptiles in Australia generally ranked oil pollution as either 'not of concern' or 'of less concern' depending on the marine region (DSEWPaC 2012a).	
Marine Mammals (Pinnipeds)	Pinnipeds are directly at risk from impacts associated with the exposure to surface, shoreline and in-water hydrocarbons. Sea surface oil Pinnipeds are vulnerable to sea surface exposures in particular given they spend much of their time on or near the surface of the water, as they need to surface every few minutes to breathe, and regularly haul out on to beaches. Pinnipeds are also sensitive as they will stay near established colonies and haul-out areas, meaning they are less likely to	Both the New Zealand fur-seal (*Arctocephalus forsteri*) and the Australian fur-seal (*Arctocephalus pusillus doriferus*) are listed marine species with habitat and breeding sites known to occur in areas potentially exposed to surface, in-water and shoreline oil above the moderate threshold. These areas are not identified as critical habitat and there are no identified BIAs for fur seals in the region. Both the Australian and New Zealand fur seals are at risk to surface oil while at sea and shoreline accumulated oil at haul out sites or rookeries. The direct effect to pups from exposure to shoreline oil at ≥100 g/m^2 could result in mortality, while

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>
practise avoidance behaviours. This is corroborated by Geraci and St. Aubins (1988) who suggest seals, sea-lions and fur-seals have been observed swimming in oil slicks during a number of documented spills.
As a result of exposure to surface oils, pinnipeds, with their relatively large, protruding eyes are particularly vulnerable to effects such as irritation to mucous membranes that surround the eyes and line the oral cavity, respiratory surfaces, and anal and urogenital orifices. Hook et al (2016) reports that seals appear not to be very sensitive to contact with oil, but instead to the toxic impacts from the inhalation of volatile components.
For some pinnipeds, fur is an effective thermal barrier because it traps air and repels water. Petroleum stuck to fur reduces its insulative value by removing natural oils that waterproof the pelage. Consequently, the rate of heat transfer through fur seal pelts can double after oiling (Geraci & St.Aubin, 1988), adding an energetic burden to the animal. Kooyman et al (1976) suggest that in fact, fouling of approximately one-third of the body surface resulted in 50% greater heat loss in fur seals immersed in water at various temperatures. Fur-seals are particularly vulnerable due to the likelihood of oil adhering to fur. Heavy oil coating and tar deposits on fur-seals may result in reduced swimming ability and lack of mobility out of the water.
<u>In-water oil</u>
Ingested hydrocarbons can irritate or destroy epithelial cells that line the stomach and intestine, thereby affecting motility, digestion and absorption.
However, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986). Volkman et al (1994) report that benzene and naphthalene ingested by seals is quickly absorbed into the blood through the gut, causing acute stress, with damage to the liver considered likely. If ingested in large volumes, hydrocarbons may not be completely metabolised, which may result in death.
<u>Shoreline oil</u>
Breeding colonies (used to birth and nurse until pups are weaned) are particularly sensitive to hydrocarbon spills (Higgins & Gass, 1993).
</td><td>
indirect effects could be negative behavioural changes associated with the smell of shoreline oil or contamination of prey.
The Australian fur seal is vulnerable to a population decline following a LOC because breeding locations are restricted to the islands of Bass Strait. It is predicted that major rookeries on The Skerries and Gabo Island may be exposed to accumulated shoreline oil at the moderate threshold.
These species are particularly vulnerable to oil because oil is believed to adhere more readily to their coats, such oiling can have significant effects to their function if foraging in areas with fresh oil. Fur seals are known to aggregate around offshore oil and gas facilities where, in the event of a release, exposure to fresh oil would occur.
The consequence of a LOC on pinnipeds is assessed as Level II.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	ITOPF (2011) report that species that rely on fur to regulate their body temperature (such as fur-seals) are the most vulnerable to oil as the animals may die from hypothermia or overheating, depending on the season, if the fur becomes matted with oil. It is reported that most pinnipeds scratch themselves vigorously with their flippers and do not lick or groom themselves, so are less likely to ingest oil from skin surfaces (Geraci & St. Aubin, 1988). However, mothers trying to clean an oiled pup may ingest oil. The Long Term Environmental Impact and Recovery report for the Iron Barren oil spill concluded that “The number of pups born at Tenth Island in 1995 was reduced when compared to previous years. There was a strong relationship between the productivity of the seal colonies and the proximity of the islands to the oil spill wherein the islands close to the spill showed reduced pup production and those islands more distant to the oil spill did not” (Tasmanian SMPC, 1999). Pinnipeds are further at risk because they appear to rely on scent to establish a mother-pup bond (Sandegren, 1970; Fogden, 1971), and consequently oil-coated pups may not be recognisable to their mothers. This is only theorised, with studies and research indicating interaction between mothers and oiled pups were normal (Davis and Anderson, 1976; Davies, 1949; Shaughnessy & Chapman, 1984). Australian sea lions are endemic to Australia, found only in South Australia and Western Australia (DSEWPaC. 2013). Australian sea-lions have 'naturally poor recovery abilities' due to 'unusual reproductive biology and life history' (TSSC, 2005). Due to the extreme philopatry of females and limited dispersal of males between breeding colonies, the removal of only a few individuals annually may increase the likelihood of decline and potentially lead to the extinction of some of the smaller colonies.	
Marine Mammals (Cetaceans)	Whales and dolphins can be exposed to the chemicals in oil through: • Internal exposure by consuming oil or contaminated prey; • Inhaling volatile oil compounds when surfacing to breathe; • External exposure, by swimming in oil and having oil directly on the skin and body; and	Several threatened, migratory and/or listed cetacean species may traverse the spill plume. The distribution and (possible (DoE, 2015b)) foraging BIAs for the Pygmy blue whale and the migration BIA for the Southern right whale may be exposed to surface and in-water concentrations above the moderate exposure threshold. The foraging BIA for the Humpback whale and breeding BIA for the Indo-Pacific

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>

• Maternal transfer of contaminants to embryos (NRDA, 2012).

<u>Surface oil</u>

Unlike with pinnipeds (see above), oil would not be expected to adhere well to the surface of cetacean skin due to the lack of hairs and the frequent sloughing of skin cells (Engelhardt 1983, Helm *et al*. 2015). In addition, oil should not readily penetrate cetacean skin due to tight intercellular bridges and thick epidermis (O'Hara & O'Shea 2001). Nevertheless, cetaceans can be exposed to oil through direct contact with the eyes, mouth (ingestion), and airways (inhalation), potentially leading to inflammation and lung congestion (Geraci & St. Aubin 1990).

Helm *et al.* (2015) suggested that inhalation of toxic compounds associated with fresh oil was of greater concern than absorption through the skin and ingestion. The inhalation of oil droplets, vapours and fumes is a distinct possibility if whales or dolphins surface in slicks to breathe. Exposure to hydrocarbons in this way could damage mucous membranes, damage airways or even cause death. Cetaceans may incidentally draw seawater and floating oil, into their lungs by breathing in splashed droplets or liquid that has collected near the blowhole just prior to inhalation. Aspiration of liquid oil can cause physical injuries to the respiratory tract by irritating tissues/membranes and can also lead to absorption of toxicants into the blood, as in inhalation exposure (Takeshita *et al*., 2017). French-McCay (2016) proposed exposure to oil concentrations of 10 g/m^2 could result in mortality to marine mammals.

Evidence suggests that many cetacean species are unlikely to detect and avoid spilled oil (Matkin *et al*. 2008). There are numerous examples where cetaceans have appeared to incidentally come into contact with oil and/or not demonstrated any obvious avoidance behaviour. Following the Exxon Valdez oil spill, Matkin *et al*. (2008) reported killer whales in slicks of oil as early as 24 hours after the spill and evidence presented by Aichinger Dias *et al.* (2017) showed that following the DWH oil spill cetaceans in the GoM came into direct contact with both oil and sheen by swimming through them.

Although in the GoM it was observed that cetaceans were able to detect the thick and dark-coloured patches of oil, detection of the lighter substances may have been more difficult. Photographs of dolphins with oil on their bodies showed that oil can adhere to and persist on cetacean skin, and contrary to suggestions from previous studies, direct contact

</td><td>

bottlenose dolphin (which extends northwards into NSW from the Victorian border) may also overlap the zone of moderate in water (dissolved) hydrocarbon.

If present, these species (and other cetaceans) may be exposed to oil in the manner described in this table.

It is plausible that individual whales could encounter surface oil above the moderate to high exposure threshold in the immediate vicinity of the release location, but the release would need to coincide with pod migration or foraging for a greater number of individuals to be present in the plume. Sightings of Blue whales in the Gippsland Basin are reasonably rare (Bannister *et al*., 1996) and acoustic detecting indicates that the Pygmy blue whale are predominantly located to the east, west and south of the OA. It is difficult to predict with certainty if a spill would lead to levels of mortality or reproductive depression that would manifest in terms of a population-level response.

The highly mobile and transitory nature of cetacean species in Bass Strait means that exposure to moderate to high levels of surface oil (in the vicinity of the release location) or moderate levels of in-water hydrocarbon is not anticipated to result in long term population viability effects. Nevertheless, taking into account that the populations of some whale species remain small relative to pre-whaling days and are thought to have a multi-decadal recovery time, mortality of even a small number of adults and or calves as result of oiling could inhibit or retard species recovery, the resultant impact is therefore assessed as **Consequence Level II**.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	with oil and resultant exposure to toxic compounds is of concern (Aichinger Dias *et al*., 2017). In water (dissolved and entrained) oil The physical impacts from ingested hydrocarbon with subsequent lethal or sub-lethal impacts are applicable to both dissolved and entrained oil. However, the susceptibility of cetaceans varies with feeding habits. Baleen whales (such as Blue, Southern right and Humpback whales) are not particularly susceptible to ingestion of oil in the water column as they feed by skimming the surface. Oil may stick to the baleen while they 'filter feed' near slicks. Toothed whales and dolphins may be susceptible to ingestion of dissolved and entrained oil as they gulp feed at depth. As highly mobile species, in general it is very unlikely that these animals will be constantly exposed to concentrations of hydrocarbons in the water column for continuous durations (e.g., >96 hours) that would lead to chronic effects. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013). Ingestion of oil may however result in acute nausea and vomiting and aspiration of oily vomitus into the lungs. Research conducted in the GoM linked aspiration pneumonia, lung abscesses, and pulmonary infections in dolphins to exposure to DWH oil (Venn-Watson *et al*., 2015a cited in Takeshita *et al.,* 2017) Some whales, particularly those with coastal migration and reproduction, display strong site fidelity to specific resting, breeding and feeding habitats, as well as to their migratory paths and this may override any tendency for cetaceans to avoid the noxious presence of hydrocarbons. The Southern right whale exhibits varying degrees of site fidelity, with the majority of females and calves returning to the same birthing location, while some also travel long distances between breeding grounds within a season (DSEWPAC, 2012c). If spilled oil reaches these biologically important habitats, the pollution may disrupt natural behaviours, displace animals, reduce foraging or reproductive success rates and increase mortality. Takeshita *et al.* (2017) concluded that the range of adverse health effects and increased mortality/reproductive failure observed in cetacean populations throughout the GoM since the DWH oil spill are consistent with the range of exposure scenarios.	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	If sufficiently high numbers of animals are impacted, the greater population may experience reduced recovery and survival rates. The restitution time for cetaceans affected at a population level is assumed to be long term, i.e. 40 years, based on consensus on recovery times for marine mammals following the DWH incident (Bock *et. al*., 2018).	
Coastal Habitats and Communities– Sandy Shoreline, Rocky Shoreline, Mangroves and Saltmarsh	**Sandy beaches** Sandy beaches provide potential foraging and breeding habitat for numerous bird, marine turtle and pinniped species. These activities primarily occur above the high tide line, with exception of haul outs. Note, most of the oil on a sandy shore will be concentrated at, and below, the high tide mark. Sandy beaches are also inhabited by a diverse assemblage (although not always abundant) of infauna (including nematodes, copepods and polychaetes); and macroinvertebrates (e.g. crustaceans). Because the sand retains oil, such animals may be killed if oil penetrates into the sediments. Long-term depletion of sediment fauna could have an adverse effect on birds or fish that use tidal flats as feeding grounds (IPIECA, 1999). Depth of penetration in sandy sediment is influenced by: • Particle size. Penetration is not generally as great on mud as on coarser sediments. • Oil viscosity. Viscous oils and mousse (water-in-oil emulsion) tend to penetrate less deeply than low-viscosity oils such as light crudes or diesel oil. • Drainage. If sediments are poorly drained (as is often the case with tidal flats remote from creeks or channels), the water content may prevent the oil from penetrating into the sediment. In contrast, oil may reach depths greater than one metre in coarse well-drained sediments. • Animal burrows and root pores. Penetration into fine sediments is increased if there are burrows of animals such as worms, or pores left where plant roots have decayed. A 100 g/m^2 threshold (considered a 'stain' or 'film', and equivalent to 0.1 mm thickness) is assumed as the lethal threshold for invertebrates on hard substrates and sediments (mud, silt, sand, gravel) in intertidal habitats. A threshold of 100 g/m^2 oil thickness would be enough to coat	There are different types of shorelines found along the Gippsland and southern NSW coast and offshore islands (including Tasmanian islands), however this coastline is dominated by wide sandy beaches with intermittent rocky shores, and salt marshes and isolated mangroves within tidal estuaries, coastal lakes and bays. The type of shoreline will influence the volume of hydrocarbon that could be stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow hydrocarbon to percolate through the sand, and weathered oil may be buried, thus increasing its ability to hold more hydrocarbon ashore over tidal cycles and various wave actions in comparison to a rocky shore; hence hydrocarbon can increase in thickness onshore over time. The maximum length of shoreline exposed to oil at the moderate threshold is 115 km and at the high threshold 39km. The high shoreline loadings would likely result in acute toxicity, and death, of many invertebrate communities, especially for the light crude release scenarios which will easily penetrate into sandy sediments. However, tidal action is expected to lead to rapid weathering of any hydrocarbons in the intertidal area and the populations of these communities would be likely to rapidly recover. Rocky shores along the Gippsland and southern NSW coastline are generally exposed and any oil deposited would be rapidly removed by wave action. Impacts on intertidal communities are typically short term unless acute exposure to fresh product causes high mortality. In Victoria, mangroves are known to occur within sheltered bays or inlets such as Western Port, Lakes Entrance and Corner Inlet. Based on the modelling results, mangrove habitats at most risk, are those near Lakes Entrance however many of the stands are in river estuaries or associated wetlands with only limited or intermittent access to the open ocean. Further north, the NSW coast mangroves may be exposed under certain conditions to shoreline accumulations of oil above moderate thresholds.

<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>
an animal and likely impact its survival and reproductive capacity (French-McCay, 2009). Based on this, areas of heavy oiling would likely result in acute toxicity, and death, of many invertebrate communities, especially where oil penetrates into sediments through animal burrows (IPIECA, 1999). However, these communities would be likely to rapidly recover (recruitment from unaffected individuals and recruitment from nearby areas) as oil is removed from the environment.
Following the Sea Empress spill (in west Wales, 1996) many amphipods (sandhoppers), cockles and razor shells were killed. There were mass strandings on many beaches of both intertidal species (such as cockles) and shallow sub-tidal species. Similar mass strandings occurred after the Amoco Cadiz spill (in Brittany, France, 1978) (IPIECA, 1999). Following the Sea Empress spill, populations of mud snails recovered within a few months but some amphipod populations had not returned to normal after one year. Opportunists such as some species of worm may actually show a dramatic short-term increase following an oil spill (IPIECA, 1999). In March 2014, small volumes of crude oil from an unidentified source (confirmed to not be offshore oil and gas production facilities) washed up along a 7-km section of sandy beach on the Victorian Gippsland coast as small (a few millimetres thick) granular balls (Gippsland Times, 2014). AMSA (2014) reported that no impacts were observed over the course of two months following the incident.
As a result of the DWH spill, oil washed up on sandy beaches of the Alabama coastline. The natural movement of sand and water through the beach system continually transformed and re-distributed oil within the beach system, and 18 months after the event, mobile remnant oil remained in various states of weathering buried at different depths in the beaches (Hayworth et al., 2011). There is also evidence that submerged oil mats (SOM) exist just offshore of the Alabama beaches (ranging in thickness from a few millimetres to several centimetres), which has resulted in the regular washing up of tar balls onto sandy beaches. These SOMs may serve as long-term sources of remnant oil to the beach ecosystem (Hayworth et al., 2011). Long-term changes to the beach ecosystem as a result of stranded oil are unknown.
Other results from beach sampling undertaken at Dapuhin Island, Alabama, in May (pre-impact) and September 2011 (post-impact) found a large shift in the diversity and abundance of microbial species (e.g., nematodes, annelids, arthropods, polychaetes, protists, fungi, algae and
</td><td>
For NSW, oil arriving would be well weathered with little lasting impact on salt marshes. Marshes in Victoria near Wilsons Promontory are not predicted to be exposed to above moderate threshold shoreline accumulation. Salt marsh are important benthic primary producers and provide habitat for other species, thus the loss of salt marshes could have long-lasting indirect effects on other organisms (EPA 2016).
The effect of a LOC on individual shorelines will depend on the type of shoreline, aspect and whether they are high or low energy shores. Shoreline recovery studies link restitution times to oil type, climate, shoreline type and results range depending on the receptors monitored and level of clean up.
The oil from the 2010 DWH spill in the GoM was documented by shoreline assessment teams as stranding on 1,773 km of shoreline (Michel et al. 2013). Shoreline clean-up activities were authorized on 660 km, or 73.3% of oiled beaches and up to 71 km, or 8.9% of oiled marshes and associated habitats. In 2013 Michel et al. reported that one year after the spill began, oil remained on 847 km; two years later, oil remained on 687 km, though at much lesser degrees of oiling. For example, shorelines characterised as heavily oiled went from a maximum of 360 km, to 22.4 km one year later, and to 6.4 km two years later.
Hence recovery can range widely from around 2 years (Sea Empress, 1996, North Sea crude) to more than 20 years for soft sediment shorelines deeply contaminated during the 1991 Gulf War spills (IOGP, 2016).
Of the shorelines of the states potentially impacted, the consequence to shorelines in Victoria is predicted to be greatest (contacted first, highest loadings and freshest oil). The resultant impact is assessed conservatively as a Consequence Level II

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	bacteria). Post-spill, sampling indicated that species composition was almost exclusively dominated by a few species of fungi. DNA analyses revealed that the 'before' and 'after' communities at the same sites weren't closely related to each other (Bik *et al.,* 2012). Similar studies found that oil deposited on the beaches caused a shift in the community structure toward a hydrocarbonoclastic consortium (petroleum hydrocarbon degrading microorganisms) (Lamendella *et al.*, 2014). **Rocky shorelines** Rocky shores encompass a wide variety of habitats. Exposure to the sun and wave energy are key factors in determining the types of plants and animals that inhabit the rocky shores. The persistence of oil is largely governed by the same forces (IOGP, 2016). Rock surfaces exposed to strong wave action are typically dominated by barnacles and limpets that are firmly attached and if oil strands on those surfaces it may result in mortality of the affected animals, but is unlikely to persist. Sheltered rocky shores in estuaries or inlets are typically dominated by macroalgae (seaweed) with various invertebrates living on or under the algae. Oil deposited in these habitats may not be washed off so quickly and recovery from impacts may take longer. **Mangroves and salt marshes** Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (DEWR 2006). The effects of surface hydrocarbons on mangroves include damage by smothering of lenticels (mangrove breathing pores) on pneumatophores or aerial prop roots, or the lower trunk; or by the loss of leaves (defoliation) due to chemical burning. It is also known that mangroves take up hydrocarbons from contact with leaves, roots or sediments, and it is suspected that this uptake causes defoliation through leaf damage and tree death (Wardrop *et al.* 1987). In-water entrained and dissolved hydrocarbons may affect mangrove communities directly through root uptake of toxic contaminants or indirectly due to effects on benthic infauna leading to reduced rates of bioturbation and subsequent oxygen stress on the plants root systems. Observed thresholds for effects are likely to vary depending on the health of the system, the hydrocarbon spilled and the environmental conditions; however, observations by Lin and Mendelssohn (1996)	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	demonstrated that more than 1 kg/m^2 of oil during the growing season would be required to affect salt marsh or mangrove plants significantly. "Subtropical and temperate coastal salt marsh" (otherwise referred to as coastal salt marsh) is listed as a TEC. This TEC is usually associated with sandy/muddy shores of estuaries and embayments along low wave energy coastlines. The physical environment for the TEC is coastal areas under regular or intermittent tidal influence, with salt marsh being the key vegetation type – that being salt-tolerant grasses, herbs, sedges, rushes and shrubs generally less than 50 cm high (DSEWPaC, 2013b). Salt marshes occur in sheltered conditions, commonly in the strandline zone, and the vegetation offers a large surface area for oil absorption and trapping. Additionally, many salt marsh grasses, which can be dominant over large areas, have corrugated leaf surfaces which increase their holding capacity. Evidence from case histories and experiments shows that the damage resulting from oiling is very variable – as are recovery times. Lighter, more penetrating oils are more likely to cause acute toxic damage than heavy or weathered oils. In areas of light to moderate oiling where oil is mainly on perennial vegetation with little penetration of sediment, the shoots of the plants may be killed, but recovery can take place from the underground systems. Good recovery commonly occurs within one to two years. Where thick deposits of viscous oil or mousse accumulate on the marsh surface, vegetation is likely to be killed by smothering and recovery delayed because persistent deposits inhibit recolonisation.	
Wetlands	Most wetlands of international importance i.e. Ramsar wetlands have minimal risk of receiving oil following a LOWC because they have no, or very narrow and/or seasonal, connections to the sea. If surface oil was to enter a Ramsar site, the level of effect would be dependent on the type of receptors exposed to oil and the proportion of the site exposed to oil as well as the nature of the oil (fresh versus weathered). Sensitive receptors found in Ramsar sites connected to the sea could include mangroves, salt marshes, fish, shorebirds and seabirds. The consequences of oil exposure to these specific receptors have been described individually in the sections above.	Under certain metocean conditions both floating surface and in-water (dissolved oil) at moderate thresholds is predicted to contact the Gippsland Lakes Ramsar wetland. Oil is predicted to accumulate at high – moderate thresholds on the shoreline at Lakes Entrance and along the Ninety Mile Beach however the presence of sand dunes between the ocean and the Gippsland Lakes wetlands means the wetland itself is highly unlikely to be affected in any manner. The consequence is assessed as **Level III.**

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
National Parks and Reserves	Potential impacts to sensitive receptors related to the shorelines of the terrestrial parks, such as coastal habitats and birds, and the waters of the marine parks, such as benthic habitats, fish, cetaceans and pinnipeds, are discussed in the appropriate sections above. Impacts on tourism and recreation from degraded aesthetic values and water quality or restricted access to the coast and recreational locales within the Parks due to clean up efforts are discussed below.	Modelling predicts contact at the moderate in-water (dissolved) threshold for five marine parks, reserves and sanctuaries (Ninety Mile Beach, Point Hicks, Cape Howe and Beware Reef in Victoria and Batemans in NSW). Dissolved hydrocarbon at the moderate threshold is also predicted to encroach upon the waters surrounding the terrestrial parks and reserves of the Kent and Hogan Groups and Curtis Island in Tasmania. Oil is predicted to accumulate above the moderate exposure threshold on the Gippsland and southern NSW coastline adjacent to several terrestrial parks and reserves including Gippsland Lakes, Cape Conran and Croajingolong in Victoria and Nadgee, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla in NSW. The consequence is assessed as **Level II** taking into consideration the length of shoreline potentially impacted and the extent of oil accumulation predicted.
AMPs	AMPs vary in their conservation objectives and specific values, but all are designed to conserve fauna, habitats and water quality over the long term. A temporary deterioration of water quality could have negative effects on organisms, such as plankton, seabirds, marine mammals and fisheries resources which in turn affect the values of that Park. These impacts are discussed individually within other sections.	Surface and in-water (dissolved) oil entering these AMPs will degrade water quality until the oil is broken down and or currents shift the weathering oil outside the boundaries of the AMPs. Thus, water quality effects are predicted to persist only over the short to medium term in the AMPs. No AMPs were predicted to experience exposure to surface oil at or above the moderate threshold. Modelling indicated that six AMPs (East Gippsland, Beagle, Flinders, Jervis, Freycinet and Central Eastern), could, depending on the prevailing wind and current direction, be exposed to moderate thresholds of dissolved oil. Taking into consideration the potential impacts to the receptors within the AMPs the overall consequence is assessed as **Level II.**
KEFs	KEFS are underwater features, and hence are not at direct risk from floating surface oil or shoreline accumulated oil. However, biological values associated with KEFs such as the Upwelling East of Eden and Shelf Rocky Reefs may be at risk from oil. Potential impacts to sensitive receptors related to the KEF Upwelling East of Eden such as plankton and cetaceans, or to the KEF Shelf Rocky Reefs such as benthic communities and fish, are discussed in the appropriate sections above.	While a spill would not affect the KEF Upwelling East of Eden itself, if the spill occurs at the time of an upwelling event, it may result in krill being exposed to in-water phase hydrocarbons. Pygmy blue whales feeding at this time may suffer from reduced availability of prey however these impacts are expected to be localised and temporary. The rocky-reef habitat of the KEF Shelf Rocky Reefs generally occurs at depths of greater than 45 m and is therefore not expected to be impacted by in water (dissolved) hydrocarbons in the upper layers of the water column. The consequence is assessed as **Level III**.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
Cultural – Indigenous and Historic	Visible sheen or oil stranded on the shoreline has the potential to reduce the visual or cultural (including activities such as camping, rituals and ceremonies) amenity of cultural heritage sites such as historic (e.g. shipwreck) or indigenous protected areas. Impacts from oil exposure are unlikely for submerged shipwrecks.	Oil sheen and, under certain conditions, oil 'slicks' are predicted to encroach upon nearshore waters in the vicinity of the Gunai-Kurnai Native Title Determination Area and a number of historic shipwrecks. Parts of the Gippsland coast over which the Gunai-Kurnai people hold native title are predicted to be exposed to moderate – high shoreline oil loadings which may lead to reduced amenity or temporary exclusions during clean-up. Impacts from degraded aesthetics of sites along the coast may take time to recover but loss of access to sites during response or for health reasons are temporary and relatively short term. The consequence level is considered **Level III** based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 4.6, Table 4-5).
Commercial Fisheries	Commercial fishing has the potential to be impacted through exclusion zones associated with the spill, the spill response and subsequent reduction in fishing effort. Exclusion zones may impede access to commercial fishing areas, for a short period of time, and nets and lines may become oiled. The impacts to commercial fishing from a public perception perspective however, may be much more significant and longer term than the spill itself. Fishing areas may be closed for fishing for shorter or longer periods because of the risks of the catch being tainted by oil. Concentrations of petroleum contaminants in fish and crustacean and mollusc tissues could pose a significant potential for adverse human health effects, and until these products from nearshore fisheries have been cleared by the health authorities, they could be restricted for sale and human consumption. Indirectly, the fisheries sector will suffer a heavy loss if consumers are either stopped from using or unwilling to buy fish and shellfish from the region affected by the spill. Impacts to fish stocks have the potential for reduction in profits for commercial fisheries, and exclusion zones exclude fishing effort. Davis *et al* (2002) report detectable tainting of fish flesh after a 24-hour exposure at crude concentrations of 0.1 ppm, marine fuel oil concentrations of 0.33 ppm and diesel concentrations of 0.25 ppm. The Montara spill (as the most recent [2009] example of a large hydrocarbon spill in Australian waters) occurred over an area fished by the Northern Demersal Scalefish Managed Fishery (with 11 licences	Several commercial fisheries may operate within the area potentially exposed in the event of a LOC. Floating oil is predicted to extend 100's of kms from the release location making it likely that in these situations an exclusion zone (or fisheries closure) would be established. There are currently no commercially viable scallop beds fished in the area potentially exposed to dissolved hydrocarbons (ABARES, 2019: VFA, 2019: Koopman *et al.,* 2018). Limited data is publicly available on the location and extent of abalone fishing within Victorian waters however a number of licences are active and it is known that harvesting occurs off Cape Conran and at Mallacoota (DEDJTR, 2019). Of the State and Commonwealth administered fisheries which overlap the PEA (see Table 5-1, Description of Environment) the fisheries most active in the area potentially exposed to hydrocarbons, and therefore potentially most at risk of socioeconomic impact from reduced market confidence, are the Southern and Eastern Scalefish and Shark Fishery (31 trawl vessels, 19 Danish-seine vessels and 21 scalefish hook vessels active in total) and the Wrasse Fishery (22 licences in total) (ABARES, 2019: VFA, 2019). A temporary fisheries closure and the flow on losses from the lack of income derived from these fisheries based on reduced market confidence and the potential for extended media coverage (potentially greater than 3 months) has the possibility of exceeding medium community disruption (> 100 – 1000 people) such as reduced employment (in fisheries service industries and the seafood supply chain). The potential economic impacts to commercial fisheries from LOC are considered to be Public Impact **Consequence Level I** based on public impact consequence

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	held by 7 operators), with goldband snapper, red emperor, saddletail snapper and yellow spotted rockcod being the key species fished (PTTEP, 2013). As a precautionary measure, the WA Department of Fisheries advised the commercial fishing fleet to avoid fishing in oil-affected waters. Testing of fish caught in areas of visible oil slick (November 2009) found that there were no detectable petroleum hydrocarbons in fish muscle samples, suggesting fish were safe for human consumption. In the short-term, fish had metabolised petroleum hydrocarbons. Limited ill effects were detected in a small number of individual fish only (PTTEP, 2013). No consistent effects of exposure on fish health could be detected within two weeks following the end of the well release. Follow up sampling in areas affected by the spill during 2010 and 2011 (PTTEP, 2013) found negligible ongoing environmental impacts from the spill. Since testing began in the month after the DWH blowout in the GoM (2010), levels of oil contamination residue in seafood consistently tested 100 to 1,000 times lower than safety thresholds established by the USA FDA, and every sample tested was found to be far below the FDA's safety threshold for dispersant compounds (BP, 2015). FDA testing of oysters found oil contamination residues to be 10 to 100 times below safety thresholds (BP, 2014). Sampling data shows that post-spill fish populations in the GoM since 2011 were generally consistent with pre-spill ranges and for many shellfish species, commercial landings in the GoM in 2011 were comparable to pre-spill levels. In 2012, shrimp (prawn) and blue crab landings were within 2.0% of 2007-09 landings. Recreational fishing harvests in 2011, 2012 and 2013 exceeded landings from 2007-09 (BP, 2014).	considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 4.5).
Tourism and Recreation	Refer also to sections on fish, cetaceans, benthic and coastal habitats and National Parks and Reserves above.	Tourism and recreation is also linked to the presence of marine fauna (e.g. whales), particular habitats and locations for swimming or recreational fishing. The modelling predicts visible oil extending into nearshore Victorian waters (including waters of Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks and Beware Reef Marine Sanctuary). Oil is predicted to contact hundreds of kilometres of shoreline at the moderate – high exposure threshold. The shoreline is dominated by sandy beaches popular for a range of recreational activities. A number of National Parks and Reserves including the very popular (Gippsland) Lakes National Park is situated along this potentially exposed coastline.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
		Short to Medium-term impacts to nature-based tourism and other human uses of beaches (and nearshore waters) may occur as a result of temporary beach closures to enable clean-up, protect human health or due to perceptions of a polluted environment that is not desirable to visit. With respect to human health, post-Macondo oil spill (April 2010) studies in December found of 17000 water samples, none exceeded USEPA benchmarks for protection of human health (OSAT, 2010) and a year later residual oil in nearshore and sandy shoreline areas was highly weathered and concentrations of constituents of concern were below levels of concern for human health (OSAT, 2011). Alaska's tourism economy took approximately two years to recover from the Exxon Valdez (BOEM, 2017). The Eastern Research Group (2014) reported that while the DWH spill had had a significant impact on several areas of tourism in the short term and had wide-ranging impacts across the GoM, the tourism economy has rebounded to pre-spill levels within four years. The extent of potential impacts to tourism and recreation depends on when the spill occurs, size and where it comes ashore. Considering the range of activities and locations, the potential for reduced amenity of areas used by coastal tourists and recreational visitors, temporary health implications and possible closures, the consequence level is considered **Level I,** based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 4.5).

7.6.3.2 Likelihood Evaluation

A rupture of a pipeline has never occurred within Esso Bass Strait Operations and is not a common occurrence in the industry.

Considering the inherent low likelihood of a rupture of a pipeline, the safeguards in place and enactment of the SMPEP and OPEP, and the rapid weathering of hydrocarbons, the likelihood of the impacts described above occurring is considered **Very Highly Unlikely (E)**.

7.6.4 Risk Ranking

Consequence	Likelihood	Risk Ranking
II (environmental) / I (public impact)	E	4 (environmental / 3 (public impact)

7.6.5 Controls

Good Practice	Adopted	Control	Rationale
Support vessel approach protocols	✓	**CM27**: Support vessel approach procedure	Support vessel approach procedure outlines the required 500 m approach and DP operational checklists complete to ensure safe approach to the platforms.
Structured operational limits criteria for dynamic positioning (DP) operations	✓	**CM28**: ASOG / CAMO procedures	The application of ASOG / CAMO risk management tools is industry best practice for DP operations. CAMO describes how to configure the vessels DP system and ASOG sets out the operational, environmental and equipment performance limits considered necessary for safe DP operations whilst carrying out a specific activity.
DP Class 2	✓	**CM29**: Support vessel DP system	DP Class 2 (redundancy so that no single fault in an active system will cause the system to fail) is the industry standard where loss of position keeping capability may cause personnel injury, pollution or damage with large economic consequences.
Pipeline Network Safety Case	✓	**CM34:** NOPSEMA accepted Safety Case	The NOPSEMA accepted Pipeline Network Safety Case demonstrates how the risks to the integrity of the pipelines will be reduced to as low as reasonably practicable (ALARP). This includes: • Safe design and operation of pipelines • Reduction of risks to ALARP • Inspection, maintenance and monitoring of pipelines

Good Practice	Adopted	Control	Rationale
Corrosion control management and monitoring program	✓	**CM55:** Corrosion monitoring and control plans for pipelines developed and actioned per FIMS process	A corrosion control and monitoring program is in place as part of OIMS System 6-2 (FIMS). The Corrosion Control and Monitoring program ensures corrosion controls are implemented (including cathodic protection and chemical corrosion inhibition) and monitors the performance of these controls. This program is in place to reduce the likelihood of corrosion in pipelines.
Subsea pipeline inspections and monitoring	✓	**CM56:** Pipeline inspection and monitoring program developed and actioned per FIMS process	Pipeline Inspection Programs is in place as part of OIMS System 6-2 (FIMS). The Pipeline Inspection and monitoring program includes underwater pipeline inspection, leak detection and in-line metal loss surveys. This program is in place to reduce the likelihood of LOC due to corrosion, failure of an unsupported span and impacts to an unprotected section of pipeline.
Pipeline isolation and depressuring	✓	**CM57:** Isolation test plan for pipeline isolation valves developed and actioned per FIMS process	Pipeline isolation is triggered by shutdown systems. Shutdowns can be put in effect by a number of initiators that indicate abnormal operating conditions (e.g. high pressures) that could bring the process to an unsafe state or an actual loss of containment of hydrocarbons (e.g. triggering gas detectors on the topsides). They can also be initiated manually. A Surface Shutdown shuts down and isolates process equipment on a platform. A Subsurface Shutdown does this and also initiates boundary isolation at the well subsurface safety valves and the pipeline LVOs (last valves on), FVOs (first valves off) and actuated SSIVs (subsea isolation valves) where installed. A Generator Shutdown shuts down the electricity generators and initiates a Surface Shutdown. A Total Platform Shutdown (TPS) initiates all of the above shutdowns and trips all sources of battery power other than those feeding hazardous area rated communications, lighting and navigation aids. Closure of the LVO / FVO during platform topsides blowdown prevents the pipeline inventory from feeding a leak. Pipeline isolation valves are in place and maintained as part of FIMS. A Subsurface Shutdown can be initiated on the platform or it can also be initiated from the Production Control Room at Longford. Other

Good Practice	Adopted	Control	Rationale
			shutdowns are initiated from the EAA or the control room on the platform. In the event of an incident, pipelines can be depressured in order to respond to a leak. Process for depressuring pipelines is specific to the location and equipment available on the relevant facility where the depressuring will take place. Facility specific procedures are in place to provide guidance to safety depressure facilities and pipelines. In general: For offshore pipelines coming onshore, platforms feeding into the pipeline can be shut in. Pressure is relieved at the platform, as far as practicable. For inter-platform pipelines, platform at the supply end to shut in and isolate at the LVO. The platform at the receiving end can reduce line pressure to flare pressure, then isolate line at the FVO. Should pipelines upstream of the damaged pipeline require depressuring during an emergency, pipelines can be depressured through the platform scraper launchers and receivers to the platform vent and drain systems.
Crane maintenance	✓	**CM42:** Crane Operations, Maintenance and Inspection Manual (COMI) - Lifting Procedures	Crane maintenance and inspection programs are undertaken in accordance with the Crane Operations Maintenance and Inspection Manual (COMI). This includes maintenance and inspection of cranes, Rigging and lifting gear and testing of equipment This is in place to minimise the likelihood of objects being dropped as they are being lifted and minimise the risk of an object being dropped onto a pipeline.
	✓	**CM40**: Flag State lifting requirements	Vessel lifting equipment maintenance standards and procedures undertaken in accordance with vessel Flag state requirements (e.g. Australia: Marine Order 32 - Cargo handling equipment). This is in place to minimise the likelihood of objects being dropped as they are being lifted and minimise the risk of an object being dropped onto a pipeline.
Location of pipelines is published and available for fishermen	✓	**CM58:** Navigational charts	The location of facilities, PSZs and pipelines are plotted on navigational chart AUS357. This is in order to reduce the likelihood of vessels and fishermen impacting pipelines when using anchors or fishing equipment.
Observation flights	✓	**CM59**: Observation during helicopter flights	Helicopter flights travel offshore routinely between all facilities to transfer personnel to and from the platforms. During these fights, helicopter pilots record any hydrocarbon sheens observed. Flights are diverted to CoP facilities routinely to observe for any indications of leaks. Should a leak be observed, helicopter pilots report this to safety and environmental coordinators to initiate further response measures as required.

Good Practice	Adopted	Control	Rationale
Oil spill response planning	✓	**CM12:** OPEP	Under the OPGGSE Regulations, the petroleum activity must have an accepted Oil Pollution Emergency Plan (OPEP) in place (Reg. 14(8). In the event of a LOC, the OPEP will be implemented. Capability is maintained to ensure OPEP can be implemented in response to an incident, as expected. This includes maintaining contracts with third party service providers to ensure required materials are available at the time of an incident.
Oil spill monitoring planning	✓	**CM35:** OSMP	The OSMP is a key part of an integrated package of environmental management documentation that also includes the environment plan (EP) and the oil pollution emergency plan (OPEP). It is defined under (Reg. 14(8) of the OPGGSE Regulations. The OSMP is the principle tool for determining the extent, severity and persistence of environmental impacts from an oil spill, and allows titleholders to determine whether their environmental protection goals are met. Esso's OSMP details the arrangements and capability in place for: • Operational monitoring of a hydrocarbon spill to inform response activities • Scientific monitoring of environmental impacts of the spill and response activities. Operational monitoring will allow adequate information to be provided to aid decision making to ensure response activities are timely, safe, and appropriate. Scientific monitoring will identify if potential longer-term remediation activities may be required Capability is maintained to ensure OSMP can be implemented in response to an incident, as expected.
Utilisation of idle fishing vessels	✓	**CM51:** Utilisation of idle vessels	Opportunities to utilise idle fishing vessels for oil spill response and monitoring activities will be taken where there is agreement of the vessel owner and where a risk assessment shows that there are no additional risks to vessels and crew.
Communication with fisheries	✓	**CM52**: Communication with fisheries	Updates on oil spill response and monitoring provided to fishery representative bodies (through SETFIA) to enable accurate information on spill status, impacts and effects of spilled hydrocarbons on seafood safety to be provided to fishing industry members and the public. Daily updates provided in the first week until the modelling is completed and then as needed, until relief well completed (and beyond if there is ongoing concern).

7.6.6 Demonstration of ALARP

ALARP Decision Context and Justification	Decision Context B Pipeline operations are a standard offshore activity. The risks associated with a loss of containment from a pipeline are well understood. Esso is experienced in the implementation of industry requirements through their existing ongoing operations. The environmental and public consequences of a LOC have been assessed as moderate – high and in recognition of the interest from both relevant stakeholders and the public about the potential impacts of a major oil spill. The utilisation of idle fishing vessels (where practicable and safe to do so) and ensuring ongoing communication with the fishing industry bodies will assist in mitigating socioeconomic impacts to commercial fisheries and the seafood supply chain. Consequently, Esso believes **ALARP Decision Context B** should apply.

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Utilisation of idle fishing vessels	Opportunities to utilise idle fishing vessels for oil spill response and monitoring activities will be taken where there is agreement of the vessel owner and where a risk assessment shows that there are no additional risks to vessels and crew.	There is minor costs associated with using idle fishing vessels including ensuring safety and training standards are met in the event of an incident. Costs are considered reasonable given the high public impact consequence	Adopted **CM51:** Utilisation of idle vessels
Communication with fisheries	Updates on oil spill response and monitoring provided to fishery representative bodies (through SETFIA) to enable accurate information on spill status, impacts and effects of spilled hydrocarbons on seafood safety to be provided to fishing industry members and the public. Daily updates provided in the first week until the modelling is completed and then as needed, until relief well completed (and beyond if there is ongoing concern).	There is minor costs associated with sending communication out to stakeholders, particularly as there has been ongoing consultation through the EP. Costs are considered reasonable given the high public impact consequence.	Adopted **CM52**: Communication with fisheries
Trenching/ burial of pipelines for protection from external damage	Retrospective burial of pipelines may reduce the likelihood of external damage outside the PSZ	Many pipelines are on the sea floor and retrospective burial is costly. Visual inspections of the pipeline are completed regularly as part of pipeline maintenance programs. Other controls in place are considered to reduce risks to ALARP (location of pipelines published on marine charts and ATBA	Not adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
		to eliminate large ships form the area). The cost of retrospective burial is considered grossly disproportionate to the reduction in risk.	

7.6.7 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Risk Assessment Process for Unplanned Events	The risk ranking is lower than Category 1	✓	The environmental risk ranking is Category 3 and the public impact risk ranking Category 2, and therefore considered acceptable.
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	The impacts associated with this aspect are potentially significant but moderate in size/scale and medium term, which is not considered as having the potential to affect biological diversity and ecological integrity.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The activity is not considered as having the potential to result in long term or irreversible environmental damage.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	• The proposed activities align with the requirements of the OPGGS Act 2006: • Schedule 3 Occupational health and safety and OPGGS(S)R. The OPGGS(S)R require the operator of each offshore facility to prepare a safety case for submission to NOPSEMA. Activities at a facility must be conducted in accordance with a safety case that has been accepted by NOPSEMA. • The following other requirements were identified as relevant to impacts from a LOC from a pipeline. Oil spills are a recognised threat to these species and proposed activity is consistent with conservation / management actions where specified: • Approved Conservation Advice for *Thinornis rubricollis* (Hooded Plover, Eastern) • Approved Conservation Advice for *Sternula nereis nereis* (Fairy Tern)

Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards	✓	There is no standard related to a LOC from a pipeline but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed activities meet: OIMS System 6-2 objectives ensure equipment is maintained over the operating life of the equipment preventing or mitigating a significant event that could result in significant and environment consequences. OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; OIMS System 8-1 objective to clearly define and communicate operations integrity requirements to contractors; OIMS System 10-1 objective to anticipate community concerns and develop response plans, as appropriate; and OIMS System 10-2 objectives to document, resource and communicate emergency response plans, and conduct training, exercises and/or drills to determine the adequacy of the plans.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	Concerns from relevant stakeholders addressed through the consultation process. Any new relevant stakeholder objections, claims or issues will be considered in line with the ongoing consultation.

7.7 Accidental Release - Loss of Well Control

7.7.1 Causes of Loss of Well Control

A loss of well control (LOWC) can occur when primary and secondary well control measures fail, which could potentially result in a release of reservoir hydrocarbons into the marine environment.

During production operations the probability of loss of containment of reservoir hydrocarbons is very unlikely. However, workover operations pose a remote chance of losing primary and secondary well control, resulting in a release of reservoir hydrocarbons to the marine environment.

7.7.2 Spill Modelling

Spill modelling was prepared for the worst case discharge scenarios to establish the extent of possible environmental impact (RPS, 2019b, 2019c, 2020). The spill modelling was prepared based on the parameters described in Table 7-23. The modelling was based on 100 spill simulations and annual analysis (i.e. over all seasons).

7.7.2.1 Discharge Scenarios and Modelling Inputs

A comprehensive review of all current, future and historically producing wells across Bass Strait wells was completed to identify potential worst case discharge scenarios.

The potential discharge scenario developed based on a failure of all preventative and mitigating barriers resulting in a loss of well control and a release of reservoir hydrocarbons.

The assessment considered all producing wells across Bass Strait including future activity on existing wells and wells which will start producing during the period of this EP (e.g. West Barracouta).

Table 7-21 Selection of worst case discharge scenario – Loss of well control

Process	Description

Identify potential discharge scenarios	In consultation with Reservoir, Wellwork and Facilities Engineers, it was identified that discharge of reservoir fluids could occur due to loss of containment during:
	• “Minor” workover
	  ○ Workovers (including P&As) where tubing remains in the well
	  ○ All wireline activities are considered ‘minor’ workovers because tubing is not removed.
	  ○ Flow during a LOWC could be via tubing
	  ○ Could be caused by:
	    ▪ Loss of barriers during wellwork
	• “Major” workover
	  ○ Workovers (including P&As) where tubing is removed from the well (also known as ‘tubing pull workovers’)
	  ○ Flow during a LOWC could be via tubing and annulus
	  ○ Could be caused by:
	    ▪ Loss of barriers during wellwork
	• Loss of containment outside of wellwork scenarios (e.g. during production; while the well is shut in)
	  ○ An incident occurs resulting in a loss of containment from the well or associated equipment
	  ○ This could occur:
	    ▪ During production
	    ▪ While the well is shut-in, suspended or temporarily abandoned
	  ○ Could be caused by:
	    ▪ Loss of barriers in the well
	    ▪ Loss of containment from well head equipment and flowlines
	For more detail about different types of workovers refer to Section 2.4.2.
	Note that wellwork (including P&A) using a Jack Up Rig (JUR) is excluded from this assessment. Impacts and risks associated with the use of a JUR are not included in this Environment Plan and these activities will be subject to assessment in separate project/campaign specific EPs. At the time of writing the rig program was under review due

Process	Description
	to COVID-19 but could include the plug and abandonment of SHA, TWA, PCA, DPA, Mulloway, Whiptail. This assessment includes consideration of seven temporarily abandoned exploration wells. P&A of these wells will be completed using a rig and will be subject to assessment in a separate EP.

Name	License	Area
WHIPTAIL 1A	VIC/L1	Close to shore
MARLIN 1	VIC/L3	Northern
HALIBUT 1	VIC/L5	Central Fields
GUDGEON 1	VIC/L6	Central fields
EAST PILCHARD 1	VIC/L9	Northern
TERAKIHI 1	VIC/L20	Central fields (further from shore)
MULLOWAY 1	VIC/RL1	Close to shore

Process	Description
Identification of potential pollutants	Oil types for different reservoirs were classified and grouped based on ITOPF Classifications (ITOPF, 2015). Hydrocarbon liquid types across the Bass Strait vary from Group I (light oils/condensate) to Group IV (heavy crude). Details of fluid properties for each reservoir can be found in Appendix A, Section 4.4. Seven samples were collected to analyse the different types of condensate and crude oils across all facilities. These samples span the range of fluid properties of Bass Strait Operations. Fluid properties sampled were selected based on a combination of oil type, production flow rates and location to ensure the range of fluid properties were modelled. Crude types selected for modelling were: • West Kingfish Crude • Halibut Crude • Flounder Crude • Snapper N Crude • Moonfish Crude Kipper and Barracouta condensates were considered to determine the volume of a worst case discharge from a gas / condensate well and were modelled in Prosper for the highest producing gas / condensate wells. As shown, the volume of the release during production operations (from a completed well with production tubing in place) is considerably lower than the WCDS for a LOWC during drilling (7.8 kbbl / day). This scenario has been assessed in the accepted JUR Drilling EP and therefore are not considered a worst case scenario. Environmental impacts have been assessed in Section 6.7 of the JUR Drilling EP available on NOPSEMAs website here and has not been addressed further in this EP. Response to condensate spills has been addressed in Appendix A of Volume 3 (in the OPEP).

Well	Daily release rate (kbbl /day)	Total release volume over 98 days (kbbl)
KPA	5.5	539
BTW	1.9	186

Process	Description
Determine characteristics of	**<u>Location</u>**

Process	Description
the discharge scenario (including the location and calculation of potential spill volumes)	Bass Strait Production can largely be separated into four different areas • Central Fields (BKA, HLA, FTA, CBA, MKA) • Close to shore (SHA, TWA, BTW, BTA, WTA, SNA, PCA, DPA) • Northern (KPA, MLA, MLB, WTN, TNA, FLA) • Southern (KFA, KFB, WKF, BMA, BMB) The Whiting platform has been excluded from this assessment as all wells have been abandoned Following the abandonment of SHA, TWA and BKA subsea facilities, there are no subsea oil wells producing in the Gippsland region. Remaining subsea facilities (KPA and BTW) produce gas and condensate (as discussed above). Therefore, all crude spill scenarios are assumed to occur at surface. **Volume** The flow rate of discharge scenarios was established based on the most recent well test data for all wells, to identify the highest producing wells. Spills from abandoned wells, during wireline activities and during production would be expected to result in a significantly lower rate of release compared to releases due to workover activities. There are a number of restrictions at surface which would restrict flow rate should an incident occur. For the purposes of this worst case scenario assessment, a spill from a workover activity have been considered as it presents a spill of the highest volume and the highest likelihood of occurrence. Wells which do not free flow were excluded from the assessment as they would not be able to flow to atmosphere for an extended period should an incident occur. The volume of the discharge scenarios was determined based on modelling a discharge scenario from the most productive well for each crude type at each location using Prosper. Prosper is a program which allows for modelling flow from reservoirs, through wells to the surface by taking into account well design, fluid flow regimes and hydraulic constraints (such as casings and valves within the well). It was assumed that the discharge scenario requires a relief well drilled by a Semi-sub rig that has a response time of 98 days, as described in Section 7.7.5.1.
Determine likelihood of the discharge scenario	The highest risk activities which could lead to a loss of containment from wells is during well workover activities. This is reflected in the IOGP Risk Assessment Data Directory – Blowout Frequency (2019) as outlined below.

Well type	Definition	Frequency of Well release	Unit
Abandoned wells	Permanently abandoned, temporarily abandoned and long-time plugged wells. Categorised as Suspended, Temporarily abandoned, Abandoned in the WOMP.	$2.3x10^{-5}$	per well year
Wireline	Wireline operations in production or injection wells (i.e., not wireline operations carried out as part of drilling and completion operations).	$2.5x10^{-5}$	per operation
Production	Wells that are used for production and injection purposes. This includes closed in production wells. Categorised as Shut in, Active in the WOMP	$4.5x10^{-5}$	per well year
Workover	Workover activities (not including wireline, snubbing or coiled tubing operations). Often referred to as “heavy workover”.	$5.7x10^{-4}$	per operation

<table>
<tr><th>Process</th><th>Description</th></tr>
<tr><td></td><td>According to the IOGP Risk Assessment Data Directory, the likelihood of a LOWC from a production or an abandoned well is less than during a workover activity.</td></tr>
<tr><td>Selection of worst case scenario</td><td>
Based on the assessment of oil type, location and volume described above, representative worst case discharge scenarios were selected at a variety of facilities to give an understanding of discharge scenarios and impacts to receptors at a representative selection of locations across the Strait. A summary of these scenarios has been provided in Table 7-22.
A summary of how these scenarios are representative of spill risks for all Bass Strait Operations is provided below.
<table>
<tr><th rowspan="3">Area</th><th colspan="3">Representative Worst Case Discharge Scenario*</th></tr>
<tr><th>Non workover (inc. production & shut-in wells)</th><th>Minor workover (inc. P&A)</th><th>Major workovers</th></tr>
<tr><td>Production
Shut in wells</td><td>Workovers where tubing is not removed</td><td>Tubing pull workovers</td></tr>
<tr><td>Central Fields
(BKA, HLA, FTA, CBA, MKA)</td><td>Non-workover discharge scenarios for Central Fields will be represented by CBA A19 workover discharge scenario due to similar crude types and lesser volume (due to reduced flow rate and restrictions at surface).</td><td>Minor workover discharge scenario in Central Fields will be represented by a workover on CBA A19 well as it has been modelled as the highest producing well in the area.</td><td>Major workover discharge scenarios for Central fields will be represented by the TNA A2 major workover scenario (refer to Northern Area). Note: CBA A19 well has a higher production rate, while TNA A2 scenario is closer to shore, therefore both have been considered.</td></tr>
<tr><td>Close to shore
(SHA, TWA, BTW, BTA, , SNA, PCA, DPA)</td><td>Non-workover discharge scenarios for close to shore will be represented by SHA 1 workover.</td><td>SNA A19 is highest producing well in the area. Although SNA-A19 has a slightly higher production rate, this scenario was not selected.
The minor workover scenario for the SHA subsea facility was selected as it is closer to shore (and was included to provide a representative subsea discharge).
Although wells which produce from the Moonfish reservoir also have a lesser production rate than the SNA-A19, the Moonfish well minor workover scenario was selected because the Group IV oil type is expected to result in a spill with higher consequences.</td><td>Major workover discharge scenario for close to shore represented by the TNA A2 major workover scenario (refer to Northern Area), as all wells in this area have a lesser production rate than TNA A2. The TNA A2 a Group IV crude (persistent oils) which is representative of the worst case crudes across Bass Strait Operations.</td></tr>
<tr><td>Northern
(KPA, MLA, MLB, WTN, TNA, FLA)</td><td>Non-workover discharge scenario represented by MLA A10 workover due to similar crude types and lesser volume (due to reduced flow rate and restrictions at surface).</td><td>Minor workover discharge scenario in Northern area will be represented by a workover on MLA A10 because it is the highest producing well in the area.</td><td>Major workover discharge scenario for Northern area represented by TNA A2 major workover, which is the highest producing well in a central production area.</td></tr>
<tr><td>Southern
(KFA, KFB, WKF, BMA, BMB)</td><td>Non-worokver discharge scenario represented by WKF W2 workover due to similar crude types and lesser volume (due to reduced flow rate and restrictions at surface).</td><td>Minor workover discharge scenario in Southern area represented by WKF W2 workover because it is the highest producing well in the area.</td><td>Major workover discharge scenario for Southern Area represented by the TNA A2 major workover scenario as all wells in this area have a lesser production rate than TNA A2. The TNA A2 a Group IV crude (persistent oils) which is representative of the worst case crudes across Bass Strait Operations.</td></tr>
</table>
*scenarios in Bold have been modelled. See Table 7-22 for modelling details

Process	Description
	<u>Moonfish Reservoir</u> Sampling was completed of crude oil from the Moonfish reservoir which indicated high wax content and low pour point. Modelling was completed on the M31 well which is currently producing from the Moonfish oil reservoir. The risk of loss of well control from production and 'minor' workovers from wells producing from the Moonfish reservoir (i.e. Wellwork activities where the worst case discharge scenario is flow through tubing only, such as wellwork where tubing remains in the well) have been assessed and are within the scope of this EP. Minor workovers for maintenance and repair activities may need to be completed on wells which are currently producing from the Moonfish reservoir. These are considered 'minor' workovers and impacts and risks have been assessed as per the consequence assessment in Table 7-25 and Table 7-26. The risk of loss of well control from 'major' workovers from wells producing from the Moonfish reservoir (i.e. wellwork activities where the worst case discharge scenario is flow through tubing and annulus such as wellwork where tubing is removed from the well) have not been assessed in this EP.

Table 7-22 Representative Worst Case Discharge Scenarios

Release Area	Close to Shore	Southern	Central Fields	Northern	Northern	Close to Shore
WCDS Selection Basis	The Seahorse scenario (SHA 1 well) represents a crude well close to shore. Note that the SHA well was abandoned in October 2020. However the modelling for this 'workover' discharge scenario was used to represent an oil spill close to shore and the flowrate is comparable with the production rate of the SNA A19. A spill from the Snapper platform would be a surface spill but given the shallow depth at the SHA location, the spill modelling is considered to be comparable to that of a surface spill.	The West Kingfish scenario (from the WKF W2 well) represents the highest performing well in the south section of Gippsland basin (although lower than the other scenarios due to reservoir decline). WKF crude is considered a Group II (Light persistent oil) which is representative of crude in this area.	The Cobia scenario (from the CBA A19 well) was determined to be the highest performing well representing the central fields. The well was not producing at the time of modelling however, predicted flow rates were determined to be the highest in the area. The Cobia scenario was modelled using Halibut crude which is classified as Group II (Light persistent oil). This is representative of the types of oil found in the Central Block reservoirs.	The Marlin scenario (from the TRA A10 well) represents the highest performing wells in the northern area. Crude samples from current Turrum (TRA) wells were not able to be analysed to produce an assay due to the water cut being too high and as such, a crude assay proxy was chosen, based on present testing and historical reservoir information. The TRA wells were modelled using West Kingfish crude. The Group II crude (Light persistent oil) is representative of the crudes in the Northern area.	The Tuna scenario was prepared to model a discharge scenario from a major workover. The TNA A2 well is expected to produce at a higher rate following workover. The TNA A2 was modelled using tubing and annular flow to represent a worst case scenario during major workover. Crude samples from current TNA wells were not able to be analysed to produce an assay due to the water cut being too high and as such, a crude assay proxy was chosen, based on present testing and historical reservoir information. The TNA well was modelled using Flounder crude. The Group IV crude (persistent oils) is representative of the worst case crudes across Bass Strait Operations.	The Snapper M31 scenario was prepared to model a discharge scenario from the Moonfish oil reservoir given its high wax content and pour point (Group IV Persistent oils). The SNA M31 scenario was modelled using tubing flow only.
Scenario description	• Minor workover / P&A • Tubing available to flow				• Major workover	• Minor workover / P&A

	• Discharge rate assumed to be constant • Modelled with actual water cut	• Tubing and annulus available to flow • Discharge rate not assumed to be constant, as limited by reserves volume and will decline. • Modelled assuming 0% water cut (note actual water cut	• Tubing available to flow • Discharge rate assumed to be constant • Modelled with actual water cut

Moonfish crude (RPS 2020)	7.2	28.8	46.9	17.2

7.7.2.2 Modelling Outputs - Weathering and Fate

The properties of the oils used in the modelling of the LOWC scenarios is shown in Table 7-23. West Seahorse-3, West Kingfish and Halibut crudes are classified as a Group II oils according to the International Tanker Owners Pollution Federation classifications (ITOPF, 2014), while Moonfish and Flounder crudes are classified as a Group IV oils due to the high pour point (above ambient temperature) (ITOPF, 2015).

On release to the marine environment, crude is predicted to be distributed over time into the following components:

- surface;
- water column, including
  - entrained (non-dissolved oil droplets that are physically entrained by wave action);
  - dissolved (principally the aromatic hydrocarbons);
- evaporated;
- stranded on shoreline and
- decayed (microbial biodegradation).

Of these components, surface hydrocarbons and dissolved aromatics have the greatest impact on receptors.

Figure 7-9, Figure 7-10, Figure 7-11, Figure 7-12, Figure 7-12 and Figure 7-13 present the fate and weathering graphs for modelled crude releases.

West Seahorse-3 crude is composed of 87.5% volatiles and semi- to low-volatile compounds and 12.5% persistent compounds. It is expected from laboratory tests that once the light end hydrocarbons are lost to evaporation, the remaining surface oil would be semi-solid in state, although it is unlikely to form a cohesive slick (RPS, 2019c).

The West Kingfish and Halibut crudes contains a relatively low proportion (approx.13% by mass) of hydrocarbon compounds that will not evaporate at atmospheric temperatures. These compounds will persist in the marine environment. The whole oil has a high wax content (approx. 25%), indicating that surface slicks of West Kingfish and Halibut crude are likely to form waxy flakes in the environment as they weather over time. Soluble, aromatic, hydrocarbons contribute approximately 23% by mass of the whole oil. Surface discharge will inhibit the process of dissolution, with compounds tending to evaporate from the water into the atmosphere (RPS, 2019b).

Evaporation rates will increase with temperature, but in general, for West Kingfish crude about 13.6% of the oil mass should evaporate within the first 12 hours (BP < 180 °C); a further 35.9% should evaporate within the first 24 hours (180 °C < BP < 265 °C); and a further 36.8% should evaporate over several days (265 °C < BP < 380 °C). For Halibut crude about 10.7% of the oil mass should evaporate within the first 12 hours, a further 34.1% should evaporate within the first 24 hours and a further 41.8% should evaporate over several days.

The Flounder crude also contains a relatively low proportion (15% by mass) of hydrocarbon compounds that will not evaporate at atmospheric temperatures. The high pour point of the whole oil (18°C) and a very high wax content (32%) indicates that this crude will likely solidify when released into the environment over the annual temperatures observed in the Gippsland Basin. Soluble, aromatic, hydrocarbons contribute approximately 15.6% by mass of the whole oil. Surface discharge will inhibit the process of dissolution, with compounds tending to evaporate from the water into the atmosphere (RPS, 2019b).

For Flounder crude in general, about 9.1% of the oil mass should evaporate within the first 12 hours, a further 36.6% should evaporate within the first 24 hours and a further 39.1% should evaporate over several days.

The weathering graphs demonstrated that the West Kingfish, Halibut and Flounder crudes tend to persist on the sea surface for approximately 20 days under low wind conditions, while a large portion of the spill volume could potentially remain entrained in the water column for extended times in the presence of winds greater than 10 knots.

Moonfish crude contains 17.2% by mass of hydrocarbon compounds that will not evaporate at atmospheric temperatures. The high pour point of the whole oil (27°C) indicates that this crude will solidify when released into the environment over the annual temperatures observed in the Gippsland Basin. The very high wax content (38.5%) indicates that surface slicks of this crude are likely to form waxy flakes as it weathers over time. Soluble, aromatic, hydrocarbons contribute approximately 17.3% by mass of the whole oil. Surface discharge will inhibit the process of dissolution, with compounds tending to evaporate from the water into the atmosphere (RPS, 2020).

The weathering graphs demonstrated that the persistent component of the Moonfish crude will remain on the sea surface for long period of times, under low wind conditions while a large portion of the spill volume could potentially remain entrained in the water column in the presence of winds greater than 10 knots. It is worth noting that due to the physical properties of the crude, stronger winds were required to push the surface oil into the water column.

For Moonfish crude in general, about 7% of the oil mass should evaporate within the first 12 hours, a further 29% should evaporate within the first 24 hours and a further 47% should evaporate over several days.

Note that evaporation rates will increase with temperature. However, volatile components (BP <180°C) are expected to evaporate within the first 12 hours, semi-volatile components (180 °C < BP < 265 °C) within the first 24 hours; and low volatility components (265 °C < BP < 380 °C) are expected to evaporate over several days.

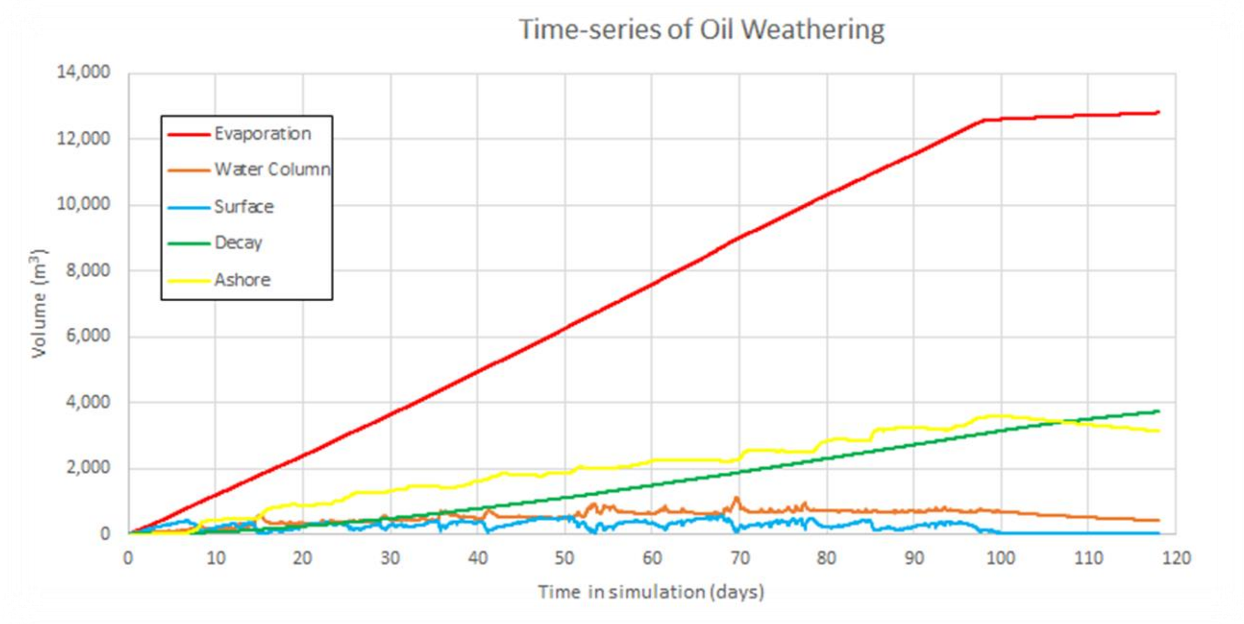

Figure 7-8 Predicted weathering and fates of West Seahorse-3 crude from modelling a selected single trajectory of a 127 kbbl LOWC release from Seahorse Subsea Facility over 98 days, tracked for 118 days

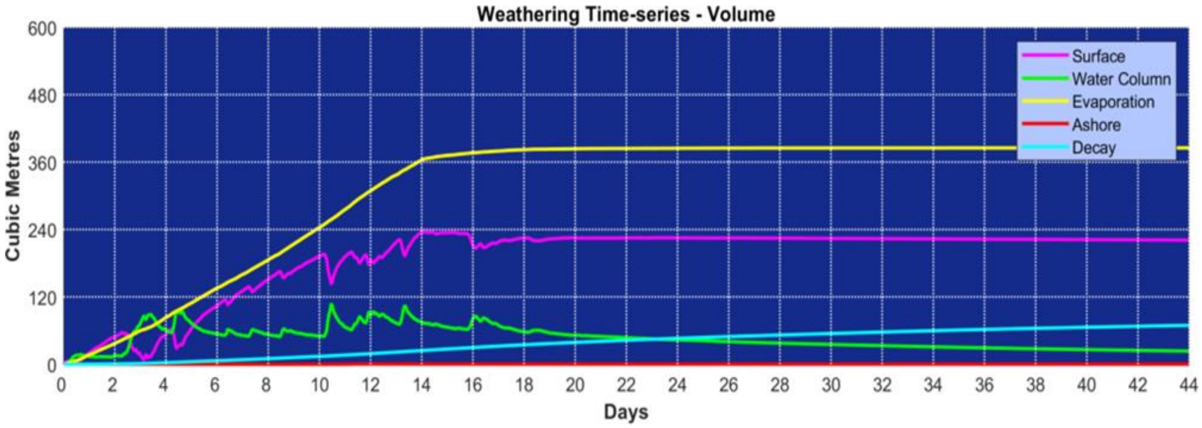

Figure 7-13 Predicted weathering and fates of Moonfish crude from modelling a single spill trajectory of a 4.41 kbbl LOWC release from Snapper Platform over 14 days, tracked for 44 days

7.7.2.3 Modelling Outputs – Stochastic and Deterministic

As described in Section 7.2.1.1, oil spill modelling predicts that the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, as a result of any spill. The PEA (refer Section 5.1) is derived from this data and is used for planning purposes to ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the EP.

Modelling is also used to inform specific impact or consequence assessments by understanding the location and extent of oil at different concentrations. There is no agreed exposure level below which environmental impacts will not occur, therefore outputs should not be interpreted as a boundary. However, mapping areas which could be moderately impacted by a spill is a useful tool for impact or consequence assessment.

The environmental sensitivities within the moderate threshold area are described in Table 7-25. The sensitivities outside of the mapped (moderately exposed) area but within the PEA are shown in Table 7-26.

,

Table 7-25 Environmental sensitivities with potential for moderate hydrocarbon exposure from a LOWC

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	**LOWC at West Kingfish Platform**	**LOWC at Cobia Platform**	**LOWC at Marlin A Platform**
Surface exposure	Moderate 10 g/m^2	Maximum distance from the release location was 150 km in an ENE direction. The zone of moderate exposure overlaps the following BIAs (99-100% probability): Birds • Black-browed Albatross - Foraging • Buller's Albatross – Foraging • Campbell Albatross - Foraging • Common Diving-petrel - Foraging • Indian Yellow-nosed Albatross- Foraging • Shy Albatross - Foraging • Wandering Albatross - Foraging Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark –Distribution & Breeding Upwelling East of Eden has 13% probability of exposure. Contact with nearshore waters at Lakes Entrance and Point Hicks (including the waters of the Point Hicks Marine National Park) is predicted with a probability of less than 10%.	Maximum distance from the release location was 2.4 km in an easterly direction. The zone of moderate exposure overlaps the following BIAs (26% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross • Short-tailed Shearwater - Foraging Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark –Distribution Does not extend into State waters or contact any National Parks and Reserves	Maximum distance from the release location was 31 km in a southerly direction. The zone of moderate exposure overlaps the following BIAs (100% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross • Short-tailed Shearwater (4% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark –Distribution • Upwelling East of Eden has 3% probability of exposure. • Does not extend into State waters or contact any National Parks and Reserves	Maximum distance from the release location was 59 km in an ENE direction. The zone of moderate exposure overlaps the following BIAs (100% probability): Birds • Antipodean Albatross – Foraging (14% probability) • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross • White-faced Storm Petrel – Foraging (14% probability) Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark –Distribution & Breeding (5% probability) Upwelling East of Eden has 100% probability of exposure. Contact with Victorian waters is predicted with a probability of 1%, however no contact with any National Parks and Reserves is predicted.
	High 100 g/m^2	-	-	-	Maximum distance from the release location was 7 km in a westerly direction. The zone of high exposure overlaps the following BIAs (70% probability): Birds • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross Marine mammals / shark • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark –Distribution

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
					Upwelling East of Eden has 70% probability of exposure.
Shoreline Exposure	Moderate 100 g/m^2	Shoreline contact at the moderate exposure threshold is predicted from Wilsons Promontory to Tuross Head (NSW), with probabilities ranging from less than 20% at the outer edge of the contact zone to between 80 and 90% along the east Gippsland coast. Note: several National Parks and Reserves lie along this coastline including Wilsons Promontory, Corner Inlet, Nooramunga, Gippsland Lakes, Lake Tyers, Cape Conran, Marlo, Croajingolong, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla. The minimum time before shoreline accumulation at the moderate threshold is approximately 2 days (in the Lakes Entrance, Seaspray area). The maximum length of shoreline exposed is 277 km (average 78 km).	None predicted from direct exposure or accumulation of surface or entrained hydrocarbons on shoreline.	Shoreline contact at the moderate exposure threshold is predicted along the far east Gippsland coast and into southern NSW with a probability of up to 15%. Note: The shoreline of Croajingolong, National Park has a probability of contact of 2%. The minimum time before shoreline accumulation at the moderate threshold is approximately 12 days (at Mallacoota, Cape Howe and the southern NSW coast). The maximum length of shoreline exposed is 12 km (average 6 km).	Shoreline contact at the moderate exposure threshold is predicted from Ninety Mile Beach to Tuross Head (NSW), with probabilities ranging from less than 10% at the outer edge of the contact zone to between 40 and 60% along the east Gippsland coast. Note: several National Parks and Reserves lie along this coastline including Gippsland Lakes, Lake Tyers, Cape Conran, Marlo, Croajingolong, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla. There is also a predicted 5% probability of contact with the shoreline of the Kent Group (TAS). The minimum time before shoreline accumulation at the moderate threshold is approximately 3 days (at Point Hicks and Gabo Island). The maximum length of shoreline exposed is 150 km (average 36.2 km).
	High 1000 g/m^2	Shoreline contact at the high exposure threshold is predicted from Wilsons Promontory to Tuross Head (NSW), with probabilities ranging from less than 10% at the outer edge of the contact zone to between 60 and 90% along the east Gippsland coast. Note: several National Parks and Reserves lie along this coastline including Wilsons Promontory, Corner Inlet, Nooramunga, Gippsland Lakes, Lake Tyers, Cape Conran, Marlo, Croajingolong, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla. The minimum time before shoreline accumulation at the high threshold is approximately 2 days. The maximum length of shoreline exposed is 99 km (average 33 km).	-	-	Shoreline contact at the high exposure threshold is predicted along the east Gippsland coast and into southern NSW with a probability of approximately 15%. The minimum time before shoreline accumulation at the high threshold is approximately 3 days (at Point Hicks and Gabo Island). The maximum length of shoreline exposed is 15 km (average 5.2 km).
In-water (dissolved) Exposure	Moderate 50ppb instantaneous	<u>0-10m water depth</u> The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to coastal receptors was only 1% at Marlo, Lakes Entrance and Lake Tyers Beach. The KEF: Upwelling East of Eden was the only KEF receptor exposed to in-water dissolved hydrocarbons (above the moderate threshold) with a low probability of 1%. Additionally, several BIAs were predicted to be exposed at the low threshold within the 0-10 m surface layer with a low probability of 1%: Pygmy blue whale – distribution and foraging, Southern right whale – migration, Shy albatross – foraging, White shark – distribution and foraging, Common diving petrel - foraging and the White-faced storm-petrel – foraging. <u>10-20m water depth</u> The greatest probability of in-water dissolved hydrocarbon exposure for the 10-20 m layer above the	<u>0-10m water depth</u> The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to coastal receptors ranged from 11% at Cape Howe / Mallacoota and the southern NSW coast to only 1-2% at Point Hicks and Croajingolong and Eurobodalla National Parks. Dissolved hydrocarbon at the moderate threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 21 and 13% respectively and contact Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks and Batemans Marine Park (NSW). Dissolved hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 10% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. KEFs potentially within the zone of moderate exposure include the Upwelling East of Eden KEF (94%), Big	<u>0-10m water depth</u> The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to coastal receptors ranged from 50 - 70% at Cape Howe / Mallacoota, Croajingolong and the southern NSW coast to less than 5% at the furthest reaches of exposure such as Lakes Entrance and Shoalhaven. Dissolved hydrocarbon at the moderate threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 95 and 78% respectively and contact Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans Marine Park (NSW). Dissolved hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 26% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. KEFs potentially within the zone of moderate exposure include Upwelling East of Eden (100%), followed by Big	<u>0-10m water depth:</u> The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to coastal receptors ranged from 80 - 90% at Cape Howe / Mallacoota, Croajingolong and the southern NSW coast to less than 7% at the furthest reaches of exposure such as Wilsons Promontory and Shoalhaven. Dissolved hydrocarbon at the moderate threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 100 and 96% respectively and contact Wilsons Promontory, Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans, Jervis Bay and Lord Howe Island Marine Parks (NSW). Dissolved hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 24% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
		low threshold was 1% predicted for the same receptors as the surface layer with the addition of Black browed albatross – foraging, Campbell albatross – foraging, Indian yellow-nosed albatross – foraging and Wandering albatross – foraging.	Horseshoe Canyon (6%), Canyons on the Eastern Continental Slope and Shelf rocky reefs (1%). AMPs: Beagle AMP (5%), East Gippsland AMP (3%), Flinders AMP (4%) and Freycinet AMP. (1%). Additionally, several BIAs were predicted to be exposed at the moderate threshold within the 0 – 10 m surface layer. The zone of moderate exposure potentially overlaps albatross, petrel and tern foraging BIAs (1-97%), and breeding BIAs (1-2%). Marine mammal / shark BIAs potentially in the zone of moderate exposure include (2-97%): Grey Nurse Shark (foraging and migration), Humpback Whale (foraging), Indo-Pacific / Spotted Bottlenose Dolphin (breeding), Pygmy Blue Whale (foraging and distribution), Southern Right Whale (migration), and White Shark (breeding, distribution and foraging). <u>10-20m water depth</u> Probability of exposure to seabirds is substantially lower than in 0-10 m water depth (below 38%). Upwelling East of Eden (38%) probability of being exposed. For the remaining receptors, the probabilities are similar to that within 0-10m depth.	Horseshoe Canyon (67%), Shelf rocky reefs (17%) and Canyons on the eastern continental slope (14%). AMPs: Beagle AMP (25%), East Gippsland AMP (31%), Flinders AMP (5%) and Jervis AMP (1%) may be exposed at moderate instantaneous thresholds Additionally, several BIAs were predicted to be exposed at the moderate threshold within the 0 – 10 m surface layer. A number of seabirds that forage near the LOWC location are predicted to have a 100% probability of exposure at moderate instantaneous dissolved hydrocarbon levels in 0-10m water depth: Short-tailed Shearwater, Shy Albatross, Wandering Albatross, and White-faced Storm-petrel. Also, Pygmy Blue Whale Southern Right Whale (migration), White Shark (distribution & foraging) were also predicted to have a 100% probability of exposure. Little Penguin & Wedge-tailed Shearwater (each 92%), Sooty Shearwater (52%), Flesh-footed Shearwater (28%), Crested Tern (24%), Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross & Wilsons Storm Petrel (each 21%) showed a lower probability during foraging, while Little Penguin (breeding: 16%), Crested Tern (breeding: 15%), Indo-Pacific/Spotted Bottlenose Dolphin (breeding: 83%), Humpback Whale (foraging: 82%), Grey Nurse Shark (foraging: 63%), Southern Right Whale (connecting Habitat: 5%), Short-tailed Shearwater (breeding: 3%), Grey Nurse Shark (migration: 61%), White Shark (breeding: 25%), White-faced Storm-petrel (breeding: 39%) also showed a lower probability. <u>10-20m water depth</u> In 10-20 m depth, the pattern is quite similar.	There is a 1% probability of contact at the moderate threshold with the Gippsland Lakes RAMSAR site. KEF Upwelling East of Eden showed 100% probability at moderate levels in 0-10m water depth. Big Horseshoe Canyon (26%), Canyons on the Eastern Continental Slope (23%), Shelf rocky reefs (27%) and Lord Howe seamount chain (1%). AMPs: East Gippsland AMP (34%), Beagle AMP (25%), Flinders AMP (4%), Jervis AMP (3%) and Freycinet and Central Eastern AMPs (1%). Additionally, several BIAs were predicted to be exposed at the moderate threshold within the 0 – 10 m surface layer. A number of seabirds that forage near the LOWC location are predicted to have a 100% probability of exposure at moderate instantaneous dissolved hydrocarbon levels in 0-10m water depth: Antipodean Albatross, Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Shy Albatross, Wandering Albatross, White-faced Storm-petrel, Wedge-tailed Shearwater, Little Penguin, Common Diving-petrel, Short-tailed Shearwater, Buller's Albatross. Also, Pygmy Blue Whale (distribution & foraging), Southern Right Whale (migration), White Shark (distribution & foraging), Humpback Whale (foraging), Indo-Pacific/Spotted Bottlenose Dolphin (breeding) and Grey Nurse Shark (migration) were also predicted to have a 100% probability of exposure. <u>10-20m water depth</u> Patterns of exposure to moderate instantaneous dissolved hydrocarbon levels were comparable in 10-20 a water depth. The probability of exposure in 20-30 m water depth was below 47% and was largely limited to a number of foraging seabirds, and other BIAs near the LOWC location. <u>20-30m water depth</u> East Gippsland, Beagle, Flinders, Jervis, Lord Howe, Central Eastern, and Freycinet AMP were predicted to have a probability less than 9% for instantaneous exposure to moderate hydrocarbons in 20-30 m water depth. Victoria (40%), NSW (35%) and Tasmania State Waters (7%) showed lower probability of exposure within 20-30 m water depth than in water depth between 0-20m. Cape Howe / Mallacoota (21%), Croajingolong (15%) and the southern NSW coast (33%) have a lower likelihood of exposure in 20-30 m water depth, with less than 5% for the furthest reaches of exposure such as Ninety Mile Beach and Shoalhaven.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)	
		LOWC at Tuna Platform	LOWC at Snapper Platform
Surface exposure	Moderate 10 g/m^2	Maximum distance from the release location was 16 km in a WSW direction. The zone of moderate exposure overlaps the following BIAs (100% probability): <u>Birds</u> • Black-browed Albatross • Buller's Albatross • Campbell Albatross • Common Diving-petrel • Indian Yellow-nosed Albatross • Shy Albatross • Wandering Albatross <u>Marine mammals</u> • Pygmy Blue Whale - Distribution & Foraging • Southern Right Whale – Migration • White Shark –Distribution Upwelling East of Eden has 100% probability of exposure. Does not extend into State waters or contact any National Parks and Reserves	No surface exposure predicted. Note (J Bernard 2020, pers. comm., 27 May): The relatively low release rate modelled (2m^3/hour) means the crude is able to spread (or entrain) more easily and quickly; and Moderate to strong wind conditions facilitate rapid dispersion and/or entrainment of the surface oil immediately after being released.
	High 100 g/m^2	-	-
Shoreline Exposure	Moderate 100 g/m^2	Only the coastline at the border of Victoria and NSW (5% probability) recorded shoreline contact above the moderate threshold. The minimum time before shoreline accumulation at the moderate threshold is more than three weeks. The maximum length of shoreline exposed is 2 km.	Shoreline contact at the moderate exposure threshold is predicted from the Curtis Islands in Bass Strait to Ulladulla (NSW), with probabilities ranging from 1 - 2% at the outer edge of the contact zone to between 15 and 25% along the east Gippsland coast. Note: several National Parks and Reserves lie along this coastline including Cape Conran and Croajingolong. The minimum time before shoreline accumulation at the moderate threshold is approximately 3.5 days (at Point Hicks). The maximum length of shoreline exposed is 66 km (average 11 km).
	High 1000 g/m^2	-	Shoreline contact at the high exposure threshold is predicted to occur at Lakes Entrance and in far East Gippsland / southern NSW with probabilities in the range of only 1 – 3%. The minimum time before shoreline accumulation at the high threshold is approximately 6.5 days (at Gabo Island). The maximum length of shoreline exposed is 5 km (average 2 km).
In-water (dissolved) Exposure	Moderate 50ppb instantaneous	<u>0-10m water depth</u> The probability of in-water dissolved hydrocarbon exposure at the moderate threshold to coastal receptors ranged from approximately 50% at Cape Howe /	No exposure predicted.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)	
		LOWC at Tuna Platform	LOWC at Snapper Platform
		Mallacoota and the southern NSW coast to only 1-2% at Shoal Haven and Woodside Beach. Dissolved hydrocarbon at the low threshold is predicted to encroach upon Victorian and NSW state waters with likelihoods of 82 and 59% respectively and contact Point Hicks and Cape Howe Marine National Parks, Beware Reef Marine Sanctuary and Batemans Marine Park (NSW). Dissolved hydrocarbon is predicted to encroach upon Tasmanian waters with a likelihood of 4% including the waters surrounding the terrestrial National Parks and Reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island. KEFs potentially within the zone of moderate exposure include the Upwelling East of Eden KEF (94%), Big Horseshoe Canyon (6%), Canyons on the Eastern Continental Slope and Shelf rocky reefs (1%). AMPs: Beagle AMP (3%), East Gippsland AMP (15%) and Flinders and Freycinet AMPs. (1%). Additionally, several BIAs were predicted to be exposed at the moderate threshold within the 0 – 10 m surface layer. A number of seabirds that forage near the LOWC location are predicted to have a 95 - 99% probability of exposure at moderate instantaneous dissolved hydrocarbon levels in 0-10m water depth: Antipodean Albatross, Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Shy Albatross, Wandering Albatross, White-faced Storm-petrel, Common Diving-petrel, and Buller's Albatross. Also, Pygmy Blue Whale (distribution & foraging), Southern Right Whale (migration) and White Shark (distribution & foraging) were also predicted to have a 99% probability of exposure. Little Penguin & Wedge-tailed Shearwater (each 88%), Sooty Shearwater (42%), Flesh-footed Shearwater, Black Petrel and Crested Tern (both 16%), Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross & Wilsons Storm Petrel (each 12%) showed a lower probability during foraging, while Little Penguin (breeding: 10%), Crested Tern (breeding: 6%), Indo-Pacific/Spotted Bottlenose Dolphin (breeding: 64%), Humpback Whale (foraging: 82%), Grey Nurse Shark (foraging: 60%), Grey Nurse Shark (migration: 52%), White Shark (breeding: 8%), White-faced Storm-petrel (breeding: 21%) also showed a lower probability. <u>10-20m water depth</u> Pattern is similar for moderate exposure at the 10-20m water depth, although all BIAs are predicted to have less than 64% probability of moderate exposure and AMPs all less than 7%.	

Table 7-26 Environmental sensitivities outside of the moderately exposed area but within the PEA from a LOWC

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
Surface Exposure	Low 1 g/m^2	Zone of low exposure extends approx. 460 km from release location in a predominantly ENE direction. There is a 40 to 80% probability of contact with nearshore waters along the Gippsland Coast between Seaspray and Cape Howe, including waters of Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks and Beware Reef Marine National Sanctuary. The minimum time before Victorian nearshore waters are exposed to visible surface oil is approximately 1.5 days. There is a predicted 27% probability of contact with the Gippsland Lakes Ramsar wetland, and predicted 7 and 47% probabilities of contact with the Beagle and East Gippsland AMPs respectively. There is an approx. 10% probability of contact with NSW nearshore waters as far north as Ulladulla.	Maximum distance extends approx. 43 km from release location in a predominantly south westerly direction. Area of low exposure overlaps (100%) with foraging bird BIAs (Black-browed Albatross, Buller's Albatross, Campbell Albatross, Common Diving-petrel and Indian Yellow-nosed Albatross, Short-tailed Shearwater, Shy Albatross, Wandering Albatross), Pygmy Blue Whale foraging and distribution BIAs, Southern Right Whale migration BIA and White Shark distribution BIA. There is also a 31% probability for overlap with the White-faced Storm-petrel foraging BIA. There is a 12% probability of surface exposure within the Upwelling East of Eden KEF. Does not extend into State waters or contact any National Parks and Reserves	Maximum distance extends approx. 239 km from release location in a predominantly north easterly direction. BIAs affected by moderate exposure (described in Table 7-25) will also be affected (100%) by low surface exposure. Additional bird foraging BIAs potentially within the zone of low exposure include Antipodean Albatross (48%), Little penguin (13%), Short-tailed shearwater (95%), Sooty Shearwater (1%), Wedge-tailed Shearwater (21%), and White-faced Storm-petrel (44%). Additional marine mammal/shark BIAs include: Grey Nurse Shark migration (1%), Humpback Whale foraging (8%), White Shark foraging (9%). There is a 96% probability of surface exposure within the KEF Upwelling East of Eden. Does not extend into State waters or contact any National Parks and Reserves	Maximum distance extends approx. 382 km from release location in a predominantly north easterly direction. There is a < 20% probability of contact with nearshore waters along the Gippsland Coast between Seaspray and Cape Howe, including waters of Point Hicks Marine National Park and Beware Reef Marine Sanctuary. There is also a predicted 5% probability of contact with the Gippsland Lakes Ramsar wetland The minimum time before Victorian nearshore waters are exposed to visible surface oil is approximately 3 days (at Point Hicks). There is an approx. 40% probability of contact with NSW waters as far north as Ulladulla, including Batemans Marine Park. Likelihood of contact with Tasmanian waters is predicted at 2% including Kent Group National Park and Marine Reserve. East Gippsland AMP is the only AMP predicted to be contacted at the low surface threshold (4%). 100% probability of surface exposure predicted for albatross species BIAs, White-face Storm petrel BIA and Common-diving petrel BIA, as well as Pygmy Blue Whale, White Shark and Southern Right Whale BIAs. The Short-tailed Shearwater BIA has a 98% probability and the Humpback Whale a 90% probability. The Black Petrel, Crested Tern, Flesh-footed Shearwater, Great-winged Petrel and Northern Giant Petrel BIAs have a 5% probability of being exposed during foraging and Wilsons Storm Petrel migration BIA (5%), while the Little Penguin Foraging (32%) and Breeding (4%) BIA may also be exposed. The Indo-Pacific/Spotted Bottlenose Dolphin Breeding BIA has a 26% probability of being exposed. There is a 100% probability of surface exposure within the KEF Upwelling East of Eden, 5% for the Canyons on the eastern continental slope and 3% for Big Horseshoe Canyon.
Shoreline Exposure	Low 10g/m^2	Shoreline contact at the low exposure threshold is predicted from Wilsons Promontory to Montague Island, with probabilities ranging from less than 20% at the outer edge of the contact zone to between 80 and 90% along the east Gippsland coast. Note: several National Parks and Reserves lie along this coastline including Wilsons Promontory, Corner Inlet, Nooramunga, Gippsland Lakes, Lake Tyers, Cape Conran, Marlo and Croajingolong. Minimum time for visible oil to shore is approx. 1.5 days. Maximum volume of oil ashore is approx. 3000 m^3 (approximately 15% of the total volume) and maximum length of shoreline exposed is 286 km (average 83 km)	None predicted from direct exposure or accumulation of surface or entrained hydrocarbons on shoreline.	Shoreline contact at the low exposure threshold is predicted only in East Gippsland and the southern NSW coast. The highest probability of contact (23%) by shoreline oil was predicted for Cape Howe/Mallacoota. The minimum time for visible oil to shore was 210 hours (8.75 days). The maximum volume of oil ashore was 46 m^3 (289 bbl) and the maximum length of shoreline exposed 17 km (average 9 km).	Shoreline contact at the low exposure threshold is predicted from Wilsons Promontory to Montague Island, with probabilities ranging from approximately 5% at the outer edge of the contact zone to between 30 and 60% along the east Gippsland and southern NSW coasts. Note: several National Parks and Reserves lie along this coastline including Wilsons Promontory, Corner Inlet, Nooramunga, Gippsland Lakes, Lake Tyers, Cape Conran, Marlo and Croajingolong in Victoria, and Nadgee, Ben Boyd, Bournda, and Mimosa Rocks in NSW. There is also a predicted 5% probability of contact with the Kent Island Group (and National Park).

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
					The maximum probability of any shoreline contact is 94% on the east Gippsland coast, with a minimum time for visible hydrocarbons ashore of 62 hrs. The maximum predicted volume ashore is 563 m^3 with a maximum length 0f shoreline exposed of 221 km (average: 60 km).
In-water (dissolved) Exposure	Low 10ppb instantaneous	0-10m water depth The probability of in-water dissolved hydrocarbon exposure at the low threshold to coastal receptors varied from 1% at Croajingolong, approx. 20% at Lakes Entrance to 37% at Point Hicks. Contact with NSW waters was predicted with a likelihood of 1%. The KEF: Upwelling East of Eden was the only KEF receptor exposed to in-water dissolved hydrocarbons (above the low threshold) with a probability of 37% and a predicted 13% probability of contact with the Gippsland Lakes Ramsar wetland. Additionally, several BIAs were predicted to be exposed at the low threshold within the 0-10 m surface layer with a probability of 37%: Pygmy blue whale – distribution and foraging, Southern right whale – migration, Shy albatross – foraging, White shark – distribution and foraging and the White-faced storm-petrel– foraging. The greatest probability of in-water dissolved hydrocarbon exposure for the 10-20 m layer above the low threshold was 23% predicted for the same receptors as the surface layer with the addition of Black browed albatross – foraging, Campbell albatross – foraging, Common diving-petrel – foraging, Indian yellow-nosed albatross – foraging and Wandering albatross – foraging. 10-20m water depth In the 10-20 m depth layer, exposure pattern is quite similar, however no contact with NSW waters is predicted.	0-10m water depth Victoria State Waters (88%), NSW State Waters (75%) and Tasmania State Waters (37%) may be exposed to low threshold instantaneous dissolved hydrocarbons including Cape Howe, Point Hicks and Ninety Mile Beach MNPs, Beware Reef Marine Sanctuary, Kent Group NP and Marine Reserve (TAS) and Batemans and Jervis Bay Marine Parks (NSW). The probability of in-water dissolved hydrocarbon exposure at the low threshold to coastal receptors varied from 1-3% at Mcloughlin's Beach, Lake Tyers Beach, Corringle , Woodside Beach and Shoal Haven, approx. 10 - 20% at Sydenham Inlet, Marlo, Cape Conran and Eurobodalla to approx. 60 - 70% at Point Hicks, Croajingolong, Cape Howe / Mallacoota and Bega Valley (southern NSW). Also Beagle AMP (37%), East Gippsland AMP (25%), Flinders AMP (4%), Freycinet & Jervis AMPs (1%). The KEF Upwelling East of Eden KEF recorded a 100% probability of low dissolved hydrocarbon exposure, followed by Big Horseshoe Canyon (64%), Canyons on the eastern continental slope (13%), and Shelf rocky reefs (21%). At the surface layer (0-10 m), the probability of dissolved hydrocarbon exposure at the low threshold to receptors is 100% for the a number of sea birds frequenting the area near the LOWC event during foraging: Antipodean Albatross, Black-browed Albatross, Buller's Albatross, Campbell Albatross, Common Diving-petrel, Indian Yellow-nosed Albatross, Short-tailed Shearwater, Shy Albatross, Wandering Albatross, White-faced Storm-petrel. The following BIAs have a 20-99% probability during foraging: Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross, Black Petrel, Crested Tern, Flesh-footed Shearwater, Little Penguin Wedge-tailed Shearwater). The White Shark (distribution), Pygmy Blue Whale (foraging & distribution) and Southern Right Whale (migration) BIAs also have a 100% probability. The following BIAs also have a high probability of exposure: White Shark (foraging: 99%; breeding: 25%), Humpback Whale (foraging: 83%), Indo-Pacific/Spotted Bottlenose Dolphin – (breeding: 77%), Grey Nurse Shark (foraging: 66%; migration: 62%), Sooty Shearwater (foraging: 62%), White-faced Storm-petrel (breeding: 39%), Little Penguin (breeding: 23%),	0-10m water depth Victoria State Waters (100%), NSW State Waters (97%) and Tasmania State Waters (43%) may be exposed to low threshold instantaneous dissolved hydrocarbons including Cape Howe, Point Hicks, Wilsons Promontory and Ninety Mile Beach MNPs, Beware Reef Marine Sanctuary, Kent Group NP and Marine Reserve (TAS) and Batemans and Jervis Bay Marine Parks (NSW). There is also 6% probability of contact with Gippsland Lakes Ramsar site. The probability of in-water dissolved hydrocarbon exposure at the low threshold to coastal receptors varied from 1% at Wilsons promontory, and Mc Loughlin's Beach, approx. 10-15% at Lakes Entrance, Lake Tyres Beach and Shoal Haven (NSW) to >90% at Point Hicks, Croajingolong, Cape Howe/Mallacoota and Bega Valley (southern NSW). Also East Gippsland AMP (62%), Beagle AMP (41%), Flinders AMP (28%), Jervis AMP (8%), Freycinet AMP (6%) and Central Eastern and Lord Howe AMPs (both 1%). Additionally, the KEF Upwelling East of Eden recorded a 100% probability of low dissolved hydrocarbon exposure. Big Horseshoe Canyon KEF (95%), Shelf rocky reefs (57%) and Canyons on the eastern continental slope (53%) showed a lower probability of exposure. The greatest probability of low dissolved hydrocarbon exposure in the 0-10 m layer was 100%, predicted for the foraging seabirds near the LOWC location: Antipodean Albatross, Black-browed Albatross, Buller's Albatross, Campbell Albatross, Common Diving-petrel, Indian Yellow-nosed Albatross, Little Penguin, Short-tailed Shearwater, Shy Albatross, Wandering Albatross, Wedge-tailed Shearwater, and White-faced Storm-petrel, as well as Humpback Whale (foraging), Pygmy Blue Whale (distribution and foraging), Southern Right Whale – (migration), White Shark (distribution and foraging). 10-20m water depth In the 10-20 m depth layer, exposure pattern is quite similar.	0-10m water depth Victoria and NSW State Waters have a 100% probability, with 38% for Tasmania State Waters including Cape Howe, Point Hicks, Wilsons Promontory, Corner Inlet, Nooramunga and Ninety Mile Beach MNPs, Beware Reef Marine Sanctuary, Kent Group NP and Marine Reserve (TAS) and Batemans and Jervis Bay Marine Parks and Booderee National Park (NSW). There is also a predicted 52% probability of contact with Gippsland Lakes Ramsar wetland and 36% for Corner Inlet Ramsar wetland. Coastal receptors: Bega Valley (southern NSW) Cape Howe / Mallacoota, Croajingolong and Point Hicks showed a 100% probability, followed Sydenham Inlet (86%), Cape Conran (80%), Marlo (78%), Eurobodalla (57%) (NSW), Corringle (52%), Lake Tyers Beach (37%), Lakes Entrance (32%), Shoal Haven (30%) (NSW), Ocean Grange (15%), Snake Island (14%), Wilsons Promontory (14%), Clonmel Island (13%), Corner Inlet (11%) and Golden Beach (10%). Seaspray, Woodside Beach, McLoughlins Beach and Port Welshpool all had less than 10% probability. NSW Central Coast, Northern Beaches, Wollongong, Kiama and Sutherland Shire each had less than 10% probability. Also, East Gippsland (86%), Beagle (42%), Jervis (20%) and Flinders AMP (17%) may be exposed, with Freycinet, Lord Howe, Central Eastern and Hunter AMP having less than 4% probability. The KEF Upwelling East of Eden KEF recorded a 100% probability of low dissolved hydrocarbon exposure in 0-10m water depth, followed by Big Horseshoe Canyon (84%), Canyons on the eastern continental slope (53%), Shelf rocky reefs (69%), Lord Howe seamount chain and Tasman Front and eddy field (both 4%), Tasmantid seamount chain (2%) and Seamounts south and east of Tasmania (1%). The greatest probability of low dissolved hydrocarbon exposure in the 0-10 m layer was 100%, predicted for the foraging seabirds near the LOWC location: Antipodean Albatross, Black-browed Albatross, Buller's Albatross, Campbell Albatross, Common Diving-petrel, Indian Yellow-nosed Albatross, Little Penguin, Short-tailed Shearwater, Shy Albatross, Wandering Albatross, Wedge-tailed Shearwater, White-faced Storm-petrel. Additionally, the following seabirds had a 95-68% probability of being exposed during foraging in 0-10m water depth: Sooty Shearwater, Black Petrel, Flesh-

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
			Crested Tern (breeding: 22%), Wilsons Storm Petrel (migration: 20%) 10-20m water depth Within 10-20 m water depth, the exposure pattern is very similar		footed Shearwater, Crested Tern, Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross. And the following seabird BIAs: Wilsons Storm Petrel (migration), White-faced Storm-petrel (breeding), Crested Tern (breeding), Little Penguin (breeding). A number of other seabird BIAs had 1-4% probability of exposure. Other BIAs with 100% probability of exposure include: Indo- Pacific/Spotted Bottlenose Dolphin (breeding), Grey Nurse Shark (migration), Humpback Whale (foraging), Pygmy Blue Whale (distribution), Pygmy Blue Whale (foraging), Southern Right Whale (migration), White Shark (distribution), White Shark (foraging), with Grey Nurse Shark (foraging: 99%) and White Shark (breeding: 82%) a slightly lower probability of exposure. Humpback Whale (migration), and Southern Right Whale (connecting Habitat) showed a 4% probability. . 10-20m water depth In the 10-20 m depth layer, the exposure pattern is quite similar to the top layer. 20-30m water depth In 20-30 m water depth, the exposure pattern is also quite similar to the layers above however probabilities are generally lower: Victoria State Waters are predicted to have a 94% probability of exposure, 87% for NSW State Waters and 26% for Tasmania State waters.
In-water (entrained) Exposure	Low 10ppb instantaneous	Note, although low entrained hydrocarbon exposure was predicted in the 10-20 m depth layer, no receptors recorded any probability of exposure above the low threshold. No exposure at any of the levels was predicted below 20 m. 0-10m water depth At the surface layer (0-10 m), the probability of low exposure to the KEF Upwelling East of Eden, Point Hicks Marine National Park, Beware Reef Marine Sanctuary and Cape Conran, Croajingolong and Sydenham Inlet coastal receptors was 100%. Additionally, several BIAs were predicted to be exposed at the low threshold with probabilities of 100%: Little penguin – foraging, Pygmy blue whale – distribution and foraging, Southern right whale – migration, White shark – breeding and distribution as well as several bird species. Contact with NSW and Tasmanian waters was predicted with likelihoods of 91% and 15% respectively. Contact with Flinders, Beagle and East Gippsland AMPs was predicted with likelihoods of 2, 22 and 40% respectively.	0-10m water depth The greatest probability of entrained hydrocarbon exposure at the low threshold was 100%, predicted during seabird foraging near the LOWC location: Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Short-tailed Shearwater, Shy Albatross, Wandering Albatross, Common Diving-petrel, Antipodean Albatross and White-faced Storm-petrel. 100% probability is also predicted for the following BIAs when near the LOWC location: Pygmy Blue Whale (distribution/foraging), Southern Right Whale (migration), White Shark (distribution/foraging). The flowing seabird BIAs have a probability below 10% during foraging near the LOWC location: Little Penguin, Wedge-tailed Shearwater, Sooty Shearwater, Black Petrel, Flesh-footed Shearwater, Crested Tern, Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross, as well as following BIAs: Little Penguin (breeding), Wilsons Storm Petrel (migration) and White-faced Storm-petrel (breeding). The Humpback Whale (foraging), Grey Nurse Shark (migration/foraging) and Indo-Pacific/Spotted Bottlenose Dolphin (breeding) have 91-98% probability,	0-10m water depth The greatest probability of entrained hydrocarbon exposure at the low threshold was 100%, predicted during seabird foraging near the LOWC location: White-faced Storm-petrel, Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Shy Albatross, Wandering Albatross, Antipodean Albatross, Buller's Albatross, Short-tailed Shearwater, Wedge-tailed Shearwater, Little Penguin, Sooty Shearwater, as well as Common Diving-petrel during breeding. 100% probability is also predicted for the following BIAs when near the LOWC location: Pygmy Blue Whale (distribution/foraging), Southern Right Whale (migration), White Shark (distribution/foraging), Humpback Whale (foraging), Grey Nurse Shark (migration/foraging). The following seabirds had an 81-83% probability when foraging near the LOWC location: Black Petrel, Flesh-footed Shearwater, Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross (83% each), Crested Tern (81%). And the following during breeding: Little Penguin (79%), Crested Tern (67%), White-faced Storm-petrel (96%). And Wilsons Storm Petrel during migration (83%).	0-10m water depth A number of seabirds foraging near the LOWC location have a 100% probability of exposure: White-faced Storm-petrel, Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Shy Albatross, Wandering Albatross, Antipodean Albatross, Buller's Albatross, Short-tailed Shearwater, Wedge-tailed Shearwater, Little Penguin, Common Diving-petrel, Sooty Shearwater, as well as White-faced Storm-petrel during breeding. Black Petrel, Flesh-footed Shearwater, Crested Tern (88% each), Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel), White-capped Albatross (85% each) also have a high probability of exposure, as has Wilsons Storm Petrel (migration: 85%), and Little Penguin and Crested Tern (87% each) during breeding. The following seabirds had less than 8% probability when foraging near the LOWC location: Black-winged Petrel, Common Noddy, Grey Ternlet, Little Shearwater, Masked Booby, Providence Petrel, Red-tailed Tropicbird, Kermadec Petrel, Sooty Tern, Black Noddy, White-bellied Storm Petrel, White Tern. And Common Noddy, Black Noddy, Flesh-footed Shearwater, Grey Ternlet, Little Shearwater, Masked

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
			while Southern Right Whale (connecting Habitat) has 18% probability. East Gippsland, Beagle and Flinders AMP have a 43-79% probability, with Freycinet and Jervis AMP 8-12% probability. KEF Upwelling East of Eden has 100% probability, followed by Big Horseshoe Canyon (91%) and Shelf rocky reefs 63% and Canyons on the eastern continental slope (55%). Victoria (98%), NSW (91%) and Tasmania State Waters (47%) have a high probability of being exposed. Marine Parks: Cape Howe 96%), Point Hicks 95%), Batemans 62%), Kent Group (47%), Beware Reef 32%), Wilsons Promontory (10%), Ninety Mile Beach (8%), Jervis Bay (7%), Booderee (6%) and Gippsland Lakes (1%). The following coastal receptors have between 79-94% probability of exposure: Croajingolong, Cape Howe / Mallacoota, Point Hicks, and Bega Valley (southern NSW), Followed by Cape Conran (38%), Marlo (36%), Eurobodalla (32%) (NSW), Corringle (32%), Shoal Haven (NSW) (28%), Lake Tyers Beach (18%), Lakes Entrance (West), Ocean Grange, and Golden Beach (: 11% each), Wilsons Promontory (10%), Seaspray (9%), Woodside Beach (7%), Lakes Entrance, Clonmel Island and McLoughlins Beach (5% each). <u>10-20m water depth</u> The foraging BIAs for the Black-browed Albatross, Bullers Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Wandering Albatross, Common Diving-petrel and Shy Albatross, the Pygmy Blue Whale distribution/foraging BIAs, White Shark distribution BIA and the KEF Upwelling East of Eden all had a 12% probability of low instantaneous entrained exposure in 10-20 m water depth.	The Black-faced Cormorant (25%), White-fronted Tern (19%) and Gould's Petrel (5%) have a lower probability of exposure during foraging, as has Short-tailed Shearwater during breeding (27%). The White Shark (breeding: 64%; Aggregation: 5%), Southern Right Whale (connecting Habitat: 30%), Humpback Whale (migration: 6%) and Indo-Pacific/Spotted Bottlenose Dolphin (foraging: 3%) may be exposed to low instantaneous entrained hydrocarbons in 0-10m water depth. East Gippsland (100%), Flinders (74%), and Beagle AMP (53%) are likely to be exposed, with lower probability for Jervis (37%), Freycinet 18%), Hunter (6%) and Central Eastern AMP (2%). Upwelling East of Eden and Big Horseshoe Canyon KEF have 100% probability of exposure, followed by Canyons on the eastern continental slope (83%), Shelf rocky reefs (80%), Tasman Front and eddy field (18%) and Seamounts South and east of Tasmania 14%). Victoria State Waters have a 100% probability of exposure, followed by NSW (99%) and Tasmania State Waters (52%). Marine Parks: Point Hicks (99%), Cape Howe (99%), Beware Reef (77%), Batemans (66%) and Kent Group (52%) have 52-100% probability of exposure, followed by Jervis Bay (28%), Booderee (22%), Gippsland Lakes (21%), Ninety Mile Beach 17%) and Arthur Bay CA (22%). Wilsons Promontory, Port Stephens - Great Lakes, Flood Plain Lower Ringarooma River, Corner Inlet Marine and Coastal Park. Nooramunga Marine and Coastal Park, Corner Inlet and Cape Portland CA have less than 9% probability of exposure. The following coastal receptors, Croajingolong (West: 99%; East: 93%), Cape Howe / Mallacoota 98%), Bega Valley 98%), Cape Conran (81%), Marlo (70%), Eurobodalla (52%) and Corringle (46%) are likely to be exposed, followed by Lake Tyers Beach (33%), Ocean Grange (27%), Golden Beach (27%), Lakes Entrance (22-24%), McLoughlins Beach (17%) and Clonmel Island (13%). The NSW Central Coast, Northern Beaches, Kiama, Mid-Coast, Lake Macquarie and Newcastle have less than 9% probability of exposure. <u>10-20m water depth</u> The pattern is similar in 10-20m water depth to that in 0-10m water depth, although at lower probability. Victoria State Waters have a 96% probability of exposure, followed by NSW (55%) and Tasmania State Waters (32%). Upwelling East of Eden has 100% probability, followed by Big Horseshoe Canyon (72%), Canyons on the	Booby, Providence Petrel, Red-tailed Tropicbird, Black-winged Petrel, during breeding. 100% probability is also predicted for the following BIAs when near the LOWC location: Pygmy Blue Whale (distribution/foraging), Southern Right Whale (migration), White Shark (distribution/foraging), Humpback Whale (foraging), Indo-Pacific/Spotted Bottlenose Dolphin (breeding), Grey Nurse Shark (migration) and Grey Nurse Shark (foraging), followed by White Shark (breeding: 95%) and Humpback Whale (migration: 10%). East Gippsland AMP has 100% probability of exposure, followed by Flinders 60%), Jervis (59%), Beagle 48%), Freycinet (21%), Towra Point (13%), Central Eastern (10%), Lord Howe (8%), Hunter AMP (7% and North Sydney Harbour (3%). KEF Upwelling East of Eden has 100% probability of exposure, followed by Big Horseshoe Canyon (98%), Shelf rocky reefs (88%), Canyons on the eastern continental slope (85%), Tasman Front and eddy field 18%). Tasmantid seamount chain and Lord Howe seamount chain has less than 8% probability. Victoria and NSW State Waters have 100% probability of exposure to low threshold instantaneous entrained hydrocarbons, with 43% for Tasmania State Waters. Marine Parks: Point Hicks & Cape Howe MNP, have 100% probability, followed by Beware Reef (95%), Batemans (87%), Jervis Bay 59%), Gippsland Lakes (40%), Kent Group (40%), Booderee (38%) and Ninety Mile Beach (35%). Wilsons Promontory, Corner Inlet, Nooramunga Marine and Coastal Park, Shallow Inlet Marine and Coastal Park, Bunurong, Port Stephens - Great Lakes, Lord Howe Island, East Coast Cape Barren Island Lagoons, and Elizabeth and Middleton Reefs Marine National Nature Reserve are below 16% probability. The following coastal receptors, Croajingolong, Cape Howe / Mallacoota, Point Hicks, and Bega Valley (southern NSW) have 100% probability. Sydenham Inlet (96%), Cape Conran (94%), Marlo (90%), Eurobodalla (73%), Shoal Haven (69%), Corringle (68%), Lake Tyers Beach (55%), Lakes Entrance (46%) Ocean Grange (41%), Golden Beach (34%), Kiama (28%), Seaspray (25%), Wollongong (25%) and Woodside Beach (20%) may be exposed, with 19% or less for Clonmel Island, McLoughlins Beach, Wilsons Promontory, Port Welshpool, Waratah Bay, Corner Inlet, Snake Island, Cape Liptrap, NSW Central Coast Southerland Shire Randwick, Waverly, Woollahra, Northern Beaches, Lake Macquarie, Newcastle, Port Stephens, Venus Bay, NSW Mid-Coast and Kilcunda. <u>10-20m water depth</u>

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)			
		LOWC at Seahorse Subsea Facility	LOWC at West Kingfish Platform	LOWC at Cobia Platform	LOWC at Marlin A Platform
				eastern continental slope (29%) and Shelf rocky reefs (11%). East Gippsland AMP has 48% probability, followed by Beagle (31%) and Flinders AMP (11%).	In the 10-20 m depth layer, the extent of instantaneous entrained hydrocarbon levels at low threshold is substantially less than in 0-10m water depth. Exposure by seabirds during foraging is less than 80%, with many seabird BIAs below 12% probability. Pygmy Blue Whale (foraging/distribution), Southern Right Whale (migration), White Shark (foraging/distribution) are below 80%, with 5-63% for Humpback Whale (foraging), Grey Nurse Shark (foraging/migration, and Indo-Pacific/Spotted Bottlenose Dolphin – and White Shark during breeding. Upwelling East of Eden KEF has an 80% probability for exposure, flowed by Canyons on the eastern continental slope (10%), Shelf rocky reefs (4%), and Big Horseshoe Canyon (2%). Victoria State Waters have a 57% probability of exposure in 10-20 m water depth, with 36% for NSW and 3% forTasmania State Waters.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)	
		LOWC at Tuna Platform	LOWC at Snapper Platform
Surface Exposure	Low 1 g/m^2	Maximum distance extends approx. 198 km from release location in a predominantly ENE direction. There is only a 1% probability of contact with Victorian waters. 100% probability of surface exposure predicted for albatross species BIAs (Black-browed Albatross, Bullers Albatross, Campbell Albatross, Common Diving-petrel, Indian Yellow-nosed Albatross, Shy Albatross, Wandering Albatross), as well as Pygmy Blue Whale and Southern Right Whale and White Shark distribution BIAs. The Antipodean Albatross (98%), White-faced Storm-petrel (98%), and Short-tailed Shearwater (5%) may be exposed during foraging, as is the White Shark Breeding BIA (6%). The KEF Upwelling East of Eden demonstrated a 100% probability of low surface hydrocarbon exposure.	Maximum distance extends approx. 984 km from release location in an ENE direction. There is up to 14% probability of contact with nearshore waters along the Gippsland coast, more likely in the east (Cape Howe/Mallacoota, Gabo Island) including waters of Point Hicks and Cape Howe Marine National Parks. There is less than 5% likelihood of contact with nearshore waters of Bega Valley (southern NSW) including Batemans Marine Park. The minimum time before Victorian and NSW nearshore waters are exposed to visible surface oil is approximately 4.5 and 6 days respectively. There is a predicted 9% probability of contact with the East Gippsland AMP. The KEF Upwelling East of Eden demonstrated a 99% probability of contact, Canyons on the eastern continental shelf 2% and Big Horseshoe Canyon and Tasman Front and eddy field 1% each.
Shoreline Exposure	Low 10g/m^2	Only Lakes Entrance, Cape Howe / Mallacoota and southern NSW (each 5% or less probability) recorded shoreline contact above the low threshold. The minimum time before shoreline accumulation at the low threshold is more than three weeks. The maximum length of shoreline exposed is 5 km.	Shoreline contact at the low exposure threshold is predicted from Curtis Island in Bass Strait to Ulladulla, with probabilities ranging from 1-2% at the outer edge of the contact zone to between 15 and 25% along the east Gippsland coast (in particular Gabo Island). Note: several National Parks and Reserves lie along this coastline including Cape Conran and Croajingolong. Minimum time for visible oil to shore is approx. 3 days at Point Hicks.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)	
		LOWC at Tuna Platform	LOWC at Snapper Platform
			Maximum volume of oil ashore is approx. 183 m^3 and maximum length of shoreline exposed is 98 km (average 15 km)
In-water (dissolved) Exposure	Low 10ppb instantaneous	<u>0-10m water depth</u> Victoria and NSW State Waters are predicted to have 100% exposure, with Tasmania State Waters at 25%. including Cape Howe, Point Hicks, Nooramunga, Wilson's Promontory and Ninety Mile Beach MNPs, Beware Reef Marine Sanctuary, Kent Group NP and Marine Reserve (TAS) and Batemans and Jervis Bay Marine Parks and Booderee National Park (NSW). There is also a predicted 5% probability of contact with Gippsland Lakes Ramsar wetland and 1% for Corner Inlet Ramsar wetland. The probability of in-water dissolved hydrocarbon exposure at the low threshold to coastal receptors varied from 1-5% at Wollongong (NSW), Sutherland Shire (NSW), Kiama (NSW), Wilsons Promontory, Corner Inlet, Clonmel island, Snake Island, Ocean Grange, and Lakes Entrance, approx. 30 - 50% at Corringle, Sydenham Inlet, Marlo, Cape Conran and Eurobodalla (NSW) to approx. 60 - 70% at Point Hicks, Croajingolong, Cape Howe / Mallacoota and Bega Valley (southern NSW). East Gippsland (65%) and Beagle AMP (24%) may be exposed, with Jervis, Flinders, Central Eastern and Freycinet AMP all below 8% probability. The KEF Upwelling East of Eden recorded a 100% probability of low instantaneous dissolved hydrocarbon exposure. Big Horseshoe Canyon (75%), Shelf rocky reefs (55%) and Canyons on the eastern continental slope (51%) and Tasman Front and eddy field and Tasmantid seamount chain (each 1%) showed a lower probability. The greatest probability of low dissolved hydrocarbon exposure in the 0-10 m layer was 100%, predicted for the foraging seabirds near the LOWC location: Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Shy Albatross, Wandering Albatross, White-faced Storm-petrel, Antipodean Albatross, Wedge-tailed Shearwater, Little Penguin, Short-tailed Shearwater, Common Diving-petrel and Buller's Albatross with Sooty Shearwater predicted to have a 95% probability, Black Petrel and Flesh-footed Shearwater a 66% probability, and Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, and White-capped Albatross 59% each, Little Penguin and Crested Tern Breeding BIA 61% each, and Wilsons Storm Petrel (migration) (59%). The following BIAs are also predicted to have a 100% probability of exposure: Pygmy Blue Whale (distribution & foraging), Southern Right Whale (migration), White Shark (distribution & foraging), Humpback Whale (foraging), Indo-Pacific/Spotted Bottlenose Dolphin	<u>0-10m water depth</u> The probability of in-water dissolved hydrocarbon exposure at the low threshold to coastal receptors varied from 1% at Eurobodalla, Shoal Haven and Montague Island in NSW, to 4 -5% at Croajingolong, Gabo Island and Cape Howe / Mallacoota, to 10% at Point Hicks. East Gippsland AMP 25% probability and Beagle AMP 1 % probability. Contact with the KEF: Upwelling East of Eden was the predicted with a probability of 10%, KEF: Canyons on the eastern continental shelf and Shelf rocky reefs both at 1%. Additionally, several BIAs were predicted to be exposed at the low threshold within the 0-10 m surface layer with the highest probabilities being 10%: Pygmy blue whale – distribution and foraging, Southern right whale – migration, Shy albatross – foraging, White shark – distribution and foraging and the White-faced storm-petrel– foraging and 6%: Little penguin – foraging, Wedge-tailed shearwater foraging, Indo-Pacific /spotted bottlenose dolphin – breeding, <u>10-20m water depth</u> Exposure pattern is very similar in 10-20 m water depth however probabilities range between 1 and 4% with a probability of 4% for contact with both Victorian and NSW waters. <u>20-30 m water depth</u> Extent of exposure at 20-30m water depth is less than layers above. Probability of contact with any receptor does not exceed 1% with a probability of 1% for contact with southern NSW waters only.

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)	
		LOWC at Tuna Platform	LOWC at Snapper Platform
		(breeding), Grey Nurse Shark (foraging & migration). White Shark (breeding: 58%). 10-20m water depth Pattern is very similar in 10-20 m water depth for low instantaneous dissolved hydrocarbon exposure.	
In-water (entrained) Exposure	Low 10ppb instantaneous	0-10m water depth A number of seabirds foraging near the LOWC location have a 100% probability of exposure: White-faced Storm-petrel, Little Penguin, Sooty Shearwater, Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Short-tailed Shearwater, Shy Albatross, Wandering Albatross, Antipodean Albatross, Buller's Albatross, as well as Common Diving-petrel (breeding) and Wedge-tailed Shearwater (breeding). The following seabirds had a 65-97% probability during foraging near the LOWC location: Black Petrel, Flesh-footed Shearwater, Great-winged Petrel, Northern Giant Petrel, Southern Giant Petrel, White-capped Albatross, Crested Tern. As well as the Little Penguin, Crested Tern and White-faced Storm-petrel during breeding, and the Wilsons Storm Petrel during migration. Other seabirds had less than 6% probability. Other BIAs with 100% probability includes: Grey Nurse Shark (migration), Pygmy Blue Whale (distribution/foraging), Southern Right Whale (migration), White Shark (distribution/foraging), Humpback Whale (foraging), Grey Nurse Shark (foraging), and Indo-Pacific/Spotted Bottlenose Dolphin (breeding). Southern Right Whale (connecting Habitat) and Humpback Whale (migration) were < 11% probability. Of the KEFs, Upwelling East of Eden had a 100% probability of exposure to low instantaneous threshold entrained hydrocarbons on 0-10m water depth, followed by Big Horseshoe Canyon (97%), Canyons on the eastern continental slope (78%) and Shelf rocky reefs (75%), other KEFs were below 6% probability: Tasman Front and eddy field, Tasmantid seamount chain, Lord Howe seamount chain, Seamounts South and east of Tasmania. East Gippsland AMP has a high probability (95%), followed by Beagle (41%), Jervis (32%), Flinders AMP (31%), Freycinet (10%) and Central Eastern and Lord Howe (each 6%). Victoria and NSW (each 100%), have a high probability of being exposed, and Tasmania State Waters (38%). Marine Parks: Point Hicks (100%), Cape Howe (100%), Beware Reef (61%), Batemans (NSW) (65%) and Kent Group (TAS) and Jervis Bay (NSW) (each 37%), followed by Ninety Mile Beach (17%).	No entrained hydrocarbon predicted below the 10m depth layer. 0-10m water depth Of the KEFs, Upwelling East of Eden had a 100% probability of exposure to low instantaneous threshold entrained hydrocarbons on 0-10 m water depth, followed by Canyons on the eastern continental slope (4%), Big Horseshoe Canyon (3%) and Shelf rocky reefs (3%). East Gippsland AMP has a probability of 11% and Beagle AMP of 6%. Victoria (81%) and NSW (51%) have a high probability of being exposed, and Tasmania State Waters only a low probability (4%). Marine Parks: Point Hicks (76%), Cape Howe (56%), Beware Reef (17%), Batemans, Jervis (NSW) and Kent Group (TAS) (each 2%) and Ninety Mile Beach and Jervis Bay (NSW) (each 1%). The following coastal receptors have between 30 - 60% probabilities of exposure: Croajingolong, Cape Howe / Mallacoota, Sydenham Inlet and Point Hicks. Followed by Cape Conran (22%), Marlo (24%), Bega Valley (southern NSW) (10%) (NSW), Corringle (8%), Lake Tyers Beach (3%) and Lakes Entrance, Woodside Beach, Clonmel Island, Eurobodalla (NSW) and Shoal Haven (NSW) (at 1% each).

Model Parameter	Exposure Value	Stochastic Modelling (based on 100 annualised spill trajectories)	
		LOWC at Tuna Platform	LOWC at Snapper Platform
		Booderee (NSW), Wilsons Promontory, Corner Inlet, Nooramunga, and Lord Howe Island (NSW) all had probabilities of between 5 and 12%. There is a 29% probability of contact with Gippsland Lakes Ramsar wetland and 9% with Corner Inlet Ramsar wetland at the low exposure threshold. The following coastal receptors have between 92 - 100% probabilities of exposure: Croajingolong, Cape Howe / Mallacoota, Point Hicks, and Bega Valley (southern NSW). Followed by Sydenham Inlet (72%, Cape Conran (62%), Marlo (61%), Eurobodalla (44%) (NSW), Corringle (38%), Shoal Haven (NSW) (39%), Lake Tyers Beach (36%), Lakes Entrance (31%), Ocean Grange (21%), Golden Beach (18%) and Wilsons Promontory, Waratah, Clonmel Island, Snake Island, Corner Inlet (in Victoria) and Sutherland Shire, Randwick, Waverly, Wollongong, Kiama, Northern Beaches and Central Coast (in NSW) (at <10% each). 10-20m water depth No receptors recorded any probability of entrained hydrocarbon exposure above the low threshold, except low probability (<3%) for a number of foraging seabirds near the LOWC location (Black-browed Albatross, Campbell Albatross, Indian Yellow-nosed Albatross, Short-tailed Shearwater, Shy Albatross, Wandering Albatross, Antipodean Albatross, White-capped Albatross, Buller's Albatross). And Wedge-tailed Shearwater, Common Diving-petrel, Indo-Pacific/Spotted during breeding; and Pygmy Blue Whale (distribution/foraging), Southern Right Whale (migration), White Shark (distribution/foraging), Bottlenose Dolphin (breeding), Humpback Whale (foraging), and Grey Nurse Shark (foraging). There was a 1% predicted probability of contacting NSW waters.	

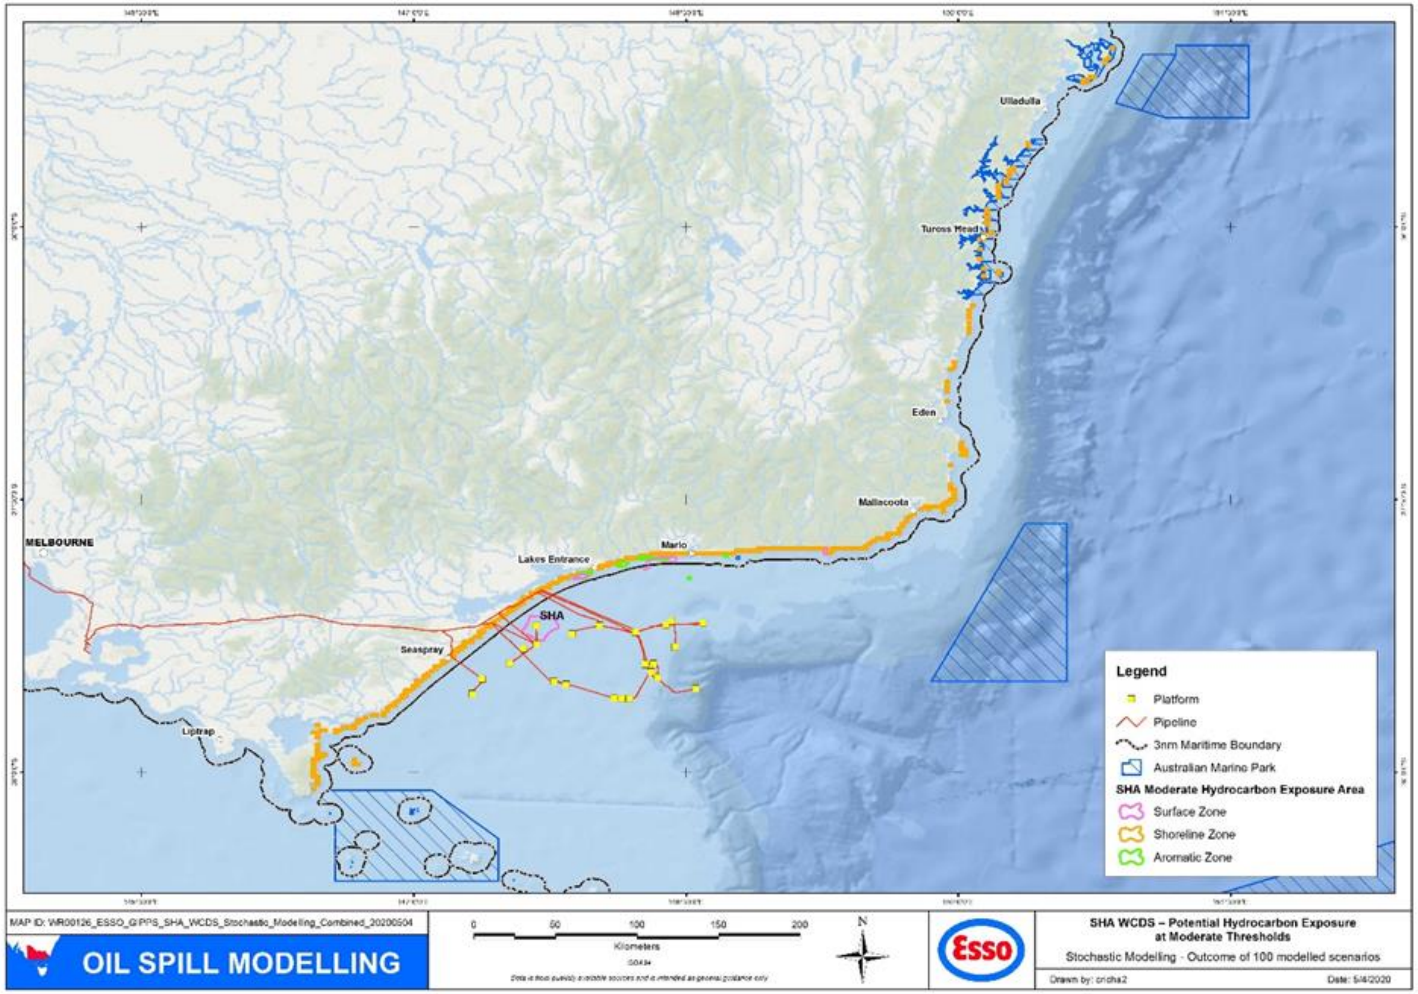

Figure 7-14 LOWC stochastic modelling output for Seahorse WCDS. Hydrocarbon exposure at the moderate thresholds (Surface: 10 g/m^2, shoreline: 100 g/m^2, and In-water (dissolved): 50 ppb instantaneous)

7.7.3 Risk Assessment

An accidental release of reservoir hydrocarbons as a result from Loss of Well Control (LOWC) has the potential to result in the following impacts:

- Change in water quality;
- Change in habitat.

As a result of change in water quality and / or habitat, further impacts may occur which include:

- Injury / mortality to fauna;
- Change in fauna behaviour
- Change to the function, interests or activities of other users.

Receptors that could be affected by a LOWC are identified in Table 7-27.

7.7.3.1 Consequence Evaluation

Consequence evaluation of potentially exposed receptors in the event of a LOWC are described in Table 7-28.

Table 7-28 Risk of surface, shoreline and in-water hydrocarbon exposure from LOWC

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
Water quality	A release of reservoir hydrocarbons has the potential to result in a change i.e. decline in water quality. Degraded water quality will potentially impact all the receptors identified in Table 7-28. These impacts are discussed individually within other sections.	Modelling predicts that surface, shoreline and in-water (dissolved) exposure will occur as a result of a LOWC. Figure 7-14, Figure 7-15, Figure 7-16, Figure 7-17, Figure 7-18 and Figure 7-19 show the extent of potential impacts to water quality (at moderate thresholds). Due to the potentially persistent nature of the hydrocarbon and the potential area of impact, the consequences to water quality are assessed as **Level III.**
Benthic Habitats – Bare Substrate, Coral, Seagrass, Macroalgae, Subtidal Rocky Reef	**Bare Substrate** While this receptor represents the 'bare sand' areas offshore, it does provide habitat for benthic invertebrates (both infauna and macroinvertebrates). Unconsolidated mixed and particulate sediments are likely to be dominated by burrowing fauna (e.g. annelid worms, molluscs, echinoderms, crustaceans, cnidarians). Many of the organisms that live in these habitats are habitat modifiers (e.g. through burrows or shell production), stabilising and/or oxygenating the sediments around them, and providing additional ecological niches for colonisation by other fauna – increasing local biodiversity. Surveys undertaken after the Montara blowout found no obvious visual signs of major disturbance at Barracouta and Vulcan shoals (Heyward *et al.,* 2010), which occur about 20-30 m below the water line in otherwise deep waters (generally >150 m water depth). Later sampling indicated the presence of low-level severely degraded oil at some shoals, though in the absence of pre-impact data, this could not be directly linked to the Montara spill. Levels of hydrocarbons in the sediments were, in any case, several orders of magnitude lower than levels at which biological effects become possible (Heyward *et al.,* 2012; Gagnon & Rawson, 2011). Studies undertaken since the DWH incident have shown that fewer than 2% of the more than 8,000 sediment samples collected exceeded the US EPA sediment toxicity benchmark for aquatic life, and these were largely limited to the area close to the wellhead (BP, 2015). Acute or chronic exposure through contact and/or digestion can result in toxicological risks to invertebrates. However, the presence of an	Exposure to in-water hydrocarbons is restricted to 30m below the surface and therefore any potential impact to benthic habitats from in-water hydrocarbons will only occur in shallower nearshore waters. The zone of moderate exposure to dissolved hydrocarbons is predicted to extend into nearshore Tasmanian (i.e. Bass Strait islands), Victorian and southern NSW waters in five of the six LOWC scenarios. The predominant benthic habitat in the Gippsland Basin is bare substrate. However, known areas of seagrass which may be exposed include at Lakes Entrance, Bemm River Estuary and Tamboon Inlet and numerous estuaries and inlets along the southern NSW coast. There is the potential that exposure could result in sub-lethal impacts, more so than lethal impacts, possibly because much of seagrasses' biomass is underground in their rhizomes (Zieman et al., 1984). Seagrass in this region isn't considered a significant food source for marine fauna. Suitable hard substrate for macroalgal beds including the threatened 'Giant Kelp' (*Macrocystis pyrifera)* occur in areas such as around Gabo Island and within the Bemm River Estuary. Little is known about the effects of oil on *M. pyrifera,* but some studies (e.g. Edgar & Barrett 2000; Reed & Lewis 1994) suggest that this species, like other macroalgae, may be some of the least sensitive marine species to oil exposure. As described opposite, intertidal species of macroalgae are more prone to direct exposure than subtidal beds, however sub-lethal toxicity effects from in-water (dissolved) hydrocarbons may be observed. Corals are not a common habitat type in the Gippsland Basin however solitary soft corals may occur where suitable hard substrate, such as rocky reef or man-made structures, is present. Sub-lethal toxicity effects may result from direct contact with in-water hydrocarbons or indirectly through feeding on contaminated prey (plankton). Impact by direct contact of benthic species with hydrocarbon in the deeper areas of the release area is not expected given the surface nature of all except the SHA

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>exoskeleton (e.g. crustaceans) reduces the impact of hydrocarbon absorption through the surface membrane. Invertebrates with no exoskeleton and larval forms may be more prone to impacts. Exposure can induce changes in burrowing depth into the substrate (which can lead to higher predation rates on some species) and can limit the growth, recruitment and reproductive capacity of some marine invertebrates (Fukuyama et al,. 1998).

Deep water benthic invertebrates are usually protected from oiling by the buoyant nature of hydrocarbons, although the depth of oil penetration is dependent on turbulence in the water column. Hydrocarbons can also reach the benthos through the settlement of oiled particles such as faeces, dead plankton or inorganic sand particles (Jewett et al., 1999).

Coral

Corals are generally located in shallow and intertidal regions, where there is the potential for exposure to surface and in-water hydrocarbons.

Experimental studies and field observations indicate all coral species are sensitive to the effects of oil, although there are considerable differences in the degree of tolerance between species. Differences in sensitivities may be due to the ease with which oil adheres to the coral structures, the degree of mucous production and self cleaning, or simply different physiological tolerances.

Direct contact of coral by hydrocarbons may impair respiration and also photosynthesis by symbiotic zooanthellae (IPIECA, 1992). Coral gametes or larvae in the surface layer where they are exposed to the slick may also be fouled (Epstein et al., 2000). Physical oiling of coral tissue can cause a decline in metabolic rate and may cause varying degrees of tissue decomposition and death (Negri and Heyward, 2000). Oil may also cling to certain types of sediment causing oil to sink to the seafloor, covering corals in oiled sediment.

Where corals come into direct contact with surface exposures (i.e., intertidal/shallow areas), they are more susceptible due to physical presence, than toxicity associated with dissolved oil components within the water column which, in some cases, may be more toxic than the floating surface slicks (Volkman et al., 1994). A range of impacts is reported to result from toxicity including partial mortality of colonies, reduced growth rates, bleaching and reduced photosynthesis.</td><td>subsea facility spill and the water depths at the spill locations. The benthic habitat of the OA (described in detail in Section 5.2.1.1) is predominantly featureless muddy, gravelly sand and no areas of rocky reef have been observed. Recent studies have shown that infaunal taxa are similar across the Bass Strait but the contribution of each to the assemblage varies Where hard substrate or points of attachment (facilities) are present, colonisation by epifauna occurs mostly in the form of sessile, invertebrate, filter feeders. The degree of colonisation varies between facilities however sponge beds have only been detected at Bream B.

Benthic invertebrate species closer to shore may be affected, although these effects will be localised and temporary. Invertebrates of value (i.e. target species, see Commercial Fisheries below) have been identified to include squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone). Filter-feeding, sessile benthic invertebrates such as sponges, bryozoans, scallops, abalone and hydroids may be exposed to sub-lethal impacts however population level impacts are considered unlikely.

The consequence of a LOWC on benthic habitats is assessed as Level II.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	Laboratory and field studies have demonstrated that branching corals appear to have a higher susceptibility to hydrocarbon exposure than massive corals or corals with large polyps. Chronic effects of oil exposure have been consistently noted in corals and, ultimately, can kill the entire colony. Chronic impacts include histological, biochemical, behavioural, reproductive and developmental effects. Field studies of chronically polluted areas and manipulative studies in which corals are artificially exposed to oil show that some coral species tolerate oil better than other species (NOAA, 2010). Reproductive stages of corals have been found to be more sensitive to oil toxicity. Fertilisation of coral species has been observed to be completely blocked in *Acropora tenuis* at heavy fuel oil concentrations of 150 ppb (Harrison, 1999), with significant reductions in fertilisation of *A.millepora* and *A. valida* at concentrations between 580 and 5800 ppb, in addition to developmental abnormalities and reduced survival of coral larvae at similar concentrations. Lower concentrations of less than 100 ppb crude oil were observed to inhibit larval metamorphosis in *A. millepora* (Negri & Heyward, 2000). Studies undertaken after the Montara incident included diver surveys to assess the status of Ashmore, Cartier and Seringapatam coral reefs. These found that other than a region-wide coral bleaching event caused by thermal stress (i.e., caused by sea water exceeding 32°C), the condition of the reefs was consistent with previous surveys, suggesting that any effects of hydrocarbons reaching these reefs was minor, transitory or sub-lethal and not detectable (Heyward *et al*., 2010). This is despite AMSA observations of surface slicks or sheen nears these shallow reefs during the spill (Heyward *et al*., 2010). Surveys in 2011 indicated that the corals exhibiting bleaching in 2010 had largely survived and recovered (Heyward *et al.,* 2012), indicating that potential exposure to hydrocarbons while in an already stressed state did not have any impact on the healthy recovery of the coral. In addition, surveys undertaken after the Montara blowout on the plateau areas of Barracouta and Vulcan shoals (Heyward *et al.,* 2010), which occur about 20-30 m below the water line in otherwise deep waters (generally >150 m water depth), and contain algae, hard coral and seagrass, found no obvious visual signs of major disturbance. **Macroalgae**	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	Macroalgae are generally limited to growing on intertidal and subtidal rocky substrata in shallow waters to 10 m depth. As such, they may be exposed to subsurface and entrained and dissolved hydrocarbons, however are susceptible to surface hydrocarbon exposure more so in intertidal habitats as opposed to subtidal habitats. Reported toxic responses to oils have included a variety of physiological changes to enzyme systems, photosynthesis, respiration, and nucleic acid synthesis (Lewis & Pryor 2013). Despite the well-established pool of literature on macroalgae exposure to petroleum oils, very few investigations have reported effects on species that are common in Australian waters (Lewis & Pryor 2013). Smothering, fouling and asphyxiation are some of the physical effects that have been documented from oil contamination in marine plants (Blumer, 1971; Cintron *et al.*, 1981). In macroalgae, oil can act as a physical barrier for the diffusion of CO_2 across cell walls (O'Brien & Dixon, 1976). The effect of hydrocarbons however is largely dependent on the degree of direct exposure and how much of the hydrocarbon adheres to algae, which will vary depending on the oils physical state and relative 'stickiness'. The morphological features of macroalgae, such as the presence of a mucilage layer or the presence of fine 'hairs' will influence the amount of hydrocarbon that will adhere to the algae. A review of field studies conducted after spill events by Connell *et al*. (1981) indicated a high degree of variability in the level of impact, but in all instances, the algae appeared to be able to recover rapidly from even very heavy oiling. The rapid recovery of algae was attributed to the fact that for most algae, new growth is produced from near the base of the plant while the distal parts (which would be exposed to the oil contamination) are continually lost. Other studies have indicated that oiled kelp beds had a 90% recovery within 3-4 years of impact, however full recovery to pre-spill diversity may not occur for long periods after the spill (French-McCay, 2004). Intertidal macroalgal beds are more prone to oil spills than subtidal beds because although the mucous coating prevents oil adherence, oil that is trapped in the upper canopy can increase the persistence of the oil, which impacts upon site-attached species. Additionally, when oil sticks to dry fronds on the shore, they can become overweight and break as a result of wave action (IPIECA, 1995).	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	The toxicity of hydrocarbons to macroalgae varies for the different macroalgal life stages, with water-soluble hydrocarbons more toxic to macroalgae (O'Brien and Dixon, 1976). Toxic effect concentrations for hydrocarbons and algae have varied greatly among species and studies, ranging 2 - 10,000,000 ppb (Lewis & Pryor, 2013). The sensitivity of gametes, larva and zygote stages however have all proven more responsive to petroleum oil exposure than adult growth stages (Lewis & Pryor, 2013). Macrophytes, including macroalgae, require light to photosynthesise. So in addition to the potential impacts from direct smothering or exposure to entrained and dissolved hydrocarbons, the presence of entrained hydrocarbon within the water column can affect light qualities and the ability of macrophytes to photosynthesise. Exposure to in-water hydrocarbons poses the greatest threat to sensitive macroalgal assemblages, specifically the Giant Kelp Forests TEC, that grow on rocky reefs from the sea floor ≥8 m below sea level. The largest extent of this TEC is in Tasmanian coastal waters. Substrate on which this TEC may occur is also found in Victoria along the west coast of Wilson's Promontory and from Sydenham Inlet to Gabo Island (DSEWPaC 2012b). . **Seagrass** Seagrasses generally grow in sediments in intertidal and shallow subtidal waters where there is sufficient light, and are common in sheltered coastal areas such as bays, lees of islands and fringing coastal reefs. As such, they may be exposed to both surface and sub-surface hydrocarbons. Submerged vegetation in nearshore areas can be exposed to oil by direct contact (i.e., smothering) and by uptake by rhizomes through contaminated sediments. Exposure also can take place via uptake of hydrocarbons through plant membranes. In addition, seeds may be affected by contact with oil contained within sediments (NRDA, 2012). When seagrass leaves are exposed to petroleum oil, sub-lethal quantities of the soluble fraction can be incorporated into the tissue, causing a reduction in tolerance to other stress factors (Zieman *et al*., 1984). The toxic components of petroleum oils are thought to be the PAH, which are lipophilic and therefore able to pass through lipid	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	membranes and tend to accumulate in the thylakoid membranes of chloroplasts (Ren *et al*., 1994). As such, the susceptibility of seagrasses to hydrocarbon spills will depend largely on distribution. Deeper communities will be protected from oiling under all but the most extreme weather conditions. Shallow seagrasses are more likely to be affected by dispersed oil droplets or, in the case of emergent seagrasses, direct oiling. Theoretically, intertidal seagrass communities would be the most susceptible because the leaves and rhizomes may both be affected. **Subtidal rocky reefs** Nearshore and offshore subtidal reef habitats are dominated by seaweeds, mobile invertebrates and fish. Potential impacts to sensitive receptors related to these reefs discussed in the appropriate sections. It was observed that the release of large quantities of fuel oil during the grounding of the Iron Baron did not substantially affect populations of subtidal reef associated organisms (Edgar & Barrett, 1995)	
Plankton	Plankton are found in nearshore and open waters beneath the surface in the water column. These organisms migrate vertically through the water column to feed in surface waters at night (NRDA, 2012). As they move close to the sea surface it is possible that they may be exposed to floating hydrocarbons but plankton also has the potential to be directly affected by in-water hydrocarbons as a result of toxicity effects. Phytoplankton are typically not sensitive to the impacts of oil, though they do accumulate it rapidly (Hook *et al*., 2016) due to their small size and high surface area to volume ratio. Oil can affect the rate of photosynthesis and inhibit growth in phytoplankton, depending on the concentration range. For example, photosynthesis is stimulated by low concentrations of oil in the water column (10–30 ppb) but becomes progressively inhibited above 50 ppb. Conversely, photosynthesis can be stimulated below 100 ppb for exposure to weathered oil (González *et al*. 2009). In addition, the potential for effects to photosynthesis (i.e. temporary suppression of primary production) from shading caused by continuous surface slicks may have implications for consumers of phytoplankton (Hook *et al.,* 2016), though a prolonged surface coverage over an extensive area would be required. During the DWH oil spill it was observed that plankton and other surface material were found to be sinking at rates of more than 10 times the normal level. It was	Plankton are likely to be exposed to in-water (dissolved) hydrocarbons above the moderate exposure threshold within a zone (up to approximately 500 km in width) extending parallel to the Gippsland and southern NSW coastline (for up to approximately 500 km from the release location). Plankton are at their highest concentrations below surface waters (e.g. 60 m water depth for phytoplankton during the day) and undertake a vertical migration which would likely reduce their potential for (and duration of) exposure to dissolved hydrocarbons in the surface layer of the water column. The impact to plankton is therefore predicted to be **Level III** with potential effects on the food web recognized.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	hypothesised that the weathered spilled oil catalysed clumping of organic particles (Schrope 2013). It is currently unclear as to whether this effect was caused by the chemical characteristics of the weathered oil, or a bacterial effect. Zooplankton (microscopic animals such as rotifers, copepods and krill that feed on phytoplankton) are vulnerable to hydrocarbons (Hook *et al*., 2016). Water column organisms that come into contact with oil risk exposure through ingestion, inhalation and dermal contact (NRDA, 2012), which can cause immediate mortality or declines in egg production and hatching rates along with a decline in swimming speeds (Hook *et al*., 2016). Plankton are generally abundant in the upper layers of the water column and is the basis of the marine food web, so an oil spill in any one location is unlikely to have long-lasting impacts on plankton populations at a regional level. Reproduction by survivors or dispersion from unaffected areas (via sea surface currents) is likely to rapidly replenish losses (Abbriano et al. 2011). Plankton have life cycles based on rapid reproduction with levels of high productivity. It is also in the nature of plankton to be dispersive. Oil spill field observations show minimal or transient effects on plankton (Abbriano *et al.* 2011). Once background water quality is re-established, plankton takes weeks to months to recover (ITOPF, 2011). Plankton found in open waters of the exposure zone is expected to be widely represented within waters of the wider Bass Strait region and generally across all waters in the south eastern offshore region, which aids in the re-establishment of communities.	
Fish	Fish can be exposed to oil through a variety of pathways, including: direct dermal contact (e.g. swimming through oil); ingestion (e.g. directly or via oil-affected prey/foods); and inhalation (e.g. elevated dissolved contaminant concentrations in water passing over the gills). Fish are generally considered vulnerable to oil spills because they inhabit areas coincident with oil exploration and production and those areas that may be subsequently impacted by an oil spill; including coral reefs, seagrasses, nearshore areas, deep offshore areas, pelagic habitats and demersal habitats (Moore & Dwyer, 1974; Gundlach & Hayes, 1978). Of the potential toxicants, monocyclic and polycyclic aromatic hydrocarbons (MAHs and PAHs) are generally regarded as the most toxic to fish.	Release locations are all located in open ocean waters and floating oil is not predicted to extend into shallow nearshore waters. Moderate surface exposure is predicted to cover a maximum area of approximately 40 km^2 (from the MLA scenario). The zone of moderate exposure to dissolved hydrocarbons is predicted to extend into nearshore Tasmanian (i.e. Bass Strait islands), Victorian and southern NSW waters in five of the six LOWC scenarios. Shallow inshore fish species including various syngnathids (seahorses, pipefish, pipehorses and seadragons) are less likely to be able to move away from in-water oils and therefore may be exposed to elevated levels. Their habitats are typically widespread and impacts are expected to be local on individual organism levels.

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>
<u>Surface oil</u>

Since fish and sharks do not generally break the sea surface, the exposure of surface hydrocarbons to fish and shark species are unlikely to occur. Near the sea surface, fish are able to detect and avoid contact with surface slicks meaning fish mortalities rarely occur in the event of a hydrocarbon spill in open waters (Volkman et al., 2004). As a result, wide-ranging pelagic fish of the open ocean generally are not highly susceptible to impacts from surface hydrocarbons. Adult fish kills reported after oil spills occur mainly to shallow water, near-shore benthic species (Volkman et al., 2004). Following the DWH incident, it was suggested that Whale sharks may be vulnerable to oiling of gills if exposed to the oil. The tendency of Whale sharks to feed close to surface waters will increase the likelihood of exposure to surface slicks and elevated hydrocarbon concentrations beneath slicks.

<u>In-water oil</u>

Exposure to hydrocarbons entrained or dissolved in the water column can be toxic to fishes. Studies have shown a range of impacts including changes in abundance, decreased size, inhibited swimming ability, changes to oxygen consumption and respiration, changes to reproduction, immune system responses, DNA damage, visible skin and organ lesions, and increased parasitism. However, many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Pelagic species are also generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in surface layers only.

Fish are most vulnerable to hydrocarbon discharges during their embryonic, larval and juvenile life stages. Oil exposure may result in decreased spawning success and abnormal larval development. Impacts on eggs and larvae entrained in the upper water column are not expected to be significant given the temporary period of water quality impairment, and the limited areal extent of the spill. As egg/larvae dispersal is widely distributed in the upper layers of the water column it is expected that current induced drift will rapidly replace any oil affected populations.
</td><td>
Although pelagic fish species may be exposed to moderate levels of dissolved oil their mobile, transitory characteristics reduce the risk of prolonged exposure. Large-scale population level effects following a LOWC on fish species, abundances or assemblage composition would be unlikely due to the wide geographical distribution of many fish in Bass Strait and the potential for rapid re-colonisation, especially in the cases of widely distributed relatively common pelagic species. Deep water demersal fish are not expected to be impacted given the presence of in-water hydrocarbons in upper layers (0 – 30 m) of the water column only.

The zone of moderate exposure to dissolved hydrocarbons may contact the White shark distribution and breeding BIAs and Grey nurse shark foraging and migration BIAs. Pelagic species of shark are at greatest risk of being exposed to oil following a LOWC given their wide foraging areas and risks of consuming contaminated prey. White sharks are known to aggregate near Ninety Mile Beach and philopatric characteristics means they may return to the place of birth to breed even if habitats are contaminated. This species is widely distributed and thus unlikely to suffer ecologically important declines in abundance.

The consequences to fish and sharks are assessed as Level II, taking into consideration the potential impacts to threatened species such as the White and Grey nurse sharks.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
Birds	Seabirds and shorebirds are sensitive to the impacts of oiling, with their vulnerability arising from the fact that they cross the air-water interface to feed, while their shoreline habitats may also be oiled (Hook *et al*., 2016). Species that raft together in large flocks on the sea surface are particularly at risk (ITOPF, 2011). <u>Sea surface oil</u> Birds foraging at sea have the potential to directly interact with oil on the sea surface some considerable distance from breeding sites in the course of normal foraging activities. Seabird species most at risk include those that readily rest on the sea surface (e.g. shearwaters) and surface plunging species (e.g. terns, boobies). As seabirds are a top order predator, any impact on other marine life (e.g. pelagic fish) may disrupt and limit food supply both for the maintenance of adults and the provisioning of young. For seabirds, direct contact with hydrocarbons can foul feathers, which may subsequently result in hypothermia due to a reduction in the ability of the bird to thermo-regulate and impair water-proofing. A bird suffering from cold, exhaustion and a loss of buoyancy may also dehydrate, drown or starve (DSEWPAC, 2011). Increased heat loss as a result of a loss of water-proofing results in an increased metabolism of food reserves in the body, which is not countered by a corresponding increase in food intake, may lead to emaciation (DSEWPAC, 2011). The greatest vulnerability in this case occurs when birds are feeding or resting at the sea surface (Peakall *et a*l., 1987). . In a review of 45 actual marine spills, there was no correlation between the numbers of bird deaths and the volume of the spill (Burger, 1993). Penguins may be especially vulnerable to an oil spill because they do not fly and therefore spend a high proportion of their time in the water when away from resting and breeding locations and readily lose insulation and buoyancy if their feathers are oiled (Hook *et al*., 2016). This species also has strong attachment to its natal area (Colombelli-Négrel 2016) and consequently, birds are likely to retain a strong attachment to a site even if the site and adjacent waters are severely contaminated by oil. The Iron Baron vessel spill (325 tonnes of bunker fuel in Tasmania in 1995) is estimated to have resulted in the death of up to 20,000 penguins (Hook *et al*., 2016).	A number of listed threatened and/or migratory seabird species may occur in the area exposed above moderate surface thresholds. Moderate surface exposure is predicted to cover a maximum area of approximately 40 km^2 (from the MLA scenario). There are foraging BIA's for several species of petrels, shearwater and albatross, however, no breeding BIAs overlap with this exposed area. Seabirds rafting, resting, diving or feeding at sea have the potential to come into contact with surface oil, ranging from moderate to high exposure, as such, acute or chronic toxicity impacts (death or long-term poor health) to seabirds are possible. Most species tend to forage on their own, though large feeding flocks will gather at rich or passing food sources. The length of shoreline predicted to be exposed to shoreline loading of hydrocarbons that may have biological impacts to birds is approximately 280 km above the moderate threshold and 100 km above the high threshold for the SHA release scenario. This section of coastline comprises mostly wide sandy beaches that provide nesting habitat for species such as Hooded plovers and terns or rocky islands and headlands that provide habitat for seabird colonies (such as Little penguin, petrels and albatrosses). The Little penguin is not considered at risk globally, but some colonies are at risk on a regional scale (Cannell *et a*l. 2016) and declines in the status of this species have been reported from Tasmania (Stevenson & Woehler 2007). Oil concentrations at the moderate to high threshold are predicted to accumulate on the shorelines of Gabo Island, which supports the world's largest Little penguin colony, The Skerries and Tasmanian Bass Strait islands such as Curtis Island potentially impacting local populations. There are many listed threatened and migratory shorebird species likely to occur in the area overlapping the extent of exposed shoreline. In the event of a LOWC, these birds are potentially at risk of shoreline exposure. Birds are not likely to be significantly affected by in-water concentrations of hydrocarbons due to their limited exposure time in the water column. Shorebirds foraging in intertidal areas or along the high tide mark and splash zone, or nest in coastal areas particularly close to the high-water mark, are most at risk of exposure effects. Because the zone of moderate in-water exposure extends into nearshore waters foraging shorebirds may be indirectly impacted by the loss of invertebrate prey.

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td><u>Shoreline oil</u>

Shorebirds are likely to be exposed to oil when it directly impacts the intertidal zone and onshore due to their feeding habitats. Foraging shorebirds will be at potential risk of both direct impacts through contamination of individual birds (e.g. fouling of feathers) and indirect impacts (e.g. fouling and/or a reduction in prey items) (Clarke, 2010). Birds that are coated in oil can also suffer from damage to external tissues, including skin and eyes, as well as internal tissue irritation in their lungs and stomachs

Breeding birds (both seabirds and shorebirds) may be exposed to oil via direct contact or the contamination of the breeding habitat (e.g. shores of islands) (Clarke, 2010). Bird eggs may subsequently be damaged if an oiled adult sits on the nest. Fresh crude was shown to be more toxic than weathered crude, which had a medial lethal dose of 21.3 mg/egg. Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos.

Toxic effects on birds may result where oil is ingested as the bird attempts to preen its feathers, or via consumption of oil-affected prey. Whether this toxicity ultimately results in mortality will depend on the amount consumed and other factors relating to the health and sensitivity of the particular bird species.

Engelhardt (1983), Clark (1984), Geraci & St Aubin (1988) and Jenssen (1994) indicated that the threshold thickness of oil that could impart a lethal dose to an individual wildlife species is 10 µm (~10 g/m^2). Scholten et al. (1996) indicates that a layer 25 µm thick would be harmful for most birds that contact the slick.</td><td>The populations of both seabird and shorebird species have a wide geographic range, meaning that impacts to individuals at one location will not necessarily extend to populations at other un-impacted locations.
Consequently, the potential consequence of risks to seabirds and shorebirds from a LOWC are considered to be Level II.

<tr><td>Marine Reptiles - Turtles</td><td>Marine turtles are vulnerable to the effects of oil at all life stages; eggs, hatchlings, juveniles, and adults. Oil exposure affects different turtle life stages in different ways; and each turtle life stage frequents a habitat with varied potential to be impacted during an oil spill. Several aspects of turtle biology and behaviour place them at particular risk, including a lack of avoidance, indiscriminate feeding in convergence zones, and large pre-dive inhalations.</td><td>While marine turtles, including threatened species, are known to occur in the area potentially exposed to hydrocarbons above surface and in-water (dissolved) moderate exposure thresholds they are not noted to reside or aggregate in significant numbers, and there are no recognised BIAs in the region.

There are no turtle nesting beaches along the Gippsland or southern NSW coastlines, so impacts to turtles from shoreline oiling will not occur.

Although the effects of hydrocarbons on marine reptiles, specifically turtles can be severe, the low density of turtles expected in the region (due to lack of BIA or</td></tr>

Marine turtles can be exposed to oil externally (e.g. swimming through oil slicks) or internally (e.g. swallowing the oil, consuming oil affected prey, or inhaling of volatile oil related compounds).
<u>Surface oil</u>
Effects of oil on turtles include increased egg mortality and developmental defects; direct mortality due to oiling in hatchlings, juveniles, and adults; and negative impacts to the skin, blood, digestive and immune systems, and salt glands. Oil can enter cavities such as the eyes, nostrils, or mouth; and oil covering their bodies may interfere with breathing because they inhale large volumes of air to dive.
Experiments on physiological and clinical pathological effects of hydrocarbons on loggerhead turtles (~15–18 months old) showed that the turtles' major physiological systems were adversely affected by both chronic and acute exposures (96 hour exposure to a 0.05 cm layer of South Louisiana crude oil versus 0.5 cm for 48 hours) (Lutcavage et al. 1995). Recovery from the sloughing skin and mucosa took up to 21 days, increasing the turtle's susceptibility to infection or other diseases, such as fibropapilloma (Lutcavage et al. 1995).
Records of oiled wildlife during spills rarely include marine turtles, even from areas where they are known to be relatively abundant (Short, 2011). An exception to this was the large number of marine turtles collected (613 dead and 536 live) during the DWH incident in the GoM, although many of these animals did not show any sign of oil exposure (NOAA 2013). Of the dead turtles found, 3.4% were visibly oiled and 85% of the live turtles found were oiled (NOAA, 2013). Of the captured animals, 88% of the live turtles were later released, suggesting that oiling does not inevitably lead to mortality.
<u>Shoreline oil</u>
Turtles may experience oiling impacts on nesting beaches and eggs through chemical exposures resulting in decreased survival to hatching and developmental defects in hatchlings. Adult females crossing an oiled beach could cause external oiling of the skin and carapace; nothing that most oil is deposited at the high-tide line, and most turtles nest well above this level. Studies on freshwater snapping turtles showed uptake of PAHs from contaminated nest sediments, but no impacts on hatching success or juvenile health following exposure of eggs to dispersed weathered light crude (Rowe et al., 2009). However, other studies found
</td><td>
aggregations) suggests that a LOWC would affect individuals rather than population level. Consequently, the potential impacts to marine reptiles are considered to be Consequence Level II.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	evidence that exposure of freshwater turtle embryos to PAHs results in deformities (Bell *et al*., 2006, Van Meter *et al.,* 2006). Turtle hatchlings may be more vulnerable to smothering as they emerge from the nests and make their way over the intertidal area to the water (AMSA, 2015). Hatchlings that contact oil residues while crossing a beach can exhibit a range of effects including impaired movement and bodily functions (Shigenaka, 2003). Hatchlings sticky with oily residues may also have more difficulty crawling and swimming, rendering them more vulnerable to predation. It should be noted that the threat and relative impacts of an unplanned discharge on some marine reptile species are considered less damaging than other stressors. Report cards produced on protected marine reptiles in Australia generally ranked oil pollution as either 'not of concern' or 'of less concern' depending on the marine region (DSEWPaC 2012a).	
Marine Mammals (Pinnipeds)	Pinnipeds are directly at risk from impacts associated with the exposure to surface, shoreline and in-water hydrocarbons. <u>Sea surface oil</u> Pinnipeds are vulnerable to sea surface exposures in particular given they spend much of their time on or near the surface of the water, as they need to surface every few minutes to breathe, and regularly haul out on to beaches. Pinnipeds are also sensitive as they will stay near established colonies and haul-out areas, meaning they are less likely to practise avoidance behaviours. This is corroborated by Geraci and St. Aubins (1988) who suggest seals, sea-lions and fur-seals have been observed swimming in oil slicks during a number of documented spills. As a result of exposure to surface oils, pinnipeds, with their relatively large, protruding eyes are particularly vulnerable to effects such as irritation to mucous membranes that surround the eyes and line the oral cavity, respiratory surfaces, and anal and urogenital orifices. Hook *et al* (2016) reports that seals appear not to be very sensitive to contact with oil, but instead to the toxic impacts from the inhalation of volatile components. For some pinnipeds, fur is an effective thermal barrier because it traps air and repels water. Petroleum stuck to fur reduces its insulative value by removing natural oils that waterproof the pelage. Consequently, the	Both the New Zealand fur-seal (*Arctocephalus forsteri*) and the Australian fur-seal (*Arctocephalus pusillus doriferus*) are listed marine species with habitat and breeding sites known to occur in areas potentially exposed to surface, in-water and shoreline oil above the moderate threshold. These areas are not identified as critical habitat and there are no identified BIAs for fur seals in the region. Both the Australian and New Zealand fur seals are at risk to surface oil while at sea and shoreline accumulated oil at haul out sites or rookeries. The direct effect to pups from exposure to shoreline oil at ≥100 g/m^2 could result in mortality, while indirect effects could be negative behavioural changes associated with the smell of shoreline oil or contamination of prey. The Australian fur seal is vulnerable to a population decline following a LOWC because breeding locations are restricted to the islands of Bass Strait. It is predicted that major rookeries on The Skerries and Gabo Island may be exposed to accumulated shoreline oil at moderate to high thresholds from five of the six discharge scenarios. Waxy crude from the SNA scenario is also predicted to accumulate at the moderate threshold on islands off Wilsons Promontory which also support significant breeding populations. These species are particularly vulnerable to oil because oil is believed to adhere more readily to their coats, such oiling can have significant effects to this function if foraging in areas with fresh oil. Fur seals are known to aggregate around

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>
rate of heat transfer through fur seal pelts can double after oiling (Geraci & St.Aubin, 1988), adding an energetic burden to the animal. Kooyman et al (1976) suggest that in fact, fouling of approximately one-third of the body surface resulted in 50% greater heat loss in fur seals immersed in water at various temperatures. Fur-seals are particularly vulnerable due to the likelihood of oil adhering to fur. Heavy oil coating and tar deposits on fur-seals may result in reduced swimming ability and lack of mobility out of the water.
<u>In-water oil</u>
Ingested hydrocarbons can irritate or destroy epithelial cells that line the stomach and intestine, thereby affecting motility, digestion and absorption.
However, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986). Volkman et al (1994) report that benzene and naphthalene ingested by seals is quickly absorbed into the blood through the gut, causing acute stress, with damage to the liver considered likely. If ingested in large volumes, hydrocarbons may not be completely metabolised, which may result in death.
<u>Shoreline oil</u>
Breeding colonies (used to birth and nurse until pups are weaned) are particularly sensitive to hydrocarbon spills (Higgins & Gass, 1993). ITOPF (2011) report that species that rely on fur to regulate their body temperature (such as fur-seals) are the most vulnerable to oil as the animals may die from hypothermia or overheating, depending on the season, if the fur becomes matted with oil.
It is reported that most pinnipeds scratch themselves vigorously with their flippers and do not lick or groom themselves, so are less likely to ingest oil from skin surfaces (Geraci & St. Aubin, 1988). However, mothers trying to clean an oiled pup may ingest oil. The Long Term Environmental Impact and Recovery report for the Iron Barren oil spill concluded that “The number of pups born at Tenth Island in 1995 was reduced when compared to previous years. There was a strong relationship between the productivity of the seal colonies and the
</td><td>
offshore oil and gas facilities where, in the event of a release, exposure to fresh oil would occur.
The consequence of a LOWC on pinnipeds is assessed as Level II.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	proximity of the islands to the oil spill wherein the islands close to the spill showed reduced pup production and those islands more distant to the oil spill did not" (Tasmanian SMPC, 1999). Pinnipeds are further at risk because they appear to rely on scent to establish a mother-pup bond (Sandegren, 1970; Fogden, 1971), and consequently oil-coated pups may not be recognisable to their mothers. This is only theorised, with studies and research indicating interaction between mothers and oiled pups were normal (Davis and Anderson, 1976; Davies, 1949; Shaughnessy & Chapman, 1984). Australian sea-lions have 'naturally poor recovery abilities' due to 'unusual reproductive biology and life history' (TSSC, 2005). Due to the extreme philopatry of females and limited dispersal of males between breeding colonies, the removal of only a few individuals annually may increase the likelihood of decline and potentially lead to the extinction of some of the smaller colonies. Note: Australian sea lions are endemic to Australia, found only in South Australia and Western Australia (DSEWPaC, 2013c).	
Marine Mammals (Cetaceans)	Whales and dolphins can be exposed to the chemicals in oil through: • Internal exposure by consuming oil or contaminated prey; • Inhaling volatile oil compounds when surfacing to breathe; • External exposure, by swimming in oil and having oil directly on the skin and body; and • Maternal transfer of contaminants to embryos (NRDA, 2012). <u>Surface oil</u> Unlike with pinnipeds (see above), oil would not be expected to adhere well to the surface of cetacean skin due to the lack of hairs and the frequent sloughing of skin cells (Engelhardt 1983, Helm *et al*. 2015). In addition, oil should not readily penetrate cetacean skin due to tight intercellular bridges and thick epidermis (O'Hara & O'Shea 2001). Nevertheless, cetaceans can be exposed to oil through direct contact with the eyes, mouth (ingestion), and airways (inhalation), potentially leading to inflammation and lung congestion (Geraci & St. Aubin 1990).	Several threatened, migratory and/or listed cetacean species may traverse the spill plume. The distribution and (possible (DoE, 2015b)) foraging BIAs for the Pygmy blue whale and the migration BIA for the Southern right whale may be exposed to surface and in-water concentrations above the moderate exposure threshold for five of the six scenarios. The foraging BIA for the Humpback whale and breeding BIA for the Indo-Pacific bottlenose dolphin (which extends northwards into NSW from the Victorian border) may also overlap the zone of moderate in water (dissolved) hydrocarbon. If present, these species (and other cetaceans) may be exposed to oil in the manner described in this table. It is plausible that individual whales could encounter surface oil above the moderate to high exposure threshold in the immediate vicinity of the release location, but the release would need to coincide with pod migration or foraging for a greater number of individuals to be present in the plume. Sightings of Blue whales in the Gippsland Basin are reasonably rare (Bannister *et al*., 1996) and acoustic detecting indicates that the Pygmy blue whale are predominantly located to the east, west and south of the OA. It is difficult to predict with certainty if a spill

<table>
<tr><th>Receptor</th><th>Impact of hydrocarbon exposure</th><th>Exposure risk assessment</th></tr>
<tr><td></td><td>
Helm et al. (2015) suggested that inhalation of toxic compounds associated with fresh oil was of greater concern than absorption through the skin and ingestion. The inhalation of oil droplets, vapours and fumes is a distinct possibility if whales or dolphins surface in slicks to breathe. Exposure to hydrocarbons in this way could damage mucous membranes, damage airways or even cause death. Cetaceans may incidentally draw seawater and floating oil, into their lungs by breathing in splashed droplets or liquid that has collected near the blowhole just prior to inhalation. Aspiration of liquid oil can cause physical injuries to the respiratory tract by irritating tissues/membranes and can also lead to absorption of toxicants into the blood, as in inhalation exposure (Takeshita et al., 2017). French-McCay (2016) proposed exposure to oil concentrations of 10 g/m^2could result in mortality to marine mammals.
Evidence suggests that many cetacean species are unlikely to detect and avoid spilled oil (Matkin et al. 2008). There are numerous examples where cetaceans have appeared to incidentally come into contact with oil and/or not demonstrated any obvious avoidance behaviour. Following the Exxon Valdez oil spill, Matkin et al. (2008) reported killer whales in slicks of oil as early as 24 hours after the spill and evidence presented by Aichinger Dias et al. (2017) showed that following the DWH oil spill cetaceans in the GoM came into direct contact with both oil and sheen by swimming through them.
Although in the GoM it was observed that cetaceans were able to detect the thick and dark-coloured patches of oil, detection of the lighter substances may have been more difficult. Photographs of dolphins with oil on their bodies showed that oil can adhere to and persist on cetacean skin, and contrary to suggestions from previous studies, direct contact with oil and resultant exposure to toxic compounds is of concern (Aichinger Dias et al., 2017).
<u>In water (dissolved and entrained) oil</u>
The physical impacts from ingested hydrocarbon with subsequent lethal or sub-lethal impacts are applicable to both dissolved and entrained oil. However, the susceptibility of cetaceans varies with feeding habits. Baleen whales (such as Blue, Southern right and Humpback whales) are not particularly susceptible to ingestion of oil in the water column as they feed by skimming the surface. Oil may stick to the baleen while they ‘filter feed’ near slicks. Toothed whales and dolphins may be susceptible to ingestion of dissolved and entrained oil as they gulp feed at depth. As
</td><td>
would lead to levels of mortality or reproductive depression that would manifest in terms of a population-level response.
The highly mobile and transitory nature of cetacean species in Bass Strait means that exposure to moderate to high levels of surface oil (in the vicinity of the release location) or moderate levels of in-water hydrocarbon is not anticipated to result in long term population viability effects. Nevertheless, taking into account that the populations of some whale species remain small relative to pre-whaling days and are thought to have a multi-decadal recovery time, mortality of even a small number of adults and or calves as result of oiling could inhibit or retard species recovery, the resultant impact is therefore assessed as Consequence Level II.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	highly mobile species, in general it is very unlikely that these animals will be constantly exposed to concentrations of hydrocarbons in the water column for continuous durations (e.g., >96 hours) that would lead to chronic effects. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013). Ingestion of oil may however result in acute nausea and vomiting and aspiration of oily vomitus into the lungs. Research conducted in the GoM linked aspiration pneumonia, lung abscesses, and pulmonary infections in dolphins to exposure to DWH oil (Venn-Watson *et al*., 2015a cited in Takeshita *et al.,* 2017) Some whales, particularly those with coastal migration and reproduction, display strong site fidelity to specific resting, breeding and feeding habitats, as well as to their migratory paths and this may override any tendency for cetaceans to avoid the noxious presence of hydrocarbons. The Southern right whale exhibits varying degrees of site fidelity, with the majority of females and calves returning to the same birthing location, while some also travel long distances between breeding grounds within a season (DSEWPAC, 2012c). If spilled oil reaches these biologically important habitats, the pollution may disrupt natural behaviours, displace animals, reduce foraging or reproductive success rates and increase mortality. Takeshita *et al.* (2017) concluded that the range of adverse health effects and increased mortality/reproductive failure observed in cetacean populations throughout the GoM since the DWH oil spill are consistent with the range of exposure scenarios. If sufficiently high numbers of animals are impacted, the greater population may experience reduced recovery and survival rates. The restitution time for cetaceans affected at a population level is assumed to be long term, i.e. 40 years, based on consensus on recovery times for marine mammals following the DWH incident (Bock *et. al*., 2018).	
Coastal Habitats and Communities– Sandy Shoreline, Rocky	**Sandy beaches** Sandy beaches provide potential foraging and breeding habitat for numerous bird, marine turtle and pinniped species. These activities primarily occur above the high tide line, with exception of haul outs. Note, most of the oil on a sandy shore will be concentrated at, and below, the high tide mark. Sandy beaches are also inhabited by a	There are different types of shorelines found along the Gippsland and southern NSW coast and offshore islands (including Tasmanian islands), however this coastline is dominated by wide sandy beaches with intermittent rocky shores, and salt marshes and isolated mangroves within tidal estuaries, coastal lakes and bays.

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
Shoreline, Mangroves and Saltmarsh	diverse assemblage (although not always abundant) of infauna (including nematodes, copepods and polychaetes); and macroinvertebrates (e.g. crustaceans). Because the sand retains oil, such animals may be killed if oil penetrates into the sediments. Long-term depletion of sediment fauna could have an adverse effect on birds or fish that use tidal flats as feeding grounds (IPIECA, 1999). Depth of penetration in sandy sediment is influenced by: • Particle size. Penetration is not generally as great on mud as on coarser sediments. • Oil viscosity. Viscous oils and mousse (water-in-oil emulsion) tend to penetrate less deeply than low-viscosity oils such as light crudes or diesel oil. • Drainage. If sediments are poorly drained (as is often the case with tidal flats remote from creeks or channels), the water content may prevent the oil from penetrating into the sediment. In contrast, oil may reach depths greater than one metre in coarse well-drained sediments. • Animal burrows and root pores. Penetration into fine sediments is increased if there are burrows of animals such as worms, or pores left where plant roots have decayed. A 100 g/m^2 threshold (considered a 'stain' or 'film', and equivalent to 0.1 mm thickness) is assumed as the lethal threshold for invertebrates on hard substrates and sediments (mud, silt, sand, gravel) in intertidal habitats. A threshold of 100 g/m^2 oil thickness would be enough to coat an animal and likely impact its survival and reproductive capacity (French-McCay, 2009). Based on this, areas of heavy oiling would likely result in acute toxicity, and death, of many invertebrate communities, especially where oil penetrates into sediments through animal burrows (IPIECA, 1999). However, these communities would be likely to rapidly recover (recruitment from unaffected individuals and recruitment from nearby areas) as oil is removed from the environment. Following the Sea Empress spill (in west Wales, 1996) many amphipods (sandhoppers), cockles and razor shells were killed. There were mass strandings on many beaches of both intertidal species (such as cockles) and shallow sub-tidal species. Similar mass strandings occurred after the Amoco Cadiz spill (in Brittany, France, 1978) (IPIECA, 1999).	The type of shoreline will influence the volume of hydrocarbon that could be stranded ashore and its thickness before the shoreline saturation point occurs (ITOPF, 2014). For instance, a sandy beach may allow hydrocarbon to percolate through the sand, and weathered oil may be buried, thus increasing its ability to hold more hydrocarbon ashore over tidal cycles and various wave actions in comparison to a rocky shore; hence hydrocarbon can increase in thickness onshore over time. The maximum length of shoreline exposed to oil at the moderate threshold is 277 km and at the high threshold 99km. The high shoreline loadings would likely result in acute toxicity, and death, of many invertebrate communities, especially for the light crude release scenarios which will easily penetrate into sandy sediments. However, tidal action is expected to lead to rapid weathering of these hydrocarbons in the intertidal area and the populations of these communities would be likely to rapidly recover. More persistent waxy residues are less likely to penetrate into intertidal sediments but may be forced to depth by wave action on high energy beaches. Oil residue retained deep beneath sediment may be protected from re-mobilisation and exposure to further weathering reduced (Lee *et al.,* 2015) Rocky shores along the Gippsland and southern NSW coastline are generally exposed and any oil deposited would be rapidly removed by wave action. Impacts on intertidal communities are typically short term unless acute exposure to fresh product causes high mortality. In Victoria, mangroves are known to occur within sheltered bays or inlets such as Western Port, Lakes Entrance and Corner Inlet. Based on the modelling results, mangrove habitats at most risk, are those near Lakes Entrance however many of the strands are in river estuaries or associated wetlands with only limited or intermittent access to the open ocean. Further north, the NSW coast mangroves may be exposed under certain conditions to shoreline accumulations of oil above moderate thresholds. For NSW, oil arriving would be well weathered with little lasting impact on salt marshes. Isolated marshes in Victoria near Wilsons Promontory potentially could be exposed to above moderate threshold shoreline accumulation from one LOWC scenario. Salt marsh are important benthic primary producers and provide habitat for other species, thus the loss of salt marshes could have long-lasting indirect effects on other organisms (EPA 2016).

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	Following the Sea Empress spill, populations of mud snails recovered within a few months but some amphipod populations had not returned to normal after one year. Opportunists such as some species of worm may actually show a dramatic short-term increase following an oil spill (IPIECA, 1999). In March 2014, small volumes of crude oil from an unidentified source (confirmed to not be offshore oil and gas production facilities) washed up along a 7-km section of sandy beach on the Victorian Gippsland coast as small (a few millimetres thick) granular balls (Gippsland Times, 2014). AMSA (2014) reported that no impacts were observed over the course of two months following the incident. As a result of the DWH spill, oil washed up on sandy beaches of the Alabama coastline. The natural movement of sand and water through the beach system continually transformed and re-distributed oil within the beach system, and 18 months after the event, mobile remnant oil remained in various states of weathering buried at different depths in the beaches (Hayworth *et al*., 2011). There is also evidence that submerged oil mats (SOM) exist just offshore of the Alabama beaches (ranging in thickness from a few millimetres to several centimetres), which has resulted in the regular washing up of tar balls onto sandy beaches. These SOMs may serve as long-term sources of remnant oil to the beach ecosystem (Hayworth *et al*., 2011). Long-term changes to the beach ecosystem as a result of stranded oil are unknown. Other results from beach sampling undertaken at Dapuhin Island, Alabama, in May (pre-impact) and September 2011 (post-impact) found a large shift in the diversity and abundance of microbial species (e.g., nematodes, annelids, arthropods, polychaetes, protists, fungi, algae and bacteria). Post-spill, sampling indicated that species composition was almost exclusively dominated by a few species of fungi. DNA analyses revealed that the 'before' and 'after' communities at the same sites weren't closely related to each other (Bik *et al.,* 2012). Similar studies found that oil deposited on the beaches caused a shift in the community structure toward a hydrocarbonoclastic consortium (petroleum hydrocarbon degrading microorganisms) (Lamendella *et al.*, 2014). **Rocky shorelines** Rocky shores encompass a wide variety of habitats. Exposure to the sun and wave energy are key factors in determining the types of plants and animals that inhabit the rocky shores. The persistence of oil is largely governed by the same forces (IOGP, 2016). Rock surfaces	The effect of a LOWC on individual shorelines will depend on the type of shoreline, aspect and whether they are high or low energy shores. Shoreline recovery studies link restitution times to oil type, climate, shoreline type and results range depending on the receptors monitored and level of clean up. The oil from the 2010 DWH spill in the GoM was documented by shoreline assessment teams as stranding on 1,773 km of shoreline (Michel *et al.* 2013). Shoreline clean-up activities were authorized on 660 km, or 73.3% of oiled beaches and up to 71 km, or 8.9% of oiled marshes and associated habitats. In 2013 Michel *et al*. reported that one year after the spill began, oil remained on 847 km; two years later, oil remained on 687 km, though at much lesser degrees of oiling. For example, shorelines characterised as heavily oiled went from a maximum of 360 km, to 22.4 km one year later, and to 6.4 km two years later. Hence recovery can range widely from around 2 years (Sea Empress, 1996, North Sea crude) to more than 20 years for soft sediment shorelines deeply contaminated during the 1991 Gulf War spills (IOGP, 2016). Of the shorelines of the states potentially impacted, the consequence to shorelines in Victoria is predicted to be greatest (contacted first, highest loadings and freshest oil). The resultant impact is assessed conservatively as a **Consequence Level II**

Effect Dimensions		Sensitivity Dimensions	
Duration	H	Irreplaceability	M
Size/Scale	H	Vulnerability	M
Intensity	M	Influence	M
M-H		M	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	exposed to strong wave action are typically dominated by barnacles and limpets that are firmly attached and if oil strands on those surfaces it may result in mortality of the affected animals, but is unlikely to persist. Sheltered rocky shores in estuaries or inlets are typically dominated by macroalgae (seaweed) with various invertebrates living on or under the algae. Oil deposited in these habitats may not be washed off so quickly and recovery from impacts may take longer. **Mangroves and salt marshes** Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (DEWR 2006). The effects of surface hydrocarbons on mangroves include damage by smothering of lenticels (mangrove breathing pores) on pneumatophores or aerial prop roots, or the lower trunk; or by the loss of leaves (defoliation) due to chemical burning. It is also known that mangroves take up hydrocarbons from contact with leaves, roots or sediments, and it is suspected that this uptake causes defoliation through leaf damage and tree death (Wardrop *et al.* 1987). In-water entrained and dissolved hydrocarbons may affect mangrove communities directly through root uptake of toxic contaminants or indirectly due to effects on benthic infauna leading to reduced rates of bioturbation and subsequent oxygen stress on the plants root systems. Observed thresholds for effects are likely to vary depending on the health of the system, the hydrocarbon spilled and the environmental conditions; however, observations by Lin and Mendelssohn (1996) demonstrated that more than 1 kg/m^2 of oil during the growing season would be required to affect salt marsh or mangrove plants significantly. “Subtropical and temperate coastal salt marsh” (otherwise referred to as coastal salt marsh) is listed as a TEC. This TEC is usually associated with sandy/muddy shores of estuaries and embayments along low wave energy coastlines. The physical environment for the TEC is coastal areas under regular or intermittent tidal influence, with salt marsh being the key vegetation type – that being salt-tolerant grasses, herbs, sedges, rushes and shrubs generally less than 50 cm high (DSEWPaC, 2013b). Salt marshes occur in sheltered conditions, commonly in the strandline zone, and the vegetation offers a large surface area for oil absorption and trapping. Additionally, many salt marsh grasses, which	

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	can be dominant over large areas, have corrugated leaf surfaces which increase their holding capacity. Evidence from case histories and experiments shows that the damage resulting from oiling is very variable – as are recovery times. Lighter, more penetrating oils are more likely to cause acute toxic damage than heavy or weathered oils. In areas of light to moderate oiling where oil is mainly on perennial vegetation with little penetration of sediment, the shoots of the plants may be killed, but recovery can take place from the underground systems. Good recovery commonly occurs within one to two years. Where thick deposits of viscous oil or mousse accumulate on the marsh surface, vegetation is likely to be killed by smothering and recovery delayed because persistent deposits inhibit recolonisation.	
Wetlands	Most wetlands of international importance i.e. Ramsar wetlands have minimal risk of receiving oil following a LOWC because they have no, or very narrow and/or seasonal, connections to the sea. If surface oil was to enter a Ramsar site, the level of effect would be dependent on the type of receptors exposed to oil and the proportion of the site exposed to oil as well as the nature of the oil (fresh versus weathered). Sensitive receptors found in Ramsar sites connected to the sea could include mangroves, salt marshes, fish, shorebirds and seabirds. The consequences of oil exposure to these specific receptors have been described individually in the sections above.	No Ramsar sites were predicted to be exposed to floating surface oil at or above the moderate threshold. Oil is predicted to accumulate at high – moderate thresholds on the shoreline at Lakes Entrance and along the Ninety Mile Beach however the presence of sand dunes between the ocean and the Gippsland Lakes wetlands means the wetland itself is highly unlikely to be affected in any manner. Under certain metocean conditions in one LOWC scenario in-water (dissolved) hydrocarbons at the moderate threshold are predicted to reach the Gippsland Lakes Ramsar site. The consequence is assessed as **Level III.**
National Parks and Reserves	Potential impacts to sensitive receptors related to the shorelines of the terrestrial parks, such as coastal habitats and birds, and the waters of the marine parks, such as benthic habitats, fish, cetaceans and pinnipeds, are discussed in the appropriate sections above. Impacts on tourism and recreation from degraded aesthetic values and water quality or restricted access to the coast and recreational locales within the Parks due to clean up efforts are discussed below.	Modelling predicts contact at the moderate in-water (dissolved) threshold for eight marine parks, reserves and sanctuaries (Wilsons Promontory, Ninety Mile Beach, Point Hicks, Cape Howe and Beware Reef in Victoria and Batemans, Jervis Bay and Lord Howe Island in NSW). Dissolved hydrocarbon at the moderate threshold is also predicted to encroach upon the waters surrounding the terrestrial parks and reserves of the Kent and Hogan Groups, East and West Moncouer Islands and Curtis Island in Tasmania. Oil is predicted to accumulate above the moderate exposure threshold on the Gippsland and southern NSW coastline adjacent to several terrestrial parks and reserves including Wilsons Promontory, Nooramunga, Gippsland Lakes, Cape Conran and Croajingolong in Victoria and Nadgee, Ben Boyd, Bournda, Mimosa Rocks, Montague Island and Eurobodalla in NSW). Under certain metocean

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
		conditions in one LOWC scenario oil at the moderate threshold is predicted to accumulate on the shoreline of the Kent Group National Park (Tasmania). The consequence is assessed as **Level II** taking into consideration the length of shoreline potentially impacted and the extent of oil accumulation predicted.
AMPs	AMPs vary in their conservation objectives and specific values, but all are designed to conserve fauna, habitats and water quality over the long term. AMPs support populations of threatened seabird, marine mammal and fish species. A temporary deterioration of water quality could have negative effects on organisms, such as plankton, seabirds, marine mammals and fisheries resources which in turn affect the values of that Park. These impacts are discussed individually within other sections.	Surface and in-water (dissolved) oil entering these AMPs will degrade water quality until the oil is broken down and or currents shift the weathering oil outside the boundaries of the AMPs. Thus, water quality effects are predicted to persist only over the short to medium term in the AMPs. No AMPs were predicted to experience exposure to surface oil at or above the moderate threshold. Modelling indicated that six AMPs (East Gippsland, Beagle, Flinders, Jervis, Freycinet and Central Eastern), could be exposed to moderate thresholds of dissolved oil. East Gippsland, Modelling predicts the exposure of AMPs resulting from a LOWC ranges widely, depending the prevailing wind and current direction, and the proximity of the AMP to the release point. Flinders and Beagle AMPs were predicted to be contacted in four of the six modelled LOWC scenarios whereas Jervis and Freycinet were contacted in three of the six and Central Eastern in only one. Taking into consideration the potential impacts to the receptors within the AMPs the overall consequence is assessed as **Level II**
KEFs	KEFS are underwater features, and hence are not at direct risk from floating surface oil or shoreline accumulated oil. Deepwater geological features, such as the Big Horseshoe Canyon and Canyons on the Eastern Continental Slope will not be impacted directly by oil. However, biological values associated with KEFs such as the Upwelling East of Eden and Shelf Rocky Reefs may be at risk from oil. Potential impacts to sensitive receptors related to the KEF Upwelling East of Eden such as plankton and cetaceans, or to the KEF Shelf Rocky Reefs such as benthic communities and fish, are discussed in the appropriate sections above.	While a spill would not affect the KEF Upwelling East of Eden itself, if the spill occurs at the time of an upwelling event, it may result in krill being exposed to in-water phase hydrocarbons. Pygmy blue whales feeding at this time may suffer from reduced availability of prey however these impacts are expected to be localised and temporary. The rocky-reef habitat of the KEF Shelf Rocky Reefs generally occurs at depths of greater than 45 m and is therefore not expected to be impacted by in water (dissolved) hydrocarbons in the upper layers of the water column. The consequence is assessed as **Level III**.
Cultural – Indigenous and Historic	Visible sheen or oil stranded on the shoreline has the potential to reduce the visual or cultural (including activities such as camping, rituals and ceremonies) amenity of cultural heritage sites such as historic (e.g. shipwreck) or indigenous protected areas. Impacts from oil exposure are unlikely for submerged shipwrecks.	Oil sheen is predicted to encroach upon nearshore waters in the vicinity of the Gunai-Kurnai Native Title Determination Area and a number of historic shipwrecks. Parts of the Gippsland coast over which the Gunai-Kurnai people hold native title are predicted to be exposed to moderate – high shoreline oil loadings which may lead to reduced amenity or temporary exclusions during clean-up. Impacts from degraded aesthetics of sites along the coast may take time to recover but loss of access to sites during response or for health reasons are

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
		temporary and relatively short term. The consequence level is considered **Level III** based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 4.6, Table 4-5).
Commercial Fisheries	Commercial fishing has the potential to be impacted through exclusion zones associated with the spill, the spill response and subsequent reduction in fishing effort. Exclusion zones may impede access to commercial fishing areas, for a short period of time, and nets and lines may become oiled. The impacts to commercial fishing from a public perception perspective however, may be much more significant and longer term than the spill itself. Fishing areas may be closed for fishing for shorter or longer periods because of the risks of the catch being tainted by oil. Concentrations of petroleum contaminants in fish and crustacean and mollusc tissues could pose a significant potential for adverse human health effects, and until these products from nearshore fisheries have been cleared by the health authorities, they could be restricted for sale and human consumption. Indirectly, the fisheries sector will suffer a heavy loss if consumers are either stopped from using or unwilling to buy fish and shellfish from the region affected by the spill. Impacts to fish stocks have the potential for reduction in profits for commercial fisheries, and exclusion zones exclude fishing effort. Davis *et al* (2002) report detectable tainting of fish flesh after a 24-hour exposure at crude concentrations of 0.1 ppm, marine fuel oil concentrations of 0.33 ppm and diesel concentrations of 0.25 ppm. The Montara spill (as the most recent [2009] example of a large hydrocarbon spill in Australian waters) occurred over an area fished by the Northern Demersal Scalefish Managed Fishery (with 11 licences held by 7 operators), with goldband snapper, red emperor, saddletail snapper and yellow spotted rockcod being the key species fished (PTTEP, 2013). As a precautionary measure, the WA Department of Fisheries advised the commercial fishing fleet to avoid fishing in oil-affected waters. Testing of fish caught in areas of visible oil slick (November 2009) found that there were no detectable petroleum hydrocarbons in fish muscle samples, suggesting fish were safe for human consumption. In the short-term, fish had metabolised petroleum	Several commercial fisheries may operate within the area potentially exposed in the event of a LOWC. In several scenarios floating oil is predicted to extend 10's of kilometres outside the platform or subsea facility PSZ (from which fishing vessels are already excluded) making it likely that in these situations an exclusion zone (or fisheries closure) would be established. There are currently no commercially viable scallop beds fished in the area potentially exposed to dissolved hydrocarbons (ABARES, 2019: VFA, 2019: Koopman et al., 2018). Limited data is publicly available on the location and extent of abalone fishing within Victorian waters however a number of licences are active and it is known that harvesting occurs off Cape Conran and at Mallacoota (DEDJTR, 2019). Of the State and Commonwealth administered fisheries which overlap the PEA (see Table 5-1, Description of Environment) the fisheries most active in the area potentially exposed to hydrocarbons, and therefore potentially most at risk of socioeconomic impact from reduced market confidence, are the Southern and Eastern Scalefish and Shark Fishery (31 trawl vessels, 19 Danish-seine vessels and 21 scalefish hook vessels active in total) and the Wrasse Fishery (22 licences in total) (ABARES, 2019: VFA, 2019). A temporary fisheries closure and the flow on losses from the lack of income derived from these fisheries based on reduced market confidence and the potential for extended media coverage (potentially greater than 3 months) has the possibility of exceeding medium community disruption (> 100 – 1000 people) such as reduced employment (in fisheries service industries and the seafood supply chain). The potential economic impacts to commercial fisheries from LOWC are considered to be Public Impact **Consequence Level I** based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 4.5).

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
	hydrocarbons. Limited ill effects were detected in a small number of individual fish only (PTTEP, 2013). No consistent effects of exposure on fish health could be detected within two weeks following the end of the well release. Follow up sampling in areas affected by the spill during 2010 and 2011 (PTTEP, 2013) found negligible ongoing environmental impacts from the spill. Since testing began in the month after the DWH blowout in the GoM (2010), levels of oil contamination residue in seafood consistently tested 100 to 1,000 times lower than safety thresholds established by the USA FDA, and every sample tested was found to be far below the FDA's safety threshold for dispersant compounds (BP, 2015). FDA testing of oysters found oil contamination residues to be 10 to 100 times below safety thresholds (BP, 2014). Sampling data shows that post-spill fish populations in the GoM since 2011 were generally consistent with pre-spill ranges and for many shellfish species, commercial landings in the GoM in 2011 were comparable to pre-spill levels. In 2012, shrimp (prawn) and blue crab landings were within 2.0% of 2007-09 landings. Recreational fishing harvests in 2011, 2012 and 2013 exceeded landings from 2007-09 (BP, 2014).	
Tourism and Recreation	Refer also to sections on fish, cetaceans, benthic and coastal habitats and National Parks and Reserves above.	Tourism and recreation is also linked to the presence of marine fauna (e.g. whales), particular habitats and locations for swimming or recreational fishing. The modelling predicts visible oil extending into nearshore Victorian waters (including waters of Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks and Beware Reef Marine Sanctuary). Oil is predicted to contact hundreds of kilometres of shoreline at the moderate – high exposure threshold. The shoreline is dominated by sandy beaches popular for a range of recreational activities. A number of National parks and Reserves including the very popular Wilsons Promontory and (Gippsland) Lakes National Parks are situated along this potentially exposed coastline. Short to Medium-term impacts to nature-based tourism and other human uses of beaches (and nearshore waters) may occur as a result of temporary beach closures to enable clean-up, protect human health or due to perceptions of a polluted environment that is not desirable to visit. With respect to human health, post-Macondo oil spill (April 2010) studies in December found of 17000 water samples, none exceeded USEPA benchmarks for protection of human health (OSAT, 2010) and a year later residual oil in nearshore and sandy shoreline areas was highly weathered and concentrations

Receptor	Impact of hydrocarbon exposure	Exposure risk assessment
		of constituents of concern were below levels of concern for human health (OSAT, 2011). Alaska's tourism economy took approximately two years to recover from the Exxon Valdez (BOEM, 2017). The Eastern Research Group (2014) reported that while the DWH spill had had a significant impact on several areas of tourism in the short term and had wide-ranging impacts across the GoM, the tourism economy has rebounded to pre-spill levels within four years. The extent of potential impacts to tourism and recreation depends on when the spill occurs, size and where it comes ashore. Considering the range of activities and locations, the potential for reduced amenity of areas used by coastal tourists and recreational visitors, temporary health implications and possible closures, the consequence level is considered **Level I,** based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 4.5).

7.7.3.2 Likelihood Evaluation

The likelihood of LOWC has been developed based on SINTEF[1] records (as presented in the IOGP Risk Assessment Data Directory for Blowout Frequencies 2019) (IOGP, 2019) which presents the recommended frequencies of blowouts and well release incident based on industry data. The likelihood for LOWC has been established based on the following assumptions:

- Drilling and well operations are defined as being "of North Sea Standard" ("Operation performed with BOP installed including shear ram and two barrier principle followed") given the relevant safety case has been developed based on European standards and references various North Sea standards (e.g. NORSOK for barrier analysis, IOGP for relief well studies, Oil & Gas UK for relief well planning).
- The type of well operation is 'Workover'
  - As described in Section 7.7.1, the worst case discharge scenarios are based on a LOWC during a workover activities
  - Other activities considered have a lower likelihood of occurrence.
- The category is 'well release'
  - The IOGP Risk Assessment Data Directory differentiates between a 'well blowout' and a 'well release'.
    - A well blowout is defined as: "An incident where formation fluid flows out of the well or between formation layers after all the predefined technical well barriers or the activation of the same have failed."
    - A well release (defined as: "An incident where hydrocarbons flow from the well at some point where flow was not intended and the flow was stopped by use of the barrier system that was available on the well at the time of the incident")

As all ExxonMobil wellwork activities require multiple barriers and controls during wellwork activities, any well integrity issue is likely to be restricted to a limited well release rather than a blow-out.

Based on these assumptions, the frequency of a well release is expected to be:

- 7.6 × 10-4 for a Gas Well
- 3.7 × 10-4 for an oil well

This indicates the chances of the activity resulting in a LOWC (and the subsequent impacts to receptors) are **Very Unlikely (D)**

7.7.4 Risk Ranking

Consequence	Likelihood	Risk Ranking
II (environmental) / I (public impact)	D	3 (environmental) / 2 (public impact)

[1] SINTEF is a comprehensive event database for blowout risk assessment. The database includes information on 642 offshore blowouts/well releases that have occurred world-wide since 1955 and overall exposure data from the US Gulf of Mexico, Outer Continental Shelf and the North Sea. The blowouts/well releases are categorized in several parameters, emphasising blowout causes.

7.7.5 Controls

Good Practice	Adopted	Control	Rationale
Well operations planning to prevent LOWC	✓	**CM32:** NOPSEMA accepted WOMP	Under Part 5 of the Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011, NOPSEMA is required to accept a WOMP to enable well activities to be undertaken. The NOPSEMA accepted WOMP demonstrates how the risks to the integrity of the wells will be reduced to as low as reasonably practicable (ALARP). Esso's NOPSEMA-accepted WOMP describes the minimum requirements for maintaining a minimum of two independent tested barriers at all times, including during wellwork activities. . Barrier integrity is verified upon installation and at periodic intervals and operations will be suspended if a barrier fails resulting in fewer than two independent barriers remaining in place.
Implementation of a safety management system which controls risks arising from major incidents and achieves safe operation of the facility	✓	**CM34:** NOPSEMA accepted Safety Case	The NOPSEMA accepted Safety Case demonstrates how the risks to the integrity of the wells will be reduced to as low as reasonably practicable (ALARP). This includes: • Planned maintenance of pressure well control equipment • Testing of well control equipment • Validation of safety critical equipment
Maintain control of well during wellwork activities	✓	**CM33** WellWork Execution Manual (WEM)	The WEM defines the processes that must be followed to ensure that well intervention activities are undertaken safely. This includes the requirement that a program is prepared for each well intervention activity which includes consideration for • completion design, • wellwork fluid selection, • formation pressure and • existing known issues. This is to ensure that there are two barriers in the well at any time during wellwork. Procedures are signed off at appropriate level of management. The WEM outlines well control equipment requirements to prevent unexpected pressure releases or blowouts Well control equipment must be installed on every well that is being completed, worked over, or serviced to reliably shut

Good Practice	Adopted	Control	Rationale
			in the wellbore and to allow for control of any influx BOP equipment classifications are determined based on the properties of the well. BOPs must be pressure tested before any wellwork activities can commence.
Maintain well integrity	✓	**CM48** Well Integrity Management System (WIMS)	WIMS defines the processes that must be followed to ensure integrity of a well is monitored and maintained until it is abandoned. Integrity of the well is monitored through pressure monitoring and equipment testing. Integrity of the well is maintained through preventative maintenance and downhole corrosion control. WIMS testing is not completed on old exploration wells.
Maintain integrity of surface well equipment	✓		WIMS defines the process for maintaining and monitoring integrity of surface equipment associated with the wellhead such as the Christmas tree, safety valves and flowlines.
Source control methodology	✓	**CM60:** Isolation test plan for Subsurface isolation valves developed and actioned per FIMS process	Shutdowns can be put in effect by a number of initiators that indicate abnormal operating conditions (e.g. high pressures) that could bring the process to an unsafe state or an actual loss of containment of hydrocarbons (e.g. triggering gas detectors on the topsides). They can also be initiated manually. • A Surface Shutdown shuts down and isolates process equipment on a platform. • A Subsurface Shutdown does this and also initiates boundary isolation at the well subsurface safety valves and the pipeline LVOs (last valves on), FVOs (first valves off) and actuated SSIVs (subsea isolation valves) where installed. • A Generator Shutdown shuts down the electricity generators and initiates a Surface Shutdown. • A Total Platform Shutdown (TPS) initiates all of the above shutdowns and trips all sources of battery power other than those feeding hazardous area rated communications, lighting and navigation aids. A Subsurface Shutdown can be initiated on the platform or it can also be initiated from the Production Control Room at

Good Practice	Adopted	Control	Rationale
			Longford. Other shutdowns are initiated from the EAA or the control room on the platform.
	✓	**CM61**: Well Kill Contingency Plan	A well control response plan has been prepared for any production well with a critical well failure on a staffed or unstaffed platform in Bass Strait. The well control response plan has been developed to be applicable to all platforms and includes the following details: • Key roles and responsibilities • Defining relevant process conditions, equipment and procedures relevant to response activities at each platform • Defining critical well failure scenarios • Identifying key equipment and materials to execute the well control response plan • Rig up drawings at each facility The well control response plan primarily focuses on bullhead killing or lubricating production wells with the Well Kill Equipment Skid. Note that well failures on subsea wells, in open water and where the platform or wellhead is inaccessible due to fire or damage are outside the scope of this document. Such situations are covered in the Drilling Emergency Preparedness and Response (EP&R) Manual
	✓	**CM62**: Drilling Emergency Preparedness and Response Manual	The Drilling Emergency Preparedness and Response (EP&R) Manual outlines the approach UIS-Wells will take in response to emergencies. The Drilling EP&R Manual Includes Quick Reference Guides for emergency response including notifications, safety and first response checklists. Wells Team specific Tier II / III Emergency Preparedness & Response Plan may be prepared to plan for an expanded response structure in the event of a large-scale drilling-related incident.
	✓	**CM63:** Monitoring relief well rig availability.	A register of the status and location of suitable rigs to drill relief wells will be maintained and will be updated on a quarterly basis. The monitoring process used to identify availability of suitable rigs and support vessels (HLVs, OSVs) is done through a system which allows Esso to determine how long the rigs are likely to be available for and therefore provides an outlook of

Good Practice	Adopted	Control	Rationale
			when availability might change in advance. Under normal circumstances, the average rig count for Australia is 16, with most of these capable of drilling a relief well in the Bass Strait area. The average rig count generally remains constant and is not expected to change significantly. In the unlikely event that there is no suitable rig available to allow a relief well to be drilled in the committed timeframe, (see Section 7.7.5.1 below) the wellwork activities will be made safe and suspended until such time as the activity can comply with this EP or the EP is resubmitted and accepted.
Oil spill response planning	✓	**CM12:** OPEP	Under the OPGGSE Regulations, the petroleum activity must have an accepted Oil Pollution Emergency Plan (OPEP) in place (Reg. 14(8). In the event of a LOWC, the OPEP will be implemented. Capability is maintained to ensure OPEP can be implemented in response to an incident, as expected. This includes maintaining contracts with third party service providers to ensure required materials are available at the time of an incident.
Oil spill monitoring planning	✓	**CM35:** OSMP	The OSMP is a key part of an integrated package of environmental management documentation that also includes the environment plan (EP) and the oil pollution emergency plan (OPEP). It is defined under (Reg. 14(8) of the OPGGSE Regulations. The OSMP is the principle tool for determining the extent, severity and persistence of environmental impacts from an oil spill, and allows titleholders to determine whether their environmental protection goals are met. Esso's OSMP details the arrangements and capability in place for: • Operational monitoring of a hydrocarbon spill to inform response activities • Scientific monitoring of environmental impacts of the spill and response activities. Operational monitoring will allow adequate information to be provided to aid decision making to ensure response activities are timely, safe, and appropriate. Scientific monitoring will identify if potential longer-term remediation activities may be required

Good Practice	Adopted	Control	Rationale
			Capability is maintained to ensure OSMP can be implemented in response to an incident, as expected.
Utilisation of idle fishing vessels		**CM51:** Utilisation of idle vessels	Opportunities to utilise idle fishing vessels for oil spill response and monitoring activities will be taken where there is agreement of the vessel owner and where a risk assessment shows that there are no additional risks to vessels and crew.
Communication with fisheries	✓	**CM52**: Communication with fisheries	Updates on oil spill response and monitoring provided to fishery representative bodies (through SETFIA) to enable accurate information on spill status, impacts and effects of spilled hydrocarbons on seafood safety to be provided to fishing industry members and the public. Daily updates provided in the first week until the modelling is completed and then as needed, until relief well completed (and beyond if there is ongoing concern).

7.7.5.1 Relief well drilling

Should implementation of relief well drilling be required to mitigate the impacts from LOWC, it is expected to take up to 98 days. The response time for a relief well is based on rig mobilisation from Dampier, assuming a semi-submersible MODU being wet-towed. The time to drill a relief well was chosen as the basis for spill volume calculations.

A detailed breakdown for response times based on the 98 day planning scenario is provided in Table 7-29. The IOGP Response Time Model Toolkit would also be utilised to plan response time for a relief well (IOGP, 2019a).

Table 7-29 Response Time Breakdown (Wet Tow Scenario)

Operation	Duration (days)	Cumulative (days)
Notifications; Mobilise specialist personnel; Initiate source control emergency response plan; Source MODU; Contract; Source AHTS.	7	7
MODU suspend well, demoor, transit to Dampier	14	21
Tow to incident location (4 knots)	30	51
Load materials	2	53
Moor and drill relief well	35	88
Weather allowance	5	93
Kill well	**5**	**98**

The 98 day drilling scenario is a conservative estimate. Mobilisation may be able to be accelerated through the use of a Heavy Lift Vessel (HLV) for MODU/JUR transport which would occur, as an example from Singapore, in approximately 85 days. An example of the breakdown of the 85 day response scenario is provided in Table 7-30.

Table 7-30 Response Time Breakdown (HLV Scenario)

Operation	Duration (days)	Cumulative (days)
Notifications; Mobilise specialist personnel; Initiate source control emergency response plan; Source MODU; Contract; Prepare for transport Source Heavy Transport Vessel; Prepare for transport operation	10	10
Load MODU	3	13
Transit Singapore to Westernport Bay	15	28
Offload MODU; Load materials	2	30
Tow to incident site; Load materials	4	34
Conduct jack-up foundation geotechnical survey; Preload	4	38
Drill relief well	35	73
Weather allowance	7	80
Kill well	**5**	**85**

A critical part of the response will be to secure a suitable MODU/JUR capable of drilling a relief well. Depending upon the location, the MODU may require the use of a HLV to expedite mobilisation (towed MODU averages 4 knots, compared with >12 knots for HLV).

The selection of a suitable MODU/JUR and support vessels would focus on the units currently operating in Australia under an accepted Safety Case that are suitable to drill the relief well (considering water depth and other well specifications). If required, a vessel Safety Case acceptance would be worked during the time it takes to mobilise the rig to the incident location (~ 51 days).

The accepted vessel Safety Case as revised for the WTA P&A campaign would be used as the basis for preparing the relief rig Safety Case and best efforts would be made to secure acceptance for the relief rig within the mobilisation timeframe. MODU/JUR, HLV and support vessels would need to meet project ballast water / biofouling requirements.

7.7.6 Demonstration of ALARP

ALARP Decision Context and Justification	Decision Context B Operation and wellwork activities are a well-established practice and the environmental and public impact risks (Category 3 Medium and Category 2 Medium respectively) associated with a LOWC are well understood and effectively managed by existing controls. The environmental and public consequences of a LOWC have been assessed as moderate – high and in recognition of the interest from both relevant stakeholders and the public about the potential impacts of a major oil spill. The utilisation of idle fishing vessels (where practicable and safe to do so) and ensuring ongoing communication with the fishing industry bodies will assist in mitigating socioeconomic impacts to commercial fisheries and the seafood supply chain. Consequently, Esso believes **ALARP Decision Context B** should apply.

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Utilisation of idle fishing vessels	Opportunities to utilise idle fishing vessels for oil spill response and	There are minor costs associated with using idle	Adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
	monitoring activities will be taken where there is agreement of the vessel owner and where a risk assessment shows that there are no additional risks to vessels and crew.	fishing vessels including ensuring safety and training standards are met in the event of an incident. Costs are considered reasonable given the high public impact consequence	**CM51:** Utilisation of idle vessels
Communication with fisheries	Updates on oil spill response and monitoring provided to fishery representative bodies (through SETFIA) to enable accurate information on spill status, impacts and effects of spilled hydrocarbons on seafood safety to be provided to fishing industry members and the public. Daily updates provided in the first week until the modelling is completed and then as needed, until relief well completed (and beyond if there is ongoing concern).	There is minor costs associated with sending communication out to stakeholders, particularly as there has been ongoing consultation through the EP. Costs are considered reasonable given the high public impact consequence.	Adopted **CM52**: Communication with fisheries
Continual WIMS monitoring of old exploration wells	Monitoring of old exploration wells could provide early indication of integrity issues.	Exploration wells have not been perforated for production, meaning the production casing is intact, further reducing pathways for reservoir to atmosphere. Exploration wells have been temporarily abandoned which reduces the likelihood of release as per IOGP Blowout Frequency Data. Exploration wells do not have infrastructure installed to allow for WIMS testing. WIMS testing would require use of an ROV and well intervention. The act of undertaking this activity would increase the likelihood of a release. The cost and increased risk of release from completing WIMS testing on old exploration wells does not provide a net benefit.	Not adopted
Early abandonment of each well, outside of P&A campaign	Abandonment of wells can minimise the likelihood of a loss of well control incident occurring.	Use of a wellwork skid to abandon a well is highly expensive requiring mobilisation of vessels, equipment and personnel to a platform. Use of a Jack Up Rig to abandon wells is more expensive than a wellwork skid and requires additional vessel support. Use of a JUR would require a supporting environment plan as the rig	Not adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
		presents a number of environmental impacts. There are significant cost and safety efficiencies in completing well abandonments as part of a campaign. As per the analysis in Section 6.7.1 above, the initiating event leading to a worst case discharge scenario is undertaking wellwork activities. The likelihood and consequence associated with shut-in, suspended and temporarily abandoned wells is less than that during wellwork activities. This indicates that, provided there are no integrity or safety drivers to abandon wells, there is no significant increase in risk for shut-in, suspended and temporarily abandoned wells, which is less than that during wellwork activities. Considering the increase in risk of release while undertaking wellwork activities, the risk reduction gained from abandonment of individual wells outside of P&A campaigns is not proportionate to the cost.	
Use of a capping stack (vertical or offset)	Capping stacks can be used on subsea wells in the event of a LOWC to reduce flow from a well and reduce the volume of reservoir fluid released.	Capping stacks cannot be used on platform based wells. Capping stacks have limited applicability on subsea facilities. OSRL's offset capping stack system is limited due to minimum depth requirements (>75 m) and long mobilisation times. Use of capping stacks is not feasible due to water depth at West Barracouta (BTW) (at 46m depth) Note that the subsea wells at Blackback (at 402m depth), Seahorse (42m depth) and Tarwhine (at 42m depth) have been abandoned and are no longer considered part of the activity (as per OPPGS Regulations (Well Operations), Reg 5.17). Use of a capping stack at the KPA location (95m) is not considered reasonably	Not adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
		practicable for the following reasons which indicate that the technical feasibility of using a capping stack at the KPA location is not feasible: • Modelling of a LOC at the KPA location indicates a ~66m radius “bubble zone” at the water line due to the shallow gas release. This eliminates the potential for vertical access capping stacks. • Use of the OSRL offset installation system (OIS) is notionally rated to 75-600m water depth and deployment is particularly challenging in shallow waters, under high discharge rates and/or high gas/oil ratio (GOR). • The KPA wells have a high GOR (0.15 sKL/SKm3) further reducing the safety and likelihood of effective use of a capping stack. • While in production, well heads are covered with trawl protection frames further reducing the likelihood that a capping stack could be deployed.	
Third level of well barriers	Increased level of protection from uncontrolled flow from a well beyond the ‘two barrier’ requirement.	The two barrier philosophy is considered industry best practice and the BOP already has multiple barriers with redundancy, specifically designed to reduce the risk to ALARP as per the WOMP.	Not Adopted
Relief well drilling rig available locally to reduce mobilisation time	Having a MODU on standby may allow the relief well to be drilled 34 days earlier, thus reducing the volume of release. There is an extremely low probability of occurrence of a source control event.	Esso Bass Strait Operations are a continuous production operation with production and wellwork activities happing on an ongoing basis. It is not feasible to have a standby MODU available throughout the lifetime of the operation. Given the high costs to the program, implementing this control measure is considered disproportionate, given that the source control event has an extremely low likelihood of occurrence.	Not Adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Relief well materials staged locally	Response time for relief well drilling is dependent on the availability of necessary well construction equipment (i.e. wellhead, casing). No meaningful reduction in time for relief well drilling as sufficient materials available as spares or can be procured within short timeframes.	Wellhead and casing requirements will be identified during the planning phase done concurrent with MODU mobilisation. Any additional equipment would be mobilised from existing ExxonMobil global inventory.	Not Adopted
Prepare detailed Relief Well Plan in advance	Detailed Relief Well Plan needs to be developed on a case by case basis. Detailed Plan can be developed immediately after LOWC scenario is fully understood, and while relief well rig is being mobilised. The benefit from preparing a detailed relief well plan without knowing specifics of the LOWC is nominal.	Sufficient time would be available to prepare a detailed relief well plan when the specific blow-out parameters for a relief well can be determined, immediately following the incident, and whilst the relief rig is being mobilised. Given the requirements for specific details and the number of different types of well locations and well designs in Bass Strait Operations, this control measure is considered disproportionate, given that the source control event has an extremely low likelihood of occurrence.	Not Adopted

7.7.7 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Risk Assessment Process for Unplanned Events	The risk ranking is lower than Category 1	✓	The environmental risk ranking is Category 3 and the public impact risk ranking Category 2, and therefore considered acceptable.
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	The impacts associated with this aspect are potentially significant but moderate in size/scale and medium term, which is not considered as having the potential to affect biological diversity and ecological integrity.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The activity is not considered as having the potential to result in long term or irreversible environmental damage.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	• The proposed activities align with the requirements of the OPGGS Act 2006: • Schedule 3 Occupational health and safety and OPGGS(S)R. The OPGGS(S)R require the operator of

Factor	Demonstration Criteria	Criteria Met	Rationale
			each offshore facility to prepare a safety case for submission to NOPSEMA. Activities at a facility must be conducted in accordance with a safety case that has been accepted by NOPSEMA. • Part 5, OPGGS (Resource Management and Administration) Regulations 2011 which require NOPSEMA to accept a WOMP to enable well activities to be undertaken. • The following other requirements were identified as relevant to impacts from a LOWC. Oil spills are a recognised threat to these species and proposed activity is consistent with conservation / management actions where specified: • Approved Conservation Advice for *Thinornis rubricollis* (Hooded Plover, Eastern) • Approved Conservation Advice for Sternula nereis nereis (Fairy Tern)
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"
	Meets ExxonMobil Environmental Standards	✓	There is no standard related to a LOC of reservoir hydrocarbons but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed activities meet: • OIMS System 6-3 Well Management, detailing Wellwork Execution Manual (WEM). • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; • OIMS System 8-1 objective to clearly define and communicate operations integrity requirements to contractors; • OIMS System 10-1 objective to anticipate community concerns and develop response plans, as appropriate; and • OIMS System 10-2 objectives to document, resource and communicate emergency response plans, and conduct training, exercises and/or drills

Factor	Demonstration Criteria	Criteria Met	Rationale
			to determine the adequacy of the plans.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	Concerns from relevant stakeholders addressed through the consultation process. Any new relevant stakeholder objections, claims or issues will be considered in line with the ongoing consultation.

Appendix A – Bass Strait Operations Inventory

Contents

List of Tables

4.1 Facilities

Table 1 Facilities (Platforms)

Item	Inventory	Staffing status [max POB]	Location	Distance to coast	Water depth	Status (as at Dec 2020)	Expected status as at 2025
Barracouta (BTA)	Barracouta platform is an eight-leg steel piled jacket. Staffed facility. 10 conductor slots, 10 conductors and 10 wells drilled. One well injects LPG into the reservoir for storage when gas demand exceeds LPG processing capacity.	Staffed [31]	VIC/L02 (38° 17' 53" S; 147° 40' 28" E)	23 km	46 m	Production	Cessation of Production
Whiting (WTA)	Whiting platform. Four leg steel piled jacket with 6 conductor slots, provision for 8 wells but 5 wells drilled. Day-only accommodation Oil production ceased in 1997 and facility was declared CoP in 2019 after studies found gas development at Whiting unviable. Wells P&A'd in 2020 and all conductors have been pulled.	Unstaffed	VIC/L02 (38° 14' 29" S; 147° 72' 20" E)	34 km	54 m	Cessation of Production	Stasis mode
Marlin A (MLA)	Marlin A platform is an eight-leg steel piled jacket. MLA and MLB are connected by an upper and lower walkway bridge. 24 slots, 24 conductors and 24 wells drilled. The majority of wells in service are classified as gas producers, with a few wells classified as oil producers and reinjectors.	Staffed [96]	VIC/L03: (38° 13' 54" S, 148° 13' 09" E)	42 km	59 m	Production	Cessation of Production
Marlin B (MLB)	Marlin B platform is an eight-leg steel piled jacket. MLA and MLB are connected by an upper and lower walkway bridge. No accommodation facilities on Marlin B. 18 conductor slots, 7 conductors and 5 wells drilled. Wells include oil production wells, gas production wells and gas re-injection wells.	Staffed [n/a, accommodation on MLA]	VIC/L03: (38° 13' 46" S, 148° 13' 16" E)	42 km	59 m	Production	Production
West Tuna (WTN)	West Tuna platform is a three-leg concrete gravity structure (CGS). Northern legs of the CGS are each designed with 24 well conductor slots. In total 48 conductors and 47 wells drilled. The majority of wells are classified as oil producers; however, they do also produce gas. A minority of wells are gas injectors and gas producers.	Staffed [82]	VIC/L04: (38° 11' 37" S, 148° 23' 15" E) **RAT** VIC/L04: (38° 11' 29"	45 km	61 m	Production	Production

Item	Inventory	Staffing status [max POB]	Location	Distance to coast	Water depth	Status (as at Dec 2020)	Expected status as at 2025
	WTN is connected to the KPA subsea facility via WTN350 pipeline and MLB via WTN450 pipeline. These pipelines are attached to WTN via a Riser Access Tower (RAT), located approximately 60 m to the north-east of WTN and connected by a bridge.		S, 148° 23' 23" E)				
Halibut (HLA)	The Halibut platform is made up of two steel piled jacket structures, each consisting of eight legs. 24 conductor slots, with 23 conductors and 22 wells drilled. All wells are classified as oil producers. HLA acts as a gathering platform. Pipeline contents from BMA, BMB, WKF, KFA, KFB, MKA, CBA and FTA platforms is combined with HLA produced oil and transferred to shore via the HLA-Shore 600 pipeline. HLA receives fuel gas from MLA through MLA-MKA100. Fuel gas from this pipeline is also exported to CBA (HLA-CBA100) and FTA (HLA-FTA100).	Staffed [44]	VIC/L05: (38° 24' 20" S, 148° 19' 07" E)	63 km	73 m	Production	Cessation of Production
Fortescue (FTA)	Fortescue platform is an eight-leg steel piled jacket. 31 slots, 31 conductors and 31 wells drilled. All wells are classified as oil producers. Ceased production in March 2020	Periodically staffed during cessation of production stage. [60]	VIC/L05: (38° 28' 50" S, 148° 20' 28" E)	62 km	69 m	Cessation of production	Stasis mode
Cobia (CBA)	Cobia platform is an eight-leg steel piled jacket. 25 slots, 25 conductors and 25 wells drilled. All wells are classified as oil producers. Cobia platform suspended production in 2014 due to a leak in the CBA300 pipeline. The pipeline was repaired and production recommenced in Q4 2019.	Staffed [58]	VIC/L05: (38° 24' 32" S, 148° 16' 36" E)	68 km	75 m	Production	Cessation of Production
Mackerel (MKA)	Mackerel platform is an eight-leg steel piled jacket. 25 slots, 25 conductors and 25 wells drilled. Ceased production in 2015. P&A in progress. Expect P&A to be completed by end of 1Q 2021.	Periodically staffed during cessation of production stage. [58]	VIC/L05: (38° 27' 04" S, 148° 18' 28" E)	72 km	93 m	Cessation of Production	Stasis mode
Kingfish A (KFA)	Kingfish A platform is an eight-leg steel piled jacket. 21 slots, 21 conductors and 21 wells drilled. Ceased production in 2015.	Periodically staffed during cessation of production stage. [41]	VIC/L07: (38° 35' 51" S, 148° 08' 35" E)	77 km	77 m	Cessation of Production	Cessation of Production
Kingfish B (KFB)	Kingfish B platform is an eight-leg steel piled jacket. 21 slots, 21 conductors and 21 wells drilled. All of the wells in service are classified as oil producers except for two which are classified as water injectors. Ceased production in 2019.	Periodically staffed during cessation of production stage. [41]	VIC/L07: (38° 35' 54" S, 148° 11' 11" E)	77 km	78 m	Cessation of Production	Cessation of Production

Item	Inventory	Staffing status [max POB]	Location	Distance to coast	Water depth	Status (as at Dec 2020)	Expected status as at 2025
West Kingfish (WKF)	West Kingfish platform is an eight-leg steel piled jacket. 33 slots, 33 conductors and 32 wells. All of the wells in service are classified as oil producers	Staffed [56]	VIC/L07: (38° 35' 39" S; 148° 06' 15" E)	72 km	76 m	Production	Cessation of Production
Tuna (TNA)	Tuna platform is an eight-leg steel piled jacket. 33 slots, 33 conductors and 33 wells drilled. Wells are classified as either oil or gas producers. One well is a gas injector.	Staffed [51]	VIC/L09: (38° 10' 16" S; 148° 25' 05" E)	43 km	59 m	Production	Production
Snapper (SNA)	Snapper platform is an eight-leg steel piled jacket. 45 slots, 39 conductors and 33 wells drilled. All wells are classified as oil or gas producers.	Staffed [79]	VIC/L10: (38° 11' 42" S; 148° 01' 26" E)	32 km	55 m	Production	Cessation of Production
Flounder (FLA)	Flounder platform is an eight-leg steel piled jacket. 27 slots, 27 conductors and 27 wells drilled. Wells produce oil and gas. Ceased production in May 2020.	Staffed. In the future, will be periodically staffed during cessation of production stage. [73]	VIC/L11: (38° 18' 44" S; 148° 26' 16" E)	58 km	93 m	Cessation of Production	Stasis mode
Bream A (BMA)	Bream A platform is an eight-leg steel piled jacket. 27 slots, 27 conductors and 27 wells drilled. Most wells are classified as oil producers, but also produce gas. Others are classified as gas producers. Ceased production in September 2020.	Periodically staffed during cessation of production stage. [80]	VIC/L13: (38° 30' 03" S; 147° 46' 15" E)	48 km	59 m	Cessation of Production	Stasis mode
Bream B (BMB)	Bream B platform is a fixed installation on a single leg CGS. 18 slots, 17 conductors and 17 wells drilled. The majority of wells are classified as oil producers. One well is classified as a gas producer and is used for gas lift. Ceased production in September 2020.	No accommodation facilities. Day visits only.	VIC/L14: (38° 31' 12" S; 147° 50' 16" E)	51 km	61 m	Cessation of Production	Cessation of Production
Dolphin (DPA)	Dolphin platform is a fixed installation on a steel gravity based monotower. The DPA platform has 2 slots, 2 conductors and 2 wells drilled. Ceased production in 2014.	No accommodation facilities. Day visits only.	VIC/L15: (38° 29' 20" S; 147° 22' 34" E)	21 km	38 m	Cessation of Production	Stasis mode
Perch (PCA)	Perch platform is a fixed installation on a steel gravity based monotower. The PCA platform has 2 slots, 2 conductors and 2 wells drilled. Ceased production in 2014.	No accommodation facilities. Day visits only.	VIC/L17: (38° 34' 15" S; 147° 19' 16" E)	24 km	42 m	Cessation of Production	Stasis mode

Table 2 Facilities (Subsea)

Item	Inventory	Location	Distance to coast	Water depth	Status (as at Dec 2020)	Expected status as at 2025
Kipper (KPA)	Kipper subsea facility connect to WTN via the WTN-RAT. Comprises production manifold, 4 x coolers, 4 flowbases with 2 wellheads (fitted with trawl protection frames). The Kipper wells are classified as gas producers. Additional subsea gas production wells are planned for the existing facility.	VIC/L25: (38°10' 53" S; 148° 35' 35" E) Or 38° 18' 11" S; 148° 59' 36 E" (BTW Campaign??)	41 km	95 m	Production	Production
Seahorse (SHA)	Seahorse subsea facility connected to BTA by an oil pipeline (SHA-BTA150), a 65 mm gas lift line and an electrohydraulic umbilical. The SHA subsea facility consists of one subsea well. The well is classified as an oil producer Subsea tree was removed following plug and abandonment in September 2020. Electrical Flying Leads, subsea tree base plate, UTA and umbilical remain in place on the seabed pending assessment as part of the Bass Strait decommissioning program. The SHA and TWA plug and abandonment activity is the subject of a separate Environment Plan. Ceased production in 2014.	VIC/L18: (38° 11' 42" S; 147° 40' 27" E)	21 km	42 m	Stasis mode	Stasis mode
Tarwhine (TWA)	Tarwhine subsea facility is connected to BTA by an oil pipeline (TWA-BTA200), a 65 mm gas lift line and an electrohydraulic umbilical. The TWA subsea facility consists of one subsea well. The well is classified as an oil producer. Subsea tree was removed following plug and abandonment in October 2020. Subsea tree base plate, UTA and umbilical remain on the seabed pending assessment as part of the Bass Strait decommissioning program. The SHA and TWA plug and abandonment activity is the subject of a separate Environment Plan. Ceased production in 2008.	VIC/L01: (38° 24' 12" S; 147° 31' 46" E)	21 km	42 m	Stasis mode	Stasis mode
Blackback (BKA)	The three BKA wells have been plugged and abandoned and the subsea trees have been removed in 2018. Disconnected flexible jumpers, electrical and chemical flying leads, UTA and PTA remain in place on seabed pending assessment as part of the Bass Strait decommissioning program, as well as the TGB for one well, below the mudline. Ceased production in 2010.	VIC/L20: (38° 32' 26" S148° 33' 16" E)	87 km	402 m	Stasis mode	Stasis mode
West Barracouta (BTW)	Two subsea gas production wells have been drilled in 2020 approximately 6 km southwest of the BTA platform. The subsea facility will consist of two subsea trees with trawl protection frames connected via jumpers and flying leads to a FLEM and UTA. This subsea facility will be controlled from BTA	VIC/L02 (38° 19' 06" S, 147° 36' 53" E)	22 km	46 m	Expected to commence production in 2021	Production

Item	Inventory	Location	Distance to coast	Water depth	Status (as at Dec 2020)	Expected status as at 2025
	via an electrohydraulic umbilical and is to be tied back to the existing BTA450 pipeline.

VIC/SL9	MLA150-KFB/KFA/WKF	MLA	KFB/KFA/WKF	53	150	Gas	Production	Production

Secondary lines are not petroleum pipelines and therefore do not have separate petroleum pipeline licences

As well as the section of the original CBA300 pipeline listed in Table 3 there are other sections of pipelines which have been flushed and are on the seabed:-

- 4km of MKA300 oil pipeline (at MKA end)
- 7km of FLA250 oil pipeline (at FLA end)
- 2 x 4.5km CBA2 100 to MKA oil pipelines (VIC/SL1)
- 1 x 4.5km MKA 25 to CBA2 chemical line
- 0.2km BTA250 to subsea vent gas line
- 0.25km MLA250 to subsea vent gas line

Subsea umbilicals:-

- 23.2km MKA to BKA electrical/hydraulic umbilical –not operating
- 4.6km MKA to CBA2 electrical umbilical –not operating

- 11.5km BTA to SHA electrical/hydraulic umbilical –not operating
- 17.6km BTA to TWA electrical/hydraulic umbilical –not operating
- 6.3km BMA to BMB control umbilical –operating
- 5.9km BTA to BTW electrical/hydraulic umbilical – will be operating by end of 2020
- 18.3km WTN to KPA electrical umbilical –operating
- 18.3km WTN to KPA fluids umbilical –operating
- 5 ea short (<0.3km) umbilicals to operate subsea valves in pipelines – all currently operating:-
    - Umbilical to subsea UV in KFA branch of MLA150 FG line near KFA
    - Umbilical to subsea UV in KFB branch of MLA150 FG line near KFB
    - Umbilical to subsea UV in MLA150 FG line near WKF
    - Umbilical to SSIV in MLB450 near SNA
    - Umbilical to SSIV in BMA350 near BMA

4.3 Wells

Table 5 Well Status Definition

Wells (as per description in Section 3.1 of Gippsland Basin Well Operations Management Plan)	
Active	Wells which flow naturally to the surface or are assisted by gas lift injection.
Shut-in	Production from, or injection into, a well has been ceased without isolating the well from the reservoir, with the intention that the operation be resumed within one year.
Suspended	Production from, or injection into, a well has been ceased by isolating the tubing from the reservoir, with the intention that the operation be resumed either after a period that is: • Short term (hour/days/weeks) or • Long term (months/years) Depending on the planned suspension duration, non-permanent barriers such as wireline plugs and kill weight fluid may be employed.
Temporarily abandoned	Reservoir has been isolated with a temporary plug and abandonment (TP&A) barrier, such as a mechanical plug or cement.
Abandoned	Reservoir has been isolated and plug and abandonment has been completed in accordance with the requirements in the WOMP.

4.4 Oil Types

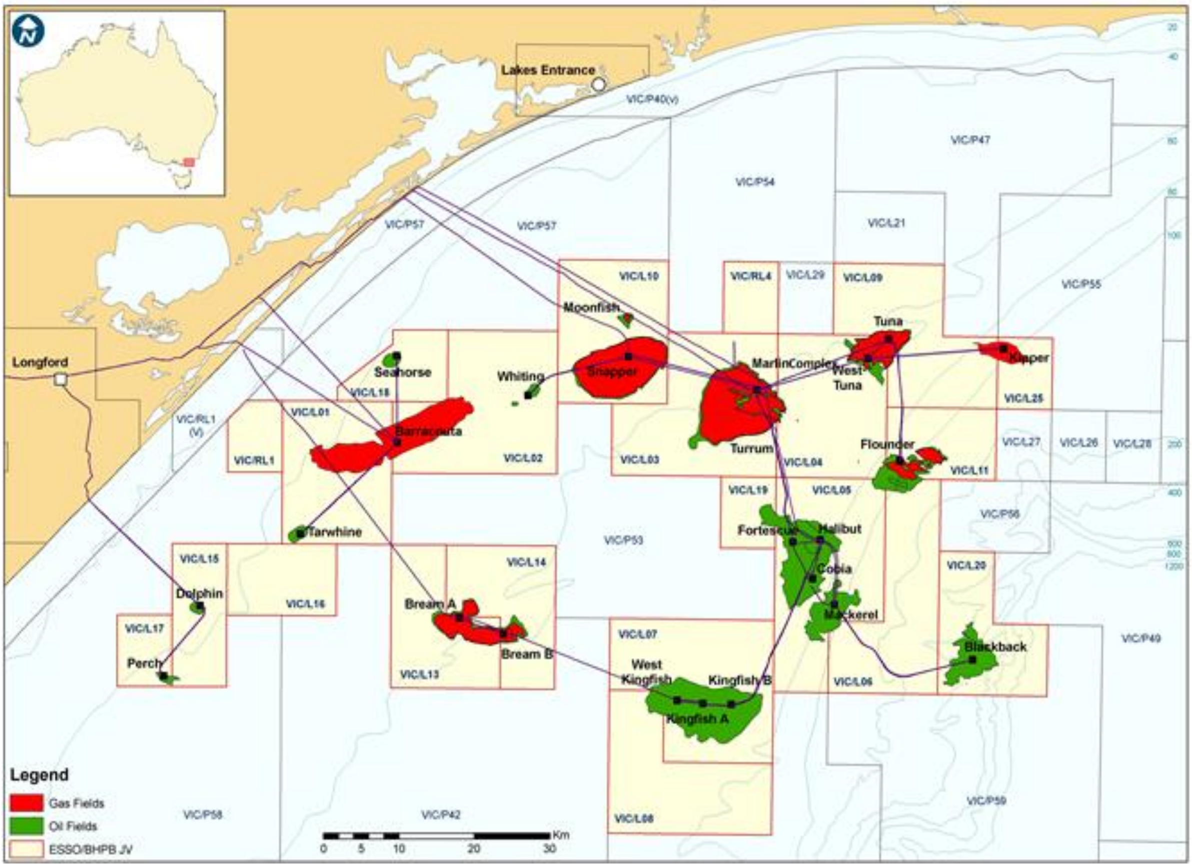
The main physical properties that affect the behaviour of spilt oil are specific gravity, distillation characteristics, viscosity and pour points. All are dependent on chemical composition such as the proportion of volatile components and the content of ashphaltenes, resins and waxes. The range of condensates and crude oils produced by the Bass Strait Operations were reviewed for each field and have been classified in accordance with groupings defined in the OPEP Section 7.2.2. Details of the data used for classifications is outlined in Table 7.

Table 7 Data used for classification of condensate and crude oil

Property	Description	Data provided
Specific Gravity	Specific gravity is an oil's density in relation to water. API gravity is an inverse measure of a petroleum liquid's density relative to that of water and it is used to compare densities of petroleum liquids.	API
Distillation characteristics	Distillation characteristics of an oil describe its volatility. Distillation characteristics are expressed as the proportions of the parent oil that distil within given temperatures. Wax content is a measure of bituminous waxy or asphaltenic residues which do not readily distil even at high temperatures.	Wax Content
Viscosity	Viscosity of an oil is its resistance to flow. High viscosity oils flow less easily than those of lower viscosity. All oils become more viscous as the temperature falls.	Data not available. Pour Point substituted.
Pour Point	The pour point is the temperature below which an oil no longer flows and is a function of its wax and ashphaltene content (ITOPS, 2011). Average water temperature for the Bass Strait is 15.7ºC (per RPS reports) and 14ºC has been used as the winter sea temperature for dispersant effectiveness testing. Therefore, it is assumed that crudes and condensates with a pour point >14ºC will be liquid at ambient temperatures.	Pour Point

At each location, a variety of oil, condensate and gas is produced from different reservoirs. As can be seen in Figure 1, the gas reservoirs (red) and oil reservoirs (green) are often layered on top of one another, meaning one facility may access multiple reservoirs and produce a variety of products. For example, multiple platforms could produce from the same reservoir (e.g. TNA and WTN producing from the Tuna M Reservoir) and/or one platform can produce from multiple reservoirs (e.g. Snapper producing from Snapper L, Snapper N and Moonfish).

Figure 1 Location of Oil and Gas Reservoirs in Bass Strait Operations



Where all data was not available, condensates and crudes have been classified according to available data and the closest available sample. Items highlighted in blue were sampled in 2019 in preparation for submission of this Environment Plan. These seven samples span the range of fluid properties of Bass Strait Operations. Over time, there will be a reduction in pressure in the reservoir due to on-going production. It is unlikely that these changes will impact composition at atmospheric temperatures and pressures. Therefore, the data available is considered to represent current conditions.

Table 8 Range of condensates and crude oils produced by the Bass Strait Operations

Field	Type	API	Pour Point (ºC)	Wax Content (%)	Oil Classification
Snapper IL	Condensate	74.7			Group 1
Tuna / West Tune M	Condensate	67.5		0.1	Group 1
Snapper N	Condensate	64.5			Group 1
Marlin	Condensate	63.1			Group 1
Batfish	Condensate	60.6		0.7	Group 1
Whiting	Condensate	58.7			Group 1
Tarwhine	Crude	55.9			Group 1
Whiting	Crude	54.8	-37	0.05	Group 1
Kipper	Condensate	54.5	-39	2.3	Group 1
Flounder	Condensate	54.0			Group 1
Seahorse	Crude	53.0			Group 1
East Pilchard	Condensate	52.5			Group 1
Turrum L	Condensate	50.8		4.3	Group 1
Barracouta	Condensate	51.6	-39	1.8	Group 1
Dolphin	Crude	46.3		2.3	Group 1

Appendix B – Inventory Maintenance And Planning End State

Infrastructure Group	Facility	Current state (as of Dec 2020)	Inspection, Maintenance, Repair Philosophy for CoP Stage	Inspection, Maintenance, Repair Philosophy for Stasis Mode Stage	Indicative Decom Timing	Provisional End State	Base Case End State expected under Section 572 of the OPGGS Act 2006	Decommissioning activity plans
Platforms - Steel Pile Jackets shallow water	Fortescue, Bream A, Whiting	Cessation of Production	• Confirm platform appurtenances (e.g. pipe supports, cable trays) are secured to minimise dropped object risks where required. • Maintain platform topsides primary and secondary structures fit for service to facilitate CoP activities. • Platform handrails and deck grating maintained on an 'as needs' basis to provide access and egress for activities being conducted during CoP stage, temporary repairs conducted where appropriate. • Helideck structural capacity required for helicopter landings maintained. • Maintain flare boom fit for service to facilitate operational flare. • Maintain jackets fit for service to facilitate staffed operations risk profile until platform is de-staffed. • Maintain jackets fit for service to facilitate de-staffed operations risk profile once platform is de-staffed (inspections reduced in line with occupancy).	• Maintain platform topsides primary and secondary structures fit for service to enable HLV removal and prevent dropped objects. • Maintain jackets fit for service to enable HLV removal. • Confirm platform appurtenances (e.g. pipe supports, cable trays) are secured to minimise dropped object risks where required	1st removal campaign	Topsides fully removed. Substructure fully removed (to seabed). Marlin A - Marlin B bridge fully removed.	Topsides fully removed Substructures fully removed to seabed.	EP for decommissioning execution activities (1st removal campaign) expected to be submitted in approximately 2025. EP for decommissioning execution activities (2nd removal campaign) expected to be submitted in approximately 2034.
	Snapper, Marlin A, Barracouta	Production Expected to reach CoP prior to 2025			1st removal campaign (Barracouta only) 2nd removal campaign (Snapper and Marlin A)			
	Marlin B, Tuna, West Tuna Riser Access Tower.	Production			2nd removal campaign			
Platforms - Steel Pile Jackets, deeper water	Kingfish A, Kingfish B, Mackerel, Flounder	Cessation of Production			1st removal campaign	Topsides - fully removed Substructure cut at approx. 55m below mean sea level and top section removed. Lower section of jacket decommissioned in situ.	Topsides fully removed Substructures fully removed to seabed.	Decommissioning strategy framework including initial justification for provisional end state included in this EP. Submission of EP(s) to seek deviation from full removal will be provided in approximately 2023. EP for decommissioning execution activities (1st removal campaign) expected to be submitted in approximately in 2025.
	Halibut, Cobia, West Kingfish	Production Expected to reach CoP prior to 2025						
Platforms - Concrete Gravity Structures	Bream B	Cessation of Production			1st removal campaign	Topsides fully removed. Substructure decommissioned in-situ.	Topsides fully removed. Substructure fully removed.	Decommissioning strategy framework including initial justification for provisional end state included in this EP. Submission of EP(s) to seek deviation from full removal will be provided in approximately 2023. EP for decommissioning execution activities (1st removal campaign) expected to be submitted in approximately 2025. EP for decommissioning execution activities (2nd removal campaign) expected to be submitted in approximately 2034.
	West Tuna	Production			2nd removal campaign	Topsides fully removed. Substructure decommissioned in-situ West Tuna - West Tuna RAT bridge fully removed.		
Platforms - Monopods	Perch, Dolphin	Cessation of Production			1st removal campaign	Fully removed.	Fully removed.	EP for decommissioning execution activities (1st removal campaign) expected to be submitted in approximately 2025.
Subsea production systems (excluding pipelines, umbilicals and umbilical	Cobia-2, Seahorse, Tarwhine, Blackback	Stasis Mode	Risk based inspections will continue to be carried out to maintain integrity	Risk based inspections of items remaining at each location will continue commensurate with the	Wells have been P&A'd, wellheads have been removed	Fully removed.	Fully removed.	The equipment removal activity will be covered under this EP which will be subject to review and

Infrastructure Group	Facility	Current state (as of Dec 2020)	Inspection, Maintenance, Repair Philosophy for CoP Stage	Inspection, Maintenance, Repair Philosophy for Stasis Mode Stage	Indicative Decom Timing	Provisional End State	Base Case End State expected under Section 572 of the OPGGS Act 2006	Decommissioning activity plans
termination assemblies which are covered below)				need to maintain integrity so as to enable full removal.	Timing of removal of remaining equipment subject to appropriate vessel availability.			assessment to ensure the scope of activities is covered.
	Kipper, West Barracouta	Production			Post end of field life, not tied to HLV campaign			EP for P&A of subsea facilities expected to be submitted in 2033/34. EP for removal activities will be covered under a separate EP post 2033/2034.
Offshore pipelines, umbilicals and associated equipment	Refer to Appendix A for listing	Production - Refer to Tables 3 & 4 in Appendix A for listing Cessation of Production / not operating - Refer to Appendix A for listing	For pipelines • LVOs, FVOs and topsides coating inspections will continue to maintain operational integrity of these items. • Pipeline internal and external corrosion will be controlled with appropriate risk based modifications to the internal and external corrosion control programs. • Risk based underwater inspections of the pipelines, risers and riser clamps will continue. For umbilicals Risk based inspections will be carried out as part of the underwater pipeline inspection programs.	For pipelines Pipeline external corrosion will continue to be controlled by existing pipeline coatings supplemented by existing pipeline anodes (where installed). Pipeline internal corrosion will be managed and risk based inspections will continue commensurate with the need to maintain integrity so as to enable full removal. For umbilicals Risk based inspections will be carried out commensurate with the need to maintain integrity so as to enable full removal.	Timing of removal subject to appropriate vessel availability.	Decommissioned in-situ (pipelines, umbilicals, pipeline stability items, pipeline end terminations, pipeline pull in sleds and umbilical termination assemblies). Fully removed (pipeline anode sleds, SSIV/MOV valve structures).	Fully removed.	Decommissioning strategy framework including initial justification for provisional end state included in this EP. Submission of EP(s) to seek deviation from full removal will be provided in approximately 2023. EP(s) for decommissioning execution activities expected to be submitted in approximately 2025. EP(s) for decommissioning execution activities expected to be submitted in approximately 2034 (for other pipelines).
Production Wells	Refer to Table 6 in Appendix A for listing of production wells	Refer to Table 6 in Appendix A for production well current status	Care & Preservation • WIMS testing and well monitoring per WOMP and internal Well Integrity Manuals. Wells suspended with deep set tubing plugs where possible. Plug & Abandonment • Downhole cement isolation plugs installed with well monitoring between abandonment phases where possible.	No further Inspection, maintenance, repair activities required as the wells have been P&A'd (decommissioned)	P&A activities are ongoing - see indicative schedule in Figure 1-3 of this EP.	Wells plugged and abandoned Conductors / subsea wellheads removed	Wells plugged and abandoned. Conductors / subsea wellheads removed.	Well P&A campaign indicative schedule included in Figure 1-3 of this EP. P&A activities undertaken on platform wells included in this EP. P&A campaigns carried out by JUR or MODU subject to separate EP submissions prior to campaign.
Exploration and appraisal wells	Mulloway-1, Whiptail-1, Halibut-1, Marlin-1, East Pilchard-1, Gudgeon-1, Terakihi-1	Temporarily abandoned	• 3 yearly ROV inspections (based on well risk characterization) for Mulloway-1, Whiptail-1a, Gudgeon-1, Terakihi-1, Halibut-1 to allow the wellhead to be inspected for oil seepage, gas bubbles, for signs of extensive corrosion, damage or excessive debris and confirmation of well status (debris cap position).	No further Inspection, maintenance, repair activities required as the wells have been P&A'd	See indicative schedule in Figure 1-3 of this EP.	Wells plugged and abandoned Subsea wellheads removed	Wells plugged and abandoned. Subsea wellheads removed.	Well P&A campaign indicative schedule included in Figure 1-3 of this EP. Exploration well P&A carried out by either JUR or MODU and subject to separate EP submission prior to campaign.

Infrastructure Group	Facility	Current state (as of Dec 2020)	Inspection, Maintenance, Repair Philosophy for CoP Stage	Inspection, Maintenance, Repair Philosophy for Stasis Mode Stage	Indicative Decom Timing	Provisional End State	Base Case End State expected under Section 572 of the OPGGS Act 2006	Decommissioning activity plans
			• 6 yearly ROV inspections (based on well status and barriers in place) for Marlin-1, East Pilchard-1 to allow the wellhead to be inspected for oil seepage, gas bubbles, for signs of extensive corrosion, damage or excessive debris and confirmation of well status (debris cap position).					
Other property (i.e. debris)	Various	N/A	None required to enable removal.	None required to enable removal.	Ongoing in accordance with suitable vessel availability.	Fully removed.	Fully removed.	Vessel activities covered in this EP.

Notes:

1: While Snapper and Marlin A are expected to reach CoP prior to 2025, the removal of these facilities is planned for the 2nd campaign as they will continue to be staffed after CoP to support Kipper and Turrum (MLB) production.

The provisional end states outlined in the table above do not preclude preparation towards complete removal as a potential decommissioning outcome, which is ongoing.

Appendix C – EPBC Act Listed Species PEA

Table 1 - EPBC Act listed fish (bony) species or species habitat that may occur within the PEA

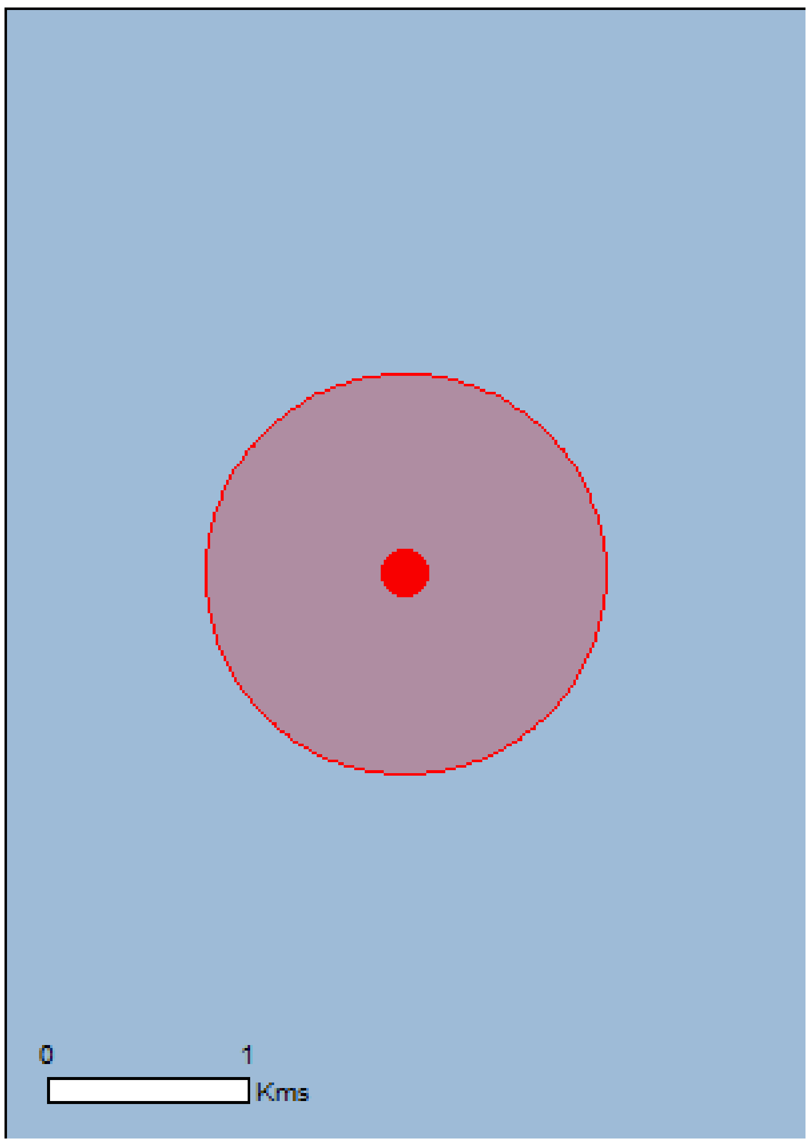
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

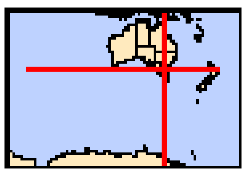
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 16:56:56



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	33
Listed Migratory Species:	36

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	10
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence

Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Fish		
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat may occur within area
Mammals		
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area

Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

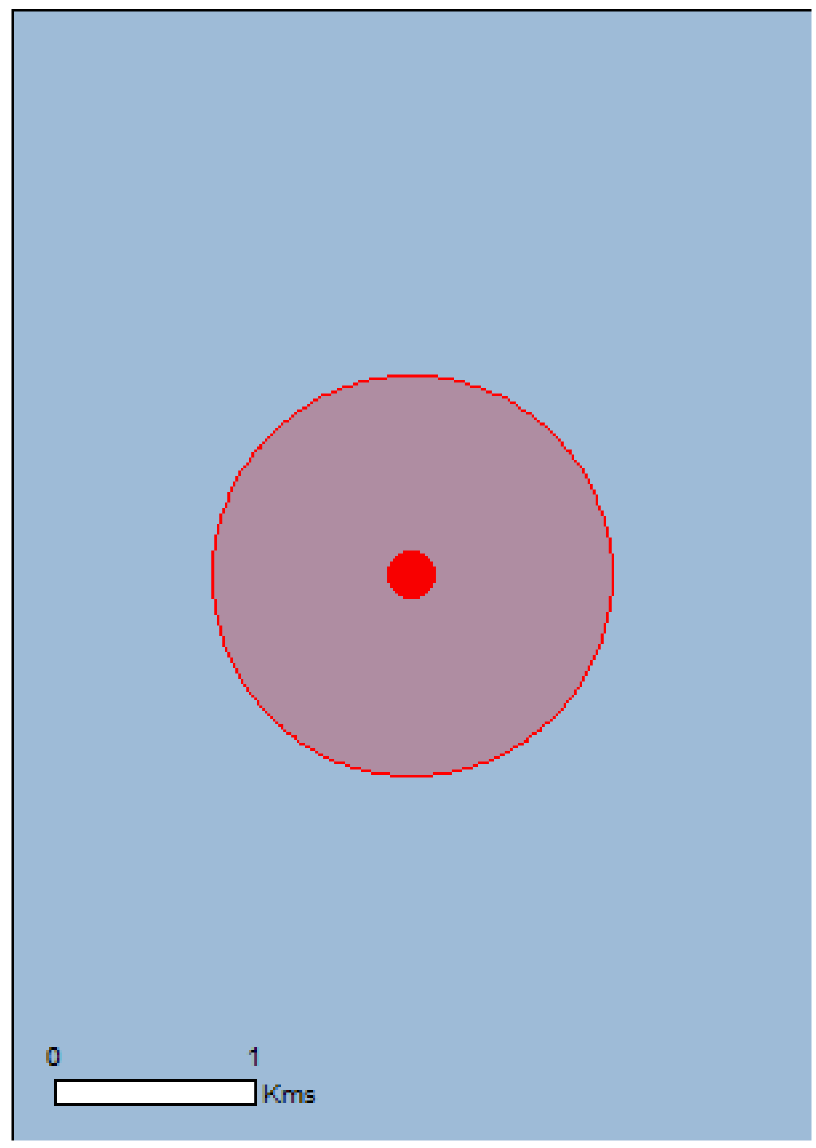
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

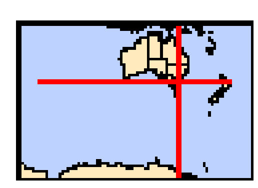
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 11:55:06



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	14
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	1

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name

Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Species or species habitat likely to occur within area
Puffinus griseus Sooty Shearwater [1024]		Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus minotaur Bullneck Seahorse [66705]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Upwelling East of Eden	South-east

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

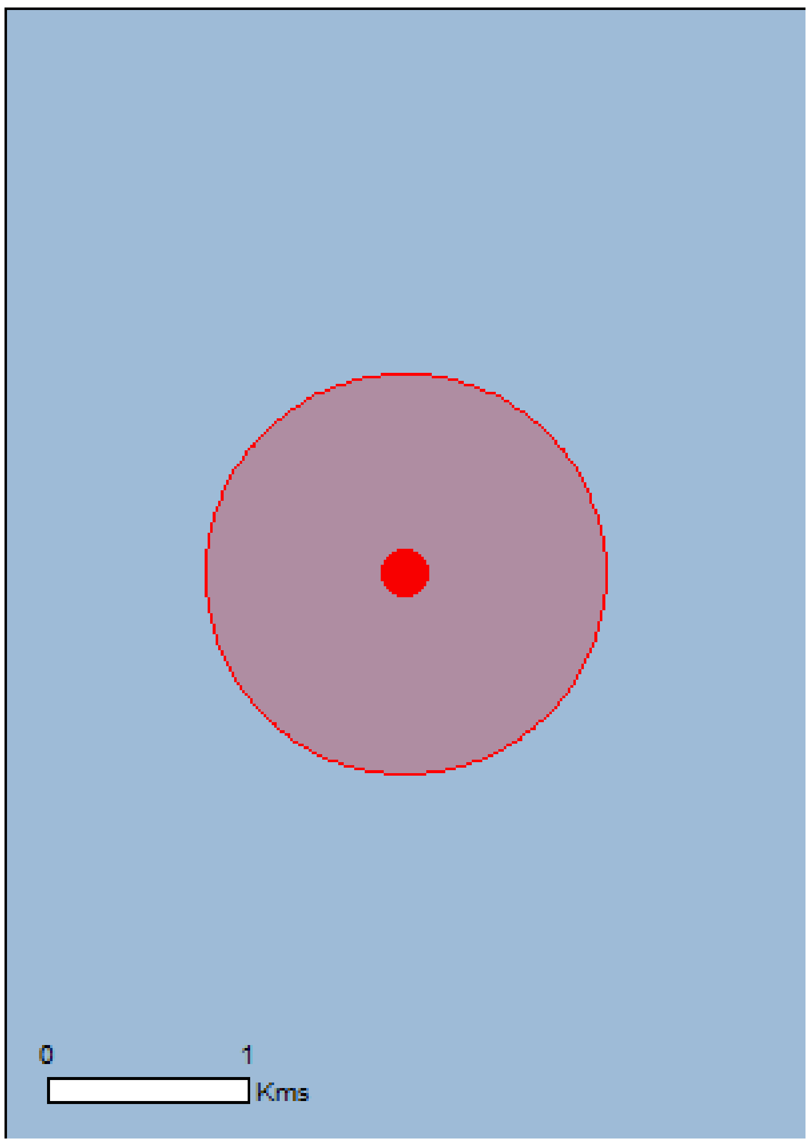
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

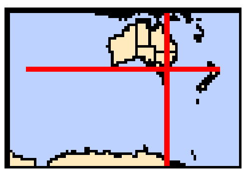
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 12/08/19 18:51:13



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	34
Listed Migratory Species:	37

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	58
Whales and Other Cetaceans:	13
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely

Name	Status	Type of Presence
		to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area

Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

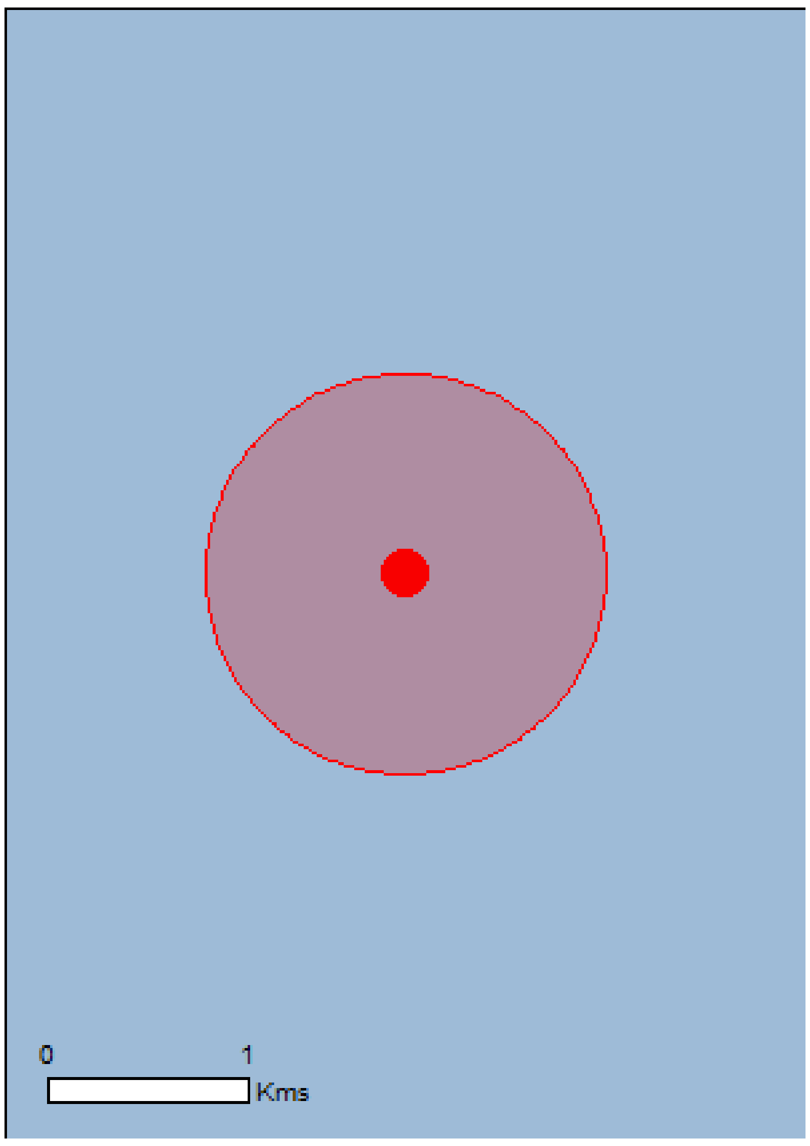
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

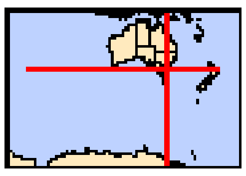
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 15:56:11



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	34
Listed Migratory Species:	37

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	58
Whales and Other Cetaceans:	13
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely

Name	Status	Type of Presence
		to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat may occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

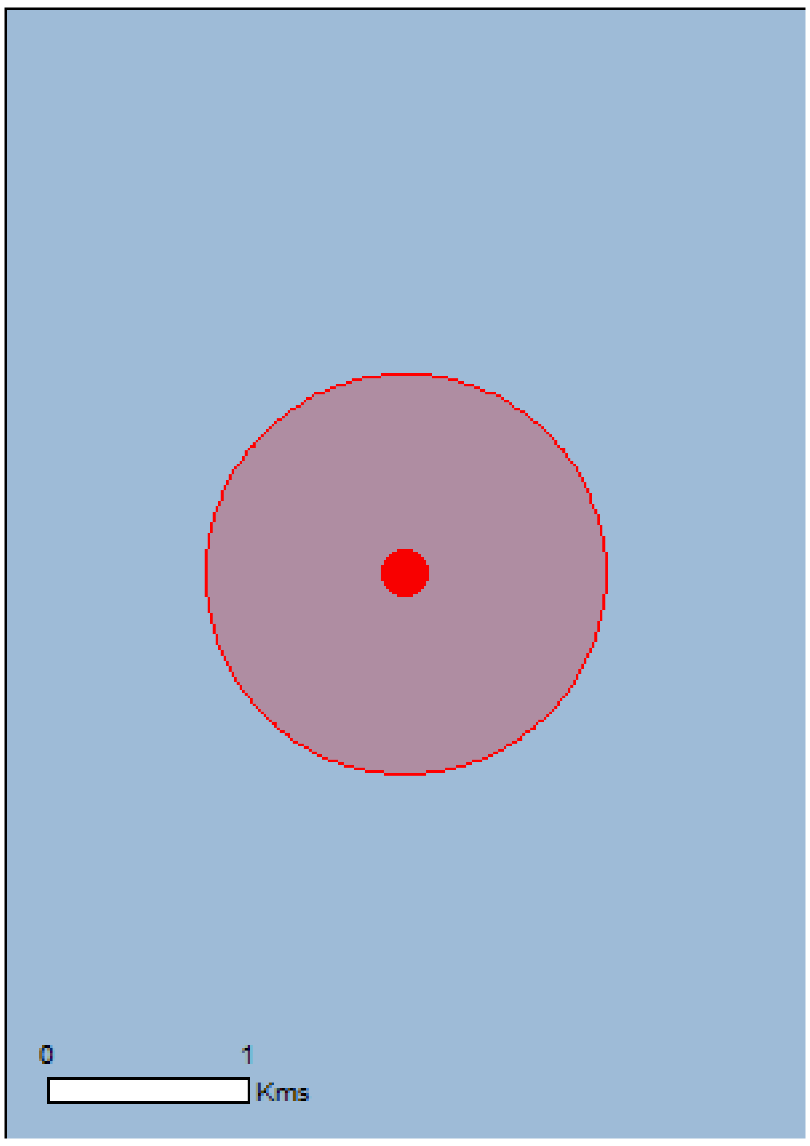
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

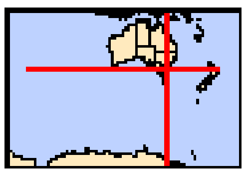
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 16:52:11



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	14
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	1

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Phoebetria fusca		
Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri		
Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta		
Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma		
Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita		
Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini		
Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi		
White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis		
Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni		
Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata		
Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta		
Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area

Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Upwelling East of Eden	South-east

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

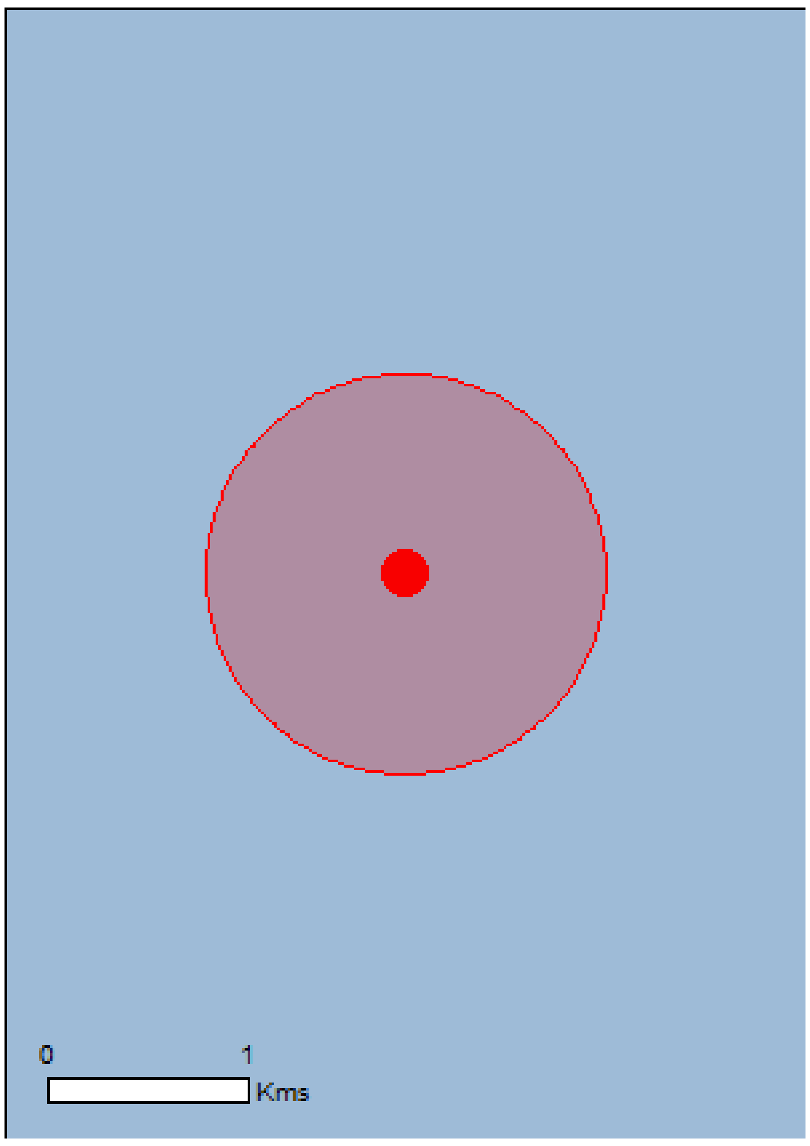
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

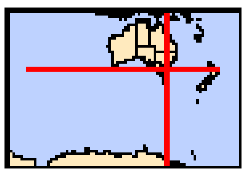
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 15:50:56



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	14
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name

[Thalassarche melanophris](#) Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
[Thalassarche salvini](#) Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Mammals		
[Balaenoptera borealis](#) Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
[Balaenoptera musculus](#) Blue Whale [36]	Endangered	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

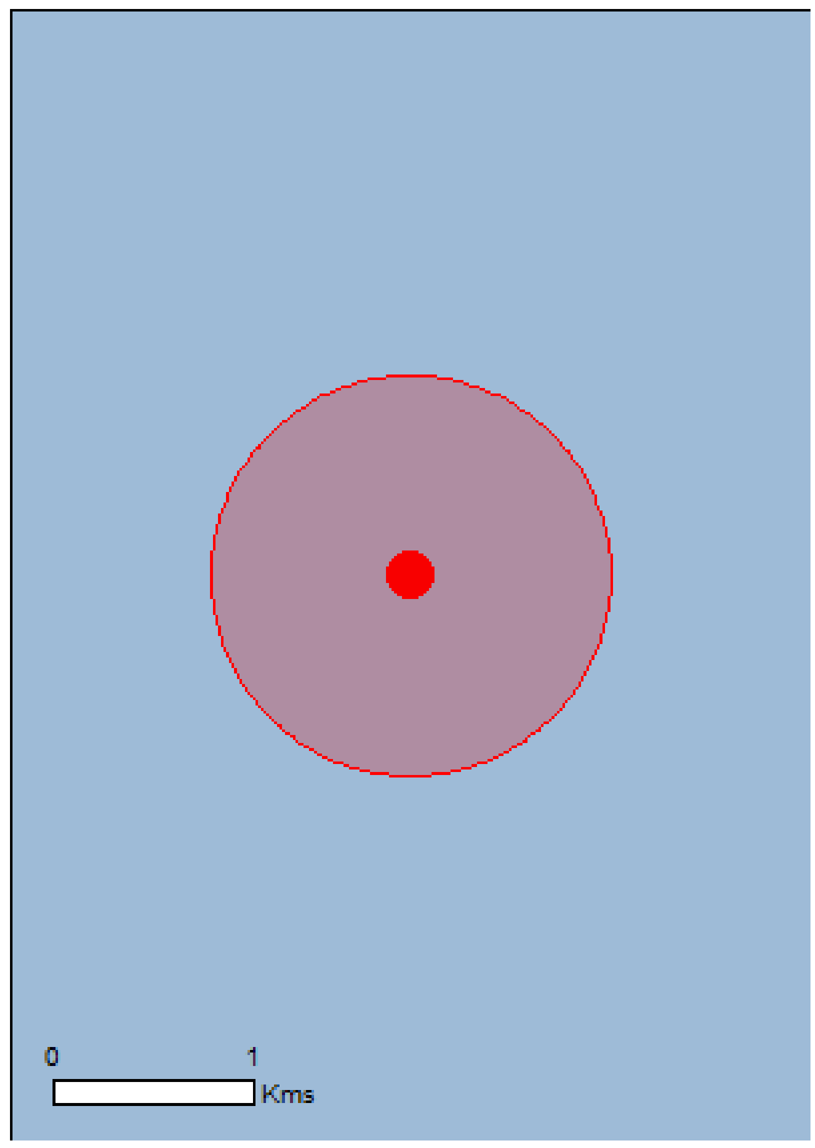
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

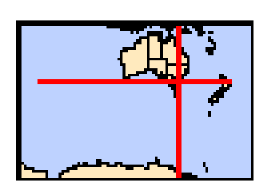
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 14/04/20 17:20:56



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	34
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	31
Whales and Other Cetaceans:	27
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name

Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Berardius arnuxii Arnoux's Beaked Whale [70]		Species or species habitat may occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area

Name	Status	Type of Presence
[Delphinus delphis] Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
[Eubalaena australis] Southern Right Whale [40]	Endangered	Species or species habitat may occur within area
[Globicephala macrorhynchus] Short-finned Pilot Whale [62]		Species or species habitat may occur within area
[Globicephala melas] Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
[Grampus griseus] Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
[Kogia breviceps] Pygmy Sperm Whale [57]		Species or species habitat may occur within area
[Kogia simus] Dwarf Sperm Whale [58]		Species or species habitat may occur within area
[Lagenorhynchus obscurus] Dusky Dolphin [43]		Species or species habitat likely to occur within area
[Lissodelphis peronii] Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
[Megaptera novaeangliae] Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
[Mesoplodon bowdoini] Andrew's Beaked Whale [73]		Species or species habitat may occur within area
[Mesoplodon densirostris] Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
[Mesoplodon hectori] Hector's Beaked Whale [76]		Species or species habitat may occur within area
[Mesoplodon layardii] Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
[Mesoplodon mirus] True's Beaked Whale [54]		Species or species habitat may occur within area
[Orcinus orca] Killer Whale, Orca [46]		Species or species habitat likely to occur within area
[Physeter macrocephalus] Sperm Whale [59]		Species or species habitat may occur within area
[Pseudorca crassidens] False Killer Whale [48]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Tursiops truncatus s. str.		
Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris		
Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Department of the Environment and Energy

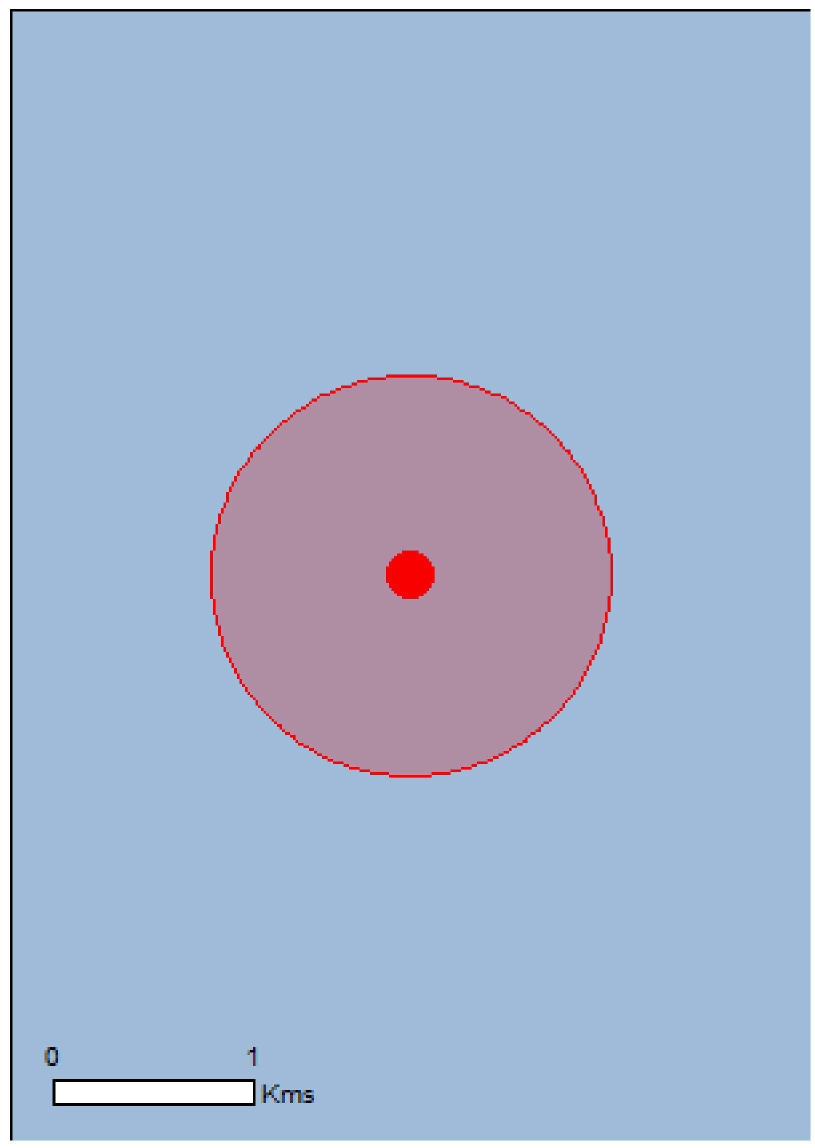
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

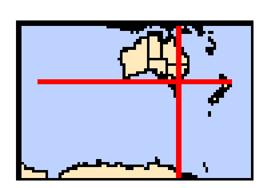
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 15:46:25



Coordinates

Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	14
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Species or species habitat likely to occur within area
Puffinus griseus Sooty Shearwater [1024]		Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus minotaur Bullneck Seahorse [66705]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

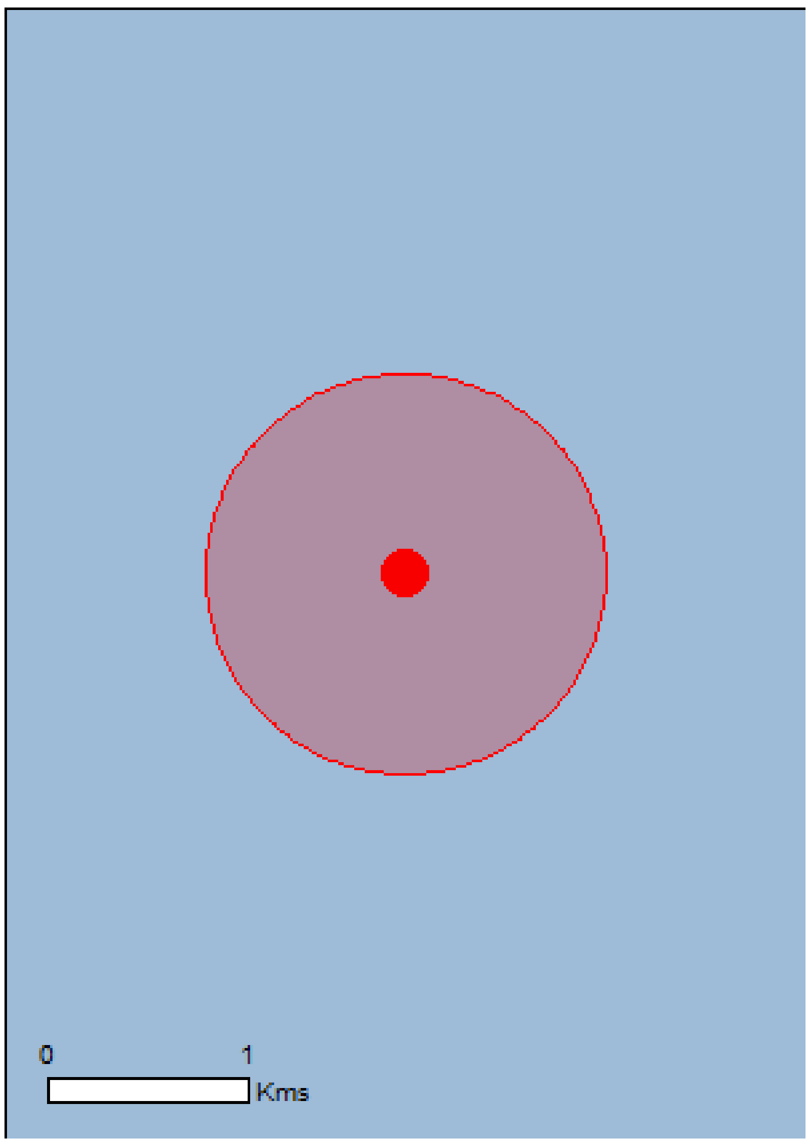
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

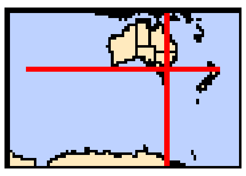
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 10:45:20



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	14
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	1

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
[Balaenoptera physalus](#) Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Species or species habitat likely to occur within area
Puffinus griseus Sooty Shearwater [1024]		Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus minotaur Bullneck Seahorse [66705]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Upwelling East of Eden	South-east

Caveat
The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

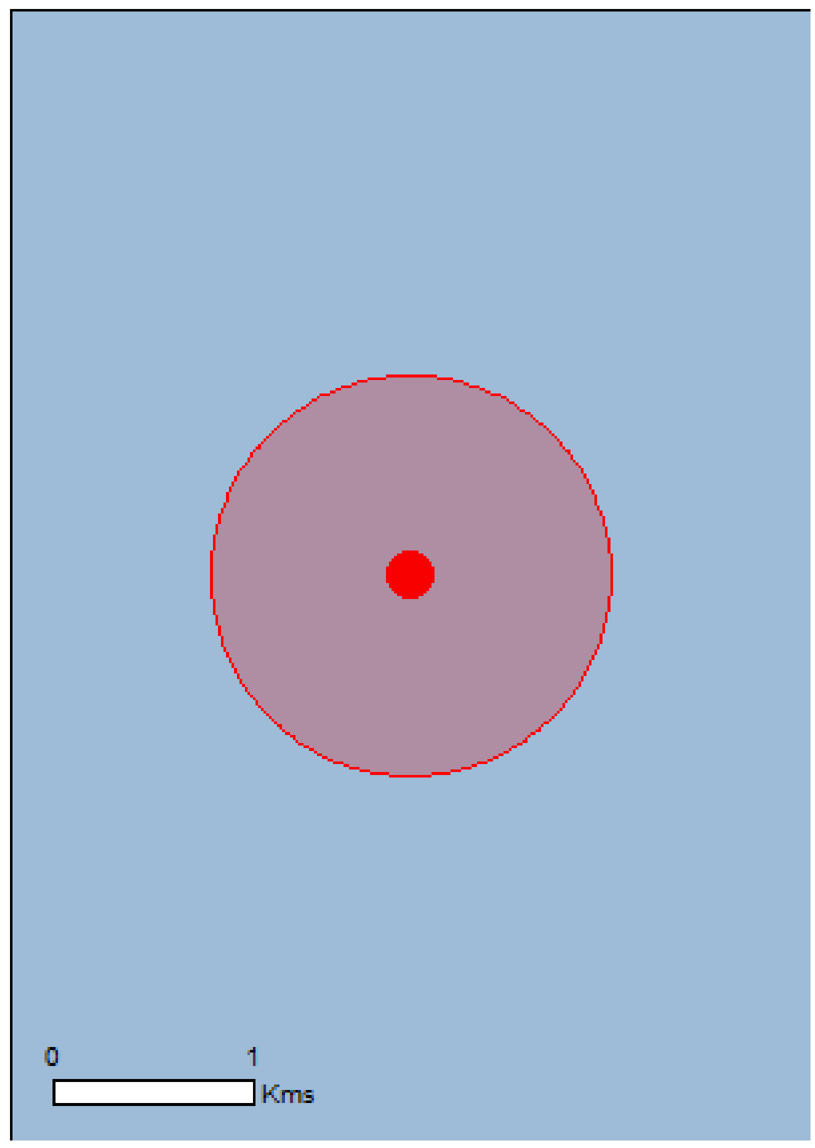
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

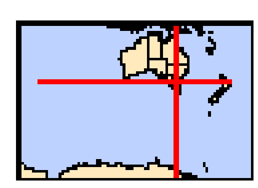
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 13/08/19 14:58:46



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	34
Listed Migratory Species:	34

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	10
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus		
Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis		
Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni		
Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora		
Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans		
Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi		
Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria		
White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea		
Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat may occur within area
Fish		
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat may occur within area
Mammals		
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		

Name	Threatened	Type of Presence
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence

Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

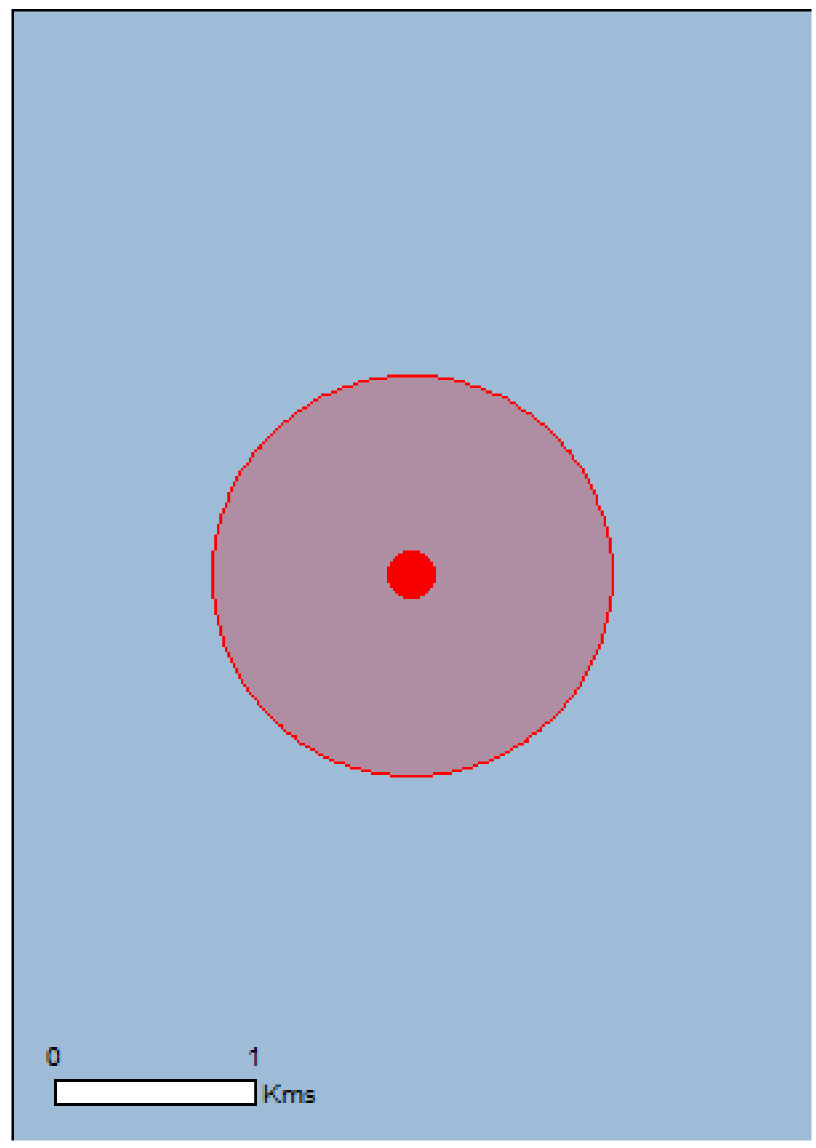
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

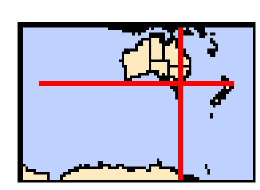
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 10:40:35



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	60
Whales and Other Cetaceans:	13
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area

Name	Threatened	Type of Presence

Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Department of the Environment and Energy

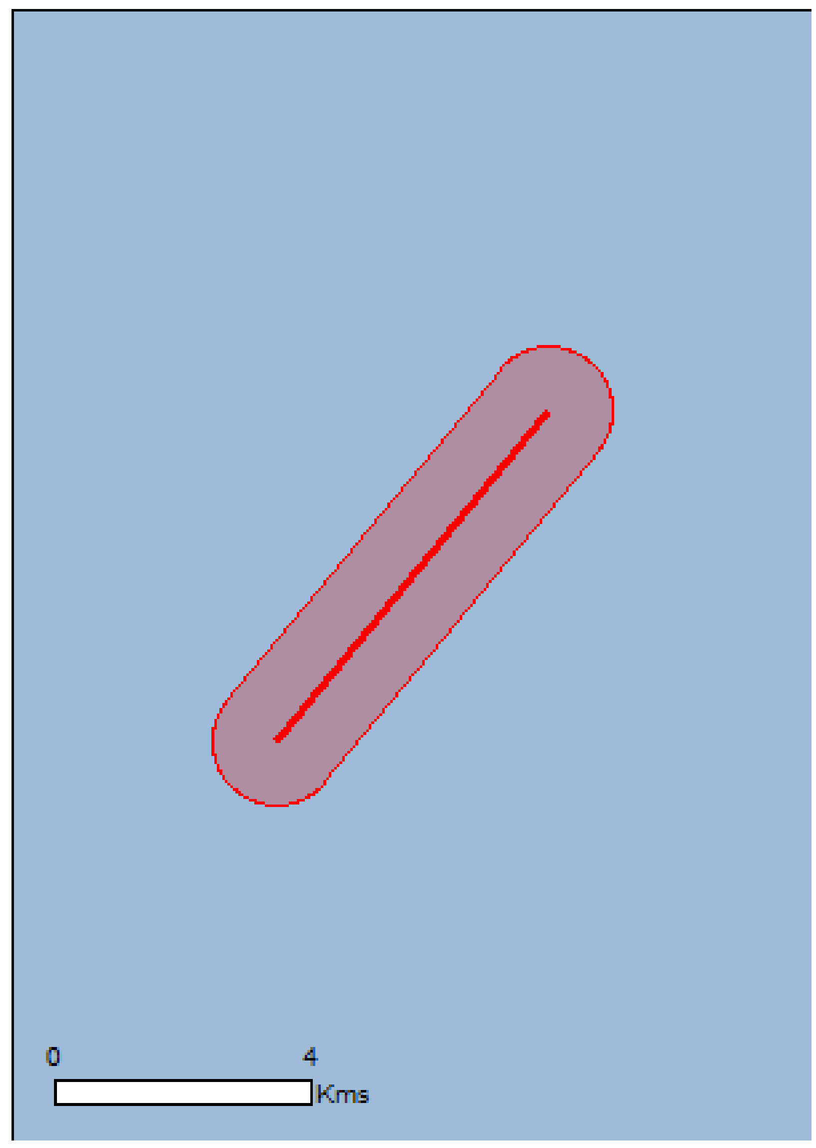
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

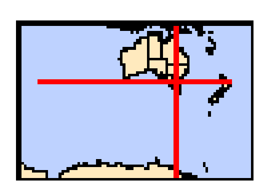
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 06/03/20 11:53:37



Coordinates

Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	33
Listed Migratory Species:	36

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	10
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Fish		
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat may occur within area
Mammals		
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat known to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area

Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 09/03/20 11:52:21

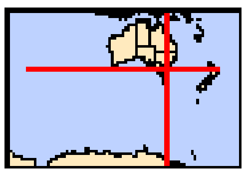
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	35
Listed Migratory Species:	39

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	59
Whales and Other Cetaceans:	14
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	1

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area

Name	Threatened	Type of Presence
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Extra Information

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Upwelling East of Eden	South-east

Caveat
The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Visualisation Assessment Summary by Facility

Facility	Sediment	Bioturbation	Shells	Dead scallops with calcification/ remnants of inverterbrates	Marine invertebrates including sponges	Fish
Figure A						
Perch	Y - fine	Possibly	Possibly few	Possibly few	on structures fewer on seabed near structures	Y
Dolphin	Y - fine	Possibly	Possibly few	Possibly few	on structures fewer on seabed near structures	Y
Tarwhine	coarse sediment	Possibly	Y - visible	Y - visible	on structures fewer on seabed near structures	Schools of fish visible
Barracouta	Sediment at all sites were dominated by coarse size fractions, with all sites (with the exception of one site – SQ1) containing more than 50% of sediments over 1 mm. (Marine Solutions, 2018)	Possibly	Y - visible	A mosaic of bioturbated coarse sand, overlaid with patchy unconsolidated bivalve beds containing erect sponges, dead scallops with calcification, fragmented dead shells and a mixture of live and dead bivalves (Marine Solutions, 2018).	on structures fewer on seabed near structures	Y
West Barracouta	Sediment at all sites were dominated by coarse size fractions, with all sites (with the exception of one site – SQ1) containing more than 50% of sediments over 1 mm. (Marine Solutions, 2018)	Possibly	Y - visible	A mosaic of bioturbated coarse sand, overlaid with patchy unconsolidated bivalve beds containing erect sponges, dead scallops with calcification, fragmented dead shells and a mixture of live and dead bivalves (Marine Solutions, 2018).	on structures fewer on seabed near structures	Y
Figure B						
Seahorse	-	Possibly	Possibly few	Possibly	on structures fewer on seabed near structures	Y
Whiting	fine to coarser sand	Possibly	overlay of shell grit	Visible patches of dead scallop or remnants of invertebrates	benthic invertebrates on structures on seabed near structures growing in uniform spread	different species of fish visible
Snapper	The natural substrate was observed as unconsolidated, dark, fine to medium grained silt/sediment (Coffey, 2010).	Small burrows and bioturbation mounds within the soft sediment, which have been created by benthic infauna such as crustaceans and polychaete worms(Coffey, 2010).	Possibly few	none visible	Marine invertebrates gowing on structures Given the lack of hard substrate, there was little to no colonisation of the seabed by benthic marine invertebrates such as bryzoans, ascidians and poriferans. Instead, there were a large number of small burrows and bioturbation mounds within the soft sediment, which have been created by benthic infauna such as crustaceans and polychaete worms (Coffey, 2010).	Y

Visualisation Assessment Summary by Facility

Facility	Sediment	Bioturbation	Shells	Dead scallops with calcification/ remnants of inverterbrates	Marine invertebrates including sponges	Fish
Figure C						
Marlin	Hard compact sand with shell grit, overlaid with fine sand ripples (Marine Solutions, 2015).	Possibly	no	possible areas of dispersed patches of dead scallop or dead invertebrates	Low-relief compacted soft sediments Hard natural substrate was absent from the surveyed area. Sponge growth was prolific on a number of pipelines laying on the seabed (Marine Solutions, 2015).	Y
West Tuna	fine to coarser sand	Possibly	overlay of shell grit	possible areas of dispersed patches of dead scallop or dead invertebrates	on structures on seabed near structures	Y
Tuna	Sand was the dominant sediment class at platform lightly muddy (<0.06mm~2%), gravelly(>2mm~23%) sand (o.6mm – 2mm - ~75%)(Coffey, 2009).	Possibly	possibly	possible areas of dispersed patches of dead scallop or dead invertebrates	few stands (or remnants) only on structures	none visible
Kipper	predominanatly bare sand shown with possibility of coarse overlay	none visible	none visible	none visible	Possibly few	Y
Figure D						
Flounder	fine sand	Possibly	no	none visible	few stands only on structures	Different schools of fish species seen
Blackback	fine to coarser sand	Possibly	no	none visible	few stands only on structures	Y
Figure E						
Fortescue	fine to coarser sand	likely	yes	possible	significant on structures little visible elsewhere	Y
Halibut	fine	possible	no	none visible	significant on structures little visible elsewhere	Y
Figure F						
Cobia	fine to coarser sand	Possibly	yes	seen in some images on MLA 150-WKF pipeline, not uniformly	significant on pipelines closer to the platform centre for both the MLA 150-WKF and the KFB 500-HLA. little visible elsewhere	Y

Visualisation Assessment Summary by Facility

Facility	Sediment	Bioturbation	Shells	Dead scallops with calcification/ remnants of inverterbrates	Marine invertebrates including sponges	Fish
Figure G						
West Kingfish	Sand was the dominant sediment class at each platform slightly muddy, gravelly sand (WKF generally had higher proportion of sand than gravel)(Cardno, 2018)	Polychaetes, crustaceans and molluscs were dominant infauna (Cardno, 2018)	Possibly	areas of dispersed patches of dead scallop	visible on structures few on seabed near structures	not visible
Kingfish A	-	Possibly	none visible	Possibly	visible on structures	Y
Kingfish B	fine	Possibly	none visible	Possibly	visible on structures	Y
Mackerel	predominanatly bare sand shown	none visible	none visible	Possibly	visible on structures	Y
Figure H						
Bream A	coarser grained, gravelly sand	likely	Possibly	seen in some images on MLA 150-WKF pipeline, not uniformly	a mix of live benthic invertebrates growing amongst what appears to be calcified remains of invertebrates. Possible small areas of sponge beds closer to platform. Radiating out to individual stands in all directions of the platform	few numbers of various fish species seen
Figure I						
Bream B	coarser grained, gravelly sand	likely	Possibly	seen in some images on MLA 150-WKF pipeline, not uniformly	significant assemblages of benthic invertebrates composed of different species evident close to the platform. Abundance distictly decreases with distance from platform. Decrease in abundance appears unifrom in all directions	different species of small and large fish in abundance

(white)	Visual assessment
(grey)	Benthic survey findings
-	Not possible to discern

Note:
Visualisation assessments are by definition, coarse scale assessments of the environment providing some quantification of abundance, diversity and seabed type. This information should be used accordingly. Targeted surveys would be required to accurately define and describe the benthic environment.

Appendix F – PFW Data File

Appendix F: PFW Data File

Note: Appendix G.1 – Breakout Box 1 further discusses chemical compounds not found in PFW across the various platforms in Bass Strait. More details about available background and reference data is found in Appendix G.2 – Breakout Box 2. Appendix G.7 – Breakout Box 7 discusses the results from in-situ water sampling showing the dispersion of metals, hydrocarbon and other analytes in water around the Tuna platform.

a = Total Chromium; b = Chromium III, c = Chromium VI; d: Taken to mean, TRH C6-C36; e = m&p Cresol; f: m-Cresol; g: p-Cresol

Table F-2 shows the levels of total sulphide in PFW, together with an approximate concentration of hydrogen sulphide based on conversions in ANZECC (2000). Per ANZECC, in general, studies reported show the observed effect concentrations of sulphide are consistent with the un-ionised H2S (hydrogen sulphide) form, not total sulphide.

Table F-2 Sulphide properties of TNA PFW relative to background levels, and dilution factor

Chemical	Maximum concentration in PFW (mg/L)	Percentage of hydrogen sulphide in total aqueous sulphide at 30C, pH 7.0-7.5 and 35% salinity#	Expected hydrogen sulphide concentration, mg/L	Background levels, mg/L*	Dilution factor to background levels of hydrogen sulphide
Sulphide	2.5	pH = 7.0: 22.4% pH = 7.5: 8.36%	0.56 0.21	Minimum: <0.01	56 21
		pH = 7.0: 22.4% pH = 7.5: 8.36%	0.56 0.21	Average 0.015	37 14
		pH = 7.0: 22.4% pH = 7.5: 8.36%	0.56 0.21	Maximum: 0.03	19 7
Maximum dilution to reach background levels					**56**

#From ANZECC, 2000, Table 8.3.10, p. 8.3-173
*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-3 shows the TOC of produced water relative to background levels of TOC in sea water. The use of TOC directly to compare to background levels is over-conservative as it assumes that any or all TOC constituents, including low molecular weight carboxylic acids, could contribute to a potential impact on the environment.

Table F-3 TOC properties of TNA PFW relative to background levels, and dilution factor

Chemical	Maximum concentration in PFW (mg/L)	Background levels*	Dilution factor to background levels of TOC
TOC	370	<1 to 2	370
Maximum dilution to reach background levels			**370**

*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-4 Particle Size Distribution for TNA PFW

Wentworth Size Classifications	2020
Total Clay % (0-4 µm)	**69.69**
Very Fine Silt % (4-8 µm)	7.60
Fine Silt % (8-16 µm)	8.06
Medium Silt % (16-31 µm)	6.38
Course Silt % (31-63 µm)	4.48
Total Silt (4-63 µm)	**26.53**
Very Fine sand % (63-125 µm)	3.39
Fine sand % (125-250 µm)	0.39
Medium sand % (250-500 µm)	0.00
Coarse sand % (500-1000 µm)	0.00
Very Coarse sand % (1000-2000 µm)	0.00
Total Sand (63-2000 µm)	**3.79**
Total Gravels (>2000 µm)	**0.00**

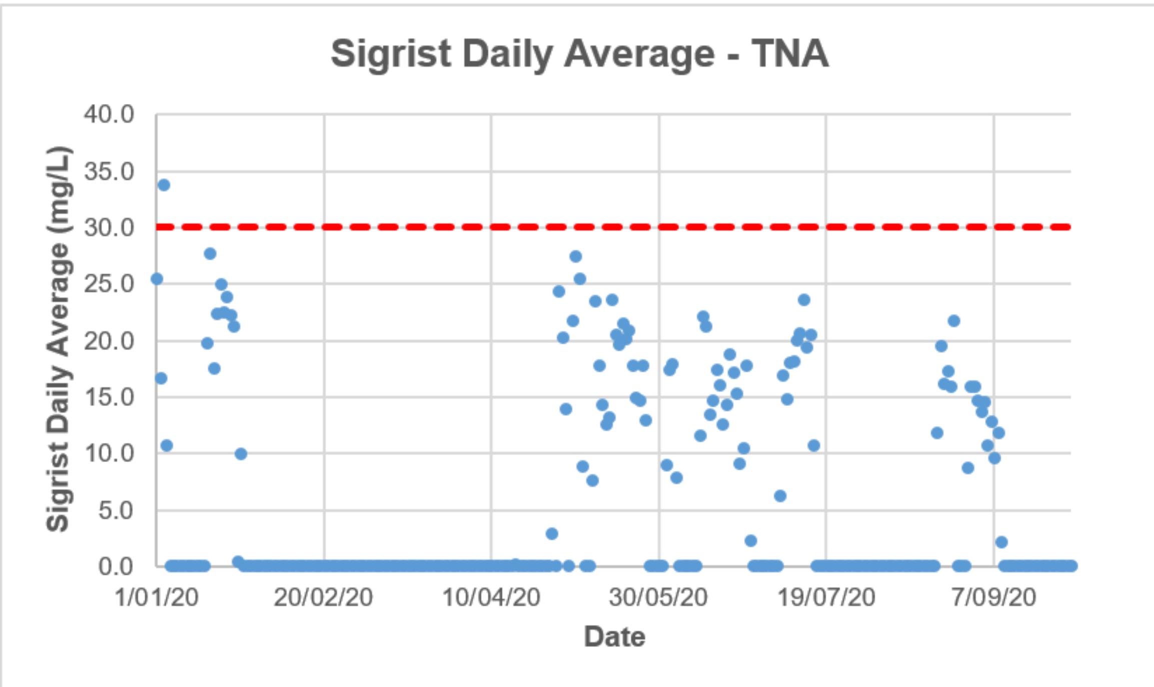

Figure F-1 Platform overboard discharge levels of oil in water (in mg/L) since 1 Jan 2020

A summary of Sigrist daily averages exceeding 30 mg/L on Tuna for the period of 1st January 2020 to 30th September 2020 is given below in Table F-5.

Table F-5 TNA Oil in water exceedances from January 2020 to September 2020

Date	Sigrist Daily Average (mg/L)	Total Oil Load (kg/day)	Comments
03/01/20	33.9	86.0	Oil in water spikes resulted in a Sigrist daily average that exceeded 30 mg/L. Reported to NOPSEMA in January monthly recordable incidents report.

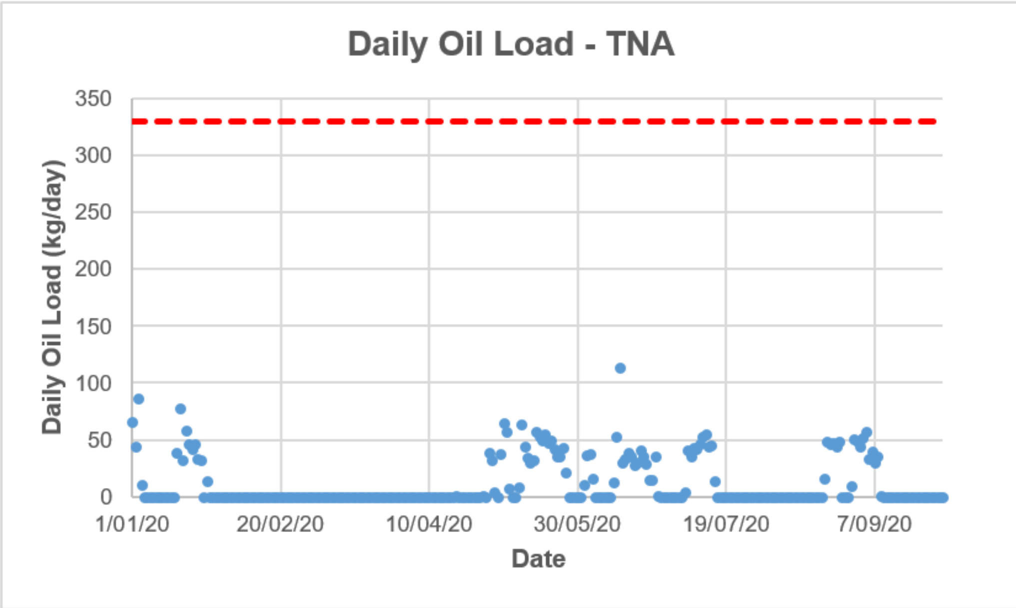

Figure F-2 Platform overboard oil load (in kg/d, mg/L oil concentration multiplied by volume discharged) since 1 Jan 2020

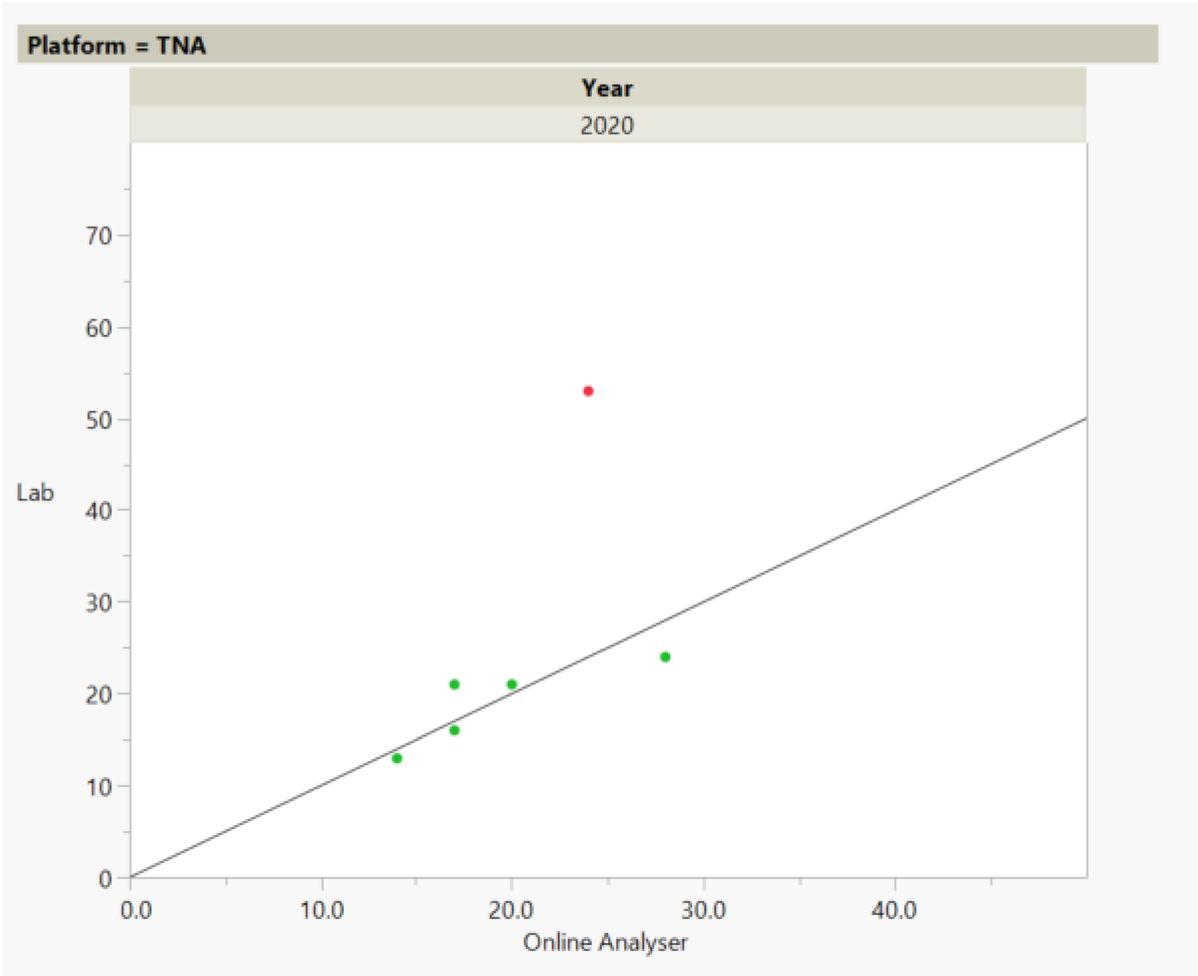

Figure F-3 Cross-check of platform online monitor readings with routine laboratory tests

Table F-6 Dispersion model inputs – Tuna platform

Parameter	Value
Discharge rate (kL/day)	11,462
Discharge temperature (°C)	80
Discharge salinity (ppt)	34
Internal diameter of outlet (inch) [m]	9.84 [0.25]
Outlet orientation	vertically downward
Depth of outlet below MSL (m)	28.8
Total water depth at site (m)	59

Figure F-4 shows the model outputs for the platform (dilution contours) with distance from the platform. The inset in Figure F-4 (b) shows there is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment.

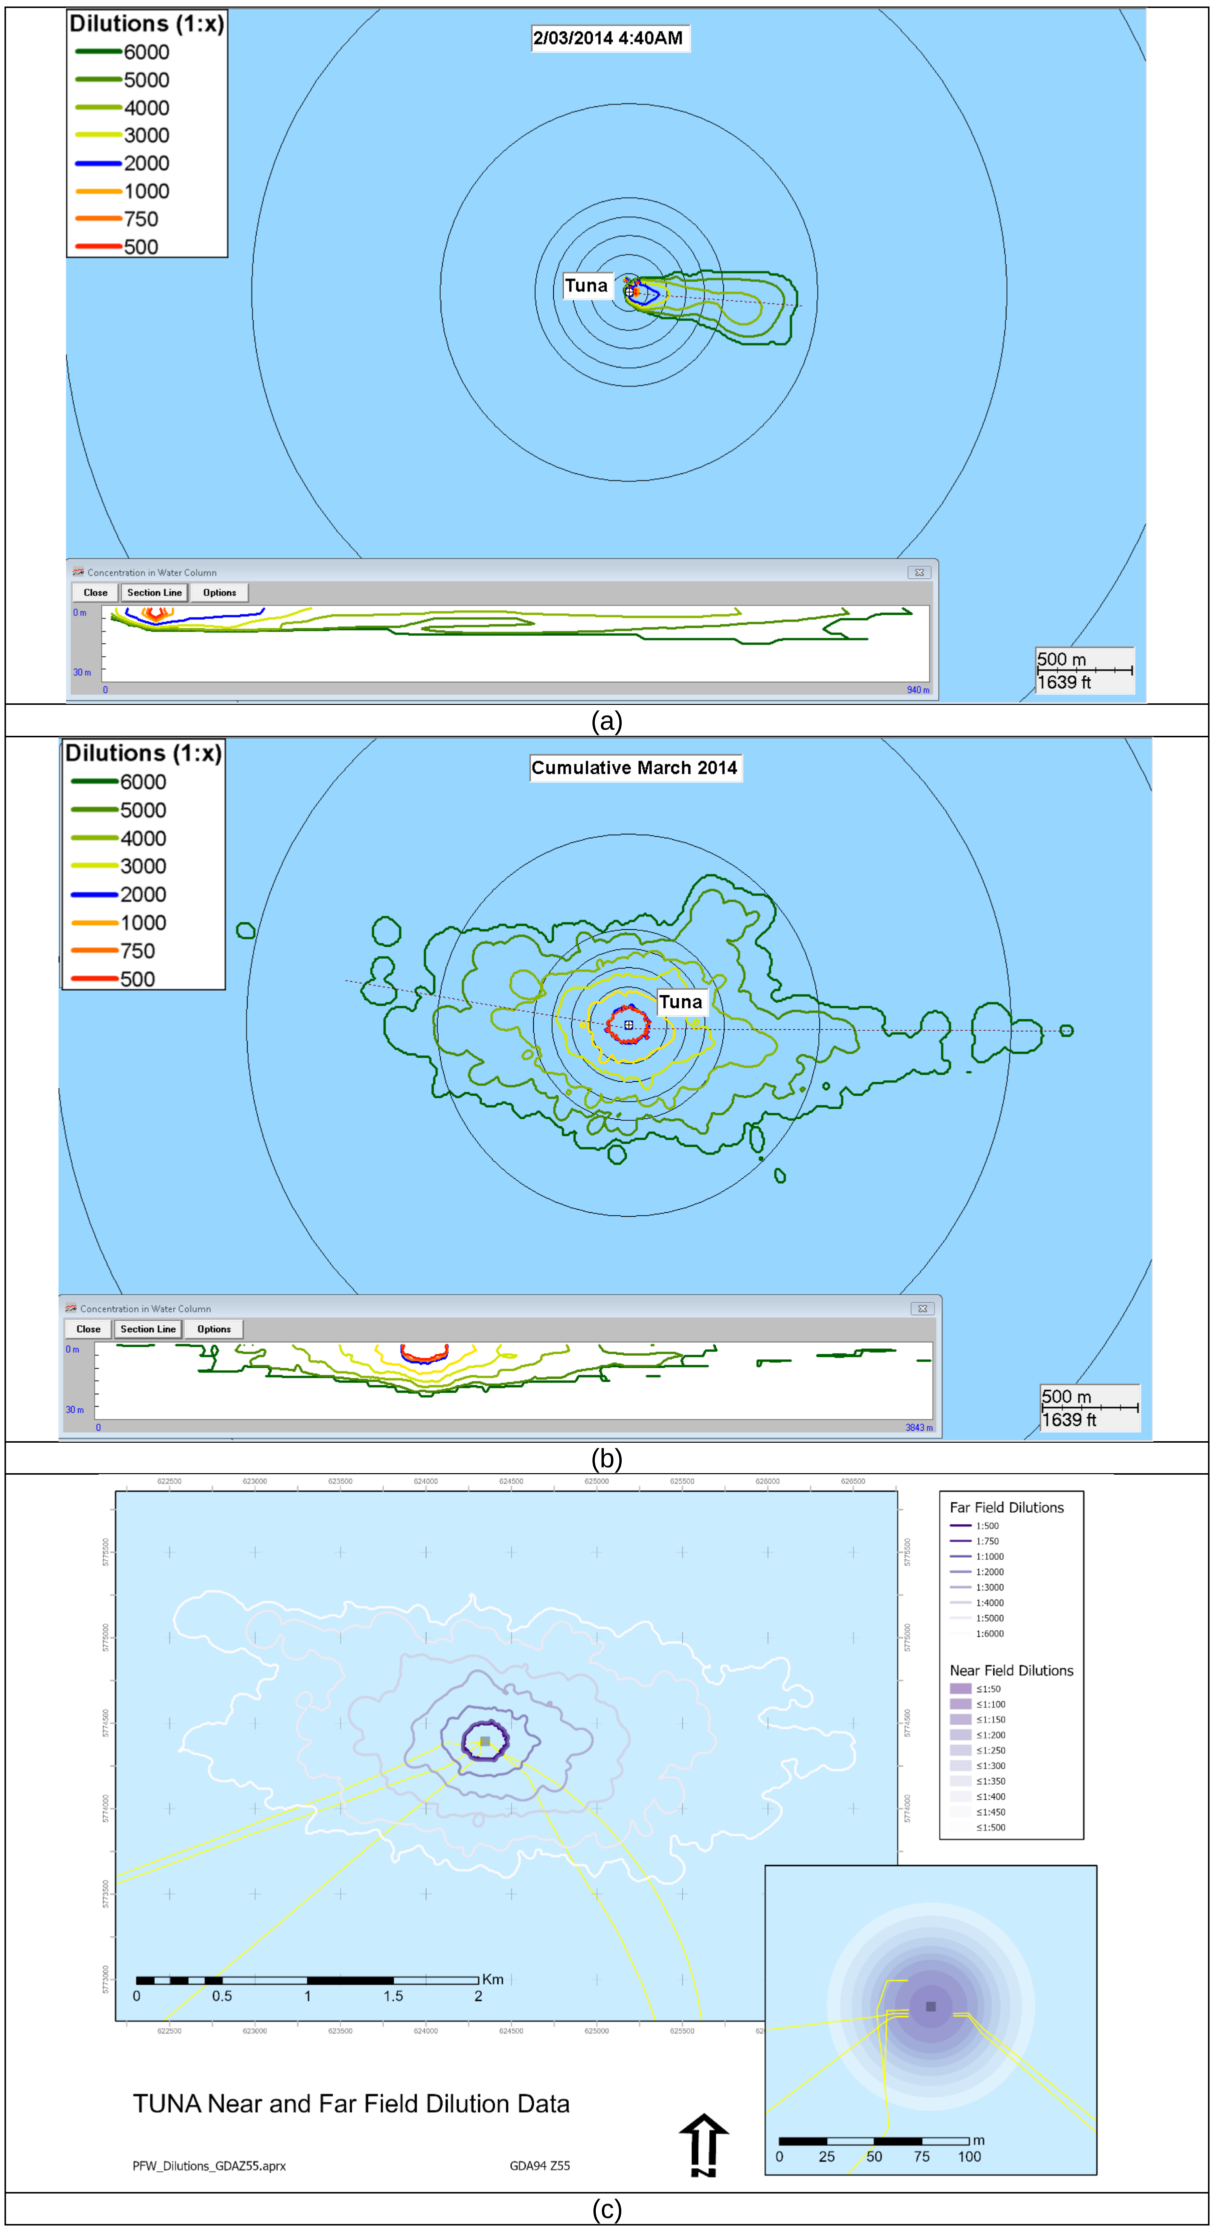

Figure F-4 **Dilution around the TNA platform and in the water column from PFW. (a) Snapshot of dilution of produced water plume around the platform, surface and cross-sectional view. (b) Summary of the dilution contours around the platform, conglomerated over one month (taking account of tide/current directions on any given day). (c) Yearly far-field dilution contours, inset are near-field contours.**

Table F-7 **Dilution factors with distance from the platform under typical currents.**

Dilution factor	Distance from platform (m)
10	1.0
50	12.5
100	19.4
200	29.0
500	130
750	140
1000	140
2000	320
3000	620
4000	840

Table F-8 Dispersion model outputs – water quality

Criteria	Dilution required (1:X)	Distance from platform
Meets physical parameters background levels	6	<1 m
Meets ANZECC 95% species protection water quality criteria	51	<19.4 m
Meets ANZECC 99% species protection water quality criteria	91	<19.4 m
Meets hydrogen sulphide background levels	56	<19.4 m
Meets TOC background levels	370	<130 m

Table F-9 Dispersion model outputs – fisheries

Criteria	Dilution required (1:X)	Distance from platform
Meets ANZECC seafood taint thresholds	40	<12.5 m

Table F-10 2014 results in percentage effluent of Tuna PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species.

Species	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
Hormosira banksii (brown algae)	1.6	3.1	2.9	1.9
Heliocidaris tuberculata (sea urchin)	6.3	12.5	10.7	7.3
Mytilus galloprovincialis (Mediterranean mussel)	6.3	12.5	16.4	10.8
Nitzschia closterium (diatom algae)	12.5	25	18.2	8.9
Allorchestes compressa (amphipod)	50	100	44.7	57.4
Lates calcarifer (barramundi)	25	50	15.3	23.9

Table F-11 2020 results in percentage effluent of Tuna PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species (E/IC50)

Test	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
72-hour microalgal growth (Tisochrysis lutea)	25	50	42.4	33.9
72-hour microalgal growth (Nitzschia closterium)	12.5	25	29.9	17.1
72-hour macroalgal germination success (Hormosira banksii)	12.5	25	39.1	22.1
1 hr sea urchin fertilisation success (Echinometra mathaei)	3.1	6.3	8.0	4.4
72-hour sea urchin larval development (Heliocidaris tuberculata)	3.1	6.3	8.2	6.0
48-hour mollusc larval development (Mytilus edulis)	1.6	3.1	10.6	5.0
5-7 day copepod larval development (Gladioferens imparipes)	<1.6	1.6	3.9	2.4
7-day fish larval development (Seriola lalandi)	0.2	0.4	0.93	0.23

Table F-12 Species sensitivity distribution output species protection levels – TNA effluent

Species sensitivity distribution outputs	2014 WET test result (% effluent)	2020 WET test result (% effluent)
95% species protection level	3.0%	0.44%
Dilution to obtain 95% species protection	33	227
Maximum dilution to obtain 95% species protection	227	
99% species protection level	1.8%	0.105%
Dilution to obtain 99% species protection	56	952
Maximum dilution to obtain 99% species protection	952	

Table F-13 Dispersion model outputs – ecotoxicity

Criteria	Dilution required (1:X)	Distance from platform
Meets 95% species protection levels based on whole effluent toxicity	227	<130 m
Meets 99% species protection levels based on whole effluent toxicity	952	<140 m

Appendix F.2 Halibut Platform PFW Data

Table F-14 Halibut platform PFW physical and chemical composition data – 2014 to 2020

Parameter	Number records	2014	2015	2015	2016	2017	2018	2019	2020	Mean	Std Error	Lower 95% confidence level	Upper 95% confidence level	Minimum detected (mg/l)	Maximum detected (mg/l)	Background levels	Dilution factor

f: m-Cresol
g: p-Cresol

Table F-15 shows the levels of total sulphide in PFW, together with an approximate concentration of hydrogen sulphide based on conversions in ANZECC (2000). Per ANZECC, in general, studies reported show the observed effect concentrations of sulphide are consistent with the un-ionised H2S (hydrogen sulphide) form, not total sulphide.

Table F-15 Sulphide properties of HLA PFW relative to background levels, and dilution factor

Physical property	Maximum concentration in PFW	Percentage of hydrogen sulphide in total aqueous sulphide at 30C, pH 7.0-7.5 and 35% salinity#	Expected hydrogen sulphide concentration, mg/L	Background levels, mg/L*	Dilution factor
Sulphide	12.0	pH = 7.0: 22.4%	2.7	Minimum: <0.01	269
		pH = 7.5: 8.36%	1.0		100
		pH = 7.0: 22.4%	2.7	Average 0.015	179
		pH = 7.5: 8.36%	1.0		67
		pH = 7.0: 22.4%	2.7	Maximum: 0.03	90
		pH = 7.5: 8.36%	1.0		33
Maximum dilution to reach background levels					**269**

#From ANZECC, 2000, Table 8.3.10, p. 8.3-173
*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-16 shows the TOC of produced water relative to background levels of TOC in sea water.

Table F-16 TOC properties of HLA PFW relative to background levels, and dilution factor

Physical property	Maximum concentration in PFW	Background levels*	Dilution factor
TOC	78	<1 to 2	78
Maximum dilution to reach background levels			**78**

*Taken from 18 reference site samples taken away from Tuna platform location.

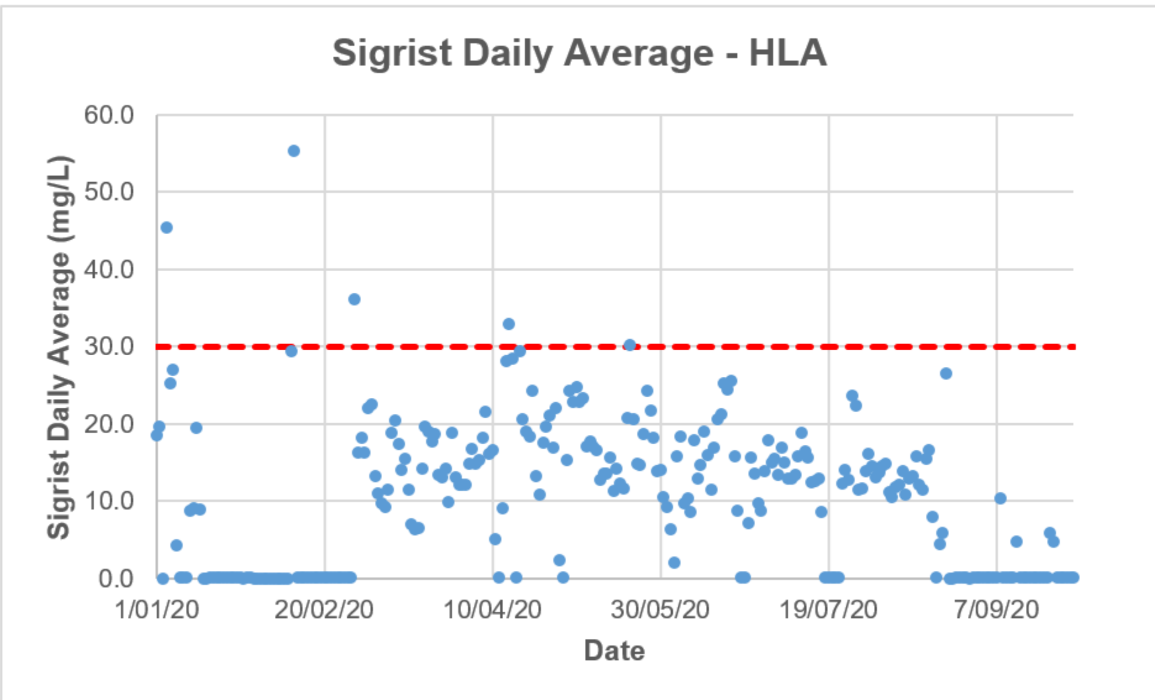

Figure F-5 Platform overboard discharge levels of oil in water (in mg/L) since 1 Jan 2020

A summary of Sigrist daily averages exceeding 30 mg/L on Halibut for the period of 1st January 2020 to 30th September 2020 is given below in Table F-17.

Table F-17 HLA Oil in water exceedances from January 2020 to September 2020

Date	Sigrist Daily Average (mg/L)	Total Oil Load (kg/day)	Comments
04/01/20	45.4	43.6	Oil in water spikes were noted due to start-up of the water handling system. Reported to NOPSEMA in January monthly recordable incidents report.
10/02/20	34.0	25.8	Platform experienced oil in water spikes upon platform start-up. Reported to NOPSEMA in February monthly recordable incidents report.
29/02/20	36.2	30.7	Platform was coming back online following shutdown. Reported to NOPSEMA in February monthly recordable incidents report.
15/04/20	33.0	137.5	Sigrist data not stored in DCS due to a malfunction. Hourly Sigrist readings were noted which exceeded 30 mg/L. Reported to NOPSEMA in April monthly recordable incidents report.
21/05/20	30.2	100.9	Oil in water spikes were noted following WIMS testing and a well kick the previous evening. Reported to NOPSEMA in May monthly recordable incidents report.

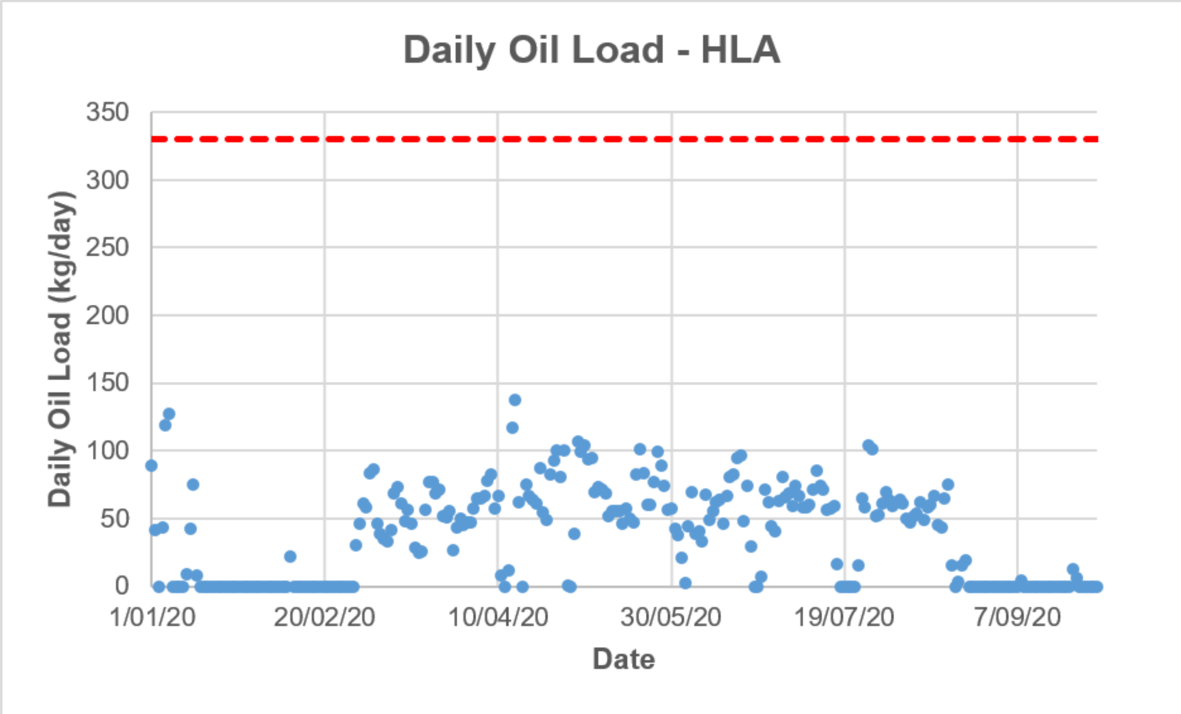

Figure F-6 Platform overboard oil load (in kg/d, mg/L oil concentration multiplied by volume discharged) since 1 Jan 2020

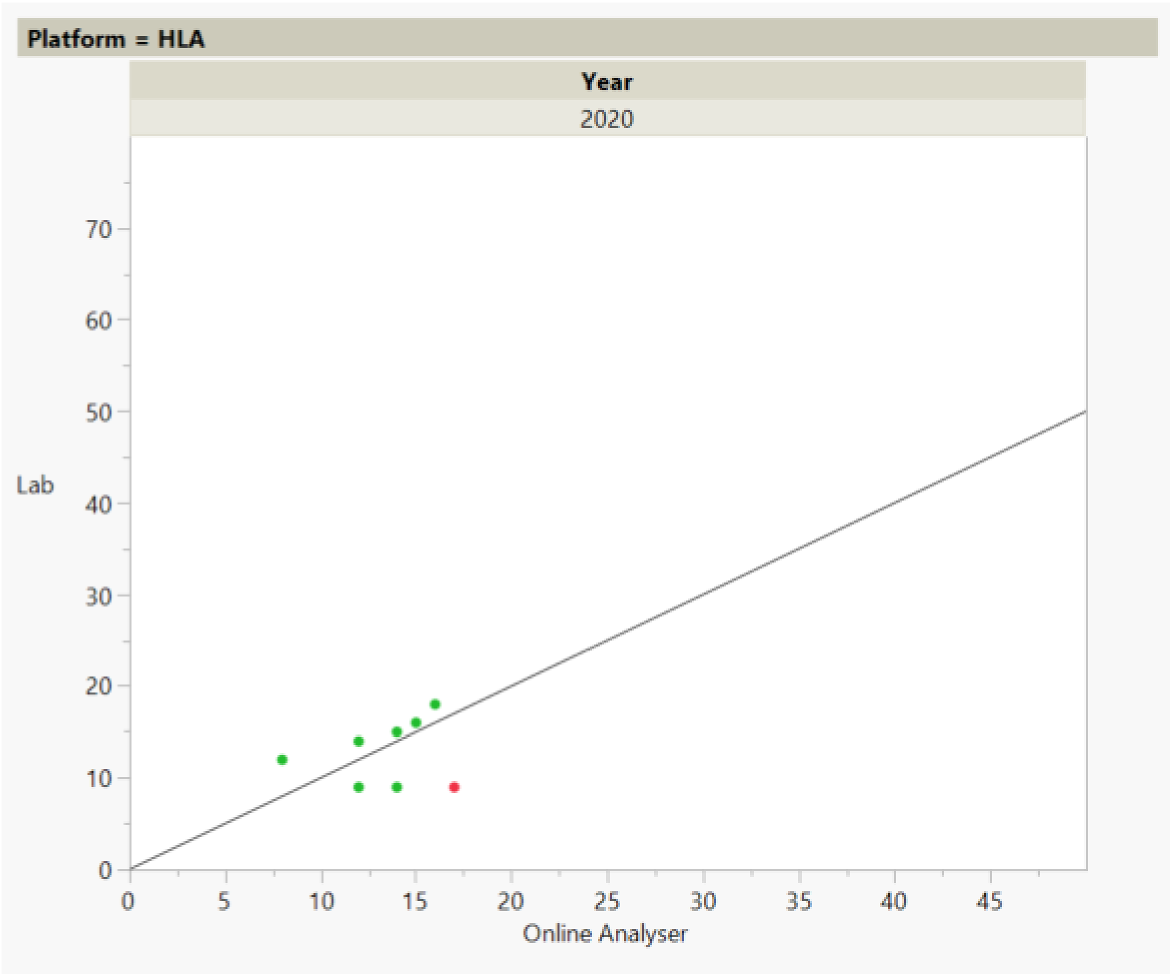

Figure F-7 Cross-check of platform online monitor readings with routine laboratory tests

Table F-18 Dispersion model inputs – Halibut platform

Parameter	Value
Discharge rate (kL/day)	12,481
Discharge temperature (°C)	89
Discharge salinity (ppt)	38
Internal diameter of outlet (inch) [m]	6.61 [0.168]
Outlet orientation	vertically downward
Depth of outlet below MSL (m)	11
Total water depth at site (m)	73

Figure F-8 show the model outputs for the platform (dilution contours) with distance from the platform. The inset in Figure F-8 (b) shows there is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment.

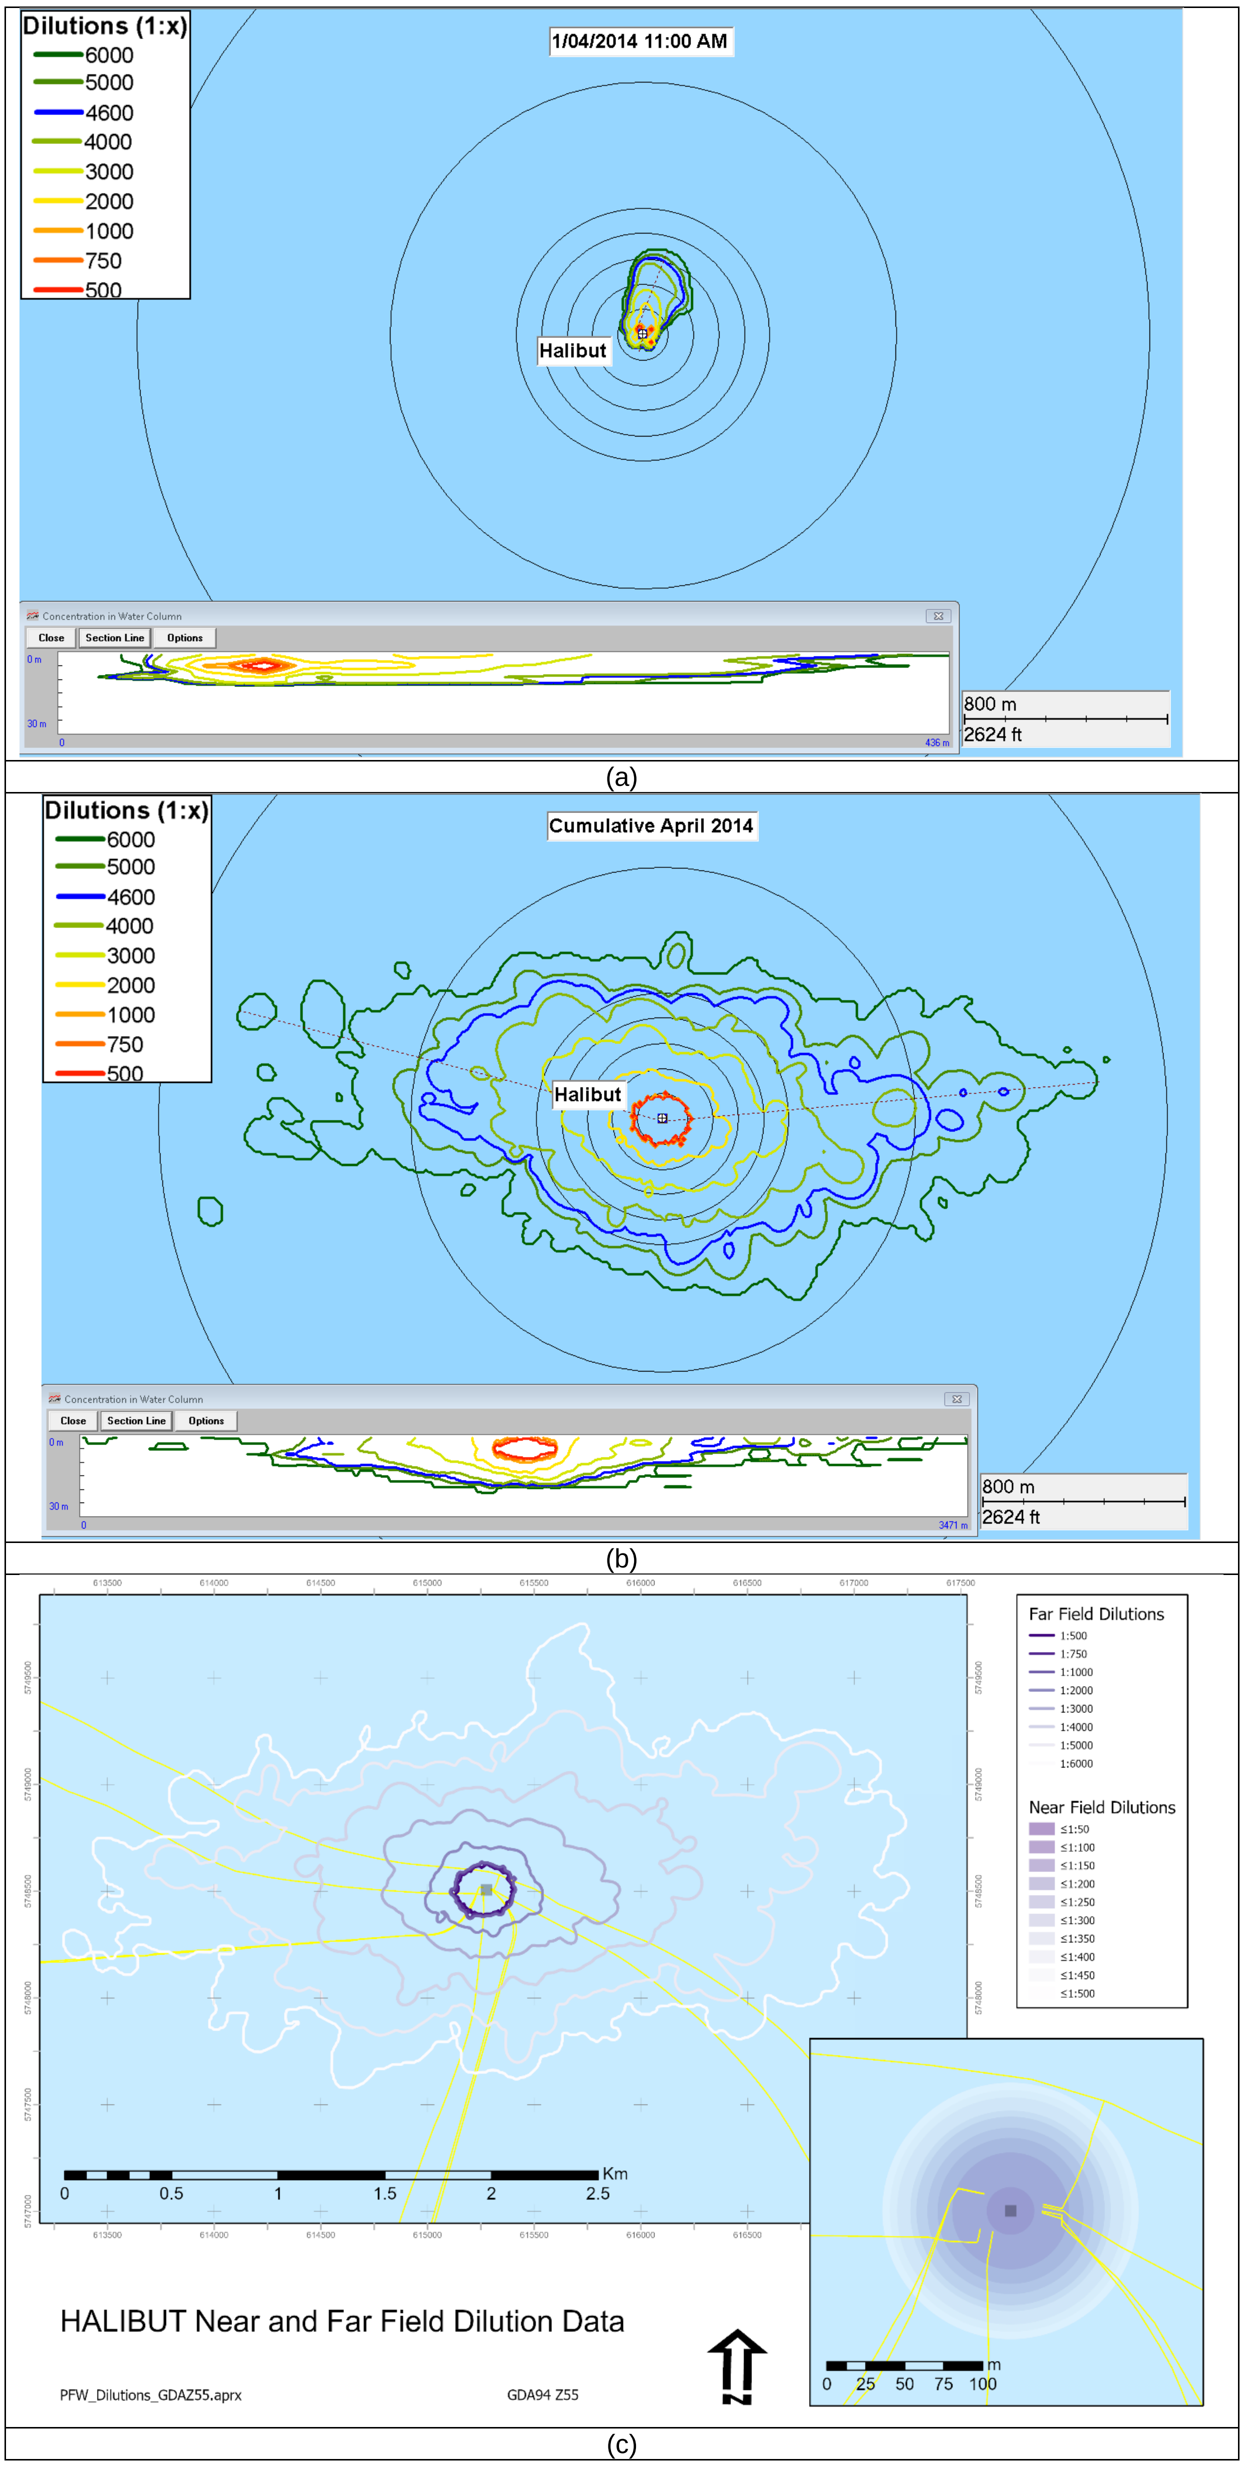

Figure F-8 **Dilution around the HLA platform and in the water column from PFW. (a) Snapshot of dilution of produced water plume around the platform, surface and cross-sectional view. (b) Summary of the dilution contours around the platform, conglomerated over one month (taking account of tide/current directions on any given day). (c) Yearly far-field dilution contours, inset are near-field contours.**

Table F-19 Dilution factors with distance from the HLA platform under typical currents.

Dilution factor	Distance from platform (m)
10	0.6
50	4.3
100	15
200	47
500	150
750	160
1000	160
2000	290
3000	630
4000	1010

Table F-20 Dispersion model outputs – water quality

Criteria	Dilution required (1:X)	Distance from platform
Meets physical parameters background levels	6	<0.6 m
Meets ANZECC 95% species protection water quality criteria	14	<4.3 m
Meets ANZECC 99% species protection water quality criteria	26	<4.3 m
Meets hydrogen sulphide background levels	269	<150 m
Meets TOC background levels	78	<15 m

Table F-21 Dispersion model outputs – fisheries

Criteria	Dilution required (1:X)	Distance from platform
Meets ANZECC seafood taint thresholds	17	<4.3 m

Table F-22 2014 results in percentage effluent of Halibut PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species (E/IC50).

Species	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
Heliocidaris tuberculata (sea urchin)	12.5	25	17.1	12.9
Mytilus galloprovincialis (Mediterranean mussel)	12.5	25	30.2	16.1
Nitzschia closterium (diatom algae)	12.5	25	18.7	N/A
Hormosira banksii (brown algae)	3.1	6.3	7.8	3.8
Allorchestes compressa (amphipod)	12.5	25	26.3	11.9
Lates calcarifer (barramundi)	50	100	68.3	52.2

Table F-23 2020 results in percentage effluent of Halibut PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species (E/IC50)

Test	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
72-hour microalgal growth (Tisochrysis lutea)	25	50	32.0	28.8
72-hour microalgal growth (Nitzschia closterium)	25	50	85.2	42.4
72-hour macroalgal germination success (Hormosira banksii)	12.5	25	32.1	21.2
1 hr sea urchin fertilisation success (Echinometra mathaei)	<0.8	0.8	1.87	0.67
72-hour sea urchin larval development (Heliocidaris tuberculata)	6.3	12.5	16.8	12.7
48-hour mollusc larval development (Mytilus edulis)	0.8	1.6	9.1	3.1
5-7 day copepod larval development (Gladioferens imparipes)	1.6	3.1	6.0	1.8
7-day fish larval development (Seriola lalandi)*	0.2	0.4	1.06	0.51

**Note that this species was not used to determine the SSD for HLA for 2020. Following delays in conducting the fish larval development test, validation of the data gave variable results requiring that this species be excluded from the SSD to ensure a representative curve*

Table F-24 Species sensitivity distribution output species protection levels – HLA effluent

Species sensitivity distribution outputs	2014 WET test result (% effluent)	2020 WET test result (% effluent)
95% species protection level	2.3%	0.59%
Dilution to obtain 95% species protection	4	169
Maximum dilution to obtain 95% species protection	169	
99% species protection level	1.0%	0.13%
Dilution to obtain 99% species protection	100	769
Maximum dilution to obtain 99% species protection	769	

Table F-25 Dispersion model outputs – ecotoxicity

Criteria	Dilution required (1:X)	Distance from platform
Meets 95% species protection levels based on whole effluent toxicity	169	<47 m
Meets 99% species protection levels based on whole effluent toxicity	769	<160 m

Appendix F.3 Snapper Platform PFW Data

Table F-26 Snapper platform PFW physical and chemical composition data – 2014 to 2020

Parameter	Number records	2014	2015	2015	2016	2017	2018	2019	2020	Mean	Std Error	Lower 95% confidence level	Upper 95% confidence level	Minimum detected (mg/l)	Maximum detected (mg/l)	Background levels	Dilution factor

Table F-27 shows the levels of total sulphide in PFW, together with an approximate concentration of hydrogen sulphide based on conversions in ANZECC (2000). Per ANZECC, in general, studies reported show the observed effect concentrations of sulphide are consistent with the un-ionised H_2S (hydrogen sulphide) form, not total sulphide.

Table F-27 Sulphide properties of SNA PFW relative to background levels, and dilution factor

Physical property	Maximum concentration in PFW	Percentage of hydrogen sulphide in total aqueous sulphide at 30C, pH 7.0-7.5 and 35% salinity#	Expected hydrogen sulphide concentration, mg/L	Background levels, mg/L*	Dilution factor
Sulphide	14.0	pH = 7.0: 22.4%	3.1	Minimum: <0.01	314
		pH = 7.5: 8.36%	1.2		117
		pH = 7.0: 22.4%	3.1	Average 0.015	209
		pH = 7.5: 8.36%	1.2		78
		pH = 7.0: 22.4%	3.1	Maximum: 0.03	105
		pH = 7.5: 8.36%	1.2		39
Maximum dilution to reach background levels					**314**

#From ANZECC, 2000, Table 8.3.10, p. 8.3-173
*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-28 shows the TOC of produced water relative to background levels of TOC in sea water.

Table F-28 TOC properties of SNA PFW relative to background levels, and dilution factor

Physical property	Maximum concentration in PFW	Background levels*	Dilution factor
TOC	820	<1 to 2	820
Maximum dilution to reach background levels			**820**

*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-29 Particle Size Distribution for SNA PFW

Wentworth Size Classifications	2020
Total Clay % (0-4 µm)	**55.49**
Very Fine Silt % (4-8 µm)	14.09
Fine Silt % (8-16 µm)	12.07
Medium Silt % (16-31 µm)	9.51
Course Silt % (31-63 µm)	6.69
Total Silt (4-63 µm)	**42.37**
Very Fine sand % (63-12 5µm)	1.99
Fine sand % (125-250 µm)	0.15
Medium sand % (250-500 µm)	0.00
Coarse sand % (500-1000 µm)	0.00
Very Coarse sand % (1000-2000 µm)	0.00
Total Sand (63-2000 µm)	**2.14**
Total Gravels (>2000 µm)	**0.00**

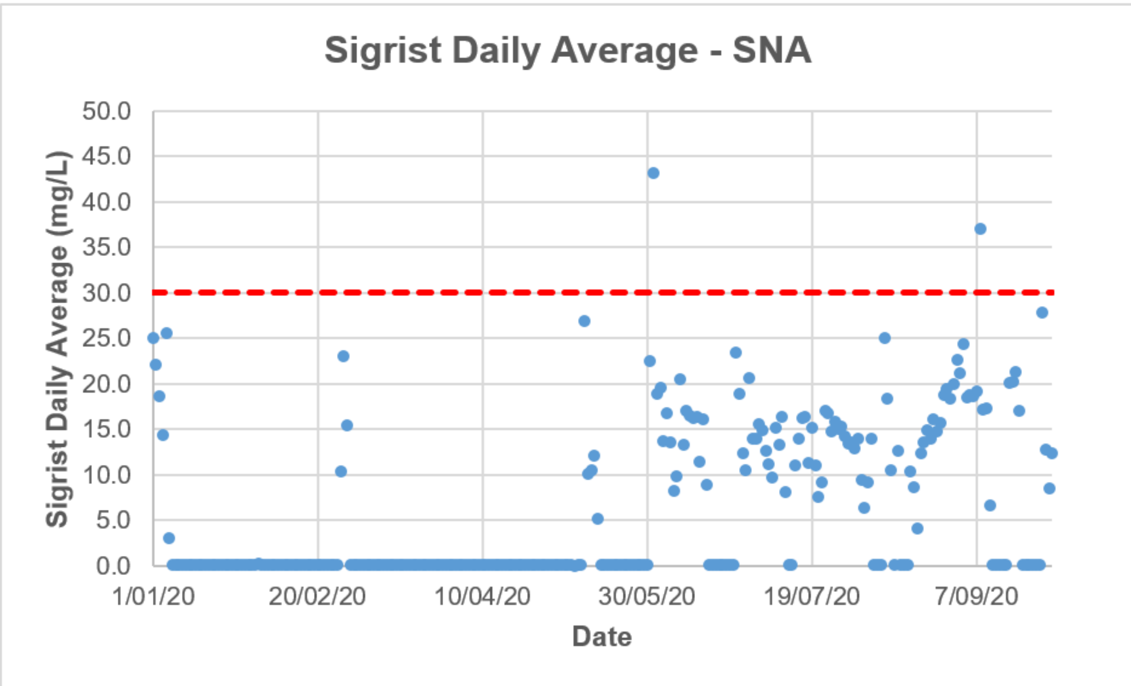

Figure F-9 Platform overboard discharge levels of oil in water (in mg/L) since 1 Jan 2020

A summary of Sigrist daily averages exceeding 30 mg/L on Snapper for the period of 1st January 2020 to 30th September 2020 is given below in Table F-30.

Table F-30 SNA Oil in water exceedances from January 2020 to September 2020

Date	Sigrist Daily Average (mg/L)	Total Oil Load (kg/day)	Comments
01/06/20	43.2	55.3	Significant foaming occurred after bringing a well online due to inhibitor which resulted in elevated readings on the Sigrist. Reported to NOPSEMA in June monthly recordable incidents report.
08/09/20	37.0	65.5	Oil in water spikes were observed after brining a well online. Reported to NOPSEMA in September monthly recordable incidents report.

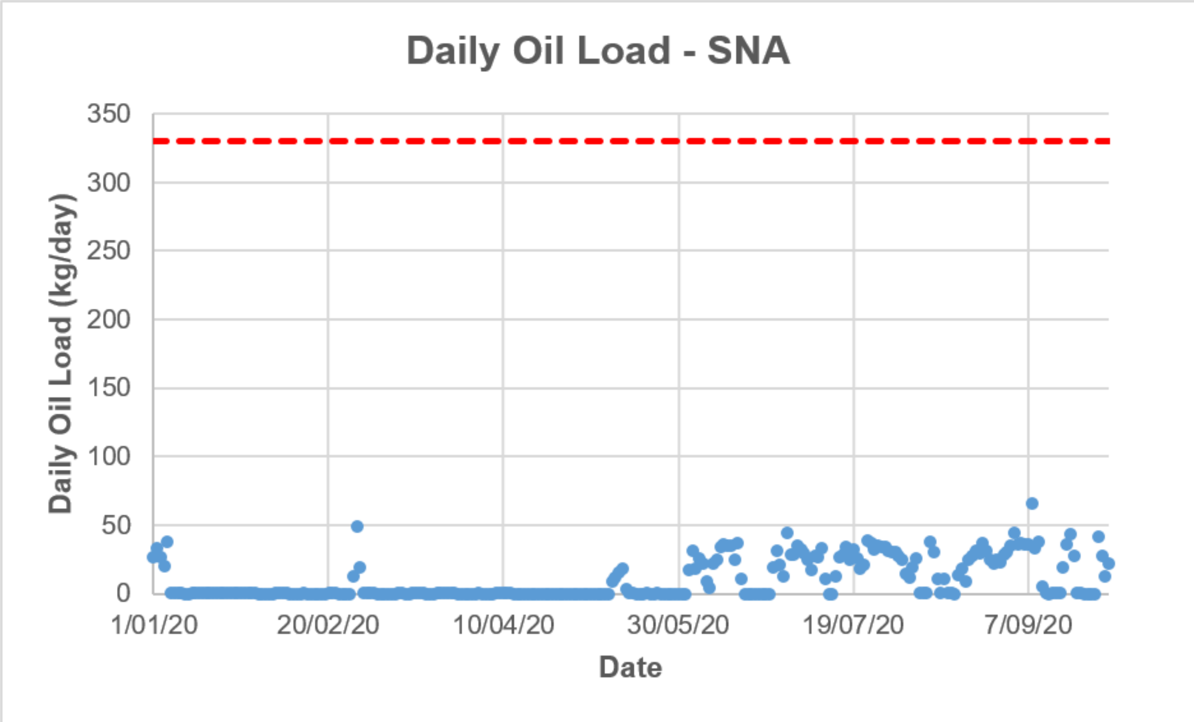

Figure F-10 Platform overboard oil load (in kg/d, mg/L oil concentration multiplied by volume discharged) since 1 Jan 2020

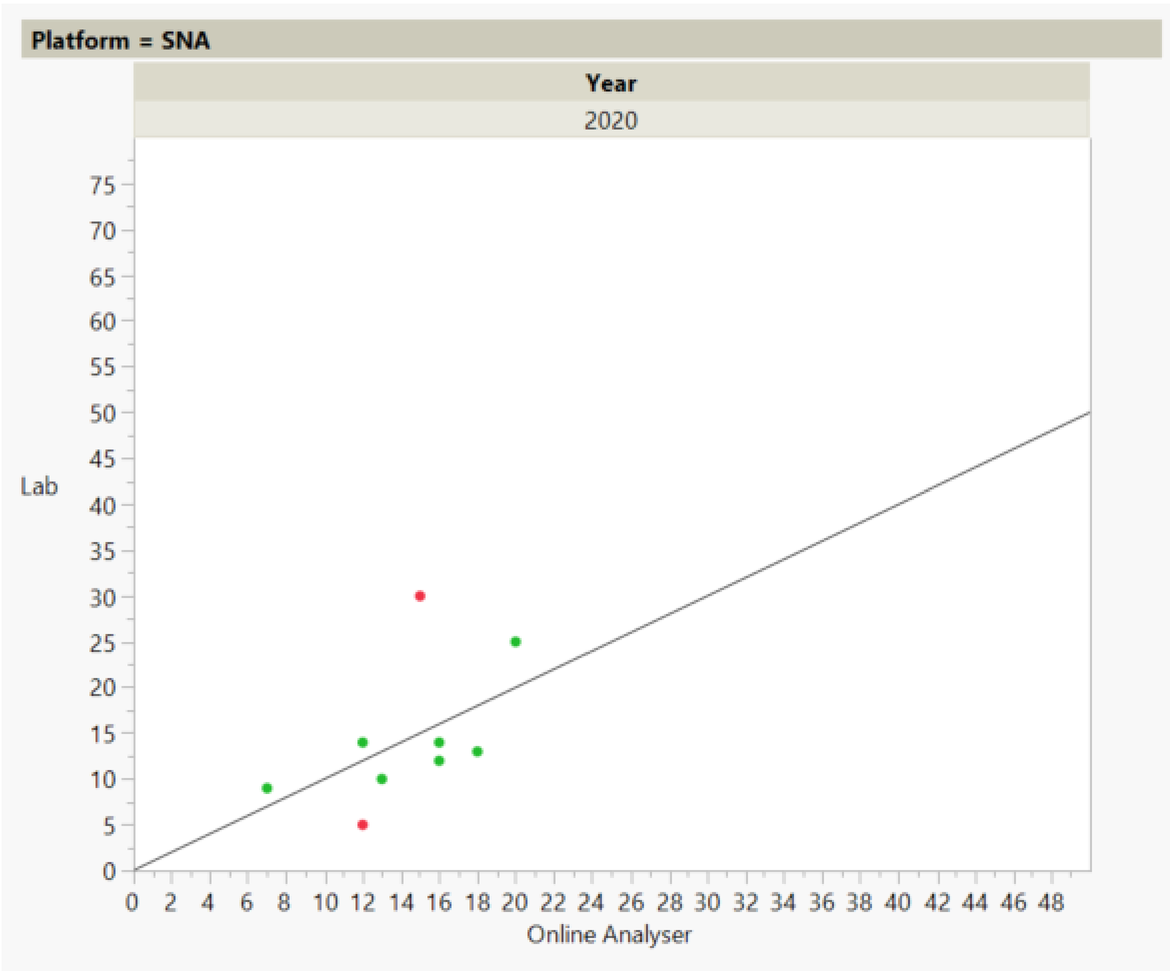

Figure F-11 Cross-check of platform online monitor readings with routine laboratory tests

Table F-31 Dispersion model inputs – Snapper platform

Parameter	Value
Discharge rate (kL/day)	4,370
Discharge temperature (°C)	80
Discharge salinity (ppt)	23
Internal diameter of outlet (inch) [m]	12.81 [0.32]
Outlet orientation	vertically downward
Depth of outlet below MSL (m)	8.2
Total water depth at site (m)	55

Figure F-12 shows the model outputs for the platform (dilution contours) with distance from the platform. The inset in Figure F-12 (b) shows there is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment.

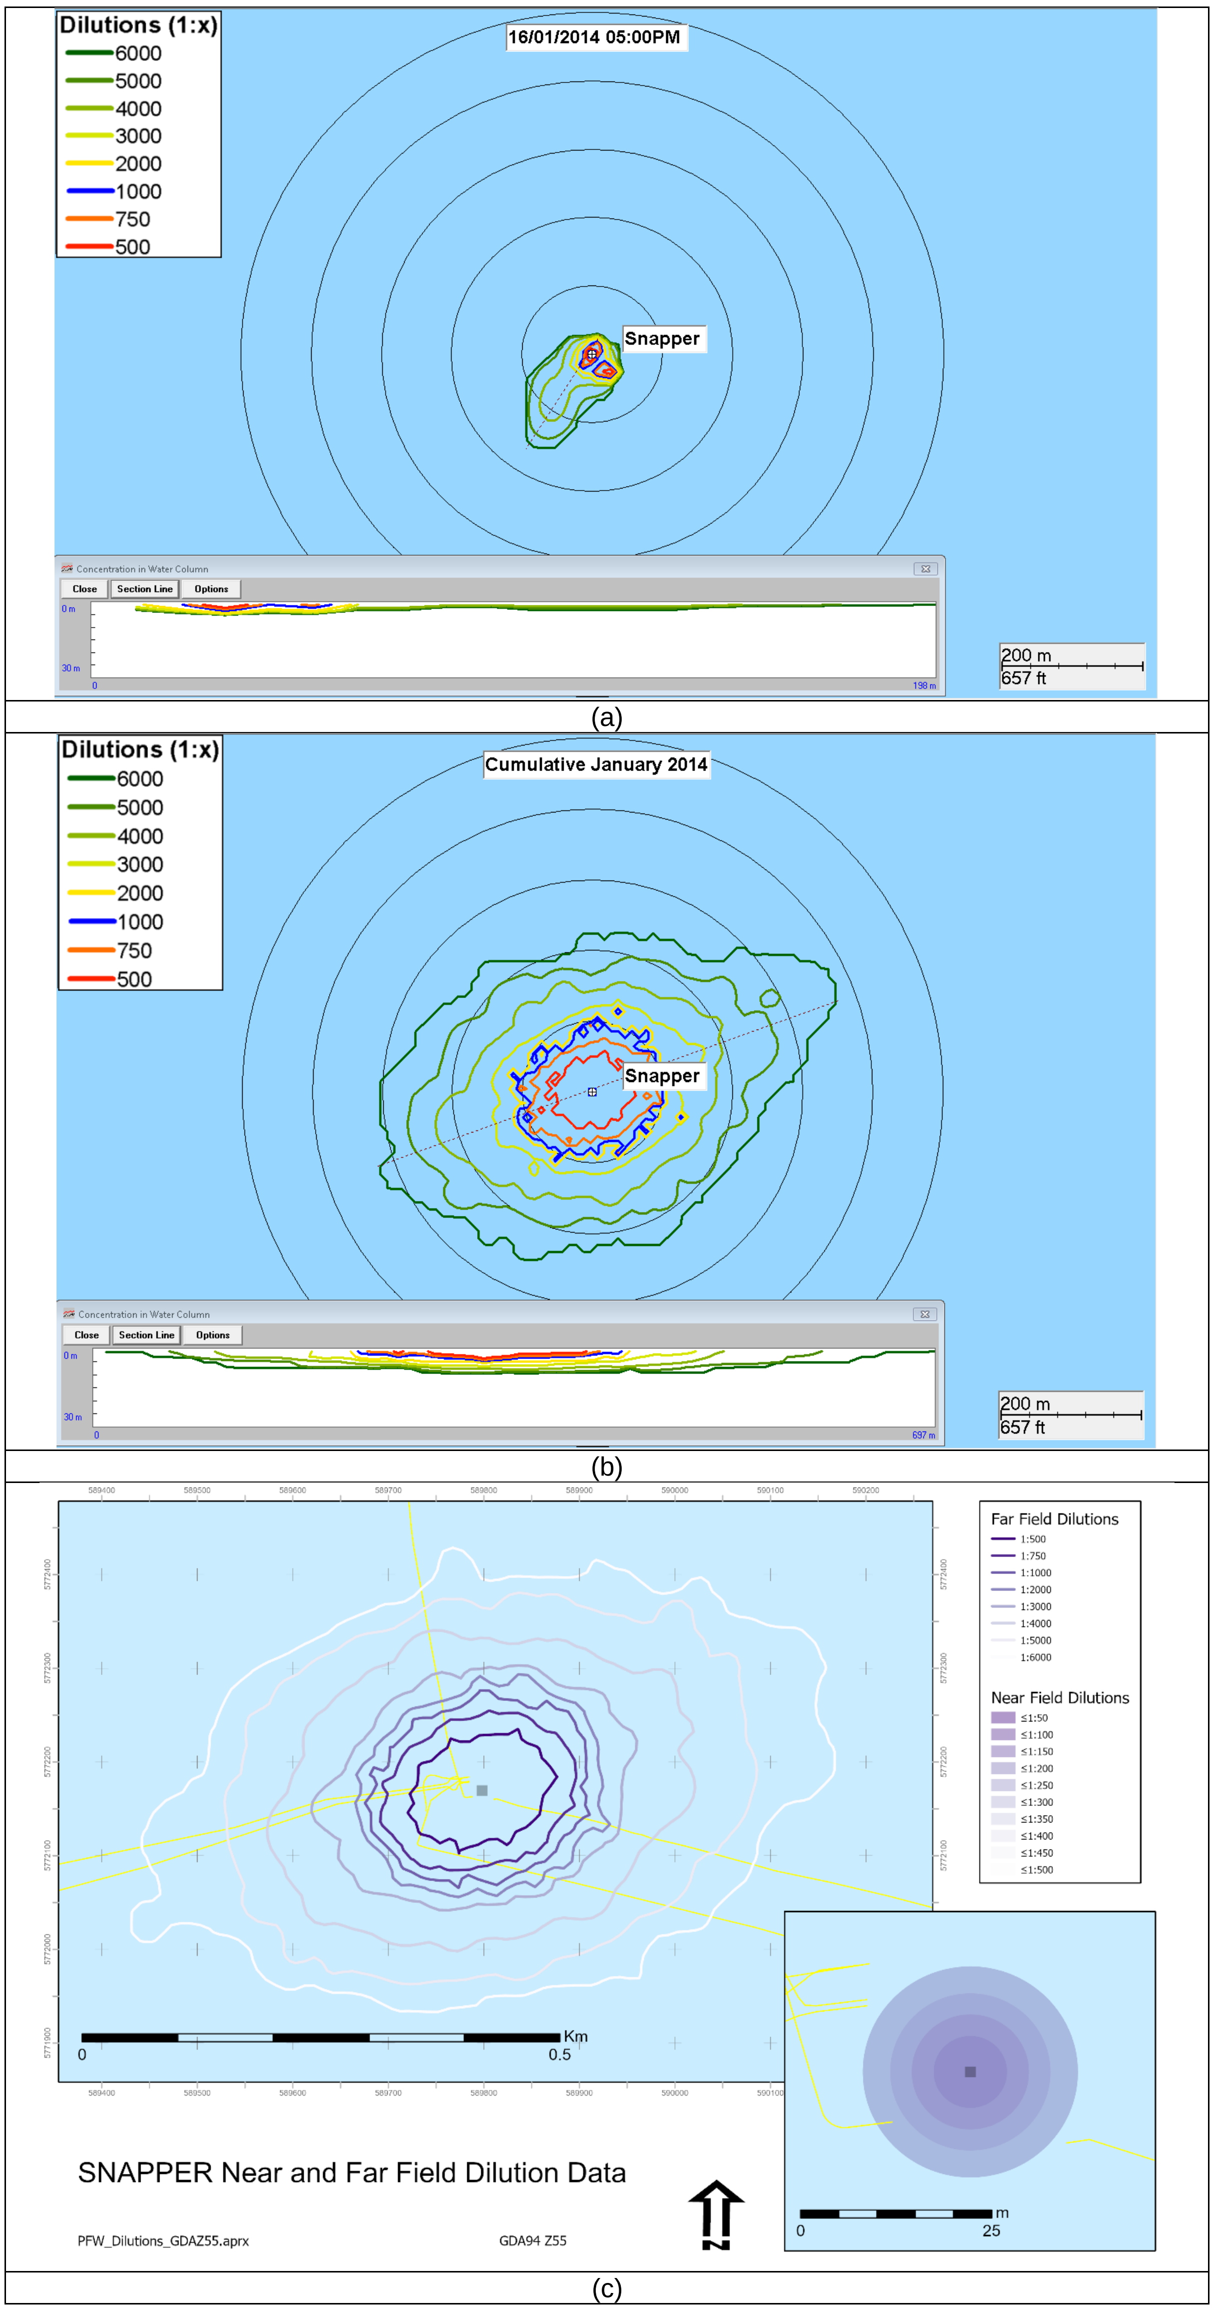

Figure F-12 Dilution around the SNA platform and in the water column from PFW. (a) Snapshot of dilution of produced water plume around the platform, surface and cross-sectional view. (b) Summary of the dilution contours around the platform, conglomerated over one month (taking account of tide/current directions on any given day). (c) Yearly far-field dilution contours, inset are near-field contours.

Table F-32 Dilution factors with distance from the SNA platform under typical currents.

Dilution factor	Distance from platform (m)
10	1.6
50	5
100	8
500	80
750	110
1000	120
2000	130
3000	170
4000	230

Table F-33 Dispersion model outputs – water quality

Criteria	Dilution required (1:X)	Distance from platform
Meets physical parameters background levels	6	<1.6 m
Meets ANZECC 95% species protection water quality criteria	105	<80 m
Meets ANZECC 99% species protection water quality criteria	3286	<230 m
Meets hydrogen sulphide background levels	314	<80 m
Meets TOC background levels	820	<120 m

Table F-34 Dispersion model outputs – fisheries

Criteria	Dilution required (1:X)	Distance from platform
Meets ANZECC seafood taint thresholds	52	<8 m

Table F-35 2014 results in percentage effluent of Snapper PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species.

Species	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
Heliocidaris tuberculata (sea urchin)	3.1	6.3	6.6	4.3
Mytilus galloprovincialis (Mediterranean mussel)	6.3	12.5	11.9	6.7
Nitzschia closterium (diatom algae)	12.5	25	26.8	15.2
Hormosira banksii (brown algae)	1.6	3.1	3	0.8
Allorchestes compressa (amphipod)	12.5	25	16.8	12.7
Lates calcarifer (barramundi)	12.5	25	17.7	16.3

Table F-36 2020 results in percentage effluent of Snapper PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species (E/IC50)

Test	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
72-hour microalgal growth (Tisochrysis lutea)	50	100	54.3	42.0
72-hour microalgal growth (Nitzschia closterium)	25	50	34.0	25.1
72-hour macroalgal germination success (Hormosira banksii)	12.5	25	27.6	18.3
1 hr sea urchin fertilisation success (Echinometra mathaei)	3.1	6.3	9.6	4.6
72-hour sea urchin larval development (Heliocidaris tuberculata)	6.3	12.5	7.5	6.7
48-hour mollusc larval development (Mytilus edulis)	6.3	12.5	12.5	8.9
5-7 day copepod larval development (Gladioferens imparipes)	0.8	1.6	2.8	1.7
7-day fish larval development (Seriola lalandi)	0.8	1.6	1.12	0.41

Table F-37 Species sensitivity distribution output species protection levels – SNA effluent

Species sensitivity distribution outputs	2014 WET test result (% effluent)	2020 WET test result (% effluent)
95% species protection level	0.75%	0.55%
Dilution to obtain 95% species protection	133	182
Maximum dilution to obtain 95% species protection	182	
99% species protection level	0.27%	0.14%
Dilution to obtain 99% species protection	370	714
Maximum dilution to obtain 99% species protection	714	

Table F-38 Dispersion model outputs – ecotoxicity

Criteria	Dilution required (1:X)	Distance from platform
Meets 95% species protection levels based on whole effluent toxicity	182	<80 m
Meets 99% species protection levels based on whole effluent toxicity	714	<110 m

Appendix F.4 West Kingfish Platform PFW Data

Table F-39 West Kingfish platform PFW physical and chemical composition data – 2014 to 2020

Table F-40 shows the levels of total sulphide in PFW, together with an approximate concentration of hydrogen sulphide based on conversions in ANZECC (2000). Per ANZECC, in general, studies reported show the observed effect concentrations of sulphide are consistent with the un-ionised H_2S (hydrogen sulphide) form, not total sulphide.

Table F-40 Sulphide properties of WKF PFW relative to background levels, and dilution factor

Physical property	Maximum concentration in PFW	Percentage of hydrogen sulphide in total aqueous sulphide at 30C, pH 7.0-7.5 and 35% salinity#	Expected hydrogen sulphide concentration, mg/L	Background levels, mg/L*	Dilution factor
Sulphide	10.0	pH = 7.0: 22.4%	2.2	Minimum: <0.01	224
		pH = 7.5: 8.36%	0.8		84
		pH = 7.0: 22.4%	2.2	Average 0.015	149
		pH = 7.5: 8.36%	0.8		56
		pH = 7.0: 22.4%	2.2	Maximum: 0.03	75
		pH = 7.5: 8.36%	0.8		28
Maximum dilution to reach background levels					**224**

#From ANZECC, 2000, Table 8.3.10, p. 8.3-173
*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-41 shows the TOC of produced water relative to background levels of TOC in sea water.

Table F-41 TOC properties of WKF PFW relative to background levels, and dilution factor

Physical property	Maximum concentration in PFW	Background levels*	Dilution factor
TOC	740	<1 to 2	740
Maximum dilution to reach background levels			**740**

*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-42 Particle Size Distribution for WKF PFW

Wentworth Size Classifications	2020
Total Clay % (0-4 µm)	**15.97**
Very Fine Silt % (4-8 µm)	31.36
Fine Silt % (8-16 µm)	38.27
Medium Silt % (16-31 µm)	10.45
Course Silt % (31-63 µm)	3.29
Total Silt (4-63 µm)	**83.38**
Very Fine sand % (63-125 µm)	0.65
Fine sand % (125-250 µm)	0.00
Medium sand % (250-500 µm)	0.00
Coarse sand % (500-1000 µm)	0.00
Very Coarse sand % (1000-2000 µm)	0.00
Total Sand (63-2000 µm)	**0.65**
Total Gravels (>2000 µm)	**0.00**

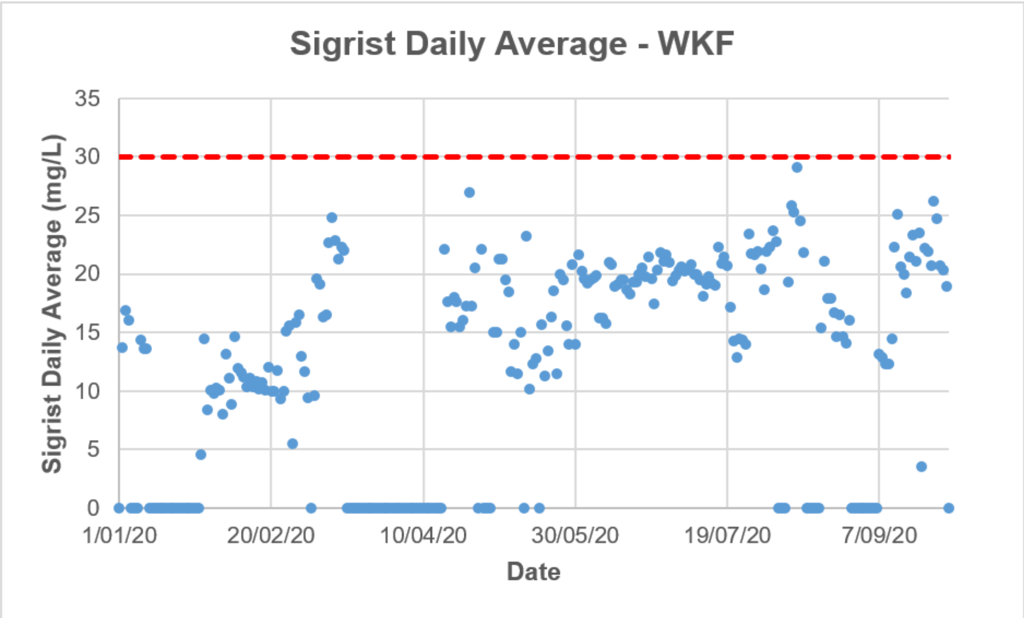

Figure F-13 Platform overboard discharge levels of oil in water (in mg/L) since 1 Jan 2020

There were no Sigrist daily averages that exceeded 30 mg/L in West Kingfish between 1st January 2020 and 30th September 2020.

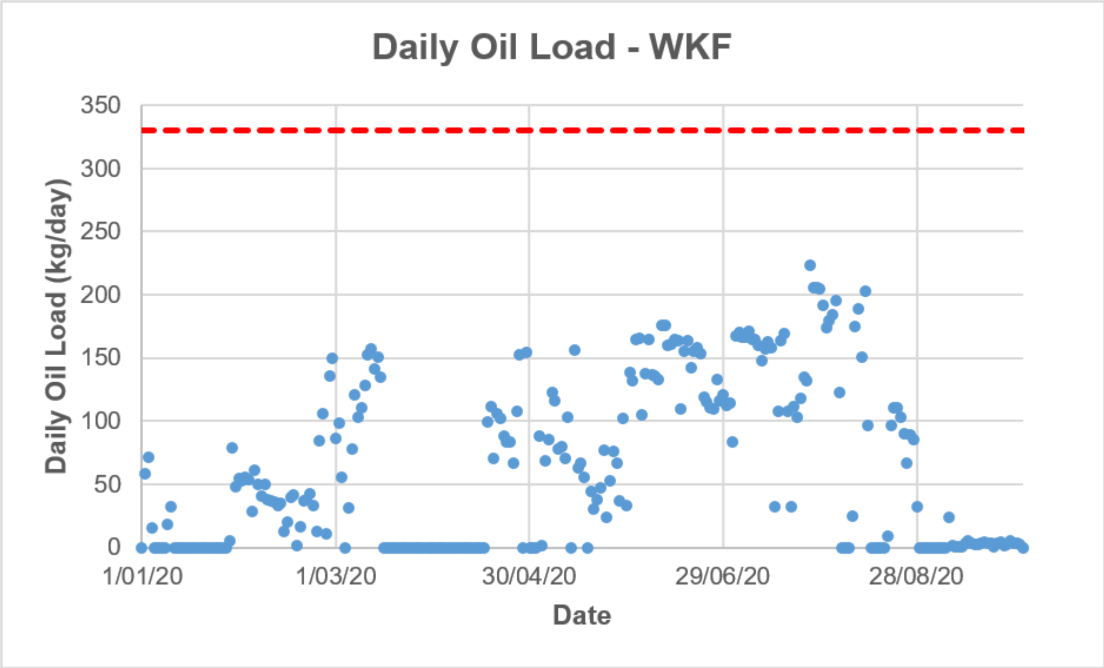

Figure F-14 Platform overboard oil load (in kg/d, mg/L oil concentration multiplied by volume discharged) since 1 Jan 2020

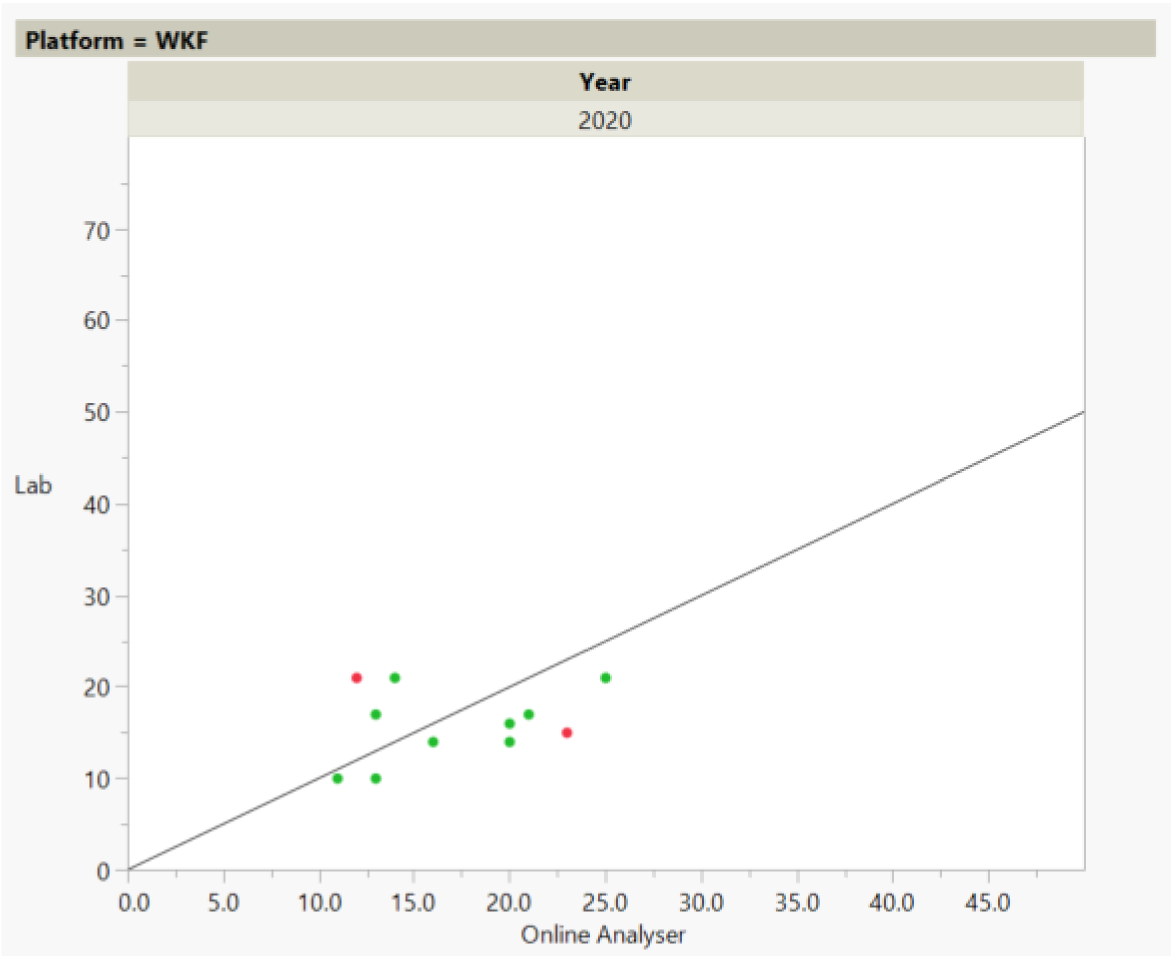

Figure F-15 Cross-check of platform online monitor readings with routine laboratory tests

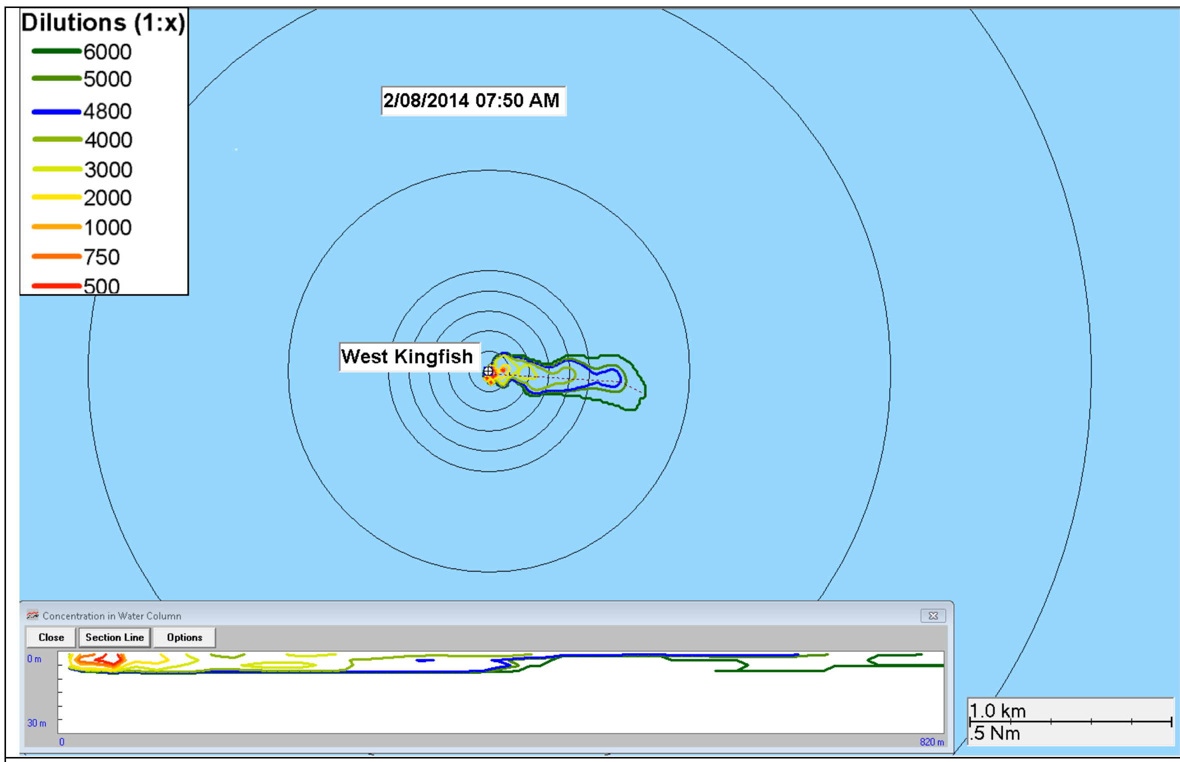
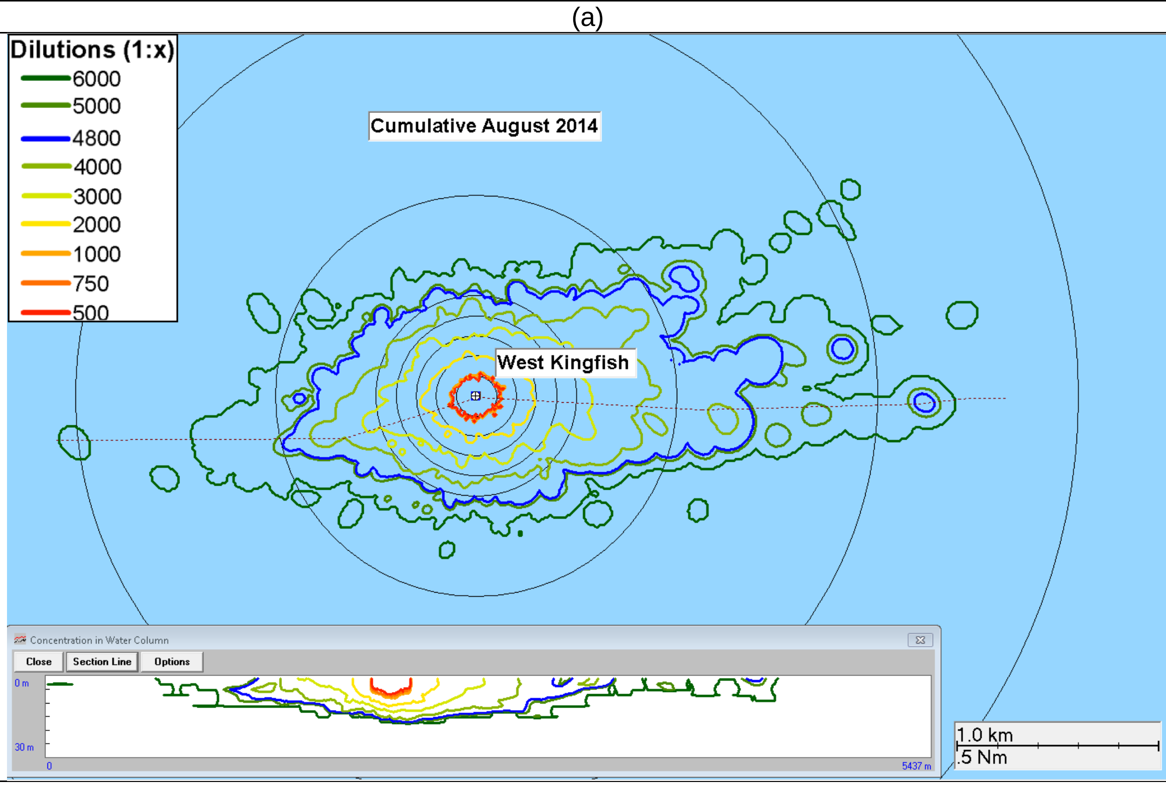
Table F-43 Dispersion model inputs – West Kingfish platform

Parameter	Value
Discharge rate (kL/day)	13,053
Discharge temperature (°C)	84
Discharge salinity (ppt)	38
Internal diameter of outlet (inch) [m]	9.84 [0.25]
Outlet orientation	vertically downward
Depth of outlet below MSL (m)	16
Total water depth at site (m)	76

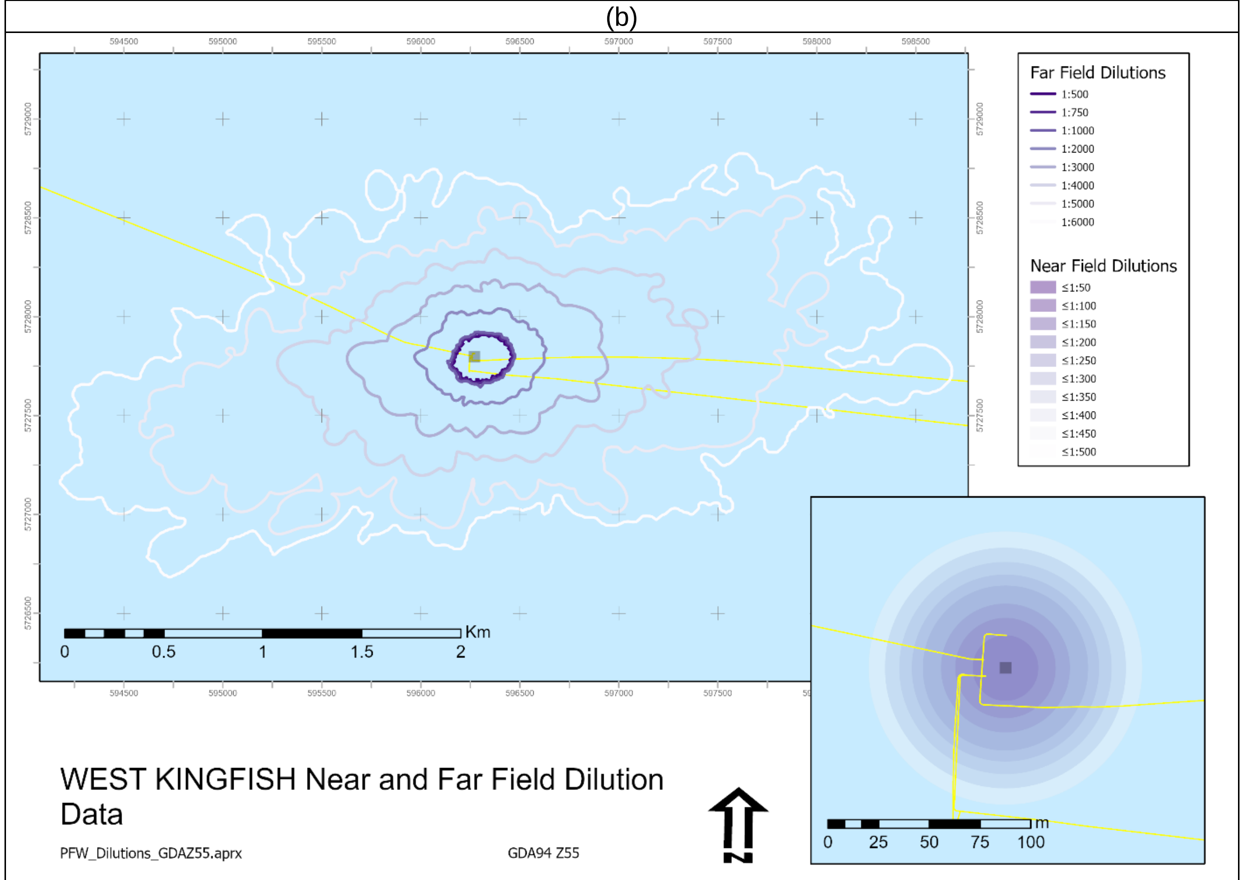
Figure F-16 shows the model outputs for the platform (dilution contours) with distance from the platform. The inset in Figure F-16(b) shows there is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment.



(a)



(b)



(c)

Figure F-16 **Dilution around the WKF platform and in the water column from PFW. (a) Snapshot of dilution of produced water plume around the platform, surface and cross-sectional view. (b) Summary of the dilution contours around the platform, conglomerated over one month (taking account of tide/current directions on any given day). (c) Yearly far-field dilution contours, inset are near-field contours.**

Table F-44 Dilution factors with distance from the WKF platform under typical currents. The distance to the highest required dilution factor to account for most and all potential PFW impacts to the marine environment is shown in italics.

Dilution factor	Distance from platform (m)
10	1.0
50	17
100	28
200	42
500	160
750	160
1000	180
2000	340
3000	680
4000	1140

Table F-45 Dispersion model outputs – water quality

Criteria	Dilution required (1:X)	Distance from platform
Meets physical parameters background levels	6	<1 m
Meets ANZECC 95% species protection water quality criteria	21	<17 m
Meets ANZECC 99% species protection water quality criteria	414	<160 m
Meets hydrogen sulphide background levels	224	<160 m
Meets TOC background levels	740	<160 m

Table F-46 Dispersion model outputs – fisheries

Criteria	Dilution required (1:X)	Distance from platform
Meets ANZECC seafood taint thresholds	14	<17 m

Table F-47 2014 results in percentage effluent of West Kingfish PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species

Species	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
Heliocidaris tuberculata (sea urchin)	12.5	25	28.7	18.7
Mytilus galloprovincialis (Mediterranean mussel)	6.3	12.5	8.4	6.3
Nitzschia closterium (diatom algae)	12.5	25	30	15.8
Hormosira banksii (brown algae)	3.1	6.3	7.4	4.4
Allorchestes compressa (amphipod)	50	100	100	89.5
Lates calcarifer (barramundi)	50	100	73.5	76.6

Table F-48 2020 results in percentage effluent of West Kingfish PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species

Test	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
72-hour microalgal growth (Tisochrysis lutea)	50	100	91.6	73.3
72-hour microalgal growth (Nitzschia closterium)	6.3	12.5	54.6	9.8
72-hour macroalgal germination success (Hormosira banksii)	25	50	54.7	31.4
1 hr sea urchin fertilisation success (Echinometra mathaei)	<3.1	3.1	10.9	4.17
72-hour sea urchin larval development (Heliocidaris tuberculata)	6.3	12.5	17.0	12.9
48-hour mollusc larval development (Mytilus edulis)	3.1	6.3	22.4	11.5
5-7 day copepod larval development (Gladioferens imparipes)	6.3	12.5	7.8	5.9
7-day fish larval development (Seriola lalandi)	<0.4	0.4	4.14	1.62

Table F-49 Species sensitivity distribution output species protection levels – WKF effluent

Species sensitivity distribution outputs	2014 WET test result (% effluent)	2020 WET test result (% effluent)
95% species protection level	3.2%	1.8%
Dilution to obtain 95% species protection	31	56
Maximum dilution to obtain 95% species protection	56	
99% species protection level	1.5%	0.82%
Dilution to obtain 99% species protection	67	122
Maximum dilution to obtain 99% species protection	122	

Table F-50 Dispersion model outputs – ecotoxicity

Criteria	Dilution required (1:X)	Distance from platform
Meets 95% species protection levels based on whole effluent toxicity	56	<28 m
Meets 99% species protection levels based on whole effluent toxicity	122	<42 m

Appendix F.5 Cobia Platform PFW Data

Table F-51 Cobia platform PFW physical and chemical composition data – 2014 to 2020

Parameter	Number records	2014	2020	2020	Mean	Std Error	Lower 95% confidence level	Upper 95% confidence level	Minimum detected (mg/l)	Maximum detected (mg/l)	Background levels	Dilution factor

b: m-Cresol
c: p-Cresol

Table F-52 shows the levels of total sulphide in PFW, together with an approximate concentration of hydrogen sulphide based on conversions in ANZECC (2000). Per ANZECC, in general, studies reported show the observed effect concentrations of sulphide are consistent with the un-ionised H2S (hydrogen sulphide) form, not total sulphide.

Table F-52 Sulphide properties of CBA PFW relative to background levels, and dilution factor

Physical property	Maximum PFW characteristic	Percentage of hydrogen sulphide in total aqueous sulphide at 30C, pH 7.0-7.5 and 35% salinity#	Expected hydrogen sulphide concentration, mg/L	Background levels, mg/L*	Dilution factor
Sulphide	12.0	pH = 7.0: 22.4%	2.7	Minimum: <0.01	269
		pH = 7.5: 8.36%	1.0		100
		pH = 7.0: 22.4%	2.7	Average 0.015	179
		pH = 7.5: 8.36%	1.0		67
		pH = 7.0: 22.4%	2.7	Maximum: 0.03	90
		pH = 7.5: 8.36%	1.0		33
Maximum dilution to reach background levels					**269**

#From ANZECC, 2000, Table 8.3.10, p. 8.3-173
*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-53 shows the TOC of produced water relative to background levels of TOC in sea water.

Table F-53 TOC properties of CBA PFW relative to background levels, and dilution factor

Physical property	Maximum PFW characteristic	Background levels*	Dilution factor
TOC	170	<1 to 2	170
Maximum dilution to reach background levels			**170**

*Taken from 18 reference site samples taken away from Tuna platform location.

Table F-54 Particle Size Distribution for CBA PFW

Wentworth Size Classifications	2020
Total Clay % (0-4 µm)	**43.50**
Very Fine Silt % (4-8 µm)	24.79
Fine Silt % (8-16 µm)	24.15
Medium Silt % (16-31 µm)	7.24
Course Silt % (31-63 µm)	0.32
Total Silt (4-63 µm)	**56.50**
Very Fine sand % (63-125 µm)	0.00
Fine sand % (125-250 µm)	0.00
Medium sand % (250-500 µm)	0.00
Coarse sand % (500-1000 µm)	0.00
Very Coarse sand % (1000-2000 µm)	0.00
Total Sand (63-2000 µm)	**0.00**
Total Gravels (>2000 µm)	**0.00**

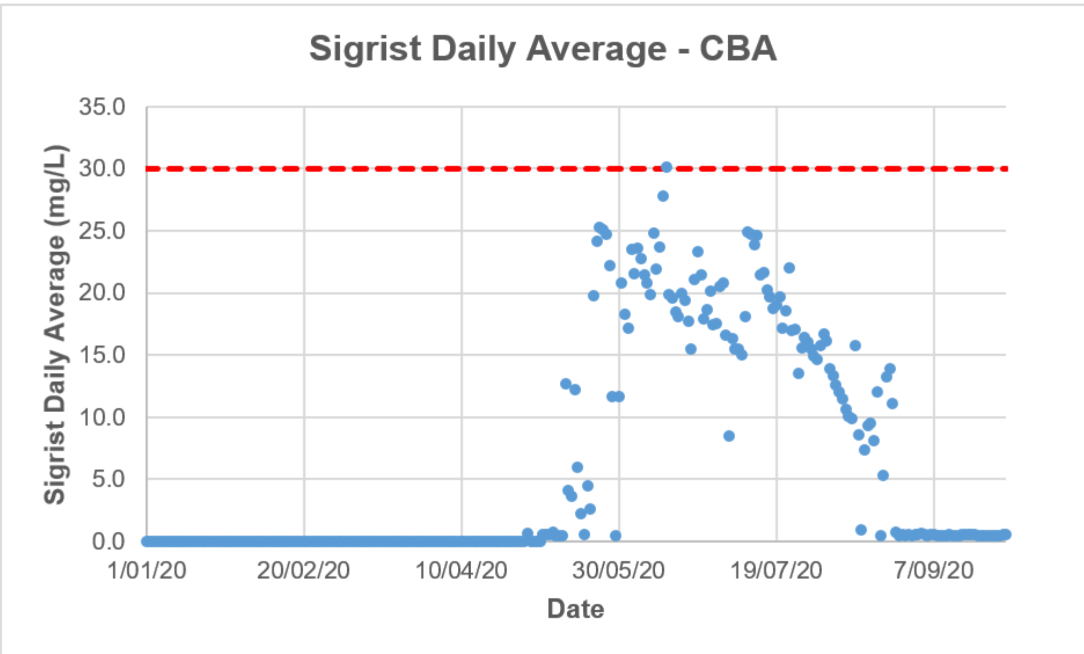

Figure F-17 Platform overboard discharge levels of oil in water (in mg/L) since 1 Jan 2020

A summary of Sigrist daily averages exceeding 30 mg/L on Cobia for the period of 1st January 2020 to 30th September 2020 is given below in Table F-55.

Table F-55 CBA Oil in water exceedances from January 2020 to September 2020

Date	Sigrist Daily Average (mg/L)	Total Oil Load (kg/day)	Comments
14/06/20	32.7	144.2	Exceedance suspected to have been caused by gas breakout due to a higher water flowrate. Reported to NOPSEMA in June monthly recordable incidents report.

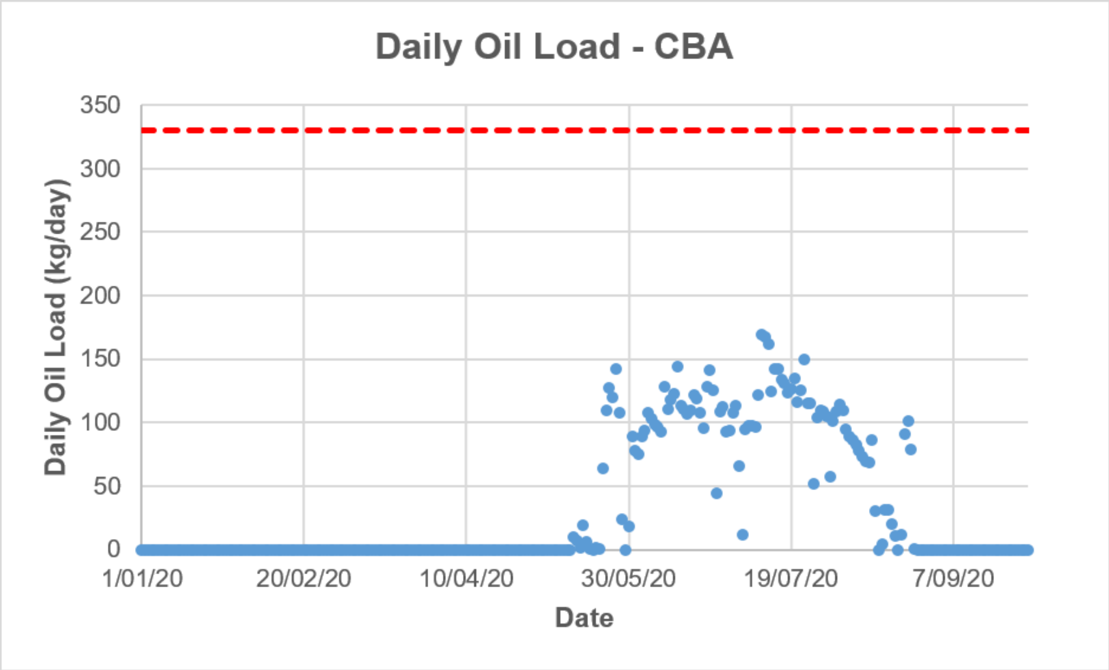

Figure F-18 Platform overboard oil load (in kg/d, mg/L oil concentration multiplied by volume discharged) since 1 Jan 2020

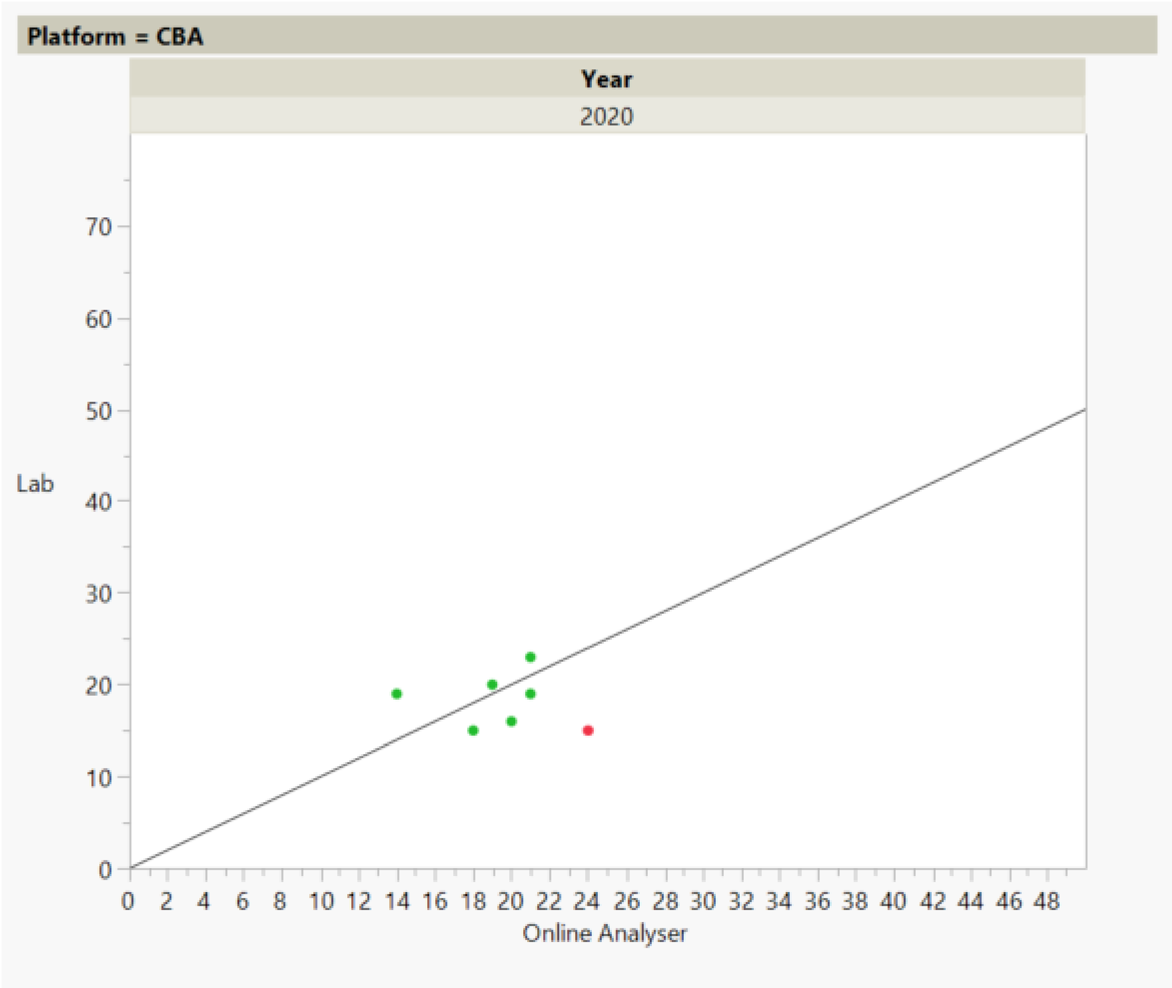

Figure F-19 Cross-check of platform online monitor readings with routine laboratory tests

Table F-56 Dispersion model inputs – Cobia platform

Parameter	Value
Discharge rate (kL/day)	15,009
Discharge temperature (°C)	53
Discharge salinity (ppt)	37
Internal diameter of outlet (inch) [m]	9.84 [0.25]
Outlet orientation	vertically downward
Depth of outlet below MSL (m)	27.7
Total water depth at site (m)	78

Figure F-24 show the model outputs for the platform (dilution contours) with distance from the platform. The inset in Figure F-24 (b) shows there is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment.

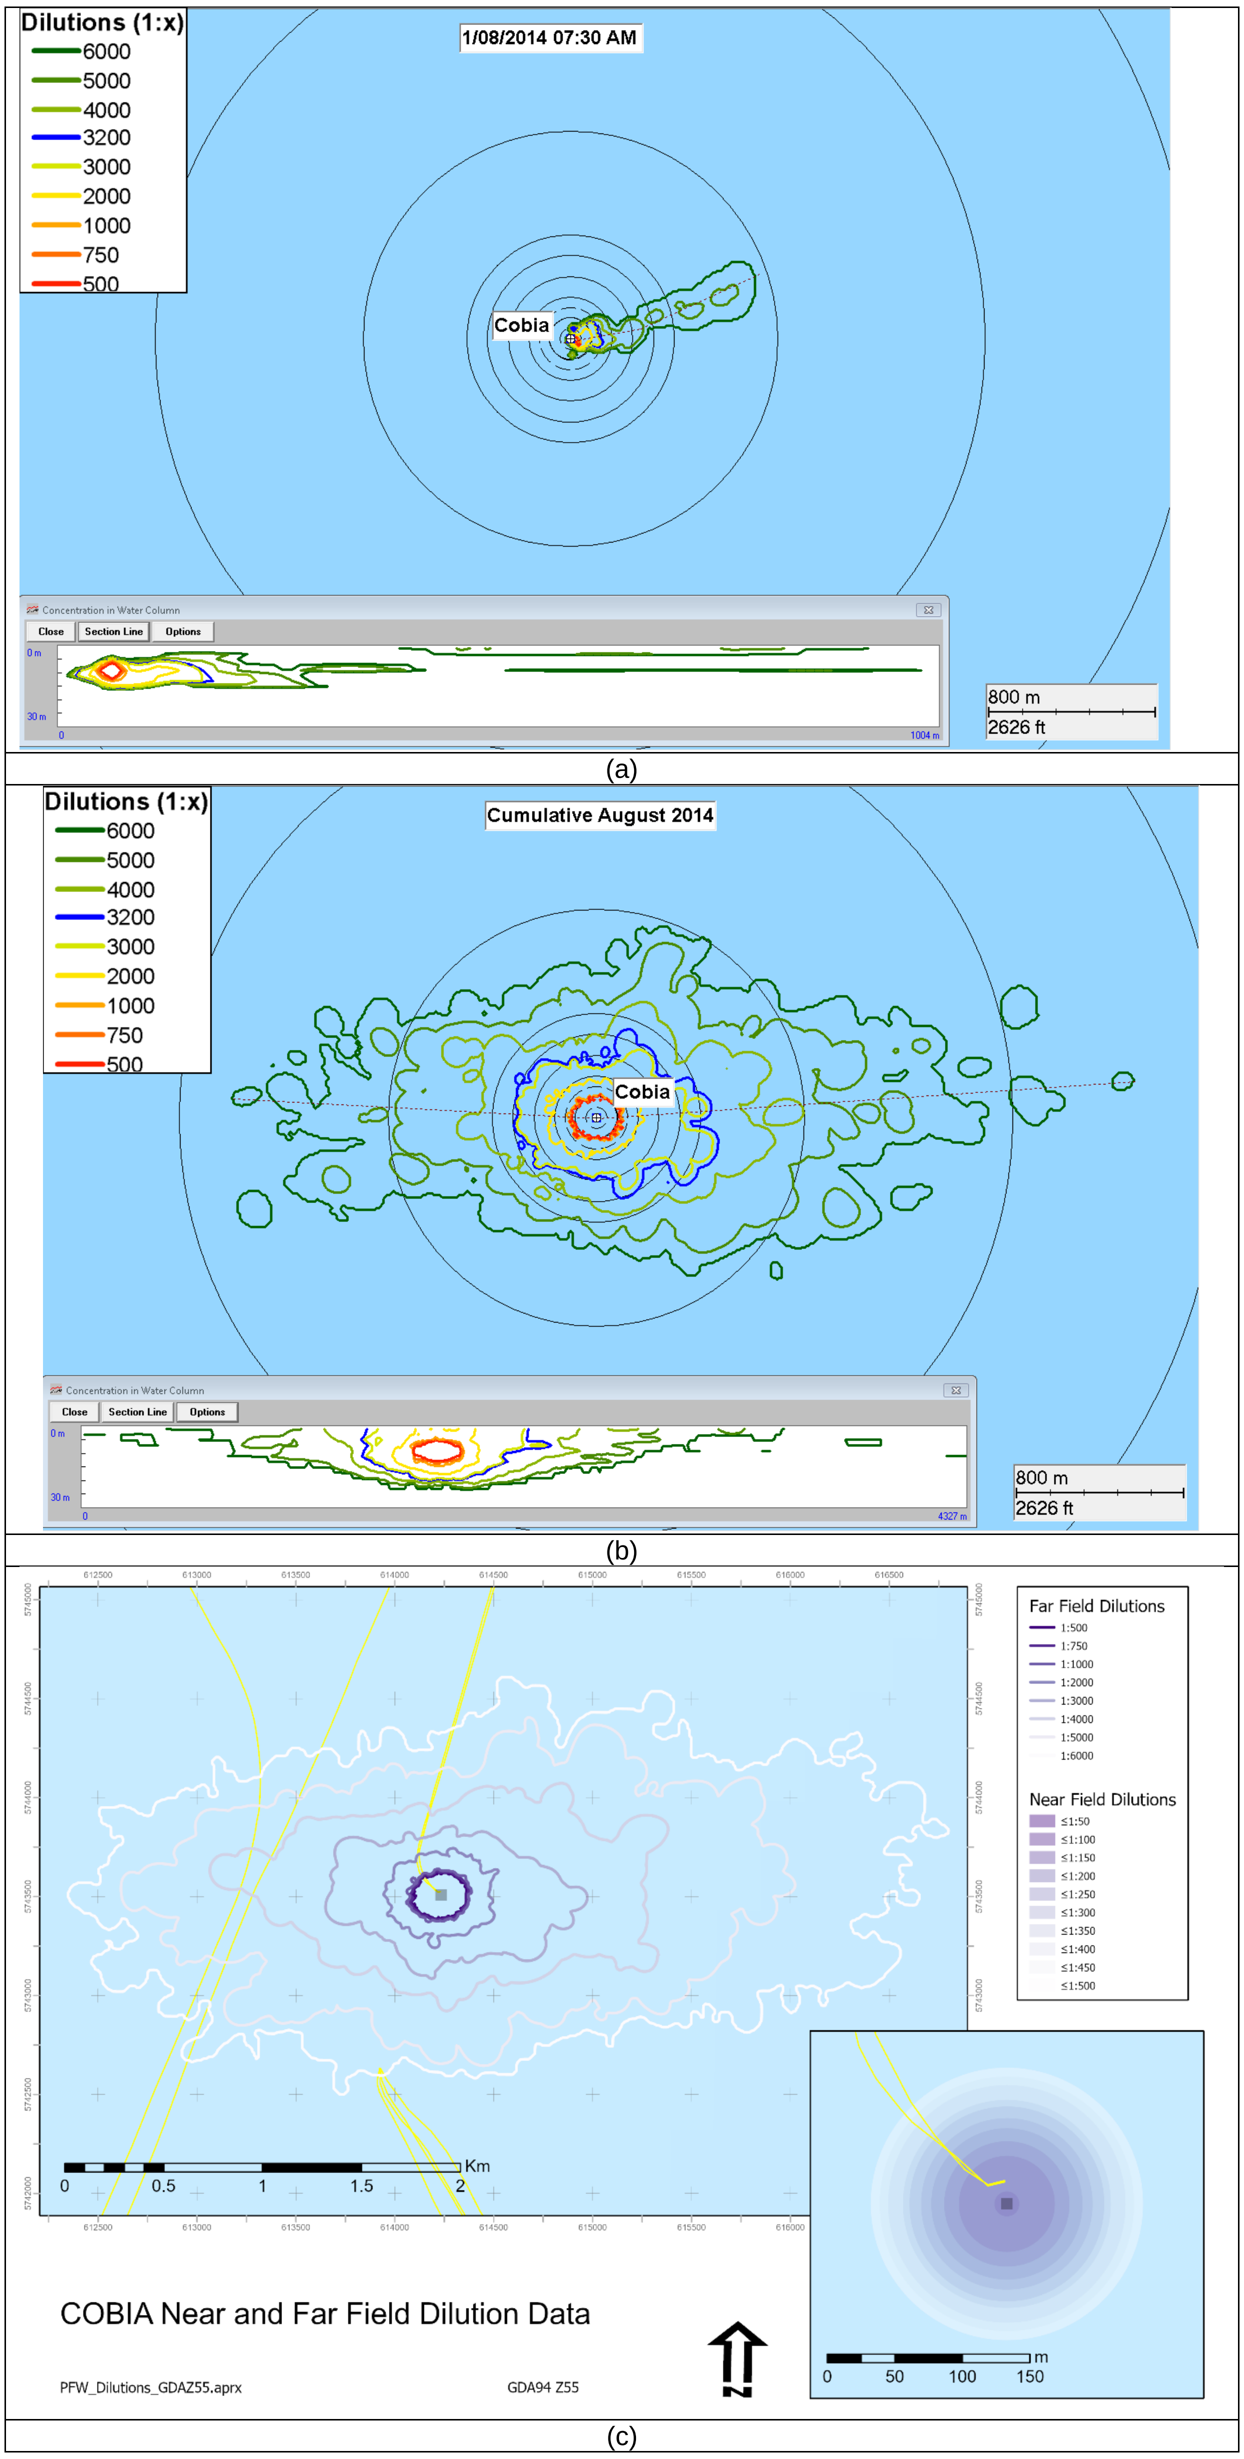

Figure F-20 **Dilution around the CBA platform and in the water column from PFW. (a) Snapshot of dilution of produced water plume around the platform, surface and cross-sectional view. (b) Summary of the dilution contours around the platform, conglomerated over one month (taking account of tide/current directions on any given day). (c) Yearly far-field dilution contours, inset are near-field contours.**

Table F-57 Dilution factors with distance from the CBA platform under typical currents.

Dilution factor	Distance from platform (m)
10	0.9
50	10
100	38
200	60
500	160
750	160
1000	180
2000	310
3000	740
4000	1200

Table F-58 Dispersion model outputs – water quality

Criteria	Dilution required (1:X)	Distance from platform
Meets physical parameters background levels	6	<0.9 m
Meets ANZECC 95% species protection water quality criteria	15	<10 m
Meets ANZECC 99% species protection water quality criteria	28	<10 m
Meets hydrogen sulphide background levels	269	<160 m
Meets TOC background levels	170	<60 m

Table F-59 Dispersion model outputs – fisheries

Criteria	Dilution required (1:X)	Distance from platform
Meets ANZECC seafood taint thresholds	10	0.9 m

Table F-60 2014 results in percentage effluent of Cobia PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species (E/IC50)

Species	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
Heliocidaris tuberculata (sea urchin)	3.1	6.3	15.4	11.6
Mytilus galloprovincialis (Mediterranean mussel)	12.5	25	24.1	13
Nitzschia closterium (diatom algae)	12.5	25	18.2	N/A
Hormosira banksii (brown algae)	6.3	12.5	15.2	6.7
Allorchestes compressa (amphipod)	25	50	34.6	N/A
Lates calcarifer (barramundi)	50	100	55	50

Table F-61 2020 results in percentage effluent of Cobia PFW for no effect concentration (NOEC), lowest effect concentration (LOEC), concentration with effects or inhibition of 10% species (E/IC10), and concentration with effects or inhibition of 50% species (E/IC50)

Test	NOEC (% effluent)	LOEC (% effluent)	E/IC50 (% effluent)	E/IC10 (% effluent)
72-hour microalgal growth (Tisochrysis lutea)	50	100	65.7	59.4
72-hour microalgal growth (Nitzschia closterium)	25	50	36.3	23.4
72-hour macroalgal germination success (Hormosira banksii)	25	50	63.3	37.2
1 hr sea urchin fertilisation success (Echinometra mathaei)	<0.8	0.8	15.0	7.45
72-hour sea urchin larval development (Heliocidaris tuberculata)	12.5	25	20.9	15.7
48-hour mollusc larval development (Mytilus edulis)	<0.8	0.8	7.7	1.2
5-7 day copepod larval development (Gladioferens imparipes)	0.8	1.6	3.16	1.18
7-day fish larval development (Seriola lalandi)	1.6	3.1	2.7	1.8

Table F-62 Species sensitivity distribution output species protection levels – CBA effluent

Species sensitivity distribution outputs	2014 WET test result (% effluent)	2020 WET test result (% effluent)
95% species protection level	3.4%	0.88%
Dilution to obtain 95% species protection	29	114
Maximum dilution to obtain 95% species protection	114	
99% species protection level	1.7%	0.5%
Dilution to obtain 99% species protection	59	200
Maximum dilution to obtain 99% species protection	200	

Table F-63 Dispersion model outputs – ecotoxicity

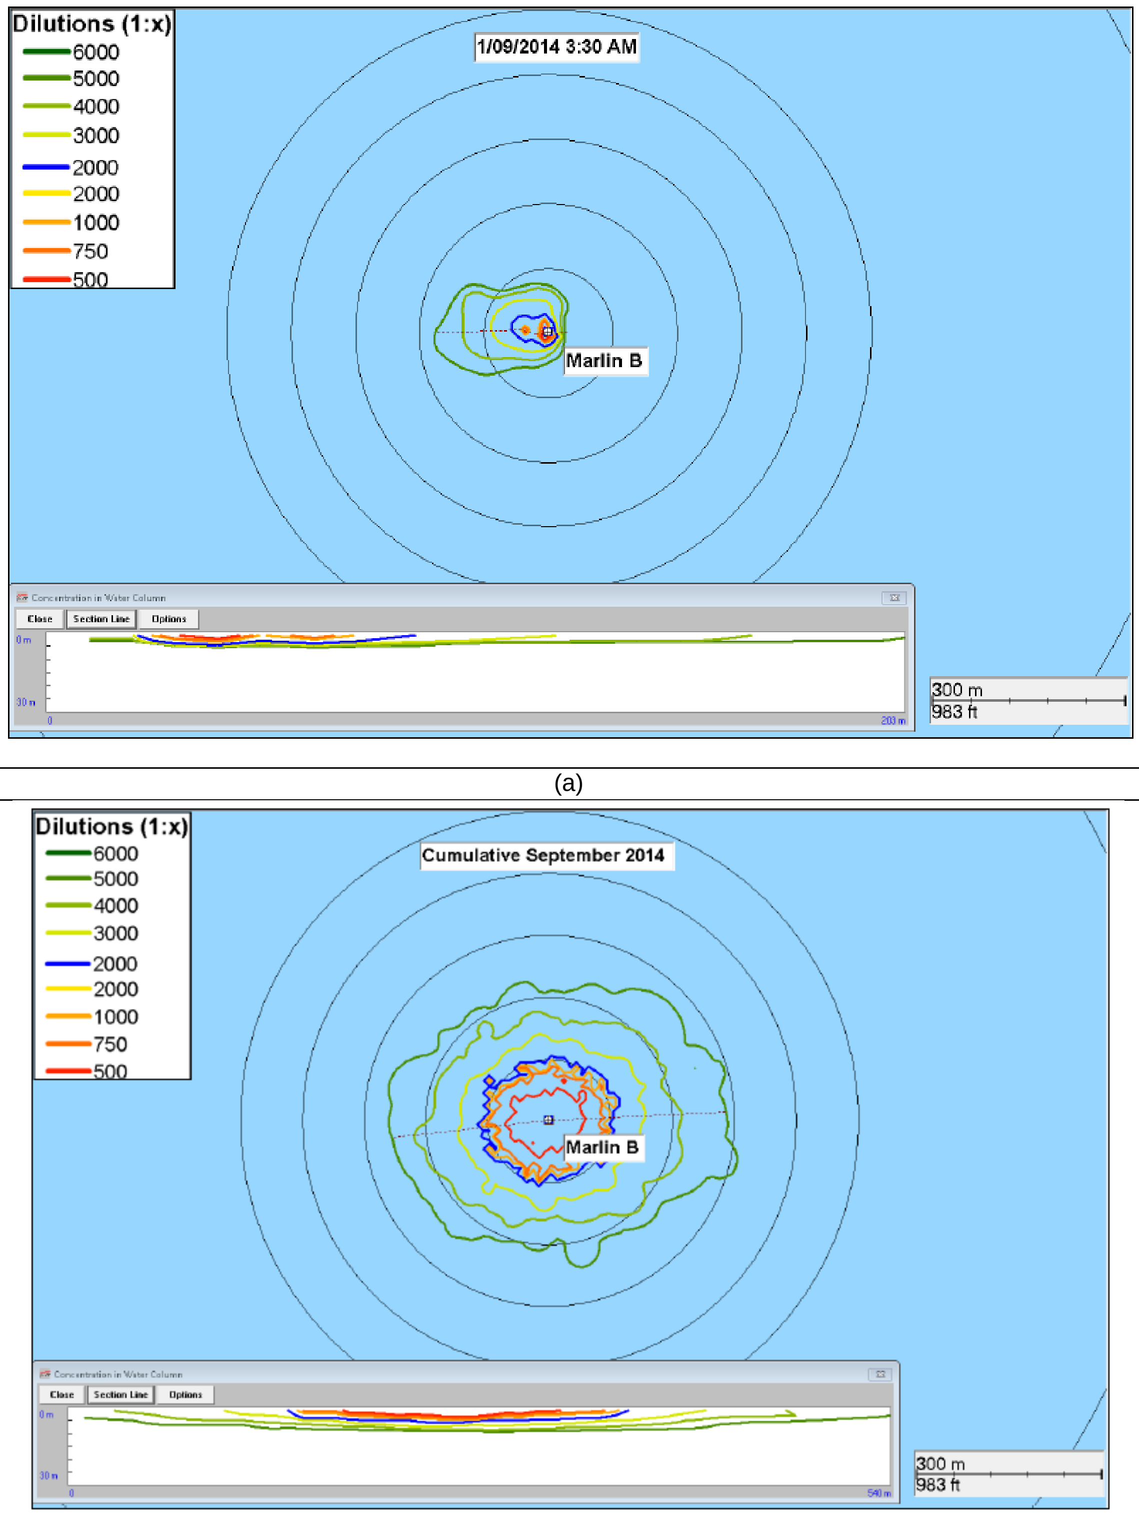
Criteria	Dilution required (1:X)	Distance from platform
Meets 95% species protection levels based on whole effluent toxicity	114	<60 m
Meets 99% species protection levels based on whole effluent toxicity	200	60 m

Appendix F.6 Marlin B Platform PFW Data

As Tuna is an analog for chemical composition, the Tuna platform dilution ratios hold. Together with the MLB-specific dispersion model outputs:

Table F-64 Dispersion model inputs – Marlin B platform

Parameter	Value
Discharge rate (kL/day)	4,800
Discharge temperature (°C)	80
Discharge salinity (ppt)	34
Internal diameter of outlet (inch) [m]	9.84 [0.25]
Outlet orientation	vertically downward
Depth of outlet below MSL (m)	11
Total water depth at site (m)	59



(a)

(b)

Figure F-21 Dilution around the MLB platform from PFW. (a) Snapshot of dilution of produced water plume around the platform, surface and cross-sectional view. (b) Summary of the dilution contours around the platform, conglomerated over one month (taking account of tide/current directions on any given day).

Table F-65 Dilution factors with distance from the MLB platform under typical currents.

Dilution factor	Distance from platform (m)
10	2.4
50	7.8
100	12
200	20
500	90
750	120
1000	140
2000	150
3000	180
4000	260

Table F-66 Dispersion model outputs – water quality

Criteria	Dilution required (1:X)	Distance from platform
Meets physical parameters background levels	6	<2.4 m
Meets ANZECC 95% species protection water quality criteria	51	<12 m
Meets ANZECC 99% species protection water quality criteria	91	<12 m
Meets hydrogen sulphide background levels	56	< 12 m
Meets TOC background levels	370	< 90 m

Table F-67 Dispersion model outputs – fisheries

Criteria	Dilution required (1:X)	Distance from platform
Meets ANZECC seafood taint thresholds	40	<7.8 m

As Tuna is an analogue for ecotoxicity, the Tuna platform dilution ratios hold. Together with the MLB-specific dispersion model outputs:

Table F-68 Dispersion model outputs – ecotoxicity

Criteria	Dilution required (1:X)	Distance from platform
Meets 95% species protection levels based on whole effluent toxicity	227	<90 m
Meets 99% species protection levels based on whole effluent toxicity	952	<140 m

Appendix F.7 Daily Oil Load Determination

Table F-69 Daily oil load allowances by platform

	OIW discharge limit (mg/L)	Max predicted discharge volume (kL/d)	Daily oil load (kg/d)	Actionable range* (k/g)
CBA	30	12000	360	300 – 360
HLA	30	10000	300	250 – 300
SNA	30	2000	60	50 – 60
TNA	30	3000	90	75 – 90
WKF	30	10000	300	250 – 300
MLB	30	2450	73.5	60 – 73.5

*(not inclusive)

Appendix G –PFW Breakout Boxes

Contents

4.1 Appendix G.1: Breakout Box 1 - Chemical Compounds Not Found in PFW Across Bass Strait

The following were not detected in any produced waters from platforms in Bass Strait (non-exhaustive):

- 2-nitrophenol,
- 2,4-dinitrophenol,
- 2-chlorophenol,
- 4-chloro-3-methylphenol,
- 2,4-dichlorophenol,
- 2,6-dichlorophenol,
- 2,4,6-trichlorophenol,
- 2,4,5-trichlorophenol,
- 2,3,4,6-tetrachlorophenol,
- pentachlorophenol,
- chlorobenzene,
- 1,2,-dichlorobenzene,
- 1-2-4 trichlorobenzene,
- 1-1-2 trichloroethane
- acenaphthylene

4.2 Appendix G.2: Breakout Box 2 - Background/Reference Data - Water

Three surveys of chemical analyses in marine water were taken at background, or reference sites during in-sea field surveys:

- Reference sites to Tuna platform
- Reference sites to West Kingfish platform
- Analysis of the West Barracouta site prior to drilling

In only one case did the background/reference ambient water quality for a chemical exceed any ANZECC water quality guideline trigger value. This was for the analyte lead, across one out of eight samples taken at Reference Site 1 and one out of eight samples taken at Reference Site 2. Lead values at these sample locations returned 3.4 μg/L and 57.3 μg/L respectively, over the ANZECC water quality 99% / 95% species protection criteria of 2.2 μg/L and 4.4 μg/L respectively. 11 samples returned non-detect (<2 μg/L) with the balance of samples (3 samples) returning between 0.3-0.8 μg/L. All other metals, hydrocarbons, phenols, nutrients etc. levels returned values below ANZECC water quality criteria.

4.3 Appendix G.3: Breakout Box 3 - Sampling of Phenols

The following phenols were not sampled however appear on the list of taint threshold values and could apply to chemicals in PFW, however, several of the more common morphs of the chemicals below were below detection thresholds and hence the less common morph is likely to also be below detection levels (e.g. 2,4-dinitrophenol was non-detect, hence 2,3-dinitrophenol as the lesser common morph is very likely also non-detect):

- 2,3-dinitrophenol,
- 2,4,6-trinitrophenol,
- 2,5-dichlorophenol,
- 3.4-dichlorophenol,
- 2-methyl-4-chlorophenol,
- 2-methyl-6-chlorophenol,
- o-phenylphenol,
- 2,3,5-trichlorophenol.

4.4 Appendix G.4: Breakout Box 4 - Whole Effluent Ecotoxicity Testing

The tests in the following table were run as part of the 2014 whole effluent ecotoxicity testing to evaluate produced water acute and chronic toxicity.

Table G-1 2014 whole effluent toxicity tests

Species	Acute / chronic test	Duration	Temperature (°C)	Test performed
Hormosira banksii (brown algae)	Chronic	72 h	18 ± 1	Macroalgal germination success
Heliocidaris tuberculata (sea urchin)	Chronic	72 h	20 ± 1	Sea urchin larval development test
Mytilus galloprovincialis (Mediterranean mussel)	Chronic	72 h	20 ± 1	Larval development test
Nitzschia closterium (diatom algae)	Chronic	72 h	20 ± 1	Marine algal growth
Allorchestes compressa (amphipod)	Acute	96 h	20 ± 1	Acute toxicity test
Lates calcarifer (barramundi)	Chronic	7 d	25 ± 1	Fish imbalance and biomass toxicity test

The tests in the following table were run as part of the 2020 whole effluent ecotoxicity testing to evaluate produced water acute and chronic toxicity.

Table G-2 2020 whole effluent toxicity tests

Species	Acute / chronic test	Duration	Temperature (°C)	Test performed
Vibrio fischeri	Acute	15 min	15	Microtox Bioassay
Tisochrysis lutea, previously called *Isochrysis galbana* (temperate strain)	Chronic	72-hour	22	Microalgal growth rate inhibition
Nitzschia closterium (temperate strain)	Chronic	72-hour	22	Microalgal growth rate inhibition
Hormosira banksii (temperate)	Chronic	72-hour	18	Macroalgal zoospore germination
Gladioferens imparipes (temperate)	Chronic	5-7-day	22	Copepod early life stage development test
Heliocidaris tuberculata (temperate)	Chronic	72-hour	20	Sea urchin larval development
Echinometra mathaei (tropical/sub-tropical)	Chronic	1-hour	25	Sea urchin fertilisation test
Mytilus edulis (temperate)	Chronic	48-hour	22	Mollusc larval development test
Seriola lalandi (tropical and temperate waters).	Chronic	7-day	22	Fish larval development

It should be noted that the most sensitive tests undertaken in 2020 for all facilities were the 7-day fish larval development (*Seriola lalandi*), the 5-7 day copepod larval development (*Gladioferens imparipes*) and the 1 hour sea urchin fertilisation (*Echinometra mathaei*). These tests were not undertaken in 2014. When comparing the tests that were undertaken in both 2014 and 2020 with exactly the same species, the majority of tests showed less toxicity in 2020 compared to 2014 (see Appendix F – PFW data file) suggesting that any observed increase in toxicity is related to the selection of tests rather than a change in toxicity of the PFW discharge streams.

Burrlioz was used to create the Species Sensitivity Distributions (SSD) with the 2020 data, however where the fit was poor ssdtools was used as an alternative. The program used for each platform was as follows:

- TNA: ssdtools
- HLA: Burrlioz
- SNA: ssdtools
- WKF: Burrlioz
- CBA: Burrlioz

4.5 Appendix G.6: Breakout Box 6 - Dispersion Model Setup and Calibration

Break Out Box 6

Setup of the model included the following components:

(1) Generate oceanographic data for the region that includes the combined influence of 3-dimensional ocean and high resolution tidal currents;

(2) Assess near-field mixing for the formation water discharge characteristics under representative annual conditions using low, moderate (typical) and high static current conditions;

(3) Establish and run a far-field passive tracer model simulating the likely mixing and dispersion of the plume under the influence of representative annual conditions;

(4) Estimate the dilution contours from the formation water discharge away from the discharge stream;

(5) Evaluate the potential for overlapping plume contours from nearby facilities.

MODELLED TIDAL CURRENTS

To accurately describe the variability in currents between the inshore and offshore region, a hybrid regional dataset was developed by combining ocean current predictions obtained from HYCOM with tidal currents developed by RPS APASA. The following sections provide a summary of the tidal currents and hybrid regional dataset and detailed hydrodynamic comparison of the modelled dataset and measured current speeds and surface elevation.

The effects of tides in the region were generated using ASA's advanced ocean/coastal model, HYDROMAP. HYDROMAP predicts the tides across the model domain due to the influence of astronomical forces, bottom friction and winds. The model employs a sophisticated nested-gridding strategy, supporting up to six levels of spatial resolution. This allows for higher resolution of tidal currents within areas of greater bathymetric coastline complexity, or a particular area of interest for a study. The methodology follows that of Davies (1977a; 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A detailed presentation of the model can be found in Isaji & Spaulding (1984). The HYDROMAP model has been thoroughly tested and verified using field measurements throughout the world over the past 30 years (e.g. Isaji & Spaulding 1984; Isaji et al. 2001; Zigic et al. 2003). HYDROMAP tidal current data has been used as input to forecast and hindcast oil spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

Tidal amplitudes and phase data used along the open boundaries of the model grid were extracted from the Topex/Poseidon global tidal database (TPX07.2 [see Fu, Del Genio & Russow 1994; NASA 2013a; NASA 2013b]). This database is derived from long-term satellite measurements. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model, using the eight largest and most significant tidal constituents for the area (M_2, S_2, K_1, O_1, N_2, P_1, K_2, and Q_1). The model then circulated the water mass over the entire grid and calculated the sea heights and resulting tidal currents at each cell. The Topex/Poseidon tidal data has been widely used by the scientific community (e.g. Ludicone et al. 1998; Matsumoto, Takanezawa & Ooe 2000; Kostianoy et al. 2003; Yaremchuk & Tangdong 2004).

To ensure that tidal predictions were accurate in the study area and throughout the model domain, modelled surface elevations were compared against measured surface elevations at Kingfish B tide station.

Surface elevations measurements were measured at the Kingfish B platform, at 6 minute intervals, over a period of 109 days between 14 March and 31 July 2002. Figure 7 illustrates the locations of the measured tide station at Kingfish B and observed tide stations defined throughout the model domain.

The tidal model was run for 30 days (April 2002) to ensure that the phase and amplitudes of the modelled surface elevations were accurately replicated throughout the spring and neap tidal cycles. Figure 8 presents the comparison plot between the tidal model and measured surface elevation at Kingfish B during April 2002. The graph highlights the model's ability to accurately reproduce the tidal oscillations in the study area. Overall, the model predicted tidal range was over estimated by less than 15 cm over a maximum tidal range of 1.72 m.

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, which is operated by the HYCOM Consortium, sponsored by the Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea-surface

Break Out Box 6

height, sea-surface temperature and in-situ temperature and salinity measurements (Chassignet et al. 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of once per day. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

Overall, the combined Ocean and tidal currents in the vicinity of the facilities were found quasi-consistent over the years from 2010 to 2014 (inclusive). Based on the strength and directionality similarities over the period from 2010 to 2014, the latest year of HYCOM currents available was selected for the modelling.

Current meter data was provided to assess the model's ability to accurately replicate the combined current speeds and directions within the study area. Current measurements in the surface layer (8m BMSL) were sampled at Barracouta, Kingfish B and Tuna A at 1 minute interval over periods of up to 4.5-5 months between March and July 2002. Additionally at the Barracouta platform, near seabed currents (40m BMSL) were also sampled at intervals of 20 minutes over a period of approximately 10 months from 25 September 2001 to 28 July 2002.

The combined modelled surface and seabed currents used in the comparison are a combination of the modelled depth-averaged tidal currents and HYCOM ocean currents at the 8-10m and 35-40m depth layer, respectively. Note that tides and ocean current data were combined to create an hourly output.

The time series plots demonstrated that in the surface layer the combined modelled current speeds and directions were in good agreement with the measured data at all three sites. The variability of ocean current speeds throughout the whole period was captured by the model. During the June and July period an excellent correlation between the directionality of the measured and modelled datasets was observed, at all three sites. Very good agreement was also observed between measured and modelled datasets near seabed currents at Barracouta. Measured current data demonstrated slightly stronger currents near the seabed than in the surface layer.

Overall, the strength of the currents was well represented by the model, meaning that the discharge plume would travel similar maximum distances using measured and modelled currents. The directionality of the modelled currents was also well represented. Therefore, over the entire period of the measured data, similar results should be expected for the predicted mixing zones using either measured or modelled currents. However, it should be noted that using point source currents will underestimate the potential for plume divergence as opposed to spatially varying currents as used in this study.

Three-dimensional salinity and temperature profiles were extracted from the World Ocean Atlas 2013 database.

NEAR FIELD MODEL

The near-field mixing of the discharged formation water was predicted using the fully three-dimensional flow model, Updated Merge (UM3) model. The model, UM3, is used for simulating single and multi-port submerged discharges and is part of the Visual Plumes suite of models maintained by the US Environmental Protection Agency (Frick et al., 2000).

The UM3 model was selected since it has been extensively tested for various discharges and found to predict the observed dilutions more accurately than other near-field models (e.g. RSB or CORMIX). In this model, the equations for conservation of mass, momentum, and energy are solved at each time step, giving the dilution along the plume trajectory. To determine the growth of each element, UM3 uses the shear (or Taylor) entrainment hypothesis and the projected-area-entrainment hypothesis. The flows begin as round buoyant jets issuing from a pipe or diffuser and can merge to a plane buoyant jet (Carvalho et al., 2002). Model output consists of plume characteristics, including centreline dilution, rise-rate, width, centreline height and diameter of the plume. Dilution is reported as the "effective dilution", which is the ratio of the initial concentration to the concentration of the plume at a given point, following Baumgartner et al. (1994).

The following parameters were used to set up the near-field models:

- The relative temperatures and salinities of the produced water plume and receiving waters;
- The produced water rate of discharge;
- The diameter and orientation of the discharge pipe;
- The depth of the discharge point relative to mean sea level;
- 3-dimensional static currents to represent local physical forcing; and

Break Out Box 6

- Ambient salinity and temperature profile.

FAR-FIELD MODEL

To quantify the likely far-field mixing and dispersion of the produced water, detailed modelling was carried out using an advanced three-dimensional plume model, MUDMAP. MUDMAP simulates produced water discharge as a conservative tracer (no reaction or decay applied) into a time-varying three-dimensional current field with the initial dilution set by the near-field modelling. The objective of the far-field modelling is to predict the extent to the mixing zones under representative annual conditions.

The far-field modelling takes into account the time-varying nature of currents as well as the potential for recirculation of the plume back to the release location for second dosing with fresh produced water. In the latter case, near-field concentrations can be occasionally increased due to the discharge plume mixing with the remnant plume from an earlier time; hence far-field modelling identifies the potential for far field accumulation under transient low mixing conditions that might occur at times in waters surrounding the release site.

MUDMAP is an industry standard computerised modelling system, which has been applied throughout the world to predict the dispersion of sediment (cuttings and muds) and liquid (produced water) discharges since 1994 (Spaulding, 1994). The model is a development of the Offshore Operators Committee (OOC) model and like the OOC model calculates the fates of discharges through three known distinct integrated stages which are the Convective decent/jet stage, dynamic collapse stage and dispersion stage (Koh and Chang, 1973; Khondaker, 2000; Brandsma and Sauer, 1983a, 1983b).

The version of the MUDMAP model applied to this study utilised only the final dispersive phase, as the initial two phases were simulated using the UM3 near-field model.

The produced water released is represented by placing a fixed number of "particles" at the release site on each model time-step. The particles represent a cloud of mass with a radius that grows in size over time, and these particles are moved on each subsequent time-step according to the horizontal and vertical components from the hydrodynamic model. The plume spread is dependent on the horizontal and vertical mixing coefficients.

The MUDMAP system is based on a conservative tracer (no reaction or decay) to examine the mixing and dilution of effluent plumes. The concentration distribution of the constituent in water is estimated using a 3-dimensional counting grid. The proportion of mass from each particle's cloud in a grid cell contributes to the total concentration in that grid cell.

The system has been extensively validated and applied for produced water discharge operations in the Northwest Shelf (e.g. Burns et. al., 1999; King and McAllister, 1997) and specifically in the Gippsland Basin for Esso's Kingfish B platform (King and McAllister, 1998).

ESTABLISHING DILUTION CONTOURS

The results of the UM3 model were analysed to provide predictions of the initial plume parameters for input into the far-field model MUDMAP, and to also provide estimates of the change in temperature and dilution of the plume.

Across all discharging platforms, the results showed that the plume would initially jet downwards before rising upward due to the lower density of the discharge plume compared to ambient receiving waters. In addition to rising vertically, the plume was also observed to travel laterally through the water column, and the speed of lateral travel was dependant on the current speed. Following the discharge, the near-field plume either reached the surface (typically under lower current conditions) or reached the end of the near-field mixing phase once their densities became equal to ambient conditions.

The maximum horizontal distance, and dilution (average and minimum (plume centre line)) upon reaching the end of near-field mixing phase, for each current speed conditions assessed was plotted.

The outputs from the near-field model were used as starting conditions in the far-field model, MUDMAP, to predict the extent to the mixing zones under typical environmental conditions. The far-field model was set up to simulate a continuous release of the designated rate of produced water during January to December 2014. The modelling results indicated that the discharge plume would flow in the direction of the ambient ocean currents, with a tidal oscillation that changed the direction with each flood and ebb tide event.

The transport of the discharged plume closely followed the direction of the tidal oscillations observed. Across all discharging platforms, on the flood tide, the plume was pulled in a westerly or south-

Break Out Box 6

westerly direction, momentarily paused and then forced towards the east, east-northeast, or east-southeast during the ebb tide. As a result of the change in directions and current velocities, the concentrations become more variable over time. Lower concentrations (higher dilution rates) were occurring during stronger currents, whereas patches of higher concentrations (lower dilution rates) tended to build up at the turn of the tide or weaker current events. The higher concentration patches were found to move as a unified group as the current speeds increased again and tended to be present within the wider plume at any one time.

Dilution zones were mapped for the month of August 2014, and then run across the entire year. The predicted minimum dilutions were calculated every 10 minutes for a continuous discharge of formation water during January to December 2014. The predominant directionality of the dilution contours were to the east to northeast and west to southwest.

The year-long simulation aimed at capturing accumulation events during periods of prolonged slack currents that could result in highly concentrated plume adverted away from the platform when the current strength returns. Therefore, these results present the “worst case” potential areas of exposure from the discharge formation water and do not illustrate the area of exposure that could be observed at any single point in time. Maximum and minimum distance from the platform for each dilution contour was plotted.

POTENTIAL FOR OVERLAPPING PLUMES

Plumes were spatially and temporally aggregated for a subset of platforms discharging PFW in close proximity to each other.

Dilution contours out to 1:6000 for Tuna and West Tuna were plotted. The contours generally aligned parallel to each other and due to their proximity, they do not significantly influence each other.

Dilution contours for Fortescue and Halibut generally aligned with each other and their outer dilution contours (1:5000+) overlapped, whilst Cobia and Mackerel were both located further to the south of Fortescue and Halibut, and their dilution contours did not overlap with any other platform. (Note: Fortescue and Mackerel are not discharging PFW, hence any discharge plotted is theoretical).

<u>MODEL RESULTS COMPARISON WITH MODELS PREVIOUSLY USED IN</u>* <u>BASS</u> *<u>STRAIT</u>

The Offshore Operators Committee Mud and Produced Water Discharge Model (OOC model) was developed by the Exxon Production Research Company, with additional support from the Offshore Operators Committee. The model provides estimates of plume behaviour resulting from cuttings and muds discharges and produced water discharges into the marine environment.

The governing equations and solution methodology for the model was originally developed by Koh and Chang (1973) and extended by the work of Brandsma and Smith (1995), Smith et al., (1994), and Brandsma and Sauer (1983) for the near-field convective phase and dynamic collapse phase of plume motion. The far-field (passive diffusion stage) employs a Lagrangian scheme of discrete clouds of particles with a defined mass. The model predicts the dynamics of the plume and concentrations in the near-field and in the far-field.

The OOC model simulates each of the three plume phases independently, but automatically links each of the phases to predict the transport and dispersion of the discharged produced water. The independent stages are necessary since the dilution of heated water occurs at different time scales and stages.

The OOC model has been used for studies worldwide, including the Gulf of Mexico, the North Sea, and in Australia at the Kingfish B platform, Bass Strait (Terrens and Tait, 1994), and Hariett A Platform, North West Shelf (King and McAllister, 1998).

The three phase simulation approach for the produced water plume is similar between both the MUDMAP/UM3 model and the OOC model. One of the key differences between the models lies in the way the dispersion coefficients are handled in the in the far-field dispersion components of the models. The MUDMAP model uses horizontal and vertical mixing coefficients, both in units of m2/s. The OOC model however, uses an ALAMDA diffusion parameter in the horizontal direction, which is a dissipation parameter and used to calculate horizontal dispersion using the 4/3 power law, with units of ft2/3/s. The vertical dispersion parameter used by the OOC model is similar to the MUDMAP vertical dispersion, but utilises the imperial system (ft^2/s).

Break Out Box 6

A review of both the MUDMAP and the OOC models was undertaken by King and McAllister (1998), where both models were used to simulate a PFW plume from the Kingfish B platform in Bass Strait. The model predictions were compared to in-water concentrations of aromatic hydrocarbons in the PFW stream, measured during operational discharge. The MUDMAP predictions of in-water concentration were found to be within a factor of 2 greater when compared to the actual in-water observations, whilst the OOC model predictions were found to be up to a factor of 3 smaller when compared to the observations.

Testing was carried out to compare the results at West Kingfish using the MUDMAP/UM3 and OOC models, when utilising the same input parameters and environmental conditions (i.e. PFW discharge characteristics, horizontal dispersion coefficients, water temperature and current speeds). The results of interest were the dilutions of the PFW stream at set distances from the facility, under static current conditions. A report by Smith (2015) outlined the expected PFW concentrations from the OOC model at 10, 25, 100 and 500 m from 12 of Esso's Bass Strait platforms. The plume dilution results were of similar magnitude as modelled by MUDMAP/UM3 and OOC model at the West Kingfish platform at the four distances specified.

MODEL RESULTS COMPARISON WITH IN-SEA STUDIES

The modelled dilution factors were validated with an in-situ water monitoring study at the Tuna platform, using a known concentration of rhodamine dye in the PFW effluent. Currents during the study were 0.2-0.3 m/s on Day 1 and 0.1-0.5 m/s on Day 2 (typical currents at Tuna platform in the model was 0.27 m/s). The actual dilution factor under typical currents were, at their smallest, 1:2286 at 72 m distance from the Tuna platform, compared to the dispersion model estimations of 1:1000 at 140 m and 1:2000 at 320 m distance from the Tuna platform.

Table G-3 Dilution factors resulting from in-situ water monitoring at Tuna

Day	Concentration in PFW (µg/L)	Maximum in-water concentration (µg/L)	Corresponding distance from the platform	Corresponding depth (m below MSL)	Dilution ratio
1	230,000 (1:5 dilution at 260 L/hr into 5422 kL/d discharge)	100.6	72	2.4	2286
		82.4	120	5.3	2791
		47.5	261	3.0	4842
		41.8	506	9.9	5502
2	240,000 1:5 dilution at 260 L/hr into 5204 kL/d discharge	57.4	115	1	4181
		32.2	358	0.02	7453
		24.3	1090	0.01	9877
		28.8	1565	0.01	8333
		21.6	2587	0.002	11111

Figure G-2 Rhodamine dye dilution factors together with model dilution factors with distance from the platform.

4.6 Appendix G.7: Breakout Box 7 - In-Situ Water Studies Around the Tuna Platform

The postulate that ANZECC 2000 water guidelines would be able to be met, at worst, outside a relatively small areal extent from the PFW discharge were tested by taking in-situ measurements of water around the Tuna platform in 2018.

Of metals detected in PFW, zinc was detected over the guideline criteria in 1 out of 34 samples, with zinc at 20 m depth only at 59 m from the platform observed at the level of 40 µg/L (ANZECC 99% criteria is 7 µg/L) and it was not detected at other depths (with LOR 5 µg/L) or in any other samples out to the monitored distance of 1574 m from the platform. The raw PFW discharge showed concentrations of <5 µg/L hence this result is unlikely to have been due to the PFW discharge.

Chromium, cobalt and copper were detected at levels above the guideline criteria in 1 out of 34 samples at 1574 m and 5 m depth at the level of 10 µg/L (99% criteria is 8 µg/L), 0.4 µg/L (0.005), and 1 µg/L (0.3 µg/L) respectively (ANZECC 99% criteria shown in brackets). All three results above 99% water quality criteria were detected in the one sample, bringing the results into question. It should be noted that the ANZECC 95% level for cobalt (1 µg/L) was not exceeded. No other metals in water exceeded ANZECC 99% criteria at any other sites near the platform. The raw PFW discharge showed copper concentrations of <0.4 to 1 µg/L hence the result is unlikely to have been due to the PFW discharge. Chromium and cobalt have never been detected in TNA PFW.

All other metals were below ANZECC 99% criteria.

Cyanide was detected at above guideline criteria (0.009 mg/L) in one inter-lab duplicate at 973 m from the platform however its parent record and field duplicate record did not detect cyanide to less than half the reported interlab duplicate level. Hence this duplicate record should be discounted. Cyanide was also detected in 1 of 34 samples at 1574 m from the platform at 10m depth at the level of 0.006 mg/L (ANZECC 99% criteria is 0.002 mg/L).

All other metals, hydrocarbons (BTEX, TRH, MAH, PAH), phenols, phthalates, solvents, nutrients and other inorganics, were below ANZECC 99% criteria within all remaining samples taken between 59 m and 1574 m distance from the platform.

The isolated observations of zinc, chromium, cobalt, copper and cyanide above the ANZECC 99% guideline criteria within 1574 m from the Tuna platform, were either in question (sample QC), were not ubiquitous with depth according to the PFW plume prediction or did not show correlation with distance from the discharge point, or were higher than raw PFW effluent concentrations, indicating the low likelihood of any temporary and localised impacts to water quality from PFW.

4.7 Appendix G.8: Breakout Box 8 - In-Sea Sediment Monitoring Around Tuna and West Kingfish Platforms

Breakout Box 8

A sediment study around the TNA and WKF platforms was conducted to determine potential impacts to sediment from PFW and/or all other historical or active discharges.

Of all Bass Strait PFW-discharging platforms, WKF in particular has the highest loading of metals (discharge volume-weighted sum of metals cadmium, chromium, cobalt, copper, lead, mercury, nickel, silver, vanadium, zinc, manganese, iron) as well as the highest potential for PAHs adhered to solids (using discharge volume and suspended solids-weighted naphthalene), and hence was the most suitable candidate for the study.

Sediment samples were collected from two zones in the vicinity of TNA and WKF platforms (Zone 1:50–180 m and Zone 2: 180–1000 m from the platform) and from two reference locations between ~8 and 13 km from any one platform and away from other PFW-discharging platforms. At each location, 18 samples were collected using a Smith Macintyre grab sampler deployed from the sampling vessel. Sediments in each sample were homogenised and their pH and redox potential measured before they were transferred to sample containers for storage and delivery to the NATA accredited analytical laboratory.

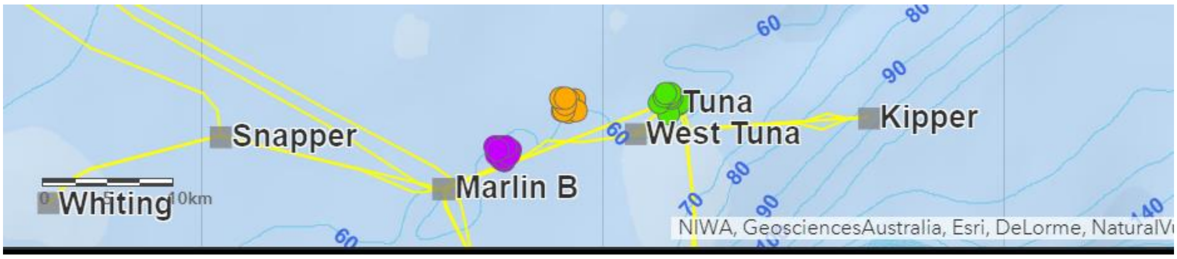

Figure G-3 Map showing sediment sample locations around Tuna platform (green), and two reference sites (orange and purple).

Figure G-4 Map showing sediment sample locations around West Kingfish platform (green), and two reference sites (orange and purple).

POTENTIAL IMPACTS FROM PFW TO SEDIMENT NEAR THE PLATFORMS

West Kingfish platform results

Overall, impacts to sediment from metals were shown to be confined to an area of 110 m around the West Kingfish platform.

Within 110 m of West Kingfish platform, only Zinc was present above the ANZECC 2013 “low” sediment quality guideline values, in a field duplicate only, in 1 of 18 samples, 109 m from the platform. No analytes were above guideline values elsewhere within Zone 1 (between 58 m and 144 m from the platform) or within Zone 2 (between 264 and 969 m). The detected zinc level was 1760m g/kg, above the “low” guideline value of 200 mg/kg and “high” guideline level of 410 mg/kg. Based on inconsistencies with the parent (non-duplicate source) of this sample for several metals (readings inconsistently high with the remainder of the data set), it can be concluded that the field duplicate analysis was corrupted and should be discounted for the study. Even if it is not discounted, zinc was

Breakout Box 8

not detected in WKF PFW between 2014-2019 and therefore is not expected to be a contributor to sediment zinc levels.

The samples showed gradients of nickel concentrations (together with other metals not present in WKF PFW - such as cobalt and lead; and other metals including barium, zinc, manganese and iron) decreasing with distance away from the platform. The overall levels of nickel and zinc in those gradients is indistinguishable from reference locations within 117 m and 83 m from the platform respectively. For all metals that showed a gradient away from the platform, no samples showed levels higher than ANZECC "low" ISQG criteria. Levels of nickel were, in 35 of 36 samples, less than 4mg/kg (ANZECC 2013 "low" criteria is 60 mg/kg), and levels of zinc were, in 32 of 36 samples, less than 45 mg/kg (ANZECC 2013 "low" criteria is 200 mg/kg).

Sediment guideline values were not exceeded anywhere around the platforms for other metals including - antimony, arsenic, cadmium, lead, manganese, mercury, or silver.

Sediment guideline values were not exceeded for hydrocarbons (speciated or total PAHs, and TRH C10-C36 levels) in samples recovered anywhere around West Kingfish platform.

The samples did not show gradients of chromium or PAHs away from the platform.

Tuna platform metals results

Overall, impacts to sediment were shown to be confined to an area of 120 m metres around the Tuna platform.

Within 120m of Tuna platform, Copper, Lead and Zinc were present above the ANZECC 2013 "low" sediment quality guideline values, with all other metals detected within guideline values.

Copper was detected above "low" guideline values in 1 of 18 samples 75 m from the platform. The levels of copper was less than two times above the guideline values at 106 mg/kg whilst the "low" guideline value is 65 mg/kg. It did not exceed the "high" guideline value of 270 mg/kg. There were no other detections in a further 18 samples elsewhere within Zone 1 (between 52 m and 129 m from the platform) and within Zone 2 (between 260 and 979 m). Copper is discharged in TNA PFW, however at less than two times the ANZECC water quality guideline in only one sample (all other samples are below detection), and hence is not expected to contribute significantly to sediment copper levels.

Lead was detected above guideline values in 2 of 18 samples at 75 m and 85 m from the platform. Lead was within guideline values elsewhere within Zone 1 (between 52 m and 129 m from the platform) and within Zone 2 (between 260 and 979 m). The levels of lead was only slightly above the "low" guideline values - lead was detected at 68.7 mg/kg and 112 mg/kg whilst the guideline value is 50 mg/kg. It did not exceed the "high" guideline value of 220 mg/kg. Lead was not detected in TNA PFW in 2014-2019, hence is not expected to be the cause of any higher lead levels in sediment.

Zinc was detected up to three times above "low" guideline values (200 mg/kg) in 2 of 18 samples at 62 and 76 m from the platform and over the "high" guideline (410 mg/kg) in 1 of 18 samples at 120 m from the platform (2260 mg/kg). There were no other detections in a further 18 samples elsewhere within Zone 1 (between 52m and 129m from the platform) and within Zone 2 (between 260 and 979 m). Zinc is discharged in TNA PFW, however it is rarely detected and at less than the ANZECC water quality guideline and hence is not expected to contribute significantly to sediment zinc levels.

The samples showed gradients of copper and zinc concentrations (together with other metals not present in TNA PFW - cobalt, lead, nickel; and other metals including barium and iron) decreasing with distance away from the platform. The overall levels of copper and zinc in those gradients is indistinguishable from reference locations within 129 m and 85 m from the platform respectively. The levels of contamination generally remain well below threshold levels – 35 of 36 samples were below 41 mg/kg for copper (the ISQL "low" threshold level is 65 mg/kg) and 34 of 36 samples were below 76 mg/kg for zinc (the ISQL "low" threshold level is 200 mg/kg) (Figure G-5(a) and Figure G-5(b)). For all other metals that showed a gradient away from the platform, only 2 of 18 samples (at 75 m and 85 m distance from the platform) showed levels of lead higher than ANZECC "low" ISQG criteria (lead is not present in TNA PFW).

Breakout Box 8

It is likely that the isolated observations above ISQL criteria close to the platform are derived at least in part from galvanized steel structures (e.g. platform structure, and steel debris on the sea floor), especially given that cobalt, lead and nickel have never been detected in TNA PFW.

Sediment guideline values were not exceeded anywhere around the platforms for other metals including - antimony, arsenic, cadmium, lead, manganese, mercury, or silver.

Sediment guideline values were not exceeded for hydrocarbons (speciated or total PAHs, and TRH C10-C36 levels) in samples recovered anywhere around Tuna platform.

The samples did not show gradients of Arsenic or PAHs away from the platform.

Figure G-5: Gradients around Tuna (mg/kg), x-axis is distance from the platform in metres. Note – negative values are where the contaminant was not detected. (a) copper; (b) zinc; Other contaminants at the platform and at reference sites: (c) nickel; (d) barium; (e) total nitrogen; (f) iron.

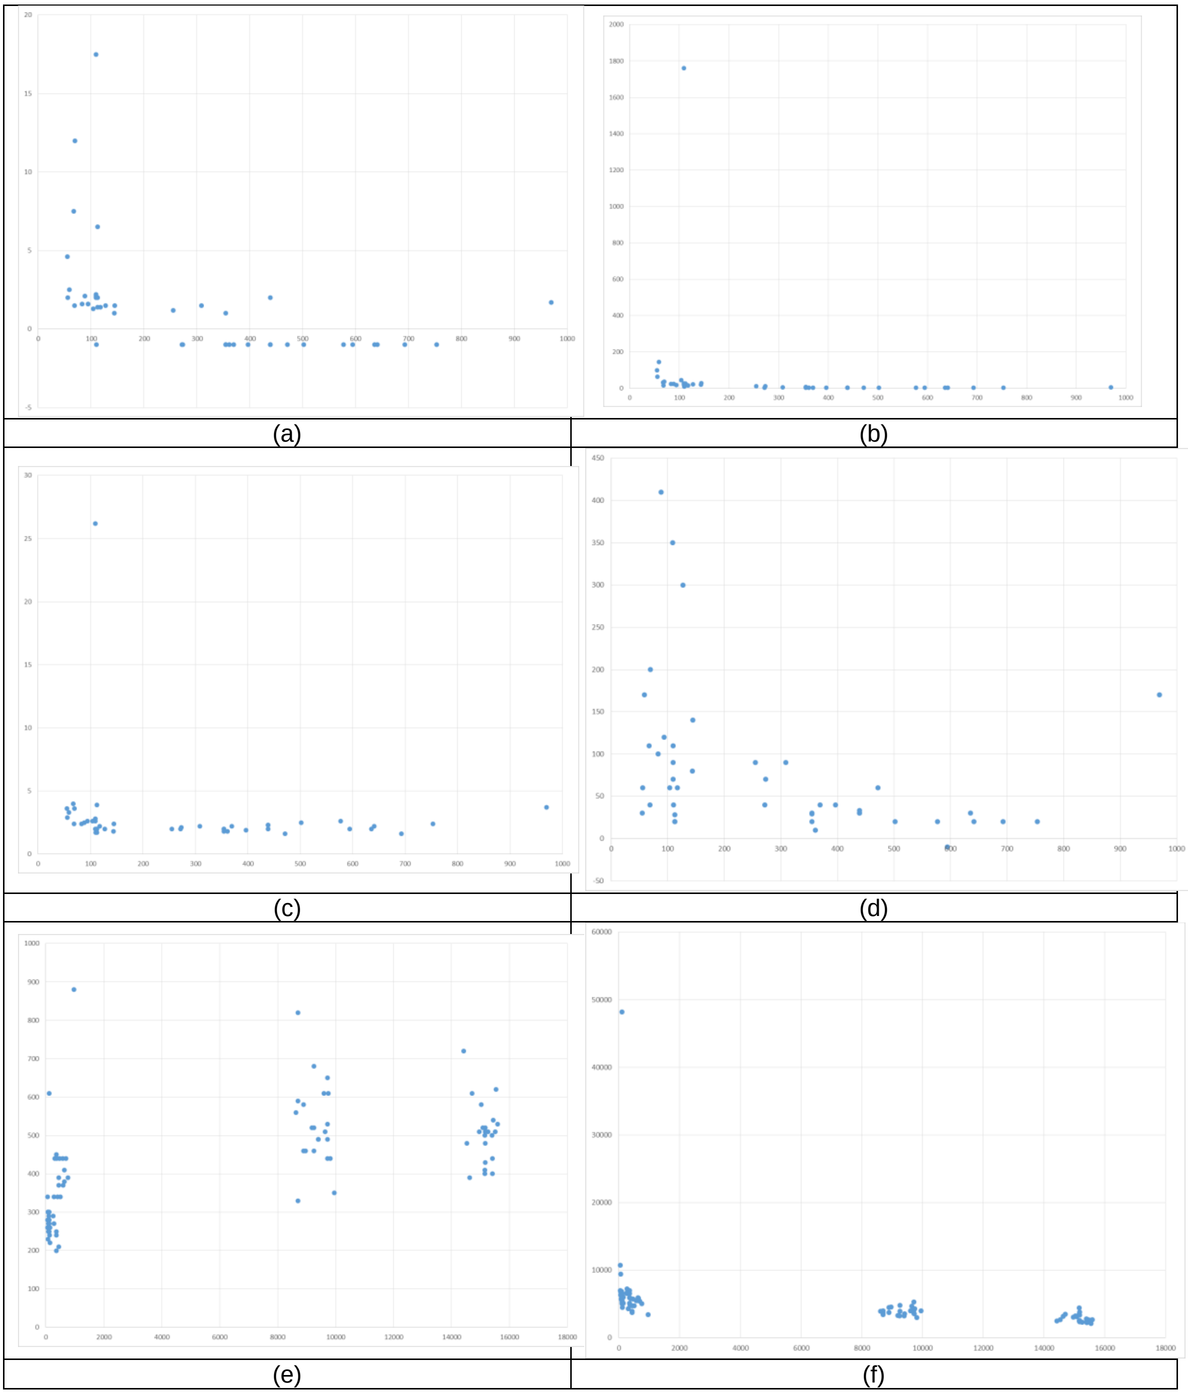

Figure G-6: Gradients around West Kingfish (mg/kg), x-axis is distance from the platform in metres. Note – negative values are where the contaminant was not detected. (a) copper; (b) zinc; (c) nickel; (d) barium; Other contaminants at the platform and at reference sites: (e) total nitrogen; (f) iron.

Changes to sediment quality near the platform versus open ocean reference sites can be expected as the platform is an industrial facility. Importantly, those analytes of primary concern in PFW (PAHs and some metals) in sediments are either non-existent (PAHs) or have been maintained at low and

Breakout Box 8

acceptable levels (metals), and changes that may be linked to PFW appear to be localised to the immediate vicinity of the platform.

SEDIMENT ENVIRONMENT AT REFERENCE SITES

Three surveys of chemical analyses in marine sediments were taken at background, or reference sites during in-sea field surveys:

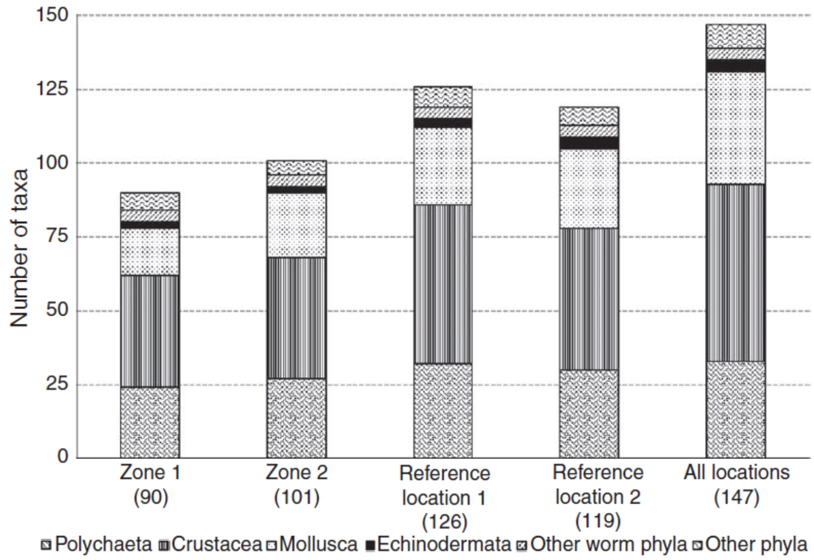
- Reference sites to Tuna platform
- Reference sites to West Kingfish platform
- Analysis of the West Barracouta site prior to drilling

In one case the background/reference sediment quality for a chemical exceeded ANZECC sediment quality guideline trigger value. This was for the analyte arsenic, across 2 out of 18 samples taken at Tuna Reference Site 1. Arsenic values at these sample locations returned 22.9 µg/L and 20.1 mg/kg respectively, marginally over the ANZECC sediment quality guideline criteria of 20 mg/kg. The balance of 16 samples at that site returned values between 12.9 mg/kg and 19.3 mg/kg. Therefore, the 2 out of 18 samples can be considered likely due to natural variation. All 18 samples at Tuna Reference Site 2, West Kingfish Reference sites 1 and 2, and West Barracouta site returned values under the ANZECC criteria for arsenic. All other metals, hydrocarbons, etc. levels returned values below ANZECC criteria.

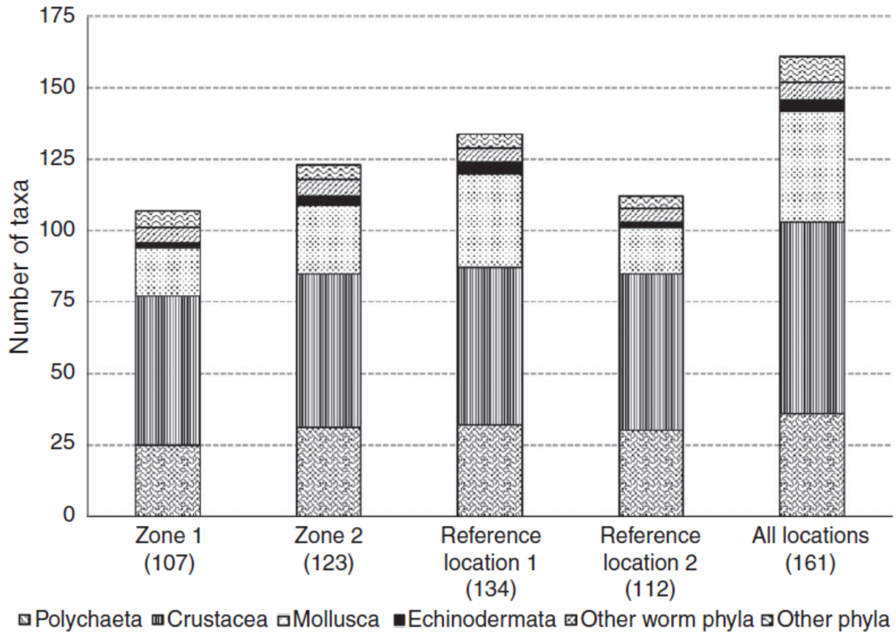
4.8 Appendix G.9: Breakout Box 9 - In-Sea Infauna Monitoring Around Tuna and West Kingfish Platforms

Breakout Box 9

Benthic infauna samples were taken around West Kingfish and Tuna platforms in 2018 as part of the in-situ monitoring study, and were analysed for number of taxa and distribution of taxa. At both platforms (both zones) and in all reference sites, crustaceans dominated the infauna, followed by polychaetes. On average, the total number of benthic infauna taxa found close to the platform in Zone 1 (50 to 150 m from WKF, 50 to 130 m from TNA) was slightly lower at the platforms than in Zone 2 (150 to 1000 m from WKF, 260 to 1000 m from TNA) and at the reference sites.



(a)



(b)

Figure G-7: Number and distribution of taxa at (a) Tuna platform and (b) West Kingfish platform.

A small fraction of around 20% total taxa (21 of more than 100 and 22 of more than 120 total taxa at TNA and WKF respectively), were significantly correlated by distance from the platform ($p<0.05$, either with decreasing/negative or increasing/positive correlation). These are shown below in Table

Breakout Box 9

G-4. Only 5 of these taxa (Amphinomidae, Onuphidae, Synopiidae, Aoridae, Nannastacidae) were present at both platforms for which Amphinomidae, Onuphidae, and Synopiidae had the same trend with distance at TNA and WKF (negative), and Aoridae and Nannastacidae had a different significant trend at TNA (negative) and WKF (positive) with distance from the platform. Differences in sediment grain size (particularly the higher proportion of gravel size particles) close to the platforms was the likely driver to the overall assemblage, due to changes in sediment particle size through altered current patterns and hydrodynamic regimes (Ambrose and Anderson 1990; Davis et al. 1982; Fabi et al. 2002; Zalmon et al. 2012), the input and entrapment of biogenic material leading to organic enrichment (Davis et al. 1982; Fabi et al. 2002; Wilding 2006), scour around structures or piles and persistence of drill cuttings in close proximity to platforms.

For 15 taxa at TNA (less than 15% of the total, 4 polychaeta, 7 crustacea, 1 mollusca and 3 worms), abundances significantly decreased with distance. Differences in sediment grain size (particularly the proportion of gravel size particles, Figure G-10) close to the platform is the main driver to the decreasing trends in abundance of these taxa at TNA with distance (Figure G-8 below). The change in abundance could not be accounted for by PFW contaminant gradients in sediments with distance from the platform.

At West Kingfish, there were no significant differences in the structure of the infaunal assemblages among Treatments; between Zone 1, Zone 2 and Reference locations. For 14 of the taxa (less than 12% of the total, 2 polychaeta, 10 crustacea, and 2 mollusca) saw significant increase in abundance with distance from WKF, which could be explained primarily by the presence of barium (a major constituent of drilling muds, the last drilling program on WKF in 2010 versus in 2005 for TNA), the presence of coarser grained sediment in very close proximity to the WKF platform (Figure G-11 below, also see Figure G-9). The change in abundance could not be accounted for by PFW contaminant gradients in sediments with distance from the platform.

Changes in infauna abundance due to natural variability of sediment particle size is a well-known phenomena (e.g. Neff, 1992; ANZECC 2000 p8.4-29).

Figure G-10: Sediment grain size – TNA

Breakout Box 9

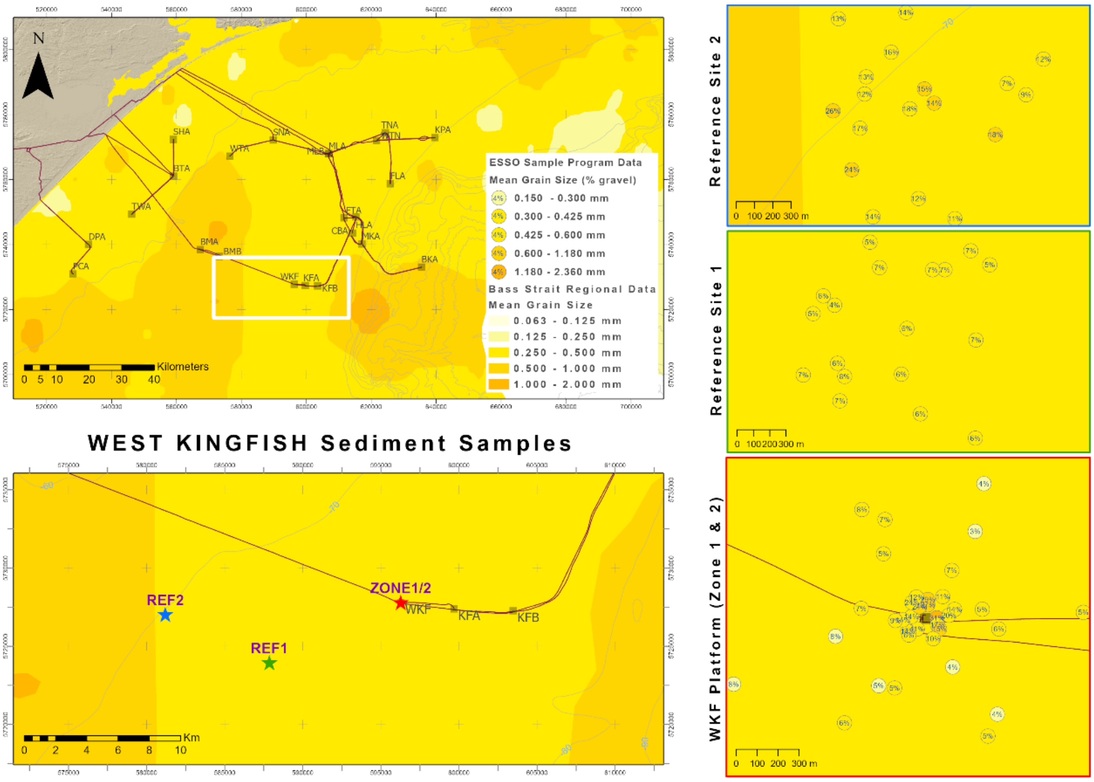

Figure G-11: Sediment grain size – WKF

4.9 Appendix G.10: Breakout Box 10 - Particle Size Distribution (PSD) and Sediment Impacts

Breakout Box 10

Grain size of sediment is generally classified in the following categories: clay (< 4 µm), silt (4 to < 63 µm), fine sand (63 to 250 µm), medium sand (250-500 µm), coarse sand (500-2000 µm) and coarse material (>2000 µm). Comparisons of the PSD in the produced water from the four facilities, showed that at least 97% of the particles are very small, of the size of clay or silt (≤63 µm). A very small percentage of PSD in the PFW is of a higher grain size, in the fine sand category (63 to < 250 µm; except for Cobia in which 100% of material is in the silt and clay sized fractions).

Further, the chemically active fraction of sediment is usually cited as that portion which is smaller than 63 µm (silt + clay) fraction (UNEP/WHO 1996). Problem contaminants are most often associated with these fine sediments because this fraction consists of particles with relatively large ratios of surface to volume and may be charged which increase the sorptive capacity for contaminants (Power and Chapman 1992). For phosphorus and metals, particle size is of primary importance due to the large surface area of very small particles. Phosphorus and metals tend to be highly attracted to ionic exchange sites that are associated with clay particles and with the iron and manganese coatings that commonly occur on these small particles. The coarse fractions are composed primarily of stable inorganic materials (e.g. quartz) and are not generally associated with chemical contamination (UNEP/WHO 1996).

Sediment deposition requires suitable hydrodynamic conditions, which depend on the type of sediment. Fine sediments cannot settle in high-energy environments (strong waves and/or strong currents). Temporary settling is possible when currents are weak (neap tide, slack tide) and in the absence of strong wave action. However, in situations where low-energy and high-energy conditions alternate, these temporary deposits will disappear. Although currents generally carry a mixture of different types of sediment, only one type of sediment will remain on the seabed after settling. This type of sediment corresponds to the most energetic conditions among the alternating conditions that occur at a specific location. In high energy environments the sediment is composed of medium to coarse sand (Van Oyen et al. 2013).

Measurements of particle size in the produced water discharge streams have shown that very high concentrations of particles are in the silt and clay sized fractions (≤63 µm), the factions in which contaminants in the produced water are most likely to be associated. This combined with the highly dynamic conditions of the water in the receiving environment suggests that these particles are not likely to settle anywhere near the sediments in the vicinity of the facility.

Actions of resuspension, bioturbation and microbial decay of those particulates in the water column and on the seabed will further reduce the concentration of settled sediments. Since the PFW plume is highly buoyant, and Bass Strait is a high energy environment, currents are likely to mobilise and disperse sediments around the platform, leading to lower overall concentrations in any one area.

1. Introduction

This volume of the Environment Plan describes potential response options available for an oil spill occurring from any of Esso's activities within the Gippsland Basin as described in:

- Volume 2: Bass Strait Operations Environment Plan,
- Volume 2a: JUR Drilling Environment Plan,
- Volume 2b: Whiting Plug and Abandonment Environment Plan#
- Volume 2c: SHA / TWA Plug and Abandonment Environment Plan#
- Volume 2d: BTW Installation, Commissioning and Initial Operations Environment Plan

#Activities completed in 2020

This volume assesses and evaluates:

- Potential environmental impacts from implementing response options in accordance with Regulation 13(6); and
- Esso's capabilities for each response option in accordance with Regulation 14(8AA).

The Oil Pollution Emergency Plan (OPEP) details the initial and ongoing actions to take following a spill incident, the response framework and organisation structure, and step by step guides for key roles and responsibilities. The OPEP is an operational document which provides the response resources available for all levels of incidents, tools for spill response assessment, timeframes to initiate a response, notifications, and steps for response escalation, monitoring and stand down.

The Oil Spill Monitoring Plan (OSMP) outlines environmental monitoring that may be implemented in the event of an oil spill to the marine or coastal environment. Information from oil spill monitoring enables the Incident Management Team (IMT) to make informed decisions regarding response options. Oil spill monitoring provides the principle tools for determining the extent, severity and persistence of environmental impacts from a hydrocarbon spill and associated response and/or remediation activities.

2. Overview of Emergency Oil Spill Response Strategies

In an oil spill event, response options and tactics employed will vary depending on a number of factors related to the specific spill incident including: oil types, volumes, location of spill and whether it is a discrete spill or an ongoing flow.

The response options for the Bass Strait are listed below:

- Source Control;
- Surveillance and Monitoring;
- Application of Dispersant;
- Containment & Recovery (Offshore and Nearshore);
- Shoreline Protection and Clean-up; and
- Oiled Wildlife Response.

In-situ burning was considered however has not been included as a viable response strategy as:

- This response strategy is not approved as part of the national plan
- This response strategy has not been used previously in Australia
- Potential issues with local community and stakeholder engagement due to visual amenity

An effective response strategy may require a combination of different response options and may be scaled up or down depending on the oil spill event.

This Volume details the following information for each response option:

- Description of Response;
- Assessment of Environmental Impacts caused by Response Activities; and

- Assessment of required capability.

Environmental Performance Outcomes (EPOs), Standards (EPSs) and Measurement Criteria (MC) have been identified and put in place to ensure environmental impacts from response activities are acceptable and reduced to as low as reasonably practicable (ALARP).

In addition, EPOs, EPSs and MC have been identified to ensure resources remain current and available to respond to an oil spill event.

The EPOs, EPSs and MC are detailed in Volume 4 of the EP for emergency response capability and in Appendix C of the OPEP for oil spill response. These will be monitored and reported as per the implementation strategy.

2.1 Environmental Impact Assessment of Oil Spill Response

All oil spill response activities are implemented with the aim of reducing the overall environmental impact of the spill however, each activity in itself may also impact the environment, therefore it is important to understand impacts, assess the level and acceptability of impacts, and reduce impacts to ALARP.

This volume addresses assessment and evaluation of the consequence of mobilising the response strategies in the Bass Strait, which considers specific environmental aspects (Section 2.1.1) and receptors in the Bass Strait environment.

The environmental impact assessment of each response option has been undertaken in accordance with the following sections which can be found in Volume 2

- Environmental Impact Assessment (including assessment of consequence)
- Demonstration of ALARP
- Demonstration of Acceptability

The environmental receptors that may be impacted in a spill scenario have been described in the Description of Environment Volume 1 and summarised in the impact tables below.

2.1.1 Environmental Aspects

After identifying and describing the possible response options, an assessment was carried out to identify environmental receptors and potential interactions between the response activities and the receiving environment. The environmental receptors identified as occurring in the area are described in the Description of Environment Volume 1. The environmental aspects have been identified for each oil spill response option and are shown in Table 2-1.

Based upon an understanding of the environmental aspects, potential impacts were defined and ecological and social receptors identified enabling a systematic evaluation to be undertaken. Many aspects align with those already described in the activity specific Impacts and Risks Volume (i.e. Volume 2, 2a, 2b etc.) such as aspects associated with vessels, therefore this volume only evaluates aspects and impacts that are unique to oil spill response activities.

Table 2-1 Applicable Environmental Aspects

Environmental Aspect	Response Strategies	Environmental Impact Assessment
Vessel related aspects		
Emissions to Air (as a result of support operations)	• Source Control • Monitoring and Surveillance • Dispersant Application • Containment and Recovery • Shoreline Protection and Clean-up	Vessel and helicopter impacts are assessed within Volume 2.

Environmental Aspect	Response Strategies	Environmental Impact Assessment
	• Oiled Wildlife Response	
Physical Interaction - Other Marine Users	• Source Control • Monitoring and Surveillance • Containment and Recovery • Shoreline Protection and Clean-up • Dispersant Application	Vessel and helicopter impacts are assessed within Volume 2.
Planned Discharge – Treated Bilge	• Source Control • Monitoring and Surveillance • Dispersant Application • Containment and Recovery	Vessel impacts assessed in Volume 2.
Planned Discharge - Deck Drainage	• Source Control • Monitoring and Surveillance • Dispersant Application • Containment and Recovery	Vessel operations impact assessment in Volume 2
Planned Discharge - Food waste	• Source Control • Monitoring and Surveillance • Dispersant Application • Containment and Recovery	Vessel impacts assessed in Volume 2.
Planned Discharge - Sewage and Greywater	• Source Control • Monitoring and Surveillance • Dispersant Application • Containment and Recovery	Vessel impacts assessed in Volume 2.
Other Aspects		
Planned Discharge – Cement	• Source Control	Impact assessment for drilling a relief well within this volume.
Planned Discharge - Drilling Muds & Cuttings	• Source Control	Impact assessment for drilling a relief well within this volume.
Planned Discharge - Operational Fluids (surface and subsurface)	• Source Control	Impact assessment for drilling a relief well ~~/ capping stack installation~~ within this volume.
Physical Presence - Seabed Disturbance	• Source Control	Impact assessment for drilling a relief well ~~/ capping stack installation~~ within this volume.
Sound Emissions	• Source Control	Impact assessment for drilling a relief well within this volume

Environmental Aspect	Response Strategies	Environmental Impact Assessment
Planned Discharge of Dispersant (subsea and surface)	• Dispersant Application	Impact assessment within this volume.
Socioeconomic (fisheries, tourism, culture)	• Dispersant Application • Containment and Recovery • Shoreline Protection and Clean-up • Oiled Wildlife Response	Impact assessment within this volume.
Water quality – from decanting	• Containment and Recovery	Impact assessment within this volume.
Physical Presence - Interaction with Fauna and Flora	• Dispersant Application • Containment and Recovery • Shoreline Protection and Clean-up • Oiled Wildlife Response	Impact assessment within this volume.
Physical Presence - Sensitive and protected areas and parks	• Dispersant Application • Containment and Recovery • Shoreline Protection and Clean-up • Oiled Wildlife Response	Impact assessment within this volume.
Waste Management and Secondary Contamination	• Dispersant Application • Containment and Recovery • Shoreline Protection and Clean-up • Oiled Wildlife Response	Impact assessment within this volume.

2.2 Assessment of Oil Spill Response Strategies and Required Capabilities

Oil pollution preparedness and response arrangements should be commensurate with the identified risk and be fit for purpose, performance based, adaptable, scalable, sustainable, and clearly identify roles and responsibilities. All necessary arrangements to support timely response to foreseeable oil pollution emergencies must be in place prior to an activity commencing, and be maintained for the duration of the activity.

As per the IPIECA & OGP (2013) guidelines, the results from the spill modelling and impact assessment of the worst case discharge scenarios (see Volume 2) provide important input related to the likelihood of different spill scenarios, the ecological and socio-economic consequences of the scenarios, and the likelihood of exposure and oil volumes in geographical areas. Such information supports response planning analysis including NEBA, establishing response strategies and assessing resource needs across all response tiers.

Assessment of Oil Spill Response Strategies aims to identify:

- Viable strategies for delivering a response with the greatest net environment benefit

- Tactical measures required to implement the identified response strategies, considering technical, practical and safety factors
- Tiered resources required to mount the tactical measures and achieve an effective and realistic response

In order to address these items, Esso engaged AMOSC to conduct a detailed review of the selected worst case discharge scenarios in order to establish:

- Response strategies and required capability to respond to each worst case discharge scenario;
- Resource and personnel requirements for mobilisation and implementation of each response strategy;
- Consideration of resources and personnel for mobilisation and implementation of applicable Tactical Response Plans (TRPs); and
- Assessment of the availability of resources from Tier I, II, III equipment stockpiles.

The results from the AMOSC assessment have been used to generate a summary of resources required, resources available and expected timeframes to mobilise the personnel and equipment for each response option within this Volume.

2.2.1 Response Strategies

For each worst case discharge scenario, a full range of response strategies were considered. Strategies which were not viable (e.g. due to oil type or proximity to sensitive receptors) were identified. The details of response strategies applicable to each worst case discharge scenario can be found in OPEP Appendix D – Quick Reference Information.

Note that these are the proposed response strategies based on the available spill response modelling information. Actual response strategies implemented will be decided using the process described in Section 2.3 and in consultation with relevant state agencies. Guidance will be sought from relevant state agencies as to external factors which may influence the implementation of planned response strategies (e.g. natural disasters, pandemics).

2.2.2 Resource Requirements and Timeframe

Resource requirements were determined for each response strategy applicable to each worst case discharge scenario. Resource and personnel requirements are determined based on modelling outputs which indicate the location and intensity of the impact. Both deterministic and stochastic modelling was referenced to understand the overall resource requirements and where these resources may need to be located.

Considerations for resource requirements for each response strategy are outlined in Table 2-2.

Table 2-2 Considerations of resource requirements for response strategies

Response Strategy	Considerations for resource requirements
Surveillance and monitoring	Time to shoreline impact Location and type of oil
Dispersant Application	Type of oil Location of spill in proximity to sensitive receptors Surface oil loading
Containment and recovery	Type of oil Location and loading to sensitive receptors Surface oil loading
Source control	Well and facility design Reservoir characteristics Release rates

Response Strategy	Considerations for resource requirements
Shoreline protection and clean-up	Time to shoreline impact Type of oil Shoreline loading Geographical distance of impact Location and loading to sensitive receptors Shoreline characteristics
Oiled wildlife response	Time to shoreline impact Type of oil Shoreline loading Potential for protected species to be located in the area

2.2.3 Assessment of required resource availability

An assessment of required resource availability has been completed based on the greatest requirements and the fastest required response time. For example, the MLA spill scenario has the greatest surface volume of oil and requires the largest volume of dispersant, therefore, resources for dispersant application have been determined based on this scenario. Details of which scenario is relevant to assessment of resource availability for each response strategy is outlined in Table 2-3. The assessments can be found in the relevant sections of this Volume 3.

Resource needs were assessed against resources available using a tiered response model, i.e. Tier 1 – Esso; Tier 2 – AMOSC; Tier 3 - National Plan / international resources to identify any gaps in capability. State owned equipment was not considered in this assessment and so provides additional capability.

A summary of the required capabilities is included in the relevant Quick Reference Guides (see OPEP Appendix D – Quick Reference Information).

Table 2-3 Applicable WCDS to Response Strategy resource requirements

Response Strategy	Relevant WCDS	
	Resources	Timeframe
Surveillance and monitoring	Applicable to all scenarios	
Dispersant Application	MLA	MLA
Containment and recovery	MLA / TNA	MLA
Source control	Specific to parameters of relevant scenario	
Shoreline protection and clean-up	SHA[1]	SHA
Oiled wildlife response	Applicable to all scenarios	

2.2.4 Demonstration of ALARP

An ALARP assessment has been completed to confirm that risks continue to be reduced to ALARP and all alternative options to meet resource requirements have been considered. Additional, alternative or improved controls considered but not adopted have also been included in the ALARP assessment.

[1] Note that the SHA well was abandoned in October 2020. However the modelling for this 'workover' discharge scenario was used to represent an oil spill close to shore

This ALARP assessment applies an 'Engineering Risk Assessment' in which a comparative assessment of risks, costs, and environmental benefit is conducted (OGUK, 2014). The cost–benefit analysis shows the balance between the environmental benefit and the cost of implementing the identified measure.

2.2.5 Ongoing monitoring and maintenance of capability

To ensure risks continue to be reduced to ALARP throughout the lifetime of the activity, performance standards and outcomes have been established to monitor response capability and ensure it is maintained.

For each response strategy, all activities have been provided a standard of performance and a performance outcome. These EPOs and EPSs will be monitored in accordance with the relevant measurement criteria (e.g. through tests and drills or validation of agreements). Refer to Volume 4 for further details.

If external factors are identified to have a potential to impact spill response capability (e.g. natural disasters, pandemics) a review of available capability against required capability will be completed to ensure risks continue to be reduced to ALARP. The management of change process will be used to make required changes or updates to capability, if required.

2.2.6 Selection of Protection Priorities

To inform prioritisation and implementation of response strategies in the event of an incident, resources at risk have been identified for each worst case scenario. These are listed in the relevant Quick Reference Guides. Protection priorities are selected based on:

- sensitivity and predicted consequence (as assessed in Volume 2)
- protected / actionable areas
- minimum time to exposure
- feedback from stakeholder engagement

In the event of an incident, the NEBA process (refer to Section 2.3) will be applied to the protection priorities defined in the Quick Reference Guides to assist in planning the response.

2.3 Net Environmental Benefit Analysis

A process known as Net Environmental Benefit Analysis (NEBA) considers the advantages and disadvantages of oil spill response options in terms of their respective impacts on the environment. NEBA recognises that oil spill response activities have the potential to cause environmental impacts but may be justifiable due to overriding benefits and/or the avoidance of further impacts. The NEBA process can be applied to offshore and nearshore spill response, and to shoreline cleanup. An effective Net Environmental Benefit Analysis is a three-step process (Table 2-4).

The Esso NEBA process has been developed using guidance documents *Response Strategy Development Using Net Environmental Benefit Analysis (NEBA)* (IPIECA, 2015) and *Guidelines on implementing spill impact mitigation assessment (SIMA)* (IPIECA, 2017).

Table 2-4 Steps of the NEBA process

Step	Activities
1	Identify and prioritise an area's ecological, socioeconomic, and cultural resources according to environmental sensitivity.
2	Evaluate feasible response options and compare them to each other in addition to the option of natural recovery in order to define environmental benefits and drawbacks for all options.
3	Select the response option or combination of options that result in the greatest environmental benefit and/or least adverse effects on key resources.

2.3.1 Identifying and categorising sensitivities

Esso has undertaken a 'preparedness NEBA' which is essentially a draft of Step 1 & 2 of the NEBA Process (Table 2-4). This tool has identified resources at risk in over 40 geographic areas in an oil spill event which are located within the Bass Strait Described Area (DA) (refer to Volume 1). The resources identified span Victoria, Tasmania, New South Wales and Queensland.

The protection priorities defined in the Quick Reference Guides and the preliminary preparedness NEBA can be referenced in the event of an incident and used as a template during the response. In the event of an incident, it will be necessary to confirm the priorities are current and supported by stakeholders, and check the response strategies are indeed feasible given the specifics of the situation.

Each resource at risk has been subdivided further into resource types e.g. sandy beach, shipwrecks, fisheries, estuaries, rocky shores etc. Each of these resource types has been allocated:

1. Intrinsic Protection Priority (IPP)
2. Spill Impact Ranking; and (SIR)
3. Protection Priority Ranking (PPR).

The Intrinsic Protection Priority is calculated through:

- Irreplaceability / Significance of a Resource (Navigatus 2011)
- Vulnerability of a resource to oiling (NOAA ESI)
- Influence (criticality to human beings, ecosystems or their components)

The Spill Impact Ranking is determined based on the following impacts:

- Time before exposure;
- Duration of exposure;
- Size/scale;
- Intensity;
- Surface thickness;
- Dissolves aromatics; and
- Entrained hydrocarbons.

The IPP and the SIR are combined to give an overall PPR.

In a spill incident, the preparedness NEBA will be updated to reflect overall incident specific PPR for each resource at risk. This is achieved by:

- Determining SIR using data from incident-specific trajectory modelling; and
- Review of the IPP with stakeholders who have current and local knowledge of the resource areas.

Once this has been completed, the NEBA can be updated to select response strategies to protect the highest priority resources at risk.

2.3.2 Evaluate feasible response options

A summary of the outcomes of potential response options for each hydrocarbon type i.e. diesel, light crude and condensate is provided in the OPEP. The preparedness NEBA details the pros and cons for each response strategy based on each resource type, taking into account the impact of the response itself on the resource. The potential effects of response options (both positive and negative) are assessed compared to the 'no intervention' option and identified as:

- Proposed;
- Viable;
- Not recommended;
- Not applicable; and
- Not viable.

The potential response options for a spill have been categorised as one of the above in the preparedness NEBA for each of the resource types within each resource area. This information is summarised in OPEP Appendix D – Quick Reference Information. In an actual incident, the spill responses should be reviewed and updated to consider fluid type, safety, feasibility, timing, current and local and knowledge of the resource areas.

2.3.3 Selecting the best or a combination of response options

This step requires a range of stakeholders to reach consensus on the relative priority of the environmentally-sensitive resources and to understand the trade-offs associated with available response technologies (IPIECA-IOGP, 2015).

Two trade-off aspects are balanced in this step (i.e., protection and response, and the benefits and drawbacks of selected response options). For the former, this priority may be influenced by the ease of protection and response, recovery times, and the importance for subsistence, economic value, and seasonal changes (IPIECA-IOGP, 2015).

Once the response options and priorities have been selected, this should be reviewed by relevant IMT members and considerations to logistics, safety and resources finalised. The NEBA is an ongoing process and should be updated on a regular basis for the duration of the spill to allow for "real-time" alignment with changing field conditions and address the health of response personnel, community health, and socioeconomic considerations (e.g. beach closures). Further, these tools should be used to gain stakeholder input on local or regional priorities, expand awareness, and gain trust in the decision-making process.

Net environmental benefit should always be a key factor when making decisions on the optimum spill response options to implement.

3. Source Control

3.1 Response Option Description

Source control activities are implemented to prevent or minimise the release of hydrocarbons into the marine environment. The release of hydrocarbons may occur from one of the following scenarios:

- Operational spills (overfills, transfers and process equipment and drains system);
- Storage tank or piping leak/rupture;
- Pipeline leak/rupture;
- Well blowout (surface and subsea).

The origin and nature of hydrocarbon spill will determine the type of source control activities required and the duration of the response. Source control activities may include:

- Isolation of tanks / pipes;
- Remote Operated Vehicle (ROV) intervention;
- Well capping;
- Relief well;
- Use of the Well Kill Equipment Skid;
- Use of resources from a third party response provider (e.g. Wild Well Control);
- Pipeline isolation, depressuring and repair.

The source of the spill will be assessed and evaluated by the Emergency Response Team (ERT) and Incident Management Team (IMT) on a case by case basis. The origin and nature of the spill (wells, pipeline or vessel) and metocean conditions will influence the source control response options selected based on technical feasibility.

An advantage of Source Control:

- Stops / minimises the flow of hydrocarbons into the environment.

Disadvantages of Source Control:

- Increase in environmental impacts from response activities e.g. planned discharges; and

- Presents safety risks.

Potential source control options are detailed below.

3.1.1 Isolation of Tanks / Pipes

Isolation provides a way for separating process systems and equipment from one another and may be used to prevent flow of hydrocarbons. Many types of isolations exist on subsea infrastructure, pipelines, wells and vessels. Isolation of a pipeline is the primary source control of containing a pipeline rupture/failure.

3.1.2 Remote Operated Vehicle (ROV) Intervention

ROVs can be used subsea to inspect the condition of wellheads, pipelines and subsea equipment and have arms which may be used to manipulate valves and manually isolate equipment. Specialist ROVs can be fitted with a range of equipment including: debris clearing tools, specialist tooling, subsea dispersant spraying capabilities, cameras and cutting tools.

Note that per NOPSEMA Guidance Note GN166, vessels remotely supporting a ROV that is being used in connection with inspection, the operation of a valve and/or the recovery of debris are not required to have a safety case. Per NOPSEMA Guidance Note GN166, if other activities are undertaken where a vessel is subject to the Australian Offshore Petroleum Safety Legislation, vessels will comply with duties of an operator and safety case.

3.1.3 Well Capping Stack

A “capping stack” is a piece of equipment that is placed over the blown-out well as a “cap.” Its purpose is to stop or redirect the flow of hydrocarbons, establishing a barrier to the marine environment. Once subsea, the capping stack is installed on the wellhead/subsea BOP to stop flow. The capping stack provides a safe barrier until the well can be permanently sealed. This option will require the use of a Construction Support Vessel (CSV) to install the capping stack.

A well capping stack has limited applicability on subsea facilities. OSRL’s offset capping stack system is limited due to minimum depth requirements (>75 m) and long mobilisation times. As described in Volume 2, Section 6.7.6, use of a capping stack is not technically feasible for any producing facilities and is not considered a viable response option.

3.1.4 Well Kill Equipment Skid

The Well Kill Equipment Skid can be used for bullhead killing or lubricating production wells in the event of a critical well failure. The dedicated Well Kill Equipment Skid is a standalone hydraulic / diesel drive unit which requires minimal platform facility support. The Well Kill Equipment Skid is stored at BBMT when it is not in use offshore.

Use of the platform based well kill equipment skid is accounted for in platform specific safety cases as part of the Well Kill Contingency Plan.

3.1.5 Third Party Well Control Equipment

In the event of a loss of well control in which flowrates are too great to be able to use the Well Kill Equipment Skid, but not great enough to warrant drilling a relief well, resources from a third party well control can be used to control a loss of containment from the well (e.g. Wild Well Control).

3.1.6 Relief Well

A relief well is constructed like a standard well, and is directionally drilled to intersect the original well to allow specialised fluids to be pumped into the well to overcome reservoir pressure and stop the flow of the original well.

3.1.7 Pipeline depressuring and watering out

Pipelines can be depressured and watered out to reduce the flow of hydrocarbons released from a pinhole. Watering out pipelines replaces hydrocarbons with produced water and reduces the volume of hydrocarbons released to sea.

Pipeline depressuring procedures are in place for each pipeline which provide guidance on how to safely depressure a pipeline at the relevant end and start platforms. Watering out procedures are also available.

3.1.8 Pipeline repair

Pipeline repair activities will be dependent on the type of initiating event and the feasible engineering solutions to repair the hole. Repairs to stem the flow of hydrocarbons would be completed using ROV from a vessel and may require the use of:

- Cap
- Plug
- Clamp
- Repair sleeve

Caps or plugs may be feasible for use to repair a pipeline after rupture however are less likely to be feasible given the difficulty in installation over a large area.

Once the hydrocarbon flow has been stemmed (or the pipeline pressure has reached equilibrium with the water if repair is not feasible), the pipeline will be repaired to reinstate production. For pinhole leaks and minor holes this could involve operation with the cap/plug/clamp/sleeve in place.

For a full rupture, a DSV with divers or a construction or pipe lay barge fitted with a dive spread will be required. This would need to mobilise from SE Asia or Europe and would likely need a number of regulatory documents prepared including a safety case, a dive safety management system and a dive project plan. Repair time is estimated to be a minimum of 3 months. Note that this is not considered a source control response option as repair of the pipeline to reinstate production will not reduce the volume of hydrocarbon released.

3.1.9 New Technologies under investigation

ExxonMobil continues to study new offshore drilling technologies including ways to mitigate the potential impacts of an uncontrolled flow of hydrocarbons to the environment for a well incident (LOWC). The following strategies are not proposed to be use as part of this Environment Plan but demonstrate ExxonMobil's commitment to continually improving knowledge and technology for source control.

- **Seawater Injection Method (SWIM**) (Jain, Nedwed, Kulkarni, Mitchell, & Meeks) utilises seawater pumped at a high rate into a failed and leaking blow out preventer (BOP) to generate enough back pressure to overcome reservoir pressure and stop the flow of oil and gas.
- **Rapid Crosslinking Polymer Injection** (Nedwed, et al., 2019) is a method that mixes monomers and a catalyst that causes a rapid polymerisation reaction, resulting in a stable solid. The reaction can occur under extreme temperatures and pressures and can withstand significant contamination from other fluids and solids.

3.2 Environmental Impact Assessment of Source Control Response

Many environmental aspects associated with implementing source control activities (e.g. aspects associated with vessels, ROV and subsea installation) apply to multiple activities and are assessed in Volume 2. Environmental aspects associated with drilling a relief well ~~and capping stack~~ are assessed below. These include:

- Physical Presence – Seabed disturbance;
- Planned Discharge – Cement;

- Planned Discharge – Drilling muds and cuttings; and
- Sound Emissions.

Further assessment of the acceptability of these impacts in an oil spill response context and controls identified for minimising the environmental impact of mobilising a source control response are described below.

Table 3-1 Environmental Impact Assessment of Source Control Options

Environmental Aspect:	Impact Assessment	Consequence Level
Relief well drilling		
Physical Presence – Seabed Disturbance	Smothering and alteration to benthic habitats can occur as a result of seabed disturbance. The type of damage that could be sustained due to smothering may include destruction of habitat. Benthic habitats and communities within the Bass Strait show natural small scale variation, however the area is mostly considered homogenous. Studies conducted by Esso (Cardno, 2019) demonstrate similarities in taxa but variation in composition between different sites. Seabed disturbance from relief well drilling activities will be limited to close proximity to existing infrastructure, and typically in areas which have previously been disturbed during installation of infrastructure. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be inconsequential or have no adverse effects. No additional controls identified.	IV
Planned Discharge – Cement	Impacts to ambient water quality from planned discharge of cement will be highly localised and temporary, with turbidity and chemical toxicity impacts quickly ceasing following discharge. Any impacts will be inconsequential or have no adverse effect, and impacts to pelagic organisms (such as plankton, fish, and marine fauna) are not expected. Once cement has hardened, the sediment quality will be permanently changed. Any impacts to ambient sediment quality will be inconsequential or have no adverse effect and impacts to benthic habitats and communities are not expected. No additional controls identified.	IV
Planned Discharge – Drilling muds and cuttings	Chemicals will be discharged to the marine environment resulting in a change in water quality. Due to the high energy marine environment, discharges will quickly dissipate. Impacts to ambient water quality will be localised and temporary, and any impacts will be inconsequential or have no adverse effect. Prior to discharge the chemicals will be assessed using the Esso Chemical Discharge Assessment Process (described as part of the Implementation Strategy in Volume 4) which uses the OCNS ranking in conjunction with toxicity, biodegradation and bioaccumulation data to determine potential impacts to the environment and acceptability of planned discharges. No additional controls identified.	IV
Sound Emissions	Gales (1982), cited in NCE (2007), reports that underwater sound measured from fixed drilling platforms did not exhibit markedly different characteristics from those engaged in production, and that none of the measured sound could be directly related to the mechanical action of the drill bits. It is therefore believed that most sound associated with drilling is created by the operation of the rig itself.	IV

Environmental Aspect:	Impact Assessment	Consequence Level
	No additional controls identified.	

Acceptability of Environmental Impact from Source Control

Factor	Demonstration Criteria	Criteria Met	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	All aspects related to source control activities, including EPO's, EPS's and controls have been detailed in Volume 2 or have been evaluated as having the potential to result in a Level IV consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	All oil spill response activities are implemented with the aim of reducing the overall environmental impact from a spill incident. Source control activities are implemented to stop the flow of oil and minimise safety risks and environmental damage. Impacts associated with source control are offset by the broader positive effects of reducing the impact of a spill incident on coastal and marine sensitivities and socio-economic receptors (e.g. fishing, tourism).

Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	• The Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009 (OPGGS(S)) requirements for NOPSEMA approved facility Safety Case.
			  • Protection of the Sea (Prevention of Pollution from Ships) Act 1983.
			  • Navigation Act 2012.
			  • Marine Order 96 (Marine pollution prevention – sewage) 2013.
			  • Marine Order 95 (Marine pollution prevention - garbage) 2013.
			All well specific source control activities will have an approved WOMP and comply with:
			  • Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011.

Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	Proposed controls meet the requirements of the ExxonMobil Drilling Emergency Preparedness and Response Manual.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and

Factor	Demonstration Criteria	Criteria Met	Rationale
			• OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised.

Table 3-2 ALARP Demonstration of Environmental Impacts from Source Control

ALARP Decision Context and Justification	Decision Context A. Source control equipment and resources (ROVs, ~~capping stacks~~, vessels and rigs for relief well drilling) are standard practices that have been accepted for use in the Australian and International Offshore Petroleum Industry in the event of a hydrocarbon spill. Impacts associated with source control activities are well understood and source control response activities have been initiated and managed by industry previously. Source control activities are aligned with company and partner values. Good Practice control(s) have been identified to ensure environmental impacts associated with implementing this response are reduced to ALARP, these controls will be implemented in a response scenario and have been included in the OPEP. Esso believes ALARP Decision Context A should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**
Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class.	✓	Vessel Requirements.	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the International Maritime Organisation (IMO) across many critical areas including the International Convention for the Safety of Life at Sea, (SOLAS), the 1988 Protocol to the International Convention on Load Lines and the International Convention for the Prevention of Pollution from Ships (MARPOL).
AMSA JRCC notified before operations commence to enable AMSA to distribute an AUSCOAST warning.	✓	Pre-start Notification.	Under the Navigation Act 2012, the Australasian Hydrographic Society is responsible for maintaining and disseminating hydrographic and other nautical information. Details for AUSCOAST warning will be provided to the JRCC (24<48 hours) prior to commencing operations.
All planned drilling discharges are evaluated in accordance with the Chemical Discharge Assessment Process.	✓	Chemical Discharge Assessment Process.	All cements, drill fluids, additives and/or their components planned for discharge are evaluated as acceptable.

Cuttings are treated to reduce Residual Oil on Cuttings (ROC).	✓	Solids Control Equipment.	It is industry standard practice to remove Non Aqueous Fluid (NAF) muds from cuttings using a combination of shale shakers and/or cuttings driers to minimise the residual oil on cuttings.

3.3 Capability Assessment of Source Control

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources to complete source control activities in a timely manner.

This section summarises outcomes of the capability assessment.

Table 3-3 Source Control Resource Availability

Activity	Resource Required	Resource Availability	Expected Timeframes
Specialist ROV	1 x ROV for subsea well pipelines intervention / SFRT and surveillance.	Resource Agreements in place with ROV specialists.	Estimated 5 days from call out request to arrival in Victoria.
Construction Support Vessel (CSV)	1 x CSV to assist in source control activities: Specialist ROV subsea well /pipelines interventions and surveillance Deployment of SFRT	Resource A construction support vessel with a current Australian safety case sourced from the Australasian region.	Estimated 32 days from spill occurring to arrival in field.
Relief Well	1 x rig per relief well.	Resource A rig will be mobilised from the Australasian region.	Estimated 98 days to drill the relief well.
Well Kill Skid	1 x well kill skid (including all relevant equipment as defined in the response plan)	Resource A well kill skid will be mobilized from BBMT or platform. Personnel Trained wellwork personnel available to operate wellwork skid	The well kill skid can be at the platform within 48 hours with appropriately trained personnel (24 hour pack up time and moved on the next available boat)
Third party well control equipment	Specialised well control equipment	Resource Agreement with Wild Well Control	Estimated time to contain well release incident is 14 days
Pipeline de-pressuring and watering out	1 x Competent operators on relevant platform	Personnel Trained personnel available to operate facilities	As soon as practicable once location of spill has been confirmed
Pipeline repair	Pipeline repair equipment Specialist ROV equipment (as above)	Resource Agreements in place with pipeline repair equipment specialists Agreements in place with ROV specialists	Available within 45 days

Table 3-4 Source Control Capabilities

Good Practice	Adopted	Control	Rationale

Established Incident Management Team.	✓	Esso Incident Management Team (IMT).	Esso's IMT includes trained personnel able fulfil Incident Commander, Operations Section Chief, Planning Section Chief, Logistics Section Chief, Safety Officer, Source Control Branch Director and Environmental Unit Lead roles.
Pre-arranged agreement with ROV provider.	✓	Agreements with ROV providers.	ExxonMobil's global agreements provides Esso with access to ROVs.
For Rig Activities: Identification of suitable support vessels and their location prior to the commencement of rig activities.	✓	Support vessel identification process.	Support vessel identification process enables understanding of the availability of suitable vessels which may reduce response time. In the event that a vessel safety case must be revised to complete the activities, Esso will work with vessel contractors to revise and resubmit the vessel safety case within one week of the incident occurring.
Pre-arranged access to Subsea First Response Toolkit (SFRT).	✓	Agreement with AMOSC for SFRT.	The agreements with AMOSC provide access to SFRT designed with the following capabilities: Survey and provide a detailed image of condition of subsea infrastructure Ability for subsea intervention
Ability to access drilling rigs in an emergency event.	✓	MoU with APPEA.	APPEA Memorandum of Understanding (MoU) states that signatories will make best endeavors to make drilling units available for transfer between operators when requested for emergency response.
Existing arrangements with source control contractors	✓	Agreement with Wild Well Control	Agreements with Wild Well Control provide access to specially trained personnel and equipment to assist in the event of a LOWC.

Table 3-5 Consideration of Additional/ Alternative/ Improved Capability for Source Control

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Pre-drilling top holes	This option may result in a reduction of 1-2 days for drilling a relief well, however due to the uncertainly of the location and trajectory it is unknown if the top hole could get utilised in specific spill scenarios. This option may result in unnecessary environmental impacts, including: • Discharge drill cuttings; • Discharge of chemicals; • Discharge of muds; and • Benthic habitat disturbance.	The position of a relief well vary in location and trajectory according to the actual conditions at the time the loss of containment event occurs. Limited reduction in days (potentially 1-2), this equates to approximately 2% of the time it would take to drill a relief well.	Not adopted.

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Standby rig during drilling activities	A rig on standby may reduce the time required to drill a relief well.	Significant costs are associated with having a standby rig. Given the high potential cost, implementing this control measure is considered grossly disproportionate, given that the source control event has an extremely low likelihood of occurrence.	Not adopted.
Purchase and have available pipeline repair equipment locally	Having pipeline repair equipment available locally may reduce the time taken to repair a pipeline and reduce the overall volume of oil released.	Pipeline repair equipment to be used is specific to the type of pipeline failure and must be determined at the time incident. Significant cost associated with having access to a wide variety of pipeline repair equipment.	Partially adopted. Some pipeline repair equipment for higher likelihood scenarios (e.g. clamps for pinhole leaks) are available locally.

4. Surveillance and Monitoring

4.1 Response Option Description

Surveillance and monitoring activities are essential in an oil spill response strategy to characterise and quantify volumes and determine the movement of the slick. This information is fundamental to mobilising an effective oil spill response strategy and critical in determining the scale and nature of the oil spill incident.

To understand the scale and fate of the oil, the spill should be observed as soon as possible and monitored throughout the response until the decision has been made to stand down.

Advantages of Surveillance and Monitoring:

- Validate trajectory and weathering models;
- Determine effectiveness of response techniques; and
- Outputs will be used to guide decision making on the use of other monitoring or response options.

Disadvantages of Surveillance and Monitoring:

- Increase in environmental impacts from response activities e.g. vessels; and
- Increase in safety risks.

A variety of surveillance and monitoring techniques can be used to gather information required to support the ongoing response. These may include:

4.1.1 Aerial and/or vessel observation

Aerial and vessel observation provides the IMT with real time data of magnitude, direction of travel, and visual characteristics of surface oil. This information can be used in response planning and forming the incident specific NEBA.

4.1.2 Computer-based modelling software

Computer software can generate maps that show predictions for the path of the oil spill. It can also forecast the effects that currents, winds, and other physical processes have on the movement of oil in the ocean. This information can be used in response planning and the incident specific NEBA.

4.1.3 Utilisation of satellite tracking buoys

Satellite tracking buoys provide real time current data to use to predict forecasts of surface behaviour of the oil and direction of travel.

4.1.4 Remote sensing from aircraft and/or satellites

Airborne remote sensing equipment supplements visual observations by using sensors which detect radiation outside of the visible spectrum.

Satellite imagery can provide real time imagery over large areas and assist with determining the movement of the slick and determining response activities

4.1.5 Water quality and oil sampling

Water sampling will confirm the properties of oil. These details can be inputted into computer based modelling for increased accuracy and assist with determining response activities.

When oil enters the marine environment, a proportion of it will float and spread out on the sea surface where it will be influenced by the wind and ocean currents. In some situations, where natural dispersion and weathering processes are considered the most appropriate response, surveillance and monitoring may be the primary response strategy.

In this case, the response will monitor the oil as it undergoes the natural weathering processes of evaporation and dispersion, in which wind and wave action breaks the oil into small droplets in the water column increasing bioavailability and allowing the oil to be naturally degraded. Higher levels of surveillance such as vessel/aircraft surveillance, oil spill trajectory modelling and deployment of satellite tracking drifter buoys are options to be considered for Level 2/3 spills given the nature and scale of the spill risk.

4.2 Environmental Impact Assessment of Surveillance and Monitoring Response

Environmental aspects associated with surveillance and monitoring were identified and evaluated in Table 4-1. All associated environmental impacts have been described and assessed within Volume 2 and no additional environmental impacts have been identified as a result of surveillance and monitoring response activities.

Table 4-1 Acceptability of Environmental Impacts from Surveillance and Monitoring

Factor	Demonstration Criteria	Criteria Met	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	All aspects related to surveillance and monitoring activities are assessed in Volume 2 and have been evaluated as having the potential to result in a Level IV consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	All oil spill response activities are implemented with the aim of reducing the overall environmental impact. Surveillance and monitoring response activities are critical in determining the scale and nature of the oil spill incident. This information is fundamental to mobilising an effective oil spill response

Factor	Demonstration Criteria	Criteria Met	Rationale
			strategy to minimise potential environmental damage from a spill incident.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	The proposed control measures align with the requirements of: • OPGGS Act 2006; • Protection of the Sea (Prevention of Pollution from Ships) Act 1983; • Navigation Act 2012 – Chapter 4 (Prevention of Pollution); • Marine Order 96 (Marine pollution prevention – sewage) 2013; and • Marine Order 95 (Marine pollution prevention - garbage) 2013.
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to the Surveillance and Monitoring however the controls proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised.

Table 4-2 ALARP Demonstration of Environmental Impacts from Surveillance and Monitoring

ALARP Decision Context and Justification	Decision Context A. The potential environmental aspects associated with mobilising a Surveillance and Monitoring response have been evaluated and no new impacts have been identified.

	Surveillance and monitoring response activities are standard practices that are routinely used in the Australian and International Offshore Petroleum Industry as well as many other industries. Impacts associated with surveillance and monitoring are well understood and well implemented by the industry. Good Practice control(s) have been identified to ensure environmental impacts associated with mobilising this response are reduced to ALARP, these controls will be implemented in a response scenario and have been included in the OPEP. Esso believes ALARP Decision Context A should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**
Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class.	✓	Vessel Requirements	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the International Maritime Organisation (IMO) across many critical areas including the International Convention for the Safety of Life at Sea, (SOLAS), the 1988 Protocol to the International Convention on Load Lines and the International Convention for the Prevention of Pollution from Ships (MARPOL).

Table 4-3 Engineering Risk Assessment

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
None Identified.			

4.3 Capability Assessment of Surveillance and Monitoring

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources to complete surveillance and monitoring activities in a timely manner. The assessment concluded sufficient resources are available within acceptable timeframes to conduct this response.

This section summarises outcomes of the capability assessment.

Table 4-4 Surveillance and Monitoring Resource Availability

Activity	Resource Required	Resource Availability	Expected Timeframe
Visual Observation - Aerial Surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Resource Esso helicopters can assist in aerial surveillance. Agreement with third party to provide fixed wing aircraft. AMSA Search and Rescue Aircraft. Personnel 4x Trained spill observers provided by Esso.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring. Twice daily aerial surveillance. *(Note: Assumes good visibility, daylight hours and suitable flying conditions).*

Activity	Resource Required	Resource Availability	Expected Timeframe
		Supplemented by AMOSC staff, AMOSC core group and OSRL.	
Visual Observation – Vessel or Asset	An observer to conduct 2 hour watch from staffed assets.	Resource Platform /Drilling Rig /Vessel Personnel 1x Observer and /or available crew.	<2 hours, from time of spill.
Manual Oil Spill Trajectory Modelling	1x trained person.	Resource Trajectory vectoring. Relevant set of marine charts for Bass Strait. GIS mapping. Personnel IMT member trained trajectory vectoring. Internal Esso GIS mapping specialists.	<4 hours of service requested.
Oil Spill Trajectory Modelling	1x contract with specialist.	Resource AMOSC - Access to RPS modelling services. OSRL – Access to modelling services. ExxonMobil EMBSI (USA) – Access to modelling (available 24/7).	<4 hours of service requested.
ADIOS - Weathering Modelling	1x trained person.	Resource Automated Data Inquiry for Oil Spills 2 (ADIOS2) installed on IMT computers. Personnel IMT personnel trained in ADIOS.	<4 hours of the service requested.
Satellite Tracking Drifter Buoys	1x buoy available.	Resource 2x tracking buoys within 12 hours. 2x Tracking buoy available 24-48 hours.	Deployed <12 hours of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
Remote Observation Using Satellite Imagery	1x contract with specialist.	Resource AMOSC agreement with KSAT. OSRL Agreement with Radiant Solutions. ExxonMobil Geospatial Emergency Response Service (available 24/7).	Initiated <24 hours of Level 3 spill occurring.
Initial Oil in Water Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Resource Vessel and crew (Esso). Initial Sampling kits available at various Esso locations. Personnel Field Service technician.	Samples obtained <24 hours of spill occurring. Analysis initiated <24 hours of receipt in laboratory. Results <5 days.

Activity	Resource Required	Resource Availability	Expected Timeframe
		Laboratory services and experienced analyst provided by NATA accredited lab as per OSMP.	
Ongoing Oil in Water Monitoring	1x vessel. 1x sampling services contract.	Resource Vessel contractor/ crew (Esso). Sampling services via environmental consultancy. Personnel Sampling services via environmental consultancy. Laboratory services and experienced analyst provided by NATA accredited lab as per OSMP.	Samples obtained 48 hours hrs. of spill occurring. Analysis initiated <24 hours of receipt in laboratory Results within 5 days.
ExxonMobil	Personnel Trained and capable Esso IMT Regional Response Team	Available to fulfil roles in accordance with requirements and timeframes in OPEP Table 3-2. Remote support <12 hours from notification. In-country support <72 hours from notification.	ExxonMobil

Table 4-5 Surveillance and Monitoring Capabilities

Good Practice	Adopted	Control	Rationale
• Pre-arranged access to helicopters for aerial surveillance.	✓	Esso helicopter fleet.	Esso owns and operates its own helicopter fleet that can be used for surveillance and monitoring.
• Pre-arranged access to fixed wing aircrafts for aerial surveillance.	✓	Arrangement with third party for provision of fixed wing aircraft.	Arrangement with third party enables provision of fixed wing aircraft.
• Pre-arranged access to vessels for Surveillance and Monitoring activities.	✓	Support vessel.	The support vessel that is used for ongoing Esso operations can be used for surveillance and monitoring.
	✓	Agreement with third party suppliers for provision of additional vessels.	Agreement with supplier of vessel services has provision for supply of additional vessels
• Pre-arranged access to trajectory modelling capabilities.	✓	Agreement with AMOSC for trajectory modelling.	Agreement with AMOSC, and the associated service level statement, includes provision for trajectory modelling.
• Pre-arranged access to satellite tracking buoys.	✓	Esso owned tracking buoys.	Esso owns satellite tracking buoys to enable quick deployment.
• Pre-arranged access to satellite imagery	✓	Agreements in place to access satellite imagery.	Agreements in place with satellite imagery provider enables access to satellite imagery services.

Good Practice	Adopted	Control	Rationale
• Pre-arranged access to water testing services.	✓	Agreement with service provider for monitoring and sampling.	Agreement with third party service provider enables access to monitoring and sampling services.
• Pre-arranged access to personnel to support Tier III response activities.	✓	ExxonMobil Regional Response Team	ExxonMobil have a global team available to assist response for Tier III activities.

Table 4-6 Consideration of Additional/ Alternative/ Improved Capability for Surveillance and Monitoring

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Night-time monitoring - infrared.	Enable night time monitoring of the location of oil on the water's surface.	Infrared may be used to provide aerial monitoring at night time, however the benefit is minimal given trajectory monitoring (and infield monitoring during daylight hours) will give good operational awareness. Safety considerations may also restrict night time operations.	Not Adopted.
Initial sampling kits available on supply vessels and rigs.	Enable rapid sampling from supply vessels and rigs	• Sampling kits on-board vessels and rigs will enable rapid sampling of the oil. • The results from the testing will provide details of the oil properties and confirm the properties of oil, assist with source identification. • Results can be used in the modelling for increased accuracy and assist with determining response activities.	Adopted.

5. Dispersant Application

5.1 Response Option Description

Dispersants enhance the rate and extent of natural dispersion in an oil spill event. The surfactants in dispersants allow wave energy to rapidly break oil slicks into small oil droplets. These droplets are pushed into the upper water column by wave action and maintained there by turbulence. The dispersed oil droplets are much more available to naturally-occurring, hydrocarbon-degrading microorganisms.

The principal ecological benefit of dispersant use is to keep oil from entering near-shore bays and estuaries, or stranding on shorelines, thereby protecting sensitive coastal habitats and the species that inhabit them. In previous oil spill incidents elsewhere in the world, it is the species in the areas near or onshore that have been most affected by an oil spill event (National Academies of Science, Engineering and Medicine, NASEM, 2019).

The mixture of solvents and surfactants that comprise typical commercial dispersants (Place et al., 2010) contain compounds with different physicochemical properties and therefore potential fates in the environment. Once introduced to open ocean waters, dispersant mixtures will be quickly diluted and subjected to degradation processes including biodegradation and photodegredation (NASEM, 2019).

For maximum effectiveness, dispersants should be applied as close to the source and as soon as possible to avoid losing the "window of opportunity". Dispersant can be applied either subsea at the source of a subsurface spill or directly to any surface slicks from aircraft or vessels.

Dispersants may be applied in a broad range of weather conditions including high winds and rough seas that may not be suitable for other strategies, e.g., mechanical containment and recovery. Dispersants are mainly amenable to certain oil types and are generally not considered to be suitable for Group I and lighter Group II oils, including diesel. The oil type and the metocean conditions (e.g. temperature, wave height, swell) will dictate the effectiveness of dispersant application.

The main objectives of dispersant application are:

- Reduce environmental impacts;
- Rapidly reduce oil toxicity through dilution;
- Enhance the natural dispersion processes;
- Enhance natural microbial biodegradation;
- Minimise impacts to shoreline habitats;
- Reduce the requirement for shoreline clean up; and
- Reduce concentrations of Volatile Organic Compounds (VOCs) at the sea surface.

The decision whether or not to use dispersants will be made after considering the potential effects of dispersed oil versus undispersed oil, i.e. after employing a Net Environmental Benefit Analysis (NEBA) process which provides a methodology for comparing the base case of no spill response to those where individual response tools (mechanical containment and recovery, subsea and surface dispersants) are considered (IPIECA, 2017). Dispersants will only be considered for use at specific locations/times where testing shows oil to be amenable and decision is supported by the spill specific conditions.

5.1.1 Surface Application

Dispersants can be applied to surface oil from vessels or aircraft. Aerial application allows wide coverage for treatment of large volumes of oil. Potential advantages include; minimal human resource, enhanced biodegradation, and ability to spray large areas in a timely manner through the use of aircraft. A potential constraint is the limited time-frame for dispersant application; there is a relatively short “window of opportunity” for treating the spilled oil before it weathers and may become too viscous, although this can vary depending on specific oil properties and environmental conditions. Aerial dispersant operations are limited to appropriate weather conditions (e.g., visibility, ceiling and winds), daylight hours, and sufficient turbulence (from waves) to mix the dispersant into the oil.

Aircrafts

Aerial application of dispersant requires aircrafts to be fitted with dispersant spraying equipment. For best effectiveness, aerial dispersant should be administered at steady airspeeds (150 kts) and low altitudes, generally 50 – 100 ft above the sea level. Aerial platforms include those available through the fixed wing aerial contract and additional aircrafts are available through OSRL.

Vessels

Vessels can be fitted with dispersant spraying equipment for surface application. For best effectiveness the dispersant should be applied to the thickest concentrations of oil, via spray arm systems or specialised dispersant spraying equipment.

5.1.2 Subsea Application

Subsea dispersant injection is the process of injecting dispersants directly into the stream of oil that is leaving the well, ideally before the oil leaves the wellhead. The process allows the dispersant to come into contact with a much greater proportion of the oil and uses the turbulent jet effect of the force of the exiting oil to mix the dispersant effectively. SSDI can be operated continuously by offshore vessels, which can locate themselves offset from the position of the well release or by using the Subsea First Response Toolkit (SFRT) located in Perth.

Subsea dispersant injection (SSDI) operations can take place continuously and are effective in ongoing spill scenarios e.g. well blow outs.

Advantages of SSDI include:

- Requires less manpower than other response options and may reduce the VOCs at the surface improving health and safety of responders;
- Delivery of the dispersant directly to the release;
- At depth, dispersed oil will be subject to greater loss of soluble components and increased dispersion than surface application;
- Subsea injection operations can take place continuously, while surface application is limited to daylight hours and favourable wind and sea state conditions.

Potential disadvantages of SSDI include the need for specialised equipment to deliver the dispersant and to monitor effectiveness, although this equipment is available from Tier 3 response organisations (NASEM, 2019).

Use of subsea dispersant is highly dependent on the specifics of the release. In the event of an incident, a number of factors will be considered to inform the use of subsea dispersant. These include:

- Release type (surface or subsea)
- Release rate
- Oil type
- Location to sensitive receptors
- Water depth
- Safety of personnel in proximity to the release location

The decision to mobilise the SFRT and to use subsea dispersant will be taken based on advice from the Source Control Branch in consultation with relevant technical, environmental and regulatory stakeholders.

ROVs

Vessels can be fitted with specialist ROVs that have SSDI capabilities for subsea dispersant application. SSDI treats oil released at the point of release which reduces the volume of dispersant required and can be applied continuously in all-weather scenarios.

5.2 Types of Dispersant Available to Esso in an Oil Spill Incident

Since the 2010 Deep Water Horizon (Macondo) spill response, the petroleum industry has invested significantly in the purchase of the most studied, modern products (Dasic Slickgone NS, Finasol® OSR 52, Corexit® EC9500A) and their placement in strategic global locations to facilitate rapid response in an event where dispersants represent a viable response option (NASEM, 2019). The Corexit products remain the most studied products available and there is a wealth of information regarding their effectiveness (high) and relative toxicity (low). As a result of this, industry continues to work toward maintaining/reinstating their status as products approved for possible use.

Several types of dispersant are available to Esso and are proposed for use during an oil spill incident. A summary of each is given in Table 5-1.

5.2.1 Dispersant Testing

Esso undertook dispersant efficacy testing on five Bass Strait crudes against two of the available dispersants (Dasic Slickgone NS and COREXIT 9500). Testing was also conducted on a third dispersant COREXIT 9527, although this is no longer available for use as it is not accepted by AMSA on the National Plan.

The testing was carried out on fresh crude, 12 hour weathered, 24 hour weathered and 48 hour weathered under Bass Strait summer and winter conditions. Each dispersant was tested at an application rate of 20:1 (oil: dispersant). A summary of the results is provided in OPEP Appendix E – Dispersant Testing Results. Key findings from the dispersant efficacy testing include:

- Testing shows that dispersant is highly effective on most types of fresh oil, but not all Esso crudes tested are amenable to dispersant;
- Non-spreading oils are considered to be non-dispersible;
- Effectiveness of dispersant decreases significantly on weathered oils;

- Once pour point of the oil is above temperature of the seawater, the dispersability rapidly drops off; and
- Dispersability of the oil generally increases at higher temperatures.

Table 5-1 Summary of dispersant stock available to Esso

Dispersant	Details	Stockpiled	AMSA OSCA Accepted	Dispersant tested on Esso Crude
Dasic Slickgone NS	Slickgone is widely used in the offshore industry worldwide and meets the requirements of the UK, French, Norwegian and Australian dispersant protocols. Extensive field trials in the UK indicate that an effective treatment rate for dispersants is approximately 1 part dispersant to 20-30 parts of oil and can be effective when applied from aircraft, vessels and directly on shorelines.	AMOSC, AMSA, OSRL	✓	✓** ✓***
Dasic Slickgone EW	Slickgone EW is the latest addition to the Dasic International product range and is exceptionally efficient on a broad spectrum of oils. It is also effective on water-in-oil emulsions (mousses) and will even delay the formation of such emulsions if applied early enough. It is highly effective at emulsifying crude oils, fuel oils and water-in-oil emulsions even at low temperatures, producing oil droplets minute enough to be retained beneath the sea surface where they are rapidly diluted by subsurface mixing and are eventually biodegraded by micro-organisms.	AMSA	✓	
Total Finasol OSR52	Finasol OSR52 provides a rapid and effective breakdown of hydrocarbons. It was the first product on the market to comply with all three major international regulations; EPA, MMO and CEDRE. It can be applied either neatly or at 10% by aircraft, boats or by hand held sprayers with backpack spray units.	OSRL	✓	
Nalco Corexit 9500A	COREXIT EC9500A contains an improved oleophilic solvent delivery system than that used in earlier formulations of Corexit. Aircraft provide the most rapid method of applying dispersants to an oil spill for aerial spraying. Corexit is a solvent-based "concentrate" dispersants, which may either be applied undiluted (neat) or sprayed in a stream of seawater. COREXIT 9500 can be used during early stages of a response and may be ~~is~~ more effective on viscous, emulsified, and weathered spills than alternative options.	Esso, BHP, AMOSC OSRL	✓	✓**

**2019 Crudes tested: Snapper, Moonfish, Flounder, West Kingfish and Halibut
*** 2012 Crudes tested: Tuna, Halibut and West Kingfish

5.2.2 Acceptance of Dispersant Application

AMSA

An oil spill clean-up agent (OSCA) is defined as a chemical, or any other substance, used for removing, dispersing, or otherwise cleaning up oil or any residual products. The Australian Maritime Safety Authority (AMSA) have products on the OSCA register which are considered to have met the requirements of acceptable practice for the National Plan.

All existing stocks of previously accepted Oil Spill Control Agents held within the National Plan (AMSA and AMOSC) inventories, as of 1 January 2012, remain acceptable for National Plan use until used or disposed of. They are listed in the OSCA Register as 'transitional OSCAs' and almost exclusively comprise the AMSA, AMOSC and Esso's pre-2012 stockpiles of dispersants

NOPSEMA

The EP submission process provides the mechanism for Esso to gain 'acceptance' for the use of location, activity or OPEP specific oil spill dispersant products and deployment strategies (e.g. surface and/or subsea application) prior to any incidents.

Any dispersant use in response to a pollution incident from an offshore petroleum activity must be carried out in accordance with an accepted EP and no additional 'approvals' are required to implement response arrangements.

State Waters

Any dispersant application within state waters (<3 nm) must be approved by the state control agency prior to use.

5.3 Environmental Impact Assessment of Dispersant Application

5.3.1 Dispersant Toxicity

Modern dispersant products (e.g., Dasic Slickgone NS, Finasol® OSR 52, Corexit® EC9500A) are a mixture of solvents and surface active agents (surfactants) with different physicochemical properties and therefore potential fates in the environment. Once released into the aquatic environment, dispersants are subject to rapid dilution, dissolution, biodegradation, and photodegradation processes (NASEM, 2019). Consequently, there is a brief time window in which marine organisms will be subject to the full toxicity of the dispersant and dispersed oil.

When a dispersant is introduced at depth by subsea injection, dispersant components will differentially dilute and dissolve, with some being retained at depth. In this situation, biota could be exposed to dilute concentrations of the more persistent and water-soluble dispersant components, such as the anionic surfactant di (2-ethyhexyl) sodium sulfosuccinate (DOSS). The US EPA benchmark for the protection of aquatic life is 40 µg/L. A study conducted by the Operational Science Advisory Team (OSAT) following the Macondo spill investigated the footprint of Corexit at sea by measuring the concentrations of DOSS. It was found that DOSS was more persistent at depth however no dispersant water quality exceedances were measured in the OSAT program (OSAT, 2010) and only one sample was found that exceeded the US EPA guideline for aquatic organisms (Gray et al., 2014). Both DOSS and the solvent used in Corexit (dipropylene glycol butyl ether) are expected to rapidly degrade following application at the cool, shallow Gippsland waters, as they are known to rapidly degrade in light (Gray et al., 2014; Glover et al., 2014), and Corexit has been shown to be microbially degraded at 5 and 20 degrees (Campo et al., 2013).

The current protocols for registering an Oil Spill Control Agent for use in Australia (described in detail by AMSA (2011)) use NATA-accredited standardised toxicity tests on a variety of taxa. These tests include lethal and sub-lethal endpoints and to be registered in Australia, the LC50 values must be greater than 10 mg/L for the tested fish larvae and crustaceans. This is considered is considered "slightly toxic" by the US EPA (Hemmer et al., 2011).

Dispersants currently used in the industry are less toxic than oil (EMSA, 2010) and recent studies have found that Corexit 9500 is not more acutely toxic in standardized tests than common household cleaning products (Word et al., 2014). All dispersants proposed to be used by Esso in the event of an incident are accepted on to the National Plan OSCA Register meaning they meet toxicology requirements for use.

CSIRO (2015) also noted that modern dispersants are much less toxic than spilled oil. However, their use can increase localised oil toxicity, but this is very short-lived due to the dilution effects and will result in much lower exposure and dosage than without dispersant use.

In laboratory experiments, dispersant components (including the solvents and surfactants) degrade rapidly, within hours to days. In field conditions, the few studies on the effects of dilution on dispersant fate and transport have shown that concentrations of dispersants reach a maximum of 5-13 ppm after surface applications and generally decrease to less than 1 ppm within minutes to hours (NASEM, 2019).

Products available today are low in toxicity and do not increase the toxicity of the dispersed oil because they are present in the water column at very low concentrations (Lessard, 2000). The toxicities of dispersants are usually lower than those of the soluble fractions of oils and this, together with the lower concentrations of dispersant in the dispersed oil, indicates that the toxicity of dispersed oil is predominantly due to the toxic components of the oil, and not the dispersant (NRC, 1989).

5.3.2 Increase in Dispersed Oil in the Water Column

The application of dispersants will increase the amount of oil that is entrained and dissolved in the water column, reducing exposure of coastal ecosystems to floating weathered oil, as well as reducing the risk of exposure of seabird and marine mammal populations to the floating oil (Bock et al. 2018; French-McCay et al. 2018; NRC 2005, 2013). It also has the potential to reduce contamination of sensitive intertidal habitats such as mangroves, coral reefs, salt marshes and sandy shores (recreational and tourist areas) through the reduction in shoreline impacts. However, in open ocean environments, the processes involved in dispersion will rapidly dilute the oil droplets and the soluble components of the oil (NRC, 2005). In fact, in deep waters, dispersants are thought to have minimal ecotoxicological effects because of dilution (NRC, 2005).

The application of surface dispersants may result in a greater risk that water column and subtidal habitats could be exposed to elevated concentrations of dispersed hydrocarbons. Surface dispersant application is usually restricted to greater than 3 nm from shorelines and in water depths greater than 10 meters. Maximum dispersed oil concentrations could reach 100-200 ppm in the top 10 meters initially, but it is expected to decrease to 1 ppm or less within 5-10 hours (Lessard, 2000).

A negative effect of subsurface dispersant injection is that the surfactants increase the bioavailability of oil components in the water column and more oil may remain at depth, potentially increasing the toxicity risk to deep-water fauna although dilution will reduce concentrations below toxicity thresholds rapidly (French-McCay et al. 2018).

Similarly, there is a potential for exposure of planktonic, pelagic, demersal and benthic organisms to increased levels of dispersed or dissolved oil components, although dilution is expected to be a significant factor (Hook & Lee, 2015).

5.3.3 Subsea Dispersant Injection (SSDI)

A variety of studies in the aftermath of the Macondo spill response in the Gulf of Mexico have shown that the dispersants that were developed for use on surface spills are also effective when applied during a subsea well response via Sub-Sea Dispersant Injection (SSDI). Research funded by the American Petroleum Institute (API) through a Joint Industry Task Force (JITF) and IPIECA/International Maritime Organization (IMO) through a Joint Industry Program (JIP) demonstrated that Dasic Slickgone NS, Finasol® OSR 52, Corexit® EC9500A are all effective at significantly reducing oil droplet size, a key measure of successful dispersant application. The work was performed at a number of independent research facilities in Europe (CEDRE, Sintef) and the US (Southwest Research Institute) and in conjunction with a number of universities including MIT and the University of Hawaii.

As a result of a reduction of oil droplet size, the surface expression of released oil is expected to be significantly reduced (NASEM, 2019), especially directly above the point of subsea release. This can help protect birds and aquatic mammals since less oil will be present in their habitats. Less surface oil will also be beneficial to response workers since there is an expectation of reduced volatile organic compounds (VOC) in the area in which they work, especially in the early stages of a response (French-McKay *et al*., 2019).

The reduction of oil droplet sizes in the water column will lead to dispersion at depth where concentrations are expected to decrease to levels well below aquatic toxicity thresholds and microbial biodegradation will be significant, even over extended periods of SSDI. A number of studies support these findings (including reports by T. Hays; R. Prince; K. Lee; D. French-McKay; NASEM 2019).

5.3.4 Impact Assessment

The application of dispersant in the event of a loss of well control and major spill will result in an increase in the proportion of spilled hydrocarbons in the water column as either dissolved or entrained oil. This has the effect of decreasing surface and shoreline loading, but increasing exposure to pelagic biota in offshore waters and possibly localised sedimentation of hydrocarbons to the seabed in the deep offshore waters.

An impact assessment has been completed to assess the impacts to receptors following the use of dispersant to mitigate a spill. The impact assessment considers the effects of increased exposure to hydrocarbons in the water column due to dispersant use and addresses any additional or reduced potential impacts from the use of dispersants, as compared to the unmitigated scenario described in Volume 2, Section 6.7.2.

This assessment has been completed based on the proposed response scenario described in Table 5-6 for dispersant application in response to the LOWC in the Northern region, as represented by the Marlin scenario (from the TRA A10 well) as described in Volume 2, Section 6.7.

This scenario has been selected as it results in the largest volume of oil spilled to surface and therefore, requires the largest volume of dispersant in response. Consistent with the assessment of dispersant toxicity described in Section 5.3.1, the impact assessment provided in Table 5-2 has been prepared based on the response scenario which results in the most oil being dispersed into the water column. Given the use of surface dispersants, this aligns with the scenario which uses the most dispersant. This being the surface and SSDI scenario described in Table 5-6.

Note that application via SSDI results in a greater volume of oil being dispersed into the water column. However, following the abandonment of SHA, TWA and BKA subsea facilities, there are no subsea oil wells producing in the Gippsland region. All producing oil wells are located on platforms and therefore, any spills from a loss of well control are assumed to occur at surface.

Remaining subsea facilities (KPA and BTW) produce gas and condensate (See Volume 2, Table 6-21). Discharge of gas with condensate is highly volatile and natural weathering processes will disperse oil and dispersant application is not considered a recommended response option. Therefore, SSDI is not considered to be a primary response option.

Through the use of surface dispersants, in-water hydrocarbon levels are likely to increase above high levels in areas predicted to be impacted by in water oil (see Volume 2, Table 6-7 and 6-8 for likelihood of impacts from LOWC) however, shoreline impacts are expected to be reduced.

Surface application of dispersant will be directed to the thickest part of the slick and to fresh oil which will be found close to the release location in water with sufficient depth to allow dilution of hydrocarbons and dispersant throughout the water column. Dispersants will only be used in Commonwealth waters, in waters of >10m depth and outside of Australian Marine Parks. Use of dispersants in State waters would only be with the approval of the State control agency.

Table 5-2 Aspect: Planned Discharge of Dispersant

Affected Receptor	**Unmitigated LOWC Consequence** (per Volume 2, Table 6-9)	**Consequence of LOWC mitigated through use of dispersant**	**Consequence Level**
Plankton	The impact to plankton is predicted to be **Level III** with potential effects on the food web recognised.	Plankton, specifically zooplankton, are vulnerable to hydrocarbons (Hook et al., 2016). Water column organisms that come into contact with oil and chemicals risk exposure through ingestion, inhalation and dermal contact (NRDA, 2012), which can cause immediate mortality or declines in egg production and hatching rates along with a decline in swimming speeds (Hook et al., 2016). Plankton are at their highest concentrations below surface waters (e.g. 60 m water depth for phytoplankton during the day) and undertake a vertical migration which would likely reduce their potential for (and duration of) exposure to dissolved hydrocarbons in the surface layer of the water column. Plankton are typically abundant in the upper layers of the water column and decline with depth. Once background water quality is re-established, plankton takes weeks to months to recover (ITOPF, 2011). Following use of dispersant, plankton are likely to be exposed to in-water hydrocarbons above the high exposure threshold along the Gippsland coastline. However, once background water quality is re-established, plankton takes only weeks to months to recover (ITOPF, 2011). Further, plankton found in open waters of the exposure zone is expected to be widely represented within waters of the wider Bass Strait region and generally across all waters in the south eastern offshore region, which aids in the re-establishment of communities. Exposure to greater concentrations of dissolved and entrained hydrocarbons due to the use of dispersants is predicted to result in short-term impacts to local plankton populations.	The impact to plankton is predicted to be consistent with the assessed LOWC scenario described in Volume 2, Table 6-9 being **Level III**.
Benthic Habitats and Communities - – Bare Substrate, Coral,	The consequence of a LOWC on benthic habitats is assessed as **Level II.**	Species residing in offshore locations are more likely to be exposed to increased ~~significant~~ levels of in-water hydrocarbons with the application of surface dispersant application depending on their water depth and location with	The consequence of a LOWC mitigated through use of dispersant application on benthic habitats is assessed as **Level II.**

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
Seagrass, Macroalgae, Subtidal Rocky Reef		respect to the spill. Impacts to deep water benthic sediments are not expected as a result of surface dispersant application. Known areas of seagrass which may be exposed to increased concentrations of dispersed oil include Corner Inlet, Lakes Entrance, Bemm River Estuary and Tamboon Inlet. There is the potential that exposure could result in sub-lethal impacts however seagrass in this region isn't considered a significant food source for marine fauna. Suitable hard substrate for macroalgal around Gabo Island and within the Bemm River Estuary may be impacted by increased concentrations of dispersed oil however are suggested to be some of the least sensitive marine species to oil exposure. Benthic invertebrate species closer to shore may be affected by increased in-water oil concentrations. Invertebrates of value (i.e. target species for fisheries) have been identified to include squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone). While exposure can lead to impacts including mortality, recovery of benthic invertebrates exposed to in-water hydrocarbons would be expected to return to background water quality conditions within weeks to months of contact. Several studies have indicated that rapid recovery rates may occur even in cases of heavy oiling (Burns et al., 1993; Dean et al., 1998). Acute or chronic exposure, through both surface contact, and/or ingestion can result in toxicological risks. However, the presence of an exoskeleton (e.g., crustaceans) will reduce the impact of hydrocarbon absorption through the surface membrane. Other invertebrates with no exoskeleton and larval forms may be more prone to impacts from pelagic hydrocarbons. Complex assemblages (e.g. sponge habitat) or deep-water slow-growing sessile invertebrates are likely to recover much more slowly. Exposure to in-water hydrocarbons poses the greatest threat to sensitive macroalgal assemblages, specifically the Giant Kelp Forests TEC. These grow on rocky reefs from the sea floor 8 metres below sea level and deeper growing towards the sea surface. Benthic invertebrates are potentially at risk of toxic impacts of exposure to in-water hydrocarbons. While exposure can lead to impacts including mortality, recovery of benthic	

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
		invertebrates exposed to entrained hydrocarbons would be expected to return to background water quality conditions within weeks to months of contact. Several studies have indicated that rapid recovery rates may occur even in cases of heavy oiling (Burns et al., 1993; Dean et al., 1998). It is possible that injury or mortality associated with acute or chronic exposure could result in a slight alteration of the local habitat and community structure, however no long-term changes to ecosystem are expected. Offshore benthic habitats are more likely to be exposed to increased ~~significant~~ levels of in-water hydrocarbons although this is expected to be limited to very shallow waters (e.g., 10 to 50m) due to the nature of surface application. These areas of highly mobile sediment, where diversity and abundance are relatively low, will likely recover quickly.	
Fish	The consequences to fish and sharks are assessed as **Level II**, taking into consideration the potential impacts to threatened species such as the White and Grey nurse sharks.	Exposure to dissolved / entrained hydrocarbons and chemicals in the water column can be toxic to fishes. Studies have shown a range of impacts including changes in abundance, decreased size, inhibited swimming ability, changes to oxygen consumption and respiration, changes to reproduction, immune system responses, DNA damage, visible skin and organ lesions, and increased parasitism. However, many fish species can metabolise hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Shallow inshore fish species including various syngnathids (seahorses, pipefish, pipehorses and seadragons) are less likely to be able to move away from in-water oils and therefore may be exposed to elevated levels or for longer periods. Their habitats are typically widespread however any impacts are expected to be local on individual organism levels. Fish are most vulnerable to hydrocarbon discharges during their embryonic, larval and juvenile life stages. Oil and chemical exposure may result in decreased spawning success and abnormal larval development. Impacts on eggs and larvae entrained in the upper water column are expected to be short term given the temporary period of water quality impairment, and the limited areal extent of the spill. As egg/larvae is widely distributed in the upper layers of the water column it is expected that current induced drift will rapidly replace any affected populations.	Consequences to fish and sharks are assessed as **Level II**, taking into consideration the potential impacts to threatened species such as the White and Grey nurse sharks.

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
		Pelagic free-swimming fish and sharks are unlikely to suffer long-term damage from exposure because dissolved/entrained hydrocarbons in water are not expected to be sufficient to cause harm (ITOPF, 2010). Pelagic free-swimming fish and sharks are also generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Demersal fish are more likely to be exposed to significant levels of in-water hydrocarbons associated with the application of ~~subsea~~ dispersant application. Predicted zones of moderate exposure to dissolved hydrocarbons contacting the White shark distribution and breeding BIAs and Grey nurse shark foraging and migration BIAs may increase to high exposure levels following use of dispersant. These species are widely distributed and areas of increased impact due to dispersed oil are not considered significant compared to overall species distribution.	
Marine Reptiles - Turtles	Although the effects of hydrocarbons on marine reptiles, specifically turtles can be severe, the low density of turtles expected in the region (due to lack of BIA or aggregations) suggests that a LOWC would affect individuals rather than population level. Consequently, the potential impacts to marine reptiles are considered to be Consequence **Level II.**	Effects to marine turtles have been assessed to be most significant for surface oil and shoreline oil (See Volume 2, Table 6-9). Marine turtles are vulnerable to the effects of oil at all life stages; eggs, hatchlings, juveniles, and adults. Marine turtles can be exposed to oil externally (e.g. swimming through oil slicks) or internally (e.g. swallowing the oil, consuming oil affected prey, or inhaling of volatile oil related compounds). Effects of oil on turtles include increased egg mortality and developmental defects; direct mortality due to oiling in hatchlings, juveniles, and adults; and negative impacts to the skin, blood, digestive and immune systems, and salt glands. French-McCay 2018 performed a comparative risk assessment for a large blowout in the Gulf of Mexico and found that turtles are the marine species that undergo the most benefit from dispersing oil because of their vulnerability to surface slicks and their long lives and slower reproduction. While marine turtles, including threatened species, are known to occur in the area potentially exposed to in-water dispersed oils they are not noted to reside or aggregate in significant numbers, and there are no recognized BIAs in the region.	Although the effects of hydrocarbons on turtles is driven by surface and shoreline oils, the low density of turtles expected in the region (due to lack of BIA or aggregations) suggests that additional in-water oil would affect individuals rather than population level. Consequently, the potential impacts to marine reptiles are considered to be **Consequence Level II.**

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
		It should be noted that the threat and relative impacts of an oil / pollution on some marine reptile species are considered less damaging than other stressors. Report cards produced on protected marine reptiles in Australia generally ranked oil pollution as either 'not of concern' or 'of less concern' depending on the marine region (DSEWPAC 2012). Impacts from increased concentrations of in-water dispersed oil are expected to be largely consistent with that of the assessed LOWC scenario described in Volume 2, Table 6	
Birds	The potential consequence of risks to seabirds and shorebirds from a LOWC are considered to be **Level II.**	Birds foraging at sea have the potential to directly interact with oil on the sea surface some considerable distance from breeding sites in the course of normal foraging activities. Seabird species most at risk include those that readily rest on the sea surface (e.g. shearwaters) and surface plunging species (e.g. terns, boobies). As seabirds are a top order predator, any impact on other marine life (e.g. pelagic fish) may impact food supply both for the maintenance of adults and the provisioning of young. However, it is likely that the use of dispersant will be offset by the decrease in surface oil and reduction in the consequences for smothering of birds feeding at the surface. For the unmitigated scenario (see Volume 2, Section 6.7.2) oil concentrations at the moderate to high threshold are predicted to accumulate on the shorelines of Gabo Island, which supports the world's largest Little penguin colony, The Skerries and Tasmanian Bass Strait islands such as Curtis Island potentially impacting local populations. Under certain metocean conditions the zone of moderate surface exposure is predicted to overlap with the Little penguin breeding BIA. Impacts to these colonies are expected to be reduced following use of dispersant due to reduced shoreline loading. There are many listed threatened and migratory shorebird species likely to occur in the area overlapping the extent of exposed shoreline. However, in the event of a LOWC, these birds are potentially at risk of shoreline exposure and are not likely to be significantly affected by in-water concentrations of hydrocarbons due to their limited exposure time in the water column. Reduction in shoreline oil as a result of dispersant application is expected to reduce impacts to shorebird species.	Given the potential impacts to birds from oil spills are largely driven by shoreline and surface impacts, the potential impacts to birds due to a LOWC mitigated through use of dispersant application is assessed to be a **Consequence Level III**

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
Marine Mammals (Pinnipeds)	The consequence of a LOWC on pinnipeds is assessed as Level II.	There may be physical impacts from ingestion of in-water and surface oil. However, as mammals are highly mobile species, it is very unlikely that these animals will be continuously exposed to elevated concentrations of dispersed hydrocarbons for extended durations (e.g. >96 hours) that could lead to chronic effects. Both the New Zealand fur-seal (*Arctocephalus forsteri*) and the Australian fur-seal (*Arctocephalus pusillus doriferus*) are listed marine species with habitat and breeding sites known to occur in areas potentially exposed to surface, in-water and shoreline oil above the moderate threshold. Both the Australian and New Zealand fur seals are at risk to surface oil while at sea and shoreline accumulated oil at haul out sites or rookeries. While some individuals may be affected, population level effects on these other transient species are considered unlikely. It is likely that the use of dispersant will be offset by the decrease in surface oil and reduction in the consequences for whales feeding at the surface. French-McCay 2018 found that marine mammals in the Gulf of Mexico also were protected by use of dispersants for the same reason as turtles. As described in Volume 2, Table 6-9, the potential impacts to pinnipeds from oil spills are largely driven by surface and shoreline impacts.	Given the potential impacts to pinnipeds from oil spills are largely driven by shoreline and surface impacts, the potential impacts to pinnipeds due to a LOWC mitigated through use of dispersant application is assessed to be a **Consequence Level III**
Marine Mammals (Cetaceans)	The consequence of a LOWC on cetaceans is assessed as **Level II**.	There may be physical impacts from ingestion of in-water and surface oil. However, as mammals are highly mobile species, it is very unlikely that these animals will be continuously exposed to elevated concentrations of dispersed hydrocarbons for extended durations (e.g. >96 hours) that could lead to chronic effects. While some individuals may be affected, population level effects on these other transient species are considered unlikely. It is likely that the use of dispersant will be offset by the decrease in surface oil and reduction in the consequences for whales feeding at the surface. Impacts from increased concentrations of in-water dispersed oil are expected to be largely consistent with that of the assessed LOWC scenario described in Volume 2, Table 6-9.	The potential impacts to cetaceans are considered to be Consequence **Level II**.
Coastal Habitats and Communities– Sandy	The impact of LOWC is assessed conservatively as a **Consequence Level II**	There are different types of shorelines found along the Gippsland and southern NSW coast and offshore islands	Given the potential impacts to coastal habitats from oil spills are largely driven by shoreline oil loading, the

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
Shoreline, Rocky Shoreline, Mangroves and Saltmarsh		(including Tasmanian islands), however this coastline is dominated by wide sandy beaches with intermittent rocky shores, and salt marshes and isolated mangroves within tidal estuaries, coastal lakes and bays. The impacts to these coastal habitats (as described in Volume 2, Table 6-9) are influenced by the volume of hydrocarbon that could be stranded ashore and its thickness before the shoreline saturation point occurs (ITOPF, 2014). Use of dispersant is expected to reduce the volume of oil that reaches the shoreline and therefore reduce impacts to coastal habitats and communities, compared to impacts assessed in Volume 2, Table 6-9.	potential impacts to coastal habitats due to a LOWC mitigated through use of dispersant application is assessed to be a **Consequence Level III**
Wetlands	The consequence of LOWC is assessed as **Level III.**	As described in Volume 2, Table 6-9, wetlands of international importance which may be impacted (e.g., Corner Inlet Ramsar Site) have minimal risk of receiving oil following a LOWC because they have no, or very narrow and/or seasonal, connections to the sea. Under certain conditions shoreline oil is predicted to accumulate at high – moderate thresholds along the shoreline of Corner Inlet, however, following use of dispersant, it would be expected that surface oil will be significantly reduced.	The consequence is assessed as **Level III.**
National Parks and Reserves	The consequence is assessed as **Level II** taking into consideration the length of shoreline potentially impacted and the extent of oil accumulation predicted.	Spill modelling predicted that no AMPs would experience exposure to surface oil at or above the moderate threshold. However, modelling indicated that six AMPs (East Gippsland, Beagle, Flinders, Jervis, Freycinet and Central Eastern), could be exposed to moderate thresholds of dissolved oil. Impacts to National Parks and Reserves along the area of shoreline exposure (as identified in Volume 2, Table 6-7 and Table 6-8) are expected to be reduced following the use of dispersant due to decreased shoreline loading. This decrease in impact to Marine Parks is consistent with the conservation management aims of the South East Marine Reserves Network Management Plan. The East Gippsland and Beagle Marine Parks are ranked as Category VI protected areas meaning they should be	The consequence is assessed as **Level III** taking into consideration the reduction in shoreline impacts due to dispersant use.

Affected Receptor	**Unmitigated LOWC Consequence** (per Volume 2, Table 6-9)	**Consequence of LOWC mitigated through use of dispersant**	**Consequence Level**
		managed mainly for ecosystem protection and passive recreation. The Flinders and Freycinet Marine Parks are ranked as Category II protected areas meaning they should be managed mainly for the ecologically sustainable use of natural ecosystems. The application of surface dispersant aims to protect and minimise the impacts to ecosystems from hydrocarbon spill releases thereby allowing future sustainable use of the ecosystems in the region.	
AMPs	The consequence is assessed as **Level III.**	Although initial spill modelling indicated that no AMPs would be exposed to moderate thresholds of in water (dissolved) oil, it may be expected that in water exposure to hydrocarbons is increased to high levels following the use of dispersant. Surface and in-water (dissolved) oil entering these AMPs will degrade water quality until the oil is broken down and or currents shift the weathering oil outside the boundaries of the AMPs. Thus, water quality effects are predicted to persist only over the short to medium term in the AMPs.	The overall consequence is assessed as **Level III.**
KEFs	The consequence is assessed as **Level III**.	While a spill would not affect the KEF Upwelling East of Eden itself, if the spill occurs at the time of an upwelling event, it may result in krill being exposed to in-water phase hydrocarbons. Pygmy blue whales feeding at this time may suffer from reduced availability of prey however, even with increased in-water hydrocarbon concentrations due to dispersant use, these impacts are expected to be localised and temporary.	The consequence is assessed as **Level III**
Cultural –Indigenous and Historic	The consequence level is considered **Level III** based on public impact consequence considerations	Use of dispersant is expected to reduce shoreline impacts to the visual or cultural (including activities such as camping, rituals and ceremonies) amenity of cultural heritage sites such as historic (e.g. shipwreck) or indigenous protected areas It is expected that use of dispersant will reduce the duration of impacts from degraded aesthetics of sites as a result of reduced shoreline loadings. Parts of the Gippsland coast over which the Gunai-Kurnai people hold native title would be exposed to lesser impacts	The consequence level is considered **Level III** taking into consideration the reduction in shoreline impacts due to dispersant use

Affected Receptor	Unmitigated LOWC Consequence (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
		than compared to the unmitigated spill described in Volume 2, Table 6-9.	
Commercial Fisheries	The potential economic impacts to commercial fisheries from LOWC are considered to be Public Impact Consequence **Level I** based on public impact consequence considerations	Several commercial fisheries may operate within the area potentially exposed in the event of a LOWC. For the unmitigated scenario (see Volume 2, Section 6.7.2), floating oil is predicted to extend 10's of kilometers outside the subsea facility PSZ (from which fishing vessels are already excluded) making it likely that in these situations an exclusion zone (or fisheries closure) would be established. Fishing areas may be closed for fishing for shorter or longer periods because of the risks of the catch being tainted by oil. Increased oil in water concentrations could result in increased fish taint and prolonged fishing restrictions. As described in Volume 2, Table 6-9, a temporary fisheries closure and the flow on losses from the lack of income derived from these fisheries based on reduced market confidence and the potential for extended media coverage (potentially greater than 3 months) has the possibility of exceeding medium community disruption (> 100 – 1000 people) such as reduced employment (in fisheries service industries and the seafood supply chain).	The potential economic impacts to commercial fisheries from LOWC are considered to be Public Impact **Consequence Level I** based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 3.5, Table 3 5).
Tourism and Recreation	The potential economic impacts to tourism and recreation from LOWC are considered to be Public Impact Consequence **Level I** based on public impact consequence considerations.	Impacts to tourism and recreation are driven by visual oil leading to reduced amenity of areas used by coastal tourists and recreational visitors, temporary health implications and possible closures. Use of dispersant is expected to reduce volume of shoreline oil meaning impacts to tourism and recreation are expected to be reduced. Modelling in Volume 2, Section 6.7 predicts visible oil extending into nearshore Victorian waters (including waters of Ninety Mile Beach, Point Hicks and Cape Howe Marine National Parks and Beware Reef Marine Sanctuary) and a number of National Parks and Reserves including the very popular Wilsons Promontory and (Gippsland) Lakes National Parks. It is expected that use of dispersant will reduce the duration of impacts from degraded aesthetics of sites as a result of reduced shoreline loadings.	Despite taking into consideration the reduction in shoreline impacts due to dispersant use, the consequence level is considered **Level I**. This is based on public impact consequence considerations (media coverage, the scope of the disruption (personal, commerce, transportation or socio-economic) and the size of the population affected) as per ExxonMobil Risk Matrix Application Guide, 2018 (Refer Section 3.5, Table 3 5).

Affected Receptor	**Unmitigated LOWC Consequence** (per Volume 2, Table 6-9)	Consequence of LOWC mitigated through use of dispersant	Consequence Level
		As described in Volume 2, Table 6-9, the extent of potential impacts to tourism and recreation depends on when the spill occurs, size and where it comes ashore.	

Table 5-3 Acceptability of Environmental Impacts from Dispersant Application

Factor	Demonstration Criteria	Criteria Met	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	The activities were evaluated as having the potential to result in a Level III to IV consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The application of dispersants will decrease the volume of oil on the surface which may reduce exposure to coastal sensitives and seabird and marine mammal populations to floating oil. Dispersant application will only be a selected following an incident NEBA, which must demonstrate potential environment impacts from dispersant outweigh the potential for shoreline, fauna and marine sensitivity impacts.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	The proposed control measures align with the requirements of the: • OPGGS Act 2006 • Protection of the Sea (Prevention of Pollution from Ships) Act 1983. • Navigation Act 2012 – Chapter 4 (Prevention of Pollution). • Marine Order 96 (Marine pollution prevention – sewage) 2013 • Marine Order 95 (Marine pollution prevention - garbage) 2013.
Internal Context	Consistent with Esso's Environment Policy	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	Proposed controls meet the requirements of the ExxonMobil Dispersant Guidelines 2008.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised.

Table 5-4 ALARP Demonstration of Environmental Impacts from Dispersant Application

ALARP Decision Context and Justification	Decision Context B Dispersant application is a standard response strategy that has been accepted for use in the Australian and International Offshore Petroleum Industry. Impacts associated with dispersant application are well understood and have been implemented by industry. The application of dispersants must be supported by an incident NEBA in commonwealth waters or have approval from state control agency within state waters. Dispersant application activities are aligned with company and partner values. Good Practice control(s) have been identified to ensure environmental impacts associated with mobilising this response are reduced to ALARP, these controls will be implemented in a response scenario and have been included in the OPEP. Esso believes ALARP Decision Context B should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**
Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class.	✓	Vessel Requirements.	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the International Maritime Organisation (IMO) across many critical areas including the International Convention for the Safety of Life at Sea, (SOLAS), the 1988 Protocol to the International Convention on Load Lines and the International Convention for the Prevention of Pollution from Ships (MARPOL).
NEBA completed prior to conducting dispersant application operations.	✓	Incident specific NEBA.	The NEBA takes into account the circumstances of spill, fate of the oil, potential environmental and social impacts and relative oil spill response options. NEBA will take into account IUCN Ranking of relevant Marine Parks.
Halting dispersant use if operational monitoring detects protected or migratory species at the water surface in the path or vicinity of spraying operations.	✓	Halt dispersant application if wildlife are identified in the area	If EPBC Act listed migratory species (e.g. whales) are observed in the immediate vicinity of dispersant operations, aerial dispersant operations will cease until the animal has not been sighted for 30 minutes or unless otherwise advised by the relevant state authority.
Dispersant pre-selection and assessment.	✓	Dispersant pre-selection and assessment.	Only dispersants listed in Section 5.2 will be utilized in the event of an incident, unless otherwise endorsed by a Statutory Authority
Pre-incident dispersant effectiveness testing	✓	Laboratory dispersant effectiveness testing.	Laboratory testing of five Gippsland crude oils against three types of dispersant has been completed under summer and winter conditions. Testing shows that dispersant is highly effective on most types of fresh oil. Effectiveness

			of dispersant decreases significantly on weathered oils.
Effectiveness of dispersant confirmed prior to application.	✓	Basic field dispersant effectiveness test.	Testing effectiveness of the dispersant on the oil spill will inform the response option strategy and assist IMT determining response activities.
Dispersant application is only accepted for: • Commonwealth waters • >10 m water depth • Outside Australian marine parks	✓	Exclusion zones	Defined area of where the application of dispersant is acceptable to reduce potential environmental impacts to marine fauna and flora.
Continuous monitoring of dispersed oil plume and visual monitoring of effectiveness.	✓	Monitoring of dispersant effectiveness	The OSMP implementation modules detail the requirement to monitor an oil slick for the effectiveness of the dispersants.
Monitoring of dispersant concentrations in water	✓	Monitoring of dispersant in water	Operational module O2 provides for monitoring of dispersant concentrations in water.
A record of the volumes of dispersant used in both subsea and surface application will be kept throughout the response.	✓	Records of dispersant volumes	The OPEP instructs IMT to record daily dispersant operations (types, volume and locations).
Dispersants will be targeted at areas of thickest oil and considerations of oil type, amenability and volume will be assessed prior to any dispersant application.	✓	Targeted dispersant application	The Exxon Mobil Oil Spill Response Field Manual details techniques for aerial and vessel ~~and to a lesser extent, subsea~~ dispersant application.
Surface dispersants only applied in daylight hours	✓	Surface dispersant only applied within daylight hours	Spraying surface oil slicks in daylight hours ensures that dispersants are targeted in areas where the oil is the thickest and helps prevent overdosing or application of dispersants in areas that will not be effective. Response during daylight hours also has significant benefits in reducing safety risks (e.g. night time flying) to personnel.
Verify effectiveness of dispersant application	✓	Additional monitoring will be implemented to verify dispersant use is effective and implemented as expected	Water monitoring (as in OSMP Module O2) will be used to monitor concentrations of hydrocarbons and dispersant in the water column.

Table 5-5 Engineering Risk Assessment

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Lab based efficacy testing for surface application on all Esso crudes against all of the dispersants detailed in table.	Provide a better understanding of the amenability of each Esso crude in relation to each dispersant stock.	The rationale for the selected 5 crudes for laboratory testing was that they represent a cross-section of the types of	Not Adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
		crudes produced in the Bass Strait. Results of testing can be found in OPEP Appendix E. Laboratory experiments and modeling are often limited by their inability to capture the complexity or scale found in the field. In the event of a spill, verification of incident specific dispersant effectiveness will be done before ongoing dispersant use occurs.	
Lab based efficacy testing for subsea dispersant injection using Esso Gippsland crudes. As part of a joint industry project, SINTEF and Cedre developed lab scale tests for measuring dispersed oil droplet distributions. Test results have shown that droplet size distributions are affected by crude type, different dispersant products and dispersant concentrations. The overall outcome was that increased SSDI effectiveness was indicated by the formation of smaller droplets. The tests have not been broadly employed.	Provide a better understanding of the effectiveness of SSDI for specific crudes and dispersant to oil (DOR) ratios	Dispersant efficacy testing has not been undertaken for subsea conditions, but industry experience estimates a subsea amenability to dispersant of approximately 50-70% effectiveness. Laboratory experiments for SSDI effectiveness testing is not as mature and available as those used for surface dispersant effectiveness measurement. The use of modeling to estimate effectiveness is often limited by an inability to capture the complexity or scale found in the field.	Not Adopted
Dispersants are selected from the Oil Spill Control Agents (OSCA) Register, including grandfathered stocks, unless otherwise endorsed by the Statutory Authority.	Dispersants which have been pre-approved for use in Australia by AMSA are placed on the Oil Spill Control Agent (OSCA) Register. The AMSA Efficacy Test Protocol for the Register (AMSA 2012) lists the toxicity testing requirements that ensure products meet the requirements of acceptable practice for the National Plan, and products with a high acute toxicity (LC50 < 10 ppm, 96 hrs.) or containing prohibited substances are not permitted.	All dispersants proposed for use meet the OSCA requirements and are listed on the National Plan Register. Capability assessments have been completed based on the use of approved dispersants and have confirmed enough dispersant is available for the proposed response.	Adopted

5.4 Capability Assessment of Dispersant Application

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources to complete dispersant application activities in a timely manner. Calculations of needs are conservative and could be overstating requirements by 25-50%. The reason for this is that capability needs have been calculated based on treating all surface oil, and do not take into account that oil will quickly disperse and spread below the ideal thickness required for spraying. Using a combination of surface (aerial or vessel application) and subsea dispersant injection significantly reduces the overall volume of dispersants required as summarised in Table 5-6. The assessment concluded sufficient resources are available within acceptable timeframes to conduct this response. This section summarises outcomes of the capability assessment.

Dispersants will be sourced from Esso's own stock in addition those available from AMOSC, AMSA National Plan Stock and OSRL. There is potential to obtain additional stock from mutual aid, and dispersant manufacturers would be requested to increase dispersant production.

Based on the capability assessment for the scenario with the highest dispersant requirement (45 m^3/day), continuity of supply can be maintained drawing on stocks as follows in Table 5-7.

Table 5-6 Dispersant source

	Surface Application only	
	Surface (Day 1-98)	**Total (98 day)**
# Aircraft	4	-
Sorties	15 / day	1455
Aerial dispersant (m^3)	42 / day	4080
Vessel dispersants (m^3)	3 / day	294
SSDI (m^3)	N/A	N/A
Total volume (m^3)	45 / day	4371
Planning assumptions:	~~Day 1:~~ 1 x air tractor available on Day 1 with 2 additional aircraft available from Day 2. Fourth aircraft from Day 3. Day 1-98. Aerial dispersant needs based on treating 100% release volume @ 20:1 application rate. No allowance made for natural weathering. Day 1-98. Vessel dispersant volume based on treating 10% of release volume @ 20:1 application rate Capability requirements based on MLA workover WCDS scenario (Refer Volume 2, Section 6.7.2) which results in the largest spill volume.	

Table 5-7 Dispersant source

Source	Location	Day
Esso	Victoria	1 to 2
AMOSC (surface)	Australia - various	3 to 7
AMOSC SFRT (50%)	Western Australia	8 to 13
AMSA	Australia – various	14 to 20
Mutual Aid	Australia – various	21
OSRL	Singapore	22 to 42
OSRL	Southampton	43 to 83
GRN	Worldwide	84+

Figure 5-1: Dispersant Supply chain

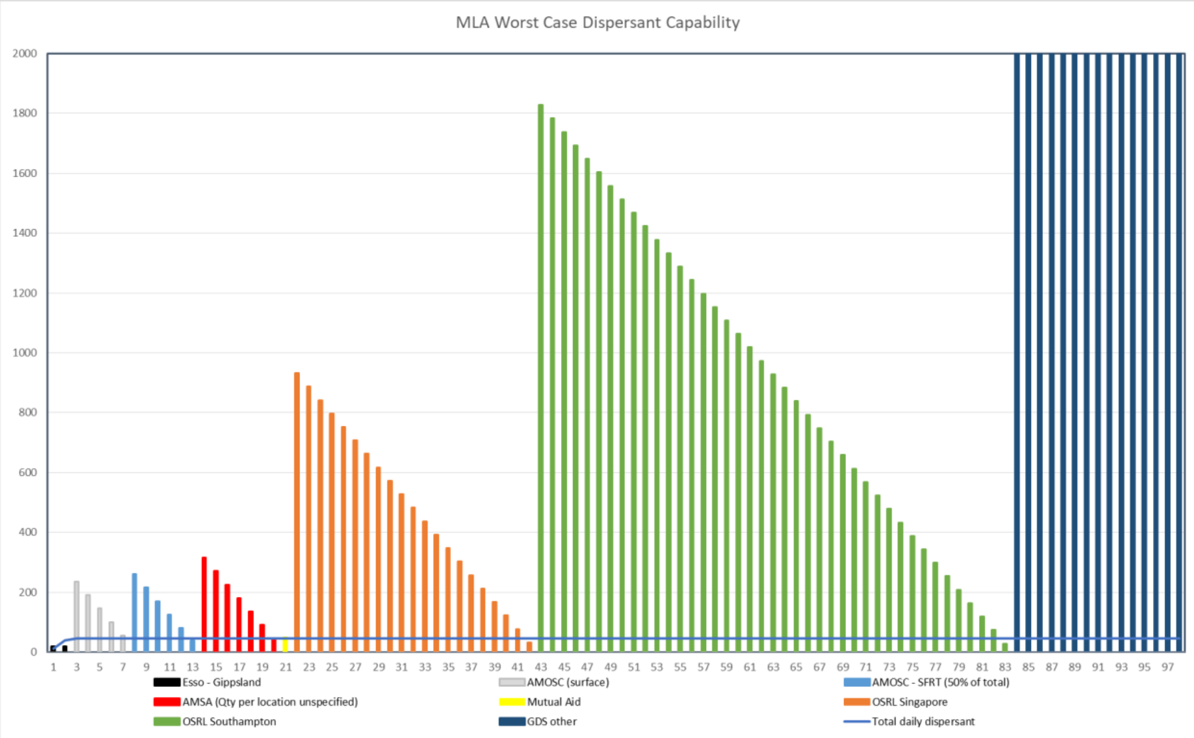

Table 5-8 Dispersant Application Resource Availability

Activity	Resource Required	Resource Availability	Expected Timeframe
Dispersant Stocks Available	4371 m^3 of dispersant based on the MLA WCDS using surface application only.	Dispersant stockpiles available in Australia between Esso, AMOSC, mutual aid and AMSA. Additional dispersant available from OSRL Global Dispersant Stockpile (GDS). GDS required after 21 days.	Victoria stockpiles <24 hours. National stockpiles <48 hours.
Dispersant Application from Aircraft*1	Ability to spray 42 m^3 of dispersant per day.	AMOSC (AMSA Fixed Wing Aerial Dispersant Contract (FWADC)) NatPlan. Air Attack Supervisor to be sourced under NatPlan arrangements to direct overhead spraying operations. Additional dispersant aircraft via OSRL.	Mobilisation of FWAD aircraft <4 hours of request for service. Dispersant application ability <24 hours. (*Note: Assumes good visibility, daylight hours and suitable flying conditions).*
Dispersant Application from Vessels	Ability to spray 4-6 m^3 of dispersant per day per strike team.	Esso Production support vessels loaded with dispersant and spraying equipment from BBMT. Agreements third party vessel operators. Vessels of opportunity are available at Barry Beach Marine Terminal, Lakes Entrance, Port Albert, Port Welshpool, Port Franklin and Mallacoota and Hobart.	1st team dispersant application ability <48 hours of request for service. 2nd team dispersant application ability <72 hours of request for service.

Activity	Resource Required	Resource Availability	Expected Timeframe
Testing Dispersant	Dispersant effectiveness test kit.	Access to 3 x test kits.	Available locally and within less than 48 hours of request.
ExxonMobil	Personnel Trained and capable Esso IMT Regional Response Team	Available to fulfil roles in accordance with requirements and timeframes in OPEP Table 3-2. Remote support <12 hours from notification. In-country support <72 hours from notification.	ExxonMobil

Table 5-9 Dispersant Application Capabilities

Good Practice	Adopted	Control	Rationale
Access to dispersant and dispersant application equipment for initial response.	✓	Esso owned dispersant stocks.	Esso owns stock of dispersant volume (estimated 12m^3) is available to mobilise for the first 24 hours of a response.
		Esso owned dispersant application equipment.	Esso have dispersant application equipment in Victoria and available to mobilise when required.
Pre-arranged access to additional dispersant stockpiles and equipment for applying dispersant.	✓	Agreement with AMOSC for dispersant capabilities.	Response capabilities maintained per service level statement including access to mutual aid and the National Plan (which provides dispersant stockpiles).
		Agreement with OSRL for dispersant capabilities.	Response capabilities maintained and available per OSRL service level statement.
Pre-arranged access to vessels for dispersant application.	✓	Support vessel.	The support vessel that is used for ongoing Esso operations can be used for dispersant application.
	✓	Agreement with third party suppliers for provision of additional vessels.	Agreement with supplier of vessel services has provision for supply of additional vessels
Pre-arranged access to personnel to support Tier III response activities.	✓	ExxonMobil Regional Response Team	ExxonMobil have a global team available to assist response for Tier III activities.

Table 5-10 Consideration of Additional/ Alternative/ Improved Capability for Dispersant Application

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Quarterly AMOSC equipment availability review.	Provides status update on available equipment.	No cost associated with this control.	Adopted.
Dispersant and application equipment stored on vessel.	Reduce time to apply dispersant.	No cost associated with control.	Adopted.

6. Containment & Recovery

6.1 Response Option Description

Containment and recovery involves controlled collection and recovery of oil from the water's surface. The response typically involves the deployment of booms and oil skimmers from suitable vessels, as well as the collection, transfer and disposal of oil and oily water recovered during the response. Floating barriers or booms are used to enclose the spilled oil on the sea surface into a suitable surface thickness, to allow its mechanical removal using a recovery device such as a skimmer, which pumps the oil from the water surface into temporary storage. The oil and water mix are stored temporarily in vessel tanks on the deck or in internal tanks. Recovered sea water may need to be decanted and returned to the sea to free up storage capacity and enable greater volumes of oil to be recovered without making the potentially long voyage back to port, increasing the effectiveness of the Containment and Recovery. The decanted water will contain traces of hydrocarbons and cannot be discharged unless approval has been provided by AMSA.

Effective containment and recovery can reduce the potential risks and impacts associated with:

- Marine fauna;
- Sensitive shoreline environments;
- Shoreline response; and
- Waste generation.

Containment and recovery is often considered the primary or preferred response option due to the minor impact of its operation on the environment, however, the overall effectiveness of containment and recovery can be limited by a combination of operational constraints and the fate of the oil on the surface (e.g. thickness and patchiness) which may include but not limited to:

- Weather: suitable weather and sea state conditions, which is estimated at <50% of the time in the Bass Strait
- Logistics: availability of suitably equipped vessels, aerial surveillance support and adequate facilities for the storage and disposal of oil and water;
- Personnel: availability of competent responders;
- Location: accessibility and transit time;
- Health and Safety: health effects from exposure to the oil and ability to safety deploy and use equipment; and
- Environment: increased environmental risks and impacts from increased vessels/ aircraft use and treatment/disposal of oily waste.

Experience has shown that the efficiency of at-sea containment and recovery operations can vary widely depending on the above constraints, and recovery is usually limited to between 5% and 20% of the initial spilled volume (IPECA /IOGP – At Sea Recovery - Good Practice Guidance). Esso propose to use containment and recovery as a targeted strategy to mitigate impacts of oil contact with sensitive receptors where other strategies have been ineffective (e.g. dispersants) or may not be viable (e.g. shoreline clean up where there are access issues).

Estimated recovery rates have been calculated based on the encounter rate of strike teams utilising 400 metre of boom with a 120 m swath width travelling at 0.5 knots. Upper and lower recovery rates were calculated based on Bonn appearance code thickness of 50 to 200 micron.

Advantages of containment and recovery:

- Containment and recovery removes hydrocarbon from the environment
- Reduces exposure to surface wildlife e.g. cetaceans, birds

Disadvantages of containment and recovery:

- Labour intensive
- Presents safety risks
- Generation of large volumes of contaminated water
  Increase in environmental impacts from response activities e.g. vessels

6.2 Environmental Impact Assessment of Containment and Recovery

Resources for offshore containment and recovery activities will include offshore vessels that will be mobilised from established ports. Nearshore containment and recovery activities are likely to be undertaken from smaller crafts that may be launched from a number of different locations along the coastline. Access to the crafts, equipment and transit to the affected areas may disturb local port operations, recreational activities, fauna and sensitive habitats.

The collection, handling and disposal of hydrocarbons introduces potential environmental impacts from the oily waste generated. The oily waste must be handled and disposed of correctly to prevent secondary contamination from contaminated equipment and decanting activities.

Environmental aspects associated with implementing containment and recovery were identified and evaluated in Table 6-1 and Table 6-2. Implementing this response option introduces new environmental aspects which are not assessed within Volume 2:

- Physical Presence - Nearshore and Shoreline Users (Socioeconomic)
- Physical Presence - Interaction with Fauna and Flora
- Waste generation and Secondary Contamination

6.2.1 Impact Assessment

An impact assessment for each environmental aspect has been undertaken and additional controls have been identified to minimise the environmental impacts associated with containment and recovery which are detailed within the ALARP assessment. Further assessment of the acceptability of these impacts in an oil spill response context and controls identified for minimising the environmental impact of containment and recovery activities are described below.

Change to the function, interests or activities of other users could occur through disruption to recreational and commercial activities from vessel operations and site access is assessed in Table 6-1.

Table 6-1 Environmental Aspect: Physical Presence - Nearshore and Shoreline Users

Affected Receptor	Impact Assessment	Consequence Level
Socioeconomic (fisheries, tourism, culture)	Recreational fishing is generally concentrated inside the Gippsland Lakes or along the Ninety Mile Beach coastline. Additional vessels and personnel in the area may cause disruption to fishing activities. The movement of personnel, vehicles and equipment may disturb or damage cultural heritage artefacts or sites. The mobilisation of equipment and personnel for containment and recovery operations will be localised. The Oil Spill Tactical Response Plans (TRPs) detail socioeconomic sensitives for each location. The response activities will be in accordance with state response agency directions and Esso will provide the incident specific NEBA, TRPs and Shoreline Protections Plan and support where requested. The additional presence of vessels and personnel will only be short-term and in localised area for the response period. Once the response has been stood down nearshore socioeconomic activities can resume without disruptions, therefore the consequence of the impacts of the response activity is considered to be Level III.	III

The environmental impacts associated with containment and recovery operations include:

- Water Quality – Decanting
- Physical Presence - Interaction with Fauna and Flora
- Physical Presence – Sensitive and protected areas and parks
- Waste generation and Secondary Contamination

Table 6-2 Environmental Aspect: Physical Presence - Interaction with Fauna and Flora

Affected Receptor	Impact Assessment	Consequence Level
Water Quality	Containment and recovery operations will generate large volumes of oily water. Within Australia, the recovered water may be decanted and returned to the sea with approval from AMSA. This frees up valuable storage capacity in the temporary storage device which would otherwise have to be emptied before response operations can continue. The discharge of the oil and water mix may lead to localised, short-term impacts. The consequence to the marine environment is considered inconsequential as the decanted water will have removed much larger volumes of the oil in the marine environment than was present from the spill incident.	III
Physical Presence - Interaction with Fauna and Flora	The sandy beaches, mangroves and salt marshes in the Bass Strait provide potential foraging and breeding habitat for numerous bird species and benthic communities. The flora and fauna within these habitats have the potential to be trampled due to increased numbers of personnel accessing sites. However, containment and recovery response activities primarily occur in the ocean with exception of haul outs and waste and equipment storage. Response activities should avoid sensitive areas unless they have been selected specifically for clean-up or OWR activities. Exclusion zones can be set up to protect these areas and minimise environmental impacts. Haul out sites will use existing road and paths for access to reduce environmental impacts associated with increased foot and vehicle traffic. Shoreline impacts are expected to be inconsequential and have no adverse effects.	IV
	Containment and recovery operations utilise booms which sit on the water's surface, therefore fauna capable of diving, such as cetaceans and pinnipeds can avoid contact. Pinnipeds are likely to be present in the largest number. Impacts to species that inhabit the water column such as sharks and fish are not expected. The noise of the vessel motors may have a positive effect on scaring marine fauna from the immediate area. The additional presence of vessels, equipment and personnel will only be short-term and in localised area for the response period, therefore, the consequence of the impacts of the response activity is considered to be Level III.	III
Physical Presence - Sensitive and protected areas and parks	Potential impacts to sensitive and protected areas may be impacted from containment and recovery activities. Human presence in sensitive areas may adversely affect important natural behaviors of biota, e.g. nesting of shorebirds and seabirds, or pinnipeds. Haul out sites for containment and recovery activities will use existing road and paths for access, therefore, the impacts to sensitive and protected areas and parks are expected to be inconsequential and have no adverse effects.	IV
Waste Management and Secondary Contamination	The Esso Bass Strait Oil Spill Response Waste Management Plan, details requirement for selecting waste management options, and equipment and storage to be utilised to prevent secondary contamination. The Tactical Response Plan - Shoreline Protection & Clean-Up and site specific Tactical Response Plans include information on staging areas and access points. The location of waste will be within the specified exclusion zone. The generation of waste will be short-term and is localised to the response area, for the duration of the response. Therefore, the	III

Affected Receptor	Impact Assessment	Consequence Level
	consequence of the impacts of the response activity is considered to be Level III.	

Table 6-3 Acceptability of Environmental Impacts from Containment and Recovery

Factor	Demonstration Criteria	Criteria Met	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity	✓	All the aspects related to containment and recovery have been evaluated as having the potential to result in a maximum Level III consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	All oil spill response activities are implemented with the aim of reducing the overall environmental impact. Containment and recovery activities may limit the volume of oil that could impact the shoreline and marine sensitivities.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	Activities will comply: • OPGGS Act 2006. • Protection of the Sea (Prevention of Pollution from Ships) Act 1983. • Marine Order 96 (Marine pollution prevention – sewage) 2013. • Marine Order 95 (Marine pollution prevention - garbage) 2013.
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to the containment and recovery however the controls proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations
External Context	Stakeholder concerns have been considered /	✓	No specific stakeholder concerns have been raised.

	addressed through the consultation process.		

Table 6-4 ALARP Demonstration of Environmental Impacts from Containment and Recovery

ALARP Decision Context and Justification	Decision Context A. Containment and recovery activities are standard practice for hydrocarbon spills to reduce hydrocarbons in the marine environment and minimise impacts to shorelines and marine sensitivities. There is a good understanding of potential impacts from containment and recovery. This response option would be supported by an incident specific NEBA. All activities undertaken in state waters will be led by the state control agency. Good Practice controls have been identified to ensure environmental impacts associated with mobilising this response are reduced to ALARP, these controls will be implemented in a response scenario and have been included in the OPEP. Esso believes ALARP Decision Context A should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**
Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class.	✓	Vessel Requirement.	The vast majority of commercial ships are built to and surveyed for compliance with the standards (i.e. Rules) laid down by classification societies. The role of vessel classification and classification societies has been recognised by the International Maritime Organisation (IMO) across many critical areas including the International Convention for the Safety of Life at Sea, (SOLAS), the 1988 Protocol to the International Convention on Load Lines and the International Convention for the Prevention of Pollution from Ships (MARPOL).
NEBA completed prior to conducting containment and recovery activities.	✓	Incident specific NEBA.	The NEBA takes into account the circumstances of spill, fate of the oil, potential environmental and social impacts and relative oil spill response options.
Containment and recovery operations only undertaken within daylight hours	✓	Containment and recovery operations only undertaken within daylight hours	Containment and recovery activities will only be undertaken in daylight hours to monitor the boom to ensure trapped fauna are released as soon as possible. Response during daylight hours also has significant benefits in reducing safety risks (e.g. injury) to personnel.
Ensure daily Containment and Recovery operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered)	✓	Daily records of oil recovered	Daily logs and records of containment and recovery operations demonstrate that CAR equipment was deployed safely, effectively and following consideration of environmental conditions.
Exclusion zones established	✓	Exclusion zones	The OPEP requires that exclusion zones are put in place which consider health and safety and environment risks. These exclusion zones are determined in consultation with the state control agency.
Discharge of de-oiled water (decanting) must meet MARPOL requirements.	✓	Decanting performed in commonwealth waters in accordance with MARPOL requirements.	MARPOL sets out requirements for discharge of de-oiled water (decanting) to avoid undue environmental impact. Decanting performed in commonwealth waters in accordance

			Prevention of Pollution from Ships) Act 1983, Section 9, subsection (2) (e)
Incident specific Waste Management Plan.	✓	Bass Strait Oil Spill Response Waste Management Plan	The Esso Emergency Response Waste Management Plan will assist in the development of an incident specific Waste Management Plan.

6.3 Capability Assessment of Containment and Recovery

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources to complete containment and recovery activities in a timely manner. The assessment concluded sufficient resources are available within acceptable timeframes to conduct this response.

This section summarises outcomes of the capability assessment.

Table 6-5 Containment and Recovery Resource Availability

Task	Resource Required	Resource Availability	Expected Timeframe
Containment & Recovery - Vessels	8 x vessels available for 4 x strike teams based on the MLA crude WCDS	Esso Support vessel. Agreement with third party vessel operators to supply additional vessels. Vessels of opportunity are available at Barry Beach Marine Terminal, Lakes Entrance, Port Albert, Port Welshpool, Port Franklin and Mallacoota and Hobart.	1x Vessel C&R strike team will be on site <48 hours of service request. 2x Vessel C&R strike teams will be on site <72 hours of service request.
Containment & Recovery Equipment	Equipment for 4 x vessel strike teams.	AMOSC Geelong stockpile 3x C&R systems. Fremantle stockpile 3 x C&R strike systems. OSRL Additional equipment available through OSRL. AMSA Additional equipment available through AMSA.	Load out from Geelong <4 hours service request. 7 C&R systems available in Victoria Additional 3 C&R systems available in Australia that can be mobilised to Gippsland within 72 hours.
Containment & Recovery Personnel	2 x trained and 4 x personnel per strike team.	Esso Core Group (10) AMOSC Staff (6) Core Group (50) OSRL Response Technicians (18)	Esso <24 hours from request AMOSC <24 hours from request of service
Waste Management	Onshore waste management arrangements.	Esso have a contract with a third party waste management service to provide transport and disposal of solid and liquid wastes. Refer Section 9.3.	<24 hours of service request.

Task	Resource Required	Resource Availability	Expected Timeframe
ExxonMobil	Personnel Trained and capable Esso IMT	Available to fulfil roles in accordance with requirements and timeframes in OPEP Table 3-2.	ExxonMobil
	Regional Response Team	Remote support <12 hours from notification. In-country support <72 hours from notification.	

Table 6-6 Containment and Recovery Resource Availability

Good Practice	Adopted	Control	Rationale
Pre-arranged access to vessels for containment and recovery activities.	✓	Support vessel.	The support vessel that is used for ongoing Esso operations can be used for containment and recovery.
	✓	Agreement with third party suppliers for provision of additional vessels.	Agreement with supplier of vessel services has provision for the supply of additional vessels.
Pre-arranged access to additional equipment for containment and recovery.	✓	AMOSC agreement.	Agreement with AMOSC provides access to additional containment and recovery equipment.
Pre-arranged access to additional labour.	✓	Personnel trained for containment and recovery activities	Agreement with AMOSC provides access to additional containment and recovery personnel.
Pre-arranged Waste facilities.	✓	Agreement with waste management contractor.	Waste arrangements for removal of waste to approved disposal or treatment facilities in accordance with EPA requirements.
Pre-arranged access to personnel to support Tier III response activities.	✓	ExxonMobil Regional Response Team	ExxonMobil have a global team available to assist response for Tier III activities.

Table 6-7 Consideration of Additional/ Alternative/ Improved Capability for Source Control for Containment and Recovery

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Standby dedicated emergency response vessel.	A dedicated standby emergency response vessel may reduce time required to implement containment and recovery activities and increase recovery capacity.	Significant costs are associated with leasing a suitable vessel. Given the high potential costs to the program, implementing this control measure is considered grossly disproportionate, given that the event has an extremely low likelihood of occurrence.	Not adopted.

7. Shoreline Protection and Clean-up

7.1 Response Option Description

Shoreline protection and clean-up consists of different techniques to prevent or reduce exposure of shoreline sensitives.

This shoreline response strategy is based on:

- Protection and deflection; and
- Shoreline response operations.

Advantages of Shoreline protection and clean-up:

- Deflection prevents oiling of sensitivities areas
- Clean-up removes hydrocarbon from the environment
- Reduces hydrocarbon exposure to wildlife e.g. cetaceans, birds

Disadvantages of Shoreline protection and clean-up:

- Presents safety risks
- Labour intensive response
- Increase in environmental impacts from response activities e.g. vessels
- May generate large volumes of waste

7.1.1 Protection and Deflection

Protection - Booms may be used to exclude slicks from targeted sensitive shorelines and/or amenities where it is safe and conditions permit access and effective deployment.

Deflection - Booms may be deployed at an angle to a drifting slick to divert oil away from targeted sensitive areas or to a collection point where it is safe to contain and recover.

Containment and Recovery – Near shore containment and recovery (refer to Section 6) may be deployed when there is little or no current and the sea-state permits.

This response is restricted by specific weather and metocean conditions and site accessibility. In strong winds, currents and/or waves this option may not be effective. In the event of an incident, the preparedness NEBA shall be updated with incident specific information to identify the priority sites for protection. Shoreline protection and clean-up will only be used as directed by state agencies.

7.1.2 Shoreline Clean-up

If a spill has reached or is predicted to reach the shoreline, an assessment of the area will be undertaken using the Shoreline Clean-up Assessment Technique (SCAT). This consists of a series of consistent and repeatable shoreline assessments that prioritise clean-up response based upon shoreline type. The assigned team will identify the appropriate shoreline clean-up technique, report the potential for, or any incidents of, oiled wildlife and undertake routine assessments throughout the response in terms of rehabilitation progress.

Shoreline clean-up consists of different manual and mechanical recovery techniques to remove oil and contaminated debris from the shoreline to reduce ongoing environmental contamination and impact.

Esso Australia and Cooper Energy have developed a Shoreline Protection and Clean-Up Plan and site specific Tactical Response Plans for Gippsland Basin oil and gas activities.

The plans outline the strategies that may be adopted and actions required to undertake safe and effective shoreline protection and clean-up response. The area assessed ranges from Port of Eden to Wilsons Promontory to Flinders Island in the Bass Strait (Figure 7-1).

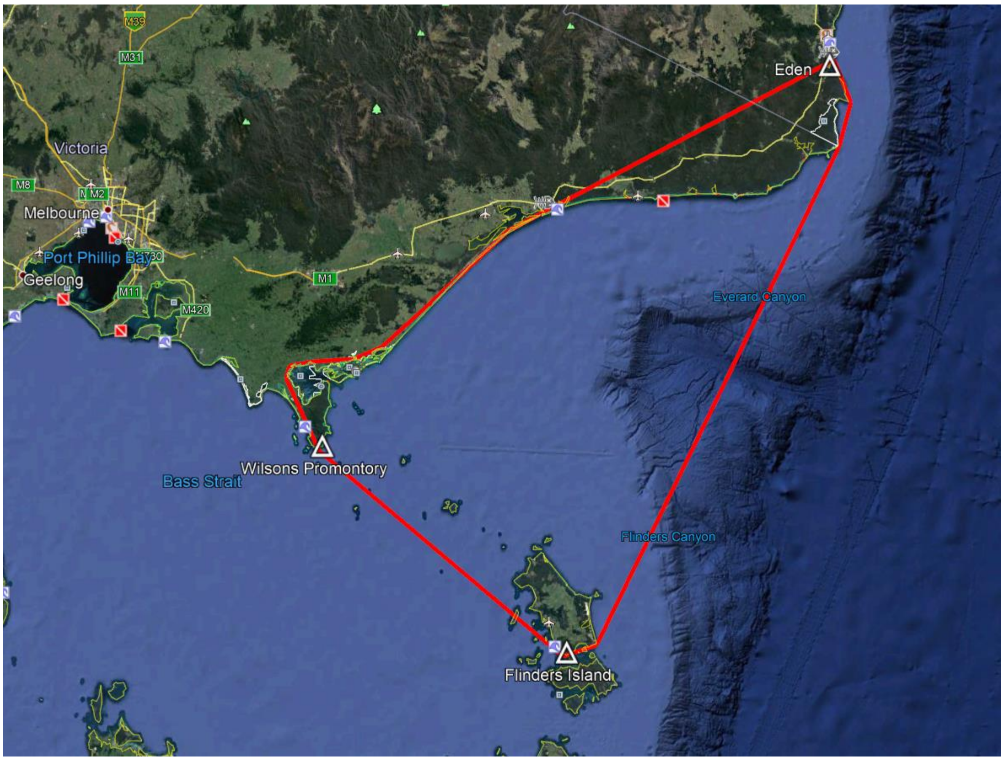

Figure 7-1 Overview of Gippsland Basin field locations

Tactical Response Plans (TRPs) are available for primary, secondary and tertiary sites that have been assessed and chosen based on appropriate access for shoreline response, shoreline type and key sensitive receptors. The application of Global Information Systems (GIS), cross referenced with the Oil Spill Response Atlas sensitivity mapping was carried out prior to site visits to validate both the identification of specific sites as ‘high priority’, and the strategies proposed for shoreline response.

The TRPs are designed to be used by both the Incident Management Team and field responders. The TRPs include the following information:

- Site description;
- Site access;
- Site constraints;
- Main sensitivities;
- Facilities / services i.e. food / accommodation / medical facilities / vessel and equipment hire;
- Key local contacts i.e. land manager, local emergency services, port authority; and
- Images / diagrams marked with staging areas, access points and tactics to be implemented.

TRPs set out a series of tasks to be executed by responders and a breakdown of resources (personnel and equipment) required to implement each task.

The locations shown in Table 7-1 have pre-drafted TRPs which should be used to guide response planning. Development of additional incident specific response plans may be required for locations without a pre-determined plan.

The collection, handling and disposal of hydrocarbons introduces potential environmental impacts from the oily waste generated. The oily waste must be handled and disposed of correctly to prevent secondary contamination from contaminated equipment and decanting activities.

7.1.3 State Government Agencies

In response to a spill, a shoreline protection and clean-up response will be led by the respective state response agency.

The National Plan also provides guidance on shoreline clean-up techniques as outlined in National Plan Guidance Response, assessment and termination of cleaning for oil contaminated foreshores (AMSA 2015).

The State Governments of Victoria, Tasmania and New South Wales will ultimately decide, through their control agencies, how oil spill response operations will occur on these shorelines, however, Esso will make the Shoreline Protection Plan and Tactical Response Plans, incident specific NEBA and resources to support the response available. Liaison Officers will be exchanged between IMTs to manage a coordinated response.

7.2 Environmental Impact Assessment of Shoreline Protection and Clean-up

Nearshore shoreline protection activities are likely to be undertaken from smaller crafts that may be launched from a number of different locations along the coastline. Access to the crafts, equipment and transit to the affected areas may disturb local fauna, sensitive habitats, and cultural heritage areas and disrupt local recreational activities.

Shore clean-up activities may disturb a number of nearshore habitats as identified in the prepared Shoreline Protection Plans. The collection, handling and disposal of hydrocarbons introduces potential environmental impacts from the oily waste generated.

7.2.1 Impact Assessment

An impact assessment for each environmental aspect has been undertaken and additional controls have been identified to minimise the environmental impacts associated with shoreline protection and clean-up which are detailed within the ALARP assessment. Further assessment of the acceptability of these impacts in an oil spill response context and controls identified for minimising the environmental impact of shoreline protection and clean-up activities are described below.

Change to the function, interests or activities of other users could occur through disruption to recreational and commercial activities from vessel operations and site access, Table 7-2.

Table 7-2 Environmental Aspect: Physical Presence - Nearshore and Shoreline Users

Affected Receptor	Impact Assessment	Consequence Level

Socioeconomic (fisheries, tourism, culture)	Recreational fishing is generally concentrated inside the Gippsland Lakes or along the Ninety Mile Beach coastline. Additional vessels and personnel in the area may cause disruption to fishing activities. The movement of personnel, vehicles and equipment may disturb or damage aboriginal and non-aboriginal cultural heritage artefacts or sites). The presence of stranded oil and clean-up operations may require temporary beach closures. The mobilisation of equipment and personnel for shoreline protection and clean-up activities will be localised. The Oil Spill Tactical Response Plans (TRPs) detail socioeconomic sensitives for each location. The response activities will be are in accordance with state response agency directions and Esso will provide the incident specific NEBA, TRPs and Shoreline Protections Plan and support where requested. The additional presence of vessels and personnel will only be short-term and in localised area for the response period. Once the response has been stood down nearshore socioeconomic activities can resume without disruptions, therefore the consequence of the impacts of the response activity is considered to be to be Level III.	III

The environmental impacts associated with containment and recovery operations include:

- Physical Presence - Interaction with Fauna and Flora
- Physical Presence – Sensitive and protected areas and parks
- Waste generation and Secondary Contamination

Table 7-3 Environmental Aspect: Physical Presence - Interaction with Fauna and Flora

Affected Receptor	Impact Assessment	Consequence Level
Physical Presence - Interaction with Fauna and Flora	Shoreline clean-up activities could lead to damage to shoreline habitats from high-pressure washing, trampling of shoreline sediments, flora and fauna from vehicles and mechanical recovery techniques, and disturbance of shoreline biota by human responders and vehicles. The sandy beaches, lakes, mangroves and salt marshes in the Bass Strait provide potential foraging and breeding habitat for numerous bird species and benthic communities. Environmental impacts to intertidal shoreline habitats and communities may have indirect effects on the food chains, affecting the macro fauna communities which they support. In addition, the removal of habitat (such as sand from beaches) may also make them more vulnerable to ongoing erosion. The Tactical Response Plans (TRPs) detail environmental sensitives for each location and the OPEP states the requirement for setting up exclusion zones in conjunction with the state control agency. Response activities should avoid these exclusion zones, unless they have been selected specifically for clean-up or OWR activities. Shoreline clean-up activities may adversely affect important natural behaviors of biota, e.g. nesting of shorebirds and seabirds, or pinnipeds. Human presence may also cause ground disturbance due to manual raking and turnover of sandy beaches or intertidal flats to remove accumulations of weathered oil, which could affect sediment infauna, cultural heritage sites. The consequences will be localised and short term, it will recover quickly once activities cease.	III

Affected Receptor	Impact Assessment	Consequence Level
	Protection and Deflection activities utilise booms which sit on the water's surface, therefore fauna capable of diving, such as cetaceans and pinnipeds can avoid contact. Pinnipeds are likely to be present in the largest number. Impacts to species that inhabit the water column such as sharks and fish are not expected. The noise of the vessel motors may have a positive effect on scaring marine fauna from the immediate area. Protection and Deflection response activities primarily occur in the ocean with exception of haul outs sites. The mobilisation of equipment and personnel for shoreline protection and clean-up activities will be localised. The Oil Spill Tactical Response Plans (TRPs) detail environmental sensitives for each location and the OPEP states the requirement for setting up exclusion zones in conjunction with the state control agency. Haul out sites will use existing road and paths for access, therefore, the shoreline impacts are expected to be inconsequential and have no adverse effects. The additional presence of vessels, equipment and personnel will only be short-term and in localised area for the response period, therefore, the consequence of the impacts of the response activity is considered to be Level III.	III
Physical Presence - Sensitive and Protected Areas and Parks	Potential impacts to sensitive and protected areas may be impacted from Shoreline protection and clean-up activities. Human activity in sensitive areas may adversely affect important natural behaviors of biota, e.g. nesting of shorebirds and seabirds, or pinnipeds. Human presence may also cause ground disturbance due to manual raking and turnover of sandy beaches or intertidal flats to remove accumulations of weathered oil, which could affect sediment infauna, cultural heritage sites, temporary exclusion of residents and tourists from amenity beaches. Haul out sites for protection and deflection activities will use existing road and paths for access, therefore, the impacts to sensitive and protected areas and parks are expected to be inconsequential and have no adverse effects. The Oil Spill Tactical Response Plans (TRPs) detail environmental sensitives for each location and the OPEP states the requirement for setting up exclusion zones in conjunction with the state control agency. The consequence to sensitive areas is assessed as localised and short term, it will recover quickly once activities cease.	III
Waste Management and Secondary Contamination	Accidental loss of waste during recovery, transport and disposal activities may result in secondary contamination. The Esso Bass Strait Oil Spill Response Waste Management Plan, details requirement for selecting waste management options and equipment and storage to be utilised to prevent secondary contamination. The Shoreline Protection and Clean-Up Plan and site specific Tactical Response Plans include information on staging areas and access points. The generation of waste will be short-term and is localised for the response period, therefore, the consequence of the impacts of the response activity is considered to be to be Level III.	III

Table 7-4 Acceptability of Environmental Impacts from Shoreline Protection and Clean-up

Factor	Demonstration Criteria	Criteria Met	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity	✓	All aspects related to shoreline protection and clean-up activities have been evaluated as having the potential to result in a maximum Level III consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	All oil spill response activities are implemented with the aim of reducing the overall environmental impact. The purpose of shoreline protection and clean-up activities is to minimise the environmental impacts resulting from an oil spill.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	The proposed control measures align with the requirements of: • OPGGS Act 2006. • Emergency Management Act 2013 (Vic). • Emergency Management Act 1989 (NSW). • Emergency Management Act 2006 (Tas). • Wildlife Act 1975 (Vic). • EPBC Act. • Wildlife Act 1975 (Vic). • Nature Conservation Act 2002 (Tas). • National Parks and Wildlife Act 1974 (NSW).
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to the shoreline protection and clean-up however the controls proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised.

Table 7-5 ALARP Demonstration of Environmental Impacts from Shoreline Protection and Clean-up Activities

ALARP Decision Context and Justification	Decision Context A Shoreline protection and clean-up activities are standard practice for hydrocarbon spills to reduce hydrocarbons in the marine environment and minimise impacts to shoreline sensitivities. There is a good understanding of potential impacts from shoreline protection and clean-up activities. This response option would be supported by an incident specific NEBA. All activities undertaken in state waters will be led by the State Control Agency. Good Practice controls have been identified to ensure environmental impacts associated with mobilising this response are reduced to ALARP. These controls will be implemented by the state led control agency in a response scenario and have been included in the OPEP. Note that the response must be led by State Control Agencies, with Esso providing support and resources when requested. Esso believes ALARP Decision Context A should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**
NEBA completed prior to conducting shoreline protection and clean-up activities application operations.	✓	Incident specific NEBA.	The NEBA takes into account the circumstances of spill, fate of the oil, potential environmental and social impacts and relative oil spill response options.
Environmental consideration of Gippsland basin local shorelines.	✓	Primary & Secondary Shoreline Tactical Response Plans (TRPs).	Shoreline Protection Plan & Tactical Response Plans (TRPs) describe the shoreline types and have categorised primary and secondary sites which have been assessed and chosen based on appropriate shoreline response options, shoreline type and key sensitive receptors. These plans will be made available to the control agency.
Incident specific Waste Management Plan.	✓	Bass Strait Oil Spill Response Waste Management Plan	The Esso Emergency Response Waste Management Plan will assist in the development of an incident specific Waste Management Plan.
Ensure daily Containment and Recovery operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered)	✓	Daily records of oil recovered	Daily logs and records of containment and recovery operations demonstrate that CAR equipment was deployed safely, effectively and following consideration of environmental conditions.
Exclusion zones established	✓	Exclusion zones	The OPEP requires that exclusion zones are put in place which consider health and safety and environment risks. These exclusion zones are determined in consultation with the state control agency.

Table 7-6 Engineering Risk Assessment

Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
Shoreline protection and clean up only undertaken within daylight hours	Undertaking shoreline protection and clean up during daylight hours to ensure personnel can see sensitive environmental receptors and minimize impacts cause by unplanned interactions with flora and fauna.	Response duration will be extended.	Yes

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
	Response during daylight hours also has significant benefits in reducing safety risks (e.g. injury) to personnel.		

7.3 Capability Assessment of Shoreline Protection and Clean-up

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources to support the State Control Agency with an effective response in a timely manner. The assessment concluded sufficient resources are available within acceptable timeframes to conduct a response should it be required. The shoreline protection and clean-up capability assessment has been completed for planning and preparedness purposes. The State Control Agency will ultimately decide what strategies are to be implemented and the quantity and source of resources to be used during an incident.

7.3.1 Shoreline protection

Tactical response plans are used to assist in determining capability requirements, taking into account the specifics of the receiving environment.

Spill modelling is used to determine required resources to undertake shoreline protection and clean up. The ExxonMobil Oil Spill Response Field Manual [2014 edition], Section 12, Tables 12-1 to 12-23 is used to calculate resources for shoreline protection and clean-up including:

- Primary equipment required
- Size/type/description of equipment
- Numbers required
- Likely treatment rates and capacities

The above information is then aligned with shoreline protection planning based on location specific tactical response plans (TRPs) that have been developed for pre-identified priority locations (see Table 7-1). There exists the potential requirement to implement multiple TRPs during a single incident. EAPL considers the numbers and response timing requirements are conservative given that:

a. Modelling of the worst case minimum time to shoreline contact has been used, and;
b. Stochastic modelling results have been used to identify the potential TRP's that may need to be implemented concurrently, and;
c. Secondary TRP locations will not necessarily require a response, should the incident occur when the estuaries are closed.

The sum of resources required to implement the identified TRPs is summarised in the activity specific Quick Reference Guides. EAPL has also considered the concurrent implementation of the worst case scenario shoreline protection requirements which include the bulk of the TRPs, totalling 22 sites with the highest resource requirements, which are summarised in Table 7-10. While these calculations consider overall requirements, modelling demonstrates that oil will accumulate on different sections of the coast over time requiring a phased approach to resource deployment and implementation of TRP's. The below table provides an example of progressive personnel requirements using the phase of response concept as detailed in the OPEP. This approach has also been used to assess phased equipment needs and availability.

Table 7-7 Progressive Personnel Required - Shoreline Impact and TRP Activation

Assessment based on Seahorse Crude WCDS Modelling as a representative example of near shore loss of well control. Seahorse has now been plugged and abandoned.

Shoreline Receptor	hrs. to impact (>100 g/m^2)	Phase of Response	TRP Activated		Trained personnel based on TRPs

Shoal Haven	734		-				

7.3.2 Shoreline protection

Strategies and resource needs for shoreline clean up have been assessed based on the shoreline type within each sector of the coastline with >100 gm/m^3 predicted shoreline loading based on stochastic modelling outputs. An indication of the level of resources required is provided using spill resource calculations. The spill resource calculations provide an indication of the levels of resources required to respond based on a number of estimates and assumptions, taking into account best practice and utilising detailed data on the shorelines involved. A detailed explanation of the resource calculations is provided in Section 7.3.3. The figures provided represent a target resource estimate and can be applied across a variety of scenarios. The resource numbers indicated are for response on a continuous basis and do not reflect a rapid initial demand for resources with slow taper off over the duration of the response. Initial resource requirements can be scaled up as required to achieve quicker results on a smaller scale response, while a larger scale response may continue to escalate.

As well as the numbers provided through resource calculations, a capability assessment for shoreline clean up was conducted based on stochastic modelling using the maximum predicted shoreline loading for each sector. This method provides an understanding of the potential resource needs for all sectors of coastline that maybe impacted, however, significantly over estimates the resources likely to be required for an individual incident.

The modelling provides an indication of the outer limits of a response however additional resources may be required for locations beyond the identified Sub-LGAs. These resources have not been considered within the scope of the capability assessment and TRP's have not been prepared for locations with low probability of moderate shoreline impact (<10%) or where shoreline impact is predicted in a minimum contact time of >7 days. Operational monitoring will be used to inform the need for incident specific response plans for these locations.

7.3.3 Shoreline clean up capability methodology

Oil spill trajectory modelling based on worst case discharge scenarios has been used to calculate shoreline response capability requirements. The modelling outputs included a summary of potential shoreline impacts, probability of impact, maximum load on the shoreline, length of shoreline affected at > 10 gm/m^2, and the length of shoreline affected at > 100 gm/m^2.

A resource ccalculator was designed using the resultant shoreline impacts, lengths of shoreline affected, degree of oiling, and best practice spill response tactics and resourcing estimates to undertake those tactics. Calculations have been based on no other interventions, such as containment & recovery or chemical dispersants, being utilised and so represent resource needs significantly greater than would be likely in an actual response where a range of strategies would be utilised in combination.

The ExxonMobil Oil Spill Response Field Manual provides industry best practice guidelines and information which was utilised as the basis for typical resources required for particular strategies and recognised shoreline types.

The resource calculator spreadsheet uses the shoreline type to determine the response strategies, then calculates the recommended number of personnel and equipment to enact the strategy. Each shoreline type may require a combination of response strategies, so each strategy per shoreline type was assigned a likelihood percentage that it would be applied. The below table shows the shoreline type, along with the strategies and percentages used in the calculations.

Table 7-8 Shoreline Clean-up – Shoreline type and methodology used for clean-up

Shoreline Type	***Clean-up method to be used***	***% of oiled shoreline type for clean-up method***
1. Manmade structures	flooding	10%
	HP, ambient-water flushing	60%
	hot water flushing	10%
	natural recovery	20%
2. Rocky Shores (sheltered)	natural recovery	100%
3. Rocky platform / cliff face (exposed)	natural recovery	100%
4. Sandy beach (mixed sand/shell)	manual removal - light oil	20%
	manual removal - heavy oil	30%
	flooding	20%
	mechanical removal	10%
	natural recovery	20%
5. Tidal flats (mud/sand) and vegetative salt/brackish marsh	LP, ambient-water flushing	30%
	natural recovery	70%
6. Shallow seagrass	natural recovery	100%
7. Reef	natural recovery	100%
8. Mangroves	LP, ambient-water flushing	20%
	natural recovery	80%

The Resource Calculator provides for calculating resources for an entire stretch of affected coastline to be cleaned in a single day. Corresponding numbers for the resources required were very large and do not take into account:

(1) External factors that act as constraints on the effective deployment or control of these resources, or secondary damage that they could cause, or

(2) The fact that these resources take time to ‘ramp-up.’

Given that a response will commence with a first strike plan and escalate from lower initial numbers to those required to manage the clean-up in the longer term, having 100% of resources from an early stage is an inaccurate representation of resources required.

In a large-scale response it has been demonstrated that 100% of the resources are unable to be applied within 7 to 10 days as the sheer numbers and the scale of the operation would be unmanageable.

Based on examples of incidents, estimates, and physical comparison of the numbers that would be both manageable and reasonably required to clean up known sections of beach within the boundaries of the modeling output, a conservative figure of 10% was applied to the calculator to best represent a target resource estimate across the variety of scenarios.

The outputs from the calculator, while indicating the level of possible resources, are not an upper limit and the reduction factor can be adjusted. Scaling up a response quickly to affect a faster resolution for a smaller scale spill can be managed through multiplication of the original resource requirements. A more accurate, detailed analysis of the resources required during an escalating response could be produced by the Logistics Section.

The table below shows estimates from the ExxonMobil Oil Spill Field Manual versus output of the Resource Calculator and indicates a reasonable correlation between the two:

Table 7-9 Comparison between ExxonMobil Oil Spill Field Manual resource recommendations and Resource Calculator output requirements for SHA shoreline cleanup

ExxonMobil Oil Spill Response Field Manual					
		lightly oiled shoreline		heavily oiled shoreline	
No timeframe	Resources Required	2 km	100 km	2 km	100 km
	Workers	10 - 20	100 – 200	50 - 100	500 – 1,000
	Foremen	1 - 2	10 - 20	5 - 10	50 - 100
Resource Calculator					
	Resources Required	2 km shoreline		100 km shoreline	
10% capacity per day for duration of spill	Foreman	2		44	
	Worker	10		420	
	Specialised Operators	2		26	
	Total People	14		490	
100% capacity per day for duration of spill	Foreman	10		440	
	Worker	84		4200	
	Specialised Operators	6		260	
	Total People	100		4900	

If relative short section of shoreline is affected, then a valid response would be the allocation of 100% of the resources available to clean it up in a day. Conversely, if hundreds of kilometres of shoreline is affected, the allocation of 100% of the required resources immediately would present a number of practical problems that could not be overcome including:

- Exceeding span of control through the divisions, branches, and clean up teams at one or more Forward Operating Bases and staging areas,
- Overloading the carrying capacity of the regional community support resources (Accommodation, messing, ablutions, etc.),
- Overloading the response location environment (Crowded carparks, traffic on beaches, etc.), and

- Under COVID-19 conditions, exceeding the ability to maintain social distancing or accommodation/isolation arrangements.
- Managing the safety and security of personnel.

Contained within the Resource Calculator is an interface which requires the input of length affected and % of shoreline type for the affected area. From these it then produces a resource list, as per below table.

Total Oiled Shoreline (km)	21
% of shoreline cleaned in 1 day.	10
Shoreline Type	**%**
Manmade Structures	0
Rocky Shorelines (Sheltered)	0
Rocky Platform / Cliff Face (Exposed)	40
Sandy Beach (mixed sand/shell)	60
Tidal Flats (Mud/Sand) and Vegetative salt/Brackish Marsh	0
Shallow Seagrass	0
Reef	0
Mangroves	0
Shoreline Total	100.00%

Resources Needed

Wheel Barrows	9	18	36	54	72

Figure 7-2 Oil Spill Response Calculator extract

Analysis of the modelling allowed determination of shoreline areas that would be impacted. Potential impact zones with a probability of impact <10% were eliminated, leaving a comprehensive list of sites with 10% or greater probability of being impacted at or above the 10 g/m^2.

Comprehensive shoreline surveys using Google Earth imagery and cross referenced with a VIC DOT layer of shoreline types was used to categorise the shoreline makeup in each Sector. Shoreline types specified were then utilised in the calculations to determine strategies and resourcing requirements.

The combined total for the sectors affected in each scenario provides total resources required for that scenario.

In addition to personnel, the Resource Calculator estimates other required resources and is based on a number of assumptions. Taken from the ExxonMobil Oil Spill Response Field Manual for each of the recommended response strategies, the following have been applied relating to the personnel columns:

- Based on 14 day shifts of workers
- Based on oil stranding daily/Continuously
- Based on 1 primary crew and a replacement crew in rotation.
- Based on heavily oiled shorelines and resources required per km.
- Based on average of shoreline strategies for each shoreline type (described previously)

For the vehicles & vessels section, all totals were based on the resources required for a stretch of shoreline affected based on the strategy used as described above in the master calculations spreadsheet.

For the Manual equipment section:

- Shovels based on 1 per worker per week

- Rakes based on 1 per worker per week
- Pick based on 1 per worker per week
- Plastic bags based on 50 per worker per day (50*20 kg each = 1000 kg/day)
- Wheel Barrows based on 1 per team (5 persons) per week then replaced

Adjustment of the percentage of shoreline cleaned per day, or the percentage of shoreline strategy applied to a given shoreline type, the resultant resources required will change, however it must be pointed out that where a range has been presented, we have erred to the worst-case scenario to produce conservative figures.

Table 7-10 Shoreline Protection and Clean-up Resource Availability

Task	Resource requirement	Resource Availability	Expected Timeframe
O3: Shoreline Assessment Personnel	SCAT teams will comprise of: • 2 shoreline assessment trained (SAT) personnel (for primary TRPs) or 1 shoreline assessment trained person (for secondary TRPs) • State representatives • Operations and safety officers as needed Trained shoreline assessment personnel needed: • 3 in first 48 hrs • 9 in hours 48 – 96 • Up to 18 post 96 hrs Based on simultaneous implementation of all TRPs described in Table 7-7.	OSMP consultant has the following trained personnel available to respond. • 12 SAT personnel available within 24 hrs. of activation. • An additional 12 SAT staff are available within 14 days of activation. SAT personnel completing SCAT assessments in the first 48hrs will be made available to complete more assessments once initial SCAT assessments are complete.	12 field personnel to be mobilised within 24 hours of activation. Additional 12 field personnel to be mobilised within 14 days of activation.
Vessels for Shoreline Protection	12 x vessels* based on SHA crude WCDS.	Gippsland Ports have suitable vessels for nearshore response activities. Agreements with third party vessel operators to supply additional vessels. Vessels of opportunity are available at Barry Beach Marine Terminal, Lakes Entrance, Port Albert, Port Welshpool, Port Franklin and Mallacoota and Hobart.	6x vessels required within 24 hours
Shoreline Protection Response Equipment	3,250 m x Shoreboom 2,025 m x Near shore boom 1 x Offshore skimming system Anchor kits + accessories Based on simultaneous implementation of all TRP's from Merriman Creek (Vic) through to Nullica River (NSW)	<u>Esso/AMOSC (Geelong)</u> Shoreboom: 2,025m Near Shore boom: 6500m Anchor kits + accessories: 47 Offshore skimming system: 8 Temporary waste storage: 12 <u>AMOSC/AMSA/Mutual Aid</u>: Shoreboom: 5750 m	Esso/AMOSC (Geelong) <48 hours of request for service. Additional equipment <5 days of request of service

Task	Resource requirement	Resource Availability	Expected Timeframe
		Near Shore boom: 10975 m Anchor kits + accessories: 112 Offshore skimming system: 30 Temporary waste storage: 65	Refer to Quick Reference Guides for scenario specific requirements
Shoreline Protection Response Personnel	Up to 518 personnel based on the SHA crude WCDS.	State Response Team >200 trained personnel. AMOSC Core group <120 trained personnel (inc Esso). Esso Esso responders Agreements in place with labour hire companies.	State Response Team Notify <2 hours of incident. Initiate request to call out core group <3 hours.
Shoreline Clean-up Personnel	Up to 1926 personnel based on the SHA crude WCDS	Esso Esso responders Agreements in place with labour hire companies. AMOSC Core group >140 trained personnel (including Esso). State Response Team >200 trained personnel.	<48 hours of request for service. Refer to Quick Reference Guides for scenario specific requirements
Waste Management	Onshore waste management arrangements.	Esso have a contract with a third party waste management service to provide transport and disposal of solid and liquid wastes.	<48 hours of service request.
ExxonMobil	Personnel Trained and capable Esso IMT Regional Response Team	Available to fulfil roles in accordance with requirements and timeframes in OPEP Table 3-2. Remote support <12 hours from notification. In-country support <72 hours from notification.	

Table 7-11 Shoreline Protection and Clean-up Capabilities

Good Practice	Adopted	Control	Rationale
Pre-arranged access to personnel for O3 Shoreline Assessment	✓	Agreement with Third Party OSMP Consultant for personnel and resources required for implementation of OSMP.	Esso has an agreement in place with a Third Party OSMP Consultant who can provide access to personnel with the required training/experience for SCAT under OSMP module O3.
Pre-arranged access to vessels for shoreline protection.	✓	Agreement with third party suppliers for provision of additional vessels.	Agreement with supplier of vessel services has provision for the supply of additional vessels.

Good Practice	Adopted	Control	Rationale
Shoreline protection and deflection equipment available.	✓	Esso owned shoreline protection and deflection equipment.	Esso owns its own equipment that can be utilised for shoreline protection and clean up
Pre-arranged access to additional equipment for shoreline protection and deflection.	✓	AMOSC agreement.	Agreement with AMOSC provides access to additional equipment for shoreline protection and clean up equipment
Pre-arranged access to additional labour.	✓	Personnel hiring agreements.	Esso has personnel hiring agreements in place which can be utilised to provide personnel for shoreline protection and clean up activities.
Pre-arranged Waste facilities.	✓	Agreement with waste management contractor.	Waste arrangements for removal of waste to approved disposal or treatment facilities in accordance with EPA requirements.
Pre-arranged Heavy Plant Equipment	✓	Agreement with contractor for heavy lift equipment	Agreement with third party provides access to heavy plant equipment for shoreline protection and clean up.
Pre-arranged access to personnel to support Tier III response activities.	✓	ExxonMobil Regional Response Team	ExxonMobil have a global team available to assist response for Tier III activities.

Table 7-12 Consideration of Additional/ Alternative/ Improved Capability for Shoreline Protection and Clean-up

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Reconfigure and relocate equipment	Reduce mobilisation times.	Relocation of equipment will be costly. The current equipment location allows for rapid mobilisation to the priority shorelines which are most likely to be impacted based on modelling. Relocation of shoreline protection and clean up equipment will only bring minimal, if any, benefits in response capability. Esso has assessed that sufficient equipment is available in Tier I & II equipment stockpiles located in Victoria to support shoreline protection and response requirements during the initial response phase (first 48hrs).	Not adopted
Resource to implement shoreline protection strategies prior to minimum shoreline contact time.	Reduce environmental impacts to estuaries.	Stochastic modelling of 100 weather and current scenarios indicates a minimum time to shore of 20hrs (Lakes Entrance / Seaspray) at low threshold and 30hrs (Lakes Entrance) at moderate threshold, with other weather combinations indicating longer times to shore. Given the complexity of implementing tactical response plan at Lakes Entrance an estimated 103 personnel are required to implement the response strategies in up to five locations. Additional cost in maintaining response capacity of this size to implement TRP's prior to shoreline impact is disproportionate to the risk.	Not adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
		Esso has assessed that sufficient equipment is available in Tier I & II equipment stockpiles located in Victoria to support shoreline protection and response requirements during the initial response phase (first 48hrs).	
Agreement with response company	Access to additional shoreline protection and clean-up equipment and personnel.	Esso owns equipment that can be used for shoreline protection and clean-up and has an agreement in place with AMOSC and OSRL to allow access to AMOSC/OSRL equipment. Esso can provide some of its own responders, has agreements in place with labour hire companies and has access to personnel from AMOSC core group and OSRL. The cost of having an agreement in place with additional response companies outweighs the small benefit that would come from such an agreement.	Not adopted
Additional agreements in place with monitoring providers	Access to additional personnel for implementation of O3 Shoreline Assessment	There would be added costs associated with having additional agreements in place and assessing and maintaining the capability to respond. While the length of shoreline to be assessed is significant, the number of field teams only needs to be enough to stay 2-3 days ahead of the shoreline operations (IPIECA, 2014) in order to support the effective and timely implementation of shoreline cleanup and protection. The Third Party OSMP Consultant has access to up to 24 staff with shoreline assessment experience. Logistics planning based on the SHA WDCS ~~and TWA P&A WCDSs~~ affected TRP's indicates that based on a scaling up of resources this would be sufficient for the implementation of the OSMP O3 module. The resources available through the existing agreement easily meet this requirement. In the case of a Level 3 incident, Esso would draw upon relationships and/or agreements with SCAT specialists that will be called upon on a best endeavours basis.	Not adopted
Increase number of trained personnel	Additional trained personnel available who could direct untrained laborers.	There is a significant cost associated with increasing the number of trained personnel and maintaining training status. Esso has access to AMOSC core group and State Response Team trained personnel in addition to agreements with labour hire companies which is sufficient to meet required the capability. Should additional personnel be required to support a response, just in time training can be utilised to train labourers and management staff for these laborers.	Not adopted
Agreements with vessel operators	Rapid and guaranteed access to vessels in the event of a spill.	As described above, Gippsland Ports can provide suitable vessels for nearshore response activities. Some agreements are in place with third party vessel operators to supply additional vessels. Capability assessment indicates that vessel requirements are able to be met so the costs	Not adopted

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
		of additional agreements with vessel operators are not justified.	
TRP / GRPs for the whole coastline	Increased understanding of capability requirements beyond the areas currently covered by TRPs.	TRPs have been developed for priority sites that are appropriate for shoreline response, covering a large stretch of coastline. TRP's are supported by the Shoreline Protection & Clean Up Plan which provides non-location specific guidance. Given the low likelihood for shoreline exposure beyond this area, the benefit of addition TRPs is considered minimal.	Not adopted

8. Oiled Wildlife Response

8.1 Response Option Description

Coastal areas are most likely to have the largest number of affected wildlife from an oil spill given that coastal areas provide habitat for breeding and foraging as well as protection from the elements. The scale of the impacts to wildlife does not correlate with the amount of oil spilled but is dependent on factors such as the timing and location of an incident, the product type, oceanography and weather patterns, and the corresponding movements of species that feed, nest or generally inhabit a particular area.

Oiled wildlife response (OWR) is a combination of activities with the objective to minimise the impacts of an oil spill on wildlife (such as birds, mammals and reptiles) by both prevention of oiling where possible and mitigating the effects on individuals following an oil spill incident.

Oiled wildlife response consists of a three-tiered approach involving:

- Primary: Situational understanding of the species/populations potentially affected (NEBA, SCAT, aerial surveillance);
- Secondary: Deterrence or displacement strategies (e.g. hazing, visual flags/balloons, barricade fences; or pre-emptive capture); and
- Tertiary: Recovery, construction of operating unit, transport, waste management, veterinary examination, triage, stabilisation, cleaning/washing, rehabilitation, release.

The oiled wildlife response may lead to the survival of vulnerable wildlife populations. The level of oiled wildlife response required can be scaled up or down based on the predicted number of wildlife affected.

Site-specific wildlife reconnaissance would be undertaken on foot, by vehicle, by vessel or by aircraft, and should be conducted across areas potentially at risk. This activity is key to gather baseline information on the numbers of wildlife present and/or individuals oiled.

Information from the reconnaissance is then used to inform the NEBA and assist the IMT to select suitable response options.

Ongoing surveillance and monitoring may utilise surveillance and monitoring aircraft and vessel resources.

An Area Response Plan has been developed for Gabo Island which provides guidance on initial oiled wildlife response actions. A number of Species Response Plans have also been developed to provide responders with guidance on appropriate response strategies for individual species.

Advantages of oiled wildlife response:

- Protection / hazing methods may minimise oiling of wildlife;
- Reduces hydrocarbon exposure to wildlife e.g. cetaceans, birds

Disadvantages of oiled wildlife response:

- Presents safety risks;
- Distress caused to wildlife;
- Labour intensive
- Increase in environmental impacts e.g. generates waste and potential for secondary contamination

8.1.1.1 Protection of nesting/haul-out sites

Sensitive areas may be protected from the spill using protection and deflection (Section 7.1.1) and containment and recovery (Section 6) response options.

8.1.1.2 Hazing and deterrence

Hazing and deterrence are terms used for activities that are undertaken to prevent or discourage wildlife from entering contaminated sites or move them away from areas that are likely to be affected by the spill. A potential negative outcome of hazing can be disturbance of target biota with potential for behavioural impacts and stress-related responses.

8.1.1.3 Pre-emptive capture

Pre-emptive capture is the capture of healthy, unoiled wildlife and transporting them to an area that is unlikely to be affected by the spill. Potential negative impacts of this method is inadequate capture techniques that have potential to cause stress, exhaustion or injury to wildlife and pre-emptive capture could cause undue impacts when oiling is not certain.

8.1.1.4 Triage assessments

Depending on the numbers and species of animals affected from the spill, a triage assessment may be required to ensure the best chance of long term survival. The assessment process is typically undertaken by a veterinarian under direction of the state agency.

8.1.1.5 Rehabilitation centres for oiled wildlife

Rehabilitation methods have been developed that aim to effectively reverse the effect of oiling, and return the health of an oiled animal back to an assumed pre-oiling state. The key stages associated with rehabilitation are:

- Capture;
- Transportation;
- Stabilisation;
- Decontamination;
- Conditioning; and
- Release.

Potential negative impacts of wildlife rehabilitation are inefficient techniques at any of the above key stages can have the potential to cause injury, stress and pressures to wildlife.

8.1.2 Waste ~~management~~

OWR generates large volumes of waste contaminated with hydrocarbon attributed to large volumes of water associated with cleaning, washing and rehabilitating the oiled wildlife. Estimated volumes are provided in Table 8-1. Refer to Section 9.3 for waste handling.

Table 8-1 Estimated Waste Types and Volumes

Waste Type	Waste Volume	No. of Units	Estimated Volume
Waste Water	1 m^3 per unit (1 unit per bird)	50[1]	50 m^3
PPE	5 kg per unit	50[1]	250 kg, ~2 m^3

[1]Number of units based upon a Level 3 incident as described in DPAW (2014). This was considered to provide a suitable indication as to the number of units potentially exposed in lieu of any other appropriate estimation tool.

8.1.3 State Government Agencies

In response to a spill, an Oiled Wildlife Response will be led by the respective state response agency.

The State Governments of Victoria, Tasmania and New South Wales will ultimately decide, through their control agencies, how oiled wildlife spill response operations will occur on these shorelines, however, Esso will make the Shoreline Protection Plan and Tactical Response Plans and resources to support the response available.

8.1.3.1 Victoria

The DELWP (Department of Environment, Land, Water and Planning) has primary responsibility for wildlife impacted by marine pollution in Victorian state waters, which will be defined in the Victorian Emergency Wildlife Plan for Marine Pollution (under development) and the Victorian State Maritime Emergencies (non-search and rescue) Plan (SMEP).

8.1.3.2 Tasmania

The control agencies within Tasmania are Tasmanian Ports Corporation (Tasports) within port waters and the Tasmanian EPA outside of port waters. The state Tasmanian Marine Oil Spill Contingency Plan (TasPlan) is administered by the EPA and is integrated with the National Plan, the Tasports Oil Spill Contingency Plan, the Tasmanian Emergency Management Plan and the Tasmanian Oiled Wildlife Response Plan (WildPlan).

8.1.3.3 New South Wales

New South Wales Maritime is the control agency for marine pollution control incidents within state waters in accordance with the NSW State Emergency Management Plan (EMPLAN) and the NSW State Waters Marine Oil and Chemical Spill Contingency Plan which is a sub-plan of the EMPLAN.

If an incident occurs in Commonwealth waters and has the potential to enter state waters, State Agencies must be immediately notified and Esso will support and provide resources when requested. Esso personnel may also be deployed under the direction of State to undertake wildlife response activities, however only trained people can interact with oiled fauna species.

8.2 Environmental Impact Assessment of Oiled Wildlife Response

Nearshore OWR activities are likely to be undertaken on foot or by smaller crafts that may be launched from a number of different locations along the coastline. Access to the crafts, equipment and transit to the affected areas may disturb local fauna and sensitive habitats.

A number of activities associated with this response involve direct contact with wildlife e.g. pre-emptive capture, rehabilitation and cleaning animals, and their release. These activities will only be undertaken by trained personnel and vets.

Wildlife rehabilitation centres will be constructed where required and should include reliable systems for the supply of potable water, electricity, heating or cooling, and ventilation that meet the specific wildlife requirements as well as amenities for personnel including food and lodging, waste disposal and communications. The construction of rehabilitation centres for OWR activities will be controlled by the state agency.

One of the disadvantages of running a rehabilitation centre is that it generates large volumes of waste. There is also a potential for secondary contamination through the handling of oiled wildlife and waste generation. The oily waste must be handled and disposed of correctly to prevent secondary contamination from contaminated equipment and PPE.

8.2.1 Impact Assessment

An impact assessment for each aspect has been undertaken and additional controls have been identified to minimise the environmental impacts associated with Oiled Wildlife Response which are detailed within the ALARP assessment. Further assessment of the acceptability of these impacts in an oil spill response context and controls identified for minimising the environmental impact of OWR activities are described below.

Change to the function, interests or activities of other users that could occur through disruption to recreational and commercial activities from an OWR are provided in Table 8-2.

Table 8-2 Environmental Aspect: Physical Presence - Nearshore and Shoreline Users

Affected Receptor	Impact Assessment	Consequence Level
Socioeconomic (fisheries, tourism, culture)	Recreational fishing is generally concentrated inside the Gippsland Lakes or along the Ninety Mile Beach coastline. Additional vessels and personnel in the area may cause disruption to fishing activities. The movement of personnel, vehicles and equipment may disturb or damage aboriginal or non-aboriginal cultural heritage artefacts or sites. The mobilisation of equipment and personnel for OWR activities will be localised. The Oil Spill Tactical Response Plans (TRPs) detail socioeconomic sensitives for each location. The response activities will be in accordance with state response agency directions and Esso will provide the incident specific NEBA, TRPs and Shoreline Protections Plan and support where requested. The additional presence of vessels and personnel will only be short-term and in localised area for the response period. Once the response has been stood down nearshore socioeconomic activities can resume without disruptions, therefore the consequence of the impacts of the response activity is considered to be Level III.	III

The environmental impacts associated with containment and recovery operations include:

- Physical Presence – Interaction with Fauna and Flora
- Physical Presence – Sensitive and protected areas and parks
- Waste generation and Secondary Contamination

Table 8-3 Environmental Aspect: Physical Presence - Interaction with Fauna and Flora

Affected Receptor	Impact Assessment	Consequence Level
Physical Presence - Interaction with Fauna and Flora	The sandy beaches, mangroves and salt marshes in the Bass Strait provide potential foraging and breeding habitat for numerous bird species and benthic communities. The flora and fauna within these habitats have the potential to be disturbed due to large numbers of personnel accessing sites. Human presence may also cause ground disturbance due to construction of OWR rehabilitation centers. Fauna casualties from OWR techniques have the potential to result in an incremental effect on fauna populations (though oiling is expected to pose a greater risk). However, there is still the potential for the techniques to result in localised degradation of the environment or effects on individuals as opposed to population level. Hazing and pre-emptive capture of wildlife may result in the prevention of species accessing their preferred resources. This approach may also result in additional disturbance/handling stress without any benefit as many species tend to return to sites from which they have been moved. This may result in reduced reproduction and reduced energy stored for migratory animals. The incorrect handling of fauna may also result in increased stress levels and therefore increased fauna casualties. OWR activities will generally be conducted onshore. Wildlife rehabilitation centers will be set up in areas which have site access, electricity and amenities for personnel including food and lodging,	III

Affected Receptor	Impact Assessment	Consequence Level
	waste disposal and communications. The Shoreline Protection and Clean-Up Plan and site specific Tactical Response Plans include information on staging areas and access points, personnel shall use existing road and paths for access to minimise the impacts of increased foot and vehicle traffic. Fauna and flora interactions as a result of oiled wildlife response and shoreline clean-up techniques will be localised and short term. Flora and fauna are expected to recover quickly once activities cease.	
Physical Presence - Sensitive and protected areas and parks	Potential impacts to sensitive and protected areas may be impacted from OWR activities. There is a potential that personnel may have to travel through sensitive areas to access wildlife or conduct hazing, wildlife deterrence activities. The OWR activities may adversely affect natural behaviors of biota, e.g. nesting of shorebirds and seabirds. Human presence may also cause ground disturbance due to construction of OWR rehabilitation centers. The mobilisation of equipment and personnel for OWR activities will be localised. The Oil Spill Tactical Response Plans (TRPs) detail environmental sensitives for each location. Temporary exclusion zones can be set up to avoid sensitive areas. The environmental consequence to sensitive marine areas is assessed as localised and short term, it will recover quickly once activities cease.	III
Waste Management and Secondary Contamination	Wildlife response activities, specifically running a rehabilitation center, generates large volumes of waste. There is a potential for secondary contamination through the handling of oiled wildlife and waste generation. The Esso Bass Strait Oil Spill Response Waste Management Plan, details requirement for selecting waste management options and equipment and storage to be utilised to prevent secondary contamination. The Shoreline Protection and Clean-Up Plan and site specific Tactical Response Plans include information on staging areas and access points. The generation of waste will be short-term and is localised for the response period, therefore, the consequence of the impacts of the response activity is considered to be Level III.	III

Table 8-4 Acceptability of Environmental Impacts from Oiled Wildlife Response

Factor	Demonstration Criteria	Criteria	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity	✓	All the aspects related to oiled wildlife response have been evaluated as having the potential to result in a maximum Level III consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	All oil spill response activities are implemented with the aim of reducing the overall environmental impact. Mobilising an OWR is an inherent part of minimising the impacts from an oil spill incident on wildlife.
Legislative and other Requirements	Legislative and other requirements have been identified and met.	✓	Legislation and other requirements have been considered as relevant and include: • OPGGS Act 2006;

			• Protection of the Sea (Prevention of • EPBC Act; • Wildlife Act 1975 (Vic); • Nature Conservation Act 2002 (Tas); and • National Parks and Wildlife Act 1974 (NSW).
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	There is no standard related to oiled wildlife response, however the controls proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised.

Table 8-5 ALARP Demonstration of Potential Impacts of Oiled Wildlife Response

ALARP Decision Context and Justification	Decision Context A Oiled wildlife response activities are standard practice for hydrocarbon spills to minimise the impacts resulting from an oil spill on wildlife. There is a good understanding of potential impacts from oiled wildlife response activities. This response option would be supported by an incident specific NEBA. All activities undertaken in state waters will be led by the state control agency. Good Practice control(s) have been identified to ensure environmental impacts associated with mobilising this response are reduced to ALARP, these controls will be implemented by the State Control Agency in a response scenario and have been included in the OPEP. Esso believes ALARP Decision Context A should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**

NEBA completed prior to conducting OWR operations.	✓	Incident specific NEBA.	The NEBA supports the implementation of the response strategies, and an operational NEBA is undertaken throughout the emergency response.
Minimise impacts to coastal environmental sensitivities.	✓	Primary & Secondary Shoreline Tactical Response Plans (TRPs).	Shoreline Protection Plan & Tactical Response Plans (TRPs) that consider local environmental sensitivities and habitats are provided to the control agency.
Incident specific Waste Management Plan.	✓	Bass Strait Oil Spill Response Waste Management Plan.	The Esso Emergency Response Waste Management Plan will assist in the development of an incident specific Waste Management Plan.
Ensure daily OWR operations are recorded (numbers, type and status of fauna)	✓	Daily OWR Records	Daily logs and records of oiled wildlife response operations demonstrate that OWR was deployed safely, effectively and following consideration of environmental conditions.
Exclusion zones established	✓	Exclusion zones	The OPEP requires that exclusion zones are put in place which consider health and safety and environment risks. These exclusion zones are determined in consultation with the state control agency.

8.3 Capability Assessment of Oiled Wildlife Response

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources to complete oiled wildlife response activities in a timely manner. The assessment concluded sufficient resources are available within acceptable timeframes to conduct this response.

Oiled wildlife is led by the state government and a variety of organisations will provide resources to assist the response, therefore

Table 8-6 details the resources available by organisation.

Table 8-6 Oiled Wildlife Resources Availability

Organisation	Resource Availability	Expected Timeframe
DELWP	<u>Resources</u> 1 x OWR Kit Bairnsdale) 1 x OWR Kit (Colac) 1 x OWR Kit (Port Phillip) 1 x OWR Kit (Warrnambool) 1 x State-wide Trailer <u>Agreement - Phillip Island Nature Park</u> 6 x staff - Wildlife emergency response. 17 x Wildlife Team Leaders. 5 x IMT Members. Approx. 45 volunteers – Collection/Facility Operations/Rehabilitation. Approx. 20 staff – Animal Feeding.	DELWP will make the decision to stand up resources which are based in Victoria. They are expected to be available <24 hours from request for services.
ExxonMobil	<u>Personnel</u> 6 x Esso Australia IMT members with OWR training Regional Response Team - OWR Core Team 12 x Trained Personnel	Remote support <12 hours from notification.

Organisation	Resource Availability	Expected Timeframe
		In-country support <72 hours from notification.
AMOSC	Resources 2 x OWR Containers (Geelong and Fremantle). 4 x OWR Box Kits. Personnel OWR Coordinator 18 x OWR Industry Team Contingency Agreements Memorandum of Understanding with Phillip Island Nature Park Call off Contract with DWYERtech NZ. A minimum of two personnel teams, to fulfil role of facilities manager and facilities coordinator.	Geelong container available onsite <24 hours of request for services. Kits would be available at site <24 hours of request for services. OWR Coordinator <24 hours OWR Industry Team <48 hours DWYERtech available <24 hours of AMOSC request for service.
OSRL	Resources 3 x OWR Search and Rescue kits 1 x OWR Intake and Triage kit 4 x Cleaning and Rehabilitation kits 1 x Wildlife Rehabilitation Unit 50% of the above inventory is available during an incident. Agreements Sea Alarm 1 x Full time availability of one Sea Alarm expert for advice and potential mobilisation to the affected site. 1 x Full time availability of one Sea Alarm expert for advice and response support. This expert will not be mobilised but provide advice and support from Sea Alarm office in Brussels or OSRL Premises.	Singapore based equipment can be mobilized to Melbourne airport <72 hours. Can be activated 24/7 as part of a wider OSRL mobilization.
AMSA	Resources 4 x OWR Containers Personnel National Plan: State/NRT Personnel (>100 persons)	Available through NATPLAN. Containers process approximately 100 units per day. Deployment of such resources to the Gippsland region would be expected to take 48-72 hours (road travel) from request for services.
NSW Maritime	Resources 1 x OWR Container	Available through NATPLAN. Containers process approximately 100 units per day. Deployment to the Gippsland region would be expected to take 48-72 hours (road travel) from request for service.
WA Department of Biodiversity and Attractions	Resources 1 x OWR Container	Deployment to the Gippsland region would be expected >72 hours (road travel) from request for service.
Waste Management Contractor	Onshore waste management arrangements.	Esso have a contract with a third party waste management service to provide transport and disposal of solid and liquid wastes.

Organisation	Resource Availability	Expected Timeframe
		4,500 m^3 bulk hard waste (soil/sand). 3,000,000 L of liquid waste (oil in water).

Table 8-7 Oiled Wildlife Resources Availability

Good Practice	Adopted	Control	Rationale
Pre-arranged access to equipment and personnel to support OWR.	✓	Agreement in place with AMOSC.	Agreement with AMOSC provides resources and equipment required for OWR activities.
Pre-arranged access to equipment and personnel to support OWR.	✓	Agreement in place with OSRL.	Agreement with OSRL will provide equipment and personnel for OWR activities.
Pre-arranged access to personnel to support oiled wildlife response.	✓	ExxonMobil Regional Response Team	ExxonMobil have a global team available for OWR activities.
Agreement with waste contractor in place.	✓	Agreement with waste management contractor.	Waste arrangements for removal of waste to approved disposal or treatment facilities in accordance with EPA requirements.

Table 8-8 Consideration of Additional/ Alternative/ Improved Capability for Oiled Wildlife Response

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Develop OWR Management Plan for the Bass Strait.	Reduced time to implement strategy.	Regulations establish that the State is responsible for management of wildlife impacted by marine pollution and the State has established plans and arrangements for this hazard. In consultation with State agencies, Esso has developed an oiled wildlife area response plan for Gabo Island and also Species Response Plans to provide supplementary information for management of oiled wildlife.	Not Adopted.

9. Waste Management

9.1 Response Option Description

The response to an oil spill often results in the rapid generation and accumulation of large quantities of oily waste. Waste generated from an oil spill response may come in many forms including; oily solid and liquid wastes, contaminated equipment and wash water from recovery activities and a range of mixed consumables required by the response team and activities.

Emulsified oil, oiled sand, gravel and entrained debris can increase the volume of waste to many times the volume of oil originally spilt. This waste often exceeds the capacity of the locally available waste management infrastructure.

The quantity of waste produced from a spill is influenced by many factors, principally the quantity of oil spilled, the environmental fate of that oil and the clean-up strategy and techniques adopted.

Waste management within Australia is regulated and managed by each state independently through each states Environmental Protection Agency (EPA). The majority of waste management activities associated with an oil spill response from a Bass Strait operation would be undertaken within Victoria.

9.2 Impact Assessment of Waste Management

Impacts from the containment and recovery of waste offshore and from clean-up of shorelines impacted by oil have been described in Section 6.2 and Section 7.2 respectively.

Accidental loss of waste during recovery, transport and disposal activities may result in secondary contamination. Secondary contamination is the spread of oil to otherwise unpolluted areas via response activities associated with people, transport and equipment. Secondary contamination could lead to pollution of the environment adjacent to storage areas or runoff of waste into waterways.

The Esso Bass Strait Oil Spill Response Waste Management Plan, details requirement for selecting waste management options and equipment and storage to be utilised to prevent secondary contamination. The Shoreline Protection and Clean-Up Plan and site specific Tactical Response Plans include information on staging areas and access points (refer Section 9.3.2 for details).

The generation of waste will be short-term and is localised for the response period, therefore, the consequence of the impacts of the response activity is considered to be Level III.

Table 9-1 Acceptability of Environmental Impacts from Waste Management

Factor	Demonstration Criteria	Criteria Met	Rationale
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity	✓	The impacts associated with generation of waste during oil spill cleanup activities have been evaluated to have a potential Level III consequence.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	The proposed control measures align with the requirements of: • OPGGS Act 2006. • Emergency Management Act 2013 (Vic). • Emergency Management Act 1989 (NSW). • Emergency Management Act 2006 (Tas). • Wildlife Act 1975 (Vic).

Factor	Demonstration Criteria	Criteria Met	Rationale
			• EPBC Act. • Wildlife Act 1975 (Vic). • Nature Conservation Act 2002 (Tas). • National Parks and Wildlife Act 1974 (NSW). • Environment Protection Act 2018 (Vic) • Environmental Management and Pollution Control Act 1994 (Tas)
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist".
	Meets ExxonMobil Environmental Standards.	✓	The responsible management of waste collected from oil spills meets the Upstream Waste Management Standards which calls for consideration of the waste hierarchy. Further, the use of piles meets expectations of the Upstream Water Management Standard The Upstream Water Management Standards and standards for appropriate disposal of contaminated water.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives.	✓	Proposed control measures meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to clearly define and communicate OI requirements to contractors. • OIMS System 10-2 objective to ensure effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised.

Table 9-2 ALARP Demonstration of Environmental Impacts from Waste Management Activities

ALARP Decision Context and Justification	Decision Context A Waste management is a standard practice resulting from hydrocarbon spills cleanup. There is a good understanding of potential impacts from waste management activities and the regulatory requirements to manage waste in accordance with State based regulations. Good Practice controls have been identified to ensure environmental impacts associated with mobilising this response are reduced to ALARP. These controls

	will be implemented by the state led control agency in a response scenario and have been included in the OPEP. Note that the response must be led by State Control Agencies, with Esso providing support and resources when requested. Esso believes ALARP Decision Context A should apply.		
Good Practice	**Adopted**	**Control**	**Rationale**
Implement measures to minimise secondary contamination at temporary storage locations	✓	Implement measures to minimise secondary contamination at temporary storage locations	In order to minimise the potential impacts from secondary contamination at waste storage locations, each hot zone temporary holding site will have • bunding adequate to hold the daily bagged totals • will be initially sampled to establish baseline 'clean' levels for final restoration • access for waste removal vehicles to transit from cold to hot zones

9.3 Capability Assessment of Waste Management

A detailed capability assessment has been undertaken to ensure that Esso has access to sufficient resources available to manage waste as a result of spill clean up operations (both offshore containment and recovery (Section 6) and shoreline protection and clean-up (Section 7)) to ensure that waste is removed from clean-up sites and disposed of in a timely manner.

The availability of resources is assured through contractual arrangements with waste handling and processing providers, response agencies, industry bodies and labour hire organisations. Incident response planning is done in accordance with the Esso Waste Management Plan. These good practice measures are summarised in Table 9-3 with additional considerations shown in Table 9-4.

Table 9-3 Waste Management Resources Availability

Good Practice	Adopted	Control	Rationale
Pre-arranged access to vessels for waste management	✓	Agreement with third party suppliers for provision of additional vessels.	Agreement with supplier of vessel services has provision for the supply of additional vessels.
Pre-arranged access to additional equipment for waste management	✓	AMOSC agreement.	Agreement with AMOSC provides access to additional resources and operational personnel for shoreline protection and clean up equipment. Temporary waste storage, decontamination stations, PPE stockpile containers and transfer pumps are included
Pre-arranged access to additional labor.	✓	Personnel hiring agreements.	Esso has personnel hiring agreements in place which can be utilised to provide personnel for waste management activities.
Reduction of solid waste volumes	✓	Training / induction of response personnel in shoreline cleanup operations	Waste volumes can be reduced through provision of just in time training to response personnel with oversight by experienced personnel.
Pre-arranged Waste facilities.	✓	Agreement with waste management contractor.	Waste arrangements for removal of waste to approved disposal or treatment facilities in accordance with EPA requirements.

Good Practice	Adopted	Control	Rationale
			Pre-planning for transport, temporary storage and scale up of waste management arrangements.
Pre-arranged Heavy Plant Equipment	✓	Agreement with contractor for heavy lift equipment	Agreement with third party provides access to heavy plant equipment for shoreline protection and clean up.
Pre-arranged access to personnel to support Tier III response activities.	✓	ExxonMobil Regional Response Team AMOSC Team & Core group OSRL	ExxonMobil have a global team available to assist response for Tier III activities. ExxonMobil has an agreement with AMOSC and OSRL to provide highly trained personnel from within AMOSC's core group and staff.
Access to Shoreline Response Trailers	✓	2 x Shoreline Response Trailers owned by Esso	Trailers equipped with shoreline cleanup first strike equipment available for immediate deployment.
Incident specific Waste Management Plan.	✓	Bass Strait Oil Spill Response Waste Management Plan	The Esso Emergency Response Waste Management Plan will assist in the development of an incident specific Waste Management Plan.

Table 9-4 Consideration of Additional/ Alternative/ Improved Capability for Waste Management

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Additional, Alternative, Improved Controls were considered but none identified.			

9.3.1 Waste capability methodology

Waste management capability assessment is based on deterministic outcomes from modelling of the worst case discharge from the facility/field with the worst-case potential. For solid waste the Seahorse workover scenario of 127 kbbl total spill volume representing a LOWC from a crude well close to shore (Refer Volume 2, Section 6.7.2), is the scenario which resulted in the largest volume of oil ashore and is used to demonstrate capability of waste handling from shoreline cleanup. For liquid waste the Marlin (MLA) workover scenario of 519 kbbl total spill volume representing LOWC from a crude well in the northern fields (Refer Volume 2, Section 6.7.2), is the scenario which results in the largest spill volume and is also the scenario used to demonstrate capability of dispersant application in Section 5.4.

The assessments are conservatively based on an unmitigated amount of oil stranding on the shoreline for solid waste and for surface oil for liquid waste. While unmitigated volumes have been used for the capability assessments, the volumes of stranded oil and surface oil will be significantly reduced in a response situation through the use of offshore response strategies such as dispersant application which will reduce the amount of surface oil for offshore containment and recovery and will therefore also result in reduced volume of oil being stranded ashore and the quantity of waste generated as a result of cleanup.

Whereas capability has been demonstrated on this SHA scenario, Esso's capability to respond is not limited to the areas described by this scenario. The response capability is designed to enable response to the areas that could be affected by a spill from the Bass Strait activities described in Volume 2.

Capability for handling waste is determined for the duration of the spill scenario (98 days), however it is important to note ~~noting~~ that:

- Victoria DoT will have a major influence on waste streams after the first 7 days,
- Victoria EPA and EM VIC will also impact waste stream decisions after 7 days.

Solid Waste

Table 9-5 shows the volume and distribution of oil ashore resulting from the SHA workover WCDS (deterministic model scenario [run 35]) which represents the largest volume of oil ashore for the Bass Strait operations activity. The total volume (without bulking) to be stranded ashore is predicted to be 3,123 m^3 affecting 14 sub-Local Government Areas, with a total shoreline length of 254 kms. The minimum time to contact is predicted to be 36 hrs, occurring at Ninety Mile Beach. Each location has been assessed based on the shoreline type (sand, rock, cliff, tidal flats etc.) to determine what proportion can be accessed to clean. The volume of oil ashore accessible to clean has been calculated based on the accessibility and a bulking factor of 10 times the volume of oil has been incorporated to allow for volume of sand and other material which is collected with the oil. The resources required to respond to this scenario spill are shown in the SHA Quick Reference Guide (QRG) (Refer Appendix A, OPEP). The QRG shows 1614 workers would be allocated for beach clean-up (807 per shift) and the table shows the workers distributed proportionally to the volume ashore at each location. Based on the assumption that the oil is stranded at a constant rate over the 98 day scenario period, the volume of waste generated per day is shown, assuming that 1 m^3 per/person/day is able to be cleaned per guidance provided in the ExxonMobil Oil Spill Response Field Manual. The volume of waste generated determines the number of trucks required per day at each location (based on 25T capacity per truck); for this worst case scenario this amounts to 13 trucks per day.

Table 9-5 Total shoreline waste volumes that may occur from a WCD Scenario (SHA crude deterministic [run 35]) - Basis for calculating resource needs

Location	Minimum time before shoreline accumulation (hours) >100 g/m^2	Max vol ashore deterministic m^3	Max length shoreline contacted deterministic	Sand %	Rock % (Sheltered)	Rock % (Cliff face/reef)	% Accessible	Avg onshore loading per day m^3	Avg onshore bulked to clean/day m^3	No of people cleaning	m^3 cleaned /day	Number of trucks needed per day	Days till full truck load collected

OWR Waste

Where oiled wildlife response (OWR) is required, it is managed by the state response agency with support from Esso through provision of resources such as fully equipped OWR containers including washing / storage facilities. The need for waste handling would be managed via the state. Based on Section 8.1.2 which identifies that for a Level 3 incident spill, per this scenario, an estimated total of 52 m^3 of OWR waste would be generated across the affected locations. This corresponds to approximately 2 – 5 trucks for handling non-flammable liquids over the duration and 1-2 trucks for solid wastes. Temporary storage would be provided at beach head control points at each impacted location and transferred to layup areas such as Longford if required before being transported to waste processing facilities.

Liquid Waste

The volume of liquid waste is calculated based on the volume of oil which is estimated to be recovered through the offshore containment and recovery strategy as described in Section 6 above. The resourcing requirements in each Quick Reference Guide (QRG) show the number of strike teams required for each spill, for the MLA Crude scenario (the scenario which results in the largest spill volume) used here to demonstrate capability, the QRG shows four strike teams will be needed to respond for offshore containment and recovery. The maximum volumes of oil and waste recovered is based on the highest volume (upper range) of oil that is predicted to be recovered each day by each strike team; therefore, the maximum volume of liquid waste per day is predicted to be 160 m^3, equivalent to 160 kL (40 m^3 x 4 strike teams). Table 9-6 shows the total waste liquid volume accumulated daily and over the duration of the spill scenario.

Table 9-6 Total liquid waste volumes that may occur from Containment & Recovery - Basis for calculating waste resource needs

Containment and Recovery	**Liquid Volume**		**Transport Needs**
	Lower range kL	Upper range kL	Trucks per day needed (Upper range)
Cleanup volume/ strike team/ day	5	40	
Number of strike teams	4	4	
Volume collected per day	20	160	6
Number of days of cleanup*	96	96	
Total amount liquid waste collected over 96 days	**1920**	**15360**	

*A conservative 96 days of cleanup is assumed with 4 strike teams, in practice the first strike team will be available within 48 hrs however the activation of 4 teams will take longer therefore reducing the volume of oil that is recovered in the initial days of the response.

Transport, storage and processing - VIC

Transportation of waste is provided by the waste contractor; Table 9-7 below shows the availability of trucks per day and their capacity. Table 9-8 provides additional equipment and temporary storage which is available within 48 hours and can be used in layup or temporary storage sites to facilitate the waste management process. Additional equipment will be hired by contractors through equipment hire services.

Table 9-7 Solid and Liquid Transport Capability Victoria

Transport**	Liquids		Solids
	ISO (Flammable)	Non Flammable	
Trucks per day	10	10	20
Volume per truck	30 kL	20 kL	25 T
Volume transported /day (1 trip each)*	300 kL	200 kL	500 T

** The number of trucks per day is based on 48 hrs+ from spill occurring, trucks are available prior to the 48 hrs but are not likely to be needed in that timeframe

*Capability is conservatively based on one trip per day per truck, multiple trips would be possible depending on the specific logistics requirements, although not needed for the scenarios presented in this EP.

Table 9-8 Additional equipment and temporary storage capability

Additional Resources	Resource		Available within 48 hours
Equipment	Cleanaway	EPA approved walking floor truck 24 t loads	3
	Fergusons	Rough terrain forklift	2
Temporary solid waste storage	Esso	Plastic drums (~200 liter)	70
		Skips approx. 15 m^3 (not suitable for transport when loaded)	5
	Cleanaway	Bulk bins hook lift 10 t pay loads;	2
Temporary liquid waste storage	Esso	Fast Tanks	5
		Stainless Steel IBC (2 kL)	15
		Plastic drums (~200 liter)	70
	AMOSC	Lancer barge (25 kL capacity)	4
		Deck Bladders (25 kL capacity)	6
		Viko Tanks (13 kL capacity)	2
		Fast Tanks	6
		Collapsible storage tank	4
		IBC (1 kL)	13
	Cleanaway	Poly Tanks (50 kL)	10

Accumulated waste is taken directly to designated waste facilities where waste can be stored and processed. Where waste volume exceeds processing rate, it is stored at the waste facility (where possible) or at offsite storage facilities where it can be progressively transported for processing.

Table 9-9 shows the storage and processing facilities available to Esso to handle solid and liquid waste. The table shows that waste facilities have capacity to store solid waste (up to 33,500 T) on site, however not liquid wastes. Where daily liquid waste volume generated exceeds the daily liquid waste processing capacity, the waste must be stored at offsite facilities and transported from there for processing. Esso's Long Island Point (LIP) facility has the capacity to store up to 63,000 kL in two separate tanks.

Table 9-9 Solid and Liquid Storage and Processing Facilities in Victoria

Facility	Liquids			Solids		
	Storage	Processing	Trucks/day	Storage	Processing	Trucks/day
	kL	kL /day	able to be processed	Tonne	Tonne/day	able to be processed
Waste Facility						
Dutson Downs		40	1.3			
Cleanaway Campbellfield		60	2			
Cleanaway Laverton		60	2			
Cleanaway Dandenong		60	2	200	60	2.4
Veolia Treatment Plant		60	2	2500	50	2
Renex Treatment Facility				25000	215	8.6
Environpacific				5500	725	29
Storage Facility						
Esso LIP Crude Oil Tank	60000					
Esso LIP Ballast Tank	3000					
Barry Beach Marine Terminal				300		
Total	**63000**	**280**	**9**	**33500**	**1050**	**42**

*The Esso Longford site can temporarily store solid waste subject to attaining an amendment to its existing licence for emergency purposes. Two separate areas have been identified that could store minimum 300 m^3 and 25,000 m^3 of solid waste respectively. Longford site would be used if required (primarily as a layup facility before transporting to waste facility) and its storage capacity would be in addition to that shown in the table above.

Figure 9-1 shows the storage and processing locations in Victoria in relation to the potential locations for shoreline accumulation per the modelling scenario. In this case, and as shown in Table 9-5, the highest volumes are accumulated at Marlo, Corringle, Ocean Grange and Lake Tyers.

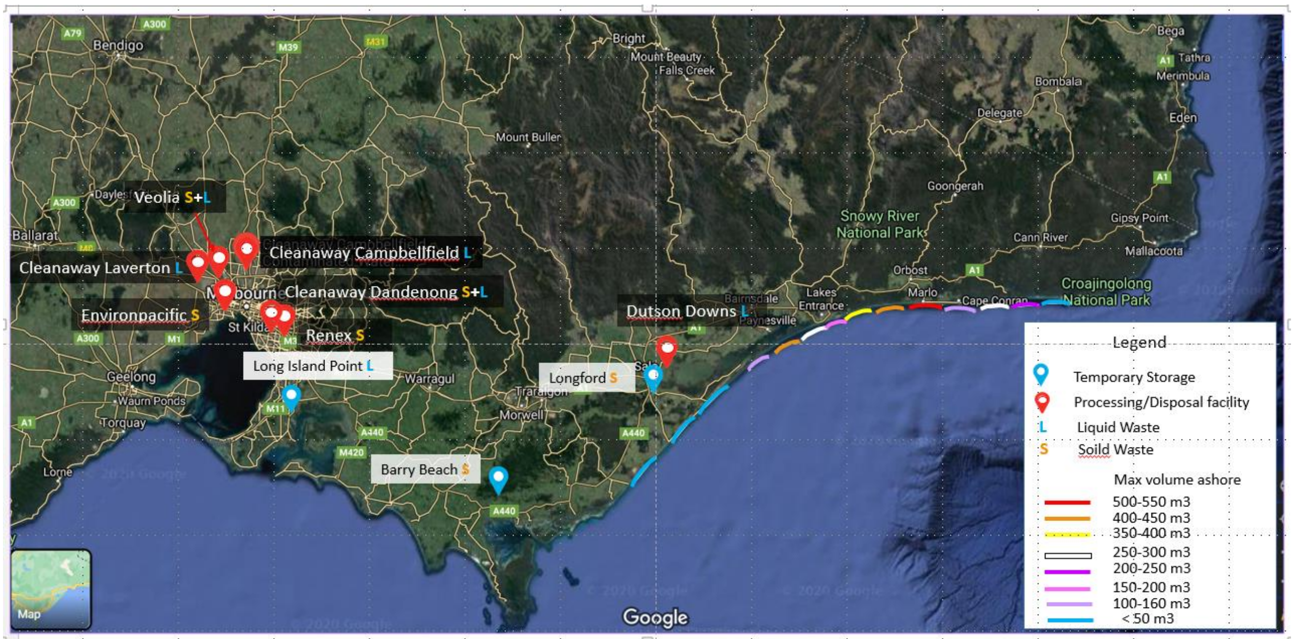

Figure 9-1 Waste storage and processing facility locations in Victoria, proximity to accumulation sites from worst case oil ashore scenario

Transport, storage and processing- NSW

If a spill reached shorelines in NSW, waste from beach clean-up would need to be processed in NSW. As offshore containment and recovery occurs near the source of the spill, it is unlikely that oily water waste collection/processing would be needed in the NSW. Table 9-10 shows transport availability in NSW. The locations available for storage and processing solids and liquids are shown in Figure 9-2. Processing capacity for NSW is shown in Table 9-11.

Table 9-10 Solid and Liquid Transport Capability NSW

Transport	Liquids		Solids
	ISO (Flammable)	Non Flammable	
Trucks per day	4	10	20
Volume per truck	20 kL	20 kL	25 T
Volume transported /day (1 trip each)	80 kL	200 kL	500 T

Figure 9-2 Waste storage and processing facilities in NSW

Table 9-11 Solid and Liquid Storage and Processing Facilities in NSW

Facility	Liquids			Solids		
	Storage	Processing	Trucks/day	Storage	Processing	Trucks/day
	kL	kL /day	able to be processed	Tonne	Tonne/day	able to be processed

Port Kembla Oily Water Treatment Plant		300	15			
Windsor	100	200	10			
Total	**740**	**580**	**29**		**3460**	**138**

9.3.1.1 Capability Summary Solid Waste

The theoretical worst case spill scenario for oil ashore (SHA workover scenario which represents the largest volume of oil ashore) predicts that 32,230 m^3 of bulked solid waste would accumulate over 14 locations on the Gippsland coast (refer Table 9-5). The daily quantities of waste collected is equivalent to the predicted amount of oil deposited ashore at each location each day, as sufficient workers for cleaning have been allocated to clean all of the oil stranded per day. Based on the daily quantity of waste collected each day (318 m^3), the number of trucks required for transporting the waste per day is 13 (refer Table 9-5). With twenty trucks being available each day for transportation of solids (refer Table

9-7), waste can be transported directly to waste processing facilities (refer Table 9-9) which have the capacity to process up to 1050 m^3 per day, or store up to 33,500 m^3 if processing was not limited. As also shown in Table 9-9, additional temporary or layup storage of solids is available at Longford, or Barry Beach Marine Terminal, closer to the affected receptor sites providing additional logistical flexibility (Refer Figure 9-1).

9.3.1.2 Capability Summary Liquid Waste

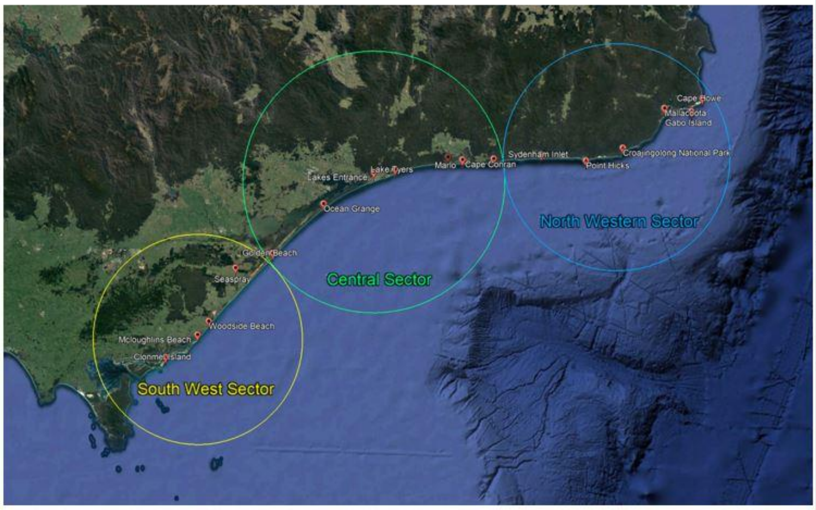
The QRG for the MLA theoretical spill scenario (the scenario which results in the largest spill volume) allocates four strike teams to enact offshore containment and recovery. The number of strike teams have been used to determine the upper range of liquid waste that would be generated, indicating that 160 kL/day would need to be handled each day for 96 days (refer Table 9-6). Liquid waste will be shipped to Barry Beach Marine Terminal where it will be offloaded directly into trucks. Table 9-6 shows that 6 trucks per day are needed to transport 160 kL, which can all be transported by ISO trucks able to handle flammable liquids if this was needed, without having to use the non-dangerous goods rated trucks. Esso would work with the transport company and the authorities to classify the liquid waste stream, however it is unlikely that all waste would be classified as flammable given it would be mixed with seawater and would have undergone some degree of evaporation and weathering.

As the waste facilities are able to process up to 280 kL/day (9 truckloads) of liquid waste, the waste would be taken directly to the facilities for processing without needing temporary storage (refer Table 9-9). If processing was not able to occur at this rate, liquids would be temporarily stored at the Esso LIP facility until such time as it could be processed.

9.3.2 Response Planning

The Waste Management Plan outlines collection and transfer methodology for the two primary waste streams – oil/water liquid stream (from offshore C&R activities) and oil/solid stream (from shorelines) as has been shown in Section 9.3.1 above. The waste plan would be enacted from Day 2 of a response to allow operational response strategies to be employed. This is consistent with the resourcing needs being shown from the 48 hr timeframe. Unmitigated marine oil spill modelling would be conducted at the time of the spill to evaluate shoreline response clean up requirements based on time of impact and geographic sectors that would likely be impacted by ~~an~~ the unmitigated marine oil spill, producing a listing and analysis of the receptors, likely volume ashore with time of predicted impact and accessibility at each location per the information provided in Table 9-5. This will form the basis for the development of incident specific response plans outlining shoreline sector designations, expected waste volumes and waste transfer processes for specific locations in each sector. The shoreline sector designations provide an overview of the scale of the response and allow a breakdown of the tasks into segments. Location specific plans within each sector describe the waste transfer process at that location with consideration given to site specific access points, hotspot storage locations and site specific equipment and resource needs. Figure 9-3 to Figure 9-5 show the overall sector designations and the central sector example for the SHA workover scenario (which represents the largest volume of oil ashore per Section 9.3) and an example of a corresponding Tactical Response Plan for one of the locations within the sector. While Esso has assessed resource requirements and has plans and necessary agreements in place to be able to execute those plans, the State Control Agency will ultimately determine how waste will be managed for any waste collected in State waters and shorelines. Through use of liaisons, Esso will coordinate access to plans and resources for waste management.

Waste Management – Overview FOR SHA WORKOVER SCENARIO	
Proposed Activity	Waste generated by shoreline clean-up teams will be collected from multiple coastal locations, transferred to centralised distribution points and then transported to designated waste treatment facilities.
Shoreline Sector Designations	The following sectors have been identified as likely to be impacted by oil from the Seahorse workover WCDS spill well location: **Sector 1 - Central Sector** **Sector 2 - South West Sector** **Sector 3 - North East Sector**



Sector Boundaries	
Map Extent	**Lat/Long**
Clonmel Is	**38°42'41.93"S** **146°42'9.00"E**
Cape Howe	**37°30'8.17"S** **149°58'42.51"E**
Potential Impacted Shoreline (kms)	**275 kms**
Predicted Total Waste Volume (WCD)	**31,230m³**

Figure 9-3 Example overall sector designations for SHA workover WCDS

Overview – Central Sector

Sector Boundaries	
Map Extent	**Lat/ Long**
Golden Beach	**38°13'41.69"S** **147°22'28. 11"E**
Cape Conran	**37°48'44.00"S** **148°43'41.85 E**
Potential Impacted Shoreline (kms)	**165 kms**
Predicted Waste Volume (WCD – 96 days)	**23,040m³**

Expected waste volumes (Per day)*			
Lakes Entrance	16m³	Lake Tyers Beach	28m³
Golden Beach	13m³	Marlo	55m³
Ocean Grange	44m³	Cape Conran	15m³
Lakes Entrance West	28m³		
Corringle	44m³	**Total**	245m³

Figure 9-4 Example Central sector designation for SHA workover WCDS

Lakes Entrance

	Waste Transfer process
1	Waste accumulated on shoreline is transported to collection points along each beach. Depending on local logistics and access for vehicles between shoreline locations, additional collection points may be used between beaches and vessel collection point.
2	Waste at collection points are transferred out of the hot zones and onto the vehicle access points at each decontamination station – vehicles are jet-washed to eliminate secondary contamination (into a bunded area) and the vehicle departs.
3	Hazardous waste is stockpiled at laydown area adjacent to both Lakes Entrance heads for transfer to B-Double.
4	Waste is either transferred to the nominated treatment facility or onto Longford waste temporary holding.

Logistics	Location	Requirements/Considerations
Primary Collection Point/s	Lakes Entrance beach (~34km) Various locations	Accessible by vehicle
Transfer Point/Laydown (Lakes Entrance East)	Eastern Beach road West of golf course 	Manual handling/mechanical lift capacity for offloading. Waste transfers to B-Double for onward movement to designated Waste Treatment Facility.
Transfer Point/Laydown (Lakes Entrance West)	Ocean Grange Track Beach Access Track 	4WD vehicles and trailers to be used for transport on Ocean Grange track, no B-Double access. Only road access to Lakes Entrance West.
Waste Treatment Facility	Primary: Dutson Downs waste treatment plant Secondary: Cleanaway Longford Gas Plant temporary storage	Pending acceptance of waste.
Personnel transfer	Great Lakes Airport (YGRL)	Regional airfield 6km North of Lakes Entrance
	Vehicle from Melbourne	~320km 4hrs.

Equipment	Units	Requirements/Considerations
25kg heavy duty plastic bags	1,760	= (27m^3/day x 40 per 1m^3) + (16m^3/day x 40 per 1m^3)
B-double truck and trailer combination	2	30t (m^3) per unit. 2 loads required per day.
Rough terrain forklift	2	One either side of the Inlet for each collection area.
UTV	2	Personnel transport in addition to 4WD and local vehicles
FOB/Sector command post	1	Facility portable office, or cabin onsite to coordinate movements

Figure 9-5 Example Tactical Response Plan for one response location within the Central sector for the SHA workover WCDS *continued overleaf*

1. Waste Management: Lakes Entrance			
Desired Outcome	Teams access the shoreline using appropriate vehicles/vessels at pre-determined sites (from SCAT recommendations) to remove waste accumulated by shoreline clean-up teams.		
Conduct	**Transport**	Vehicles/vessels capable of providing access to Lakes Entrance for team or teams of personnel (up to 25 pax) to manually or mechanically remove accumulated waste.	
		Vehicle (or potentially vessels) capable of transporting teams and equipment to and from pre-determined sites, and waste (plastic bag waste) from Lakes entrance West to Lakes Entrance East collection point.	
	Equipment		
	Offshore – for all vessels	Waste storage – sealed skips or containers capable of holding collected hazardous waste	
		Decontamination equipment – full decontamination of personnel and shoreline equipment	
		HSSE and First Aid equipment (May include specialist safety equipment related to the treatment of issues related to local region or environment)	
	Onshore	Waste storage – heavy duty plastic bags (Max 25lt)	
		Shoreline response tools and equipment (appropriate collection and cleaning equipment will require validation prior to or during deployment)	
		Site setup and site management equipment	
		Communications equipment (UHF, VHF, Satphone, Spot gen3, BGAN)	
		HSSE equipment including PPE and First Aid	
		Decontamination equipment – personnel decontamination to reduce potential for secondary contamination as personnel leave the shoreline.	
	Personnel	Divisional Command	HSE Safety Officers
		Sector Commands	General labourers
		Team Leads	Local Ranger
		Decontamination Teams	
	Method	All-terrain vehicles are used to transport personnel and equipment to pre-determined locations along the Lakes Entrance shoreline. Teams transfer by day from vehicle to the shoreline and conduct waste recovery operations. Welfare, equipment movements and waste collection are managed with ongoing vessel & vehicle support and teams are returned to the mainland overnight.	

Figure 9-5 Example Tactical Response Plan for one response location within the Central sector for the SHA workover WCDS

WWV	ExxonMobil Drilling Worldwide Ventures
VM	Vessel Master

1 Spill Response Operations

This section of the plan details the actions that Esso will undertake in the event of a hydrocarbon spill resulting from an Esso activity.

All staff are to be guided by the spill response incident flow chart in Figure 1-1.

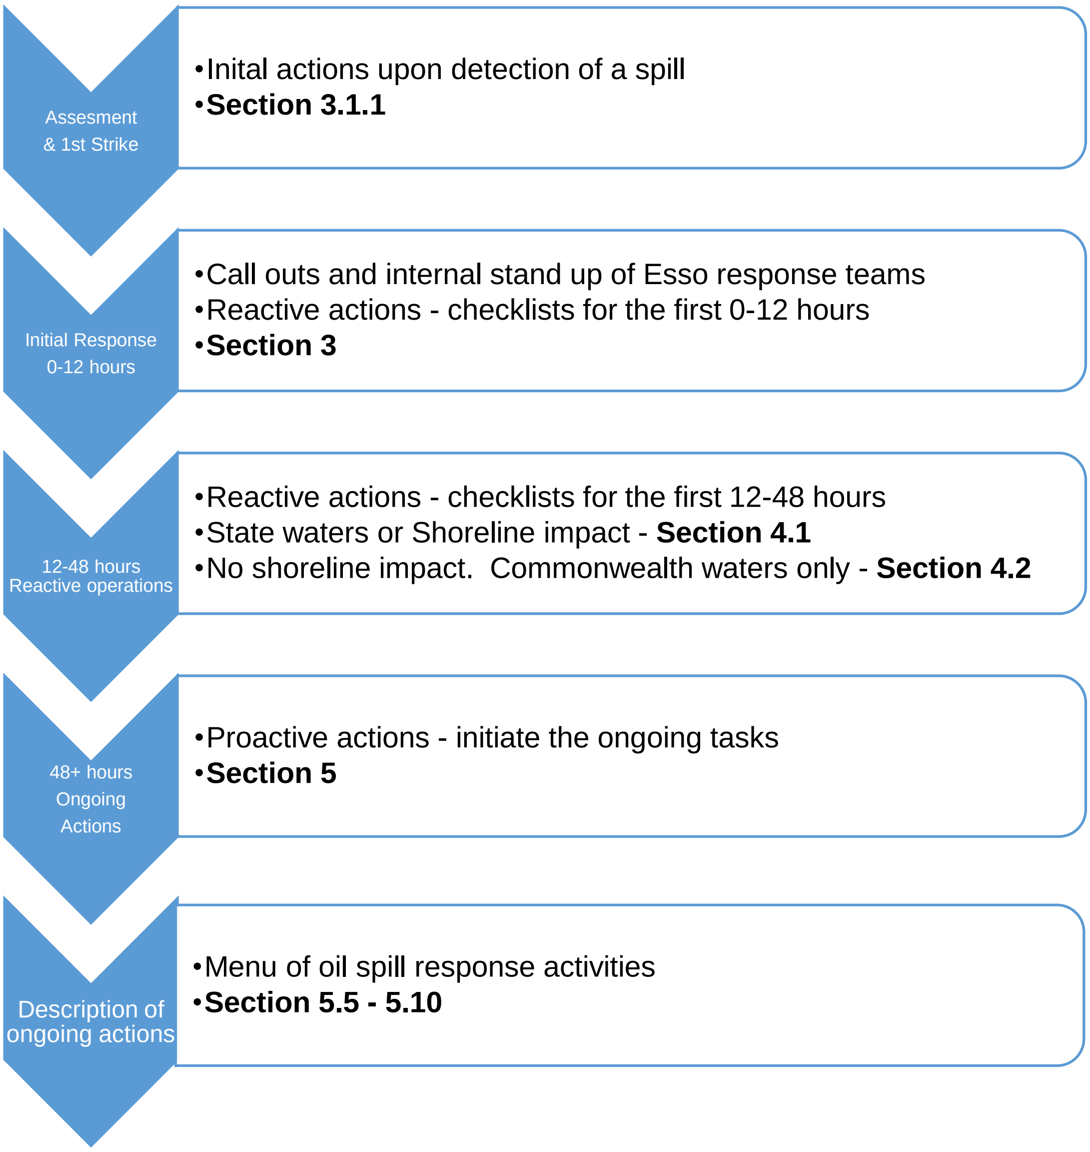

Figure 1-1 Spill Response Incident Flow Chart

Sustain spill response until termination end points (refer to Section 5) and environmental performance objectives are reached for each activity.

2 Quick Reference OPEP Information

2.1 Location

This OPEP applies to spills from petroleum activities linked to Esso's Gippsland Basin operations and project activities as described in Volume 2 (and Volumes 2a, 2b, 2c, 2d etc., hereafter referred to as Volume 2) of the Environment Plan.

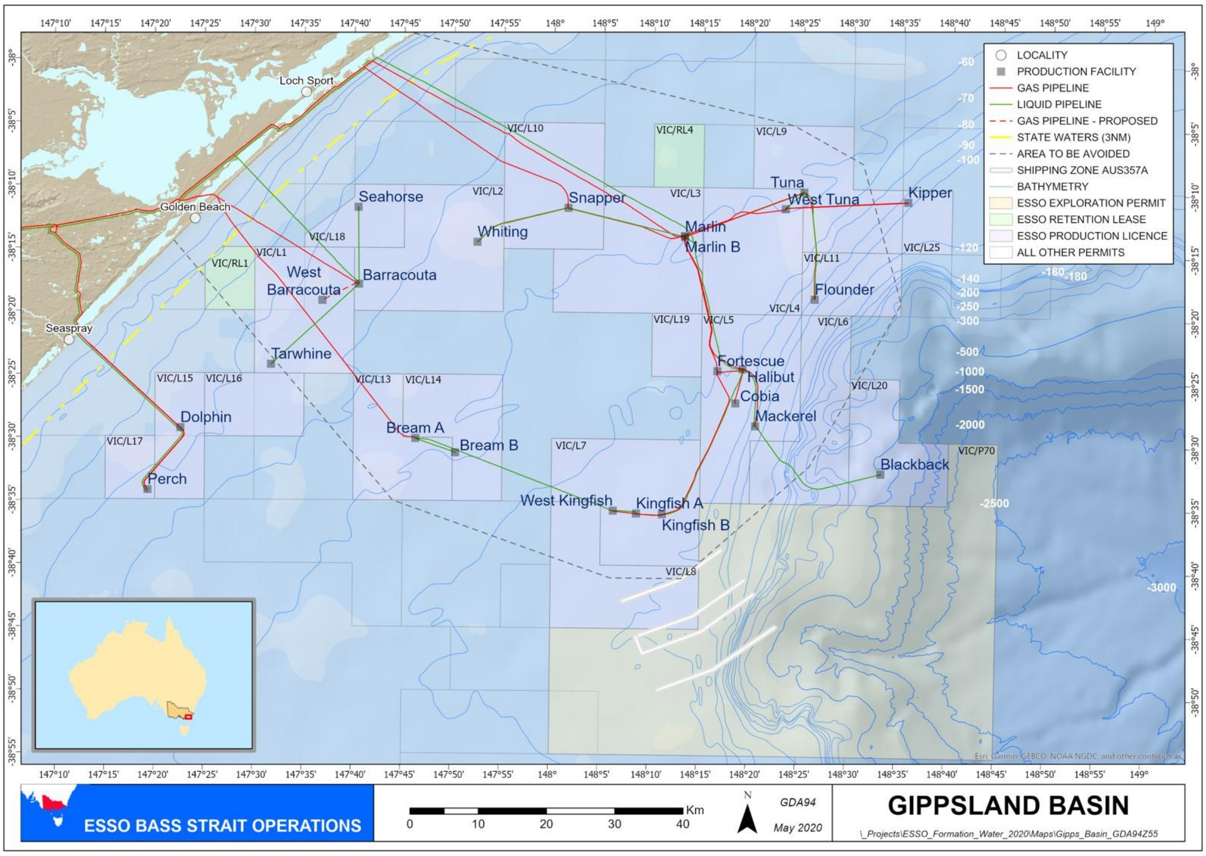

Figure 2-1 Asset Location

2.2 Potential Oil Types

- Condensates (Group I)
- Marine Diesel Oil (Group II)
- Light Crude (Group II)
- Persistent Crude (Group IV)

Properties of hydrocarbons used for modelling are detailed in Section 7.2.2.

2.3 Potentially Exposed Area

Stochastic spill trajectory modelling has been conducted to evaluate the effect of worst case discharge scenarios from Esso's Bass Strait petroleum activities.

In addition to the stochastic modelling, deterministic runs were also assessed and presented based on the following criteria;

1. largest volume of oil on shorelines;
2. longest length of shoreline contacted at or above 100 g/m^2 (actionable shoreline oil);

3. minimum time before contact to nearby shoreline by visible oil (0.5 g/m^2); and
4. largest swept area of oil on the sea surface above 10 g/m^2 (actionable sea surface oil).

The criteria listed above were determined for the "worst case" simulation between the modelled scenarios.

Appendix D - Quick Reference Guides provides maps and a descriptions of predicted impacts of the representative worst case scenarios.

An extensive description of the different types of sensitivities can be found in Volume 2 of the Environment Plan related to each activity.

3 Initial Oil Spill Response Actions – Assessment & Escalation 0–12 hours

3.1 Flowchart of Initial Processes

Upon detection of a spill, Esso will undertake a three-step process, as follows:

1. Assessment of Spill

↓

2. Notifications and Immediate Actions

↓

3. Stand Down or Monitoring or Escalation

Each step is outlined in greater detail below.

3.1.1 Assessment of Spill – Emergency Response Incident Management Teams

Upon detection of a spill, Esso will form a field-based Emergency Response Team (ERT), which will undertake the following actions:

- Begin a risk assessment in order to determine (and then execute) safety mitigations,
- Determine the size, bearing/trajectory and fate (weathering) of the spill,
- Judge the potential environmental impacts and the appropriate actions necessary to reduce those impacts,
- Execute any available source control options/first-strike response actions, and
- Notify the shore-based Esso duty IC of the incident await further instructions as to the appropriate actions to take.

The ERT is to use the following checklist as a way to direct these immediate steps.

Table 3-1 ERT Immediate Actions

ERT Immediate Actions			
Who	**What**	**Minimum time to implement**	**✓/✗**
Observer of Spill	Report the spill to the Offshore Installation Manager (OIM) or Vessel Master (VM).	ASAP	☐
OIM/VM	Secure operations, assess and report damage. Isolate spill source if it is safe to do so – implement pipeline de-pressurisation or leak response procedures. Refer to ERM V2-052-008 for response to unknown source.	ASAP	☐
OIM/VM	Ensure that all personnel are accounted for.	ASAP	☐
OIM/VM	Conduct a hazard assessment to determine the potential for fire, explosion, and hazardous/toxic vapours as well as to define the personal protective equipment (PPE) needed by responders.	ASAP	☐

ERT Immediate Actions			
OIM/VM	Implement spill mitigation measures to prevent further oil from entering the water, providing it is safe to do so. Activate the ERT as required.	ASAP	☐
OIM/VM	Report the incident to the Field Superintendent. The Field Superintendent is then to initiate upward internal communications to the Duty Incident Commander. Observe and include the following information in the brief: • Number of injuries. • Note ongoing immediate hazards to life (such as risk of fire or explosion). • Description of incident. • Location of the incident. • Status of source. • Time of incident. • People and assets involved in the incident. • Current field objectives/actions. • Details of support required from the Esso IMT.	ASAP	☐
OIM/VM	Observe and report on weather and sea states, including: • Current/tide-stream speed, direction and period • Wind speed, direction and period • Wave height and direction • Swell height and direction.	ASAP	☐
OIM/VM	Observe and determine the spill trajectory (manual estimation), noting: • The speed and direction of the spill.	ASAP	☐
OIM/VM	Observe and determine the likely spill type and volume: • Is the source contained, ongoing, isolated or stopped? • Provide a visual description of the slick (e.g. is it breaking up, floating, sinking, etc.) • What type of spill is it (diesel, gas, condensate, slops, light crude or waxy crude oil)? • Calculate/estimate the spill volume	ASAP	☐
OIM/VM	Observe and note any immediate sensitivities in the area at risk from the spill: • Note the presence of people, environmental sensitives (e.g. fauna, reef, etc.), as well as any of Esso's or other organisations' assets.	ASAP	☐
OIM/VM	Request helicopter overflight and commence regular surveillance of the spill. Evaluate spill weathering.	ASAP	☐
OIM/VM	Remain available to update the Offshore Incident Management Team.	Ongoing	☐
OIM/VM	Evaluate the incident and determine the incident classification/level based on the below national plan levels (refer to Table 3-3). Confirm this level with the on-call/duty Incident Commander.	ASAP	☐
OIM/VM	Report the incident to NOPSEMA as per Table 3-4.	ASAP and within 2hours	☐

Once the Duty IC has been notified of the spill, go to Table 3-2.

Table 3-2 IMT Immediate Actions

IMT Immediate Actions			
Who	What	Minimum time to implement	✓/✗
Duty IC	Establish communications with the Platform/Vessel/ERT Leader, obtain situational awareness briefing and determine the next steps. Confirm the following details with the field-based team: • Incident details – what happened? • What are the current field operations? • What are the immediate incident objectives and priorities? • What support is required from the Esso IMT in order to execute the immediate objectives?	ASAP	☐
IC	Activate the Esso IMT – Deputy IC, OSC, PSC, LSC, SO and EUL, following which: • Provide an initial incident briefing to the Esso IMT • Commence the incident action-planning process • Commence the size-up of the incident • Establish incident response aim and objectives and offer support to the affected facility. • Begin working to meet incident and oil spill response objectives.	< 60 mins	☐
IC	Notify the ESG Leader of the incident and request ESG support as required.	ASAP	☐
IC	Notify SHE&S, P&GA and security of the incident.	ASAP	☐
IC	In conjunction with the PSC, EUL and the SHE&S team, determine and confirm the appropriate response level. Use the *Response Level Assessment* Table 3-3 below to drive this process.	4 hours	☐
IC, PSC and OSC	Determine the response required of Esso: • Stand down – no spill/no oil left • Level One – monitoring of site-based response until completion • Level Two or Three – significant field and IMT escalation with significant additional resources required.	5 hours	☐
Once ERT- and IMT-based assessment tasks are completed, move on to Section 3.1.2			

3.1.2 Notifications and Immediate Actions

Once a spill has occurred, the Esso IMT is required to complete several statutory notifications, which vary based on the spill level. Notifications and immediate actions are to be concurrently completed by different members and sections of the IMT.

As these tasks are completed, the Esso IMT should be aiming to mobilise resources in line with the following guide:

Table 3-3 Response Level Assessment & Resourcing Guide

Response Level Assessment

On the basis of information gathered by the ERT/IMT, and in conjunction with the PSC/SHE&S team, a spill level is to be determined using the following indicators:

Criteria	Level One Indicators	Level Two Indicators	Level Three Indicators
Type	Non-persistent oils (>50% loss after 24 hours)	Persistent oils (<50% loss after 24 hours)	Persistent oils (<25% loss after 24 hours)
Location	Located within a 3 NM radius of the spill location	Spreading/moving into adjacent waters, presenting a threat to state waters	Spreading/moving into state waters and shorelines
Direction/heading	Not moving/heading offshore	Heading onshore/towards state waters	
Spill status	Small single release	Ongoing/large single release	
Ecological impact	Isolated impacts/no impact; natural recovery expected within days/weeks	Significant impacts across a single area; natural recovery may take weeks/months	Significant impacts across a large area; recovery may take months/years
If any one of the above criteria are triggered, adopt the higher-level response until de-escalation can occur.			

Resourcing Guide by Level		
Level 1 Response	Level 2 Response	Level 3 Response
• Dealt with predominantly by the ERT, using existing Esso business-as-usual resources*. • Supported by Victoria-based Esso resources; may involve the use of AMOSC technical advice or resources. • Of short duration. • Requires Tier One (local) resources.	• Requires assistance external to the site and a formal command and control structure. • IMT and ERT stood up; planning ‘P’ process implemented as soon as possible. • ERT resources supplemented by AMOSC resources, Victoria State and NatPlan resources. • Of short or medium-term duration. • Potential for significant state government engagement (shoreline and P&GA). • Requires both Tier One and Tier Two resources.	• Requires expanded IMT and full use of ICS processes with multiple planning periods. • Planning ‘P’ process used fully. • Extensive external national and (potentially) global resources (both in terms of personnel and technical and equipment-based resources). • Results in a lasting campaign/project duration. • Requires significant state and Australian government engagement. • Tiers One, Two and Three resources mobilised.

**Esso activities involving other facility operators (e.g., MODU for a drilling campaign) may form agreements through bridging documents to coordinate Level 1 response activities within the assigned operating area (usually 500m radius from location).*

The required notifications are outlined in Table 3-4.

Table 3-4 Notifications

Notifications			
Who	**What**	**Minimum time to implement**	**✓/✗**
IC or Deputy IC	A reportable incident is one that has caused, or has the potential to cause, moderate to significant environmental damage (interpreted as the following): • Unplanned release of hydrocarbon liquid or chemicals exceeding > 80 L into the marine environment caused by, or suspected to have been caused by, petroleum activities. • Unplanned injury or death of a cetacean or listed threatened/migratory/marine species caused by, or suspected to have been caused by, petroleum activities. Required for: all spills > 80 L Ensure the NOPSEMA Duty Officer has been notified: Tel: 1300 674 472 Relay the known key facts of the spill – location, source, size and type – as well as incident factors causing the spill, and current assessed spill level.	<2 hours	☐
EUL	Follow up with a written record of the oral notification to NOPSEMA as soon as practicable.	As soon as practicable	☐
EUL	A written report must be provided to NOPSEMA as soon as practicable, but in any case within 3 days[1] of a reportable environmental incident (as described above) unless otherwise agreed by NOPSEMA. This report can be made on NOPSEMA report form N-03000-FM0831. A copy of the written report must be given to both NOPTA and DJPR ERR within 7 days of giving the written report to NOPSEMA.	<3 days < 7 days after report given to NOPSEMA	☐
Vessel Master	Required for: all spills from vessels. Notify the Rescue Coordination Centre: Tel: 1800 641 792 Follow up with the completion and submission of a pollution report. https://www.amsa.gov.au/forms/harmful-substances-report-polrep-oil Relay the known key facts of the spill – location, source, size and type – as well as incident factors causing the spill, and current assessed spill level.	<2 hours <24 hours	☐
EUL	Required for: all spills > 80 L Notify the DJPR ERR and NOPTA via email: Email: DJPR: Operational.reports@ecodev.vic.gov.au Email: NOPTA: reporting@nopta.gov.au Relay the known key facts of the spill – location, source, size and type – as well as incident factors causing the spill, and current assessed spill level.	<6 hours	☐

[1] As per Schedule 3 of the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) and as outlined in the NOPSEMA Notification and Reporting of Environmental Incidents Guidance Note N-03000-GN0926.

Notifications			
Who	**What**	**Minimum time to implement**	**✓/✗**
IC or Deputy IC	Requirement: all spills that could impact Victorian state waters (> 80 L). Notify the DOT SREC State Duty Officer: Tel: 0409 858 715 Email: semdincidentroom@ecodev.vic.gov.au Relay the known key facts of the spill – location, source, size and type – as well as incident factors causing the spill, and current assessed spill level. For Level Two and Level Three spills, exchange liaison officers between Esso and the DOT SREC.	<6 hours	☐
	Required for: all spills that could impact NSW waters. Notify the *Transport for NSW* Duty Officer of the need to stand-up state response arrangements. Transport for NSW Duty Officer: Tel: 02 9962 9074		☐
	Required for: all spills that could impact Tasmanian waters. Notify the Tasmanian DPIPWE of the need to stand-up state response arrangements. Tasmanian DPIPWE Pollution Incidents and Complaints: Tel: 1800 005 171 The initial verbal notification must be followed up by an email containing a more detailed Pollution Incident Report to incidentresponse@epa.tas.gov.au		☐
EUL	Required for: all spills that are within a marine park, or could impact a marine park. Notify the Director of National Parks via the 24-hour Marine Compliance Duty Office: Tel: 0419 293 465	<12 hours	☐
EUL	Required for: all spills that impact or have the potential to impact on matters of national environmental significance (NES) including protected and migratory species, Commonwealth Marine Reserves and Ramsar Wetlands. Notify the Department of Agriculture, Water and the Environment: Tel: 1800 803 772	< 12 hours	☐
Once all appropriate authorities have been notified, move onto the appropriate immediate actions tables, for levels **one, two** or **three** below, depending on severity.			

Following the notifications, immediate actions by spills level are as follows coded by planning, operations, and logistics sections/areas:

Table 3-5 Level One - 0-12 hour Actions

Level One 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
IC	In conjunction with the ESG leader, ensure all necessary regulatory notifications have been made.	12 hours	☐
IC	Commence the planning cycle (the 'stem' of the planning 'P'): • Establish incident aim • Establish incident response aim and objectives • Determine appropriate initial strategies and tactics to achieve objectives.	ASAP – <2 hours	☐
OSC	If the source is not controlled, establish a Source Control Branch to develop and implement the Source Control Plan.	ASAP	☐
OSC	Undertake aerial surveillance: • Deploy surveillance by crew change or contracted aircraft. • Initiate mobilisation of a trained aerial observer – Esso or AMOSC. • Obtain photographs or video footage. • Obtain completed aerial observer's report and pass to the PSC/SITL.	ASAP, then 2x daily	☐
OSC	Deploy a regular watch of the affected assets/vessel – confirm heading/changes to the situation.	ASAP then by reporting exception.	☐
LSC	Confirm the location of aerial and marine assets currently contracted to Esso.	4 hours	☐
PSC	Initiate specific elements of O1 of OSMP, including the tasks below.	ASAP	☐

PSC	Monitor and predict weather and sea states:
	• Consult meteorology services to determine water current and wind speed data, either from http://www.bom.gov.au, http://www.marineweather.net.au, or MetConnect (http://www.metconnect.co.nz):
	  ○ Username: Esso
	  ○ Password: basswx.
		4 hours	☐

PSC	Conduct a manual forecast of the spill trajectory: • Determine the direction of the spill. • Determine if the spill is likely to cross into state waters or shorelines or if it might impact other sensitivities.	4 hours	☐
PSC	Should oil cross into state waters or impact shorelines, organise third-party trajectory modelling of the spill trajectory: • Organise urgent oil-spill trajectory modelling via AMOSC, OSRL, or EMBSI.	4 hours	☐
SITL	Establish a common operating picture – a graphical representation of the spill and its location. • Display overflight, OSTM/manual vectoring data on CoP.	4 hours	☐

Level One 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
PSC	Prepare and disseminate SITREPs as more information becomes available. The IC is responsible for determining the frequency of these updates.	Ongoing	☐
PSC	Consult the preparedness NEBA and Appendix D – Quick Reference Information to identify potential exposed environmental sensitivities based on spill trajectory, and develop an incident action plan, including a spill-specific NEBA (ref OPEP 5.2).	12 hours	☐
EUL	Activate the OSMP 'O' modules 1.1, 1.2, 1.3 and 4.1	ASAP	☐
EUL	Review the OSMP to determine which other modules may need to be initiated.	ASAP	☐
Once these actions are complete, please move to **Section Four** of this plan			

* Ability to deploy subject to available daylight and weather conditions

Table 3-6 Level Two - 0-12 hour Actions

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
IC	Seek alignment on incident objectives from the ESG.	ASAP	☐
IC	In conjunction with the ESG leader, confirm all necessary regulatory notifications have been made.	<2 hours	☐
IC	Commence the planning cycle (the 'stem' of the planning 'P'): • Establish the incident response aim. • Establish the incident objectives. • Determine appropriate strategies and tactics to achieve objectives.	ASAP – <6 hours	☐
IC	Establish a locally based Esso IMT, including representatives from the Deputy IC, Ops SC, Aviation Unit, Log SC, Planning SC, Environmental Unit and Situation Unit.	<2 hour	☐
IC	Establish a line of communications with DOT IMT and exchange Liaison Officers.	ASAP – <2 hours	☐
IC/OSC/PSC	Determine and agree on the need for a separate Source Control Branch	ASAP	☐
OSC	If the source is not controlled, establish a Source Control Branch to develop and implement the Source Control Plan.	ASAP	☐
OSC	Undertake aerial surveillance: • Initiate aerial surveillance using the crew change helicopter or contracted aircraft. • Initiate the mobilisation of a trained aerial observer – Esso or AMOSC • Obtain photographs or video footage of the incident • Obtain a completed aerial observer's report and pass to the PSC/SITL.	ASAP, then twice daily	☐
OSC	Mobilise a satellite tracking buoy to spill location (weather dependent).	ASAP – <12 hours	☐
LSC	Confirm the location of aerial and marine assets currently contracted to Esso. Confirm the location and availability of vessels of opportunity in Victoria, as follows: • Contact Atoll Offshore on 03 5116 1511 or 0409 803 588. • Contact Bhagwan Marine on +61 7 3907 3111 or 0409 979 551. • Confirm the location and availability of aerial assets that may be used for aerial observation. • Contact Bairnsdale Air Charter on 03 5152 4617. • Consider utilisation of idle fishing vessels (which meet required specifications) by calling Gippsland Ports on 0427 610 025 (Harbour Master) or 0427 833 388 (Chief Executive Officer)	4 hours	☐
LSC	Notify the waste contractor of potential resource needs.	<12 hours	☐

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
LSC	Notify the marine and aviation FOBs of the need to conduct spill response operations and prepare area and hardstand. Marine bases • BBMT Marine Supervisor 0407 846 457 • Lakes Entrances 03 5116 1511 (Atoll Offshore) • Airfields • Esso Longford Heliport 03 5143 4256 • Bairnsdale Airport 0447 132 980	<6 hours	☐
LSC	Identify and call-out Esso Core Group members – establish current location and timeframe to deploy to field-based ICP.	<6 hours	☐

LSC	Request that the AMOSC Technical Advisor come to the site (IMT) and that the AMOSC Operations Officer enters the field (ICP).
	Request that AMOSC undertake the call-out of CG resources (these should be mobilised in the Gippsland region).
	Request that AMOSC hire and mobilise x 6 satellite tracking buoys to Longford Heliport.
	Discuss potential equipment and service needs (Must be spill-size and type specific) with AMOSC, consisting of:
	• Equipment for three x offshore containment & recovery strike teams, each comprising:
	  ○ 3 reels of Ro-boom (or a single high speed sweep system)
	  ○ Skimmer package comprising an LWS500 or similar
	  ○ Temporary vessel storage (deck bladders, intermediate bulk containers or towable barges)
	• Equipment to execute the shoreline TRPs
	  ○ Shore seal boom; fence boom; anchor kits and ancillaries.
	• Dispersant and National Plan aerial dispersant spraying capability.
	• Liaison to National Plan for the use of Victorian based C&R equipment
		<3 hours	☐

LSC	Stage BBMT-based dispersant and offshore containment and recovery equipment for deployment, consisting of: • 1 x AFEDO dispersant spray sets. • 10m^3 IBCs of Corexit 9500a • Waste liquid storage (vessel dependent). Move equipment package to wharf face, ready for load out.	<6 hours	☐
LSC	Prepare LIP-based nearshore/shoreline oil spill response equipment for deployment.	<24 hours	☐
LSC/PSC	Contact the waste management provider. Refer to PSC for advice on potential volumes and types of waste.	<24 hours	☐
PSC	Initiate specific elements of O1 of OSMP, including the tasks below.	ASAP	☐

PSC	Monitor and predict weather and sea states:
	• Consult meteorology services to determine water current and wind speed data, either from http://www.bom.gov.au, http://www.marineweather.net.au, or MetConnect (http://www.metconnect.co.nz):
	  ○ Username: Esso
	  ○ Password: basswx.
		4 hours	☐

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
PSC	Conduct ADIOS2 forecasting of oil weathering and conduct manual vectoring of the spill trajectory, as follows: • Determine the direction of the spill. • Determine if the spill is likely to cross into state waters or shorelines or if it might impact other sensitivities.	4 hours	☐
PSC	Conduct a third-party trajectory modelling of the spill trajectory: • Organise urgent oil spill-trajectory modelling using AMOSC, OSRL, or EMBSI.	4 hours	☐
SITL	Establish a common operating picture – a graphical representation of the spill and its location. Display overflight and OSTM/manual vectoring data on the CoP.	6 hours	☐
PSC	Prepare and disseminate SITREPs as more information becomes available. The IC is responsible for determining the frequency of these updates.	Ongoing	☐
EUL	Consult the NEBA (Ref OPEP Section 5.2), identify potential exposed environmental sensitivities based on spill trajectory, and develop an incident action plan, including a spill-specific NEBA (ref OPEP 5.2).	ASAP	☐
EUL	Activate the OSMP 'O' modules 1.1, 1.2, 1.3, 2.1, 2.3 and 4.1	ASAP	☐
EUL	Review the OSMP to determine which other modules may need to be initiated.	ASAP	☐
EUL	Liaise with the States Scientific Support Coordination if it is anticipated that state waters or shorelines will be impacted.	6 hours	☐
EUL	Assess the need for and coordinate additional personnel to support the environmental unit.	12 hours	☐
EUL	Assess the need for and coordinate the development of specific plans, including the following: • Wildlife Management Plan • SCAT Plan • WMP • Sample Plan • Dispersant Plan • Remediation Plan. Monitor the environmental consequences of any actions. Participate in the development of plans for the next operational period.	12 hours	☐
Once these actions are complete, please move to **Section Four** of this plan.			

Table 3-7 Level Three - 0-12 hour Actions

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
IC	Seek alignment on incident objectives from the ESG.	ASAP	☐
IC	In conjunction with the ESG leader, confirm all necessary regulatory notifications have been made.	<2 hours	☐
IC	Commence the planning cycle (the 'stem' of the planning 'P'): • Establish the incident response aim. • Establish the incident objectives. • Determine appropriate strategies and tactics to achieve objectives.	ASAP – <6 hours	☐
IC	Establish full, locally-based Esso IMT including representatives from Deputy IC, Ops SC, Aviation Unit, Log SC, Planning SC, Environmental Unit and Situation Unit.	<2 hours	☐
IC	Establish a line of communications with the Control Agency IMT and exchange Liaison Officers.	<2 hours	☐
IC	Offer a line of communication with the AMSA and swap liaison officers.	<2 hours	☐
IC / ESG	Initiate the activation of the ExxonMobil Regional Response Team. Tel: +44 1372 223 232	<24 hours	☐
IC/OSC/PSC	Determine and agree on the need for a separate Source Control Branch.	<2 hours	☐
OSC	If the source is not controlled, establish a Source Control Branch to develop and implement the Source Control Plan (this should be made up of pipeline or well engineering teams).	ASAP	☐
OSC	Undertake aerial surveillance: • Initiate aerial surveillance using the crew change helicopter or contracted aircraft. • Initiate the mobilisation of a trained aerial observer – Esso or AMOSC. • Obtain photographs or video footage of the incident. • Obtain a completed aerial observer's report and pass to the PSC/SITL.	ASAP, then twice daily	☐
OSC	Mobilise a satellite tracking buoy to spill location (weather dependent).	ASAP – <12 hours	☐
OSC	Deploy a twice-daily watch from assets/vessel – confirm heading/changes to the situation.	ASAP then by reporting exceptions.	☐
OSC/LSC	On the advice of the Drilling Engineer/Source Control Branch, mobilise the Subsea First Response Toolkit (SFRT) via the AMOSC.	4 hours	☐

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
LSC	Confirm the location of aerial and marine assets currently contracted to Esso. Confirm the location and availability of vessels of opportunity in Victoria, as follows: • Contact Atoll Offshore on 03 5116 1511 or 0409 803 588 • Contact Bhagwan Marine on +61 7 3907 3111 or 0409 979 551. Confirm the location and availability of aerial assets of opportunity that are suitable for aerial observation tasks. • Contact Bairnsdale Air Charter on 03 5152 4617.	<3 hours	☐

LSC	Request that 3 x AMOSC Technical Advisors come to the site (IMT) and that 3 x AMOSC Operations Officers are deployed to enter the field (Marine or aviation ICPs).
	Request that AMOSC undertake the call-out of CG resources (these should be mobilised in the Gippsland region).
	Request that AMOSC hire and mobilise x 6 satellite tracking buoys to Longford Heliport.
	Discuss potential equipment and service needs (spill-type specific) with AMOSC, consisting of:
	• Equipment for three x offshore containment & recovery strike teams, each comprising:
	  ○ 3 reels of ro-boom (or high speed sweep system)
	  ○ Skimmer package comprising and LWS500 or similar
	  ○ Temporary vessel storage (deck bladders, intermediate bulk containers or towable barges)
	• Equipment to execute the shoreline TRPs
	  ○ shore seal boom; fence boom; anchor kits and ancillaries
	• Dispersant – 50 m^3 of Corexit 9500A to be moved to Bairnsdale Airport.
	For worse case loss of well containment scenarios:
	• Additional booming and skimming equipment from Fremantle and Exmouth for a further three x C & R strike teams
	• Liaison to National Plan for the use of Victorian, NSW and South Australian based C&R equipment, sufficient for a further four Strike teams.
	• Refer to Quick Reference Guides in Appendix D for further detail
		<3 hours	☐

LSC	Notify the marine and aviation FOBs of the need to conduct spill response operations and prepare area and hardstand. Marine bases • BBMT Marine Supervisor 0407 846 457 • Lakes Entrances 03 5116 1511 (Atoll Offshore) • Airfields • Esso Longford Heliport 03 5143 4256 • Bairnsdale Airport 0447 132 980	<6 hours	☐

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
LSC	Identify and call-out Esso Core Group members – establish current location and timeframe to deploy to field-based ICP	<6 hours	☐
LSC	Request OSRL technical resources and notify the OSRL Duty Manager of the potential need for resources, as follows: • Contact the OSRL Duty Manager in Singapore +65 6266 1566. • Request 5 x Technical Advisors to mobilise and join the IMT.	<6 hours	☐
LSC	Stage BBMT-based dispersant and offshore containment and recovery equipment for deployment: • 1 x AFEDO dispersant spray sets. • 10m^3 IBCs of Corexit 9500a • Waste liquid storage (vessel dependent). Move equipment package to wharf face, ready for load out.	<6 hours	☐
LSC	Notify waste contractors to prepare for potential liquid, and solid wastes – specific amounts and types to be determined.	<12 hours	☐
LSC	Prepare LIP-based nearshore/shoreline oil-spill response equipment for deployment.	<24 hours	☐
LSC/PSC	Contact the waste management provider PSC for advice on potential volumes and types of waste.	<24 hours	☐
PSC	Initiate specific elements of O1 of OSMP, including the tasks below.	ASAP	☐

PSC	Monitor and predict weather and sea states:
	• Consult meteorology services to determine water current and wind speed data, either from http://www.bom.gov.au, http://www.marineweather.net.au, or MetConnect (http://www.metconnect.co.nz):
	  ○ Username: Esso
	  ○ Password: basswx.
		4 hours	☐

PSC	Conduct ADIOS2 forecasting of oil weathering and conduct manual vectoring of the spill trajectory, as follows: • Determine the direction of the spill. • Determine if the spill is likely to cross into state waters or shorelines or if it might impact other sensitivities.	4 hours	☐
PSC	Conduct third-party trajectory modelling of spill trajectory: • Organise urgent oil-spill trajectory modelling via Esso/APASA/AMOSC. • Does the spill cross into state waters, shorelines or impact other sensitivities?	4 hours	☐
SITL	Establish a common operating picture – a graphical representation of the spill and its location. Display overflight and OSTM/manual vectoring data on the CoP.	4 hours	☐
PSC	Prepare and disseminate SITREPs as more information becomes available. The IC is responsible for determining the frequency of these updates.	Ongoing	☐

Level Two 0-12 hours			
Who	**What**	**Minimum time to implement**	**✓/✗**
EUL	Consult the NEBA (Ref OPEP section 5.2), identify potential exposed environmental sensitivities based on spill trajectory, and develop an incident action plan, including a spill-specific NEBA (ref OPEP 5.2).	ASAP	☐
EUL	Activate the OSMP 'O' modules 1.1, 1.2, 1.3, 1.4, 1.5, 2.1, 2.2, 2.3 and 4.1.	ASAP	☐
EUL	Review the OSMP to determine which other modules may need to be initiated.	ASAP	☐
EUL	Liaise with the States Scientific Support Coordination if it is anticipated that state waters or shorelines will be impacted.	6 hours	
EUL	Assess the need for and coordinate additional personnel to support the environmental unit.	12 hours	☐
EUL	Assess the need for and coordinate the development of specific plans, including the following: • Wildlife Management Plan • SCAT Plan • Waste Management Plan • Sample Plan • Dispersant Plan • Remediation Plan. Monitor the environmental consequences of any actions. Participate in the development of plans for the next operational period.	12 hours	☐
Once these actions are complete, please move to **Section Four** of this plan.			

4 Initial Oil Spill Response Actions: Reactive Operations 12–48 hours

Following the immediate action and assessment process, Esso will establish an IMT structure appropriate to mount actions as required for the response. Recommended minimum IMT structures are as below in Figure 4-1.

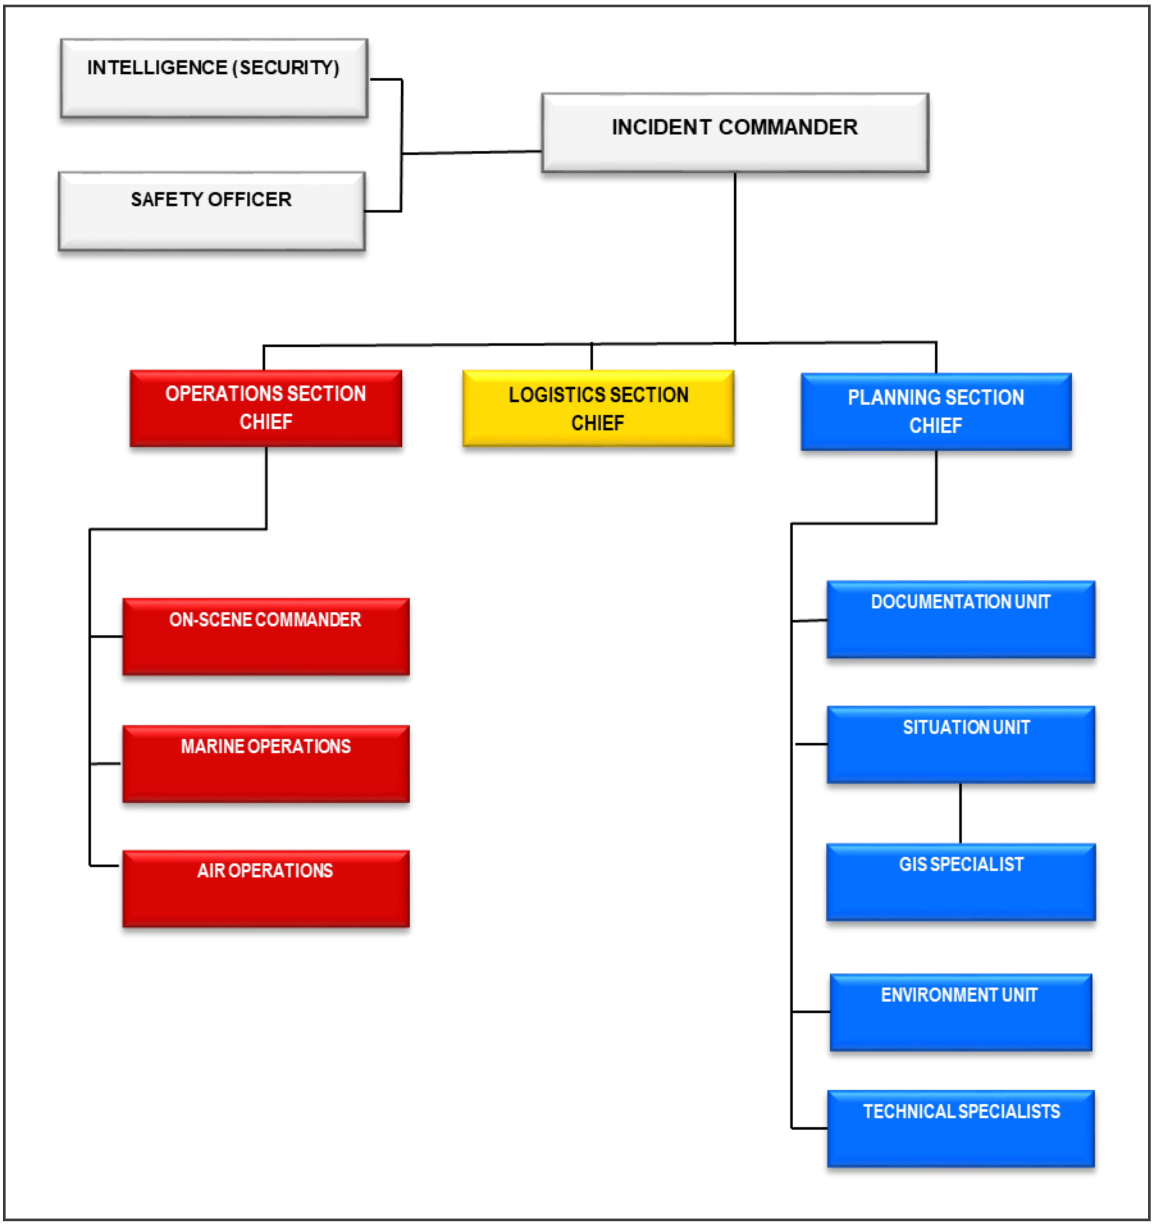

Figure 4-1 Level one – IMT for Localised Response Activities and Impacts (Offshore Incident Management Team)

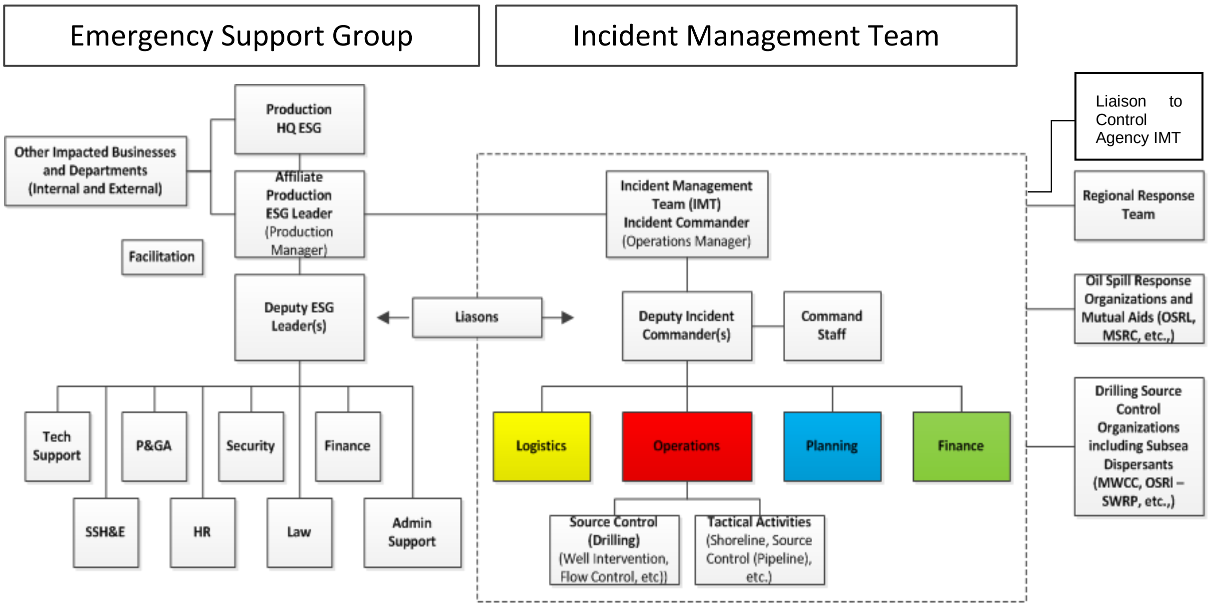

(Note: Source control and operational divisions to be added/retired as required by incident objectives).

Figure 4-2 Level Two/Three – Esso IMT for Expanded Multi-Jurisdictional Impacts

Once the IMT is established, the following checklists are to be used by the functional areas of the IMT to assist each area to execute tasks in support of spill response strategies:

Spill Classification	Relevant Section
Level Two/Three Spills: State water & predicted shoreline impacts.	Section 4.1
Level Two/Three Spills: Commonwealth water impacts & no predicted State water or shoreline impacts.	Section 4.2
Level One Spills: localised	Section 4.3

4.1 Level Two and Three Spills – State Water and Shoreline Impacts.

In Victoria, DOT will assume responsibility for marine pollution incidents in coastal waters, up to 3 nautical miles from shore. Esso, as the petroleum titleholder, is the control agency for marine pollution incidents in Commonwealth waters resulting from an offshore petroleum activity. In the event of a marine pollution incident originating in Commonwealth waters that impacts or threatens State waters, DOT assumes jurisdictional control for such incidents within coastal waters from a State consequence management perspective. Esso will work with DOT to ensure an adequate response, including provision of personnel, equipment and other response resources.

DOT's role of control agency will not extend to response operations in Commonwealth waters including those directly associated with source control or relief well drilling; management of these operations will be performed by Esso. Emergency Management Liaison Officers (EMLOs) may be required between DOT's and Esso's Incident Management Team (IMT).

In the event of a cross-jurisdictional marine pollution incident, the Esso and DOT will work collaboratively, sharing response resources and providing qualified personnel to the DOT IMT. To facilitate effective coordination between the two control agencies and their respective IMTs, a Joint Strategic Coordination Committee (JSCC) will be established. The control and coordination arrangements for cross-jurisdictional maritime emergencies is outlined in Figure 4-3.

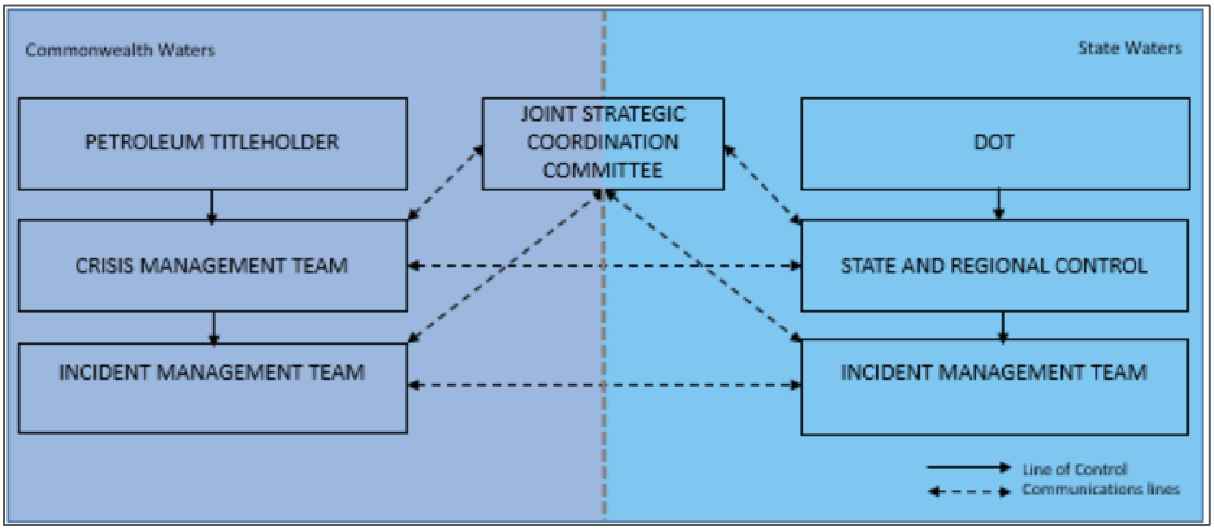

Figure 4-3 Joint Strategic Coordination Committee arrangements

The role of the JSCC is to ensure appropriate coordination between the respective IMTs established by multiple control agencies. The key functions of the JSCC include:

- Ensuring key objectives set by multiple IMTs in relation to the marine pollution incident are consistent and focused on achieving an effective coordinated response.
- Resolving competing priorities between multiple IMTs.
- Resolving competing requests for resources between the multiple IMTs, including those managed by Australian Maritime Safety Authority (AMSA), such as national stockpile equipment, dispersant aircraft and the National Response Team.
- Resolution of significant strategic issues as they arise during the incident response.
- Ensuring that there is a shared understanding of the incident situation and its meaning amongst all key stakeholders.
- Ensuring there is agreement on how information is communicated to the public, particularly those issues that have actual or perceived public health implications.
- Ensuring adequate coordination and consistency is achieved in relation to access and interpretation of intelligence, information and spill modelling to promote a common operating picture.

The JSCC is a committee, not a team operating from a specified location. The JSCC will be administered by DOT and the inaugural JSCC meeting will be convened by the State Controller Maritime Emergencies (SCME) once both the titleholder and DOT formally assume the role of control agency in respective jurisdictions.

The JSCC will be jointly chaired by the SCME and Esso's nominated senior representative, who will determine whom will sit in the committee for a coordinated response. As the relevant jurisdictional authority in Commonwealth waters, NOPSEMA may opt to participate in the JSCC as they see fit.

While the above arrangements described are specific to Victoria, Esso will work with other NSW or Tasmania State government IMT's in a similar manner should their State waters or shorelines be impacted.

For further information on Tasmanian cross jurisdiction arrangements, refer to EPA Tasmania - Offshore Petroleum Industry Guidance Note

Table 4-1 Incident Management Team Tasking

<table>
<tr><th colspan="3">Incident Management Team Tasking</th></tr>
<tr><td colspan="3">Establish an Incident Management Team that oversees the implementation of oil spill response measures – Unity of Command Model with DOT</td></tr>
<tr><td colspan="2">Tactic: Establish and staff a full Esso IMT</td><td>Completed?</td></tr>
<tr><td>IC / ESG Lead</td><td>Nominate Liaison Officers for Control Agency IMT

Nominate senior company representative to participate in JSCC</td><td>☐

☐</td></tr>
<tr><td>PSC

Day One</td><td>Establish full Esso IMT
• Call out IC/OSC/LSC/PSC/Situation & Enviro Units.
• Staff each function with teams – actual and virtual.</td><td>☐</td></tr>
<tr><td>PSC

Day two</td><td>• Review team make up for current, and future operational period.
• Ensure that functional areas are aligned with the needs of the response.</td><td>☐</td></tr>
<tr><td colspan="2">Tactic: Draft and execute an Incident Action Plan</td><td>Completed?</td></tr>
<tr><td>IC lead</td><td>Commence planning cycle ('stem of P')</td><td>☐</td></tr>
<tr><td>PSC

Day One</td><td>• Complete the initial IAP (ICS 201s);
  ○ Establish current operational period aim, objectives, strategy, tactics & resources.
  ○ Draft 24, 48 & 72 incident potential worksheet (size up).
  ○ Complete NEBA.
  ○ Determine the potential <u>shoreline impact</u>.
  ○ Assess weather and sea state for the next 48 hours for suitability to conduct <u>marine response</u> and/or <u>aviation response</u> activities.
• NEBA outcomes to drive the selection of strategies from Table 4-3 onwards.
• Exchange Liaison Officers between Control Agency IMT and Esso IMT.
• Use Liaison Officers to inform Control Agency IMT of Esso ICS201 outputs.</td><td>☐</td></tr>
<tr><td>EUL

Day One / Two</td><td>• Undertake an environmental risk assessment of each proposed tactical execution of strategy (below actions – shoreline/marine/aviation operations).</td><td>☐</td></tr>
<tr><td>PSC

Day Two</td><td>• Review the ICS201 from the previous day
  ○ Are the aim, objectives, strategies, tactics & resources still current given the current conditions for the operational period?
  ○ Review response organisation and staffing needs.
  ○ Continue execution of previous day's plan.
  ○ Modify the plan.
• In consultation with IC, assess readiness to move into the Proactive Planning Phase.
• IMT commences proactive planning cycle (Planning 'P')</td><td>☐</td></tr>
<tr><td>OSC

Day One</td><td>• Plan and execute immediate/first strike operations (as per the list below), and include the following:
• Shoreline operations
  ○ Close off sensitive areas through the implementation of Tactical Response Plans (TRP).
  ○ Provide materials and personnel to state response teams to undertake shoreline SCAT surveys.
  ○ Provide materials and personnel to state response teams to undertake further shoreline protection.</td><td>☐</td></tr>
</table>

Incident Management Team Tasking		
	○ Marine operations – vessel-based dispersant and containment & recovery operations, ○ Vessels – direct vessel of opportunity fleets. ○ Equipment – source from Esso, AMOSC, NatPlan and OSRL. ○ Personnel – source from Esso, AMOSC, AMOSC Core Group, NatPlan CG, ExxonMobil Regional Response Team, OSRL. • Aviation operations – surveillance and dispersant operations. • Operations to follow the relevant section of ExxonMobil Field Response Manual and/or Shoreline Treatment Plans.	
Safety Officer Day One	• Complete Safety Risk Assessment of all operational activities. • Incorporate Safety Risk Assessment into a Safety Plan.	☐
OSC / Source Control Branch Director Day one	• Execution of source control arrangements as required: ○ Activate Australia Wells Team Tier II/III Emergency Response Plan. ○ Pipeline response plan. • Activate source control resource contracts/assistance contracts: ○ SFRT – AMOSC ○ SWIS – OSRL ○ Wild Well Control • Activate pipeline repair • Activate marine salvers	☐
LSC Day Two	• Request and stage resources into Gippsland to enable long-term operations to occur: ○ Integration of Level Two and Level Three resources into the response. • Execute the waste management plan: ○ Call out the third-party contractor (Cleanaway), ○ Liaise with EPA for ongoing waste management requirements (temporary storage and transportation). • Equipment mobilisation for temporary storage and decontamination.	☐

Table 4-2 Surveillance Monitoring & Visualisation (SMV) Strategy

Surveillance Monitoring & Visualisation (SMV) Strategy		
Tactic: Satellite tracking buoys will be deployed to monitor the leading edge of the slick and deployed in 24-hour intervals to indicate swept pathways.		Completed?
OSC Day one	• Deploy satellite tracking buoys (STBs) from Longford (via helicopter or vessel). Place on the leading edge of the spill • Tracking Buoy Deployment Instructions	☐
	• Request AMOSC for all available STBs to be contracted to Esso • STBs moved to Longford ASAP	☐
Day two +	• Monitor location of deployed STBs ○ At last light, deploy STB close to the spill source	☐
• Tactics: Twice daily manned overflights will be undertaken to monitor the spreading, location, and weathering of the slick.		Completed?
OSC Day One	• Commence twice daily aerial overflights to determine size/bearing ○ Obtain a completed aerial observer's report and pass to the PSC/SITL. ○ Use crew change helicopter where possible.	☐

Surveillance Monitoring & Visualisation (SMV) Strategy		
	○ If Esso asset unavailable, contact and contract the use of third-party aircraft.	
OSC / PSC/LSC	• Activate Bairnsdale Air Charter for overflight duties • Request aircraft to fly over the Gippsland shoreline, noting the status (closed/open) of the following intermittently open estuaries: ○ Davis Creek - 37°34'43.46"S, 149°44'59.14"E, ○ Bunga Arm - 37°56'50.00"S, 147°48'18.98"E ○ Lake Tyers - 37°51'33.78"S, 148° 5'18.55"E ○ Merrimen Creek - 38°22'56.18"S, 147°11'4.26"E ○ Mueller River - 37°46'44.51"S, 149°19'41.29"E ○ Shipwreck Creek - 37°38'51.45"S, 149°41'58.05"E ○ Sydenham Inlet - 37°46'49.61"S, 149° 1'11.26"E ○ Tamboon Inlet - 37°46'39.31"S, 149° 9'11.11"E ○ Thurra River - 37°46'56.67"S 149°18'45.94"E ○ Yeerung River - 37°47'28.02"S, 148°46'26.67"E • Report this data back to the EUL/PSC	☐
OSC Day two	• Continue twice daily aerial overflight to determine size/bearing ○ Use crew change helicopter where possible). ○ If Esso asset unavailable, contact and contract the use of third-party aircraft. ○ Aircraft over slick 30 mins after first light. • Use the location of deployed satellite tracking buoys as initial extents for aircraft bearing	☐
Tactics: Daily oil spill trajectory modelling will be used to predict the weathering and direction that the oil will spread.		Completed?
PSC Day One; then each day	• Request OSTM runs to verify data gained through manual means via AMOSC twice daily. The request should include: ○ 12/24/36/48/60/72 hour outlook deterministic trajectory modelling. ○ Shoreline loadings (1, 10 and 100 gm p/sqm) – time frames, volumes and locations. ○ Request via initial phone call and completion of Oil Spill Trajectory Modelling request form . ○ Data to be relayed back to the Situation Unit. ○ Via AMOSC, request the Technical Officer to be deployed to the Esso IMT to provide direct support to the Situation Unit. • For facility coordinates, refer to Gippsland platform location coordinates	☐
Tactics: Set a twice-daily watch to confirm the extent and spreading of the spill from the assets.		Completed?
OSC Day One; then each day	• If there is a spill from a manned asset, set a two-hourly watch to confirm the bearing/size. • Have observers take photographs or video. Where possible, include vessels or other objects in photos to provide scale.	☐
Tactics: Establish the Esso Common Operating Picture in the Esso IMT.		Completed?
OSC / SITL Day one, then for the duration of the spill	• Establish Esso's Common Operating Picture • Commence data capture and graphical display. • Key data to be displayed include: ○ Spill location, ○ Spill extent, direction and trajectory, ○ Environmental sensitives , ○ Bass Strait oil & gas facilities, ○ Location of the staging area and forward operating base ○ Esso-controlled contracted resources – aircraft and vessels, and ○ Third-party-controlled potential resources of opportunity – aircraft and vessels.	☐

Surveillance Monitoring & Visualisation (SMV) Strategy		
Tactics: OSMP as triggered.		Completed?
	Activate the various Operational Monitoring Programmes contained within the OSMP: ○ O1 – O5 as per triggers in OSMP	☐
For Level Three Spills only		
Tactics: Obtain satellite imagery of the spill location.		Completed?
PSC/ SITL	• Request satellite imaging of spill ○ Refer to ExxonMobil Production Geospatial Emergency Response Service) • Alternative options: ○ Request satellite imagery via AMOSC. ○ Request satellite imagery via OSRL – Agreement in place with Radiant Solutions	☐

Table 4-3 Shoreline Protection and Clean up Strategy

Shoreline Protection and Clean up Strategy		
Note: Implementation is dependent on NEBA and oil trajectory.		
Tactic: Inform and agree with Control Agency IMT tactical execution of shoreline planning.		Completed?
PSC/Esso LO Day one, then each day	• Inform DOT/ Control Agency IMT of Esso's intention to undertake planning for shoreline impacts. • Using data from SMV, establish shoreline planning: ○ Shoreline extents. ○ Nearest potential Incident Command Points. ○ Shoreline incident control structure (sectors, segments & divisions). ○ Draft a sector command structure. ○ Shoreline access points - people and vehicles. • Share this data with DOT Control Agency IMT for implementation.	☐
Tactics: Commence pre-impact surveys and pre-impact shoreline cleaning.		Completed?
OSC Day 1	• Commence pre-impact surveys ○ Shoreline surveys by foot – AMOSC and Esso personnel. ○ Shoreline surveys by air – UAV / contracted platforms.	☐
OSC Day 2	• Implement operations ○ Commence shoreline pre-cleaning for areas at immediate risk (first light of day 2).	☐
Tactics: Implement Shoreline TRP's to reduce oil impact on sensitive receptors.		Completed?
PSC Day one	• Based on trajectory, agree with Control Agency IMT regarding the shoreline TRPs to be implemented	☐
LSC Day One	• Esso to tally equipment and personnel required for the selected TRPs ○ Mobilise equipment from (i) Esso stockpiles, (ii) AMOSC Geelong stockpile & (iii) Gippsland Ports/State equipment cache.	☐

Shoreline Protection and Clean up Strategy		
	○ Request personnel from Esso CG and operational workforces; AMOSC Staff/Core Group & Gippsland Ports. • Decide upon ICP's and shoreline staging areas (east and west extents) for equipment. • Commence the mobilisation of equipment and personnel to the staging area (Lakes Entrance – Bullock Island or BBMT).	
OSC Day One,	• Liaise with Gippsland Ports (on ground 1st strike agency) to commence execution of TRPs. • Commence TRP implementation (based on the agreement with Control Agency IMT/Gippsland Ports).	☐
Tactics: Mass mobilisation of equipment, personnel and support for large-scale shoreline operations.		Completed?
LSC Day 1	• Activate supply and service contracts for ground support; • Establish equipment staging areas, • Use a third-party to identify accommodation providers (hotels, motels, caravan parks, and campsites), • Select ground transport providers (bus charter), • Use a third-party to identify remote camp options including: ○ Locations ○ Services ○ Catering ○ Laundry ○ Water treatment options	☐
LSC Day 1	• Activate specialised labour and OSR equipment support ○ Request AMOSC core group projections. ○ Request AMOSC immediate deployment of availed CG to lead shoreline clean up teams (<24 hours). ○ Include PPE, shoreline consumables, and other shoreline kits. ○ Request OSRL shoreline team leaders (operations).	☐

Table 4-4 Marine Dispersant, and Containment & Recovery Operations

Marine Dispersant, and Containment & Recovery Operations		
Note: Dependant on NEBA and oil trajectory.		
Tactic: Establish strike teams able to undertake containment and recovery, and/or dispersant operations.		Completed?
LSC Day One	• Establish BBMT as initial Marine FOB. • Secure four vessels for marine operations – if not engaged in other safety critical mission. • Direct vessels to BBMT to load out equipment. • Direct AMOSC to shift C&R equipment from Geelong to BBMT: ○ 6 x offshore boom reels. ○ 2 x offshore skimmer unit. • If vessel tanks are <500 m3 arrange temporary storage units. • Move BBMT offshore vessel based dispersant systems to wharf edge: ○ 2 x afedo dispersant spray systems. ○ 20 m^3 dispersant (10 per vessel). • Request available Esso Core group recall for duty – vessel-based operations from day two. • Load out vessel for operations.	☐
OSC	• Prepare ICS204 for vessel-based C&R and dispersant operations: ○ Refer to Appendix A draft ICS204 for operations.	☐

Marine Dispersant, and Containment & Recovery Operations		
Day One		
OSC Day Two	• Brief teams to the two separate ICS204. • Direct strike teams (each strike team comprises a pair of vessels) to area of operations: • For dispersant operations, field test must be conducted prior to operational spraying, with results reported to the IMT. • Report back of OSMP O2.2 to validate dispersant effectiveness. • PSC to confirm based on the field dispersant testing move to large scale operational spraying. • Volume of dispersant used to be reported to SITL	☐
Tactic: Establish Marine Forward Operating Base for ongoing large-scale marine operations.		Completed?

LSC
 	
Day Two
	• Based on shoreline impacts, plan for either/or BBMT and Lakes Entrance as marine FOB for ongoing C&R operations:
	  ○ Offshore C&R operations (large vessel operations – wharf considerations - under keel clearance, width, vessel availability).
	  ○ Nearshore/shoreline vessel support operations.
	• Demarcate in each location:
	  ○ OSR Equipment receipting and laydown areas.
	  ○ Office and briefing space.
	  ○ Temporary waste storage area (coming off vessel, after shift).
		☐

Tactics: Request and contract extended offshore response support – escalated resourcing.		Completed?

LSC
 	
Day two
	• Contract additional vessels for C&R:
	  ○ Nearshore/shoreline needs – marine surveyed vessels.
	  ○ Coastal/offshore needs – marine surveyed.
	• Shift all Esso OSR equipment to BBMT/Lakes Entrance:
	  ○ Boom reels.
	  ○ Skimmer units.
	  ○ Temp storage.
	  ○ Dispersant spray sets.
	• Operations and Planning to advise how many strike teams are required. Refer to applicable Quick Reference Guide in Appendix D for guidance on resource requirements for worst case scenarios
	• Request and shift AMOSC nearshore and offshore C&R equipment, and all shoreline equipment to BBMT/Lakes Entrance:
	  ○ Offshore booms reels.
	  ○ Offshore skimmer packages (in addition to TRP requirements)
	  ○ Nearshore/shoreline booming equipment.
	  ○ Nearshore/shoreline skimming packages.
	  ○ Shoreline surveillance equipment – drone, unmanned aerial vehicle.
		☐

Table 4-5 Aviation Dispersant Operations

<table>
<tr><th colspan="3">Aviation Dispersant Operations</th></tr>
<tr><td colspan="3">Note: dependant on NEBA, oil type and oil trajectory</td></tr>
<tr><td colspan="2">Tactic: Mobilise tier two aviation dispersant operations and dispersant resupply.</td><td>Completed?</td></tr>
<tr><td>LSC

Day One</td><td>Source domestic dispersant spraying aircraft via AMOSC (AMSA Fixed Wing Aerial Dispersant) NatPlan link:
Aircraft to move to Bairnsdale as nominated airfield.
Request re-location of dispersant stockpiles to Bairnsdale from Esso BBMT (10 m^3).
Request AMOSC Geelong to move all available Corexit 9500a and Slickgone NS to Bairnsdale airfield.</td><td>☐</td></tr>
<tr><td>OSC/Aviation Branch Director

Day One</td><td>Complete actions per checklists in the Aerial Dispersant Operations Plan for Oil Spills in Bass Strait
1st spraying operation – Victoria-based aircraft to fly to Bairnsdale as the nominated airfield
Secondary overhead coverage aircraft to be provided by third party contractor.
2nd and subsequent operations to be undertaken from Bairnsdale Airport.
2nd and 3rd aircraft arriving during day two of operation.
Establish communications links with AMSA air base manager and dispersant loading operator.
Volume of dispersant used to be reported to SITL</td><td>☐</td></tr>
<tr><td>OSC/Aviation Branch Director

Day One</td><td>Prepare and brief on ICS204 for aerial dispersant operations:
Refer to attached draft ICS204 for operations.
Field test spray to be conducted prior to operational spraying, with results reported to the IMT.
Field test spray to be reported via visual efficacy results from overhead aircraft and on-scene vessels.</td><td>☐</td></tr>
<tr><td>PSC /EUL</td><td>- Ensure ongoing OSMP deployment of O2.2</td><td>☐</td></tr>
<tr><td>OSC/Aviation Branch Director

Day Two</td><td>Prepare and brief on ICS204 for aerial dispersant operations with additional aircraft.
Update Aerial Dispersant Operations Plan with additional aircraft:
Refer to attached drafted ICS204 for operations
Field test spray to be conducted prior to operational spraying, with positive results reported to the IMT.
Field test spray to be reported via visual efficacy results from overhead aircraft and on-scene vessels.
Mount on-going operations of dispersant based
Volume of dispersant used to be reported to SITL</td><td>☐</td></tr>
<tr><td colspan="3">For level three crude oil spills only</td></tr>
<tr><td colspan="2">Tactic: Consider tier three aviation dispersant resupply</td><td></td></tr>
<tr><td>LSC

Day Two</td><td>Based on dispersant dosage rates per day, predict future ten day dispersant needs. If AMOSC and Esso forward stockpiles are <50 m^3, request dispersant via OSRL:
Request OSRL activation of Global Dispersant Stockpiles:
Develop mobilisation plan with OSRL to shift dispersant to Australia utilising freight aircraft operating from Singapore.</td><td>☐</td></tr>
</table>

Table 4-6 Oiled Wildlife Response Strategy

Oiled Wildlife Response Strategy		
Note: Dependant on NEBA and oil trajectory		
Tactic: Through the DOT/ Control Agency IMT, liaise with DELWP and aid their Concept of Operations for *Oiled Wildlife Response*.		Completed?
PSC/EUL Day 1	• Based on the NEBA, fates and trajectory modelling, ascertain likely wildlife impacts – provide this data to DOT/ Control Agency IMT. • Send Liaison Officer to Control Agency IMT. • Propose tactics to Control Agency IMT that may reduce wildlife impacts. Refer to Area Response Plan or Species Response Plans for guidance.	☐
OSC Day 1	• Establish Industry OWR coordinator (from AMOSC) to oversee Esso OWR activity.	☐
LSC Day 1	• As requested, or directed by DELWP and based on the advice of the OWR Coordinator, stand up AMOSC OWR resources: ○ Facility support contract ○ Equipment and clean-up resources from Geelong ○ Equipment and clean-up resources from Perth ○ AMOSC OWR support team • Establish availability of ExxonMobil RRT personnel trained in OWR. • Coordinate ground transport, accommodation, and other support needs for industry response personnel.	☐
LSC Day 2	• Deploy requested OWR resources to the DELWP OWR ICP/field facility.	☐
OSC/Industry OWR coordinator Day 2	• Execute Esso OWR response operations as required or directed by Control Agency IMT.	☐

4.2 Level Two and Three Spills – Commonwealth Waters, No Predicted Shoreline Impacts

Table 4-7 Incident Management Team

<table>
<tr><th colspan="2">Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts
Incident Management Team</th><th></th></tr>
<tr><td colspan="2">Tactic: Establish and staff a full Esso IMT that oversees the implementation of oil spill response measures.</td><td>Completed?</td></tr>
<tr><td>IC
Day One</td><td>• Establish Esso IMT:
o Call out IC/OSC/LSC/PSC/Situation and Environmental Unit.
o Staff each function with teams – actual and virtual.</td><td>☐</td></tr>
<tr><td>IC
Day two</td><td>• Review team make up for current, and future operational period.
• Assess if the functional areas aligned with the needs of the response.</td><td>☐</td></tr>
<tr><td colspan="2">Tactic: Draft and execute an incident action plan</td><td>Completed?</td></tr>
<tr><td>IC lead</td><td>• Commence planning cycle (‘stem of P’).</td><td>☐</td></tr>
<tr><td>PSC
Day One</td><td>• Complete the initial IAP (ICS 201’s):
o Establish current operational period aim, objectives, strategy, tactics and resources
o Draft 24, 48 and 72 incident potential worksheet (size up)
o Complete NEBA
o Confirm the low potential for shoreline impact, or shoreline impact for monitoring only (>10gm/sqm.)
• Assess weather and sea state for the next 48 hour for suitability to conduct marine response and/or aviation response activities.
• Exchange Liaison Officers between Control Agency IMT, AMSA and Esso.
• Use Liaison Officers to inform Control Agency IMT of Esso ICS201 outputs and SitReps.
• Undertake risk assessment of each proposed tactical execution of strategy (below actions – marine/aviation operations).</td><td>☐</td></tr>
<tr><td>PSC
Day Two</td><td>• Review the ICS201 from the previous day. Assess :
o The aim, objectives, strategies, tactics and resources suitability against the current conditions for the operational period.
o Review response organization and staffing needs.
o Continue execution of previous day’s plan
o If needed, modify the plan.
• In consultation with IC, assess readiness to move into Proactive Planning Phase.
• IMT commences planning cycle (planning ‘p’).</td><td>☐</td></tr>
<tr><td>OSC
Day Two</td><td>• Plan and execute immediate/first strike operations (as per following checklist). Include:
• Marine operations – dispersant, containment and recovery.
o Vessels – Vessels of Opportunity.
o Equipment – Esso, AMOSC, NatPlan and OSRL.
o Personnel – Esso, AMOSC, AMOSC CG, NatPlan CG, Esso RRT, OSRL.
• Aviation operations – surveillance, and dispersant operations
o Aircraft.</td><td>☐</td></tr>
<tr><td>OSC/SC Branch Manager</td><td>• As needed execution Source Control arrangements:
o Activate Australia Wells Team Tier II/III Emergency Response Plan.
o Pipeline Emergency Response Plan.</td><td>☐</td></tr>
</table>

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Incident Management Team		
Day one	○ Containment contracts/assistance contracts: ○ Subsea first response toolkit– AMOSC, Oceaneering and AdEnergy ○ Subsea well intervention service - OSRL ○ Wild Well Control. • Activate pipeline repair. • Activate marine salvers.	
LSC Day Two	• Request and stage resources into Gippsland to enable long term operations to occur: ○ Integration of tier two and tier three resources into the response. • Execute waste management plan: ○ Call out third party contractor (Cleanaway) ○ Estimate volumes of liquid waste consistent with large scale containment and recovery. • Equipment mobilization – temporary storage and decontamination. • Supporting resources for response personnel.	☐

Table 4-8 Surveillance Monitoring and Visualisation Strategy

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Surveillance Monitoring and Visualisation Strategy		
Tactic: satellite tracking buoys will be deployed to monitor the leading edge of the slick; and deployed in 24-hour intervals to indicate swept pathways.		Completed?
OSC Day one	• Deploy STB from Longford (helicopter or vessel) – place on leading edge of spill. • Tracking Buoy Deployment Instructions	☐
	• Request AMOSC all available STB's to be contracted to Esso: STBs move to Longford as soon as possible. At last light, deploy STB from the spill source.	☐
Day two +	• Monitor location of deployed STBs: At last light, deploy STB from the spill source.	☐
Tactics: twice daily manned overflights will be undertaken to monitor the spreading, location, and weathering of the slick.		Completed?
OSC Day One	• Commence twice daily aerial overflights to determine size/bearing: Divert aircraft to track spill (or use of scheduled crew change helicopter routing). If Esso asset unavailable, contact and contract the use of third-party aircraft.	☐
OSC Day two	• Continue twice daily aerial overflight to determine size/bearing: Divert vessel/aircraft to track spill (or use of scheduled crew change helicopter routing). If Esso asset unavailable, contact and contract the use of third-party aircraft. Aircraft over slick 30 mins after first light	☐

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Surveillance Monitoring and Visualisation Strategy		
	Use location of deployed satellite tracking buoys as initial extents for aircraft bearing.	
Tactics: daily oil spill trajectory modelling will be used to predict the weathering and direction that the oil will spread.		Completed?
PSC Day One; then each day	• Request through AMOSC twice daily OSTM runs to verify data gained through manual means, request to include: 12/24/36/48/60/72-hour outlook deterministic trajectory modelling. Potential for shoreline or state water contact • Data to be relayed back to the SITU. • Request through AMOSC for OSTM third party be deployed into the Esso IMT to provide direct support to the SITU. • Monitor movement of tracking buoys. Fastwave Dashboard - User guide	☐
Tactics: Set a twice daily watch to confirm the extent and spreading of the spill from the assets.		
OSC Day One; then each day	• If spill from a manned asset, set two hourly watch to confirm bearing/size.	☐
Tactics: OSMP as triggered		Completed?
	Activate the various Operational Monitoring Programmes contained within the OSMP: • O1 – O5 as per triggers in OSMP	☐
Tactics: Establish the Esso Common Operating Picture in the Esso IMT		Completed?
OSC/SITL Day one, then for the duration of the spill	• Establish Esso's CoP. • Commence data capture and graphical display. • Key data to be displayed includes: Spill location. Spill extent, direction and trajectory. Environmental sensitives. Bass Strait oil and gas facilities. Passing ships. Esso controlled contracted resources – aircraft and vessels. Third party controlled potential resources of opportunity – aircraft and vessels.	☐
For Level Three Spills only		
Tactics: Request satellite imagery of the spill location.		Completed?
PSC/ SITL	• Request satellite imaging of spill Refer ExxonMobil Production Geospatial Emergency Response Service Alternative options: • Request satellite imagery via AMOSC. • Request satellite imagery via OSRL – Agreement in place with Radiant Solutions.	☐

Table 4-9 Marine Dispersant, and Containment & Recovery Operations

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Marine Dispersant, and Containment & Recovery Operations		
Note: This strategy is dependent on NEBA outcomes and oil trajectory		
Tactic: Establish strike teams able to undertake containment and recovery, and/or dispersant operations.		Completed?
LSC Day One	• Establish BBMT as initial Marine FOB. • Secure four vessels for marine operations – if not engaged in other safety critical mission. • Direct vessels to BBMT to load out equipment. • Direct AMOSC to shift C&R equipment from Geelong to BBMT: 6 x offshore boom reels. 2 x offshore skimmer unit. If vessel tanks are <500 m3 arrange temporary storage units. • Move BBMT offshore vessel based dispersant systems to wharf edge: 2 x afedo dispersant spray systems. 30 m3 dispersant (15 per vessel). • Request available Esso Core group recall for duty – vessel-based operations from day two. • Load out vessel for operations.	☐
OSC Day One	• Prepare ICS204 for C&R and dispersant operations: Refer to draft ICS204 for operations Appendix A.	☐
OSC Day Two	• Brief teams on the two separate ICS204. • Direct strike teams (each strike team comprises a pair of vessels) to area of operations: For dispersant operations, field test must be conducted prior to operational spraying, with positive results reported to the IMT. PSC to confirm based on the field dispersant testing move to large scale operational spraying.	☐
Tactic: Establish Marine FOBs for ongoing large-scale marine operations.		Completed?
LSC Day Two	• Based on shoreline impacts, plan for either/or BBMT and Lakes Entrance as marine FOB for ongoing C&R operations: Offshore C&R operations (large vessel operations – wharf considerations - under keel clearance, width, tug availability). Nearshore/shoreline vessel support operations. • Demarcate in each location: OSR Equipment receipting and laydown areas. Office and briefing space. Temporary storage of waste management (coming off of vessel after shift).	☐
Tactics: Request and contract level three offshore response support – escalated resourcing.		Completed?
LSC	• Contract additional vessels for C&R: Nearshore/shoreline need – marine surveyed vessels.	☐

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Marine Dispersant, and Containment & Recovery Operations		
Day two	Coastal/offshore need – marine surveyed. • Shift all Esso OSR equipment to BBMT/Lakes Entrance: Boom reels. Skimmer units. Temp storage. Dispersant spray sets. • Request and shift AMOSC nearshore and offshore C&R equipment, and all shoreline equipment to BBMT/Lakes Entrance: Offshore booms reels. Offshore skimmer packages. Shoreline surveillance equipment – drone, Unmanned aerial vehicles.	

Table 4-10 Aviation Dispersant Operations

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Aviation Dispersant Operations		
Note: This strategy is dependent on NEBA outcomes and oil trajectory.		
Tactic: Mobilise tier two aviation dispersant operations and dispersant resupply.		Completed?
LSC Day One	• Source domestic dispersant spraying aircraft Via AMOSC (AMSA Fixed Wing Aerial Dispersant) NatPlan link: Victorian based aircraft move to Bairnsdale as nominated airfield. • Request re-location of dispersant stockpiles to Bairnsdale from Esso BBMT (10 m^3). • Request AMOSC Geelong to move Corexit 9500a and Slickgone NS to Bairnsdale airfield.	☐
OSC/Aviation Branch Director Day One	• Complete actions per checklists in the *Aerial Dispersant Operations Plan for Oil Spills in Bass Strait*: ○ 1st spraying operation – Victoria-based aircraft to fly to Bairnsdale as the nominated airfield. ○ Secondary overhead coverage aircraft to be provided by third party contractor. ○ 2nd and subsequent operations to be undertaken from Bairnsdale Airport. ○ 2nd and 3rd aircraft arriving during day two of operation. ○ Volume of dispersant used to be reported to SITL • Establish communications links with AMSA air base manager and dispersant loading operator.	☐
OSC/Aviation Branch Director Day One	• Prepare and brief on ICS204 for aerial dispersant operations: Refer to draft ICS204 for operations- Appendix A Field test spray to be conducted prior to operational spraying, with positive results reported to the IMT. Field test spray to be reported via visual efficacy results from overhead aircraft and on-scene vessels.	☐
PSC/EUL	• Ensure ongoing OSMP deployment of O2.2	
OSC/Aviation Branch Director	• Prepare and brief on ICS204 for aerial dispersant operations with additional aircraft. • Update *Aerial Dispersant Operations Plan* with additional aircraft:	☐

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Aviation Dispersant Operations		
Day Two	Refer to attached draft ICS204 for operations Field test spray to be conducted prior to operational spraying, with positive results reported to the IMT. • Field test spray to be reported via visual efficacy results from overhead aircraft and on-scene vessels. • Mount ongoing operations.	
Tactic: Consider the mobilisation of tier three dispersant resupply		Completed?
LSC Day Two	• Calculate dispersant 'burn rate' and if it exceeds Australian national stockpiles, request OSRL activation of Global Dispersant Stockpiles. Refer to Quick Reference Guide in Appendix D for WCDS resource requirements. • Develop mobilization plan with OSRL and Chapman Freeborn to shift dispersant to Australia – freight aircraft operating from Singapore.	☐

Table 4-11 Oiled Wildlife Response Strategy

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Oiled Wildlife Response Strategy		
Note: This strategy is dependent on NEBA outcomes and direction with the DELWP.		
Tactic: Through the DOT/Control Agency IMT, engage with DELWP and provide assistance to their Concept of Operations for *Oiled Wildlife Response*.		Completed?
PSC/EUL Day 1	• Based on the NEBA, fates and trajectory modelling, ascertain likely wildlife impacts – provide this data to DELWP and DOT. Refer to Area Response Plan and Species Response Plan for guidance. • Send Liaison Officer Control Agency IMT. • Advise ExxonMobil RRT Coordinator of potential resource needs. • Determine likely tactics to reduce wildlife impacts: Hazing Trans-location Other OSR tactics.	☐
OSC Day 1	• Establish Industry OWR coordinator (from AMOSC) to oversee Esso OWR activity.	☐
LSC Day 1	• As requested, or directed by DELWP and on the basis of advice of the OWR Coordinator, stand up AMOSC OWR resources: Facility support contract. Equipment and clean-up resources from Geelong. Equipment and clean-up resources from Perth. AMOSC OWR support team.	☐
LSC Day 2	• Deploy requested OWR resources to the DELWP OWR ICP/field facility.	☐
OSC/Industry OWR coordinator	• Execute Esso OWR response operations as required or directed by DELWP.	☐

Level two and three spills - Commonwealth Waters, No Predicted Shoreline Impacts Oiled Wildlife Response Strategy		
Day 2		

4.3 Level One Spills – Commonwealth Waters, Localised Impacts Only

Table 4-12 Incident Management Team

Level one spills - Commonwealth Waters, Localised Impacts Only Incident Management Team		
Tactic: Establish and staff the Esso IMT that oversees the implementation of oil spill response measures		Completed?
IC Day One	• Establish IMT: Identify IC/OSC/ PSC and Environmental Units.	☐
IC Day two	• Review team make up for current, and future operational period. • Are the functional areas aligned with the needs of the response?	☐
Tactic: Draft and execute an Incident Action Plan		Completed?
IC lead	• Commence planning cycle ('stem of P').	☐
PSC Day One	• Complete the initial IAP (ICS 201 sheet): Establish current operational period aim, objectives, strategy, tactics and resources. Draft 24- and 48-hours incident potential worksheet (size up). Complete NEBA. Confirm the potential for sensitivity impacts. Confirm feasibility of 1st strike marine response for C&R or Dispersant operations. Confirm feasibility of 1st strike aviation response. • Inform DOT of Esso intent – provide ICS201 and SitRep. • Undertake risk assessment of any proposed tactical execution of strategy (below actions – marine/aviation operations).	☐
PSC Day Two	• IMT continues planning cycle (stem of the planning 'p'). • Review the ICS201 from the previous day: Confirm suitability of the aim, objectives, strategies, tactics and resources for the operational period? Review the appropriateness of the spill response level. Continue execution of previous day's plan and modify as needed.	☐
OSC Day Two	• Plan and execute immediate/first strike operations (as per following checklist) as determined appropriate: • Marine operations – dispersant and containment and recovery, Vessels - Vessels of Opportunity, Equipment – Esso, AMOSC, Personnel – Esso/Esso CG, AMOSC. • Aviation operations – surveillance operations: Aircraft.	☐

Level one spills - Commonwealth Waters, Localised Impacts Only Incident Management Team		
OSC/SC Branch Manager Day one	• As needed execution Source Control arrangements: Activate Australia Wells Team Tier II/III Emergency Response Plan. • Containment contracts/assistance contracts. • Activate pipeline repair. • Activate marine salvers.	☐
LSC Day Two	• Monitor asset staging: Confirm that business as usual locations and assets are adequate for the response.	☐

Table 4-13 Surveillance Monitoring and Visualisation Strategy

Level one spills - Commonwealth Waters, Localised Impacts Only Surveillance Monitoring and Visualisation Strategy		
Tactics: twice daily manned overflights will be undertaken to monitor the spreading, location, and weathering of the slick.		Completed?
OSC Day One	• Commence twice daily aerial overflights to determine size/bearing: Divert aircraft to track spill (or use of scheduled crew change helicopter routing). If Esso asset unavailable, contact and contract the use of third-party aircraft.	☐
OSC Day two	• Continue twice daily aerial overflight to determine size/bearing: Divert vessel/aircraft to track spill (or use of scheduled crew change helicopter routing). If Esso asset unavailable, contact and contract the use of third-party aircraft.	☐
Tactics: daily oil spill vectoring and weathering analysis to predict the direction that the oil will spread, and its degradation.		Completed?
PSC Day One; then each day	• EUL to undertake vectoring (manual trajectory) and weathering: 12/24-hour outlook. Weathering based on the ADIOS2 computer programme. Data to be relayed back to the SITU. • Should analysis show state water/shoreline impacts, request of AMOSC OSTM through third party.	☐
Tactics: Set a twice daily watch to confirm the extent and spreading of the spill from the assets.		Completed?
OSC Day One; then each day	• If spill from a manned asset, set two hourly watch to confirm bearing/size.	☐
Tactics: OSMP as triggered		Completed?
OSC / EUL	• Activate the various Operational Monitoring Programmes contained within the OSMP.	☐

Level one spills - Commonwealth Waters, Localised Impacts Only Surveillance Monitoring and Visualisation Strategy		
Day One; then each day		
Tactics: Establish the Esso Common Operating Picture in the Esso IMT		Completed?
OSC/SITL Day one, then for the duration of the spill	• Establish Esso's COP. • Commence data capture and graphical display. • Key data to be displayed includes: Spill location. Spill extent, direction and trajectory. Environmental sensitives. Bass Strait oil and gas facilities. Passing ships. Esso controlled contracted resources – aircraft and vessels. Third party controlled potential resources of opportunity – aircraft and vessels.	☐

Table 4-14 Marine Dispersant, and Containment & Recovery Operations

Level one spills - Commonwealth Waters, Localised Impacts Only Marine Dispersant, and Containment & Recovery Operations		
Note: This strategy is dependent on NEBA outcomes and oil trajectory		
Tactic: Establish one x strike team to undertake containment and recovery, and/or dispersant operations.		Completed?
LSC Day One	• Establish BBMT/Lakes Entrance (Bullock Island) as initial Marine FOB. • Secure two vessels for marine operations – if not engaged in other safety critical mission. • Direct vessels to BBMT to load out equipment. • Direct AMOSC C&R offshore boom to BBMT wharf edge and load out: 3 x offshore boom reels 1 x offshore skimmer unit If vessel tanks are <500 m3 arrange for temporary storage units. • Move BBMT offshore vessel based dispersant systems to wharf edge: 1 x afedo spray system. 10 m^3 dispersant. • Mobilise satellite track buoy to platform and/or vessel • Request available Esso Core group recall for duty – vessel-based operations from day two. • Load out vessel for operations.	☐
OSC Day One	• Prepare ICS204 for C&R and dispersant operations: Refer to draft ICS204 for operations - Appendix A	☐
OSC Day Two	• Brief teams to the two separate ICS204. • Direct strike teams to area of operations: For dispersant operations, field test must be conducted prior to operational spraying, with positive results reported to the IMT. PSC to confirm based on the field dispersant testing move to large scale operational spraying.	☐

Table 4-15 Oiled Wildlife Response

Level one spills - Commonwealth Waters, Localised Impacts Only Oiled Wildlife Response		
Note: This strategy is dependent on NEBA outcomes and oil trajectory.		
Tactic: Through the DOT, engage with DELWP and provide support to their Concept of Operations for *Oiled Wildlife Response*.		Completed?
PSC/EUL Day 1	• Based on the NEBA, fates and trajectory vectoring, ascertain likely wildlife impacts – provide this data to DELWP and DOT. • Refer to Area Response Plan and/or Species Response Plans to determine likely tactics to reduce wildlife impacts: Hazing Trans-location Other OSR tactics.	☐
LSC Day 1	• As requested, or directed by DELWP and based on advice of the OWR Coordinator, stand up AMOSC OWR resources: Facility support contract. Equipment and clean-up resources from Geelong. Equipment and clean-up resources from Perth. AMOSC OWR support team.	☐
OSC/Industry OWR coordinator Day 2	• Execute Esso OWR response operations as required or directed by DELWP.	☐

5 Ongoing Incident Management Activities 48 hours +

Note: From this point forward, IMT members are to utilise their Incident Management handbooks and IMT role descriptions to guide their daily activities, with this OPEP informing the subject matter expertise.

By following the checklists in section three and four, an appropriately sized and resourced IMT will have been set up, with operational resources deployed and pre-moved to execute confirmed and likely time-sensitive response strategies.

Sections of the OPEP continue to be colour coded to provide section-specific guidance to command, planning, operations, and logistics sections/areas.

Spill response operations are to continue during each operational period to put in place desired environmental outcomes until termination criteria can be applied to the tactical implementation of each spill response strategy.

Esso's Operational Monitoring Programme will inform the application of measures, and the Scientific Monitoring Programme will need to continue parallel to the response operations until such time as its own independent termination criteria have been met.

Once Esso has moved through the first 48 hours of response, laying the foundation for an ongoing response, the IMT and spill response operations will settle on a planning and operations implementation cycle, based on the ICS planning 'p'.

This section describes the (1) process used to evaluate oil spill response strategies by the Environmental Unit of the planning section and the (2) guidelines for the operations section to execute the chosen strategies.

The IMT is expected to go through the planning 'p' on a daily basis, even if the outcome of that process is to validate the current Incident Action Plan as appropriate for multiple operational periods.

5.1 Incident Action Planning Process

Once established, the task of the IMT is to establish situational awareness by gathering information, analysing this data, and applying the appropriate, defensible procedures and processes listed in the OPEP and EP to reduce harm to the environment.

The cornerstone document to guide the response to this end is the production and execution of the 'Incident Action Plan' – the business plan for the response.

In its basic form, an IAP is a simple document that tells responders what they need to do to resolve/mitigate an unplanned incident. It will include an aim, objectives, description of the situation, a worst case 'size up' consequence description, a NEBA, a description of what resources are at risk, and the activities that will be undertaken to resolve the situation/minimise environmental impacts.

For all oil spills, a level one IAP will comprise the completion of the following documents that comprise the Initial IAP:

- Weather report
- ICS201-1 Incident Briefing Map/Sketch
- ICS201-2 Summary of Current Actions
- ICS201-3 Organisation Chart
- ICS201-4 Resource Summary
- Notification Status Report

Additional forms may be used as required. Refer to Incident Management Handbook – IAP Preparation Guidance – Initial IAP Listing.

For level two and level three spills, a more comprehensive IAP is to be developed. This will require significant IMT resources to ensure that the plan is developed properly and that operations are simultaneously undertaken. The content of the IAP will be determined by the Incident Commander in consultation with the Planning Section Chief. Typically required components include

- Weather Report
- Incident Map
- ICS 202 Incident Objectives
- ICS 203 Organisation Assignment List
- ICS 204 Assignment List
- ICS 205 Communications Plan
- ICS 206 Medical Plan
- ICS 207 Organisation Chart

Note: Refer to Incident Management Handbook – IAP Preparation Guidance – Detailed IAP Listing for further guidance.

Note: The IAP must also include two additional pieces of analysis specific to the oil spill response

A description of the ICS 232 – Resources at Risk (derived from the execution of the SMV strategy)

An analysis of the benefits and dis-benefits of executing oil spill response strategies – the NEBA (derived from the execution of the SMV strategy).

The typical daily work pattern for the production of the IAP is as follows:

Time	Meeting [ICS 230]	Attendance
ASAP (<4hours)	• Initial Incident Brief • Initial incident IC/UC meeting	• IC Command Staff reps; General Staff reps • Handover meeting/brief
0800	• Objectives Meeting • Review/ identify objectives for the next operational period.	• Esso IC; Command Staff reps; General Staff reps
1000	• Command & General Staff Meeting • IC/UC gives direction to Command & General staff including incident objectives and priorities.	• Incident Commander • Public Information Officer • Liaison Officer • Safety Officer • Legal • Security / Intelligence Officer • Operations Section Chief • Planning Section Chief • Logistics Section Chief • Finance Section Chief • Documentation Unit Lead • Situation Unit Lead
1100	• Strategic stakeholder briefing • Brief OPICC/NOPSEMA/States	• Esso ESG Leader • Esso Incident Commander • Liaison Officer • OPICC • NOPSEMA • DOT
1300	• Tactics Meeting • Develop/Review primary and alternate strategies to meet Incident Objectives for the next Operational Period.	• Operations Section Chief • Planning Section Chief • Logistics Section Chief • Finance Section Chief • Resource Unit Lead • Documentation Unit Lead • Situation Unit Lead • Env. Unit Lead • Safety Officer • Documentation Unit Lead

Time	Meeting [ICS 230]	Attendance
1500	• Planning Meeting • Review status and finalize strategies and assignments to meet Incident Objectives for the next Operational Period.	• Esso Incident Commander • Agency Representative • Public Information Officer • Liaison Officer • Security/Intelligence Officer • Legal Officer • Operations Section Chief • Planning Section Chief • Logistics Section Chief • Finance Section Chief • Resource Unit Lead • Documentation Unit Lead • Situation Unit Lead • Env. Unit Lead • Safety Officer • Documentation Unit Lead
1700	• Operations Brief • Present IAP and assignments to the Supervisors / Leaders for the next Operational Period.	• Esso Incident Commander • Operations Field leadership • Safety Officer • Public Information Officer • Liaison Officer • Security Officer • Legal Officer • Section Chiefs • Documentation Unit Lead • Resource Unit Lead • Situation Unit Lead • Environment Unit Lead

This cycle is represented in the planning ‘p’ below, Figure 5-1, with key written outputs noted by the arrows.

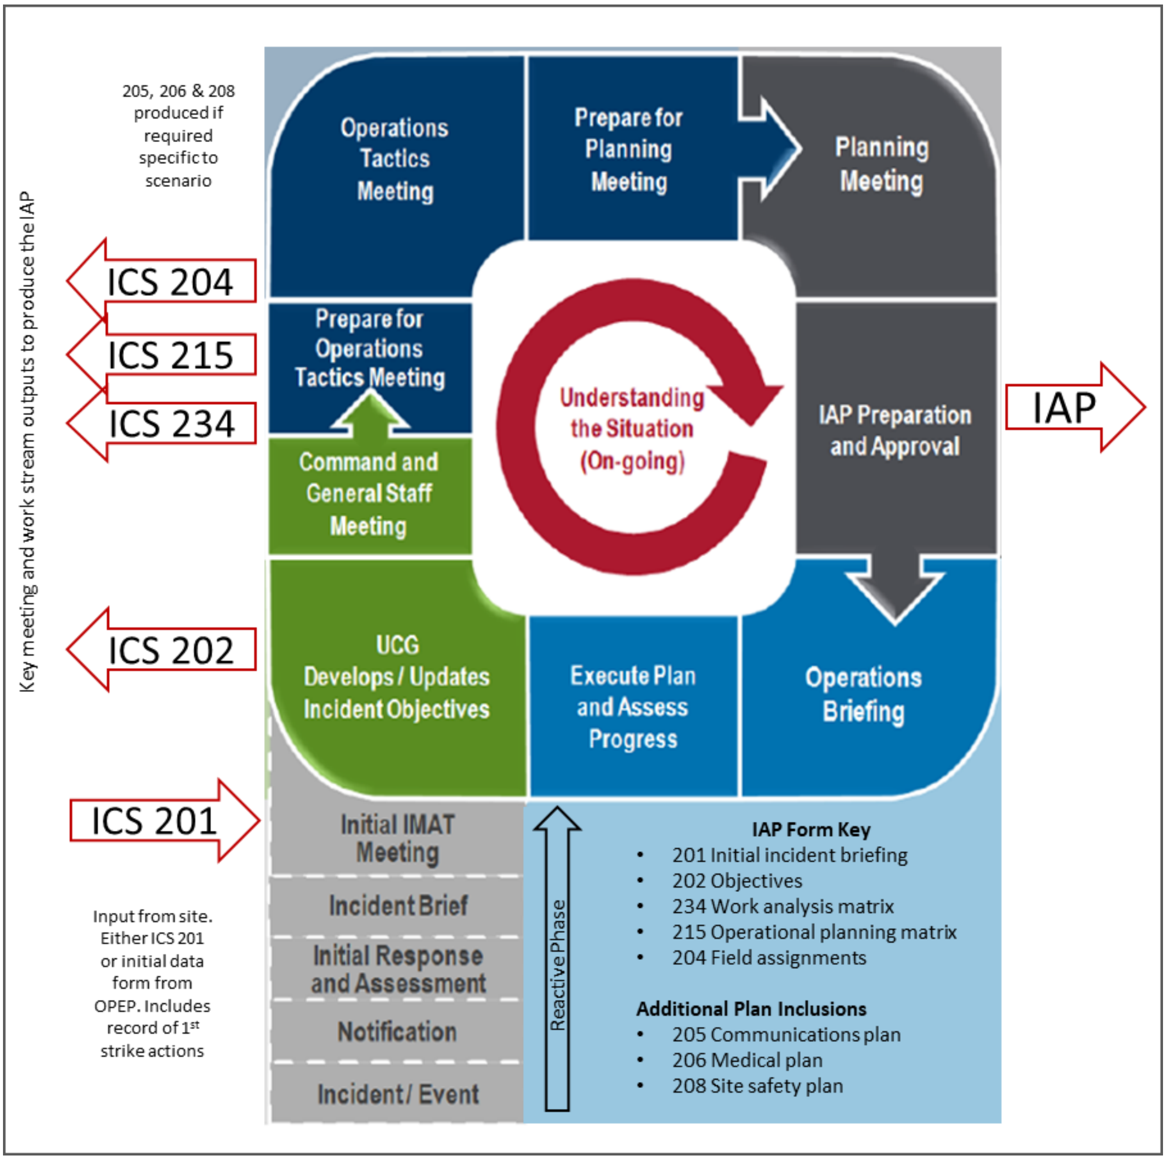

Figure 5-1 Incident Planning

5.2 Selection of Response Strategies – Net Environmental Benefit Analysis

Activity specific protection priorities and selection of response options are summarised in Appendix D – Quick Reference Information.

A 'preparedness NEBA' (which is essentially a draft of Step 1 & 2 of the NEBA Process described in Volume 3, Table 2-4) can be referenced in the event of an incident and used as a template during the response.

A summary of potential applicable response options for different types of hydrocarbon spills has also been provided below.

In the event of an incident, it will be necessary to check the priorities defined in the Quick Reference Guides (Appendix D) are current and supported by stakeholders, and check the response strategies are indeed feasible given the specifics of the situation.

Key:

P	Proposed	The tactic will be deployed where safe to do so and where the NEBA indicates the strategy will result in net environmental benefit, and if the response or the spill is likely to impact State waters, the response will be approved by the State Authority.
V	Viable	The tactic will be considered as a viable option, but deployment may not be warranted because of the size of spill, conditions, and other factors at the time of the spill.
NR	Not recommended	The tactic may be viable but is not recommended either due to safety considerations or impacts of the tactic itself.
NV	Not viable	The potential to deploy the tactic effectively is limited.
NP	Not practical	The tactic cannot be implemented for the resource type; e.g., resource type is inaccessible.
NA	Not applicable	The resource type does not warrant this response.

NEBA Summary - Diesel Spill

Offshore receptor	Exclusion zone	Hazing to deter wildlife	Monitoring and natural dispersion	Marine-based containment and recovery	Protection deflection	Chemical treatment, e.g., dispersant application (surface)
1. Open marine environment	P	V	P	NV	NR	NR
2. Seabed	NA	NA	P	NV	NA	NR
3. Subtidal rocky reefs	V	NA	P	NV	NA	NR
4. Estuaries	V	V	P	NV	P	NR
5. Shipwrecks	V	NA	P	NV	NA	NR
6. Fisheries: Southern shark and scalefish	P	NA	P	NV	NR	NR
7. Fisheries: Southeast fishery	P	NA	P	NV	NR	NR
8. Fisheries: Southern scallop	P	NA	P	NV	NR	NR
9. Fisheries: Southern rock lobster	P	NA	P	NV	NR	NR
10. Fisheries: Abalone	NA	NA	P	NV	NR	NR
11. Shoreline	P	P	P	NR	P	NR

NEBA Summary - Light Crude Spill

Offshore resource type	Exclusion zone	Hazing to deter wildlife	Monitoring and natural dispersion	Marine-based containment and recovery	Protection deflection	Chemical treatment, e.g., dispersant application (surface)
1. Open marine environment	P	V	P	V	V	V
2. Seabed	NA	NA	P	NA	NA	NA
3. Subtidal rocky reefs	P	NA	P	V	NR	NR
4. Estuaries	V	V	P	NA	P	NR
5. Shipwrecks	P	NA	P	V	NR	NA
6-10. Fisheries	P	NA	P	V	NA	P except in shallow water over sessile aquaculture.
11. Shoreline	P	P	P	V	V	NR

NEBA Summary - Condensate Spill

Offshore resource type	Exclusion zone	Hazing to deter wildlife	Monitoring and natural dispersion	Marine-based containment and recovery	Protection deflection	Chemical treatment, e.g., dispersant application (surface)
1. Open marine environment	P	V	P	NR	NR	NR
2. Seabed	NA	NA	P	NA	NA	NA
3. Subtidal rocky reefs	P	NA	P	NR	NR	NR
4. Estuaries	P	V	P	NR	NR	NR
5. Shipwrecks	P	NA	P	NR	NR	NR
6-10. Fisheries	P	NA	P	V	NA	NR
Shoreline impacts	P	P	P	V	V	V

Where shoreline impacts are predicted, a response-specific NEBA will be undertaken, in conjunction with DOT, to determine and agree on the appropriate response strategies.

A simple grouping of these tactics by location / hydrocarbon type:

Location	Loss of diesel, lubricating, condensate or mechanical oils	Crude oil releases
All locations	• Surveillance, monitoring, and visualisation • Exclusion zones, considering health and safety and environment risks are determined in consultation with the control agency. • Oiled wildlife response	
Spill site	• Source control (BOP intervention, relief well drilling, pipeline engineering efforts)	
Offshore environment (Commonwealth waters)	• Mechanical dispersion	• Chemical dispersant • Containment and recovery
Offshore and nearshore environments (Commonwealth and coastal waters)		• Containment and recovery
Coastlines and islands	• Protection deflection • Containment and recovery • Shoreline response – assessment and clean-up • Oiled wildlife response	

Each tactic will be applied in a manner as determined by a dynamic planning process, adapted at the time to the current weather and sea conditions.

NEBA instructions:

For all spills, a spill-specific NEBA needs to be developed as outlined in Figure 5-2 and summarised as follows:

a. Select the appropriate NEBA worksheets from http://ishareteam1.na.xom.com/sites/EMPC0263/EPP/Environment%20Plans/6_NEBA.xlsx by oil type.

b. Refer to OSRA[2] maps and cull non-relevant Resource Types according to the areas of the environment that are predicted to be impacted.

c. Review the protection priority of the remaining resources (using relevant sections of EP Volume 2 Section (Loss of Containment / Loss of Well Control). Also refer to Quick Reference Information for specific activities OPEP- Appendix D.

d. Review and expand on each of the benefits and disbenefits within the NEBA worksheet according to incident-specific details and further response considerations.

e. Assess the effectiveness of the response strategies in protecting the resources at risk.

f. Summarise the preferred strategy into the Incident Action Plan.

[2] The Oil Spill Response Atlas (OSRA) is a national database and decision support system in a computerised GIS format. It is designed to provide comprehensive information about Australia's coastal resources and spill response logistics. OSRA includes information on: shoreline geomorphology, marine habitats, environmental resources, cultural and heritage sites, commercial resources, logistics and infrastructure information to support spill response. OSRA is accessed through AMSA in emergency situations.

Detailed information on priorities for protection, potential impacts, and preferred response strategies will be used in conjunction with incident-specific trajectory modelling and real-time conditions to determine the most appropriate incident-specific response.

Using the outputs of the NEBA as a feed into the planning 'P' process, the IMT will then draft/validate tactical plans for specific areas and execute those plans.

A link to the NEBA tool can be found here:

NEBA Tool

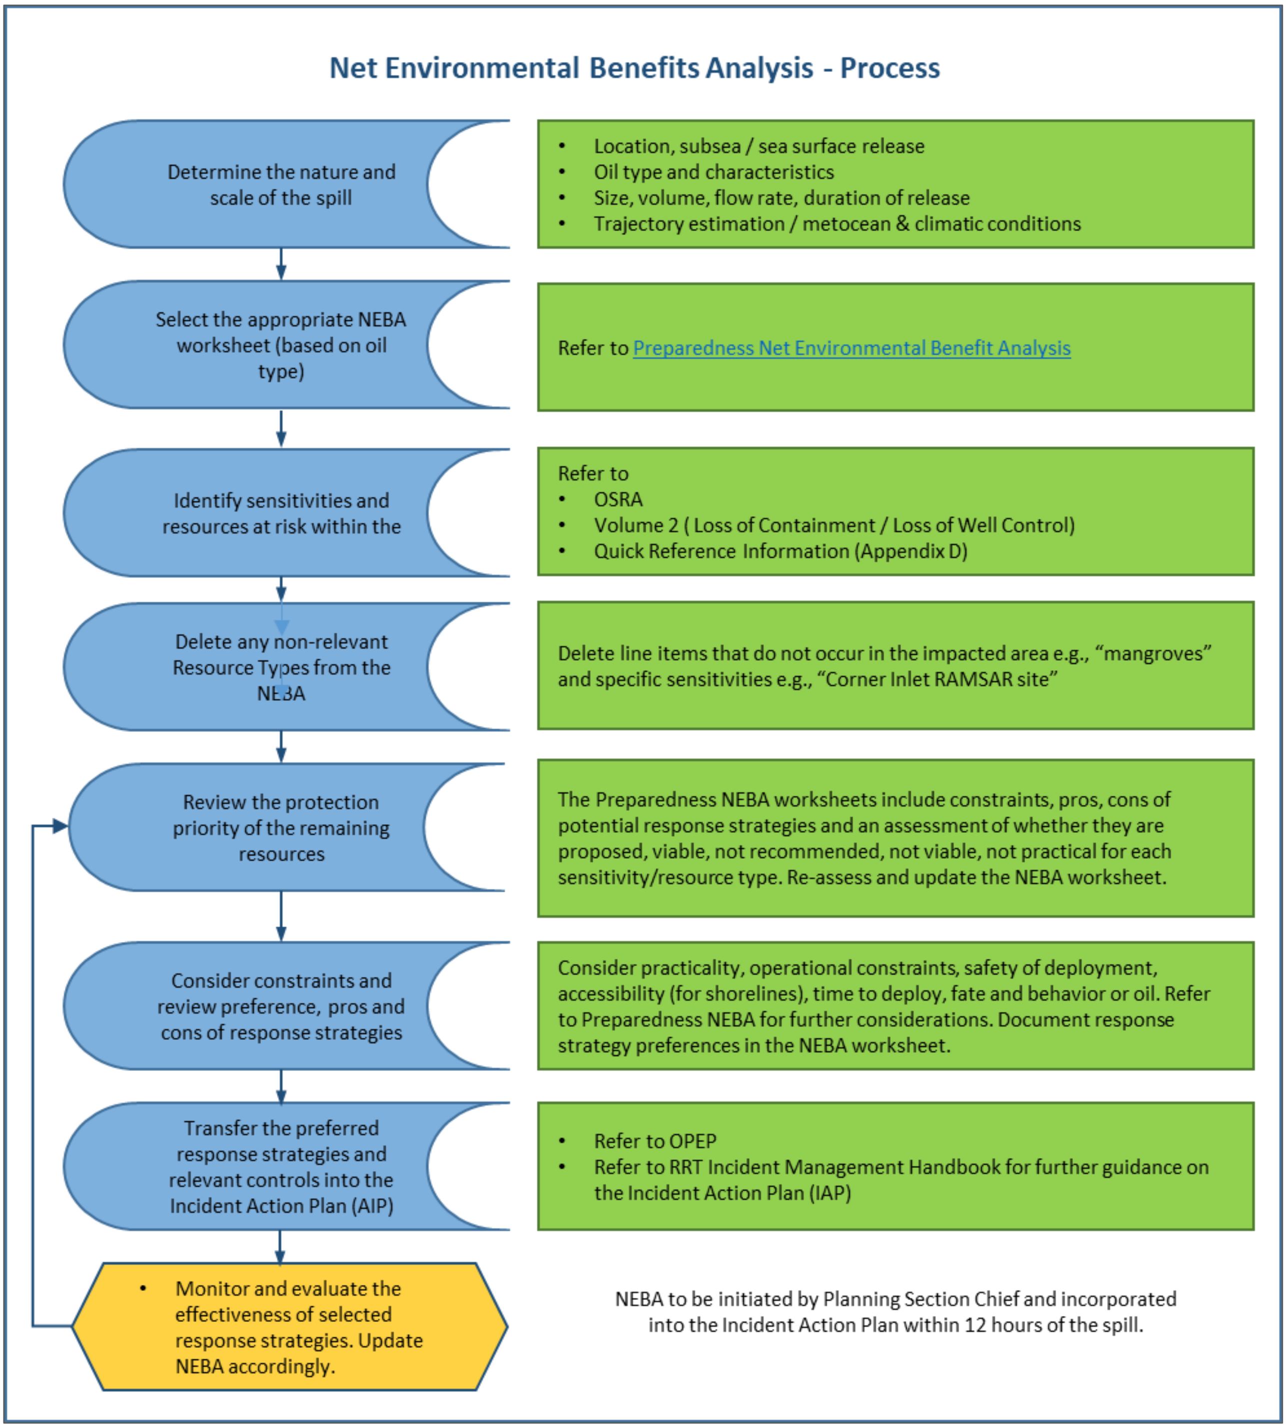

Figure 5-2 NEBA Process Flowchart

5.3 Cone of Response

For all offshore spills, Esso will utilise a 'cone of response' approach to spill response operations. This means proportioning resources to the spill response strategies that have a bulk removal/treatment affect closest to the source of the spill. The 'cone' is visually depicted below:

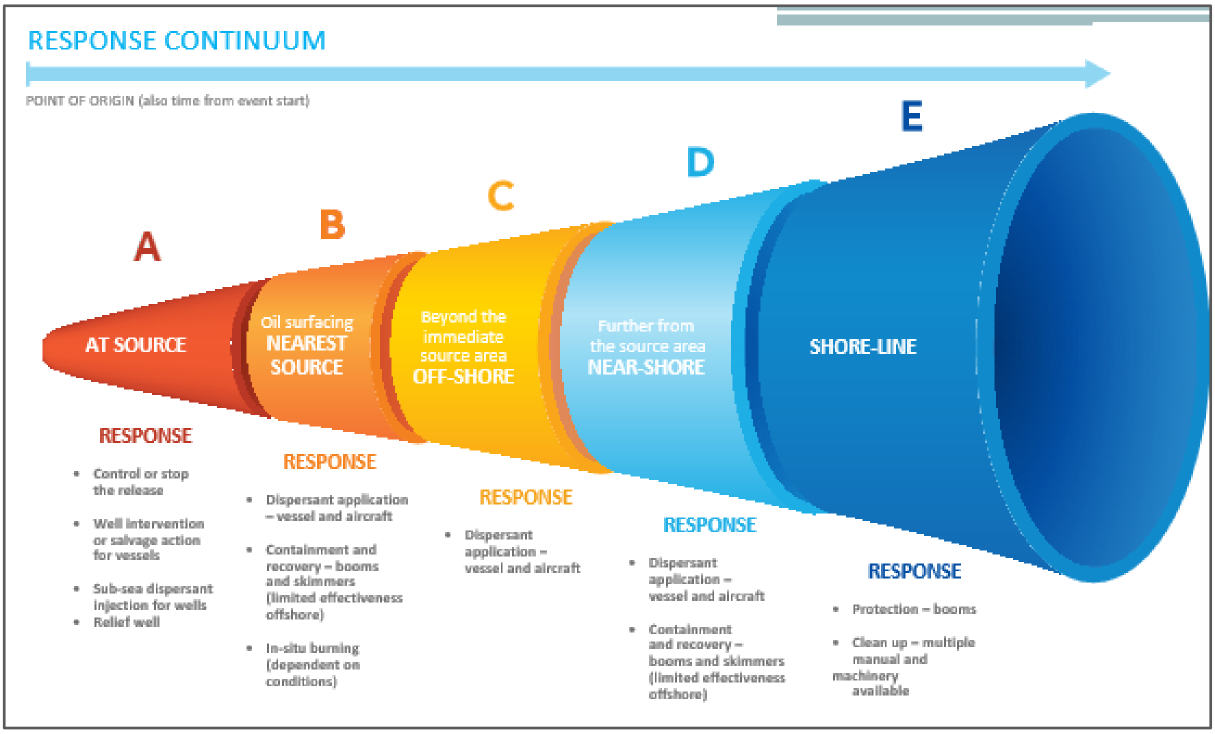

Figure 5-3 Cone of Response

For spills in near-shore waters or where shoreline impacts are imminent (<48 hours), the cone will be modified – Esso's efforts will focus on minimising impacts to sensitives, particularly the shoreline, while also prioritising control of the source of the spill. Once shoreline protective/response measures are in place, efforts will revert back other areas of the 'cone'.

The 'cone' directs response resources to where maximum effectiveness will occur. Using this methodology, each tactic or strategy is executed cogniscent of the volume of remaining oil to be treated from the previous strategy.

In practical terms this means that Esso will, in priority order:

1. Capitalise on window of opportunity for dispersant application with appropriate type and quantity of dispersant to reduce bulk surface and shoreline loading; and then
2. Utilise offshore and nearshore containment & recovery strike teams to recover oil not dispersed, so as to reduce bulk surface and shoreline loadings; and then
3. In coordination with control agency, execution of shoreline protection measures, to reduce volumes of remaining oil from reaching and impacting shore-based sensitivities.

The following is a description of each oil spill response strategy that Esso will put in place where applicable to the incident:

5.4 Source Control

Strategy Description:

Well intervention, subsea infrastructure repairs, pipeline repair and vessel salvage will be used as appropriate to the source of the spill to control and cease the uncontrolled flow of hydrocarbons into the environment.

Relevant environmental performance outcomes and standards are provided in Appendix C.

Source Control	
Response Objective	To prevent further uncontrolled release of hydrocarbons into the marine environment.
Critical Outputs	Wells/drilling: All source control operations will be done in accordance with the Esso Gippsland Well Kill Contingency Plan (for source control using the Well Kill Skid) and the Drilling Emergency Preparedness and Response Manual (where required) relevant to that particular well and the source control options within that plan. Depending on the circumstances, the plans outlines the following options that will be followed: • Blowout preventer intervention • Seabed debris clearance • Rig for relief well drilling. Pipeline/subsea infrastructure: All pipeline/subsea infrastructure will be done in accordance with [Pipeline Management Plan]. Pipeline repairs include the use of ROVs with cutting or working tools, valve interventions, and pipeline de-pressurisation. Vessel salvage: Esso will provide support to AMSA or Marine Safety Victoria to ensure appropriate salvage operations.
Planning Section Instructions	As per individual source control plan/incident action plan.
Operations Section Instructions	
Logistics Section Instructions	

5.5 Surveillance and Monitoring

Strategy Description:

Using field observations and modelling, the IMT will assess the incoming data to plan and tailor spill response operations to the scenario of the day. This process will continue for the duration of the response.

Relevant environmental performance outcomes and standards are provided in Appendix C.

Surveillance and Monitoring	
Response Objective	To gather information and validate planning assumptions to adjust response plans as appropriate to the scenario. To quantitatively assess the extent, severity, persistence, and recovery environmental values and sensitivities affected by the spill.
Critical Outputs	Level One Spills: • Aerial Surveillance • Oil Spill Trajectory Monitoring (Vectoring + ADIOS). Level Two Spills (in addition to the above) • Twice daily Oil Spill Trajectory Modelling. • Continuous monitoring from Oil Spill Tracking Buoys. • Surveillance from: Production assets – 4 hourly watch Aircraft – 2 x daily overflights Vessels – Opportunistically to sense check aerial observations. • Shoreline surveys (pre-emptive and post impact). • Operational and Scientific Monitoring programmes. Level Three Spills (in addition to the above) • Satellite photography runs as requested by the SITU.

Surveillance and Monitoring	
Planning Section Instructions	The Planning Section – Environment and Situational units in particular – needs to receive and interpret field/modelling data to inform • The Net Environmental Benefit Assessment. • The list of Resources at Risk from the spill. • The development of the ICS 201 and IAP (for level two and three spills). Critical Daily Tasking: • Drive the planning process (refer to IMH schedules and timings). • Liaise with OSC to ensure field activities are in place to gather field data. • Liaise with LSC to activate and then receive the OSTM. • Establish and activate the OSMP with data reporting back to the SITU. • Gather data, establish, and keep up to date Status Boards and CoP GIS (refer to IMH Section 6). The Planning Section will ensure that the SMV strategy is scaled up or down to provide sufficient information for the IMT to plan and execute appropriate oil spill response activities. All data gathered through remote means are to be captured and displayed in the Common Operating Picture (Esso GIS) so that all members of the IMT have situational awareness. For level two or three spills, the Planning Section includes coordination of SCAT teams on shorelines, feeding data directly into the SITU.
Operations Section Instructions	The Operations Section is to task assets (marine and aviation divisions; shoreline) to gather data that can be used by the Planning Section to inform the development of the IAP and the operational response. This is done as a part of the execution of the IAP developed the previous day. Critical Daily Tasking: • Execute the IAP for the current Operational period. • Liaise with the PSC to ensure that field tasking (ICS 204) is drafted and used for SMV proposes. • All Spills:

Surveillance and Monitoring	
	• Direct aviation assets to complete aerial surveillance consistent with aerial observer guides and standard operating procedures. Spill Level Two and Above • Deploy satellite tracking buoys (Longford and third party). • Direct dedicated aviation assets to undertake surveillance with trained aerial observers. • Direct marine assets to undertake surveillance. • Set watch from manned platforms (4-hour report back). • Deploy vessel for OSMP activities.
Logistics Section Instructions	The Logistics Section is to activate contracts and provide ongoing services and supply (from in-house resources or from third parties) in support of the execution of this strategy. Critical Daily Tasking: All Spills: • Business-As-Usual assets to be redeployed as per operational requirements – Dispersant spraying strike team. • Shift dispersant to BBMT as per 1st strike checklist. Activate contract with AMOSC and request dispersant. Spill Levels Two and Three • Maintain Air Operations base at Bairnsdale • Activate contracts with third-party aircraft providers. • Marine Operations Base at BBMT or Lakes Entrance. • Activate contract with AMOSC, request aerial observers for daily sorties, satellite tracking buoys to Longford, and twice-daily OSTM. Spill Level Three Only • Activate contract with AMOSC/internal for the provision of Satellite photography services.
Termination Criteria	Detectable oils are below the thresholds outlined in the OSMP

5.6 Dispersant Operations

Strategy Description:

Dispersant will be applied to ongoing crude oil spills using, aircraft and/or vessel.

Relevant environmental performance outcomes and standards are provided in Appendix C.

Dispersant Operations	
Response Objective	To reduce consequences to surface and shoreline values and sensitivities. To increase the bioavailability of oil for microbial breakdown.
Critical Outputs	Level One Spills: Based from BBMT; one vessel-based dispersant strike team. Daily dispersant spray capacity will be based on amount spilled. Levels Two and Three Spills (surface) Based from BBMT; two vessel-based dispersant strike teams Based from Bairnsdale Airfield; up to three air tractor aircraft (AT502 & AT802) flying multiple daily sorties to spray oil located in Commonwealth waters. Surge Resources – Dependent on observations of dispersant effectiveness and additional need determined by the IMT at the time For dispersant operations that project the exhaustion of Australia's dispersant supplies, global dispersant stockpiles from Singapore, may be air freighted to Australia and shifted to the operating airfields Based on the WCDS daily dispersant maximum spray requirements is calculated to be no greater than 42 m^3 per day.
Planning Section Instructions	The Planning Section – Environment Unit in particular – needs to assess on a daily basis that dispersant use will demonstrably achieve net positive outcomes. Chemical dispersants are not recommended for diesel or Group 1 oil spills. Demonstrable positive outcomes include reduction in large-scale shoreline loadings, particularly on remote coastlines such as the Bass Strait Islands, the wilderness areas of far-east Gippsland, Corner Inlet, and surrounding estuaries, and sensitivity specific positive impacts as demonstrated by the daily NEBA. Dispersants are only to be used in Commonwealth waters, where water depths (>10M) and currents will encourage mixing and dispersion. Dispersants are <u>not</u> to be used in State waters without approval of the Control Agency IMT. The state must be notified if dispersants used offshore have the potential to enter state waters. Critical Daily Tasking: • Develop incident specific dispersant operations plans based on the *Aerial Dispersant Operations Plan for Oil Spills in Bass Strait* plan (controlled copy available on AMOSC website).

Dispersant Operations	
	• Establish through a daily Net Environmental Benefit Assessment the ongoing benefit of dispersant spraying. • Ensure that operational and scientific monitoring programmes are in place, with data being collated and sent back to the EUL and SITU • Ensure daily dispersant operations are recorded (types, volumes, and locations). • Predict future dispersant ‘consumption/burn rates’ across all delivery means. • Assist operations to draft daily ICS 204 operations orders used by the aviation branch and complete the AMSA/AMOSC JSOP for the deployment of the FWADC. • The Planning Section needs to continuously monitor dispersant operations and scale them up or down to the number of daily sorties required to provide 100% spray coverage of slightly weathered (24 hours) crude oil. Dispersant selection will preference: • Dispersants listed on the AMSA Oil Spill Control Agents Register. • Those with highest efficacy testing against Esso Bass Strait crudes. Refer to 2019 Esso Dispersant Testing Report for details of laboratory analysis of a range of dispersants on Gippsland crude oils. A summary of the results is provided in Table E-1 in Appendix E. All data gathered through the OSMP in relation to dispersant operations are to be captured and displayed in the Common Operating Picture (Esso GIS) so that all members of the IMT have situational awareness.
Operations Section Instructions	The Operations Section, Marine, Aviation, and Source Control Branch Directors will task assets under their command to undertake daily dispersant operations as a part of the execution of the IAP developed the previous day. • Aviation operations will be split between: • Bairnsdale (AMSA/NatPlan-provided small air tractor aircraft and attack aircraft) • Longford Heliport. • Operational planning needs to assert control around the two distinct aircraft types. Safety planning to include separate, dedicated search and rescue (SAR) capability. Operational planning for aerial surface application will be based on the *Aerial Dispersant Operations Plan for Oil Spills in Bass Strait* and the completion of the AMSA / AMOSC FWADC JSOP available at www.amosc.com.au. Vessel spraying operations will come out of BBMT/Lakes Entrance on 3-4 day swings, dependent on deck space for dispersant and waste. Resupply will occur at these locations. Critical Daily Tasking: All Spills: • Execute the IAP for the current operational period. • Liaise with the PSC to ensure that field tasking (ICS 204) is drafted and used for dispersant operations. – Maintain records of dispersant application including quantities, types, and locations of spraying. Refer Appendix A for draft ICS 204. • Direct-vessel-based dispersant operations. • Spill Levels Two and Above (in addition to the above):

Dispersant Operations	
	• Operations are to be directed to the thickest part of the slick, to fresh oil. • De-confliction of aerial and vessel-based dispersant spraying – SimOps planning needs to be part of the daily tasking. • Vessel assigned for the OSMP water sampling/monitoring activities.
Logistics Section Instructions	The Logistics Section is to activate contracts and provide ongoing services and supply (Esso resources and/or from third parties) in support of the execution of this strategy. This is focused on aerial operations from Essendon and Bairnsdale and vessels from BBMT and Lakes Entrance. For level two and three spills, the key tasks are to Ensure correct activation with AMOSC of the AMSA fixed wing aerial dispersant spraying contract – aircraft is to move to Bairnsdale airfield for ongoing operations Ensure internal (Esso-owned stockpiles) dispersants are moved to the aerial and marine operational points Ensure AMOSC and NatPlan stockpiles of dispersant are moved to aerial and marine operational points If needed, ensure activation of OSRL for large dispersant aircraft and transfer by air of additional dispersant to Australia. Critical Daily Tasking: • Monitoring dispersant rate of use. • Sustaining marine/aviation operations with contractors and third parties to ensure that operations can continue: • Operational bases, • Services and supply for operations. • Anticipate future needs of the operations
Termination Criteria	Dispersant operations will cease based on any of the below triggers: • NEBA determines that dispersant operations no longer provide demonstrable environmental benefits. • Oil is too weathered for effective operations.

5.7 At-Sea Containment and Recovery (Vessel Based)

Strategy Description:

Using containment boom and skimmers, strike teams will corral fresh oil and then mechanically recover it into vessel tanks and temporary storage.

Relevant environmental performance outcomes and standards are provided in Appendix C.

At-Sea Containment and Recovery (Vessel Based)	
Response Objective	To recover spilt oil before shoreline or other sensitivity contact. To remove bulk floating oil and improve water quality.
Critical Outputs	For Level One Spills (subject to NEBA): • Using a pair of large vessels, offshore booms will be towed in the optimal configuration to concentrate and collect floating oil. Alternatively, single vessel high speed booming systems may be used. • The optimal mechanical skimmer for the type and condition of oil will be used to recover as much oil as possible from the pocket of the boom. • Refer to the *ExxonMobil Oil Spill Response Handbook* s. 5 for more information on booming configurations. For level two and above spills (subject to NEBA): • Based from BBMT and Lakes Entrance, up to six strike teams (each comprising two vessels) may be needed considering the volume of oil required to be collected via this method. Each will use the configurations noted above. In ideal conditions, 'advanced' booming techniques will be used to concentrate oil using two pairs of vessels per strike team. • Vessels of opportunity from fishing and offshore service fleets will be sourced from around southern Australia. • Equipment and trained personnel will come from Esso, AMOSC, AMOSC Mutual Aid and Australian National Plan (government) stockpiles. These will be cascaded in from stockpiles across Australia. • Daily calculated volumes of oil to be contained and recovered through this method will be between 150 m^3 and 450 m^3 of oil in total.
Planning Section Instructions	The Planning Section to determine through the NEBA, and surveillance and monitoring inputs, that Containment and Recovery operations should be conducted. In particular, Containment and Recovery operations will be used to reduce shoreline loadings, particularly on remote coastlines such as the Bass Strait Islands, the wilderness areas of far-east Gippsland, Corner Inlet, and surrounding estuaries, and sensitivity-specific positive impacts as demonstrated by the daily NEBA. Weather conditions in Bass Strait are known to be volatile and challenging, so forward 24-48-hour forecasts (wave and swell height; wind speed) must be within operational limits for this tactic to proceed.

At-Sea Containment and Recovery (Vessel Based)	
	Containment and recovery activities should only be carried out during daylight hours. Critical Daily Tasking: • Establish through a daily Net Environmental Benefit Assessment the ongoing benefit of Containment and Recovery • Ensure that weather conditions are amenable to safe and effective operations • Ensure that the operational and scientific monitoring programme is in place, with data being collated and sent back to the EUL and SITU • Ensure daily Containment and Recovery operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered) • Assist operations to draft daily ICS 204 operations orders used by the marine division for Containment and Recovery. Refer Appendix A for draft ICS 204 • Seek approval from AMSA to decant separated water to increase waste storage of recovered oil (refer to decanting IPEICA Good Practise Guide #17 http://www.oilspillresponseproject.org/wp-content/uploads/2016/02/JIP-17-Decanting.pdf) and National Plan Guidance NP-GUI016 for further details. • Working with the safety officer, ensure that WHS risks are appropriately identified and managed. • Plan temporary waste reception facilities at BBMT and Lakes Entrance. • Activate long-term waste treatment contracts from temporary waste storage sites. All data gathered through the OSMP in relation to Containment and Recovery operations are to be captured and displayed in the Common Operating Picture (Esso GIS) so that all members of the IMT have situational awareness. The Planning Section needs to continuously monitor Containment and Recovery operations and scale them up or down as needed when compared to the other spill response strategies. As the oil changes over time (weathering) Containment and Recovery will likely become favoured over dispersant operations.
Operations Section Instructions	The Operations Section and Marine Branch Directors will task assets under their command to undertake Containment and Recovery operations as part of the execution of the IAP developed the previous day. Vessels will operate in pairs, focusing on different sections of the thickest part of the slick within the Containment and Recovery zone. Utilise overhead aerial assets to provide real-time direction to the vessel strike teams. Where approved, regular de-canting by strike teams is to be done to maximise the volume of oil recovered from the vessel’s waste tanks. Safety planning for this strategy must focus on de-confliction with aerial or vessel based dispersant operations. Operational planning will be based on *ExxonMobil Oil Spill Response Handbook* s. 5.

At-Sea Containment and Recovery (Vessel Based)	
	Critical Daily Tasking: All Spills: • Execute the IAP for the current Operational period. • Liaise with the PSC to ensure that field tasking (ICS 204) is drafted and used for C&R operations. Refer Appendix A for draft ICS 204 • Ensure daily Containment and Recovery operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered. • Operations are to be directed to continuous parts of the slick to maximise effectiveness. • SimOps planning needs to be a part of the daily tasking. • Vessels assigned for the OSMP water sampling/monitoring activities.
Logistics Section Instructions	The Logistics Section is to activate contracts and provide ongoing services and supply (from Esso resources and/or third parties) in support of the execution of this strategy. This is focused on supporting Containment and Recovery strike team operations from BBMT and Lakes Entrance. Vessels of opportunity are to be sourced and wet chartered through Esso's marine team. Oil spill response equipment is to be sourced from AMOSC, NatPlan sources, and OSRL if required. Logistics is to use the technical advice of AMOSC LO/OSRL LO as to the best equipment selection for the operation at the time. Factors to be considered include • Known and anticipated weather conditions. • Weathering of oil. • Anticipated volumes of oil. • Length of operation/swing. Only large/heavy offshore booms are to be ordered from providers (i.e. 1.5 metres in height or greater), or advanced booming single vessel systems (i.e. NOFI Current buster 2/4/6/8/ or SpeedSweep Systems) with skimmer selection focusing on high capacity, high volume oil removal (i.e. greater than 30 m^3 per hour pumping capacity). For Level One Spills: • Utilise the chartered Esso vessels to load out equipment from BBMT with Esso OSR trained personnel. • Contract AMOSC personnel and AMOSC CG personnel if needed.

At-Sea Containment and Recovery (Vessel Based)	
	For Levels Two and Three: • Request additional skimming equipment, booms, and temporary storage from AMOSC to match the need, as directed by the planning section – quantities and types of equipment. • Request AMOSC personnel and AMOSC CG in numbers suitable for equipment deployment. • Contract offshore surveyed vessels suitable for strike team duties – deck size and bollard 'pull'. • Ensure that temporary storage facilities at BBMT and Lakes Entrance are in place to receive the volume of waste that will be offloaded from the strike teams. • Ensure that waste contractors are in place to remove the temporary waste from BBMT and Lakes Entrance to final waste storage/disposal sites or processing. Critical Daily Tasking: • Sustain the activities for the duration of the spill with contractors and third parties to ensure that operations can continue Marine Bases. Services and supply for operations – vessel consumables, goods, and resupply. • Track vessels for compliance with Esso marine requirements. • Track volumes of oil recovered by strike teams and anticipate temporary storage requirements at marine bases.
Termination Criteria	Containment and Recovery operations will cease based on any of the below triggers: • NEBA determines that Containment and Recovery operations no longer provide demonstrable environmental benefits. • OSMP triggers are met. • Oil is too thin for effective booming and containment to take place • Weather/sea conditions make Containment and Recovery operations unsafe or ineffective.

5.8 Protection of Sensitive Shoreline Resources

Strategy Description:

Booms will be used to protect shoreline resources and to corral oil for skimming.

Relevant environmental performance outcomes and standards are provided in Appendix C.

Protection of Sensitive Shoreline Resources	
Response Objective	To recover spilt oil before shoreline or other sensitivity contact. To remove bulk floating oil and improve water quality.

Critical Outputs	For All Spills
	• Modelling predicts shoreline impacts over time
	• Where shoreline impact is predicted a Tactical Response Plan (TRP) will be implemented
	• TRPs consist of detailed response information and resources required including the equipment and personnel to carry out identified taskings related to the protection of specific sensitivities
	• Taskings within the TRPs include:
	  ○ SCAT
	  ○ Pre-cleaning of shoreline
	  ○ Protection and deflection booming
	  ○ Containment and recovery
	• Primary TRP sites identify sensitivities permanently exposed which will require a definitive response. The TRP identifies specific tasks aimed at minimising environmental impact.
	• Secondary TRP sites identify sites at which exposure is seasonal or irregular and require confirmation of a requirement prior to response. The TRP identifies sensitivities, site information, likely response strategies, and resources required that would require validation based on conditions at time of event
	• Secondary TRP sites that do not require a response would allow additional resources to be directed towards other response activities

Protection of Sensitive Shoreline Resources

Planning Section Instructions

The Planning Section EUL to provide advice about whether there are any specific sections of coastline with high-value sensitivities – in these areas, specific tactical planning should be put in place.

All planning for protection of coastlines is to be done in conjunction with the Control Agency IMT.

The following locations have pre-drafted TRPs which should be used to guide response planning.

Primary Sites

SITE NAME	Site Type	Latitude	Longitude

TRPs may need to be drafted in conjunction with the operations section for locations without existing TRPs. Shoreline TRPs and shoreline clean-up more generally should be executed consistent with guidance in the Tactical Response Plan - Shoreline Protection & Clean Up and/or the *ExxonMobil Oil Spill Response Handbook* s.12.

Critical Daily Tasking:

- Establish through a daily Net Environmental Benefit Assessment and SMV the ongoing benefit of shoreline booming.
- Ensure that weather conditions are amenable to safe and effective operations.
- Ensure that an operational and scientific monitoring programme is in place, with data being collated and sent back to the EUL and SITU.
- Ensure daily operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered).
- Assist operations to draft daily ICS 204 operations orders used by the shoreline and nearshore division for booming.
- Work with the DOT LO to ensure agreement on the location of specific tactical operations.
- Work with the safety officer to ensure that WHS risks are appropriately identified and managed.
- Plan local temporary waste reception facilities co-located with shoreline recovery.
- Activate long-term waste treatment contracts from temporary waste storage sites.

Operations Section Instructions

The Operations Section and Shoreline Protection Branch Director will need to coordinate with the DOT to ensure that resources under Esso command undertake shoreline protection tactics consistent with the requirements of the DOT.

Protection of Sensitive Shoreline Resources	
	The Shoreline Protection Branch must work closely with the Planning Section to draft and 'truth' tactical response plans. Plan drafting will be prioritized based on time frame of impacts – with soonest and most critical sensitivities being done first. All operations are to be consistent with the IAP developed the previous day. The Shoreline Protection Branch is to divide the tasking between teams that are geographically focused – each with a number of plans to execute. For protection / deflection booming, teams will need to continuously monitor boom for effectiveness and adjust for changes in tide, current, and weather. When booming is used for containment with recovery operations, effective temporary waste storage must also be put in place. Safety planning for this strategy must focus on remote operations, the use of manual handling risks, and potential for exposure to hydrocarbons. Operational planning will be based on Tactical Response Plan - Shoreline Protection & Clean Up and/or the *ExxonMobil Oil Spill Response Handbook* s.12. Critical Daily Tasking: All spills • Execute the IAP for the current operational period. • Liaise with the planning section to ensure that field tasking (ICS 204's) is drafted and used for shoreline protection operations. • Booming operations are to be continuously monitored to ensure ongoing effectiveness. • SimOps planning needs to be part of the daily tasking. Operations must also adhere to good practice decontamination practices, establishing and keeping to hot, warm, and cold zones as well as personnel and equipment washdown facilities. Site setup must follow the practices outlined in the *ExxonMobil Oil Spill Response Handbook*.
Logistics Section Instructions	The Logistics Section is to activate contracts and provide ongoing services and supply (from in-house resources or from third parties) in support of the execution of this strategy.

Protection of Sensitive Shoreline Resources	
	Shoreline protection strike teams may be directed to put in place tactics along any part of the mainland, Bass Strait, or Tasmanian Islands. Logistical support will be required at each of these locations to support spill response – moving operators in and out of these locations and supporting them while they are there. In extreme non-assessable locations, this could require rotary wing aircraft moving personnel and freight and equipment lifts/movement. The logistics section must ensure the correct type and volume of spill response equipment is divided into caches for each of the tactical response plans. This includes • Appropriate lengths of shoreline and shore seal booms, including land and sea anchoring systems. • Smaller portable skimming systems. • Temporary waste storage (on-site) of a volume equivalent to anticipated recovery. Support and services for on ground operators must also be provisioned, including • Shelter • Sustenance • Ablutions • Transport. The Logistics Section is to liaise with DOT on the shoreline needs and then utilise Esso standing support contractors for the provision of these services where there are gaps between what the DOT is able to provide and the need. Logistics is to also use the technical advice of AMOSC LO/OSRL LO as to the best equipment selection for the operation at the time. Factors to be considered include • Known and anticipated weather conditions. • Weathering of oil. • Anticipated volumes of oil. • Duration of operation. The logistics section is to prioritise Esso and AMOSC equipment for deployment for the execution of shoreline protection booming, with NatPlan/DOT/OSRL equipment to be deployed if there is a shortfall.

Protection of Sensitive Shoreline Resources	
	For All Spills: • Tally up the total amount of booms, number of skimmers, and ancillaries required based on the recommended tactical response plans and those that are drafted at the time. These totals are to be tallied, and requests made to Esso, AMOSC and to AMSA for equipment as required. • Tally up the amount of personnel required to implement and monitor the tactical response plans: Source these personnel from the same sources as above – Esso and AMOSC, AMSA (NatPlan), and OSRL – and divide these personnel into appropriate teams. • Source the required transport and accommodation appropriate to the number of responders. Critical Daily Tasking: • Validate the quantities of oil spill equipment and personnel – adjust as needed. • Monitor that transfers, accommodation and provisioning arrangements are fit for the purpose. • Validate that temporary waste management storage capacity at each site is sufficient.
Termination criteria	Oil no longer threatens sensitive receptors. DOT directs that Esso is to demobilise from sites.

5.9 Shoreline Clean-up

Strategy Description:

Shorelines will be (1) assessed using SCAT and (2) shoreline treatment recommendations put in place.

Relevant environmental performance outcomes and standards are provided in Appendix C.

Shoreline Cleanup	
Response Objective	To remove bulk stranded oil from accessible shorelines and speed up natural recovery of habitats.
Critical Outputs	<u>Initial Response</u> - EAPL coordinate with contractors (GHD / AMOSC) and jurisdiction (Vic DoT) to mobilise SCAT teams to conduct shoreline assessment - EAPL mobilise Shoreline Response Planning function - SCAT feedback initiates development of initial Shoreline Treatment Recommendations (STRs) - EAPL/AMOSC/Vic DoT support initial shoreline clean-up operations <u>Planned Phase – Decision Making</u> - EAPL resources support jurisdiction in maintaining ongoing SCAT program and development of STRs - EAPL resources support jurisdiction in development of Shoreline Response Plan (SRP) <u>Planned Phase – Project Implementation</u> - EAPL resources support jurisdiction in implementation of SRP and support operations <u>Response Completion/Termination</u> - EAPL resources continue to support SCAT inspections
Planning Section Instructions	All planning for protection of coastlines is to be done in conjunction with the Control Agency IMT. The Planning Section will oversee two distinct elements of the shoreline response: (1) Gathering data through the SCAT function (using Esso's or the State's collector application) and, (2) Using this data to plan for an extended shoreline clean-up.

Shoreline Cleanup	
	Shoreline surveys will ideally be done in conjunction with jurisdictional control agencies. Shoreline clean-up operations must be performed under the control and coordination of jurisdictions, unless this has been formally devolved to Esso or another group. Data Collection SCAT teams undertaking field surveys need to consistently gather data on shoreline type, oiling description, and clean-up recommendations. This data gathering is a planning, not operations, function, so it becomes a prominent field component of the planning section. Ideally, teams will be multi-disciplinary/multi-agency and include an oil spill operator (for practical clean-up recommendations) combined with an environmental advisor/scientist. SMEs should be consulted for specialist shoreline types or where there are specific sensitivities exist (e.g. indigenous heritage areas). Data will be fed back from these teams to the Esso GIS CoP, allowing (close to) real-time data sharing with the IMT and forward planning for future operations. Critical Daily Tasking: • SCAT teams form up in the morning, head out to the fields, and report back on data collected. • Shoreline Treatment Recommendations to be issued for the section of the shoreline where oiling has occurred. These form the basis of the ICS204 for shoreline clean-up operations. • Where oil is likely to affect the shoreline, SCAT teams should be recommending the pre-cleaning of beaches to reduce future organic waste. Shoreline Clean-up Based on the data collected from the SCAT surveys, work assignments (ICS 204 or similar) to be drafted that guide clean-up teams to execute the shoreline treatment recommendations. Shoreline divisions based on a span of control adequate to manage clean-up teams will need to be agreed on and established with the jurisdictional control agency. Pre-defined shoreline sectors have been developed for the Victorian coastline and should form the basis of planning. The EUL to provide advice on whether there are any specific sections of coastline with high-value sensitivities – in these areas, specific separate shoreline cleaning will be required. Refer to Tactical Response Plan - Shoreline Protection & Clean Up and/or the *ExxonMobil Oil Spill Response Handbook* for further guidance. Critical Daily Tasking: • Establish through a daily Net Environmental Benefit Assessment and SMV the ongoing benefits of shoreline clean-up.

Shoreline Cleanup	
	• Ensure that weather conditions are amenable to safe and effective operations. • Ensure that the operational and scientific monitoring programme is in place, with data being collated and sent back to the EUL and SITU. • Ensure daily operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered) • Assist operations to draft daily ICS 204 operations orders used by the shoreline clean-up operations. • Work with the DOT LO to ensure agreement on the location of specific tactical operations. • Work with the safety officer to ensure that WHS risks are appropriately identified and managed. • Plan local temporary waste reception facilities co-located with the shoreline clean-up. • Activate long-term waste treatment contracts from temporary waste storage sites.
Operations Section Instructions	Based on the advice received from Esso by DOT, the Operations Section, Shoreline Clean-Up Branch, will work along with DOT to ensure that resources under Esso command undertake shoreline clean-up consistently and under the control of the DOT. With no marine, aviation, or other spill response/source control interventions, the predicted shoreline loadings for all discharge scenarios are provided in Appendix D Quick Reference Information. These volumes will be reduced with spill response measures, but oil is still very likely to be stranded along the coastline in the majority of modelled scenarios. Shoreline divisions based on a span of control adequate to manage these clean-up teams will need to be agreed on and established with the jurisdictional control agency. Esso's resources are likely to work in a blended teams with State resources. Teams to execute the shoreline treatment recommendations developed by the SCAT teams in the planning section. Shorelines within the Potentially Exposed Area are predominantly fine, medium, and coarse-grained beaches, interspersed with rocky headlands. There also exists a number of estuarine systems which shelter much higher sensitivity shorelines. The principle issue for response will be accessing the more isolated portions of coastline (far-east Victoria) and how to manage and stage large work forces working in these areas. Safety planning for this strategy must focus on remote operations, manual handling risks, and potential for exposure to hydrocarbons. Operational planning should be based on the Tactical Response Plan - Shoreline Protection & Clean Up and/or the ExxonMobil Oil Spill Response Field Manual s 12, and the instructions given by the Control Agency. Critical Daily Tasking: All Spills: • Execute the IAP for the current operational period. • Liaise with the planning section to ensure that field tasking (ICS 204's – Shoreline Treatment Recommendations) is drafted and used for shoreline protection operations. • Work closely with the DOT Operations Officer as required to ensure ongoing unity of command. • Shoreline clean-up is continuously monitored to ensure ongoing effectiveness. • SimOps planning needs to be a part of the daily tasking.

Shoreline Cleanup	
	Operations must also adhere to good practice decontamination practices, establishing and keeping to hot, warm, and cold zones, as well as personnel and equipment washdown facilities.
Logistics Section Instructions	Based on the advice received from Esso by DOT, the Logistics Section will work alongside with DOT to ensure that resources are deployed to assist in the shoreline clean-up consistent with the request of the jurisdictional control agency DOT. With no marine, aviation, or other spill response/source control interventions, the predicted shoreline loadings for all discharge scenarios are provided in Appendix D Quick Reference Information. These volumes will be reduced with spill response measures, but oil is still very likely to be stranded along the coastline in the majority of modelled scenarios. Shoreline divisions based on a span of control adequate to manage these clean-up teams will need to be agreed on and established with the jurisdictional control agency. Key support from Esso in this task includes • Activation of labour hire contracts* to provide 50 – 500 personnel available for medium-term (2–4 months) shoreline clean-up tasking. • AMOSC CG personnel to supervise and oversee clean-up teams. • Safety and Security personnel to support response activities • Working with the EPA and Esso's waste management contractor to come up with acceptable bunded temporary storage areas for recovered waste. • Deployment of all AMOSC, mutual aid, and NP temporary storage equipment to points along the coastline as directed by the DOT. • Activation of accommodation, transport, and sustenance. * *Utilise base business contractor or escalate to ExxonMobil Contingent Worker Contractors team to coordinate hire of additional personnel. Critical Daily Tasking: All Spills: • Execute the IAP for the current operational period; • Liaise with the planning/operations section to ensure that support and services for the ICS 204's – Shoreline Treatment Recommendations are delivered. • Work closely with the DOT logistics section to deliver services and supply under a unity of command. • Ensure that recovered waste is efficiently managed. • Develop a forward plan of rotations for shoreline staff engaged in physical labouring activity.
Termination Criteria	• Shoreline operations will cease once pre-spill levels are returned, and/or by direction of the jurisdiction control agency.

5.10 Oiled Wildlife Response

Strategy Description:

Esso will assist the state-led OWR response with equipment and technical personnel as requested.

Relevant environmental performance outcomes and standards are provided in Appendix C.

Oiled Wildlife Response	
Response Objective	Esso assists state government efforts through the timely provision of industry OWR resources.
Critical Outputs	For All Spills: • Esso will activate the OWR resources of AMOSC and OSRL, equipment, personnel, and technical. • These resources will be provided to the Control Agency led IMT for use in reducing the impact of oil on wildlife.
Planning Section Instructions	Allocate an Esso IMT member to act as Liaison Officer to Control Agency IMT. A dedicated Liaison Officer for oiled wildlife response will likely be required. This role may be filled by the AMOSC OWR Coordinator. Details of numbers, type, status and type of fauna impacted by marine pollution to be collated by SITU. Daily ICS 204 work assignments to be developed in consultation with Operations, Logistics and Control Agency IMT. Utilise Area Response Plans and/or Specied Response Plans to assist with incident specific response planning.
Operations Section Instructions	Support OWR activities as directed by Control Agency IMT and per ICS 204 work assignments
Logistics Section Instructions	On request from Control Agency IMT, mobilise OWR equipment from AMOSC and/or OSRL. AMOSC • 2x OWR Containers (Geelong and Fremantle) • 4x OWR Box Kits • OWR Facilities support via DwyerTech contract • OWR Industry Team • AMOSC OWR Coordinator OSRL* • 3x OWR Search and Rescue kits • 1x OWR Intake and Triage kit • 4x Cleaning and Rehabilitation kits

Oiled Wildlife Response	
	• 1x Wildlife Rehabilitation Unit * 50% of the above inventory is available during an incident. Sea Alarm (via OSRL) • 1x Full time availability of one Sea Alarm expert for advice and potential mobilisation to the affected site. • 1x Full time availability of one Sea Alarm expert for advice and response support (based in Brussels). ExxonMobil RRT • RRT OWR Core Team • Third party OWR specialists Equipment owned by State agencies will be requisitioned via the Control Agency IMT under NatPlan arrangements.
Termination Criteria	Resources are no longer required/requested by the State government.

5.11 Waste Management

An oil spill waste management plan AUGO-EV-ELI-011 has been developed which provides guidance on contractor activation, equipment available, waste segregation, storage and disposal options. This document should be referenced to develop an incident specific waste management plan.

Esso holds a number of waste management contracts with third parties that will be called upon in the event of a spill. These parties will be used to:

- Provide a waste subject matter expert to the logistics section of the IMT;
- Work with the EPA to put in place waste management chains from point of collection to final disposal; and
- Ensure that the waste management practises put in place are ethical, legal and follow Australian best practise waste management principles.

Different wastes will be generated from a variety of different sources including:

- Liquid wastes (oil / water) – collected offshore by vessels from the shoreline through booming operations;
- Bulk hard wastes (oils mixed with organic materials, sand, rocks, pebbles, etc.) collected in bulk from shorelines by mechanical and manual means;
- Sundry wastes generated as a result of employing a large temporary workforce including PPE, waste from catering, etc.

Esso's waste management resource capability is described in detail in Section 9.3.1 of Volume 3. Relevant environmental performance outcomes and standards are provided in Appendix C.

6 Concept of Plan

6.1 Purpose

The purpose of the Esso Bass Strait Oil Pollution Emergency Plan (OPEP) is to describe the actions and arrangements Esso Australia has in place to respond to an oil pollution incident from any one of the company's Bass Strait petroleum activities (refer Figure 2-1).

Spills can range from Tier One, small single event releases, to Tier Two-Three, ongoing/large releases. This plan is designed to provide the full range of available response options and plans for all spills, regardless of the Tier level and is therefore, not specific to a particular activity or scenario.

It is designed such that the Incident Management Team and Emergency Response Team have immediate access to the full suite of response action plans (from Tier One to Tier Two-Three) and can select and implement the appropriate plan based on the specific emergency situation.

This OPEP provides the processes and tools to be able to select and apply the viable response options (and therefore eliminate options that are not viable) for the specific spill event.

6.2 Objectives

The objectives of this OPEP are to:

- Define the roles and responsibilities for Esso to assess and then respond to an oil spill;
- Describe the process for deployment of oil spill response strategies that will be used by Esso (and its partners);
- Describe the procedures for mobilising company, industry and national support resources to support these spill response strategies;
- Clearly outline guidance to plan-users on how the above is to be undertaken, consistent with regulatory requirements;
- Integrate Esso's response with relevant government and industry plans:
- National Plan for Maritime Environmental Emergencies (National Plan)[3]
- Victorian Maritime Emergencies (Non-Search & Rescue) Plan (SERP [NSR]) [4]
- NSW State Waters Marine Oil and Chemical Spill Contingency Plan4
- Tasmanian Marine Oil Spill Contingency Plan (TASPLAN) [5]
- The Australian Industry Cooperative Oil Spill Arrangements (AMOSPlan)[6] and
- Describe how Esso will implement its Incident Management System in responding to oil spills; and
- Describe the link for ExxonMobil's global resources and services to be deployed as part of Esso's local response.

6.3 Scope

This OPEP provides oil spill response plans to respond to any spill from Esso's Bass Strait operations and project activities. Project activities which could result in a spill to environment have been identified as:

- Drilling
- Well operations (platforms, both manned and unmanned)
- Workovers of wells
- Workovers of subsea, seabed or platform infrastructure

[3] https://www.amsa.gov.au/forms-and-publications/Publications/national_plan.pdf.

[4] https://www.emv.vic.gov.au/responsibilities/state-emergency-plans/state-maritime-emergencies-non-search-and-rescue-plan

[4] http://www.rms.nsw.gov.au/documents/about/environment/oil-spill-contingency-plan-nsw-state-waters.pdf

[5] http://epa.tas.gov.au/Documents/TasPlan.pdf

[6] http://www.amosc.com.au/amosc.php

- Pipelines running from offshore fields to coastlines, and
- Plug and abandonment activities.

Specifics of the scope of accepted activities is contained in relevant Environment Plans applicable to this OPEP. This OPEP has been prepared to be applicable to the following Environment Plans:

- Jack Up Rig Drilling
- Bass Strait Operations
- West Barracouta Installation, Commissioning and Initial Operations

For vessel activities that enable Esso's petroleum activities, the OPEP includes arrangements for Esso to respond to such spills under the direction of the relevant control agency.

The geographic scope of activities as directed by the OPEP (particularly for level two and three hydrocarbon spills) would likely apply to an area significantly beyond Esso's petroleum titles. This includes Commonwealth waters off south eastern Australia, and state waters of Victoria, New South Wales (NSW) and Tasmania. Staging areas for activities as far as practicable will be based in Victoria.

6.4 Division of Responsibilities

Spill response activities in the zones outlined above are shared between a number of parties, known as control agencies (organisations leading response activities) and support agencies (organisations that help with the provision of labour, platforms, or services). The (legal) obligation to respond is outlined as below:

Table 6-1 Control Agencies

Location of spill	Source	Control Agency for oil spills	Supporting Agency
Commonwealth Waters (>3NM from shorelines)	Petroleum activity	Esso	AMSA
	Ship associated with petroleum activity	Esso as first responder, under the direction of the Australian Maritime Safety Authority	Esso
State waters or shorelines (<3NM of coastline)	Petroleum activity / Ship	State Government (Vic — DOT; NSW — Transport for NSW; Tas — EPA) with Esso supporting operations	Esso, local state port authorities, AMSA, state-based wildlife agencies

In all instances of spills from Esso's petroleum activities, Esso's response activities should be considered to be regulated by NOPSEMA and directed by this OPEP, until such time as another control agency verifies its intention to stand up and assert control.

As a response grows in size and complexity, a range of other parties and agencies may become involved, either to acquit a legislative obligation, or to provide support to a control agency.

In all cases, for spills originating from Esso assets and activities, Esso will facilitate the provision of resources to the control agency for their use in mitigating the consequences of the spill.

6.5 Safety, Health and Environment Policy

Oil spill response activities under the control of Esso shall be implemented in a manner that reflects Esso's legal commitments to best practice workplace health and safety (WHS). That is, in accordance with (1) Esso's Safety, Health and Environmental policies and consistent with the outcomes sought from the (2) National Plan guidance paper *NP–GUI–026: Marine oil spill response health and safety*.

Prior to implementing spill response operations, for activities that are outside Esso's business as usual operations, activities will be risk assessed and should additional consequences be introduced, these shall be mitigated as appropriate.

Esso will develop and implement a spill safety plan which documents this process.

Safety risk mitigation measures, using a mix of process and personnel safety, will be put in place using the established hierarchy of control methods, as shown below in the Fig 10:

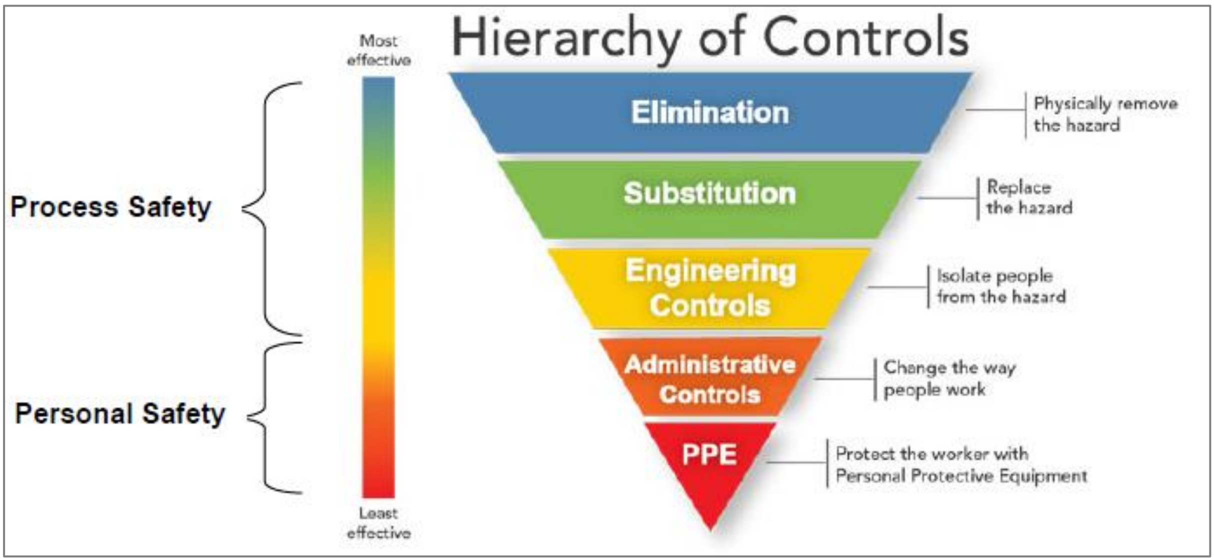

Figure 6-1 Workplace Health and Safety Hierarchy of Controls for Risk Mitigation

'Baseline' measures such as establishing controlled entry at polluted sites, wearing personal protective equipment and the use of safe working practices supported by suitable training, will be an integral part of response operations.

In cases where available measures to reduce the risk of injury or detrimental health implications cannot be lowered to an acceptable level, that activity or specific response strategy will not be viable until conditions change. Examples of this include situations where fresh hydrocarbons are releasing vapours, where sea conditions prevent safe working on the deck of a vessel, or where platforms and assets no longer present stable safe working platforms.

In implementing spill response activities, Esso, its contractors, and other parties supporting the response, shall always be mindful of the company's emergency response priorities, using the acronym 'PEAR':

P – People, E – Environment, A – Assets, R – Reputation

6.6 Interface with Other Documentation and Plans

This OPEP is a component of the EP in force for the specific Esso petroleum activity taking place and outlines the measures that Esso will put in place for hydrocarbon spills from that activity.

The OPEP also has a relationship with a number of other key Esso documents as outlined below:

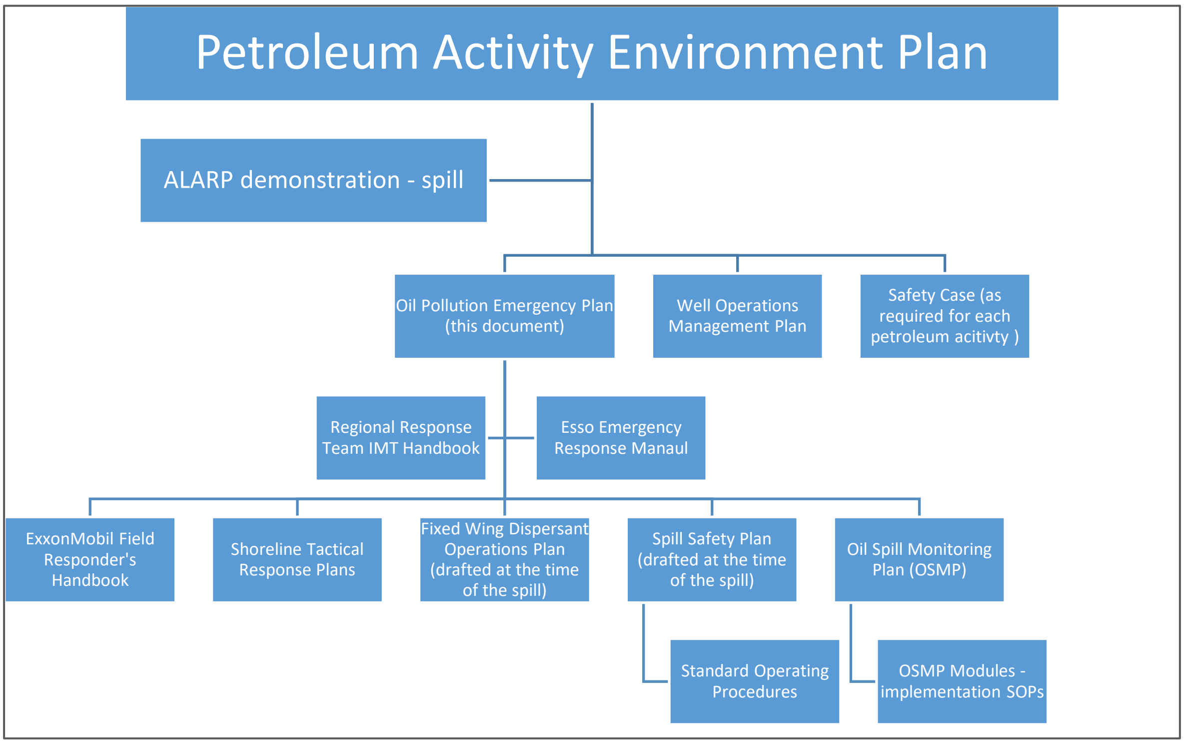

Figure 6-2 OPEP Relationship With Other Key Esso Environmental Documentation

This OPEP also has a number of linkages to external third-party spill response plans or documents. These outline how Esso is to engage with national and state government agencies for the provision of assistance to Esso, or from Esso to those parties, for spill response activities, and who is ultimately ‘in charge’ of clean up efforts in a particular geographical area. These links are detailed below:

Table 6-2 External Plans That Inform and Influence Actions Under This OPEP

Plan / Document
National Plan for Maritime Environmental Agencies (National Plan) (AMSA, 2020) National Plan for Maritime Environmental Emergencies 2020 (amsa.gov.au)
Outlines the resources and services that may be provided by AMSA and other government agencies to assist Esso Details nationally consistent processes and procedures spill response management and tactics and Outlines a range of guidance documents on the same.
Victorian Maritime Emergencies (Non-Search & Rescue) Plan https://www.emv.vic.gov.au/responsibilities/state-emergency-plans/state-maritime-emergencies-non-search-and-rescue-plan
Specifies control agency responsibilities and obligations under Victorian laws in Victorian waters. Specifies the mechanism by which Esso will engage to support the state for oil spill response and wildlife affected by marine pollution.
Victorian State Emergency Management Plan Victorian State Emergency Management Plan (SEMP).pdf (emv.vic.gov.au)
Outlines agency obligations for emergency management in Victorian state waters and shorelines.
Tasmanian Marine Oil Spill Contingency Plan (TASPLAN) https://epa.tas.gov.au/Pages/Document.aspx?docid=558
Specifies response agency responsibilities and obligations under Tasmanian laws in Tasmanian waters Specifies the mechanism by which Esso will support the state for oil spill response.
NSW State Waters Marine Oil and Chemical Spill Contingency Plan https://www.emergency.nsw.gov.au/Pages/publications/plans/sub-plans/state-waters-marine-oil-and-chemical-spill-contingency-plan.aspx
Specifies control agency responsibilities and obligations under NSW laws in NSW waters Specifies the mechanism by which Esso will support the state for oil spill response.
AMOSPlan www.amosc.com.au
Outlines the support (people, services and equipment) from AMOSC to Esso. Outlines the mutual aid (people, services and equipment) available from AMOSC's members to Esso. Details process to access surge spill response people, services and equipment.

7 Concept of Spill Response Operations

Esso's concept of operations for responding to spills is based on Esso's environmental commitment detailed in the ExxonMobil Environment Policy.

This translates to a series of commitments by Esso for each occasion that a loss of containment occurs or is suspected. Esso will undertake

1. To conduct early and accurate identification of split hydrocarbons
2. To conduct an assessment and identification of defensible and proportionate spill response strategies
3. To tactically implement identified spill response strategies in a timely fashion and
4. To monitor the effectiveness of those strategies in order to achieve Esso's stated environmental performance outcomes for this OPEP.

Esso will mobilise its significant national and global processes, services, contracts and resources to achieve the above.

7.1 Reactive and Proactive Response Stages

This OPEP is broken into two broad sections: (1) background, contextual and supporting information; and (2) response processes. Response processes are then broken down into two further stages: (A) assessment / reactive planning and (B) proactive planning stages.

(A) Assessment/reactive planning are the actions that Esso will undertake in the field by the Esso IMT based on a first-pass assessment of the situation. They are the best planned, reactive actions that can be reasonably expected to assist in achieving Esso's Environmental Performance Outcomes (EPO). Should the assessment indicate a Level Two or Three spill, many of these actions will be focused on the mobilisation of resources likely to be used in future operational periods for the tactical spill response.

(B) Proactive planning is the more settled, longer term project planning mode that Esso will undertake. It requires the mobilisation and setup of a full incident management team and will be supported by Esso's Emergency Support Group for strategic support.

7.1.1.1 Incident Management System

Esso Australia has adopted the global ExxonMobil standard of the incident control system (ICS) as its internal incident management system. ICS maps well onto, and is compatible with, the Australian interagency incident management system (AIIMS) adopted by Australian governments under the National Plan.

At the core of ICS is the concept of the 'planning p'. This is a standardised, systemic process used to identify and then action all incidents. It follows a basic five-step process outlined below:

1. Understand the situation
2. Establish incident objectives and strategy
3. Develop the plan that details the tactics to achieve the strategy/(ies)
4. Prepare and disseminate the plan
5. Execute, evaluate, and revise the plan

These steps are turned into the flow diagram below. This OPEP has the assessment/reactive and proactive stages mapped onto this diagram:

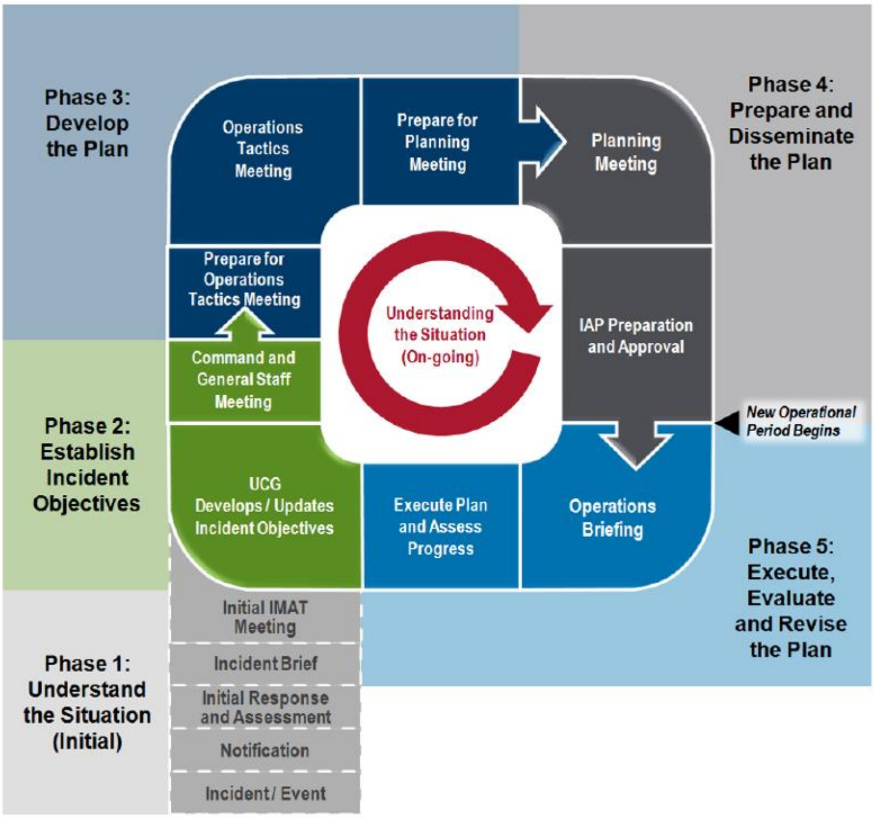

Figure 7-1 ICS Planning 'P'

Esso considers the use of ICS as one of the key controls to develop a robust and defensible incident action plan, which in turn is critical to achieve the best environmental outcomes at the time of the spill.

7.2 Banding of Responses Based on Control Agency Triggers and Stakeholder Interfaces with Esso

To hasten the implementation of appropriate spill response measures, Esso has developed three different action lists for use by the incident management team, based on the proximity of spilt oil to Victorian coastal waters and shorelines. The intent behind this 'banding' is to establish response measures which quickly establish the structure of and implement the most time critical responses using available resources.

Figure 7-2 outlines this intent:

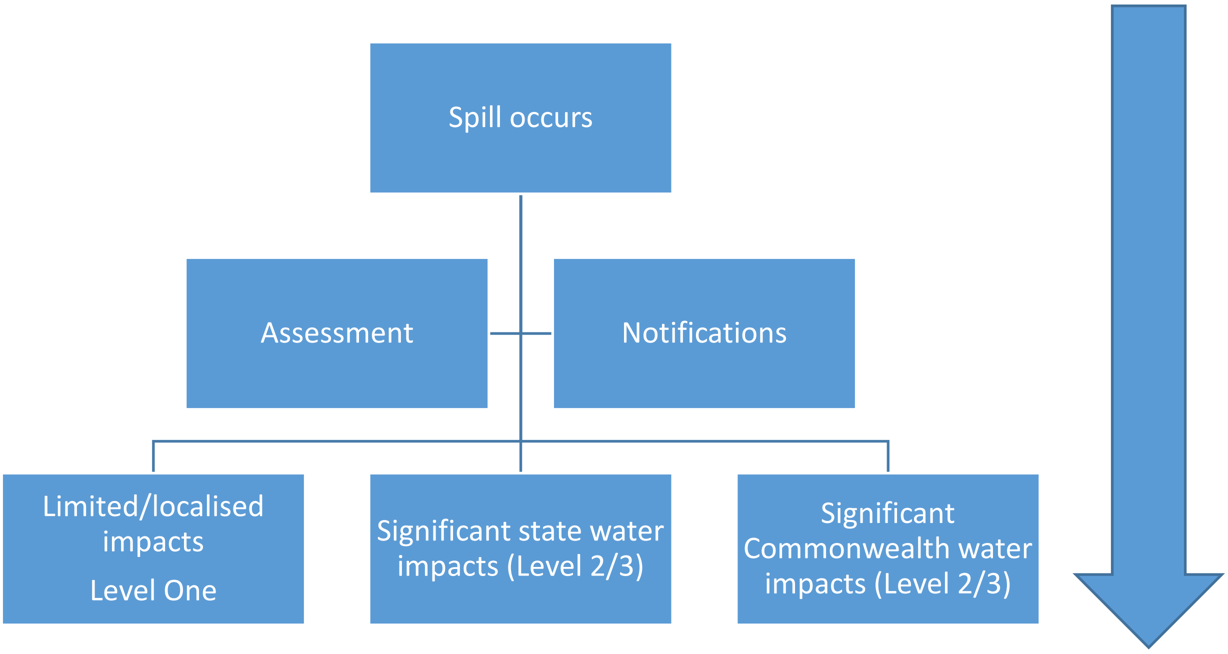

Figure 7-2 Banding Responses

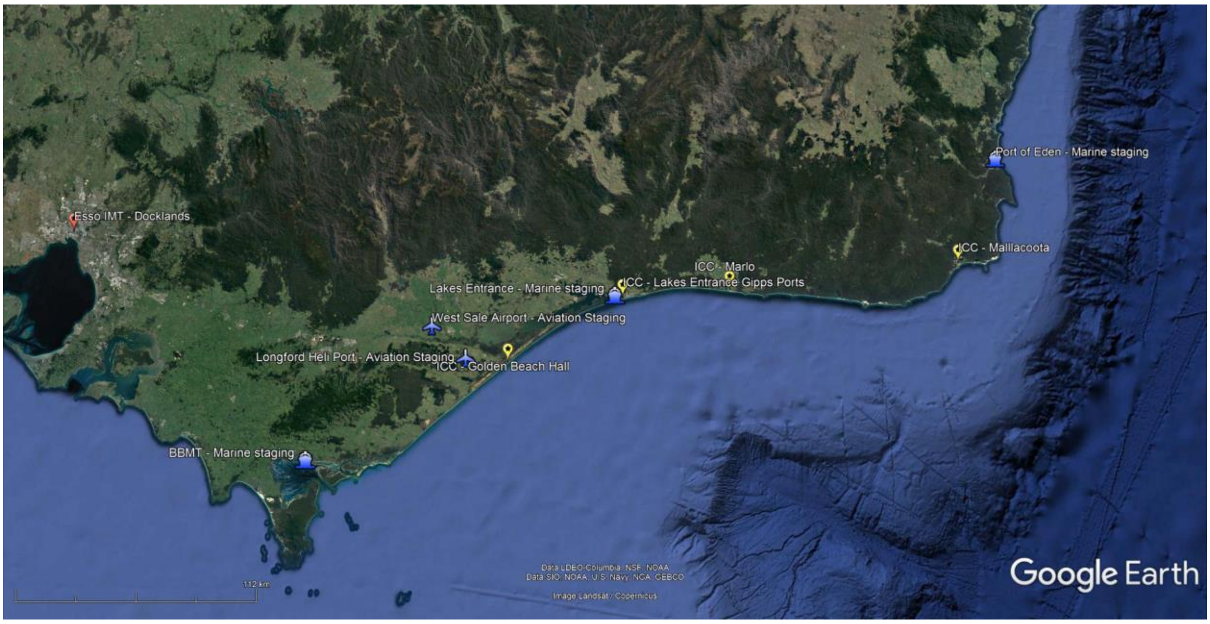
7.2.1 Command Points, Staging and Locations

Esso has a number of operational hubs located in metropolitan Melbourne and Gippsland, which have been predetermined as suitable areas to stage marine, aviation and personnel operations. If available for use, incident command points will be located in Victorian government identified regional ICCs (ref: Victorian Emergency Operations Handbook, pp 117).

These are as below:

Type of area	Location	Address
Incident Command Centre	Esso HQ, Docklands Melbourne	9/644 Collins Street Melbourne, VIC
Gippsland Incident Command Points	Bullock Island, Lakes Entrance	2 Bullock Island Lakes Entrance, VIC
Equipment staging area	Longford Plants, Longford	Garretts Rd, Longford, Vic
	Barry Beach Marine Terminal	Main Access Rd, Agnes VIC
Marine staging areas	Barry Beach Marine Terminal	Main Access Rd, Agnes VIC
	Bullock Island, Lakes Entrance	2 Bullock Island Lakes Entrance, VIC
Fixed wing staging areas & heliports	Bairnsdale Airport	345 Bengworden Road, Bairnsdale, Vic
	Longford Heliport	Garretts Rd, Longford, Vic

The relative location of these points is show on the map below:



7.2.2 Oil Characteristics

The main physical properties that affect the behaviour of spilt oil are specific gravity, distillation characteristics, viscosity and pour points.

In the event of a spill, these oils will weather, or degrade, differently depending on the oil type and its physical / chemical properties as well as on the weather, the sea conditions and the length of time it is exposed to these conditions.

7.2.2.1 Diesel

Diesel is loaded from supply vessels onto all offshore platforms and is stored on platforms and vessels in bulk tanks. It is used in vessel and platform engines and operating equipment such as cranes.

Diesel (Group[7] 2 Oil) is a common marine fuel and is classed as a medium petroleum distillate. Marine diesel is a mixture of both volatile and persistent hydrocarbons.

Behaviour when spilt generally, rapid spreading, rapid evaporation and some dispersion or dissolution. Diesel may emulsify at low temperatures when fresh, but the emulsification is likely to be ‘unstable’.

Marine diesel contains 95% light hydrocarbons (or non-persistent constituents) that are likely to evaporate when exposed to the atmosphere. The remaining 5% is composed of heavy hydrocarbons (or persistent compounds) that may persist on the sea-surface for extended periods.

The viscosity of marine diesel does not change significantly over time and hence has a strong tendency to physically entrain into the upper water column as oil droplets in the presence of waves but can refloat to the surface if wave energies abate (APASA, 2013).

7.2.2.2 Condensate

Condensate is a Group 1 liquid hydrocarbon resulting from a change in pressure and or temperature of gas — ‘liquid gas’.

[7] Classification of petroleum-based oils or ‘oil groups’ are compiled from various IMO, ITOPF, US EPA and US Coastguard publications. Ref AMSA 2012 Table 8 for classification criteria.

When spilt, condensate behaves in a manner similar to diesel, with generally rapid spreading, rapid evaporation and dispersion/dissolution. There is a low likelihood of emulsification. However, it may contain inert, relatively non-toxic waxes which will persist for some time as they degrade.

Condensates comprise a very high content of volatile (or non-persistent) constituents (~97–99%). Therefore, it is expected that any hydrocarbons reaching the sea-surface would quickly be lost to the atmosphere via evaporation. Smaller droplets may remain in the water column for a longer period undergoing microbial degradation over time. Any persistent (heavy) hydrocarbons may persist longer in the form of small solid relatively non-toxic waxy flakes on the sea-surface or entrained in the water column in turbulent waters given the rough environmental conditions of the region.

7.2.2.3 Light Crude

Light crude oil is produced from a number of fields in the Gippsland Basin. .

Analysis of crudes indicates volatiles and semi to low volatile compounds constitute 84.8 - 86.3%. The remaining heavy hydrocarbons (or persistent compounds) will persist in the environment for a longer period of time as a liquid or semi-solid state, either on the sea surface, entrained in the water column or on shore. The nature of the weathered residues is likely to be a sticky, waxy paste-like oil that will become more crystalline over time as it weathers further.

The loss of volume through evaporation for some crude oils may be offset by tendency to form viscous emulsions ('water in oil'). Oils with more than 3% by weight of asphaltenes create 'stable emulsions' while oils containing less than 3% by weight of asphaltenes only develop unstable emulsions (Fingas and Fieldhouse, 2004).

The maximum value of asphaltenes present in the light crude oils are all less than 0.05%wt so are unlikely to form stable emulsions that would impact on shoreline response and clean-up strategies. It is more likely that only temporary emulsions are likely to be generated and only at sea.

7.2.2.4 Waxy Crude

Waxy crudes are produced from some reservoirs, including Flounder and Moonfish. These crudes contain a high proportion of wax–with a corresponding high pour point. Waxy crudes are likely to solidify in the environment as it weathers over time.

The properties of these crudes classify them as a Group IV oil due to the high pour point (above ambient temperature) according to ITOPF (2014).

Given the tendency to form solid masses at ambient sea temperatures, the opportunity to use and effectiveness of chemical dispersants is diminished.

7.2.2.5 Summary of Hydrocarbon Characteristics Used in Oil Spill Trajectory Models

The physical characteristics of the oil types that were used for modelling are as follows:

	Density @ 15˚C	API	Dynamic Viscosity	Pour Point	Wax Content	Oil Property Category
Marine Diesel Oil (MDO)	829 kg/m^3	37.6	4.0 cP @ 25°C	-14 ºC	-	Group II (light persistent oil)
Condensate (surrogate)	770.6 kg/m^3	52.15	0.14 cP @ 25ºC	-3 ºC	-	Group I (non-persistent oils)
Barracouta Condensate	772.3 kg/m^3	51.6	1.291 @ 20ºC	-39 ºC	1.8%	Group I (non-persistent oils)
Kipper Condensate	760.6 kg/m^3	54.5	0.91 @ 20ºC	-39 ºC	2.3%	Group I (non-persistent oils)

	Density @ 15˚C	API	Dynamic Viscosity	Pour Point	Wax Content	Oil Property Category
West Seahorse 3 Crude	792.5 kg/m^3	48.0	2.0 cP @ 20ºC	-15 ºC	-	Group II (light persistent oil)
West Kingfish Crude	798.1 kg/m^3	45.7	2.4 cP @ 20°C	9°C	25%	Group II (light persistent oil)
Halibut Crude	821.5 kg/m^3	40.6	3.4 cP @ 20°C	0°C	23.7%	Group II (light persistent oil)
Flounder Crude	799.9 kg/m^3	45.3	2.8 cP @ 20°C	18°C	32%	Group IV oil due to the high pour point
Moonfish Crude	887.6 kg/m^3	27.8	5.14 (at 40 °C)	27°C	38.5%	Group IV oil due to the high pour point

8 Supporting Activities to Operations

8.1 Tiered Response Arrangements – Equipment, People and Staging Areas

Logistical and support arrangements for the supply of people, equipment and resources will operate in a tiered approach as below:

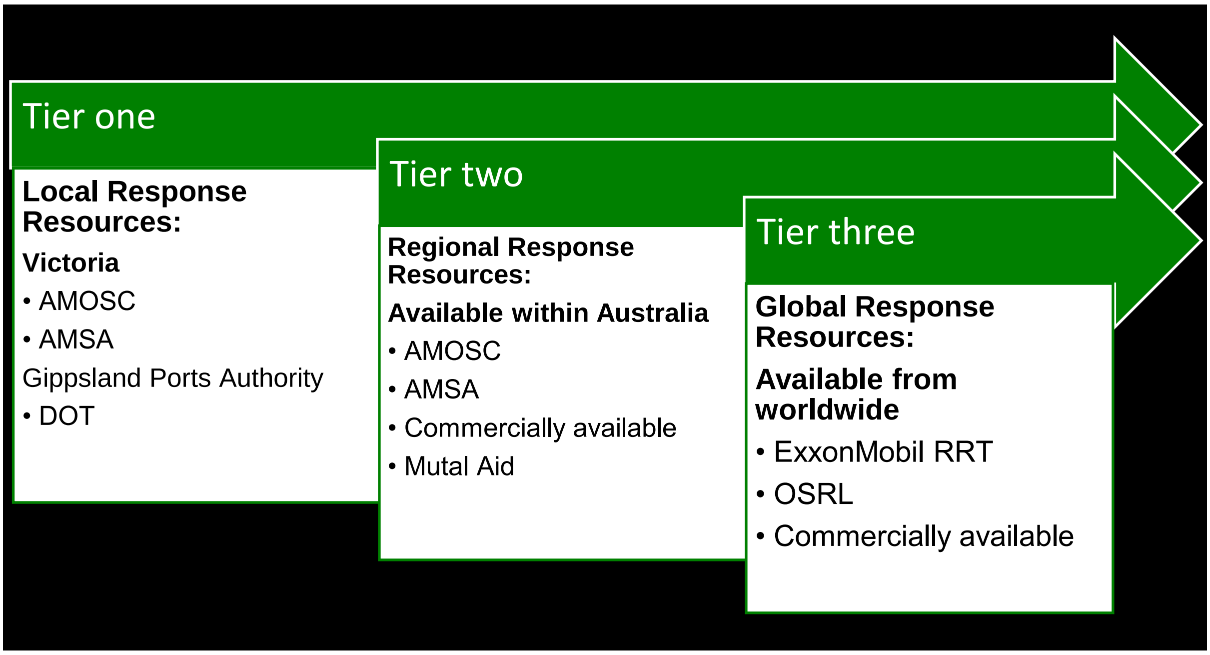


Figure 8-1 Tiered Response Arrangements

8.1.1 Tier 1 – Local Response Resources

EAPL maintains two stockpiles of oil spill response equipment based in the Gippsland region of Victoria at the Barry Beach Marine Terminal and the Long Island Point Fractionation Plant. The stockpiles include equipment suitable for offshore operations, dispersant application, shoreline and nearshore protection, and shoreline clean-up. Quantities of equipment held between the two locations are sufficient, based on the activation of TRPs in line with modeling indications of impact, to provide an initial response and include:

- shoreline protection/deflection boom
- shoreline skimming systems
- offshore booming packages
- offshore skimming systems
- shoreline temporary storage units,
- dispersant and
- decontamination kits

EAPL's immediate spill response equipment will come from its own tier one stockpiles and additional detail of capability in the initial phase of response is included in the Quick Reference Guides. For an up to date list of EAPL's oil spill response equipment refer to ***EAPL OSR Equipment List.***

EAPL maintain trained oil spill response personnel to mobilise an initial response to support the enactment of TRPs, SCAT, and shoreline clean-up.

8.1.2 Tier 2 – Regional Response Resources

Response is conducted by Esso using resources available from within Australia.

In response to a Tier 2 activation EAPL has the capability to mobilise sufficient oil spill response specific resources via AMOSC, AMSA (National Plan), third party contractors, and mutual aid (Industry stockpiles via AMOSPlan). A tiered response would evolve from the 'Initial Response Phase' into a 'Planned Phase – Decision Making', before graduating to a 'Planned Phase – Project implementation'. Staffing requirements for the initial phase would be met by the following with additional support continuing to be provided based on jurisdictional requirements in later phases.

AMOSC
As a member of AMOSC, equipment and resources from the Geelong, Fremantle, Broome, and Exmouth stockpiles are available for mobilisation to Gippsland. The bulk of the equipment, based in Geelong, is available within <12 hours. Additional equipment in Fremantle, Exmouth and Broome can be mobilised to Gippsland as needed by road or air.
A full inventory of AMOSC equipment is available from the AMOSC website
http://www.amosc.com.au/equipment.php

In addition to the AMOSC stockpiles, membership of AMOSC provides access through AMOSPlan to equipment, personnel, and resources owned or held by other oil companies within Australia. Further details of mutual aid capability is available through the AMOSC website above.

AMSA / National Plan Equipment
EAPL has access to AMSA equipment Australia-wide through AMOSC and the National Plan. AMSA maintains significant stockpiles of equipment in Melbourne, Adelaide, Brisbane, Dampier, Darwin, Devonport, Fremantle, Sydney, and Townsville. The closest National Plan stockpile is located in Melbourne, less than 7hours from the furthest point of eastern Gippsland in Victoria. A full inventory of AMSA equipment is available from the AMSA website:
https://amsa-forms.nogginoca.com/public/equipment.html?loc=%2Fapi%2Fv1%2Fasset%2F2615901

Oil Spill Response Personnel
In addition to the Tier 1 capacity provided by trained EAPL oil spill response personnel, EAPL can activate and mobilise AMOSC staff and AMOSC Core Group, and, through National Plan arrangements, state and national response team personnel.

General Personnel
Surge labour hire personnel can be accessed through local providers and EAPL contractors.

ExxonMobil also has a Singapore based Contingent Worker Contractors Team who can coordinate hire of additional personnel through a number of labour hire firms that ExxonMobil routinely work with to fulfil additional capacity requirements for longer term shoreline clean-up of a Tier 2 spill.

8.1.3 Tier 3 – Global Response Resources

Response is conducted by Esso using internationally available resources.

Additional resources, personnel and equipment shall be sourced internationally from Oil Spill Response Ltd through the Singapore base, and then from its other bases around the world to Gippsland. Esso global resources — such as the Regional Response Team — can also be mobilised to Gippsland or the IMT.

ExxonMobil Regional Response Team

The ExxonMobil Regional Response Team (RRT) is a Tier 3 Incident Management Team and is made up of approximately 500 trained personnel from across all business and service lines. The RRT is managed as two sub-teams, with one for the Americas and the other covering the rest of the world. Resources can be shared across regions as needed.

RRT Activation: +44 1372 223 232 (24/7 hotline)

The RRT's structure and processes are based on the Incident Command System (ICS). All RRT members receive initial training in the ICS and oil spill response through participation in the ExxonMobil University of Spill Management course. Additional training is provided based on role and function.

In the event of a major incident, the RRT can provide personnel and expertise to the Business Line to undertake an effective and sustained response. Services that can be provided by the RRT include, and are not limited to, the following:

Command

- Provide experienced Incident Commanders and Facilitators to work with the local Business Line in coordinating the response.

Operations

The RRT is able to provide experienced response team and coordination of third party experts for activities including:

- On water recovery
- Protection / deflection
- Shoreline clean up
- SCAT
- Waste Management
- Surveillance and monitoring
- Dispersant application
- Oiled wildlife response

Planning

- Development of the Incident Action Plan
- Resource Tracking
- Volunteer Management
- Situation mapping / Common Operating Picture
- Modelling
- Environmental specialist
- SCAT coordination
- Documentation and translation services

Logistics

- Mobilisation of Equipment & Personnel (including third party equipment)
- Customs/Freight Clearance advice
- Staging Area set up
- Security of impacted sites
- Personnel Transportation
- Accommodation for Response Personnel
- Food and Beverage for Response Personnel
- Procurement Services of Required Materials and Services
- Communications Equipment and Services
- Establish and manage large Incident Command Centre

Finance

- Claims Handling
- Time & Cost tracking
- Guidance on ExxonMobil's System of Management Controls
- Response Inquiry Centre - establish and manage a call centre to handle these inquiries in the local language.

Safety, Security & Health

- Industrial hygiene professionals to assist with establishing a safe working environment.
- Safety plans - undertake task risk assessment and implementing mitigating measures.
- Medical professionals to ensure the well-being of the responders.
- Security specialist to assist with planning and monitoring security in the areas of operations.

Public & Government Affairs

- Media and Social Media Monitoring
- Develop Communications Materials and Incident Website
- Organise Press Conferences, Town Hall Meetings and Official Visits

Law

- Provide guidance on all matters of a legal nature

OSRL

From the Esso global Tier 3 response contractor (OSRL) Esso can access 50% of the available stock. To this end the figures quoted for OSRL are representative of 50% of the total stockholding. A full inventory of OSRL equipment is available from the OSRL website http://www.oilspillresponse.com/activate-us/response-equipment

OSRL (UK) mobilisation to Gippsland, 3–5 days. OSRL (Singapore) mobilisation to Gippsland 2–4 days

Ambipar

ExxonMobil has an agreement with Ambipar Response (Ambipar) for provision of emergency response support.

During an incident Ambipar can support the ExxonMobil by providing up to 9 trained responders, per the contract, organized as a Tactical Team and Operational Team. These include:

- Tactical Team: Incident and Crisis Management Advisor and Technical Advisor to liaise with RRT leadership and direct the Ambipar Operational Team;
- Operational Team: Team Leader and 6 Response Specialists who can provide a range of intervention services including clean-up, assessment, remediation, confined space entry and decontamination.

Provision also exists to increase the number of Ambipar personnel, subject to availability.

Ambipar also maintain their own response equipment stockpile. The existing agreement does not provide assured access to equipment.

Activation and coordination of Ambipar is the responsibility of the RRT.

ICS 204 Vessel Dispersant Application

Appendix B – OPEP Consultation Plan

Relevant control agencies

The OPGGS Environmental Regulation 11A establishes that titleholders (and those with access authority) detail consultation arrangements with relevant control agencies within the potentially exposed area as described in the Environment Plan.

To address this, control agencies within the potentially exposed area as described in the Environment Plan shall be consulted to inform content of the OPEP (see Table B-1).

Relevant control agencies will act as a single point of contact for their jurisdiction and may coordinate review and comment from other agencies.

Table B-1 Relevant control agencies (includes but not limited to)

Control Agency	Relevance
Australian Maritime Safety Authority	Commonwealth government agency responsible for maritime safety, protection of the marine environment including marine pollution and maritime aviation search and rescue.
Department of Transport (VIC)	Relevant for unplanned events. A branch of Transport Safety Victoria, working closely with vessel operators and waterway and port managers to provide expert knowledge, education, support and direction
Transport for NSW (NSW)	Relevant for unplanned events. The control agency for marine pollution incidents impacting NSW state waters. NSW waters could potentially be affected by an extended duration unplanned event.
Department of Primary Industries, Parks, Water and Environment (TAS)	Relevant for unplanned events as the control agency for marine pollution in Tasmanian state waters.

Sufficient time

Four to six weeks is generally considered sufficient time for relevant control agency to complete an internal review, based on prior feedback.

Relevant information

The following information may be provided to relevant control agencies:

- Brief description of activity, including the intended schedule, location, distances to nearest landfall and map
- Worst case discharge volumes
- Known or indicative oil type/properties
- Amenability of oil to dispersants
- Brief description of existing environment and protection priorities
- Key inputs and outputs of the environmental risk assessment
- Outcomes of oil spill trajectory modelling, including predicted times to enter State waters and contact shorelines
- Details on initial response actions and key activation timeframes
- Potential Incident Control Centre arrangements
- Potential staging areas / Forward Operating Base
- Details on response strategies
- Details on proposed IMT structure
- Details on exercise and testing arrangements of OPEP/OSCP

This list has been extracted from the EPA Tasmania – Offshore Petroleum Industry Guidance Note – Annex 3 and forms the basis of information provided. Additional information may be requested by individual agencies.

The information may be provided in summary form or through the provision of a draft EP or OPEP.

Ongoing consultation

The methods and content of ongoing consultation will be determined with relevant stakeholders and may include meetings, exercises, forums or written communication (see Table B-2).

Table B-2 Ongoing consultation with relevant stakeholders

Stakeholder	Meeting	Exercises	Collaborative Forums	Ad-hoc
Victoria State Control Agency **Department of Transport (DoT)**	Annual meeting	Annual review of Esso OSR exercise plan Participation in Esso and/or State exercises	Regional Marine Pollution Reference Group	Prior to commencement of new activities Changes to risk
Victoria Department Environment, Land, Water & Planning	Annual meeting	Annual review of Esso OSR exercise plan Participation in Esso and/or State exercises	Regional Marine Pollution Reference Group	-
NSW State Control Agency	Annual meeting	Participation in Esso and/or State exercises	-	Prior to commencement of new activities Changes to risk
Tasmania State Control Agency **Department of Primary Industries, Parks, Water and Environment**	Annual meeting	Participation in Esso and/or State exercises	-	Prior to commencement of new activities Changes to risk
Australian Maritime Safety Authority	Annual meeting	Participation in Esso, National Plan and/or State exercises	ES&T Workshops	Prior to commencement of new activities Changes to risk
Gippsland Ports	-	Participation in Esso, Regional and/or State exercises	Regional Marine Pollution Reference Group Esso Community Day	-
East Gippsland Shire Council	-	-	Regional Marine Pollution Reference Group Esso Community Day	-
Victorian Environmental Protection Authority	-	-	Regional Marine Pollution Reference Group	-

Consultation during an unplanned event

In the occurrence of an unplanned event, the methods and content of consultation with relevant stakeholders may be determined by notification requirements and can include meetings, phone calls or written communication (see Table B-3).

Table B-3 Consultation with relevant stakeholders during an unplanned event

Stakeholder	Incident Notification Requirement	Trigger	Method
Australian Maritime Safety Authority	Required for all spills from vessels	Notification requirement met NatPlan resources needs Impact to shipping	PolRep / SitRep Liaison Officer JSCC
Department of Agriculture, Water and the Environment **Parks Australia - Director of National Parks**	Required for all spills that are within a marine park, or could impact a marine park.	Notification requirement met	Verbal
Department of Agriculture, Water and the Environment	Required for all spills that impact or have the potential to impact on matters of national environmental significance (NES)	Notification requirement met	Verbal
Aboriginal Affairs Victoria		Planned shoreline protection or clean-up activities	Via Control Agency IMT
NSW State Control Agency **Transport for NSW**	Required for: all spills that could impact NSW waters.	Notification requirement met	SitRep Liaison Officer JSCC
VIC Department of Environment, Land, Water and Planning (Wildlife)		Potential impact to wildlife	Via Control Agency IMT OWR Coordinator / Liaison
VIC Department of Environment, Land, Water and Planning (Energy Emergency)		Potential impact to supply	Via ESG
TAS State Control Agency **Department of Primary Industries, Parks, Water and Environment**	Required for: all spills that could impact Tasmanian waters.	Notification requirement met	SitRep Liaison Officer JSCC
TAS Parks and Wildlife Service			Via Control Agency IMT
VIC State Control Agency **Department of Transport - SREC**	All spills that could impact Victorian state waters (> 80 L).		SitRep Liaison Officer JSCC
VIC Environment Protection Authority			Via Control Agency IMT
Transport Safety Victoria - Maritime Safety			Via Control Agency IMT
Parks Victoria		Impact to State waters or shoreline	Via Control Agency IMT

Stakeholder	Incident Notification Requirement	Trigger	Method
		ParksVic resources required	
NSW Department of Primary Industries		Impact to NSW State waters or shoreline	Verbal
VIC Department Jobs, Precincts & Regions - Earth Resources Regulation	Required for: all spills (80 L).	Notification requirement met	SitRep Liaison Officer JSCC
East Gippsland Shire Council			Via Control Agency IMT
Victorian Regional Channels Authority			Via Control Agency IMT
East Gippsland Catchment Management Authority			Via Control Agency IMT
National Offshore Petroleum Titles Administrator	Required for: all spills (80 L).		SitRep
National Offshore Safety Environmental Management Authority	Required for: all spills (80 L).		SitRep

Appendix C – Oil Spill Response Implementation

Table C-1: Environmental Performance – Oil Spill Response

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
To coordinate spill response operations in a timely manner to minimise impact to the environment	Incident Management	Incident Management Team	Trained personnel are available to fulfil Incident Commander, Operations Section Chief, Planning Section Chief, Logistics Section Chief, Safety Officer and Environmental Unit Lead roles within <1 hour of call out.	• IMT log records timing of events/assigned tasks
		Regional Response Team	Esso will assess requirement to mobilise RRT to support response activities for tier III response. If assessed to be required, RRT support will be made available: • <12 hours from notification for remote support • <72 hours for in country support	• IMT log records • Incident Action Plan
		Initial Oil Spill Response Actions: Assessment & Escalation 0–12 hours	Actions are implemented per timeframes detailed in OPEP Table 3-1 ERT Immediate Actions, Table 3-2 IMT Immediate Actions.	• IMT log • Common Operating Picture • Completed OPEP checklists
		Notifications	Notify authorities in accordance with regulatory requirements per Table 3-4 of OPEP	• IMT log (with supporting ICS forms) • Notification records /reports
To prevent further unplanned releases to the environment	Source control	Relief well drilling	Tier II / III ER Planning - Preliminary Relief Well Plan is completed before relief well is drilled with incident specific details. Including (estimate of cumulative days shown in brackets): • Site survey (ROV) conducted to confirm predetermined well location • Predetermined requirement for personnel and equipment mobilised (10 days to confirm and start mobilisation)	• Incident Specific Tier II / III Relief Well Plan • IMT Log • Incident Action Plan • Daily Drilling reports

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
			• Predetermine Dynamic Kill program confirmed or modified • Relief rig requested under Mutual Aid Agreement (or from Singapore – whichever is faster) mobilised with accompanying tug (or heavy lift vessel) (Relief Rig sourced within 10 days with plans to mobilise) • Relief Well specialist/SFRT/ROV contractors mobilised • Mobilisation of materials and equipment for relief well per confirmed drill program (Rig and equipment on location within 53 days) • Relief well drilling (35 days to drill) • Well secured within total estimate 98 day period	
		Well Kill Skid	Well Kill Skid is mobilised to platform within 48hours of first response. Well Kill is executed in accordance with the Esso Bass Strait Well Kill Contingency Plan.	• IMT Log • Incident Action Plan
		Third Party Well Control Equipment	Incident specific well control plan is developed by Third Party Well Control contractor. Equipment is mobilised to platform and response executed in accordance with well control plan (estimated 14 days).	• Incident Specific response plan • IMT Log • Incident Action Plan
		Pipeline de-pressuring and watering out	Pipelines are de-pressured and/or watered out in accordance with the relevant procedures as soon as practicable once a spill is identified.	• IMT Logs • Platform logs
		Pipeline repair	Where feasible, pipeline repair activities are undertaken in accordance with relevant repair procedures (estimated 45 days).	• IMT Logs • Incident Action Plan

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		Vessel Requirements	Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class. Where applicable: • Vessels with class certification are verified by International Association of Classification Societies (IACS) member. • Vessels comply with AMSA Domestic Commercial Vessel (DCV) requirements	• Vessel class certificates where applicable • Records of compliance with DCV requirements
		Chemical Discharge Assessment Process	All cement, drill fluids and additives planned for discharge are evaluated as acceptable in accordance with the Chemical Discharge Assessment Process.	Chemical assessment records confirm cements, drill fluids, additives, and/or their components are evaluated as acceptable prior to use / discharge.
		Solids Control Equipment	Solids control equipment (shale shakers and centrifuge/dryer) will treat cuttings to a level below 10% retained oil on dry weight basis; averaged over each well section, where Non Aqueous Fluid is used.	Retort test reports document residual oil on cuttings (ROC) measured.
Gather information and validate planning assumptions for current action plan and understand the extent, severity, persistence of the oil and potential environmental sensitives at risk.	Surveillance Monitoring & Visualisation (SMV) Strategy	Oil spill trajectory modelling (OSTM)	Implement OSMP module: • O1.2 Trajectory estimation Module to be implemented within 4 hours of initiation criteria.	• IMT log • Incident Action Plan • Oil spill trajectory modelling reports • Operational monitoring reports
		Oil Spill Tracking Buoys (STB)	Implement OSMP module: • O1.4 Remote observation Module to be implemented in accordance with requirements and timeframes in Section 3.1 of the OSMP. Satellite tracking buoys will be deployed in 24 hour intervals.	• IMT log • Incident Action Plan • OPEP checklist • Operational monitoring reports
		Satellite Imagery	Implement OSMP module: • O1.5 Satellite imagery Module to be implemented in accordance with requirements and timeframes in Section 3.1 of the	• IMT log • Incident Action Plan • Imagery reports • Operational monitoring reports

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
			OSMP (within 24 hours of initiation criteria being met).	
		Aircraft Surveillance	Implement OSMP module: • O1.3 Aerial or underwater observation Module to be implemented in accordance with requirements and timeframes in Section 3.1 of the OSMP (within 4 hours of initiation criteria being met).	• IMT log • Incident Action Plan • Observation reports • Operational monitoring reports
		Water and Oil quality monitoring	Implement OSMP modules: • O2.2 Fluorometry • O2.3 Water samples; Modules to be implemented in accordance with Section 3.2 of the OSMP.	• IMT log • Incident Action Plan • Laboratory reports • Operational monitoring reports
		OMSP Termination Criteria	Monitoring under OSMP modules O1 and O2 continued until termination criteria set out in Sections 3.1 and 3.2 of the OSMP are met.	• IMT log • Final operational monitoring reports
To prevent further unplanned releases to the environment		Vessel Requirements	Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class. Where applicable: • Vessels with class certification are verified by International Association of Classification Societies (IACS) member. • Vessels comply with AMSA Domestic Commercial Vessel (DCV) requirements	• Vessel class certificates where applicable • Records of compliance with DCV requirements
To reduce consequences to surface and shoreline values and sensitivities and increase the bioavailability of oil for microbial breakdown.	Dispersant Application	Dispersant spraying aircraft	Mobilise dispersant spraying Fixed Wing Aerial Dispersant (FWAD) aircraft within <4 hours of request for service. Dispersant application ability within <24 hours with up to 4 flights per day.	• IMT log • Incident Action Plan • Completed OPEP checklists
		Dispersant spraying vessels	Mobilise dispersant spraying vessels within the following timeframes;	• IMT log

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
			• 1st team dispersant application ability <48 hours of request of service • 2nd team dispersant application ability <72 hours of request for service Vessels can spray up to $3m^3$ of dispersant per day.	• Incident Action Plan • Completed OPEP checklists
		Incident specific NEBA	NEBA assessment is completed prior to dispersant use.	• IMT log • Incident Action Plan • Incident specific NEBA
		Halt dispersant application if wildlife are identified in the area	If EPBC Act listed migratory species (e.g. whales) are observed in the immediate vicinity of dispersant operations, aerial dispersant operations will cease until the animal has not been sighted for 30 minutes or unless otherwise advised by the relevant state authority.	• Observation reports • IMT log
		Vessel Requirements	Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class. Where applicable: • Vessels with class certification are verified by International Association of Classification Societies (IACS) member. • Vessels comply with AMSA Domestic Commercial Vessel (DCV) requirements	• Vessel class certificates where applicable • Records of compliance with DCV requirements
		Dispersant pre-selection and assessment	Only dispersants listed in Volume 3 Section 5.1 will be utilised, unless otherwise endorsed by the Statutory Authority	• IMT log • Incident Action Plan • Records stating dispersant types, locations, types and volumes
		Laboratory dispersant effectiveness testing	Laboratory dispersant effectiveness test results will be used to inform if use of dispersant is likely to reduce environmental impacts giving	• IMT log • Incident Action Plan

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
			consideration to elapsed time, weathering and selection of dispersant with highest efficacy.	
		Basic field dispersant effectiveness test	Dispersants will be test sprayed on all crude oil spills for efficacy prior to operational.	• IMT log • Report records
		Exclusion zones	Dispersant application is only accepted for: • Commonwealth waters, and • >10 m water depth, and • Outside Australian marine parks Dispersants are <u>not</u> to be used in State waters without approval of the Control Agency IMT.	• IMT log • Incident Action Plan • Incident specific NEBA • Approvals from Control Agency IMT
		Monitoring of dispersant in water and effectiveness	Implement OSMP module: • O2: Water and Oil Sampling In accordance with requirements and timeframes in Section 3.2 of the OSMP.	• IMT log • Incident Action Plan • Common Operating Picture • Operational monitoring reports
		Records of dispersant volumes	A record of the volumes of dispersant used in surface application will be kept throughout the response.	• IMT log • Incident Action Plan • Records stating dispersant types, locations, types and volumes • Completed OPEP checklist
		Surface dispersant only applied within daylight hours	Surface dispersants only applied in daylight hours	• IMT log • Incident Action Plan • Records stating dispersant types, locations, types and volumes

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		Targeted dispersant application	Dispersants will be targeted at areas of thickest oil and considerations of oil type, amenability and volume will be assessed prior to any dispersant application.	• IMT log • Incident Action Plan • Records stating dispersant types, locations, types and volumes
To recover spilt oil before shoreline or other sensitivity contact.	Containment and recovery	Vessel Requirements	Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class. Where applicable: • Vessels with class certification are verified by International Association of Classification Societies (IACS) member. • Vessels comply with AMSA Domestic Commercial Vessel (DCV) requirements	• Vessel class certificates where applicable • Records of compliance with DCV requirements
		Incident specific NEBA	A incident specific NEBA is completed.	• IMT log • Incident Action Plan • Incident specific NEBA
		Containment and recovery operations only undertaken within daylight hours	Containment and recovery activities will only be undertaken in daylight hours to ensure trapped fauna are released as soon as possible.	• IMT log • Incident Action Plan • Records of fauna released
		Daily records of oil recovered	Daily Containment and Recovery operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered)	• IMT log • Incident Action Plan • Records stating locations, types and volumes of oil recovered
		Exclusion Zones	Exclusion zones are put in place which consider health and safety and environment risks. These exclusion zones are determined in consultation with the relevant statutory agency.	• IMT log • Incident Action Plan • Records stating exclusion zones

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		Decanting performed in commonwealth waters in accordance with MARPOL requirements	AMSA must approve all decanted separated water to increase waste storage of recovered oil.	• IMT log • Incident Action Plan • Records of decanted water (oil in water) concentrations • Approval from AMSA
		Bass Strait Oil Spill Response Waste Management Plan	An incident specific Waste Management Plan is developed to ensure management of waste in accordance to Australian best practices and principals.	• IMT log records • Incident Action Plan • Incident specific waste management plan
		Containment & Recovery vessels	Mobilise containment and recovery vessels in accordance with the following timeframes; • 1x vessel C&R strike team on site <48 hours of service request • 2x vessel C&R strike team on site <72 hours of service request.	• IMT log records • Incident Action Plan • OPEP checklists
Reduce oil impact on shoreline environmental sensitivities	Shoreline Protection and Clean-up	Shoreline Assessment	Implement OSMP modules: • O3.1 Shoreline segmentation • O3.2 Shoreline character • O3.3 Oil on shorelines • O3.4 Shoreline profile In accordance with requirements and timeframes in Section 3.3 of the OSMP. Up to 12 trained shoreline assessment field personnel will be available in the first 24 hours. Up to an additional 12 trained shoreline assessment field personnel will be available in the first 14 days.	• IMT log • Incident Action Plan • Operational monitoring reports • Field reports

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		Shoreline Tactical Response Plans (TRPs)	Where shoreline contact is predicted, implement shoreline TRPs in consultation with control agency	• IMT log • Incident Action Plan • OPEP checklist
		Incident specific NEBA	A incident specific NEBA is completed	• IMT log • Incident Action Plan • Incident specific NEBA
		Daily records of oil recovered	Daily Shoreline Protection and Clean-up operations are recorded (location, estimated amount of oil recovered, estimated amount of water recovered)	• IMT log • Incident Action Plan • Records stating locations, types and volumes of oil recovered
		Exclusion Zones	Exclusion zones are put in place which consider health and safety and environment risks. These exclusion zones are determined in consultation with the control agency.	• IMT log • Incident Action Plan • Records stating exclusion zones
		Shoreline clean up personnel	Where shoreline contact is predicted from operational monitoring to be accumulations >100m/m^3, shoreline clean up personnel will be mobilised in the first 48 hours including up to • 4 Foreman • 20 Labourers • 4 Specialised Operators The shoreline clean up personnel will be mobilised up to: • 188 Foreman • 1614 Labourers • 124 Specialised Operators	• IMT log • Incident Action Plan • OPEP Checklists

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		Shoreline protection equipment	Where shoreline contact is predicted from operational monitoring to be accumulations >100m/m^3, shoreline clean up equipment is mobilised from closest stockpile in the first 48 hours including up to • 650m Shoreboom • 650m x Nearshore boom • 1x Offshore skimmer system • 12 x Fast Tanks • Anchor kits + accessories The shoreline clean up equipment to be mobilised from State/AMOSC/AMSA/OSRL stockpiles up to the following • 3,250m x Shoreboom • 2,025m x Nearshore boom • 1x Offshore skimmer system • 12 x Fast Tanks • Anchor kits + accessories	• IMT log • Incident Action Plan • OPEP Checklists
		Shoreline protection personnel	Where shoreline contact is predicted, shoreline protection personnel will be mobilised in the first 48 hours including up to • 27 Foreman • 82 Labourers • 63 Specialised Operators The shoreline clean up personnel will be mobilised up to: • 84 Foreman • 245 Labourers • 189 Specialised Operators	• IMT log • Incident Action Plan • OPEP Checklists

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		Shoreline protection and clean-up operations only undertaken within daylight hours	Shoreline protection and clean-up activities will only be undertaken in daylight hours to minimise impacts caused by unplanned interactions with flora and fauna.	• IMT log • Incident Action Plan
		Bass Strait Oil Spill Response Waste Management Plan	An incident specific Waste Management Plan is developed to ensure management of waste in accordance to Australian best practices and principals.	• IMT log records timing of events/assigned tasks • Incident specific waste management plan
		Waste Management transport and disposal	Where shoreline contact is predicted from operational monitoring to be accumulations >100g/m^2, shoreline clean up equipment is mobilised from closest stockpile from 48 hours including up to Solid and Liquid storage and processing of waste available is up to: • 63000 KL of liquid storage • 280 KL/day of liquid processing • 10 iso flammable liquid trucks/ day • 10 non flammable liquid truck/ day • 33500 Tonne of solids storage • 1050 Tonne/day of solid processing • 20 Tonne solids trucks/ day	• IMT log • Incident Action Plan
		Implement measures to minimise secondary contamination at temporary storage locations	Soil will be initially sampled to establish baseline “clean” levels. Establish bunding adequate to hold the daily bagged totals	• IMT log • Incident Action Plan • Final operational monitoring reports

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
		OSMP Termination Criteria	Monitoring under OSMP module O3 continued until termination criteria set out in Section 3.3 of the OSMP are met.	• IMT log • Final operational monitoring reports
Change in water quality is limited to that allowed under MARPOL		Vessel Requirements	Vessel compliant with MARPOL Annex I, IV, V and VI as appropriate to vessel class. Where applicable: • Vessels with class certification are verified by International Association of Classification Societies (IACS) member. • Vessels comply with AMSA Domestic Commercial Vessel (DCV) requirements	• Vessel class certificates where applicable • Records of compliance with DCV requirements
Monitor, evaluate and reduce environmental impact on fauna	Oiled Wildlife Response (OWR)	Incident specific NEBA	A incident specific NEBA is completed	• IMT log • Incident Action Plan • Incident specific NEBA
		Shoreline Tactical Response Plans (TRPs)	Where OWR is predicted: • Inform and agree with Control Agency IMT tactical execution of planning OWR • Based on trajectory, agree with Control Agency IMT regarding applicable Shoreline TRPs. • Commence mobilisation of equipment, personnel and support for OWR	• IMT log • Incident Action Plan
		Daily OWR Records	Daily OWR operations are recorded (numbers, type and status of fauna)	• IMT log • Incident Action Plan • Records stating numbers, type and status of fauna
		Exclusion Zones	Exclusion zones are put in place which consider health and safety and environment risks. These exclusion zones are determined in consultation with the control agency.	• IMT log • Incident Action Plan

Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
				• Records stating exclusion zones
		Fauna Observation	Where oiled wildlife impacts are predicted, implement OSMP modules: • O4.1 Fauna observation (at sea) • O4.2 Fauna observations (onshore) Modules to be implemented in accordance with requirements and timeframes in Section 3.4 of the OSMP.	• IMT log • Incident Action Plan • Operational monitoring reports
		Oiled wildlife personnel and subject matter expertise	Esso will consult with Control Agency IMT on requirements for OWR clean-up personnel, for all spills that impact wildlife. Esso will mobilise OWR personnel from own, AMOSC and tier three providers to meet DELWP requests	• IMT log records • Incident Action Plan • Record of oiled wildlife personnel and subject matter expertise
		Bass Strait Oil Spill Response Waste Management Plan	An incident specific Waste Management Plan is developed to ensure management of waste in accordance to Australian best practices and principals.	• IMT log records • Incident Action Plan • Incident specific waste management plan
		OSMP Termination Criteria	Monitoring under OSMP module O4 continued until termination criteria set out in Section 3.4 of the OSMP are met.	• IMT log • Final operational monitoring reports
Monitor and evaluate environmental impact and recovery from the spill and response activities.	Scientific Monitoring	Oil Spill Monitoring Program	Implement OSMP modules S1-S9, as required: • S1: Hydrocarbons in intertidal sediments and water • S2: Hydrocarbons in offshore sediments and water • S3: Fish and shellfish taint and toxicity for human consumption • S4: Short-term impacts to oiled fauna and flora	• IMT log • Incident Action Plan • Scientific monitoring reports

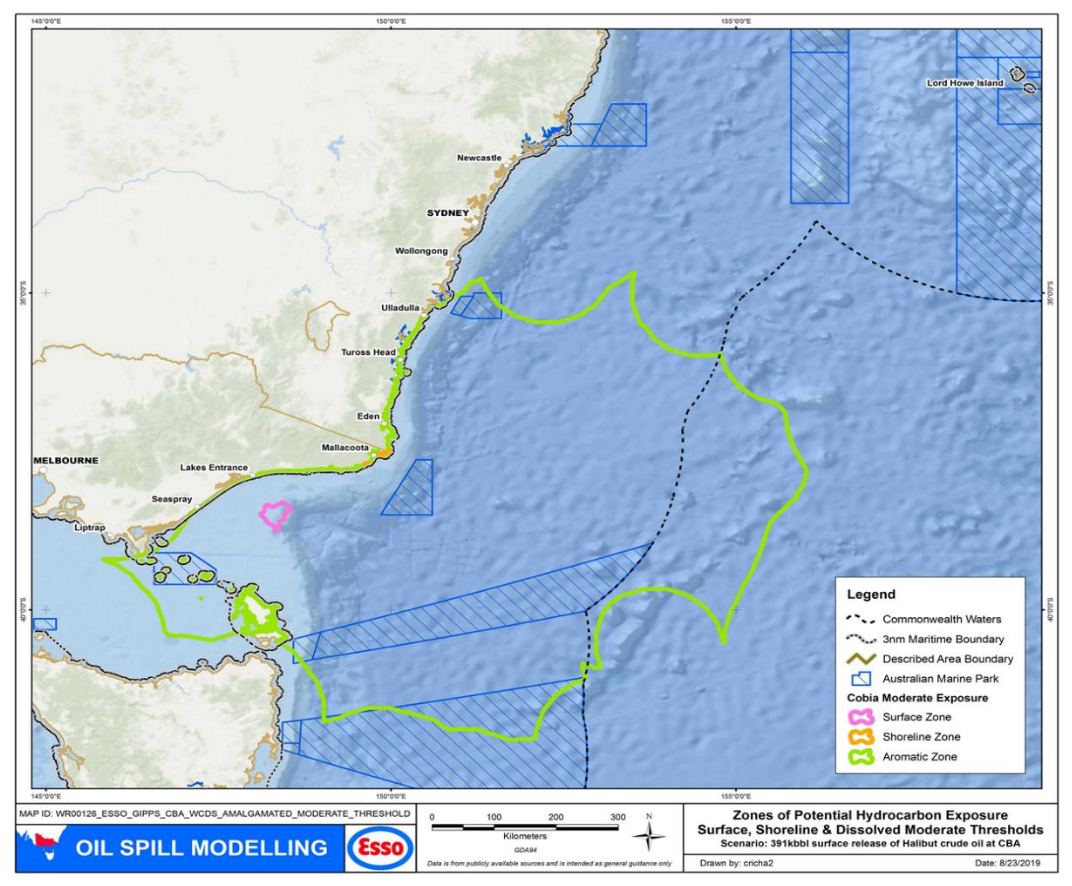
Performance Outcome	Strategy	Control	Performance Standard	Measurement Criteria
			• S5: Recovery of commercial and recreational fisheries • S6: Recovery of fauna • S7: Recovery of subtidal and intertidal benthic habitat • S8: Recovery of coastal flora • S9: Recovery of Ramsar values Modules to be implemented in accordance with requirements and timeframes in Section 4 of the OSMP.	
		OSMP Termination Criteria	Monitoring under OSMP module S1-9 continued until termination criteria set out in Section 4 of the OSMP are met.	• IMT log • Final operational monitoring reports

Appendix D – Quick Reference Information

Information specific to a well blowout (WCDS) from a platform during base business operations is provided below. For further details, refer to the Bass Strait Environment Plan (AUGO-EV-EMM-002 & AUGO-EV-EMM-004).

1. Field Location / Oil properties

Location / operational area



Production Licence No.	VIC/L5 Cobia (CBA) platform
Coordinates	Latitude 38° 27’ 04” S
	Longitude 148° 18’ 28” E

Oil type and name	**Halibut Crude***	
	Density @ 15˚C (kg/m^3)	821.5
	API	40.6
	Dynamic Viscosity (cP @ 25°C)	3.4
	Pour Point (ºC)	0
	Oil Property Category	Group II light persistent oils

	Composition	
	Aromatics (%)[1]	23.2%
	Emulsion Water Content (%)	7%
	Saturates (%)	71.9%
	Wax Content (%)	23.7%
	Volatile (%) (BP <180°C)	15.2
	Semi-volatile (%) (BP 180 - 265°C)	25.6
	Low volatility (%) (BP 265 - 380°C)	41.6
	Residual (%) (BP> 380°C)[2]	17.6

*****Leeder Analytical Report No. L190131 Chemical and Physical Testing of Seven Crudes and Condensates dated 31 May 2019.

1 *Soluble, aromatic, hydrocarbons, (including BTEX), tend to evaporate into the atmosphere.*

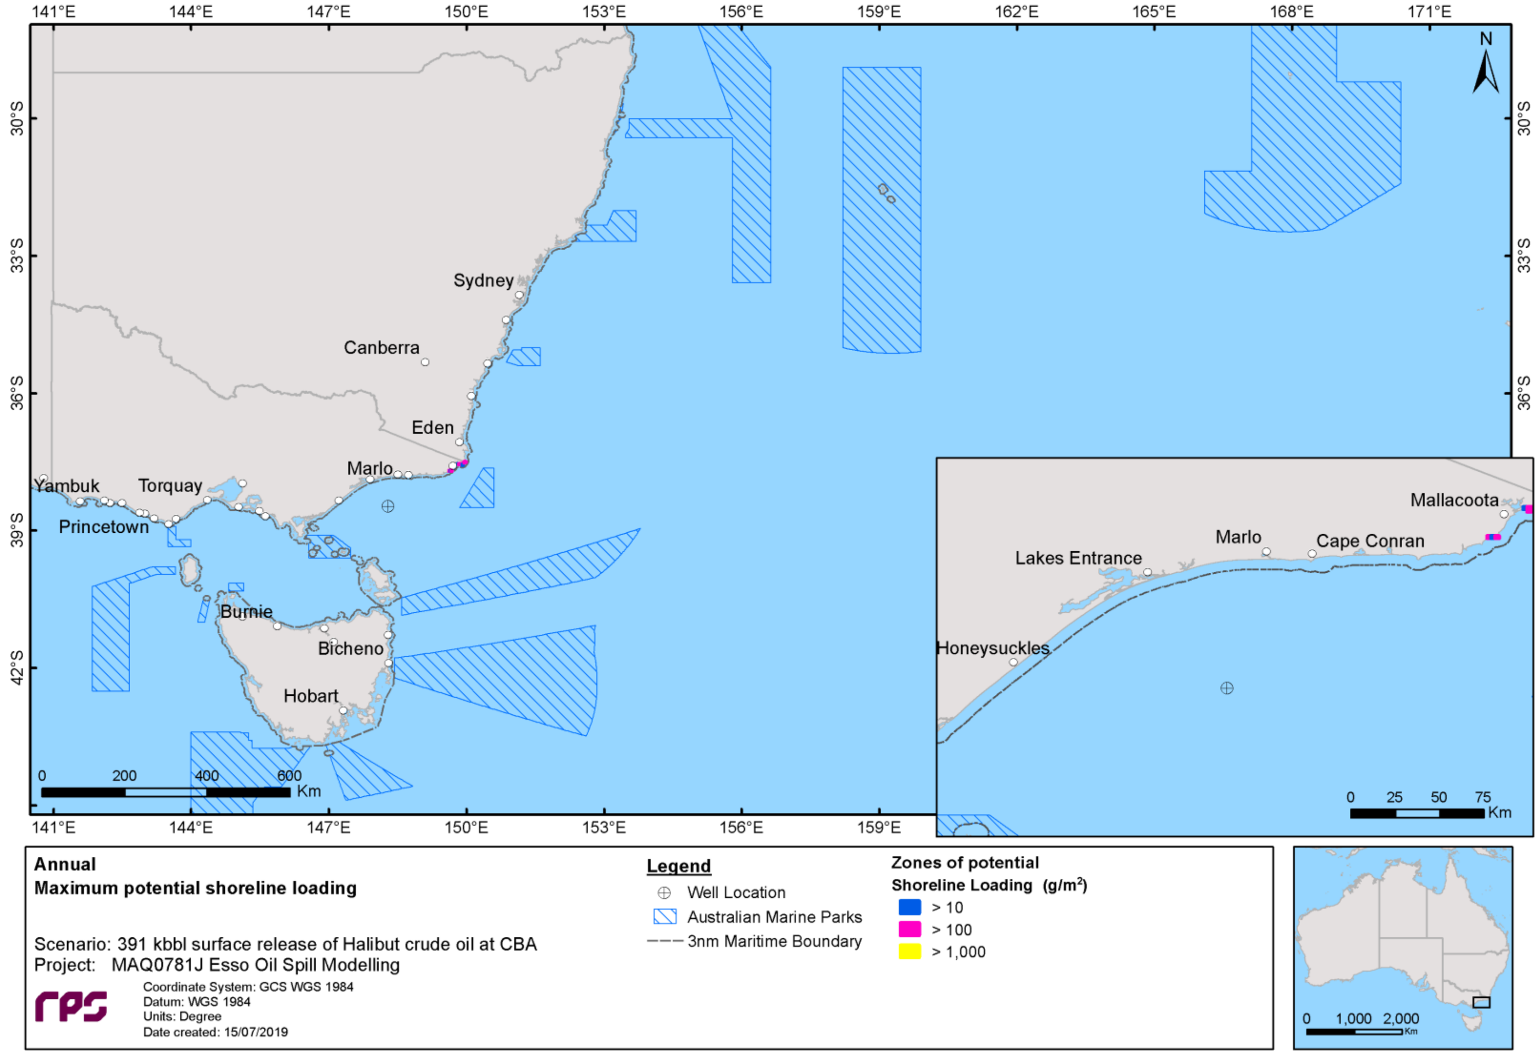
2 *Residual Hydrocarbons will persist in the marine environment. It will remain in a liquid state when released into the environment over the annual temperatures observed in the Gippsland Basin*

2. What's the worst that could happen?

	Cobia (CBA)
Modelled Oil Pollution Scenario (WCDS)**	Level 3 Spill A complete loss of well control (tubing flow to surface only) resulting in a release of crude until source control is effective (98 days – based on worst case scenario where relief well drilling is required).
Oil type and name	Halibut Crude
Release rate (bbl/day)	3,990
Spill Volume (bbl)	391,000
Dominant Weathering process	Evaporation
Approximate evaporation rate (depending on temperature)	
within the first 12 hours	10.7%
within the first 24 hours	a further 34.1%
over several days.	a further 41.8%
Probability of contact to any shoreline (%)	23 (at Cape Howe / Mallacoota)
Absolute minimum time for visible oil to shore (hrs)	210 (at Gabo Island)
Maximum volume ashore (m^3)	46
Maximum length of the shoreline (km) **at 10 g/m^2** **at 100 g/m^2** **at 1,000 g/m^2**	 17 12 -
Weathering over the duration of LOWC (98 days) (based on deterministic modelling)	
Evaporation (%)	50%
Decay (%)	43%
Water column (%)	7%
Surface/Shoreline (%)	<1%

**RPS Report No. MAQ0781J Gippsland Basin Production Activities Oil Spill Modelling dated 7 August 2019

Exposure - Shoreline



Maximum potential shoreline loading for the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds. Results are based on a 391,000 bbl surface release of Halibut Crude over 98 days at Cobia Platform, tracked for 118 days. The results were calculated from 100 spill trajectories.

3. Resources at Risk

	Receptor	<12 hrs	12-48 hrs	>48 hrs	>1week (hrs)
Minimum time to oil exposure on sea surface at moderate threshold	BIAs: • Seabirds – Foraging • Pygmy Blue Whale – Distribution/Foraging • Southern Right Whale – Migration • Great White Shark – Distribution KEFs: • Upwelling East of Eden Note: no predicted contact with State waters	 ✓ ✓ ✓ ✓ 		 ✓	
Minimum time to shoreline accumulation of oil at moderate threshold	• Bega Valley (southern NSW) • Cape Howe/Mallacoota • Croajingalong				296 296 968

Protection priorities based on sensitivity and predicted consequence (as per EP Volume 2), protectable/actionable areas, and minimum time to exposure in this area are:

Gabo Island due to high sensitivity and significant fauna populations (Little penguins, Storm petrels, Hooded plover, Fur seals).

Mallacoota due to sensitivity of estuary mouth, Hooded plover habitat

Nadgee Lake and Nadgee River due to pristine coastal landscape within the Nadgee Nature Reserve (NSW) and significant Wilderness Area.

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Light Crude Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of crude oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the direction of movement of the spill and natural break-up and dissipation of spill. Monitoring will also be used to assess the need for, and effectiveness of, active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna. Use of dispersants may eliminate, or minimise oil impacting sensitive resources including Gabo Island.	Over 40% of the Halibut crude should evaporate within the first 24 hrs. However, about 13.6% of the crude is considered persistent and so use of dispersant may reduce volume of oil impacting shorelines. Laboratory testing has shown dispersant to be highly effective on fresh Bass Strait crude (48-99% effective), with effectiveness decreasing significantly after 12 hours of weathering. Dispersants should be applied to fresh oil closest to the source to maximize effectiveness.	Yes	✓
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes. Targeted containment and recovery can be utilised to reduce impact to sensitive areas such as Gabo Island where access for shoreline protection is limited (see below: Protection of Sensitive Shoreline Resources).	Suitable thickness for recovery will be present making containment and recovery viable but likely of low effectiveness. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Yes	✓
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Light crude released at the CBA platform may contact the shoreline along the far east Gippsland coast and the southern coast of NSW, with modelling predicting shortest time of recoverable levels to shore as more than a week. Tactical Response Plans have been developed to protect Gabo Island and sensitive estuary openings along this section of coastline.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis	Yes	✓
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	OWR is likely to be required. Although the distance of the platform from the coast reduces likelihood of extensive wildlife oiling onshore, individuals may become oiled in the vicinity of the spill. Operational monitoring will be used to inform the need for OWR to be implemented.	Yes	✓

6. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	ROV debris clearing / subsea intervention	1 x ROV and 1 x vessel SFRT (via AMOSC) and 1 x vessel 1 x contract well control specialists (WWC/OSRL)	Estimated 5 days (from call out request to arrival in Victoria) Estimated 7 days (from Perth to BBMT via road transport) 2 days (from Singapore)

Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

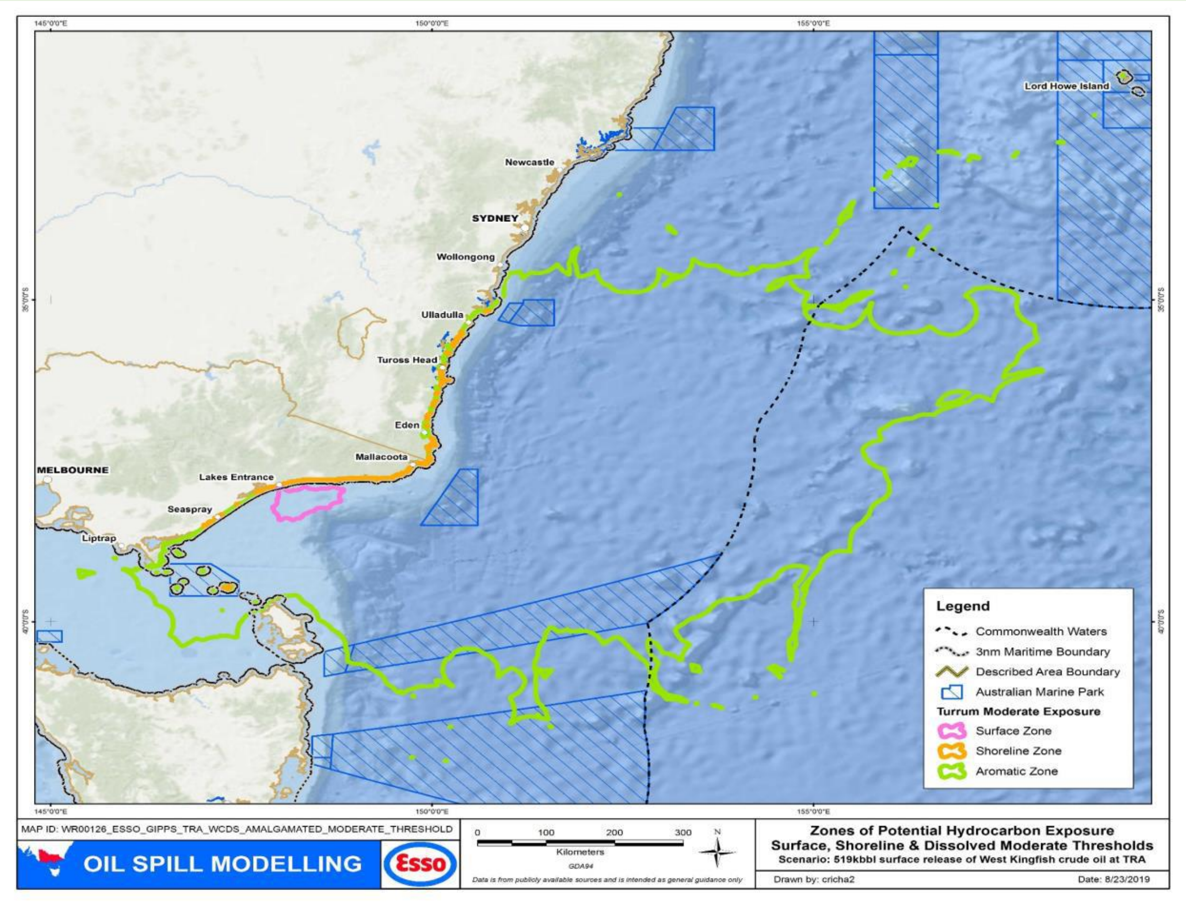
Modelling indicates that the spill does **not** intersect the coastline until after 1 week.

However in the unlikely event of a spill, should trajectory modelling predict shoreline contact, sufficient resources are available to be initiated within 48 hours (in most cases sooner). Modules in addition to those required to monitor the spill may be initiated and resources mobilised to priority monitoring locations as determined at the time.

Information specific to a well blowout (WCDS) from a platform during base business operations is provided below. For further details, refer to the Bass Strait Environment Plan (AUGO-EV-EMM-002 & AUGO-EV-EMM-004).

1. Field Location / Oil properties

Location / operational area



Production Licence No.	VIC/L03 Marlin A (MLA) platform
Coordinates	Latitude 38° 13’ 54” S
	Longitude 148° 13’ 09” E

Oil types and name	**West Kingfish Crude**	
	Density @ 15˚C (kg/m^3)	798.1
	API	45.7
	Dynamic Viscosity (cP @ 25°C)	2.4
	Pour Point (ºC)	9
	Oil Property Category	Group II light persistent oils

	Composition	
	Aromatics (%)[1]	23%
	Emulsion Water Content (%)	27%
	Saturates (%)	72%
	Wax Content (%)	25%
	Volatile (BP <180°C)	13.6 %
	Semi-volatile (BP 180 - 265°C)	35.9 %
	Low volatility (BP 265 - 380°C)	36.8 %
	Residual (BP> 380°C)[2]	13.7%

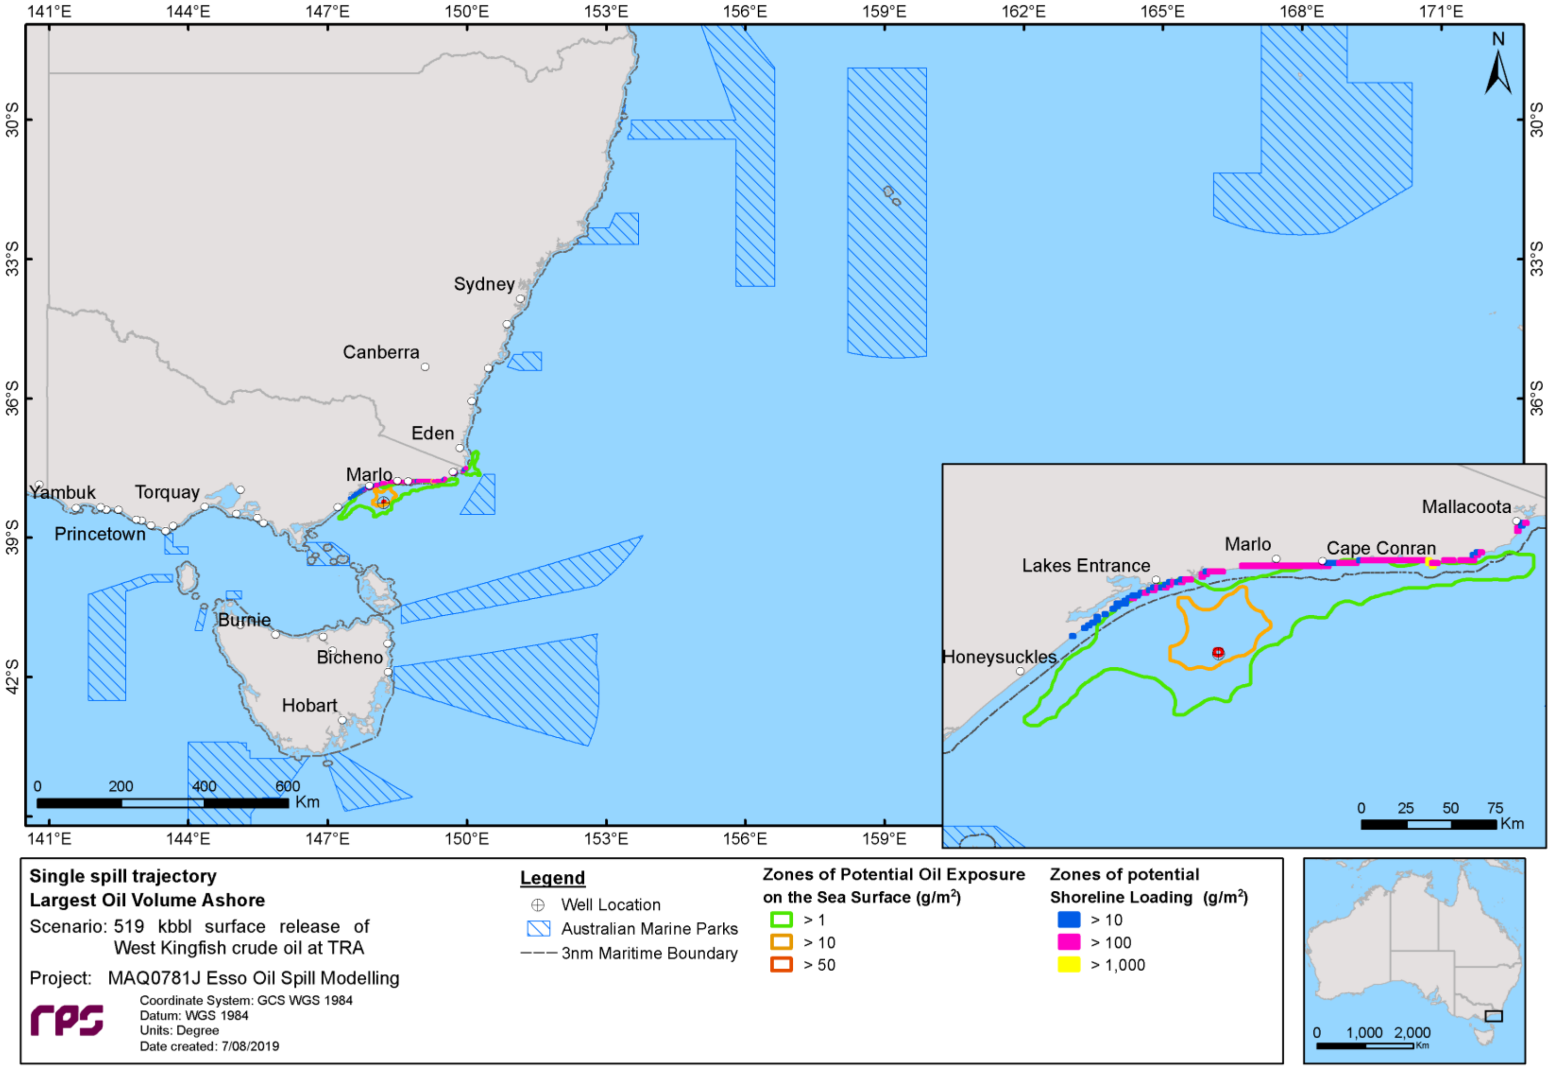
1 *Soluble, aromatic, hydrocarbons, (including BTEX), tend to evaporate into the atmosphere.*

2 *Residual Hydrocarbons will persist in the marine environment. It will remain in a liquid state when released into the environment over the annual temperatures observed in the Gippsland Basin*

2. What's the worst that could happen?

	Marlin A (MLA)
Modelled Oil Pollution Scenario (WCDS)	Level 3 Spill A complete loss of well control (tubing flow to surface only) resulting in a release of crude until source control is effective (98 days – based on worst case scenario where relief well drilling is required).
Oil types and name	West Kingfish Crude
Release rate (bbl/day)	5,296
Spill Volume (bbl)	519,000
Dominant Weathering process	Evaporation
Approximate evaporation rate (depending on temperature)	
within the first 12 hours	13.6%
within the first 24 hours	a further 35.9%
over several days.	a further 36.8%
Probability of contact to any shoreline (%)	94 (East Gippsland – at Gabo Island, Point Hicks)
Absolute minimum time for visible oil to reach shoreline (hrs)	62 (at Point Hicks)
Maximum volume ashore (m^3)	563.3
Maximum length of the shoreline (km) at 10 g/m^2 at 100 g/m^2 at 1,000 g/m^2	 221 150 15
Weathering over the duration of LOWC (98 days) (based on deterministic modelling)	
Evaporation (%)	64%
Decay (%)	29%
Water column (%)	6%
Surface/Shoreline (%)	<1%

Exposure – Shoreline



Zones of potential exposure on the sea surface and shoreline for the trajectory with the largest volume of shoreline loading. Results are based on a 519,000 bbl surface release of West Kingfish Crude over 98 days at Marlin A Platform, tracked for 118 days.

3. Resources at Risk

	Receptor	<12 hrs	12-48 hrs	>48 hrs	>1week (hrs)
Minimum time to oil exposure on surface at moderate threshold	**BIAs:** • Seabirds – Foraging • Pygmy Blue Whale – Distribution/Foraging • Southern Right Whale – Migration • White Shark – Distribution/Breeding **KEFs:** • Upwelling East of Eden Note not predicted to contact State waters	 ✓ ✓ ✓ ✓/- ✓		 - /✓	
Minimum time (hrs) to shoreline accumulation of oil at moderate threshold	• Point Hicks			62	
	• Gabo Island			70	
	• Kent Island Group			136	
	• Cape Conran			134	
	• Corringle			134	
	• Wellington			142	
	• Croajingalong			158	
	• Ocean Grange			154	
	• Lake Tyers Beach			162	
	• Cape Howe/Mallacoota			168	
	• Marlo				176
	• Lakes Entrance				180
	• Bega Valley (southern NSW)				188

	• Sydenham Inlet				246
	• Woodside Beach				274
	• Eurobodalla (NSW)				526
	• Shoal Haven (NSW)				530
	• Montague Island (NSW)				830

Protection priorities based on sensitivity and predicted consequence (as per EP Volume 2), protectable/actionable areas, and minimum time to exposure in this area are:

Gabo Island due to high sensitivity and significant fauna populations (Little Penguins, Storm Petrels, Fur seals, Hooded plover).

Mallacoota due to sensitivity of estuary mouth, Hooded plover habitat.

Nadgee Lake and Nadgee River due to pristine coastal landscape within the Nadgee Nature Reserve (southern NSW) and significant Wilderness Area,

Croajingolong National Park including **Sydenham Inlet, Betka Inlet, Wingan Inlet.**

Marlo due to sensitivity of Snowy River estuary / mouth.

Lake Tyers due to sensitivity of waterway, Hooded plover habitat

Lakes Entrance permanently open river mouth to the Gippsland Lakes being a recognised Ramsar site, marine flora and fauna, marshes, wetlands, estuarine habitat, shorebird/seabird colonies, amenity beaches, surf club, commercial fishing, tourism, dive sites, recreational aquatic activities, waterway amenity access.

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Light Crude Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of crude oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the direction of movement of the spill and natural break-up and dissipation of spill. Monitoring will also be used to assess the need for, and effectiveness of, active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna. Use of dispersants may eliminate, or minimise oil impacting sensitive resources including Gabo Island.	Over 40% of the West Kingfish crude should evaporate within the first 24 hrs. However, about 13.7% of the crude is considered persistent and so use of dispersant may reduce volume of oil impacting shorelines. Laboratory testing has shown dispersant to be highly effective on fresh Bass Strait crude (48-99% effective), with effectiveness decreasing significantly after 12 hours of weathering. Dispersants should be applied to fresh oil closest to the source to maximize effectiveness.	Yes	✓
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	Suitable thickness for recovery will be present for only a very short period, making containment and recovery viable but likely of low effectiveness. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Yes	✓
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Light crude released at the MLA platform may contact the shoreline along the Gippsland coast and the southern coast of NSW, with modelling predicting shortest time of recoverable levels to shore as approximately 3 days. Modelling predicts that a light crude spill may intersect the coastline after approximately 3 days at locations around:

- Point Hicks (Croajingolong National Park)
- Gabo Island

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the **priority monitoring locations** listed above:

- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

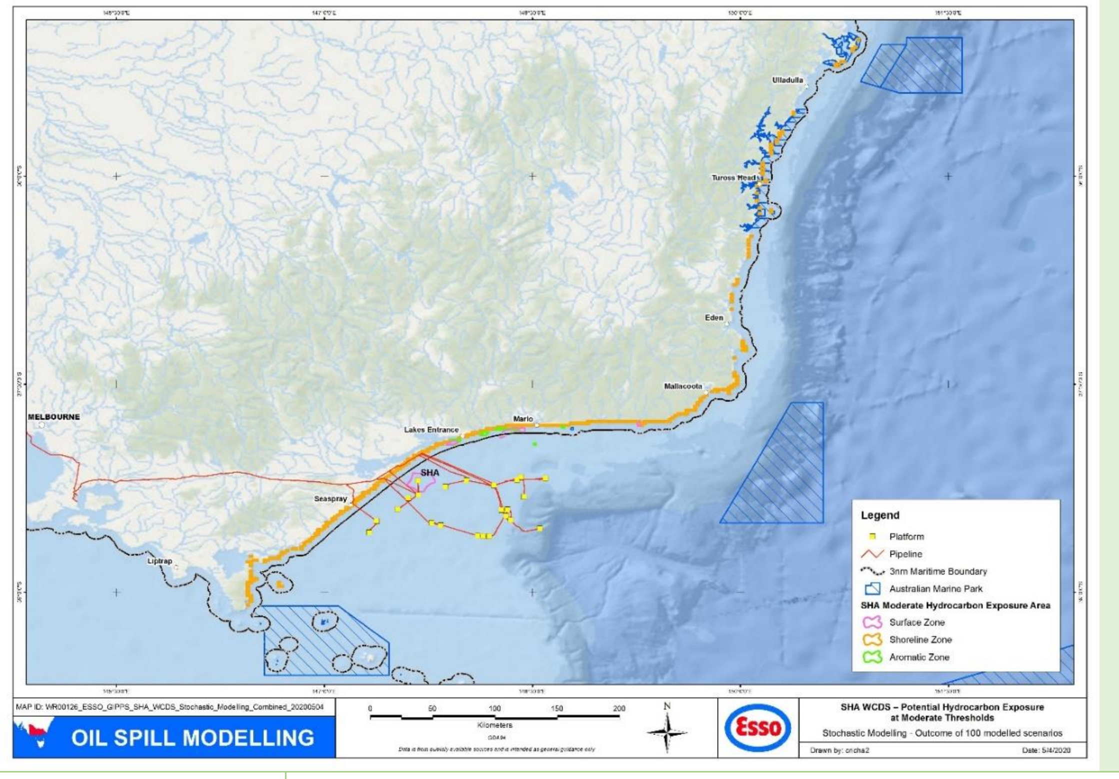
NOTE:

Seahorse wells were plugged and abandoned in 2020 and so this scenario is no longer possible, however, this scenario has been retained as an example of a crude oil spill close to shore

Information specific to a well blowout (WCDS) from the Seahorse subsea facility during base business operations is provided below. For further details, refer to the Bass Strait Environment Plan (AUGO-EV-EMM-002 & AUGO-EV-EMM-004).

1. Field Location / Oil properties

Location / operational area



Production Licence No.	VIC/L18 Seahorse (SHA) subsea facility				
Coordinates	Latitude 38° 11' 42" S				
	Longitude 147° 40' 27" E				
Water Depth	43 m

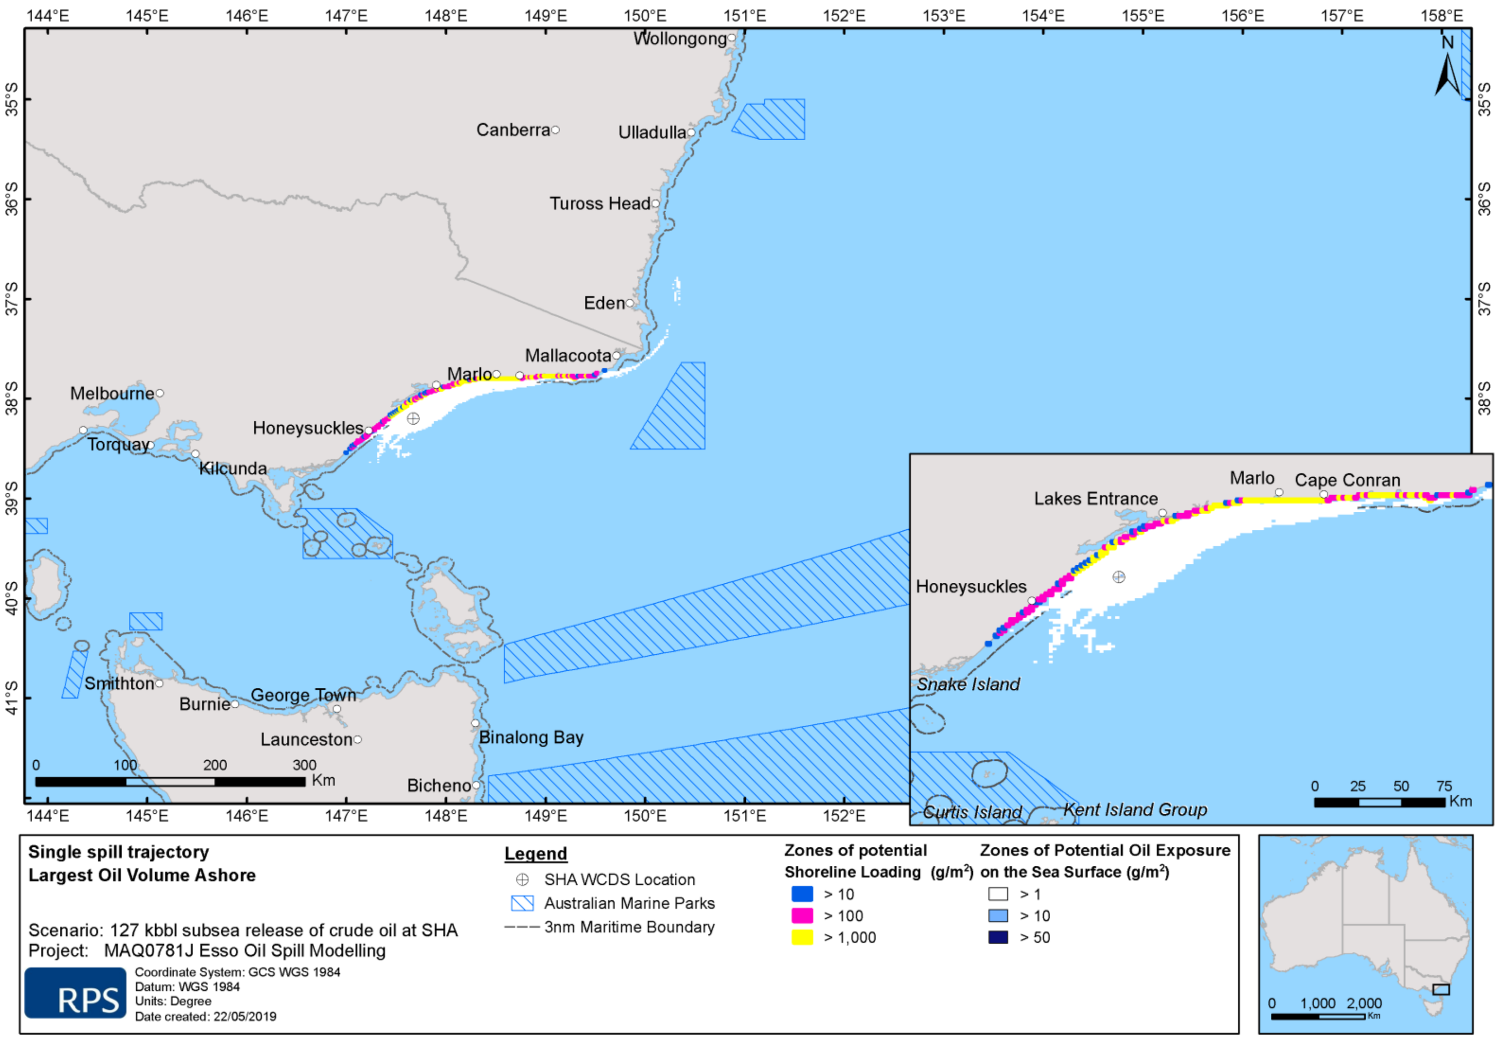
Release rate (bbl/day)	1296
Spill Volume (bbl)	127,000
Dominant Weathering process	Evaporation
Probability of contact to any shoreline (%)	100 (East Gippsland)
Absolute minimum time for visible oil to reach shoreline (hrs)	36 (at Ninety Mile Beach)
Maximum volume ashore (m^3)	3,123
Maximum length of the shoreline (km) at 10 g/m^2 at 100 g/m^2 at 1,000 g/m^2	 286 277 99
Weathering over the duration of LOWC (98 days) (based on deterministic modelling)	
Evaporation (%)	74 - 63
Decay (%)	18
Water column (%)	2
Surface/Shoreline (%)	6 – 15

Exposure –Shoreline



Zones of potential exposure on the sea surface and shoreline loading (over the 118 day simulation) for the trajectory with the largest oil volume ashore. Results are based on a 127,000 bbl subsea release of crude oil over 98 days at the Seahorse Subsea Facility, tracked for 118 days, 8 pm 7th of November 2008.

3. Resources at Risk

	Receptor	<12 hrs	12-48 hrs	>48 hrs	>1week (hrs)
Minimum time to oil exposure on surface at moderate threshold	BIAs:				
	• Seabirds – Foraging		✓		
	• Pygmy Blue Whale – Distribution/Foraging		✓		
	• Southern Right Whale – Migration		✓		
	• White Shark – Distribution/Breeding		✓		
	KEFs:				
	• Upwelling East of Eden				✓
	• Lakes Entrance				✓
	• Point Hicks				✓
Minimum time (hrs) to shoreline accumulation of oil at moderate threshold	• Ninety Mile Beach		36		
	• Seaspray		42		
	• Lakes Entrance		47		
	• Lake Tyers Beach			50	
	• Marlo			53	
	• Cape Conran			54	
	• Golden Beach			55	
	• McLoughlins Beach			59	
	• Point Hicks			72	
	• Cape Howe/Mallacoota			89	
	• Gabo Island			90	
	• Sydenham Inlet			99	
	• Croajingolong			101	
	• Bega Valley (southern NSW)				235
	• Clonmel Island				276
	• Snake Island				296
	• Wilsons Promontory				323
	• Eurobodalla (NSW)				338
	• Montague Island (NSW)				340
	• Shoal Haven (NSW)				734

Protection priorities based on sensitivity and predicted consequence (as per EP Volume 2), protectable/actionable areas, and minimum time to exposure in this area are:

Lakes Entrance permanently open river mouth to the Gippsland Lakes being a recognised Ramsar site, marine flora and fauna, marshes, wetlands, estuarine habitat, shorebird/seabird colonies, amenity beaches, surf club, commercial fishing, tourism, dive sites, recreational aquatic activities, waterway amenity access.

Lake Tyers due to sensitivity of waterway, Hooded plover habitat, recreational activities.

Marlo due to sensitivity of Snowy River estuary / mouth, recreational activities.

Mallacoota due to sensitivity of estuary mouth, Hooded plover habitat, nature based tourism, recreational activities.

Gabo Island due to high sensitivity, significant fauna populations (Little penguin colony, Seabird rookery, Fur seal colony), Giant Kelp.

Croajingolong National Park including **Sydenham Inlet, Betka Inlet, Wingan Inlet** (and The Skerries Fur seal colony).

Nadgee Lake and Nadgee River due to pristine coastal landscape within the Nadgee Nature Reserve (southern NSW), nature based tourism and significant Wilderness Area.

Wilsons Promontory very popular nature based tourism and recreational location, significant wetland and riparian habitats, Seabird rookery, Fur seal colony, Shorebird habitat, seagrass communities.

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Light Crude Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of crude oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the direction of movement of the spill and natural break-up and dissipation of spill. Monitoring will also be used to assess the need for, and effectiveness of, active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna. Use of dispersants may eliminate, or minimise oil impacting sensitive resources including Gabo Island, Wilsons Promontory	A considerable proportion of the West Seahorse-3 crude should evaporate within the first 24 hrs. However, about 12.5% of the crude is considered persistent and so use of dispersant may reduce volume of oil impacting shorelines. Laboratory testing has shown dispersant to be highly effective on fresh Bass Strait crude (48-99% effective), with effectiveness decreasing significantly after 12 hours of weathering. Dispersants should be applied to fresh oil closest to the source to maximize effectiveness.	Yes	✓
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	Suitable thickness for recovery will be present for only a short period, making containment and recovery viable but likely of low effectiveness. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Yes	✓
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Light crude released at the SHA platform may contact the shoreline along the Gippsland coast from Wilsons Promontory to the NSW border and extending along the southern coast of NSW with modelling predicting shortest time of recoverable levels to shore as approximately 1.5 days. Tactical Response Plans have been developed to protect Gabo Island and sensitive estuary openings along this section of coastline.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis	Yes	✓
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	OWR is likely to be required as a result of extensive shoreline oiling.	Yes	✓

5. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	ROV debris clearing / subsea intervention	1 x ROV and 1 x vessel SFRT (via AMOSC) and 1 x vessel 1 x contract well control specialists (WWC/OSRL)	Estimated 5 days (from call out request to arrival in Victoria) Estimated 7 days (from Perth to BBMT via road transport) 2 days (from Singapore)

		0-10m	10-20m
	< 10%	Flinders AMP Kent Group NP	Nil

Modelling predicts that a light crude spill may intersect the coastline after approximately 36 hours at:

- Ninety Mile Beach

And after approximately 48 hours at locations around:

- Lakes Entrance
- Lake Tyers Beach
- Marlo
- Cape Conran

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the **priority monitoring locations** listed above:

- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

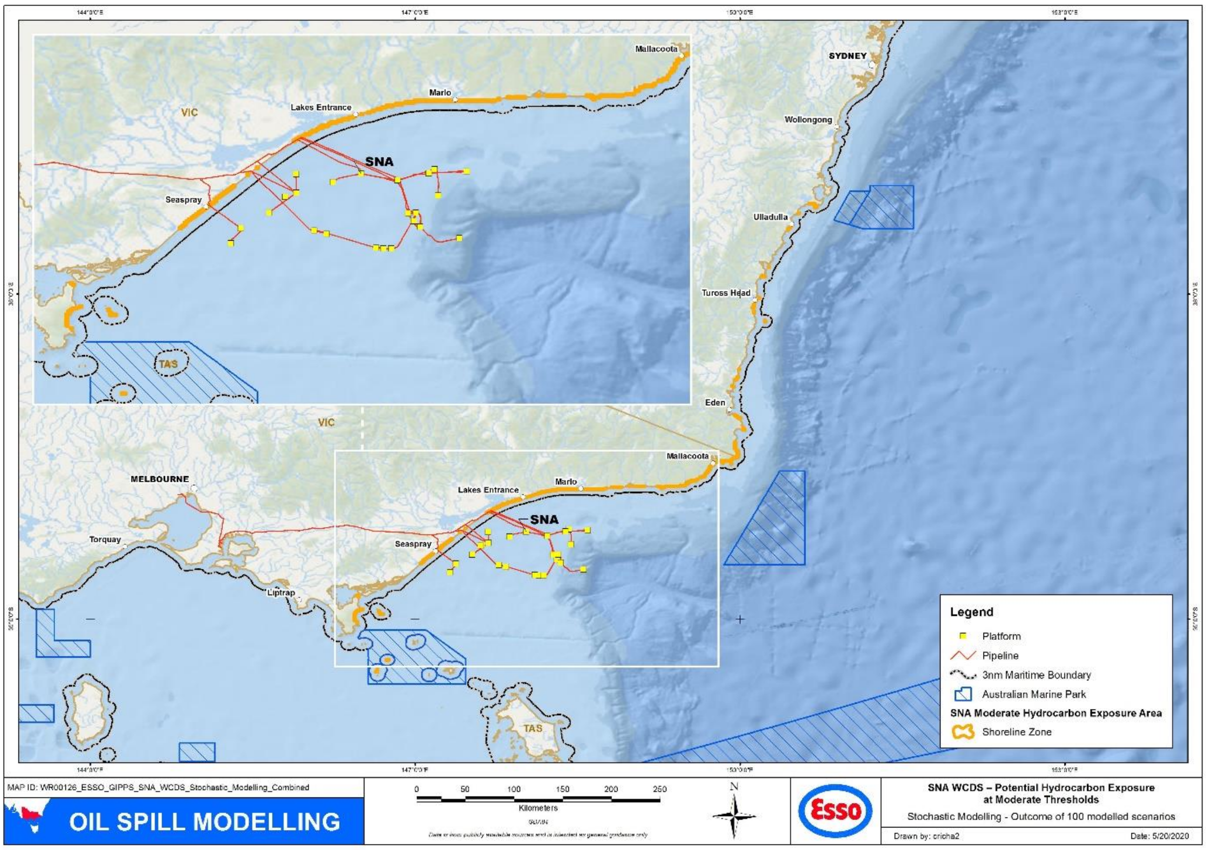
These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP**.**

In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

Information specific to a well blowout (WCDS) from the Snapper platform during base business operations is provided below. For further details, refer to the Bass Strait Environment Plan (AUGO-EV-EMM-002 & AUGO-EV-EMM-004).

1. Field Location / Oil properties

Location / operational area



Production Licence No.	VIC/L10 Snapper (SNA) platform
Coordinates	Latitude 38°11' 42" S
	Longitude 148° 01' 26 E

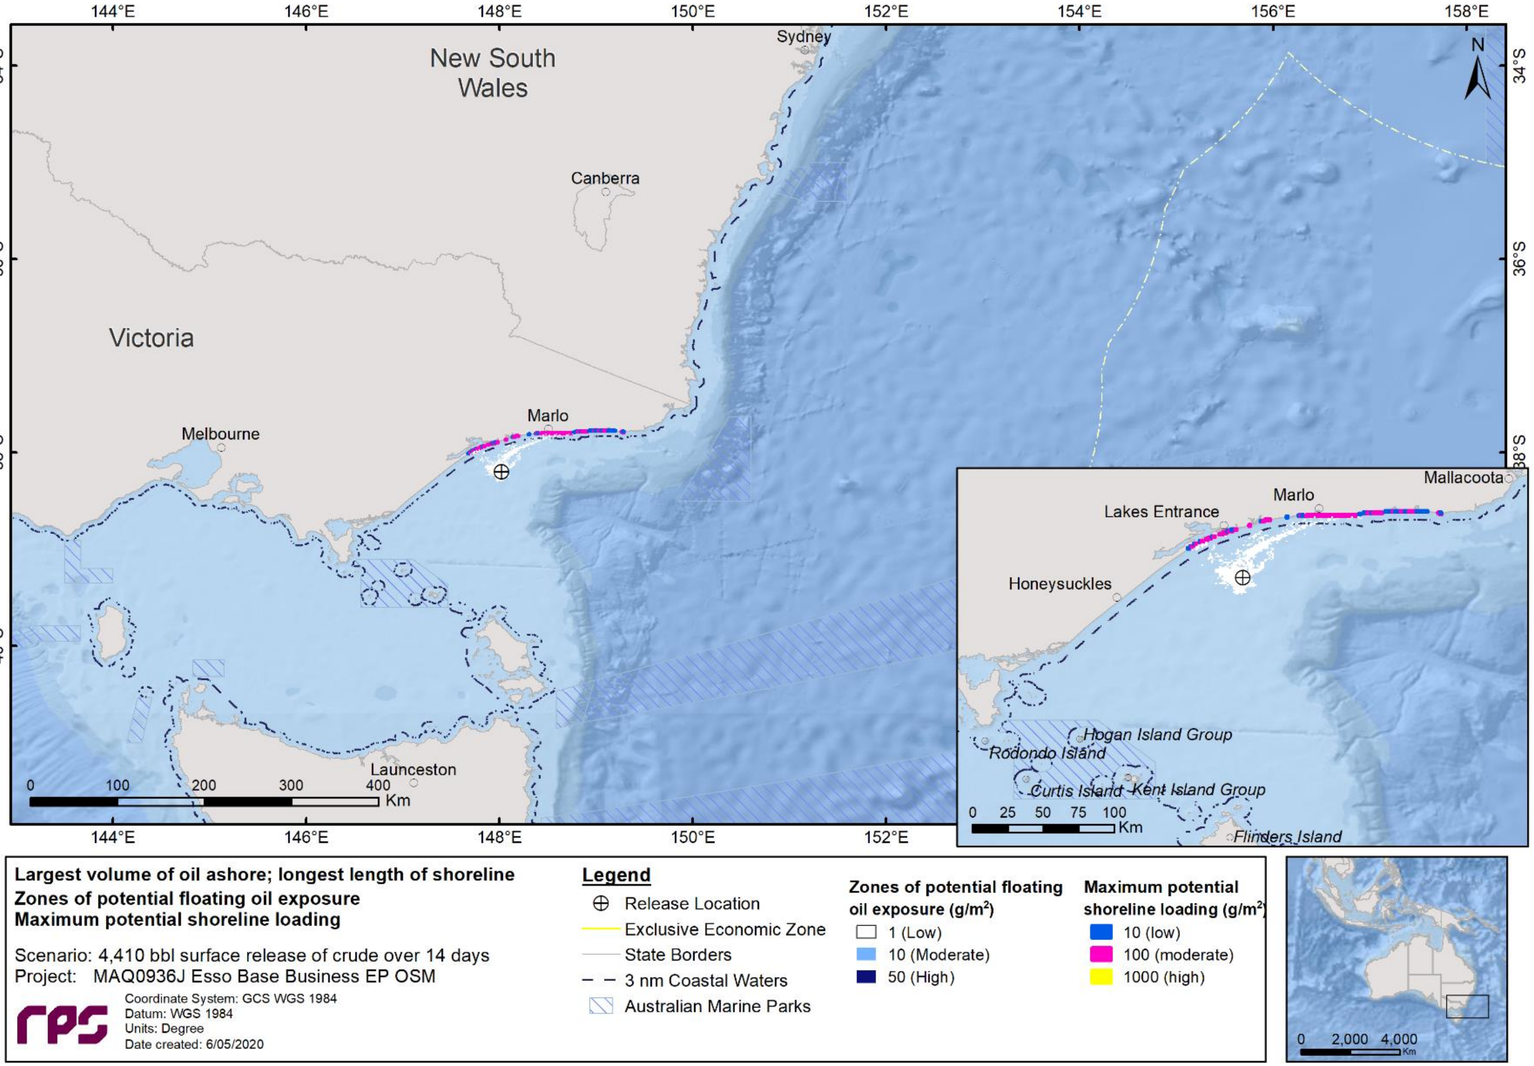
2. What's the worst that could happen?

	Snapper (SNA)
Modelled Oil Pollution Scenario (WCDS)**	<u>Level 3 Spill</u> A complete loss of well control (tubing flow to surface only) resulting in a release of crude until source control is effective (14 days).
Oil type and name	Moonfish Crude
Release rate (bbl/day)	315
Spill Volume (bbl)	4,410
Dominant Weathering process	Evaporation
Approximate evaporation rate (depending on temperature)	
within the first 12 hours	7.15%
within the first 24 hours	a further 28.75%
over several days.	a further 46.9%
Probability of contact to any shoreline (%)	64 (East Gippsland in particular Gabo Island)
Absolute minimum time for visible oil to shore	3 days (at Gabo Island)
Maximum volume ashore (m^3)	183
Maximum length of the shoreline (km) **at 10 g/m^2** **at 100 g/m^2** **at 1,000 g/m^2**	 98 66 5
Weathering over the duration of LOWC (98 days) (based on deterministic modelling)	
Evaporation (%)	62 - 55
Decay (%)	9 - 16
Water column (%)	3 - 6
Surface (%)	1 - 32
Shoreline (%)	25 - 0

**RPS Report MAQ0936J Base Business Operations in the Gippsland Basin Oil Spill Modelling dated 18 May 2020. Note this modelling used results from Leeder Analytical Report No. L190131 Chemical and Physical Testing of Seven Crude and Condensates dated 31 May 2019.

Exposure - Shoreline



Zones of potential exposure on the sea surface and shoreline for the trajectory with the largest volume of shoreline loading and longest length of shoreline contact. Results are based on a 4,410 bbl surface release of Moonfish Crude over 14 days at Snapper Platform, tracked for 44 days. 6 am 21st January 2011.

3. Resources at Risk

	Receptor	<12 hrs	12-48 hrs	>48 hrs	>1week (days)
Minimum time to oil exposure on surface at moderate threshold	There is no predicted oil exposure on the sea surface at the moderate threshold.				
Minimum time to shoreline accumulation of oil at moderate threshold	• Montague Island (NSW)				14 days
	• Shoal Haven (NSW)				19 days
	• Eurobodalla (NSW)				19 days
	• Bega Valley (southern NSW)			144 hrs	
	• Croajingolong			144 hrs	
	• Gabo Island			96 hrs	
	• Cape Howe / Mallacoota			144 hrs	
	• Point Hicks			84 hrs	
	• Sydenham Inlet				11 days
	• Cape Conran				9 days
	• Marlo			144 hrs	
	• Corringle				9 days
	• Lake Tyers Beach				7 days
	• Lakes Entrance				7 days
	• Ocean Grange				20 days
	• Seaspray				13 days
	• Golden Beach				20 days
	• Woodside Beach				13 days
	• Seal Islands				10 days
	• Wilsons Promontory				21 days
	• Corner Inlet				21 days

Protection priorities based on sensitivity and predicted consequence (as per EP Volume 2), protectable/actionable areas, and minimum time to exposure in this area are:

Gabo Island due to high sensitivity and significant fauna populations (Little penguins, Storm petrels, Hooded plover, Fur seals).

Croajingolong National Park including **Sydenham Inlet, Betka Inlet, Wingan Inlet** (and The Skerries Fur seal colony).

Mallacoota due to sensitivity of estuary mouth, Hooded plover habitat

Nadgee Lake and Nadgee River due to pristine coastal landscape within the Nadgee Nature Reserve (southern NSW), nature based tourism and significant Wilderness Area.

Marlo due to sensitivity of Snowy River estuary / mouth, recreational activities.

Lakes Entrance permanently open river mouth to the Gippsland Lakes being a recognised Ramsar site, marine flora and fauna, marshes, wetlands, estuarine habitat, shorebird/seabird colonies, amenity beaches, surf club, commercial fishing, tourism, dive sites, recreational aquatic activities, waterway amenity access.

Lake Tyers due to sensitivity of waterway, Hooded plover habitat, recreational activities.

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Light Crude Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of crude oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the direction of movement of the spill and natural break-up and dissipation of spill. Monitoring will also be used to assess the need for, and effectiveness of, active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna. Use of dispersants may eliminate, or minimise oil impacting sensitive resources including Gabo Island.	Pour point of this oil is 33ºC and so solid masses are likely to form at ambient sea temperature limiting the ability to apply dispersant. Laboratory test of dispersant effectiveness on fresh Moonfish crude indicates low efficacy (<4%). Modelling indicates no surface accumulation of oil at moderate (or actionable) threshold of 10g/m^2	Not viable	X
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes. Targeted containment and recovery can be utilised to reduce impact to sensitive areas such as Gabo Island where access for shoreline protection is limited (see below: Protection of Sensitive Shoreline Resources).	Modelling indicates no surface accumulation of oil at moderate (or actionable) threshold of 10g/m^2, however, containment and recovery maybe a viable strategy should operational monitoring indicate the sufficient quantities of oil. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Unlikely	✓
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Crude is predicted to impact shorelines in east Gippsland within 3 days. Tactical Response Plans have been developed to protect sensitive estuary openings along this section of coastline.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis	Yes	✓
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	OWR is likely to be required as a result of shoreline oiling.	Yes	✓

5. Response Resources Required

	Emulsion Water Content (%)	22%
	Saturates (%)	82.6%
	Wax Content (%)	32%
	Volatile (BP <180°C)	9.1%
	Semi-volatile (BP 180 - 265°C)	36.6%
	Low volatility(BP 265 - 380°C)	39.1%
	Residual (BP> 380°C)[2]	15.0%

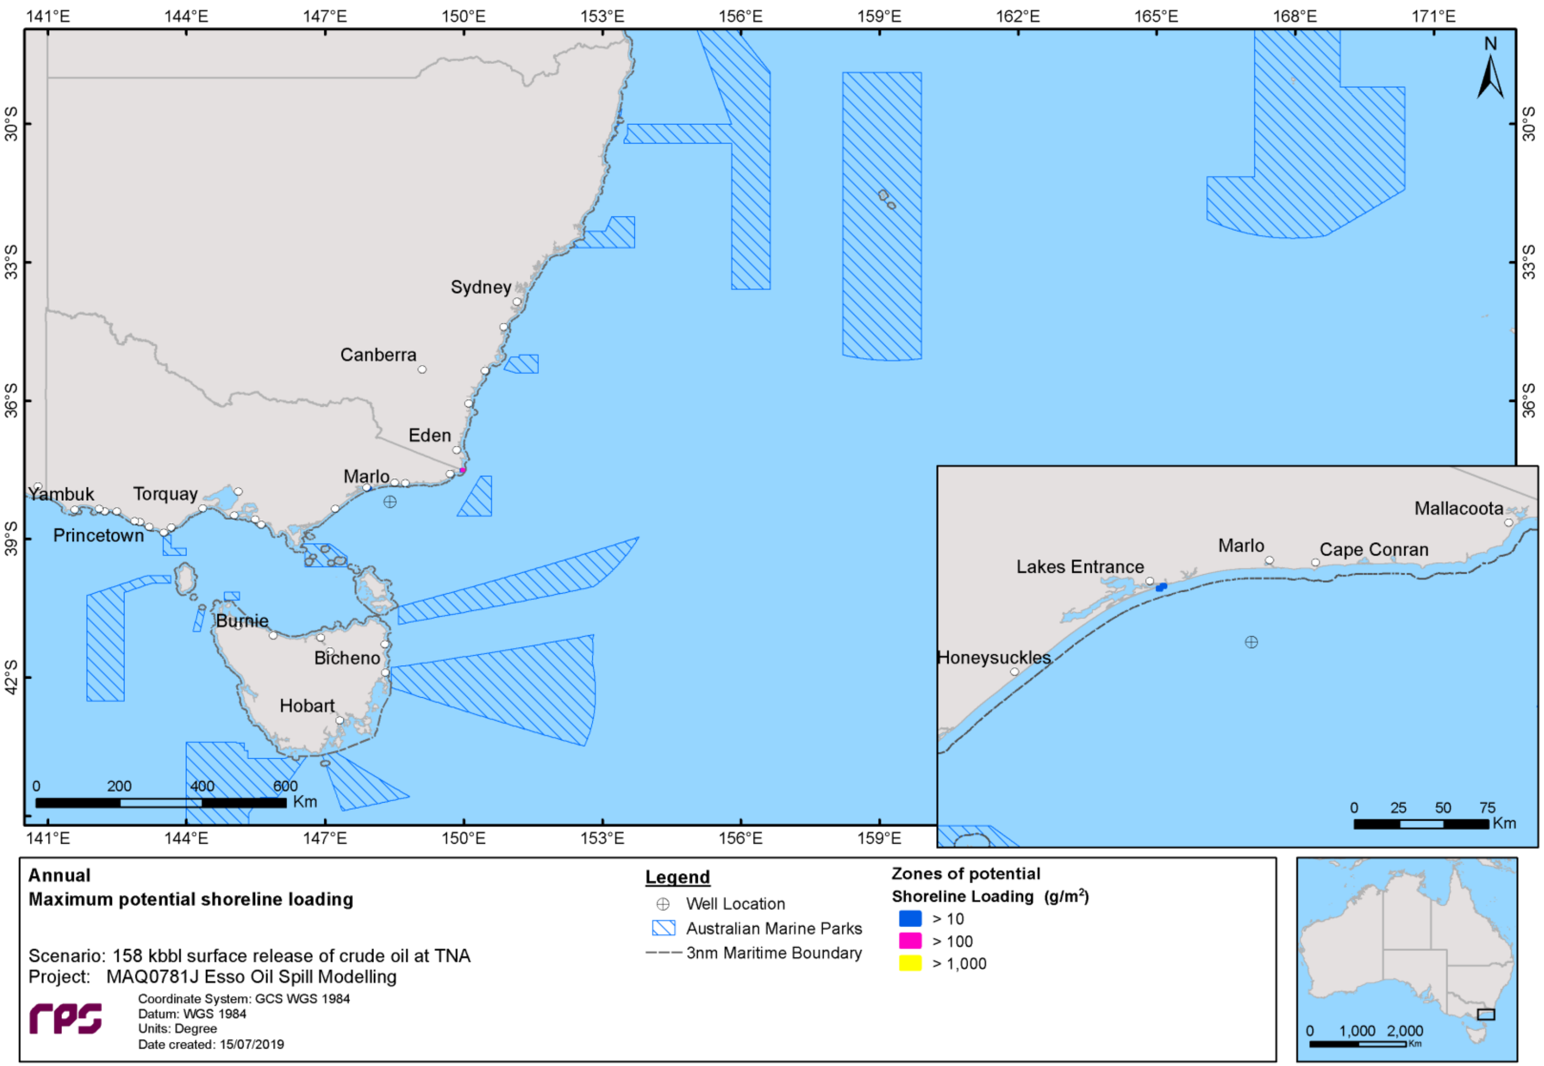
1 *Soluble, aromatic, hydrocarbons, (including BTEX), tend to evaporate into the atmosphere.*

2 *Residual Hydrocarbons will persist in the marine environment. It will remain in a liquid state when released into the environment over the annual temperatures observed in the Gippsland Basin*

2. What's the worst that could happen?

	Tuna (TNA)
Modelled Oil Pollution Scenario (WCDS)	Level 3 Spill A complete loss of well control (tubing flow to surface only) resulting in a release of crude until source control is effective (98 days – based on worst case scenario where relief well drilling is required).
Oil types and name	Flounder Crude
Release rate (bbl/day)	1,612
Spill Volume (bbl)	158,000
Dominant Weathering process	Evaporation
Approximate evaporation rate (depending on temperature)	
within the first 12 hours	9.1%
within the first 24 hours	36.6%
over several days.	39.1%
Probability of contact to any shoreline (%)	10 (East Gippsland – at Cape Howe/Mallacoota)
Absolute minimum time for visible oil to reach shoreline (hrs)	596 (East Gippsland – at Cape Howe/Mallacoota)
Maximum volume ashore (m^3)	6
Maximum length of the shoreline (km) at 10 g/m^2 at 100 g/m^2 at 1,000 g/m^2	 5 2 -
Weathering over the duration of LOWC (98 days) (based on deterministic modelling)	
Evaporation (%)	53%
Decay (%)	39%
Water column (%)	8%
Surface/Shoreline (%)	<1%

Exposure - Surface



Maximum potential shoreline loading for the low (≥ 10 g/m²), moderate (≥ 100 g/m²) and high (≥ 1,000 g/m²) thresholds. Results are based on a 158,000 bbl surface release of Flounder Crude over 98 days at Tuna Platform, tracked for 118 days. The results were calculated from 100 spill trajectories.

3. Resources at Risk

	Receptor	<12 hrs	12-48 hrs	>48 hrs	>1week (hrs)
Minimum time to oil exposure on surface at moderate threshold	BIAs: • Seabirds – Foraging • Pygmy Blue Whale – Distribution/Foraging • Southern Right Whale – Migration • White Shark – Distribution KEFs: • Upwelling East of Eden Note not predicted to contact State waters	 ✓ ✓ ✓ ✓ ✓			
Minimum time (hrs) to shoreline accumulation of oil at the moderate threshold	• Bega Valley (southern NSW)				596

Protection priorities based on sensitivity and predicted consequence (as per EP Volume 2), protectable/actionable areas, and minimum time to exposure in this area are:

Nadgee Lake and Nadgee River due to pristine coastal landscape within the Nadgee Nature Reserve (NSW) and significant Wilderness Area

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Light Crude Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of crude to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the direction of movement of the spill and natural break-up and dissipation of spill. Monitoring will also be used to assess the need for, and effectiveness of, active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Over 40% of the Flounder crude should evaporate within the first 24 hrs. Pour point of this oil is 18C and so solid masses are likely to form in cold water/weather limiting the opportunity to apply dispersant, however, laboratory testing has shown dispersant to be highly effective on fresh Flounder crude (48-99% effective), with effectiveness decreasing significantly after 12 hours of weathering. Dispersants should be applied to fresh oil closest to the source to maximize effectiveness. Note: the TNA platform is located far enough offshore for modelling to predict that a worst-case crude oil spill poses only a minor threat to the coastline or sensitivities within State waters.	Unlikely	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	Modelling indicates that suitable thickness of oil will be available for making containment and recovery viable but likely of low effectiveness. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Yes	✓
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Light crude released at the TNA platform may contact the shoreline along the far east Gippsland coast and the southern coast of NSW, with modelling predicting shortest time of recoverable levels to shore as more than a week.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis	Unlikely	x
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Although the distance of the platform from the coast reduces likelihood of extensive wildlife oiling onshore, individuals may become oiled in the vicinity of the spill. Operational monitoring will be used to inform the need for OWR to be implemented.	Yes	✓

5. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	ROV debris clearing / subsea intervention	1 x ROV and 1 x vessel SFRT (via AMOSC) and 1 x vessel 1 x contract well control specialists (WWC/OSRL)	Estimated 5 days (from call out request to arrival in Victoria) Estimated 7 days (from Perth to BBMT via road transport) 2 days (from Singapore)
	Relief well	1 x MODU (via APPEA mutual aid agreement) 1 x contract engineering support (WWC/OSRL) Well construction material	Estimated 85 days (via HLV from Singapore)
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	N/A	
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP O1.5 Satellite Imagery	1 x contract.	
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Aerial dispersant	Dispersant Aircraft	Maximum 12.85 m^3/day Total volume 1,259 m^3 2 x AT-802 Air Tractors carrying out 5 sorties per day. 1 x observation platform	1 x Air Tractor required within 24 hours
Offshore Containment & Recovery	Boom Skimming system Vessels	8 x 200m 4 8 (4 strike teams)	1 strike team required within 48 hours

Response Option	Strategy	Resource	Timeframe
Protection of Sensitive Shoreline Resources	Personnel OSR Equipment Vehicles / Vessels	Nil	Unlikely to be required
Shoreline Clean-up[*1]	Personnel	2 Foreman 6 Labourers 2 Specialised Operators	Required within 24 hours 2 x Foreman 6 x Labourers 2 x Specialised Operators
	Vehicles and Vessels	1 x ATV 1 x Truck/Vehicle 1 x Front End Loader / Dozer 1 x Dump Truck	Required within 24 hours 1 x Truck/Vehicle
	OSR Equipment	1 x Pump 1 x skimmer w/pump 6m x Inshore Boom 6m x Sorbent boom/snares 1m x Shoreline flushing pipe	
	Manual Equipment	10 x Shovels 10 x Rakes 10 x Picks 500 x Plastic Bags 2 x Wheel barrows	Required within 24 hours 1 x Shoreline Response Trailers

*1 Calculated resources requirement are for planning purposes only. Actual response strategies and resource needs to be determined in consultation with the State control agency.Based on peak volume on shoreline with predicted loading of 100 mg/m^3 or greater. Assumed 10% of the shoreline being cleaned up in any 1 day (and a continuous re-oiling of the shoreline). 10% shoreline clean up used for planning purposes only. Actual resources to be determined in consultation with State control agency

Relevant Tactical Response Plan (TRP)	Nil

Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

Modelling indicates that the spill does **not** intersect the coastline until after 1 week.

However in the unlikely event of a spill, should trajectory modelling predict shoreline contact, sufficient resources are available to be initiated within 48 hours (in most cases sooner). Modules in addition to those required to monitor the spill may be initiated and resources mobilised to priority monitoring locations as determined at the time.

Information specific to a well blowout (WCDS) from the West Kingfish platform during base business operations is provided below. For further details, refer to the Bass Strait Environment Plan (AUGO-EV-EMM-002 & AUGO-EV-EMM-004).

1. Field Location / Oil properties

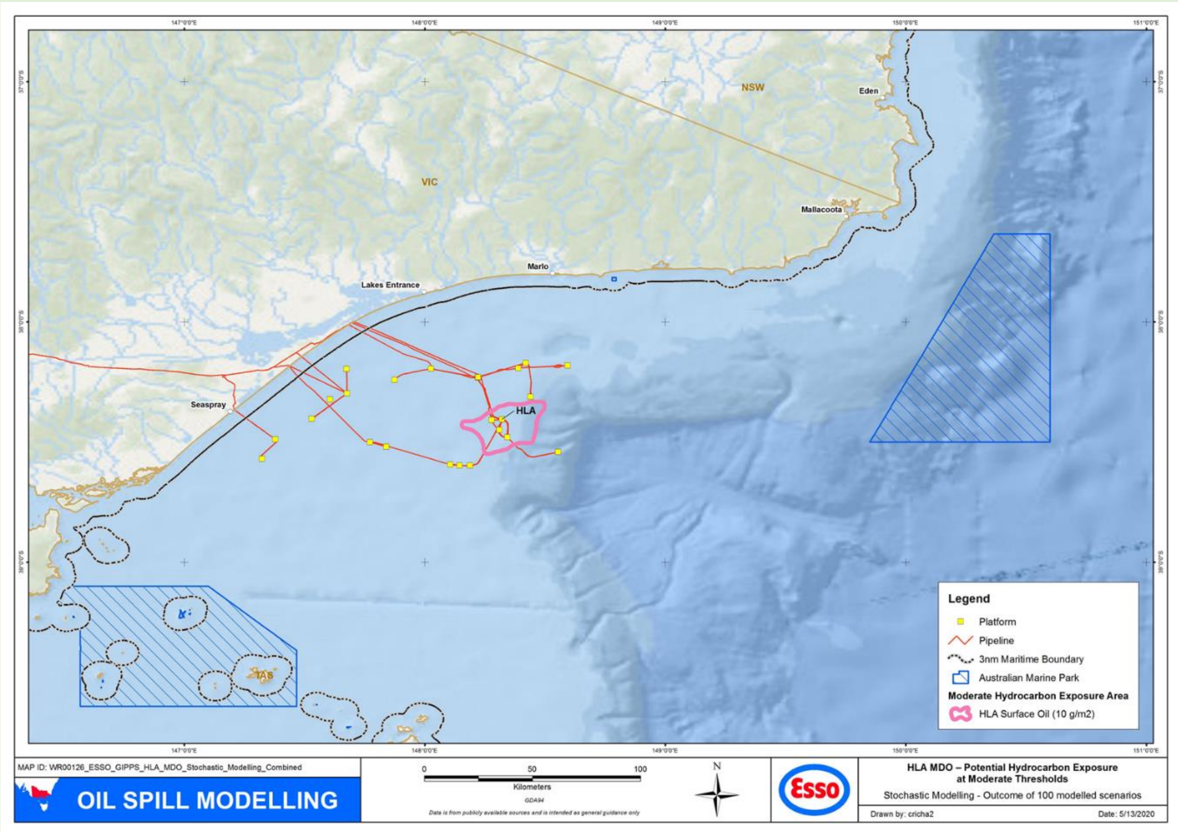
Modules in addition to those required to monitor the spill may be initiated and resources mobilised to priority monitoring locations as determined at the time.

Information specific to a MDO spill from a vessel collision at the Halibut platform during Bass Strait Operations is provided below. For further details, refer to the Bass Strait Operations Environment Plan.

1. Field Location / Oil properties

Location / operational area



Production Licence No.	VIC/L05 Halibut (HLA) platform	
Coordinates	Latitude	38°24’15.30” S
	Longitude	148°19’12.91” E
Oil types and name		Marine Diesel Oil (MDO)
	Density @ 15˚C	829 kg/m^3
	API	37.6
	Dynamic Viscosity	4.0 cP @ 25°C
	Pour Point	-14 ºC
	Wax Content	-
	Oil Property Category	Group II light persistent oil

2. What's the worst that could happen?

Halibut	
Worst case oil pollution scenario	Level 2 Vessel collision (220 m^3 of MDO over 6 hours) at HLA location
Dominant Weathering process	Evaporation
Approximate weathering predicted (from deterministic modelling)	Based on deterministic modelling, approximately: • 68% MDO is predicted to evaporate* • 15% MDO is predicted to remain in the water column* • 17% MDO is predicted to have decayed* • Nil shoreline impacts predicted for this scenario

*Evaporation, in water and decay results based on WKF predicted data

Exposure – Sea Surface HLA MDO

No shoreline contact is predicted at any threshold.

The maximum distance and direction travelled by hydrocarbon on the sea surface at each threshold from the release location is shown below:

Moderate threshold (10–50 g/m2): 15.5 km east-north east

High threshold (>50 g/m2): 3 km east

3. Resources at Risk

Halibut		
Minimum time to oil exposure on the sea surface at moderate threshold	< 12 hours	Great White Shark distribution BIA Southern Right Whale migration BIA Pygmy Blue Whale distribution and foraging BIAs Seabirds foraging BIAs
	12 – 48 hours	KEF – Upwelling East of Eden
	> 48 hours	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil
	12 – 48 hours	nil
	> 48 hours	nil

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a MDO spill without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Dispersant application is not recommended for MDO as it spreads rapidly to a thin layer. Insufficient time to respond while suitable surface thicknesses are present. Dispersant droplets are known to penetrate through the thin oil layer and cause 'herding' of the oil. This creates areas of clear water but is not successful dispersion. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	Not viable	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	MDO spreads rapidly to a thickness of less than 10 µm. Containment is ineffective at these thicknesses.	Not viable	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	No shoreline contact predicted	Not required	x
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	No shoreline contact predicted	Not required	x
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given limited size and rapid spreading of the MDO spill large scale OWR is unlikely to be required. Distance from coastline also reduces likelihood of extensive wildlife oiling, however individuals may become oiled in the vicinity of the spill. OWR may be implemented if required, to be assessed on case-by-case basis.	Yes	✓

5. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	As per vessel SOPEP	-	-
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	1 x observer (to conduct 2 hour watch)	<2 hours from time of spill
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	< 4 hours of service requested.
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Protection of Sensitive Shoreline Resources	Shoreline protection	N/A - No shoreline contact	
Oiled Wildlife Response	DELWP will make the decision to stand up resources which are based in Victoria	To be determined by DELWP	Available <24 hours from request for services

Relevant Tactical Response Plan (TRP)	N/A

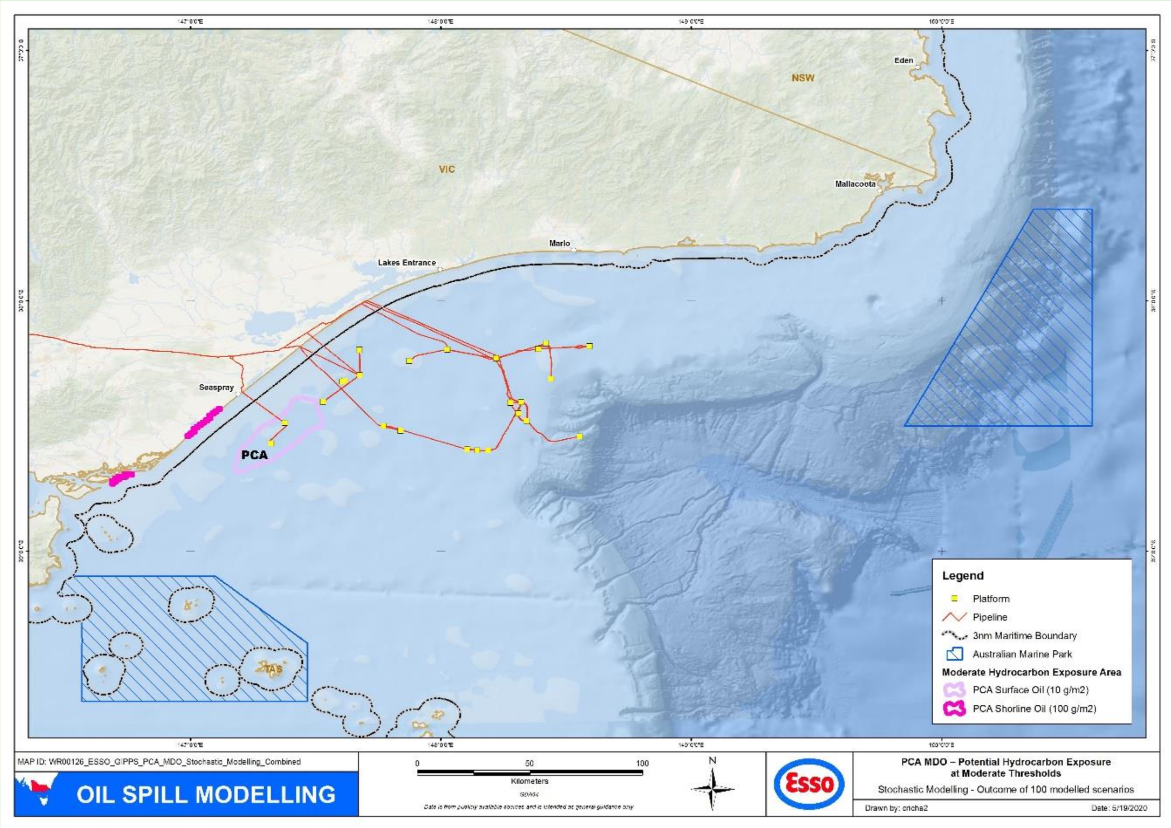
Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

Modelling does not predict any shoreline contact at the moderate threshold. However in the unlikely event of a spill, should trajectory modelling predict shoreline contact, sufficient resources are available to be initiated within 48 hours (in most cases sooner). Modules in addition to those required to monitor the spill may be initiated and resources mobilised to priority monitoring locations as determined at the time.

Information specific to a MDO spill from a vessel collision at the Perch platform during Bass Strait Operations is provided below. For further details, refer to the Bass Strait Operations Environment Plan.

1. Field Location / Oil properties

Location / operational area

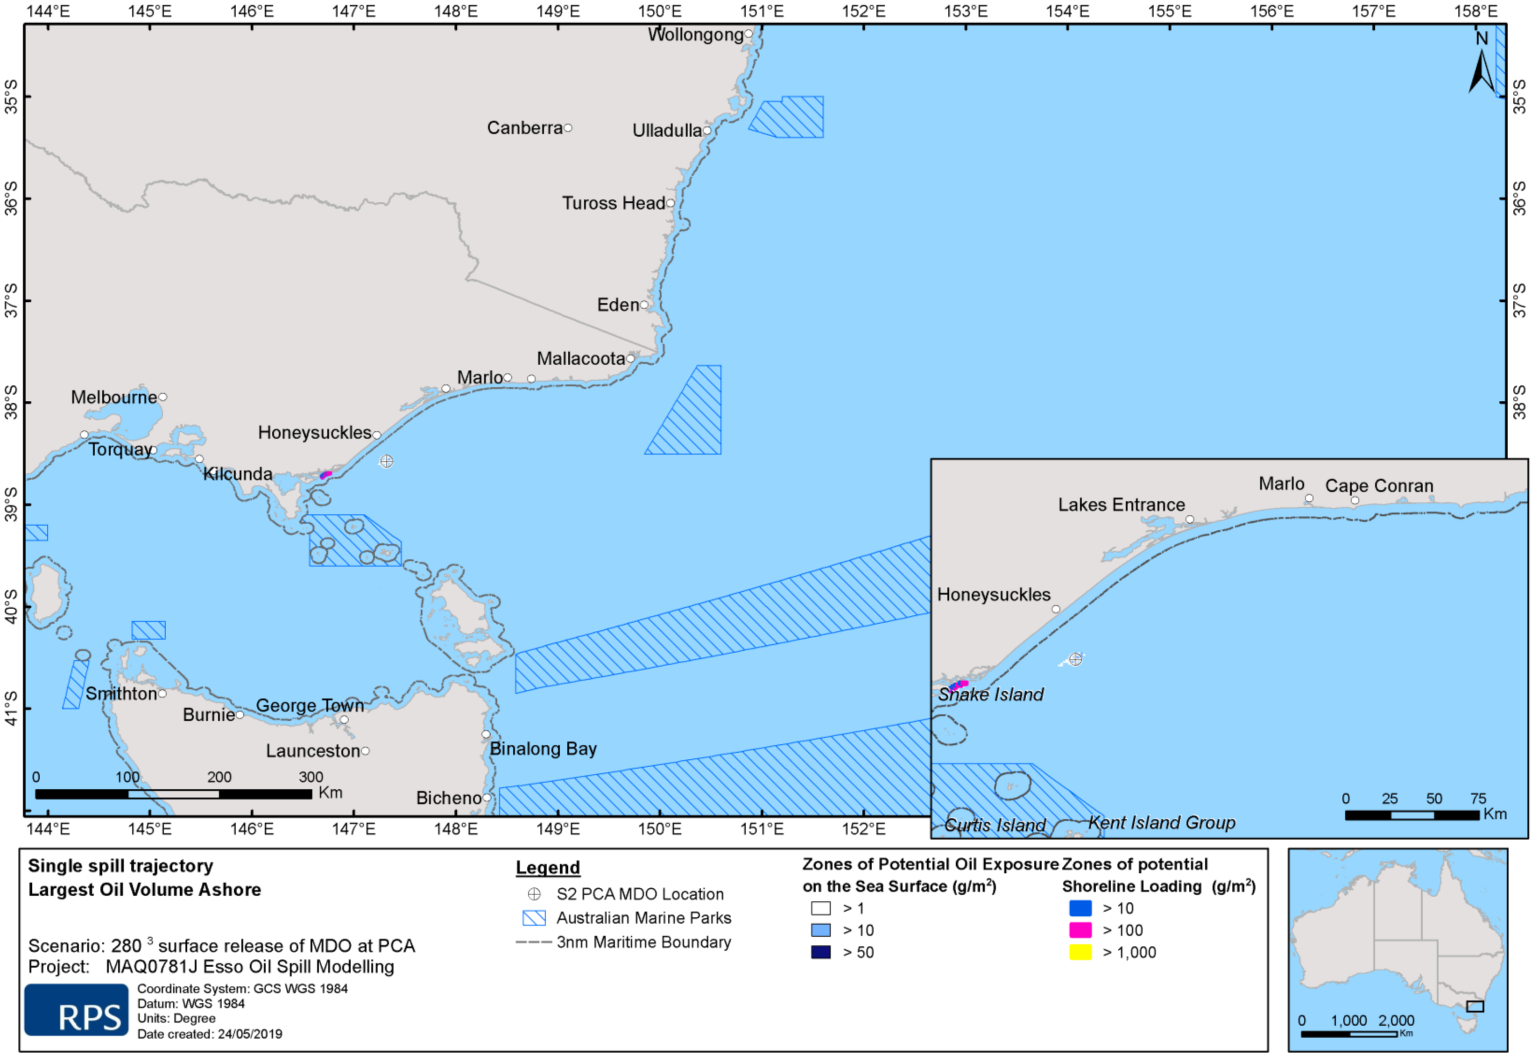


Production Licence No.	VIC/L17 Perch (PCA) platform	
Coordinates	Latitude	38° 34' 15" S
	Longitude	147° 19' 16" E
Oil types and name		Marine Diesel Oil (MDO)
	Density @ 15˚C	829 kg/m^3
	API	37.6
	Dynamic Viscosity	4.0 cP @ 25°C
	Pour Point	-14 ºC
	Wax Content	-
	Oil Property Category	Group II light persistent oil

2. What's the worst that could happen?

Perch	
Worst case oil pollution scenario	Level 2 Vessel collision (280 m^3 of MDO over 6 hours) at PCA location
Dominant Weathering process	Evaporation
Approximate weathering predicted (from deterministic modelling)	Based on deterministic modelling, approximately: • 53 - 40% MDO is predicted to evaporate. • 17 - 22 % MDO is predicted to remain in the water column • 22 - 31% MDO is predicted to have decayed • 8% MDO is predicted to arrive ashore

Exposure –Shoreline and Sea Surface



Zones of potential exposure on the sea surface and shoreline loading for the trajectory with the largest oil volume ashore. Results are based on a 280 m^3 surface release of MDO over 6 hours at the Perch Platform, tracked for 30 days, 12 am 2nd of June 2012.

3. Resources at Risk

Perch		
Minimum time to oil exposure on the sea surface at moderate threshold	< 12 hours	Great White Shark distribution and breeding BIAs Southern Right Whale migration BIA Pygmy Blue Whale distribution and foraging BIAs Seabirds foraging BIAs
	12 – 48 hours	nil
	> 48 hours	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil
	12 – 48 hours	Wellington (i.e. coastline of Wellington Shire) Woodside Beach
	> 48 hours	nil

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a MDO spill without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Dispersant application is not recommended for MDO as it spreads rapidly to a thin layer. Insufficient time to respond while suitable surface thicknesses are present. Dispersant droplets are known to penetrate through the thin oil layer and cause 'herding' of the oil. This creates areas of clear water but is not successful dispersion. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	Not viable	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	MDO spreads rapidly to a thickness of less than 10 µm. Containment is ineffective at these thicknesses.	Not viable	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	MDO spreads rapidly to a thickness of less than 10 µm. Corralling of surface hydrocarbons close to shore is not expected to be effective for MDO and is thus not expected to provide sufficient benefit. However, diverting oil away from inlets or creek / river mouths to protect sensitive sites may be undertaken. There is a very low probability that MDO spilled at the PCA location may contact the shoreline along the coastline of Wellington Shire.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	There is a very low probability that MDO spilled at the PCA location may contact the shoreline along the coastline of Wellington Shire and Woodside Beach. There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis.	Yes	✓
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given limited size and rapid spreading of the MDO spill large scale OWR is unlikely to be required. Distance from coastline also	Yes	✓

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
		reduces likelihood of extensive wildlife oiling, however individuals may become oiled in the vicinity of the spill. OWR may be implemented if required, to be assessed on case-by-case basis.		

5. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	As per vessel SOPEP	-	-
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	1 x observer (to conduct 2 hour watch)	<2 hours from time of spill
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	< 4 hours of service requested.
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Protection of Sensitive Shoreline Resources[*1]	Personnel	1 Foreman 4 Specialised Operators	Required within 24 hours
	OSR Equipment	Nil	
	Vehicles and Vessels	1 x Front End Loader / Dozer	Required within 24 hours
Shoreline Clean-up[*1]	Personnel	1Foreman 8 Labourers 2 Specialised Operators	< 24 hours from request for services
	Vehicles and Vessels	1 x ATV 1 x Truck/Vehicle

Oiled Wildlife Response	DELWP will make the decision to stand up resources	To be determined by DELWP	Available <24 hours from request for services

Response Option	Strategy	Resource	Timeframe
	which are based in Victoria		

*1 Calculated resources requirement are for planning purposes only. Actual response strategies and resource needs to be determined in consultation with the State control agency.

Relevant Tactical Response Plan (TRP)	Merriman Creek (Seaspray)

6. Oil Spill Monitoring

PCA		
Sensitivities – Probability of contact with dissolved hydrocarbons at moderate threshold	> 90%	nil
	50 - 90%	nil
	50 – 75%	nil
	25 – 50%	nil
	10 – 25%	nil
	< 10%	nil
Marine Parks – Probability of contact with entrained hydrocarbons at low threshold (0-10m)	> 90%	nil
	75 - 90%	nil
	50 - 75%	nil
	25 - 50%	Cape Howe MNP Point Hicks MNP
	10 – 25%	Beware Reef Marine Sanctuary
	< 10%	Beagle AMP East Gippsland AMP Flinders AMO Batemans MP Ninety Mile Beach MNP Kent Group NP Gippsland Lakes Ramsar wetland

Modelling predicts that an MDO spill may intersect the coastline after 28 hours at locations around:

- Wellington (i.e. coastline of Wellington Shire)
- Woodside Beach

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the priority monitoring locations listed above:

- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

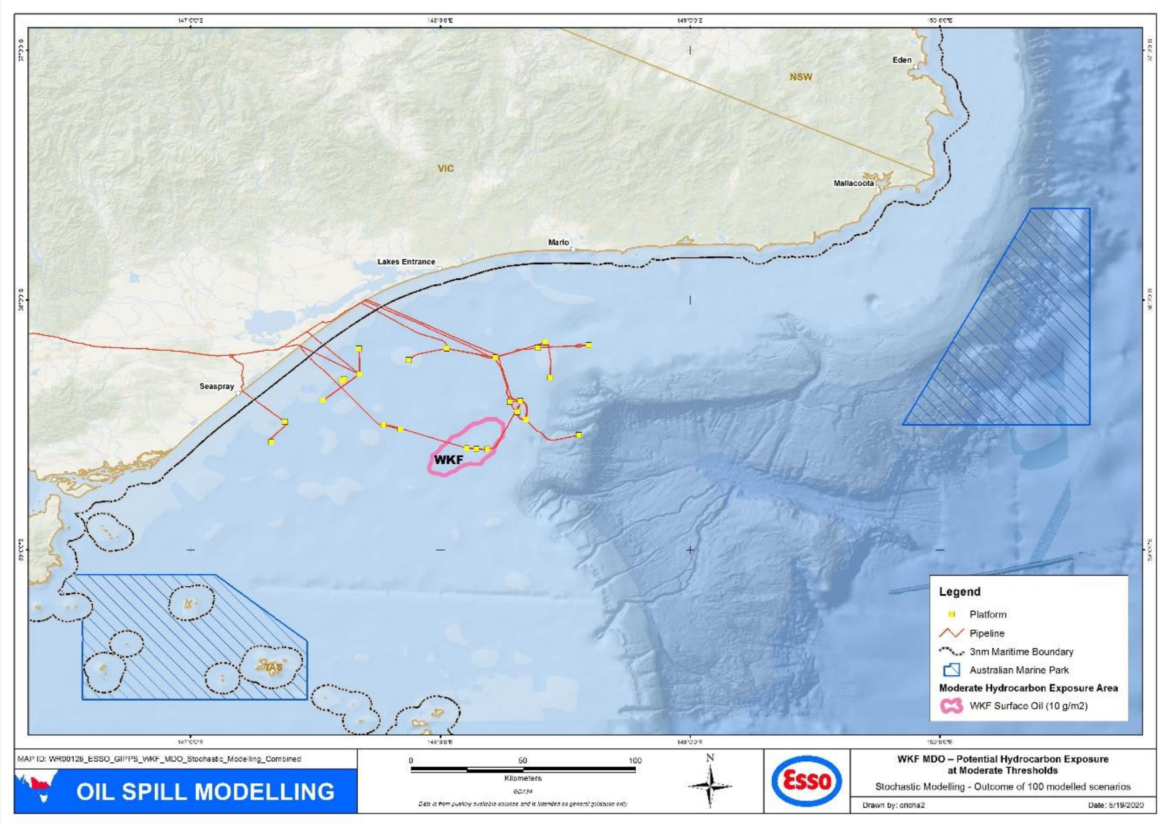
These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

Information specific to a MDO spill from a vessel collision at the West Kingfish platform during Bass Strait Operations is provided below. For further details, refer to the Bass Strait Operations Environment Plan.

1. Field Location / Oil properties

Location / operational area

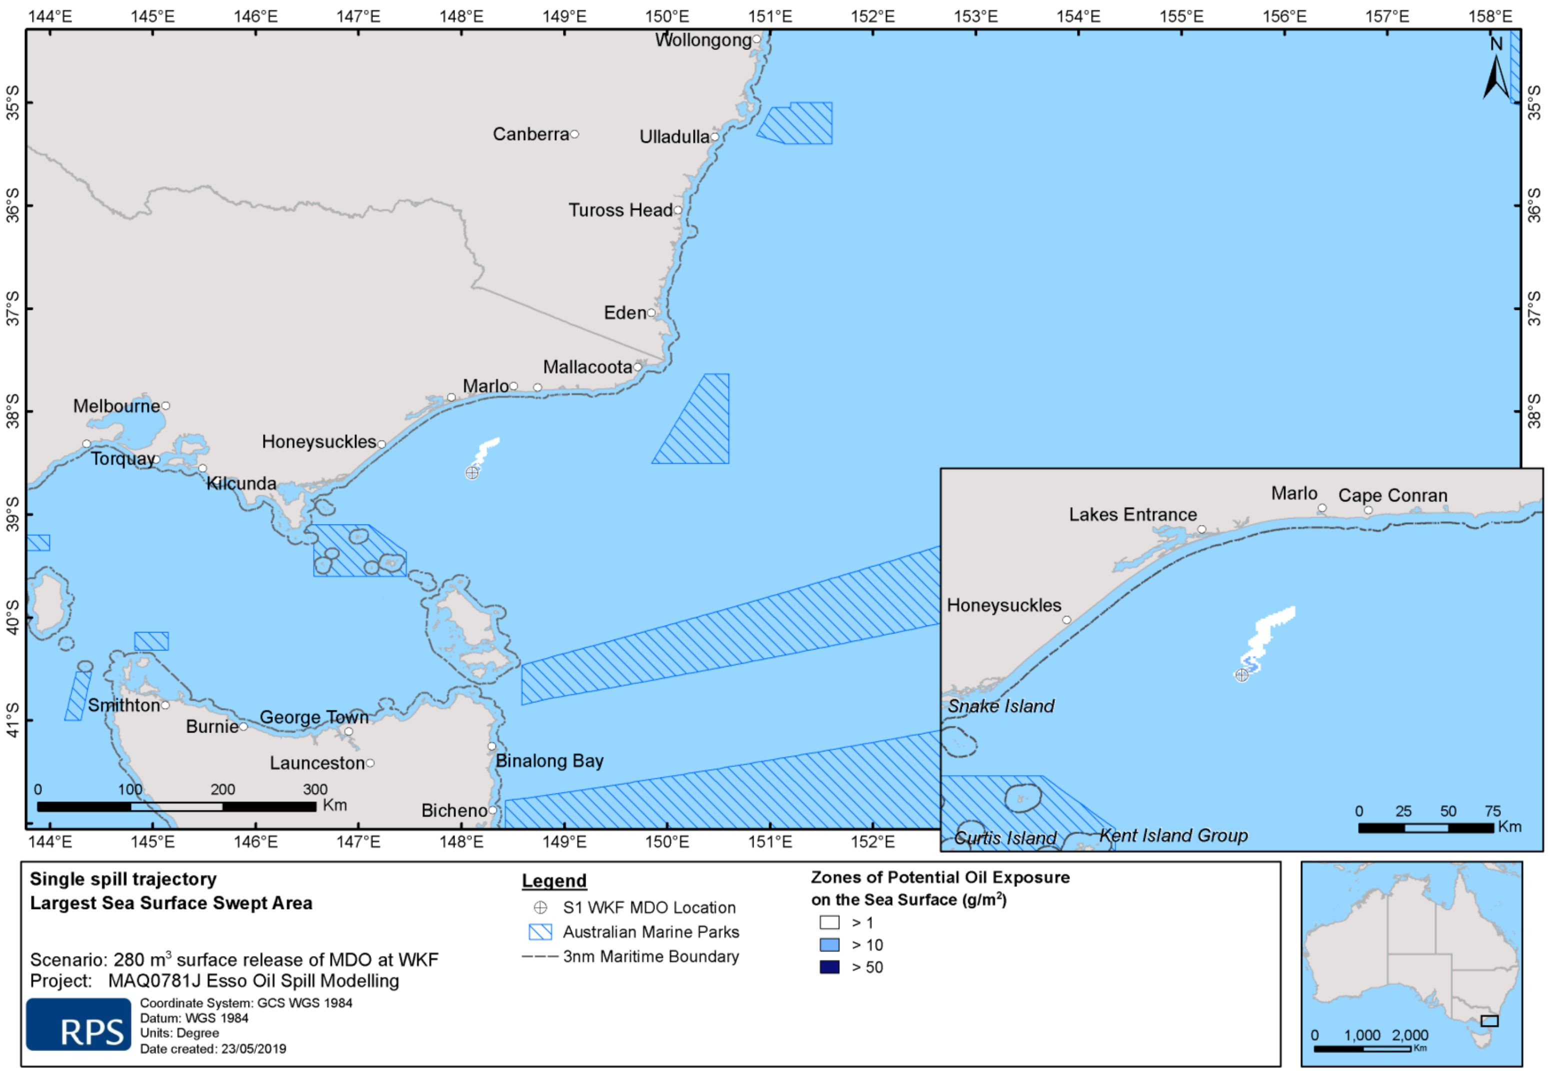


Production Licence No.	VIC/L07 West Kingfish (WKF) platform	
Coordinates	Latitude	38° 35’ 39" S
	Longitude	148° 06’ 15" E
Oil types and name		Marine Diesel Oil (MDO)
	Density @ 15˚C	829 kg/m^3
	API	37.6
	Dynamic Viscosity	4.0 cP @ 25°C
	Pour Point	-14 ºC
	Wax Content	-
	Oil Property Category	Group II light persistent oil

2. What's the worst that could happen?

West Kingfish	
Worst case oil pollution scenario	Level 2 Vessel collision (280 m^3 of MDO over 6 hours) at WKF location
Dominant Weathering process	Evaporation
Approximate weathering predicted (from deterministic modelling)	Based on deterministic modelling, approximately: • 68% MDO is predicted to evaporate. • 15% MDO is predicted to remain in the water column • 17% MDO is predicted to have decayed • Nil shoreline impacts predicted for this scenario

Exposure – Sea Surface



Zones of potential exposure on the sea surface for the trajectory with the largest sea surface swept area at the 10 g/m^2 threshold. Results are based on a 280 m^3 surface release of MDO over 6 hours at West Kingfish, tracked for 30 days, 8 am 22nd of June 2009.

3. Resources at Risk

Perch		
Minimum time to oil exposure on the sea surface at moderate threshold	< 12 hours	Great White Shark distribution BIA Southern Right Whale migration BIA Pygmy Blue Whale distribution and foraging BIAs Seabirds foraging BIAs
	12 – 48 hours	nil
	> 48 hours	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil
	12 – 48 hours	nil
	> 48 hours	nil

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a MDO spill without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Dispersant application is not recommended for MDO as it spreads rapidly to a thin layer. Insufficient time to respond while suitable surface thicknesses are present. Dispersant droplets are known to penetrate through the thin oil layer and cause 'herding' of the oil. This creates areas of clear water but is not successful dispersion. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	Not viable	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	MDO spreads rapidly to a thickness of less than 10 µm. Containment is ineffective at these thicknesses.	Not viable	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	No shoreline contact predicted	Not required	x
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	No shoreline contact predicted	Not required	x
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given limited size and rapid spreading of the MDO spill large scale OWR is unlikely to be required. Relevant Tactical Response Plan (TRP)	N/A

6. Oil Spill Monitoring

West Kingfish		
Sensitives – **Probability of contact with dissolved hydrocarbons at moderate threshold**	> 90%	nil
	50 - 90%	nil
	50 – 75%	nil
	25 – 50%	nil
	10 – 25%	nil
	< 10%	nil
Marine Parks – **Probability of contact with entrained**	> 90%	nil
	75 - 90%	nil
	50 - 75%	nil

West Kingfish		
hydrocarbons at low threshold (0-10m)	25 - 50%	nil
	10 – 25%	Cape Howe MNP Point Hicks MNP
	< 10%	Beagle AMP East Gippsland AMP Flinders AMP Batemans MP Beware Reef Marine Sanctuary Kent Group NP

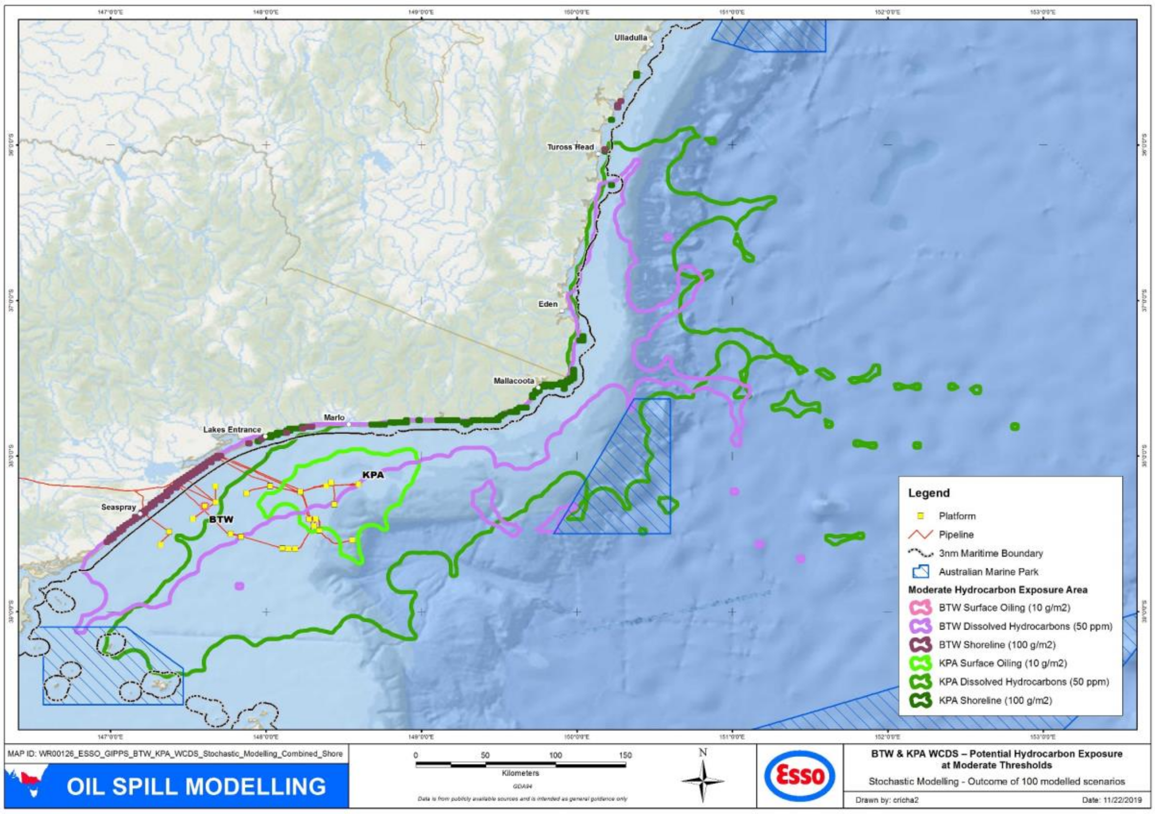
Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

Modelling does not predict any shoreline contact at the moderate threshold. However in the unlikely event of a spill, should trajectory modelling predict shoreline contact, sufficient resources are available to be initiated within 48 hours (in most cases sooner). Modules in addition to those required to monitor the spill may be initiated and resources mobilised to priority monitoring locations as determined at the time.

Information specific to the West Barracouta (BTW) drilling campaign is provided below. For further details, refer to the JUR Drilling Environment Plan.

1. Field Location / Oil properties

Location / operational area

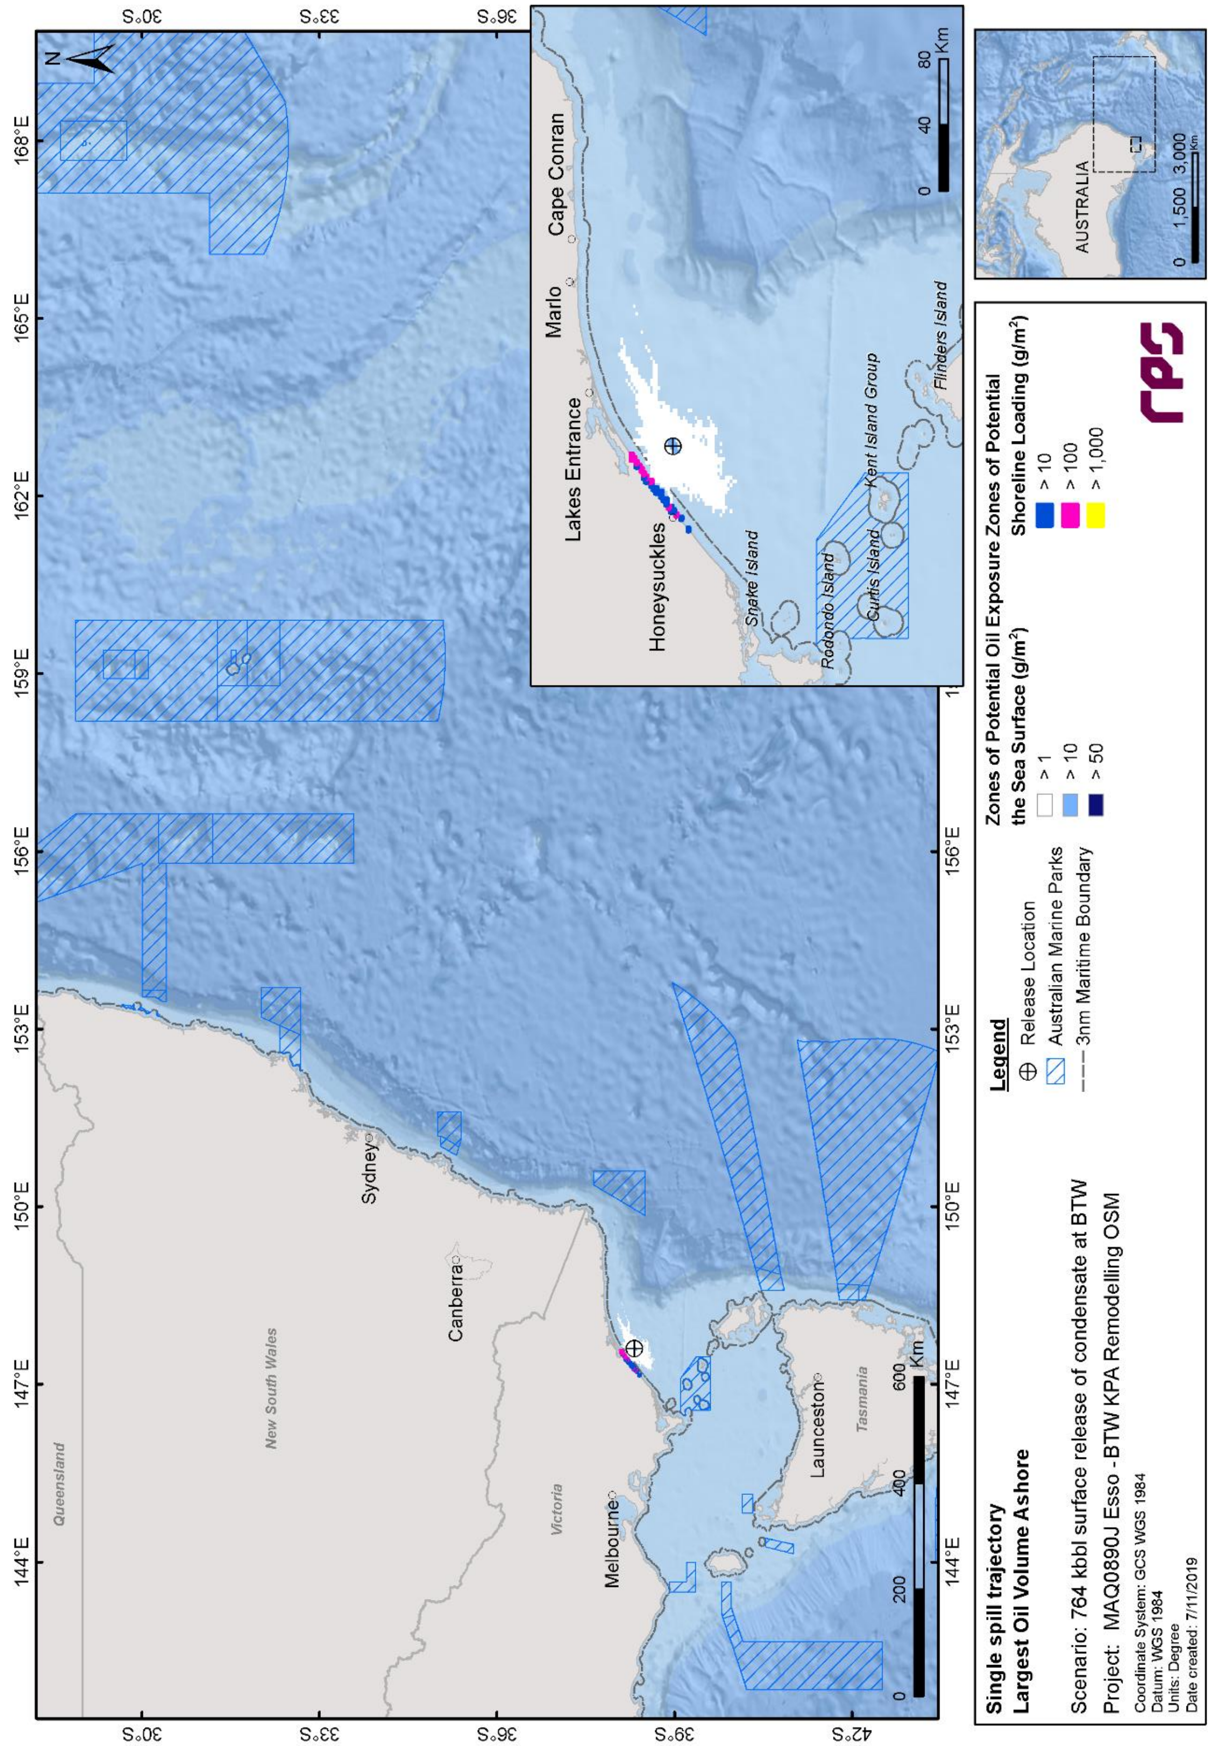


Production Licence No.	West Barracouta VIC/L1	
Coordinates		West Barracouta
	Latitude	38° 19’ 06” S
	Longitude	147° 36’ 53” E
	Depth	45.5 m

Oil types and name		Barracouta Condensate			
	Density @ 15˚C	772.3 kg/m^3			
	API	51.6			
	Dynamic Viscosity	1.291 @ 20ºC			
	Pour Point	-39 ºC			
	Wax Content	1.8%			
	Oil Property Category	Group I non-persistent oils			
	Boiling Point Distribution (°C)	Volatile (<180°C) 43.1 %	Semi-volatile (180-265°C) 30.8 %	Low volatility (265-380°C) 23.8 %	Residual (>380°C) 2.3 %

2. What's the worst that could happen?

West Barracouta	
Worst Case Discharge Scenario	<u>Level 3 Spill</u> A complete loss of well control (no drillpipe in hole) resulting in a release of: 764.0 kbbl condensate until source control is effective (98 days).
Dominant Weathering process	Evaporation
Approximate weathering predicted **(from deterministic modelling)**	• 92% condensate evaporates • 7% decay/ biodegrade • 1% remain within the water column • <0.1% on shoreline



Zones of potential exposure on the sea surface and shoreline loading for the trajectory with the largest oil volume ashore. Results are based on a 764,000 bbl (121,466 m^3) surface release of Barracouta condensate over 98 days at the West Barracouta well, tracked for 118 days, 8 pm 10th of August 2011

Resources at Risk

		West Barracouta
Minimum time to oil exposure on the sea surface at moderate threshold	< 12 hours	Great White Shark distribution and breeding BIAs Southern Right Whale migration BIA Pygmy Blue Whale distribution and foraging BIAs Seabirds foraging BIAs
	12 – 48 hours	nil
	> 48 hours	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil
	12 – 48 hours	nil
	> 48 hours	Ninety Mile Beach Lakes Entrance Ocean Grange Seaspray Woodside Beach
	> 1 week	Golden Beach Corringle

Protection priority based on sensitivity and predicted consequence (as per EP Volume 2a), protectable/actionable areas, and minimum time to exposure in this area is:

Lakes Entrance - permantly open river mouth to the Gippsland Lakes being a recognised Ramsar site, marine flora and fauna, marshes, wetlands, estuarine habitat, shorebird/seabird colonies, amenity beaches, surf club, commercial fishing, tourism, dive sites, recreational aquatic activities, waterway amenity access.

The other potentially contacted areas are primarily sandy beaches or river mouths that are not permanently open.

3. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Condensate Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of condensate to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a condensate spill from the BTW wells without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Condensate from the BTW wells is highly volatile and will be removed from the sea surface by evaporation. Dispersant is ineffective on Group I oils due to the very low viscosity and high volatility. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	Not viable	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	Condensate from the BTW wells is removed rapidly from the surface through evaporation. Suitable thickness for recovery will be present for only a very short period, making containment and recovery option ineffective. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Not viable	x
In-situ Burning	In-situ burning (burning oil in place) can quickly eliminate large quantities of spilled oil.	Condensate from the BTW wells is removed rapidly from the surface through evaporation. Suitable thickness for burning will be present for a very short period, making in-situ burning option ineffective. In Bass Strait sea, conditions likely to be suitable only 50% of the time.	Not viable	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Condensate released at the BTW location may contact the shoreline along the Ninety Mile Beach (most likely near Ocean Grange, very low likelihood further east at Lakes Entrance or Corringle). Condensate spreads rapidly and corralling of surface hydrocarbons close to shore is not expected to be effective and is thus not expected to provide sufficient benefit. However, diverting oil away from inlets or creek / river mouths to protect sensitive sites may be undertaken.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	Condensate released at the BTW location may contact the shoreline along the Ninety Mile Beach (most likely near Ocean Grange, very low likelihood further east at Lakes Entrance or Corringle). There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis.	Yes	✓

Response Option	Benefits	Effectiveness on Condensate Spill	Viable Response?	Net Benefit?
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given rapid removal from surface through evaporation and therefore limited surface exposure, OWR is unlikely to be required. Distance of drilling locations from coastline also reduces likelihood of extensive wildlife oiling, however individuals may become oiled in the vicinity of the spill. OWR may be implemented if required, to be assessed on case-by-case basis.	Yes	✓

4. Response Resources Required

The below resources needs are based on worst case discharge scenario. Actual resource requirements to be determined based on incident specific assessment.

Response Option	Strategy	Resource	Timeframe
Source Control	ROV debris clearing / subsea intervention	1 x ROV and 1 x vessel SFRT (via AMOSC) and 1 x vessel 1 x contract well control specialists (WWC/OSRL)	Estimated 5 days (from call out request to arrival in Victoria) Estimated 7 days (from Perth to BBMT via road transport) 2 days (from Singapore)
	Relief well	1 x MODU (via APPEA mutual aid agreement) 1 x contract engineering support (WWC/OSRL) Well construction material	Estimated 85 days (via HLV from Singapore)
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	N/A	
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP O1.5 Satelite Imagery	1 x contract.	
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Protection of Sensitive Shoreline Resources[*1]	Personnel	115 Personnel (Peak)	Required within 48 hours
	OSR Equipment	300m x Shoreboom 650m x Near shore boom 300m x Offshore boom 10 x Fast Tanks Anchor kits + accessories	50% required within 48 hours

	Vehicles and Vessels	1 x Vessel C&R (offshore) 1 x Vessel C&R (near shore) 2 x Workboat 1 x Front End Loader / Dozer	Required within 48 hours
Shoreline Clean-up[*2]	Personnel	12 Foreman 100 Labourers 8 Specialised Operators	50% required within 72 hours
	Vehicles and Vessels	4 x ATV 4 x Truck/Vehicle 1 x Front End Loader / Dozer 2 x Dump Truck	100% required within 72 hours
	OSR Equipment	1 x Pump 84m x Inshore Boom 84m x Sorbent boom/snares 14m x Shoreline flushing pipe	100% required within 72 hours
	Manual Equipment	160 x Shovels 160 x Rakes 160 x Picks 32000 x Plastic Bags 32 x Wheel barrows	50% required within 72 hours
Oiled Wildlife Response	DEWLP will make the decision to stand up resources which are based in Victoria	To be determined by DELWP	Available <24 hours from request for services

[*1] Based on simultaneous implementation of all relevant TRPs for protection of river mouths.

[*2] Based on clean up of shoreline with predicted loading of 100 g/m^2 or greater. Assumed 5% of the shoreline being cleaned up in any 1 day (and a continuous re-oiling of the shoreline). Maximum volume ashore 102m^3 (BTW).

Relevant Tactical Response Plan (TRP)	Lake Tyers Lake Bunga Lakes Entrance Merriman Creek (Seaspray)

Modelling predicts that a condensate spill may intersect the coastline after 48 hours at locations around:

- Lakes Entrance
- Seaspray
- Ocean Grange

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the **priority monitoring locations** listed above:

- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

The table below estimates the required resources needed to implement the OSMP modules in the field in the event of an example WCDS for BTW. It is estimated that 29 field teams could be required to implement all the modules. Assuming these teams are deployed simultaneously, 90 - 130 specialists and scientists could be required to staff these teams. It can be seen from Sections 2.7.3 and 2.7.5 of the OSMP that the Third Party OSMP Consultant has sufficient resources available to meet this demand. Per Section 2.7.2 of the OSMP, Survey Plans will be developed upon activation of the OSMP which will determine the monitoring requirements for the specific spill.

OSMP - Example response (number of survey units) relevant to BTW WCDS Deterministic OSTM.

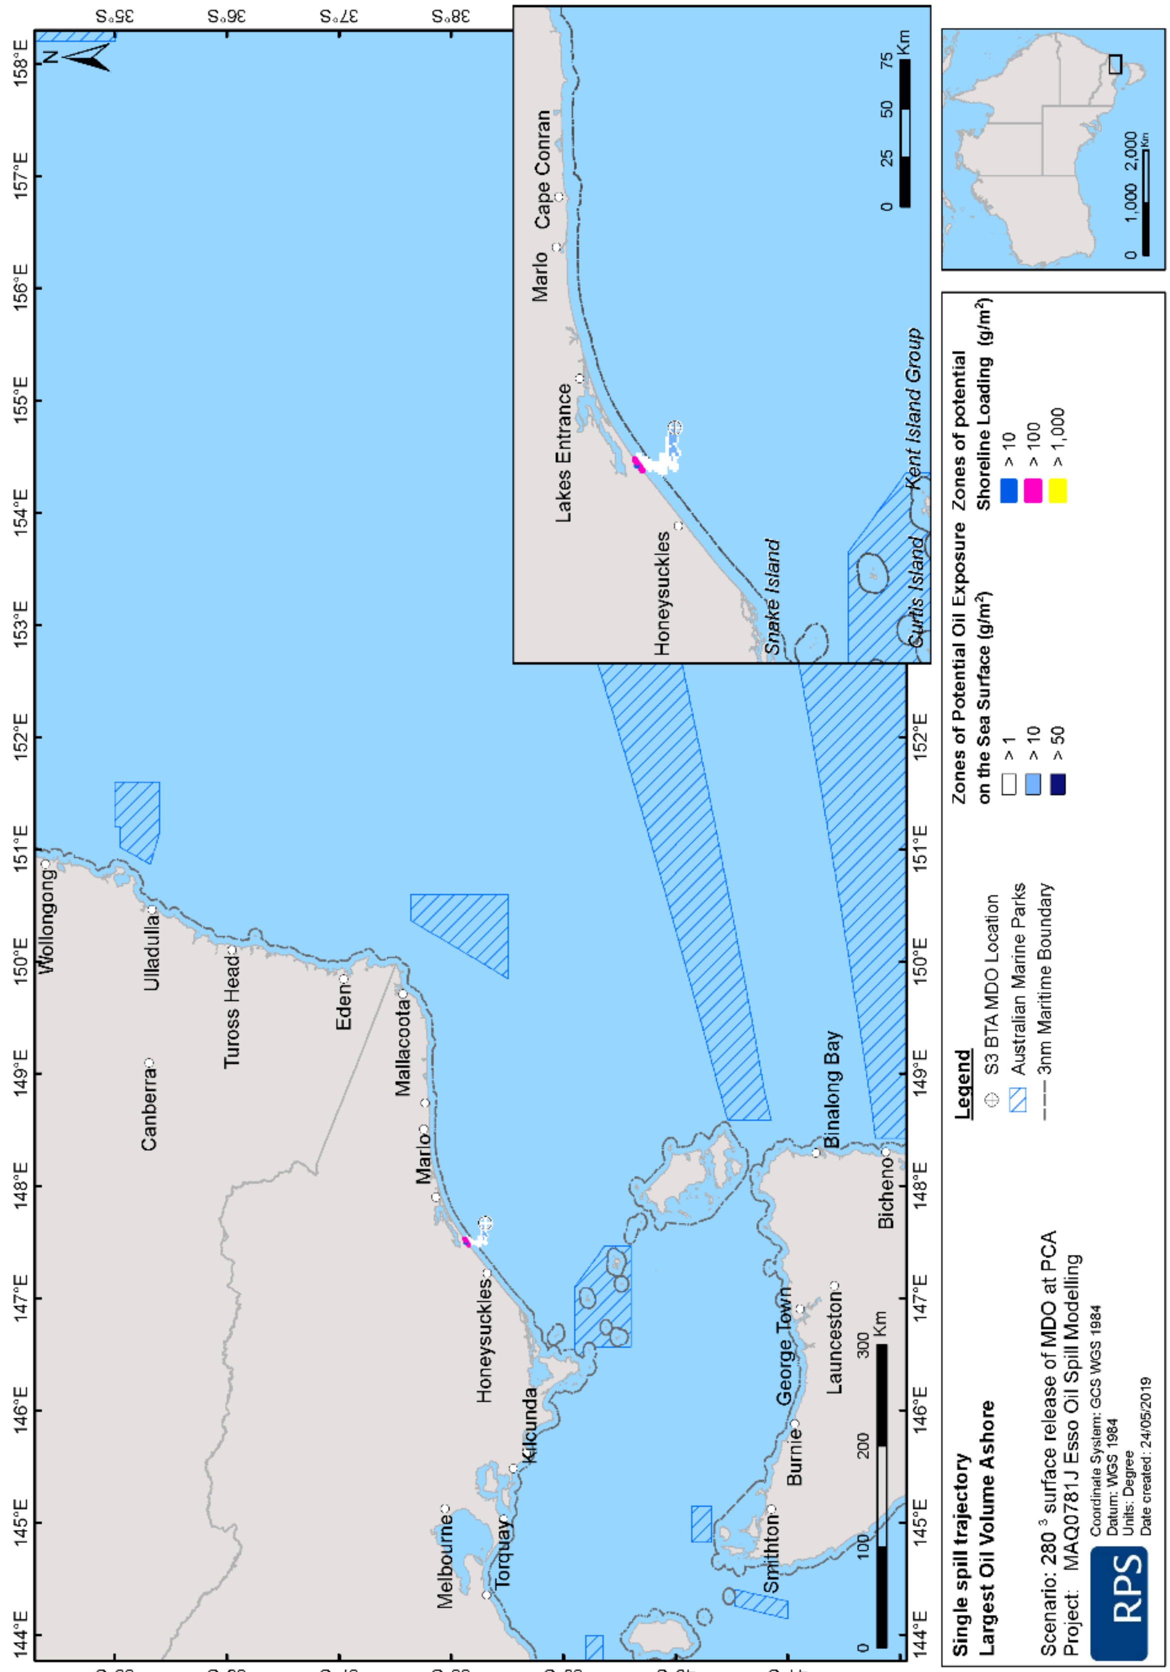
2. What's the worst that could happen?

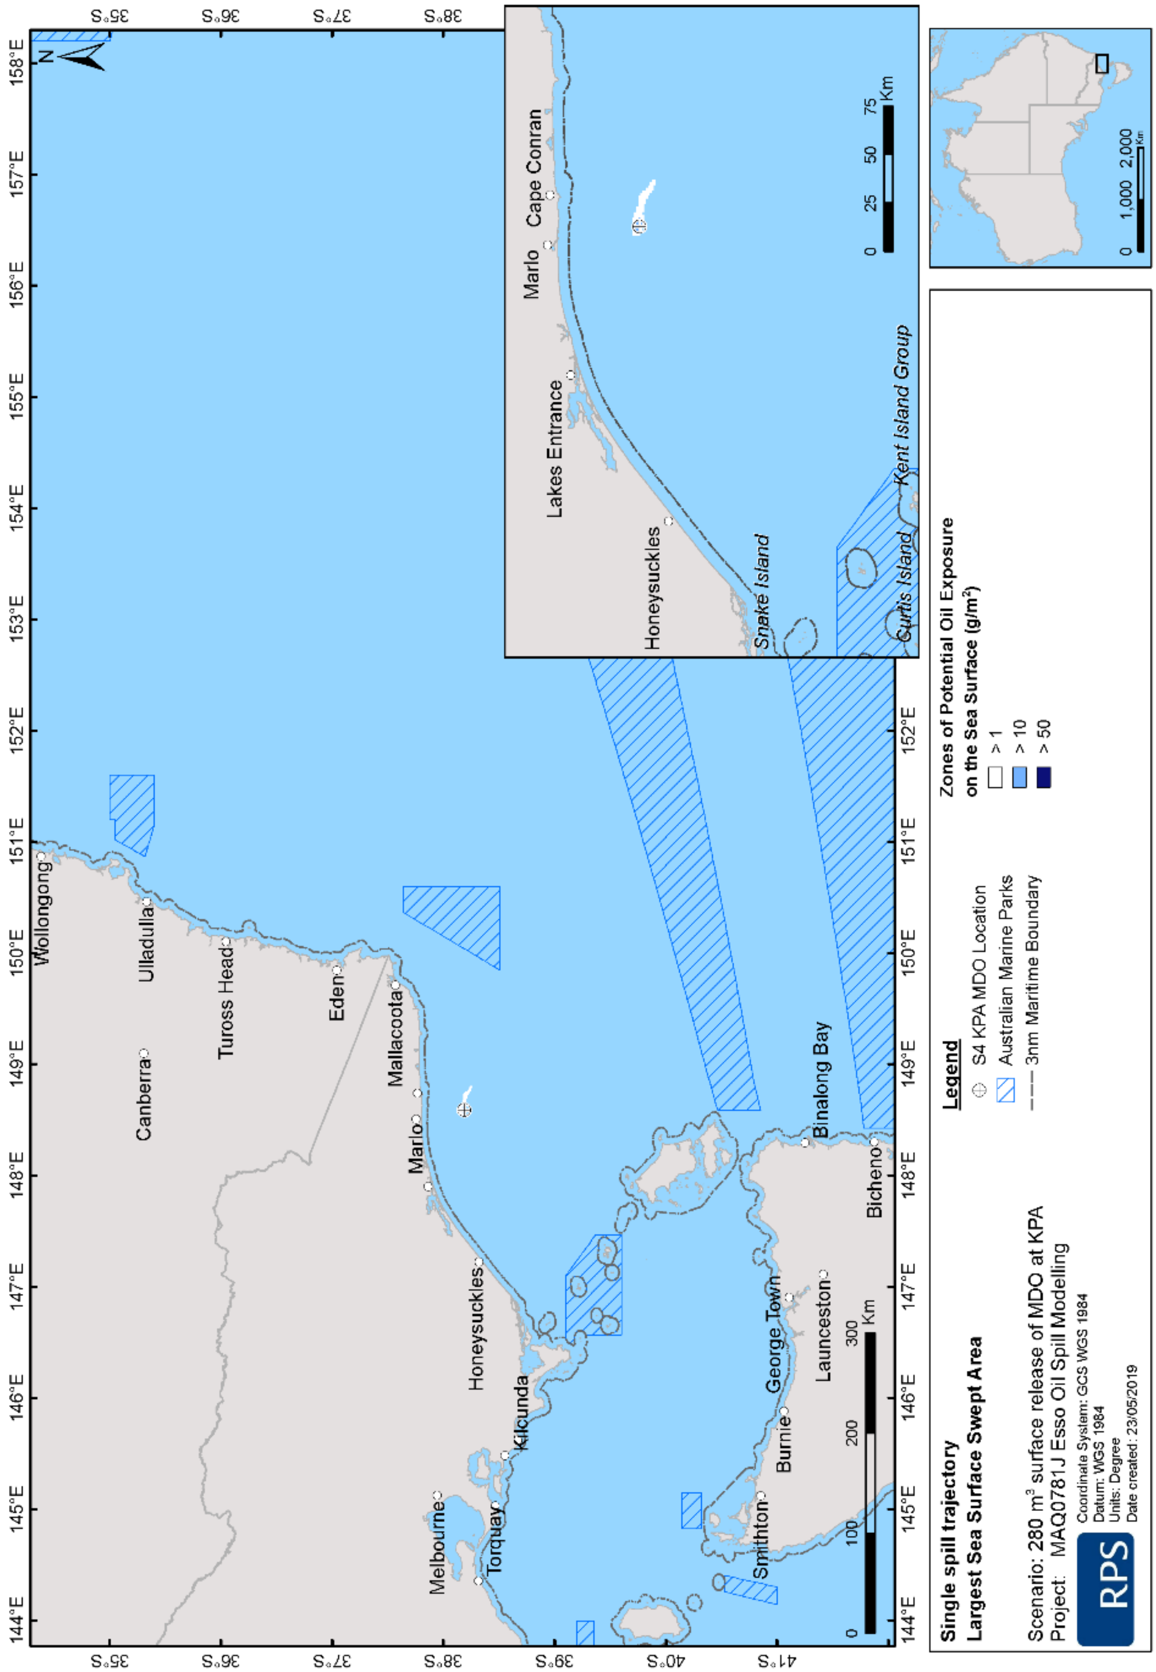
West Barracouta / Kipper	
Worst case oil pollution scenario	Level 2 Vessel collision (280 m^3 of MDO over 6 hours) at either drilling location
Dominant Weathering process	Evaporation
Approximate weathering predicted (from deterministic modelling)	Based on deterministic modelling, approximately: • 70 - 90% MDO is predicted to evaporate. • 5 – 15% MDO is predicted to remain in the water column • Shoreline impacts may occur depending on proximity to shore (8% MDO predicted to arrive ashore if the spill originates at the West Barracouta operational area)

Exposure – Sea Surface BTW



Zones of potential exposure on the sea surface and shoreline loading for the trajectory with the largest oil volume ashore, longest length of shoreline contacted above the 100 g/m^2 threshold and the minimum time before exposure to immediate nearshore waters by visible oil (0.5 g/m^2). Results are based on a 280 m^3 surface release of MDO over 6 hours at the Barracouta Platform, tracked for 30 days, 3 am 22nd of October 2011.

Exposure – Sea Surface KPA



Zones of potential exposure on the sea surface for the trajectory with the largest sea surface swept area at the 10 g/m^2 threshold. Results are based on a 280 m^3 surface release of MDO over 6 hours at the Kipper Facility, tracked for 30 days, 10 am 17th of May 2011.

3. Resources at Risk

		West Barracouta	Kipper

	12 – 48 hours	nil	nil
	> 48 hours	nil	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil	nil
	12 – 48 hours	nil	nil
	> 48 hours	Wellington Ocean Grange Seaspray	nil

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a MDO spill without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Dispersant application is not recommended for MDO as it spreads rapidly to a thin layer. Insufficient time to respond while suitable surface thicknesses are present. Dispersant droplets are known to penetrate through the thin oil layer and cause 'herding' of the oil. This creates areas of clear water but is not successful dispersion. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	Not viable	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	MDO spreads rapidly to a thickness of less than 10 µm. Containment is ineffective at these thicknesses.	Not viable	x
In-situ Burning	In-situ burning (burning oil in place) can quickly eliminate large quantities of spilled oil.	MDO spreads rapidly to a thickness of less than 10 µm. Containment, and therefore also in-situ burning, is ineffective at these thicknesses.	Not viable	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	The KPA location is sufficiently far from shore that coastline impact is not expected. There is a low probability that MDO spilled at the BTW location may contact the shoreline along the Ninety Mile Beach. MDO spreads rapidly to a thickness of less than 10 µm. Corralling of surface hydrocarbons close to shore is not expected to be effective for MDO and is thus not expected to provide sufficient benefit. However, diverting oil away from inlets or creek / river mouths to protect sensitive sites may be undertaken.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	The KPA location is sufficiently far from shore that coastline impact is not expected. There is a low probability that MDO spilled at the BTW location may contact the shoreline along the Ninety Mile Beach. There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis.	Yes	✓
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given limited size and rapid spreading of the MDO spill large scale OWR is unlikely to be required. Distance from coastline also reduces likelihood of extensive wildlife oiling, however individuals may become oiled in the vicinity of the spill. OWR may be implemented if required, to be assessed on case-by-case basis.	Yes	✓

5. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	As per vessel SOPEP	-	-
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	1 x observer (to conduct 2 hour watch)	<2 hours from time of spill
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	< 4 hours of service requested.
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Protection of Sensitive Shoreline Resources	Shoreline protection	5x booming systems (based on Lakes Entrance TRP which has the highest resource requirements).	<24 hours from request for services
		Approx. 100 personnel (based on Lakes Entrance TRP which has the highest resource requirements).	Notify State Duty Officer <2 hours of incident. Initiate request to call out core group <3 hours.
Shoreline Clean-up	Provision of personnel to support CA	15m^3 recovery per team per day based on ~~33~~ teams of 15 people. Maximum volume ashore 25 m^3.	< 24 hours from request for services
Oiled Wildlife Response	DELWP will make the decision to stand up resources which are based in Victoria	To be determined by DELWP	Available <24 hours from request for services

Relevant Tactical Response Plan (TRP)	Merriman Creek (Seaspray)

6. Oil Spill Monitoring

		West Barracouta	Kipper
Sensitivities – Probability of contact with dissolved hydrocarbons at moderate threshold	> 90%	nil	nil
	50 - 90%	nil	nil
	50 – 75%	nil	nil
	25 – 50%	nil	nil
	10 – 25%	nil	nil
	< 10%	nil	nil
Marine Parks – Probability of contact with entrained hydrocarbons	> 90%	nil	nil
	75 - 90%	nil	nil
	50 - 75%	Point Hicks Marine National Park	nil
	25 - 50%	Cape Howe Marine Park	nil
	10 – 25%	Beware Reef Marine Sanctuary	Cape Howe Marine National Park Point Hicks Marine National Park
	< 10%	Beagle AMP East Gippsland AMP Batemans Marine Park Ninety Mile Beach Marine National Park Gippsland Lakes Ramsar wetland	Beagle AMP East Gippsland AMP Flinders AMP Freycinet AMP Beware Reef Marine Sanctuary Batemans Marine Park

Modelling predicts that an MDO spill may intersect the coastline after 48 hours at locations around:

- Seaspray,
- Ocean Grange;
- Wellington.

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the priority monitoring locations listed above:

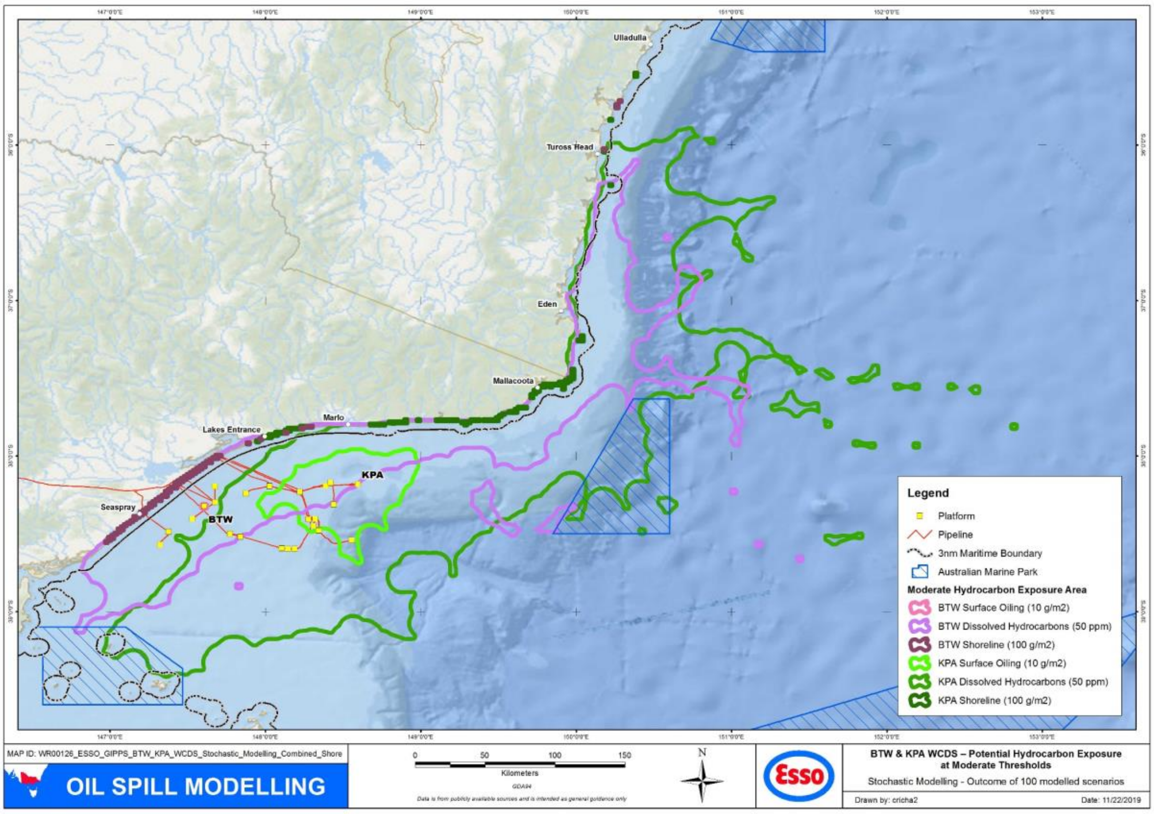
- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP**.** In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

Information specific to the Kipper (KPA) drilling campaign is provided below. For further details, refer to the JUR Drilling Environment Plan.

1. Field Location / Oil properties

Location / operational area



Production Licence No.	Kipper Subsea Facility VIC/L25	
Coordinates		Kipper
	Latitude	38°10' 53" S
	Longitude	148° 35' 35” E
	Depth	95 m

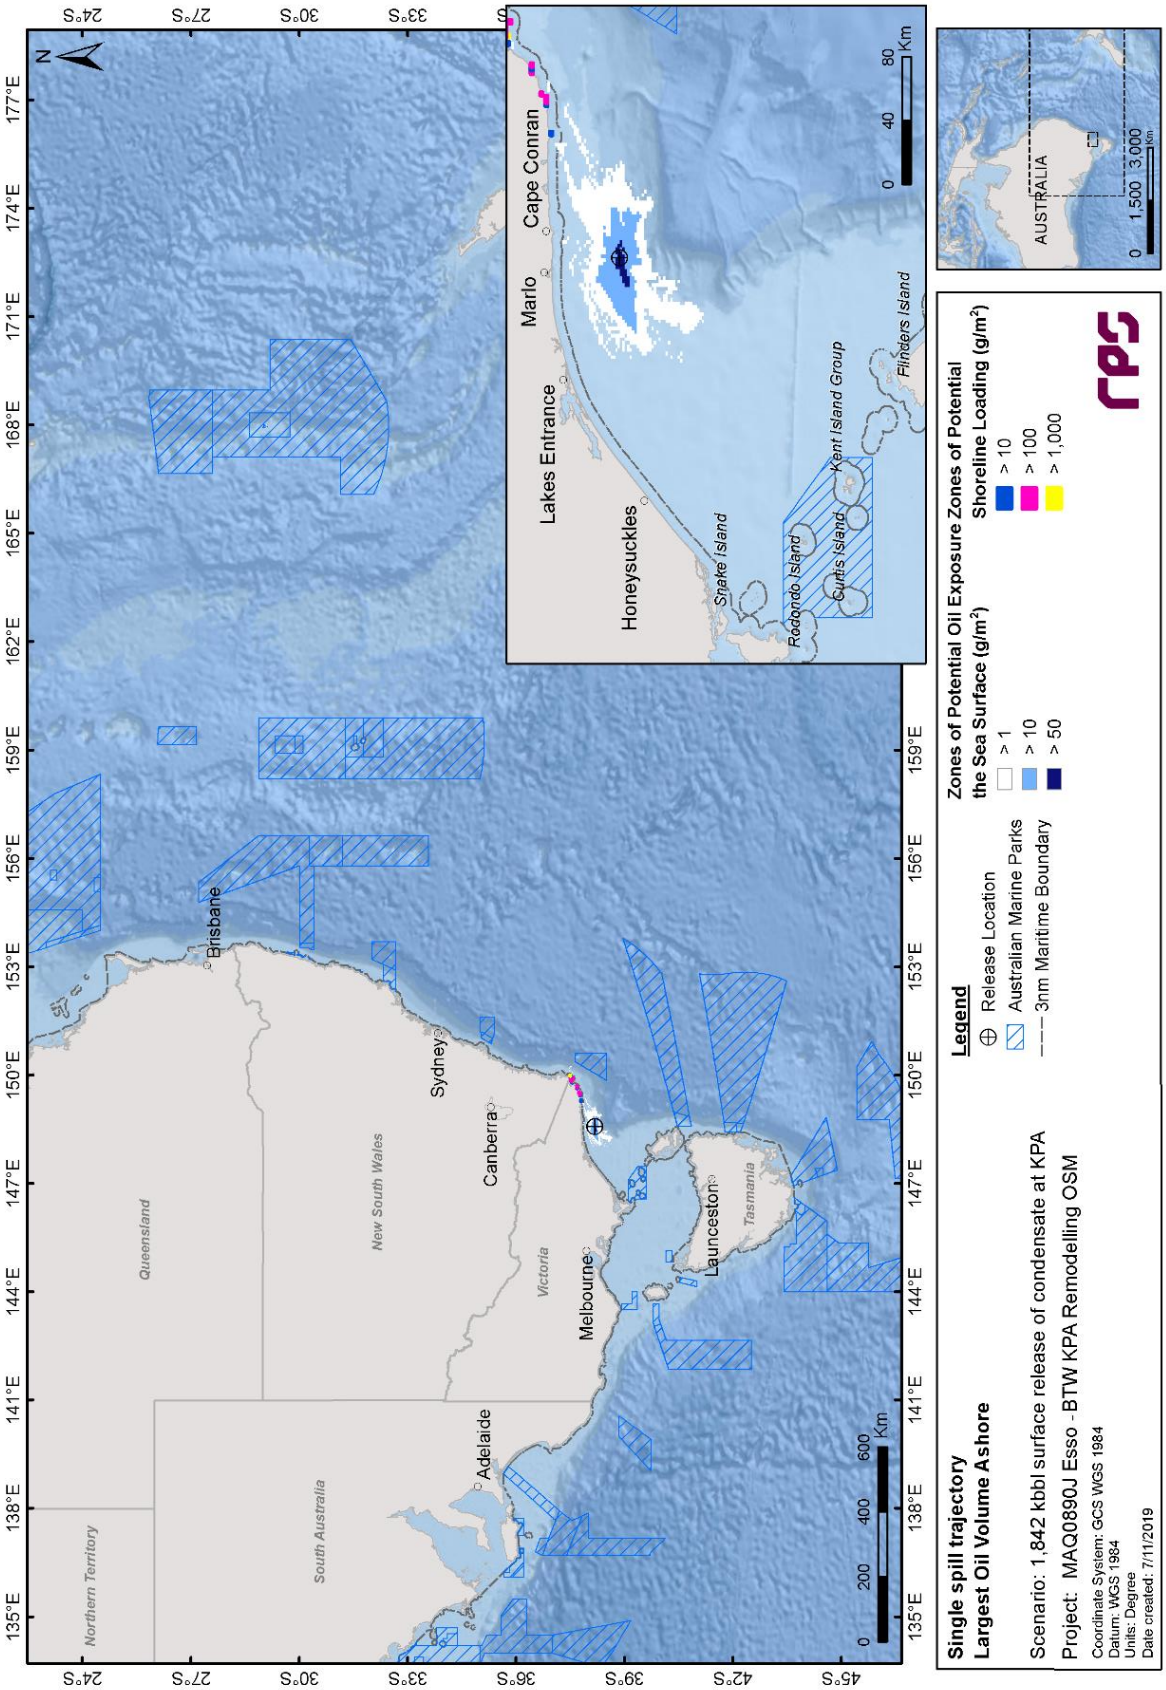
	Density @ 15˚C	760.6 kg/m^3			
	API	54.5			
	Dynamic Viscosity	0.91 @ 20ºC			
	Pour Point	-39 ºC			
	Wax Content	2.3%			
	Oil Property Category	Group I non-persistent oils			
	Boiling Point Distribution (°C)	Volatile (<180°C) 55.0 %	Semi-volatile (180-265°C) 34.8 %	Low volatility (265-380°C) 9.6 %	Residual (>380°C) 0.6 %

2. What's the worst that could happen?

	Kipper
Worst Case Discharge Scenario	Level 3 Spill A complete loss of well control (no drillpipe in hole) resulting in a release of: 1842.0 kbbl condensate until source control is effective (98 days).
Dominant Weathering process	Evaporation
Approximate weathering predicted (from deterministic modelling)	• 71% condensate evaporates • 22% decay/ biodegrade • 7% remain within the water column • <0.1% on shoreline



Zones of potential exposure on the sea surface and shoreline loading for the trajectory with the largest oil volume ashore and longest length of shoreline contact. Results are based on a 1,842,400 bbl (292,918 m^3) surface release of Kipper condensate over 98 days at the Kipper Facility, tracked for 118 days, 11 pm 11th of March 2011

3. Resources at Risk

		Kipper
Minimum time to oil exposure on the sea surface at moderate threshold	< 12 hours	nil
	12 – 48 hours	Seabird foraging BIA
	> 48 hours	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil
	12 – 48 hours	nil
	> 48 hours	Point Hicks
	> 1 week	Bega Valley Shire coast (including Bournda National Park Mimosa Rocks National Park Croajingolong National Park Gabo Island Cape Howe Lake Tyers Beach Lakes Entrance Cape Conran Coastal Park Montague Island Nature Reserve) City of Shoalhaven coast (including Conjola National Park Booderee National Park Jervis Bay National Park)

Protection priority based on sensitivity and predicted consequence (as per EP Volume 2a), protectable/actionable areas, and minimum time to exposure in this area are:

- **Gabo Island** – Giant Kelp, Little Penguin colony, Seabird rookery, Fur seal colony
- **Mallacoota** – Estuary inlet, nature based tourism, recreational activities

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on Condensate Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of condensate to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a condensate spill from the BTW and KPA wells without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Condensate from the BTW and KPA wells is highly volatile and will be removed from the sea surface by evaporation. Dispersant is ineffective on Group I oils due to the very low viscosity and high volatility. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	Not viable	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	Condensate from the BTW and KPA wells is removed rapidly from the surface through evaporation. Suitable thickness for recovery will be present for only a very short period, making containment and recovery option ineffective. In Bass Strait sea conditions likely to be suitable for containment and recovery operations only 50% of the time.	Not viable	x
In-situ Burning	In-situ burning (burning oil in place) can quickly eliminate large quantities of spilled oil.	Condensate from the BTW and KPA wells is removed rapidly from the surface through evaporation. Suitable thickness for burning will be present for a very short period, making in-situ burning option ineffective. In Bass Strait sea, conditions likely to be suitable only 50% of the time.	Not viable	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	Condensate released at the KPA location may contact the shoreline along the East Gippsland coast (most likely at Gabo Island, Cape Howe / Mallacoota) or the Southern NSW coast near Bega. Condensate spreads rapidly and corralling of surface hydrocarbons close to shore is not expected to be effective and is thus not expected to provide sufficient benefit. However, diverting oil away from inlets or creek / river mouths to protect sensitive sites may be undertaken.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	Condensate released at the KPA location may contact the shoreline along the East Gippsland coast (most likely at Gabo Island, Cape Howe / Mallacoota) or the Southern NSW coast near Bega.	Yes	✓

Response Option	Benefits	Effectiveness on Condensate Spill	Viable Response?	Net Benefit?
		There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis.		
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given rapid removal from surface through evaporation and therefore limited surface exposure, OWR is unlikely to be required. Distance of drilling locations from coastline also reduces likelihood of extensive wildlife oiling, however individuals may become oiled in the vicinity of the spill. OWR may be implemented if required, to be assessed on case-by-case basis.	**Yes**	✓

5. Response Resources Required

The below resources needs are based on worst case discharge scenario. Actual resource requirements to be determined based on incident specific assessment.

Response Option	Strategy	Resource	Timeframe
Source Control	ROV debris clearing / subsea intervention	1 x ROV and 1 x vessel SFRT (via AMOSC) and 1 x vessel 1 x contract well control specialists (WWC/OSRL)	Estimated 5 days (from call out request to arrival in Victoria) Estimated 7 days (from Perth to BBMT via road transport) 2 days (from Singapore)
	Relief well	1 x MODU (via APPEA mutual aid agreement) 1 x contract engineering support (WWC/OSRL) Well construction material	Estimated 85 days (via HLV from Singapore)
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	N/A	
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP O1.5 Satelite Imagery	1 x contract.	
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Protection of Sensitive Shoreline Resources[*1]	Personnel	66 Personnel (Peak)	Required within 7 days
	OSR Equipment	975m x Shoreboom 150m x Near shore boom 1125 x Sandbags Anchor kits + accessories	Required within 7 days

	Vehicles and Vessels	2 x Vessel (shallow draft) 1 x Vessel C&R (near shore) 8 x UTV 3 x Front End Loader / Dozer	Required within 7 days
Shoreline Clean-up*2	Personnel*	14 Foreman 116 Labourers 8 Specialised Operators	50% required within 8 days
	Vehicles and Vessels	5 x ATV 5 x Truck/Vehicle 1 x Front End Loader / Dozer 2 x Dump Truck 1 x Landing craft / barge	100% required within 8 days
	OSR Equipment	1 x Pump 99m x Inshore Boom 99m x Sorbent boom/snares 16m x Shoreline flushing pipe	100% required within 72 hours
	Manual Equipment	188 x Shovels 188 x Rakes 188 x Picks 37000 x Plastic Bags 38 x Wheel barrows	50% required within 72 hours
Oiled Wildlife Response	DEWLP will make the decision to stand up resources which are based in Victoria	To be determined by DELWP	Available <24 hours from request for services

*1 Based on simultaneous implementation of all relevant TRPs for areas indicated in minimum time before shoreline contact deterministic modelling.

*2 Based on clean up of shoreline with predicted loading of 100 g/m^2 or greater. Assumed 5% of the shoreline being cleaned up in any 1 day (and a continuous re-oiling of the shoreline). Maximum volume ashore 186m^3 (KPA).

Modelling predicts that a condensate spill may intersect the coastline after 48 hours at locations around:

- Point Hicks

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the **priority monitoring locations** listed above:

- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP**.**

In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

The table below estimates the required resources needed to implement the OSMP modules in the field in the event of an example WCDS at KPA. It is estimated that 40 field teams could be required to implement all the modules. Assuming these teams are deployed simultaneously, 120 -160 specialists and scientists could be required to staff these teams. It can be seen from Sections 2.7.3 and 2.7.5 of the OSMP that the Third Party OSMP Consultant has sufficient resources available to meet this demand. Per Section 2.7.2 of the OSMP, Survey Plans will be developed upon activation of the OSMP which will determine the monitoring requirements for the specific spill.

OSMP - Example response (number of survey units) relevant to KPA WCDS Deterministic OSTM.

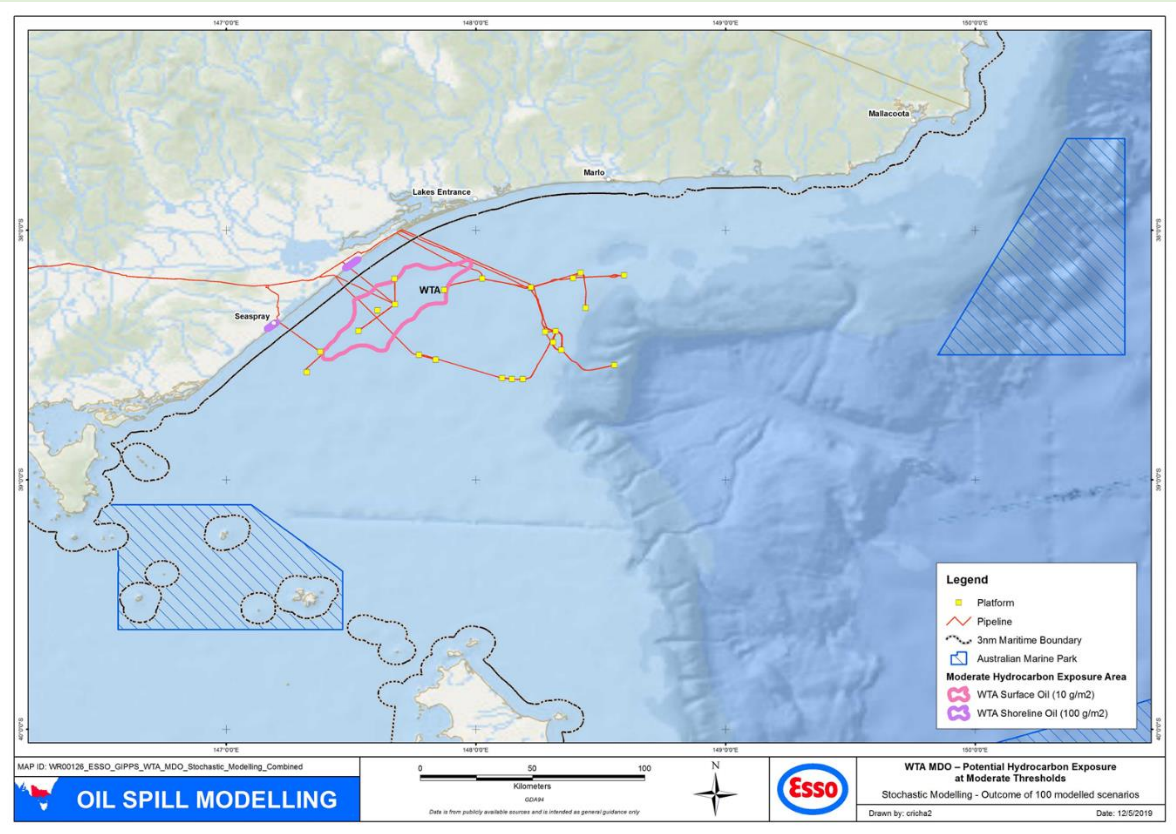
Information specific to a MDO spill from a vessel collision during the Whiting campaign is provided below. MDO spill from Barracouta platform is used for planning purposes. For further details, refer to the JUR Drilling Environment Plan.

1. Field Location / Oil properties

Location / operational area

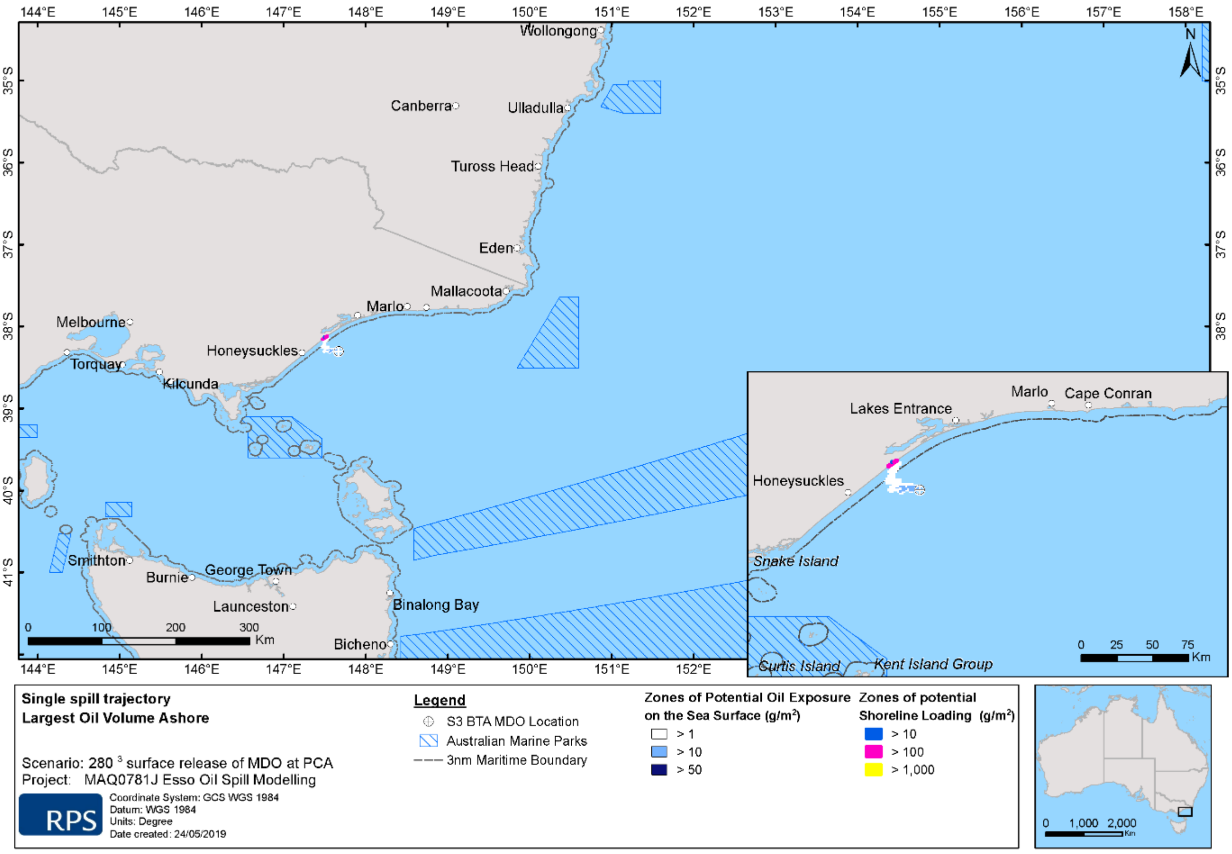


Production Licence No.	Whiting (WTA) VIC/L2	
Coordinates		Whiting
	Latitude	38° 14' 29" S
	Longitude	147° 52' 20" E
	Depth	54 m
Oil types and name		Marine Diesel Oil (MDO)
	Density @ 15˚C	829 kg/m^3
	API	37.6
	Dynamic Viscosity	4.0 cP @ 25°C
	Pour Point	-14 ºC
	Wax Content	-
	Oil Property Category	Group II light persistent oil

2. What's the worst that could happen?

Whiting	
Worst case oil pollution scenario	Level 2 Vessel collision (280 m^3 of MDO over 6 hours) at WTA location
Dominant Weathering process	Evaporation
Approximate weathering predicted (from deterministic modelling)	Based on deterministic modelling, approximately: • 70 - 90% MDO is predicted to evaporate. • 5 – 15% MDO is predicted to remain in the water column • Shoreline impacts may occur depending on proximity to shore (8% MDO predicted to arrive ashore if the spill originates at the WTA operational area (as represented by modelling from Barracouta)

Exposure – Sea Surface WTA



Zones of potential exposure on the sea surface and shoreline loading for the trajectory with the largest oil volume ashore, longest length of shoreline contacted above the 100 g/m^2 threshold and the minimum time before exposure to immediate nearshore waters by visible oil (0.5 g/m^2). Results are based on a 280 m^3 surface release of MDO over 6 hours at the Whiting (as represented by modelling from Barracouta), tracked for 30 days, 3 am 22nd of October 2011.

3. Resources at Risk

Whiting		
Minimum time to oil exposure on the sea surface at moderate threshold	< 12 hours	Great White Shark distribution and breeding BIAs Southern Right Whale migration BIA Pygmy Blue Whale distribution and foraging BIAs Seabirds foraging BIAs
	12 – 48 hours	nil
	> 48 hours	nil
Minimum time to shoreline accumulation of oil at moderate threshold	< 12 hours	nil
	12 – 48 hours	nil
	> 48 hours	Wellington Ocean Grange Seaspray

4. Strategic NEBA and selection of response options

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
Source Control	Limit flow of hydrocarbons to environment.	Only viable option to stop flow of oil to the marine environment.	Yes	✓
Surveillance and Monitoring	Although surveillance is not an active intervention to treat or remove oil pollution, it is critical to effective response both in the initial stages of an incident and during ongoing response operations.	Surveillance and monitoring used to observe the natural break-up and dissipation of a MDO spill without the need for active intervention.	Yes	✓
Dispersant Application	Dispersants act by allowing hydrocarbons to be mixed into the upper layers of the water column, which accelerates the biodegradation process. Removes oil from the water surface, protecting leeward shorelines and providing benefit to sea-surface air breathing fauna.	Dispersant application is not recommended for MDO as it spreads rapidly to a thin layer. Insufficient time to respond while suitable surface thicknesses are present. Dispersant droplets are known to penetrate through the thin oil layer and cause 'herding' of the oil. This creates areas of clear water but is not successful dispersion. Application of dispersant can contribute to water quality degradation through chemical application, without removing surface oil. Considered not to add sufficient benefit.	**Not viable**	x
Containment & Recovery (Vessel Based)	Booms and skimmers to contain surface oil where there is a potential threat to environmental sensitivities. Relies on calm sea conditions, thicknesses >10µm to collect and adequate deployment timeframes.	MDO spreads rapidly to a thickness of less than 10 µm. Containment is ineffective at these thicknesses.	**Not viable**	x
In-situ Burning	In-situ burning (burning oil in place) can quickly eliminate large quantities of spilled oil.	MDO spreads rapidly to a thickness of less than 10 µm. Containment, and therefore also in-situ burning, is ineffective at these thicknesses.	**Not viable**	x
Protection of Sensitive Shoreline Resources	Booms and skimmers deployed to protect environmental sensitivities. Environmental conditions (e.g. current, waves) limit application.	There is a low probability that MDO spilled at the WTA location may contact the shoreline along the Ninety Mile Beach. MDO spreads rapidly to a thickness of less than 10 µm. Corralling of surface hydrocarbons close to shore is not expected to be effective for MDO and is thus not expected to provide sufficient benefit. However, diverting oil away from inlets or creek / river mouths to protect sensitive sites may be undertaken.	Yes	✓
Shoreline Clean-up	Last response strategy to remove oil from the environment due to potential impact.	There is a low probability that MDO spilled at the WTA location may contact the shoreline along the Ninety Mile Beach. There are various shoreline techniques that are appropriate for this type of hydrocarbon, a shoreline clean-up may be effective for reducing shoreline loadings where access is possible, to be assessed on a case-by-case basis.	Yes	✓

Response Option	Benefits	Effectiveness on MDO Spill	Viable Response?	Net Benefit?
Oiled Wildlife Response (OWR)	Consists of capture, cleaning and rehabilitation of oiled wildlife. May include hazing or pre-emptive captive management.	Given limited size and rapid spreading of the MDO spill large scale OWR is unlikely to be required. Distance from coastline also reduces likelihood of extensive wildlife oiling, however individuals may become oiled in the vicinity of the spill. OWR may be implemented if required, to be assessed on case-by-case basis.	Yes	✓

5. Response Resources Required

Response Option	Strategy	Resource	Timeframe
Source Control	As per vessel SOPEP	-	-
Surveillance and Monitoring	OSMP O1.1 Weather and Sea State	1 x observer (to conduct 2 hour watch)	<2 hours from time of spill
	OSMP O1.2 Trajectory Estimation	1 x contracted modeller.	< 4 hours of service requested.
	OSMP Module O1.3 and O4.1 Aerial surveillance	1x observer per aircraft. Aircraft to have 100nm range and 3 hour duration.	Initial overflight <4 hours service requested. Trained observer <12 hours of spill occurring.
	OSMP Module O1.4 Tracking buoy	1x buoy available.	Deployed <12 hrs of spill occurring (dependent on weather conditions) (Level 2 & 3 spill).
	OSMP Module O2.1 and O2.3 Water and Oil Sampling	1x vessel. 1x initial sampling kit. 1x contract with laboratory.	Samples obtained <24 hrs of spill occurring. Analysis initiated <24 hours of receipt in laboratory.
Protection of Sensitive Shoreline Resources	Shoreline protection	5x booming systems (based on Lakes Entrance TRP which has the highest resource requirements).	<24 hours from request for services
		Approx. 100 personnel (based on Lakes Entrance TRP which has the highest resource requirements).	Notify State Duty Officer <2 hours of incident. Initiate request to call out core group <3 hours.
Shoreline Clean-up	Provision of personnel to support CA	15m^3 recovery per team per day based on teams of 15 people. Maximum volume ashore 25 m^3.	< 24 hours from request for services
Oiled Wildlife Response	DELWP will make the decision to stand up resources which are based in Victoria	To be determined by DELWP	Available <24 hours from request for services

Relevant Tactical Response Plan (TRP)	Merriman Creek (Seaspray)

6. Oil Spill Monitoring

Whiting		
Sensitivities – Probability of contact with dissolved hydrocarbons at moderate threshold	> 90%	nil
	50 - 90%	nil
	50 – 75%	nil
	25 – 50%	nil
	10 – 25%	nil
	< 10%	nil
Marine Parks – Probability of contact with entrained hydrocarbons	> 90%	nil
	75 - 90%	nil
	50 - 75%	Point Hicks Marine National Park
	25 - 50%	Cape Howe Marine Park
	10 – 25%	Beware Reef Marine Sanctuary
	< 10%	Beagle AMP East Gippsland AMP Batemans Marine Park Ninety Mile Beach Marine National Park Gippsland Lakes Ramsar wetland

Modelling predicts that an MDO spill may intersect the coastline after 48 hours at locations around:

- Seaspray.
- Ocean Grange,
- Wellington.

As such, and in addition to the modules that are required to monitor the spill, within 48 hours the following modules may be initiated and resources mobilised to the priority monitoring locations listed above:

- O3 Shoreline assessment
- O4 Fauna observations
- O5 Air quality sampling
- O6 Sediment sampling
- S1 Hydrocarbons in intertidal sediments and water
- S4 Short term impacts to oiled flora and fauna

These modules are to be implemented to allow any potential impacts to identified natural values that are present in the area at which intersection of the coastal zone may occur. All identified environmental receptors in the area will be subject to monitoring. Sufficient resources are available to undertake monitoring and these are detailed in the OSMP.

In accordance with the timeframes for module implementation outlined in the OSMP, all of the above modules can be implemented within 48 hours (in most cases, sooner) at the priority monitoring locations. Timing for implementation of the remaining scientific modules will be as detailed in the module.

Appendix E – Dispersant Testing Results

Table E-1: Dispersant efficacy on different Bass Strait crudes at an application rate of 20:1 (oil:dispersant)

Quick Reference: Operational Monitoring Initiation & Termination Criteria

Module	Sub-Module(s)	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Implementation Time [2]
O1: Oil spill surveillance	O1.1 Weather and sea state; O1.2 Trajectory estimation; and O1.3 Aerial or underwater observation;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred	Planning Section Chief (PSC) (or delegate)	✓ The IMT IC (or delegate) considers that continuation of monitoring under O1[1] will not result in a change to the scale or location of active response options; **or** ✓ Two consecutive aerial or underwater observations show that oil has weathered and dissipated to <0.3 g/m^2; or Bonn appearance 1; or ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O1[1] may increase overall environmental impact.	Within 4 hours of initiation criteria being met.
	O1.4 Remote observation;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms the event as a Level 2 or Level 3 hydrocarbon spill.			Within 24 hours of initiation criteria being met.
	O1.5 Satellite imagery;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms the event as a Level 3 hydrocarbon spill;			Within 24 hours of initiation criteria being met.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O1 is to commence.			Per above
O2: Water and oil sampling	O2.1 Collection of an oil sample	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred	PSC (or delegate)	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response**.**	As soon as practicable following initiation criteria being met
	O2.2 Fluorometry O2.3 Water samples;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms the event as a Level 2 or Level 3 hydrocarbon spill; **or**			Within 24 hours of initiation criteria being met.

Module	Sub-Module(s)	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Implementation Time [2]
		✓ Application of dispersant has been selected as a response option by the IMT IC (or delegate).			
	O2.4 Dispersant Monitoring	✓ Application of dispersant has been selected as a response option by the IMT IC (or delegate).			
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O2 is to commence.			Per above
O3: Shoreline assessment	O3.1 Shoreline segmentation O3.2 Shoreline character O3.3 Oil on shorelines	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Results of Module O1 monitoring predict that shorelines could be impacted.	PSC (or delegate)	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response; **or** ✓ Results of Module O1 and O3.3 monitoring demonstrate that shorelines have not been impacted and will not be impacted; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O3[1] may increase overall environmental impact.	Within 24 hours of initiation criteria being met
	O3.4 Shoreline profile	✓ Modification of the shoreline profile is identified as a recommended strategy (e.g. through mechanical construction of pits, berms, or bulk waste removal)			Within 24 hours of initiation criteria being met
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O2 is to commence.			Per above
O4: Fauna observations	O4.1 Fauna observation (at sea)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred	PSC (or delegate)	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or**	Within 4 hours of initiation criteria being met
	O4.2 Fauna observations (onshore)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms that data from Modules O1 and/or O3 predicted/confirmed shoreline exposure.			Within 24 hours of initiation criteria being met.

Module	Sub-Module(s)	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Implementation Time [2]
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O4 is to commence.		✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O4[1] may increase overall environmental impact.	Per above
O5: Air quality	O5.1 Personnel and area monitoring O5.2 Laboratory analysis	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Confirmation by the Safety Officer (SO) (or delegate) that a health and safety risk to personnel is present	SO (or delegate)	✓ The Safety Officer SO (or delegate) has determined that there is no longer a health and safety risk; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response.	Within 12 hours of initiation criteria being met.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O5 is to commence.			Per above
O6: Sediment sampling	O6.1 Sediment samples (intertidal)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms that data from Modules O1, O2 and/or O3 have predicted/confirmed exposure of intertidal benthic substrate.	PSC (or delegate)	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O6[1] may increase overall environmental impact.	Within 24 hours of initiation criteria being met
	O6.2 Sediment samples (offshore);	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure of offshore benthic substrate.			Within 24 hours of initiation criteria being met
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O6 is to commence.			Per above

Notes:

1. *Decision to terminate monitoring can be made for each individual sub-module independently.*

2. *A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.*

Quick Reference: Scientific Monitoring Initiation & Termination Criteria

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
S1: Hydrocarbons in intertidal sediments and water	S1.1 Water samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure of intertidal waters	PSC (or delegate)	✓ Ambient hydrocarbon concentrations in intertidal waters have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Ambient hydrocarbon concentrations in intertidal waters are below relevant ANZECC & ARMCANZ (2000) 99% species protection levels.	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met;	Sampling and analysis plan to be ready within 24 hours of initiation criteria being met; Mobilisation and monitoring to commence within 24 hours of activation.
	S1.2 Sediment samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure of intertidal or shoreline sediments		✓ Ambient hydrocarbon concentrations in intertidal sediments have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Ambient hydrocarbon concentrations in intertidal sediments are below relevant ANZECC & ARMCANZ SQGV (Simpson *et al*. 2013) or NAGD (CoA 2009).			
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial		✓ Agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
		implementation of S1 is to commence.					
S2: Hydrocarbons in offshore sediments and water	S2.1 Water samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure to offshore waters	PSC (or delegate)	✓ Ambient hydrocarbon concentrations in offshore waters have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Ambient hydrocarbon concentrations in offshore waters are below relevant ANZECC/ARMCANZ (2000) 99% species protection levels.	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met;	Sampling and analysis plan to be ready within 24 hours of initiation criteria being met; Mobilisation and monitoring to commence within 24 hours of activation.
	S2.2 Sediment samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O1, O2 or O6 has confirmed exposure to either benthic substrate or waters within bottom 1 m of seabed		✓ Hydrocarbon concentrations in offshore sediments have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Hydrocarbon concentrations in offshore sediments are below relevant ANZECC/ARMCANZ SQGV (Simpson *et al*. 2013) or NAGD (CoA 2009) trigger levels.			

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S2 is to commence.		✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			
S3: Fish and shellfish taint and toxicity for human consumption	S3 Fish/shellfish tissue samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O2/O6 or scientific modules S1/S2 has confirmed either: (a) in-water hydrocarbon concentrations are above guideline levels known to cause tainting (Table 4.4.5 in ANZECC & ARMCANZ 2000); or (b) sediment hydrocarbon concentrations are above SQGV levels (Simpson *et al*. 2013) ✓ Principal Investigator through the EUL (or delegate) has determined that data	PSC (or delegate)	✓ Two sequential sample sets show ambient hydrocarbon concentrations are below guideline levels for tainting in ANZECC & ARMCANZ 2000); **and either** ✓ PAH and non-hydrocarbon constituent levels in fish and shellfish tissue have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ PAH and non-hydrocarbon constituent levels in fish and shellfish tissue are at or below levels specified by Food Standards Australia New Zealand (FSANZ).	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met	Sampling and analysis plan to be ready within 7 days of initiation criteria being met; Mobilisation and monitoring to commence within 7 days of activation.

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
		from operational modules O2/O6 or scientific modules S1/S2 has confirmed either: (a) in-water non-hydrocarbon constituent concentrations are above guideline levels known to cause tainting (Table 4.4.5 in ANZECC & ARMCANZ 2000); or (b) sediment hydrocarbon concentrations are above SQGV levels (Simpson *et al*. 2013) **and** ✓ Agreement has been reached with the Jurisdictional Authority relevant to the spill to initiate the monitoring					
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S3 is to commence.		✓ **Or,** Agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			
S4: Short-term impacts to oiled fauna and flora	S4.1 Fauna surveys (vessel-based)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and**	PSC (or delegate)	✓ Disturbance parameters (e.g. mortality, percentage oiled fauna/flora) have returned to within the expected natural dynamics	Principal Investigator through the EUL, in agreement with the	Within 24 hours of initiation criteria being met	Sampling and analysis plan to be ready within 24 hours of initiation criteria being met;

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
	S4.2 Fauna surveys (land-based) S4.3 Oiled fauna hydrocarbon testing;	✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O4 has confirmed the presence of oiled fauna.		of baseline state and/or control sites; **or** ✓ Hydrocarbon concentrations from fauna samples have returned to within the expected natural dynamics of baseline state and/or control sites.	Jurisdictional Authority relevant to the spill		Mobilisation and monitoring to commence within 24 hours of activation.
	S4.4 Flora surveys	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O3 has confirmed the presence of oiled shorelines					
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S4 is to commence.		✓ Agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			
S5: Recovery of commercial and	S5 Desktop review of fishery stock;	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal	PSC (or delegate)	✓ Catch per Unit Effort (CPUE) for fishery stock assessments have returned to within the expected natural dynamics of baseline state and/or control sites; **or**	Principal Investigator through the EUL, in agreement with the	Within 24 hours of initiation criteria being met	Desktop assessment to commence within 24 hours of activation.

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
recreational fisheries		waters has occurred; and Principal Investigator through the EUL (or delegate) has confirmed that either: (a) Data from S3 confirms tainting in fish or shellfish tissue; or (b) Advice has been provided to government to restrict, ban or close a fishery; or (c) Declarations of intent by commercial fisheries or government agencies to seek compensation for alleged or possible damage.		✓ The physiological and biochemical parameters in the studied species have returned to baseline levels;	Jurisdictional Authority relevant to the spill		
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S5 is to commence.		✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
S6: Recovery of fauna	S6 Fauna surveys	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred, **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational module O4 or scientific module S4 has confirmed the exposure of fauna	PSC (or delegate)	✓ Disturbance parameters (e.g. estimated population) have returned to within the expected natural dynamics of baseline state and/or control sites	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met	Sampling and analysis plan to be ready within 7 days of initiation criteria being met; Mobilisation and monitoring to commence within 7 days of activation.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S6 is to commence.		✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			
S7: Recovery of subtidal and intertidal benthic habitat	S7.1 Habitat mapping; S7.2 Macroalgae and sponges S7.3 Benthic infauna monitoring; S7.4 Intertidal and subtidal fish monitoring	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational module O2/O6 or	PSC (or delegate)	✓ Disturbance parameters (e.g. species composition, percent cover) and health parameters (e.g. leaf condition) have returned to within the expected natural dynamics of baseline state and/or control sites	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met	Sampling and analysis plan to be ready within 7 days of initiation criteria being met; Mobilisation and monitoring to commence within 7 days of activation.

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
		scientific module S1/S2/S4 has confirmed the exposure of either benthic substrate or waters within bottom 1 m of seabed					
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S7 is to commence.		✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring			
S8: Recovery of coastal flora	S8.1 Habitat mapping; S8.2 Condition monitoring	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational module O3 or scientific module S4 has confirmed the exposure of coastal flora	PSC (or delegate)	✓ Disturbance parameters (e.g. abundance, percent cover) and health parameters (e.g. leaf condition) have returned to within the expected natural dynamics of baseline state and/or control sites.	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met	Sampling and analysis plan to be ready within 7 days of initiation criteria being met; Mobilisation and monitoring to commence within 7 days of activation.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S8 is to commence.		✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			

Module	Sub-Module	Initiation Criteria	Position responsible for Initiation	Termination Criteria	Position responsible for Termination	Activation Time[1]	Implementation Time
S9: Recovery of Ramsar values	S9 Desktop review of wetland values	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that (a) data from operational module O3 has confirmed the exposure of a Ramsar wetland; and (b) data from scientific modules S1, S4, S6, S7 or S8 confirm an impact to water/sediment quality, flora or fauna in the wetland.	PSC (or delegate)	✓ Wetland values that are important to the ECD* have returned to within the expected natural dynamics of baseline state and/or control sites. * as described in relevant Ramsar site documents prepared per the National ECD Framework	Principal Investigator through the EUL, in agreement with the Jurisdictional Authority relevant to the spill	Within 24 hours of initiation criteria being met	Desktop assessment to commence within 24 hours of activation.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S9 is to commence.		✓ **Or**, agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.			

Notes:

1. A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.

Quick Reference: Event Level and Monitoring Modules

Spill Event	O1: Oil spill surveillance					O2: Water and oil sampling				O3: Shoreline assessment				O4: Fauna observations		O5: Air quality		O6: Sediment sampling

List of Figures

1. Introduction

1.1 Purpose

This Bass Strait Oil Spill Monitoring Plan (OSMP) is a key component of the environmental management framework (which also includes activity-specific Environment Plans (EP) and the Bass Strait Oil Pollution Emergency Plan (OPEP)) for offshore petroleum activities operated by Esso Australia Resources Pty Ltd (Esso) within the Gippsland region (Figure 1-1).

This OSMP outlines environmental monitoring that may be implemented in the event of a hydrocarbon spill to the marine or coastal environment. Information from operational monitoring provides situational awareness enabling the Incident Management Team (IMT) to make informed decisions regarding response options. Oil Spill monitoring modules are the principle tools for determining the extent, severity and persistence of environmental impacts from a hydrocarbon spill and associated response and/or remediation activities.

Note, this plan focuses on Oil Spill monitoring of a hydrocarbon spill event only. Hydrocarbon spill risks, prevention and response activities are described in the activity-specific EP and OPEP.

This OSMP is supported by a set of internal implementation guides for each of the Oil Spill monitoring modules. It is important to note that the implementation guides are not a prescriptive set of procedures that must strictly be followed, but are intended to provide Esso and their monitoring providers with sufficient information to efficiently finalise a monitoring design of an appropriate nature and scale in the event of a hydrocarbon spill. It is expected that individual monitoring plans and operating procedures would only be finalised once a spill event has occurred. This is essential to ensure the finalised monitoring plan/s are fit for purpose and tailored to the specific location, hydrocarbon type, environmental sensitivities, and the nature and scale of the individual spill.

This OSMP is to be read in conjunction with the activity-specific EP and OPEP when considering the existing environment, environmental impacts, risk management, performance standards, reporting compliance, and the decision processes that will apply in the event of a spill occurring.

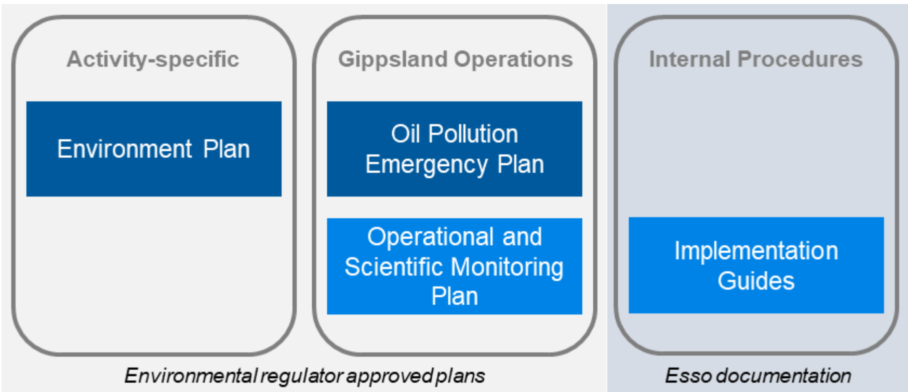

Figure 1-1: Environmental management framework for offshore petroleum activities in the Gippsland region

1.2 Objectives

The objectives of this OSMP are:

- Identify and describe the Oil Spill monitoring that may be implemented in the event of a hydrocarbon spill to the marine or coastal environment;

- Demonstrate an appropriate degree of readiness to implement this monitoring in the event of a hydrocarbon spill to the marine or coastal environment.

1.3 Scope

1.3.1. Activity types

This OSMP is relevant to all Esso petroleum activities within the Gippsland region regulated under the Commonwealth *Offshore Petroleum and Greenhouse Gas Storage Act 2006 (OPGGS) (Environment) Regulations 2009* and the Victorian *OPGGS Regulations 2011*. This includes, but is not limited to:

- Vessel operations;
- Drilling and completions;
- Well workovers and interventions;
- Subsea activities;
- Pipelay activities;
- Operations; and
- Decommissioning.

The OSMP modules provide for the rapid assessment of the extent of spread of oil from a Level 2 or Level 3 spill and effects on the environment both as a result of the spilt hydrocarbons and any oil spill response activities that may be used in the clean-up of the oil or any monitoring activities that may occur in response to the spill. The OSMP modules include provision for the rapid assessment of impacted and potentially affected wildlife including those listed as Matters of National Environmental Significance (MNES) under the EPBC Act (1999).

1.3.2. Hydrocarbon types and states

Esso's petroleum resources within the Gippsland region include both crude oil and natural gas; and petroleum activity related vessels typically use marine diesel oils. This OSMP is relevant to all hydrocarbon types and states (i.e. fresh and weathered); and all distributions throughout the environment (i.e. surface, entrained, dissolved and shoreline). Activity specific hydrocarbon properties are provided in the OPEP Appendix D Quick Reference Information.

1.3.3. Geographical extent

This OSMP is relevant and applicable to all Commonwealth and State marine and coastal areas that are potentially at risk of exposure to hydrocarbons in the event of a spill resulting from petroleum activities. Petroleum titles and selected environmental features within the vicinity of the Gippsland region is shown in Figure 1-2.

The spatial boundaries of an individual monitoring study will depend primarily on the actual or potential exposed area affected by the spill. Spatial boundaries will be sufficient to meet monitoring objectives, usually by determining impacted areas and the level of effects, linking effects to the spill source, and supporting decisions on clean-up strategies. Monitoring may also be undertaken outside the boundaries of a spill where monitoring programs require un-impacted reference sites. The spatial extent of a monitoring study would only be finalised once a spill event has occurred.

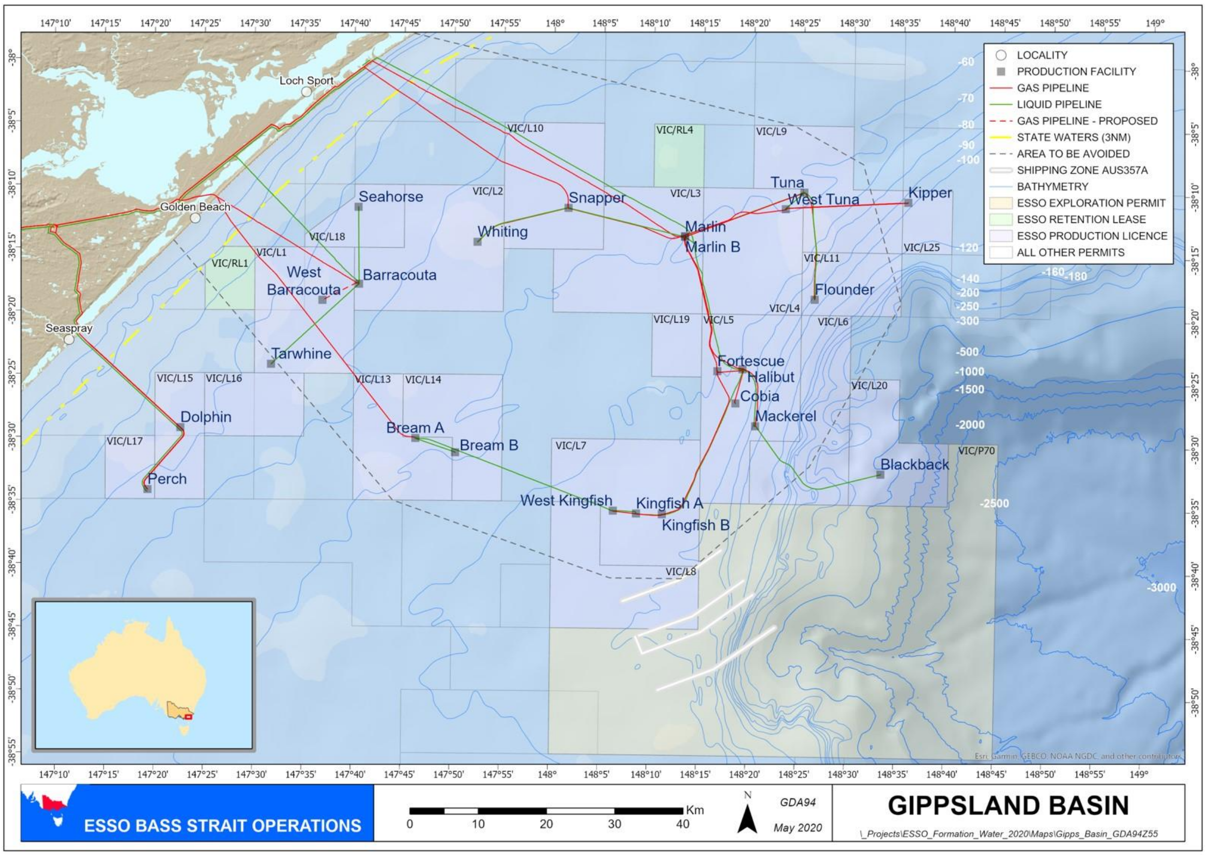

Figure 1-2: Esso assets within the Gippsland region

1.4 Regulatory requirements

Table 1-1 provides guidance on the OSMP requirements of the Commonwealth OPGGS (Environment) Regulations 2009, and Victorian OPGGS Regulations 2011, and reference to the relevant section of this document which addresses that requirement.

This OSMP incorporates regulatory guidance from the following documents:

- Guidance Note – Oil pollution risk management (NOPSEMA 2018)
- Information Paper – Oil Spill monitoring programs (NOPSEMA 2016).

Table 1-1: Relevant Commonwealth and State environmental regulations for OSMPs

Regulation	Relevant section in this OSMP
OPGGS (Environment) Regulations	
Part 2, Division 2.3, Regulation 14 (5) The implementation strategy must include measures to ensure that each employee or contractor working on, or in connection with, the activity is aware of his or her responsibilities in relation to the environment plan, including during emergencies or potential emergencies, and has the appropriate competencies and training.	Sections 2.4 and 2.5
Part 2, Division 2.3, Regulation 14 (8AA) The oil pollution emergency plan must include adequate arrangements for responding to and monitoring oil pollution, including the following: (a) the control measures necessary for timely response to an emergency that results or may result in oil pollution; (b) the arrangements and capability that will be in place, for the duration of the activity, to ensure timely implementation of the control measures, including arrangements for ongoing maintenance of response capability; (c) the arrangements and capability that will be in place for monitoring the effectiveness of the control measures and ensuring that the environmental performance standards for the control measures are met; (d) the arrangements and capability in place for monitoring oil pollution to inform response activities.	Sections 2, 3, and 4
Part 2, Division 2.3, Regulation 14 (8D) The implementation strategy must provide for monitoring of impacts to the environment from oil pollution and response activities that: (a) is appropriate to the nature and scale of the risk of environmental impacts for the activity; and (b) is sufficient to inform any remediation activities.	Sections 2, 3, and 4
Victoria OPGGS Regulations	
Part 2.2, Division 3, Regulation 16 (5) The implementation strategy must include measures to ensure that each employee or contractor working on, or in connection with, the activity is aware of his or her responsibilities in relation to the environment plan, including during emergencies or potential emergencies, and has the appropriate competencies and training	Sections 2.4 and 2.5

1.5 Target audience

In the event of a hydrocarbon spill, Esso is responsible for the implementation and adherence to this OSMP. This OSMP is intended for use by, but not limited to:

- Incident Management Team (IMT) personnel including:
  - Incident Commander (IC);
  - Operations Section Chief (OSC):
  - Planning Section Chief (PSC);
  - Environment Unit Lead (EUL)
  - Safety Officer (SO)
- Platform Emergency Response Team (ERT) personnel including:
  - Offshore Installation Manager (OIM);
  - Vessel Master (VM);
- Esso environment team;
- Monitoring provider personnel including:
  - Principal Investigator;
  - Monitoring/Field teams.

2. OSMP Framework and Implementation

2.1 Types of monitoring

Oil spill monitoring has been divided into two types (Oil Spill) which are undertaken for two distinct, but closely related, purposes (NOPSEMA 2016).

Operational monitoring collects information about the spill and associated response activities to aid planning and decision making for executing spill response or clean-up operations. Operational monitoring may include both initial response phase monitoring (i.e. rapid qualitative and observational data gathering for situational awareness) and advanced response phase monitoring (i.e. quantitative measurement) (Hook *et al*. 2016). Operational monitoring typically finishes when the spill response is terminated.

Six operational monitoring modules have been identified (see Section 3):

- O1: Oil Spill Surveillance;
- O2: Water and Oil Sampling;
- O3: Shoreline Assessment;
- O4: Fauna Observations;
- O5: Air Quality;
- O6: Sediment Sampling.

Scientific monitoring focusses on evaluating environmental impact and recovery from the spill and response activities. Scientific monitoring may be undertaken over an extended period to fully understand impacts.

Nine scientific monitoring modules have been identified (see Section 4):

- S1: Hydrocarbons in Intertidal Sediments and Water;
- S2: Hydrocarbons in Offshore Sediments and Water;
- S3: Fish and Shellfish Taint and Toxicity for Human Consumption;
- S4: Short-Term Impacts to Oiled Fauna and Flora;
- S5: Recovery of Commercial and Recreational Fisheries;
- S6: Recovery of Fauna;
- S7: Recovery of Subtidal and Intertidal Benthic Habitat;
- S8: Recovery of Coastal Flora;
- S9: Recovery of Ramsar Values.

Operational monitoring studies inform offshore and nearshore/shoreline response strategies, and information collected during these studies may trigger scientific monitoring. Oil Spill monitoring studies may occur simultaneously (i.e. scientific monitoring can start before a response operation is completed). Note, some data that may be used within scientific monitoring analyses can also only be collected during the initial phase of the oil spill response (e.g. 'reactive' baseline data) (Hook *et al*. 2016).

2.2 Initiation and termination of monitoring

Initiation and termination criteria have been defined for each individual operational monitoring (Section 3) and scientific monitoring (Section 4) module. The criteria for the initiation and termination of monitoring modules will be assessed on a daily basis during a response operation, and then as-required for any ongoing scientific monitoring modules.

Initiation for operational monitoring modules is typically dependent on presence of a spill, response options being implemented and information from surveillance activities. Termination criteria are typically based on there being no benefit to response planning or a response has ceased, no increase in environmental risk, compliance with relevant environmental guidelines or benchmarks (where available). Termination criteria for operational monitoring also require that any related scientific monitoring initiation criteria have been assessed.

Initiation for scientific monitoring modules is typically dependant on information from operational monitoring results, specifically outcomes of monitoring, evaluation and surveillance (MES) activities, and indications that relevant environmental guidelines or benchmarks have been exceeded (where available). Scientific monitoring may also be needed to determine if ecological impact criteria as defined in the OPEP for Response Level 1 are met or not (and if not an incident should be escalated to a higher level). Termination criteria are based on sufficient evidence to demonstrate no impact from hydrocarbon and/or a return to the expected natural dynamics of the area.

All monitoring modules can also be initiated by the IMT IC (or delegate) irrespective of other criteria being met. This may be an independent Esso decision, or made in conjunction with the relevant Jurisdictional Authority. Depending on the scenario, these studies may be a full or only partial implementation of the relevant operational or scientific module.

The safety of sampling personnel will be assed prior to the collection of any samples and will only occur if safe to do so. Sampling collection will only occur in daylight hours and when wind and sea states allow for the safe collection of samples. It may not be safe for a vessel to get close to a spill if there is positive gas detection. Samples will be undertaken when the presence of spilt oil is detectable.

2.3 Implementation guides

The implementation guides, which sit behind each of the modules outlined in Sections 3 and 4, are not a prescriptive set of procedures that must strictly be followed, but are intended to provide Esso and their monitoring providers with sufficient information to efficiently finalise a monitoring design of an appropriate nature and scale in the event of a hydrocarbon spill. The guides include:

- A description of minimum requirements, adopted standards and/or best practice guidance for monitoring design, sampling techniques and reporting requirements;
- A list of resources (e.g. equipment, personnel) recommended to implement the monitoring;
- Draft standard operating procedures.

It is expected that individual monitoring plans and operating procedures would only be finalised once a spill event has occurred. This is essential to ensure the finalised monitoring plan/s are fit for purpose and tailored to the specific location, hydrocarbon type, environmental sensitivities, and the nature and scale of the individual spill.

Where practicable, the draft standard operating procedures are aligned with existing standards and processes (e.g. Hook *et al*. 2016; NOAA 2006).

2.4 Roles and responsibilities

The key roles (and their associated responsibilities) for the implementation of this OSMP are shown in Table 2-1. Depending on the scale of the event, individual people may perform multiple roles; similarly, multiple people may share the same role.

Table 2-1: Key roles and responsibilities relating to implementation of the OSMP

Role	Responsibilities
IMT IC	• Day to day responsibility for facilitating/coordinating monitoring activities under this OSMP; • Initiation and termination of operational monitoring modules; • Initiation of scientific monitoring modules
PSC	• Initiating Oil Spill monitoring modules when initiation criteria met; • Coordination analysis and distribution of data obtained through operational monitoring, including integration of data into the common operating picture
EUL	• Advising IC on which Oil Spill monitoring modules should be implemented when initiation criteria met; • Activation and liaison with service providers to implement scientific modules • Facilitating/coordinating data and reports from monitoring to the IMT for use in response planning; • Initiation and termination of operational monitoring modules, based on advice from the Principal Investigator; • Initiation and termination of scientific monitoring modules, based on advice from the Principal Investigator • Report review and approval for scientific monitoring modules, prepared by the monitoring team.
OIM / VM	• Initiation of spill surveillance in the initial response phase of a spill; • May undertake day to day responsibilities (e.g. under delegation from the IMT IC).
Principal Investigator	• Responsible for implementation of a particular operational or scientific monitoring module; • Review and/or carry out study's monitoring reporting requirements; • Provides advice with respect to environmental issues as required, including initiation and termination of monitoring modules.
Field Teams	• Implement the operational or scientific monitoring module; • Data QA/QC and reporting; • Compliance with the requirements of this OSMP

2.5 Training and competency

Minimum competencies and experience for key OSMP-specific roles for the operational and scientific modules are detailed in the “Responsibilities, competencies and resources” section of each module in this OSMP. The OSMP Specific team will be scaled up according to the severity of the incident based on external capabilities.

The Esso ERT/IMT have completed oil spill response competency and training in accordance with Table 9-2 in Volume 4 of the EP. In addition to this the Environment Unit Lead is required to have a relevant tertiary degree in engineering, environment science, environmental management or similar. The selection of the Environmental Unit Lead is based on relevant experience as an Environment Advisor, with experience and/or training in the implementation of monitoring programs.

Based on the severity of an oil spill additional resources may be brought in from the ExxonMobil Regional Response Team to support the IMT.

2.6 External Resources

Resources for monitoring (e.g. personnel and equipment) may be outsourced to contractors. Esso currently has a contract in place with a local environmental consultancy to provide this environmental support. In the event that additional resources are required, other consultancy capacity will be utilised (as needed) and may extend to specialist contractors such as research agencies engaged in long-term marine monitoring programs.

Esso will also access specialist capabilities as required (e.g. OSTM via AMOSC).

Esso has identified a pool of NATA accredited laboratories with capabilities for undertaking analyses required as part of Oil Spill monitoring scopes (Table 2-6).

2.7 Third Party OSMP Consultant

2.7.1. Roles and responsibilities

The Third Party OSMP Consultant has an organisation that allows for considerable support to the field, laboratory and office teams involved in the implementation of the OSMP and its modules. Details of the support roles that may be required for the implementation of the OSMP are provided in Table 2-2.

Table 2-2: Summary of support roles (as required)

Role	Responsibilities
Third Party OSMP Consultant Project Director (PD)	Point of contact at a project level for high level contractual and commercial issues Final approver of key deliverables produced by Third Party OSMP Consultant During OSMP implementation high level of liaison with IMT
Third Party OSMP Consultant Project Manager (PM)	Overall project program, progress, budgets, & reporting Management of Third Party OSMP Consultant project team Responsible for Third Party OSMP Consultant Sub-consultancy, subcontractor and Service Provision agreements Client liaison/coordination at IMT level During OSMP implementation: • Command and control of OSMP activities undertaken by Third Party OSMP Consultant • Liaison with IMT • Overarching implementing and monitoring the OSMP activities undertaken by Third Party OSMP Consultant Reports to Third Party OSMP Consultant Project Director
Third Party OSMP Consultant Operations Officer	Overall coordination and management of OSMP modules undertaken by Third Party OSMP Consultant Review and sign off of OSMP deliverables produced from modules undertaken by Third Party OSMP Consultant Ensuring technical compliance and maintaining quality of OSMP deliverables During OSMP implementation for modules implemented by Third Party OSMP Consultant: • Organise initial response mobilisation • Coordinate OSMP operations • Organise mobilisation/escalation/de-escalation/demobilisation activities • Assist Planning and Logistical Officers in development of field activity synergies among operational and scientific monitoring modules Reports to Third Party OSMP Consultant Project Manager
Task Leader (Third Party OSMP Consultant)	Ensuring technical compliance and maintaining quality of allocated operational or scientific monitoring module deliverables from modules implemented by Third Party OSMP Consultant

Role	Responsibilities
	Review of allocated operational or scientific monitoring module deliverables During OSMP implementation assist in coordination and management of allocated operational or scientific monitoring module Reports to Third Party OSMP Consultant Operations Officer
Field Supervisor (Third Party OSMP Consultant)	During OSMP implementation for modules implemented by Third Party OSMP Consultant responsible for SSHE requirements and meeting survey technical objectives during field monitoring Reports to Third Party OSMP Consultant Operations Officer
SSHE Advisor (Third Party OSMP Consultant)	Third Party OSMP Consultant SSHE Advisory role and monitors compliance Review/Approval of SSHE documentation (SSHE Plan, JSA) SSHE Incident Investigations and Reporting Reports to Third Party OSMP Consultant Project Manager Supports SSHE & SP performance reviews Prepare SSHE Alerts and deliver SSHE trainings, briefings
SSHE Focal Point (Third Party OSMP Consultant)	SSHE liaison with Esso SSHE Performance reports Supports project adherence to SSHE Plan Reports to Third Party OSMP Consultant Project Manager
Project Controls Officer (Third Party OSMP Consultant)	PRISM Set Up & Maintenance EVM & Reporting Scheduling Change management, document control, invoicing Reports to Third Party OSMP Consultant Project Manager
Environment & Approvals Officer	Environmental Approvals Licences, Permits, Statutory Approvals Reports to Project Manager
Quality Assurance Officer	Internal QA audits Reports to Project Manager
Third Party OSMP Consultant Logistics Officer	Reports to Project Manager During OSMP implementation: • Organise plant (e.g. aircraft, vessels) • Estimate future service and support requirements • Provision of logistics advice to Operations and Planning Officers
Third Party OSMP Consultant Planning Officer	Reports to Project Manager During OSMP implementation: • Collect, analyse and utilise OSMP information • Risk analysis of technical OSMP service provision (e.g. weather, spill behaviour, projections) • Maintain record of communications and actions including resources requested/allocated/in use.
Third Party OSMP Consultant Safety Officer	Reports to Project Manager During OSMP implementation: • Provide SSHE services in support of the OSMP activities • Review and approve all SSHE documentation in the provision of OSMP services • Risk analysis of SSHE OSMP service provision (e.g. cyclones, interface issues) and that services undertaken in a safe matter
Third Party OSMP Consultant Admin Officer	Reports to Project Manager During OSMP implementation: • Same as role of Project Controls Officer during OSMP implementation

Role	Responsibilities
Principal Investigator	Reports to Project Manager • Responsible for implementation of a particular operational or scientific monitoring module; • Review and/or carry out study's monitoring reporting requirements; • Provides advice with respect to environmental issues as required, including initiation and termination of monitoring modules.
Field Teams	Reports to Principal Investigator • Implement the operational or scientific monitoring module; • Data QA/QC and reporting; • Compliance with the requirements of this OSMP

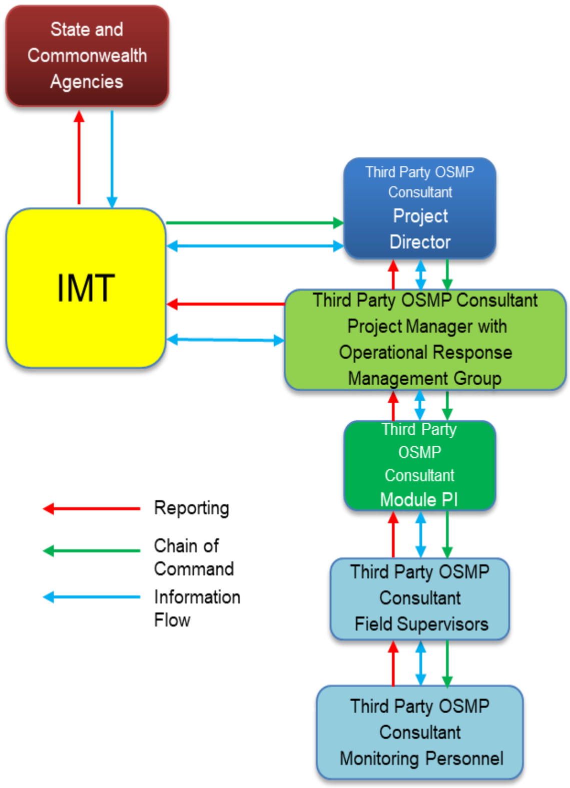

Figure 2-1: OSMP modules implementation organogram between Esso and the Third Party OSMP Consultant

2.7.2. OSMP resourcing

In the activation of the OSMP substantial resources are likely to be required for an extended period of time. Although it is more likely that discontinuous deployment periods are likely this has not been assumed in developing this resourcing strategy (i.e. continuous requirement assumed). The resourcing needs are based on the likely requirements for information.

The operational modules together with S1, S2 and S4 will commence at notification of a spill. Scientific modules have slightly differing needs as their aim is to assess the potential impacts and recovery from a spill. However there may be a need to collect reactive baseline data prior to hydrocarbons contacting the environment and potentially causing impacts to that environment. There are a number of scientific modules that are therefore initiated soon, if not immediately, after notification of a spill in order to collect a reliable reactive baseline as existing baseline data may not be available.

Generally, the following resourcing procedure will be adhered to:

- The Third Party OSMP Consultant Planning Officer and Third Party OSMP Consultant Operations Officer will develop Survey Plan(s) to meet the objectives of OM(s) survey(s) that are provided by the IMT IC. Surveys may entail carrying out acquiring information for multiple OMs with individual ground, vessel and aerial survey teams on the same plant to optimise synergies and efficiencies.
- Field personnel and office-based personnel will be sourced from the organisations that comprise the OSMP team (Table 2-3). The Mobilisation Plan will identify a pool of field staff from which to select for mobilisation to meet initial requirements. Thereafter, during escalation and/or maintenance of the OM modules staff across the pool of field personnel pool will be selected on the basis of availability and capabilities to meet the survey(s) objectives.
- The Task Leaders in consultation with the Third Party OSMP Consultant Logistics Officer will be responsible for organising equipment and laboratory supplies (if needed) for their respective modules. The Operational Response Management Group (ORMG) will support Task Leaders to facilitate the transport of equipment and laboratory supplies
- Office-based personnel will be mobilised on an 'as needed' basis for data analysis and reporting for all OM modules to ensure timely information flow to the IMT for response planning and assessment.

Details for key OSMP resources are summarised in Table 2-3.

Table 2-3: OSMP resources list

Resource/Provider	Personnel/Equipment/Service
Third Party OSMP Consultant	25x field and 20x office personnel in Victoria (marine scientists, wildlife observers) 4 - 10 4WD vehicles available Laboratory for basic WQ analysis and biological analysis Aircraft management Marine monitoring equipment
Subconsultant 1	4 field personnel 3 office personnel Vessel-based wildlife observers Vessel management Water/sediment/plankton sampling and equipment Equipment
Subconsultant 2	4 field personnel 3 office personnel Vessel-based wildlife observers Vessel management Water/sediment/plankton sampling and equipment Equipment
Subconsultant 3	2 field personnel 3 office personnel Vessel-based wildlife observers Vessel management Water/sediment/plankton sampling and equipment Equipment

Resource/Provider	Personnel/Equipment/Service
Vessels	Offshore vessel Inshore vessel Inshore vessel
Air	Fixed wing aircraft

2.7.3. Field staff resources available

The Third Party OSMP Consultant has sufficient resources in terms of personnel to meet the staffing needs of the monitoring program in both the immediate and longer term. The Third Party OSMP Consultant has prepared logistics plans for each worst case discharge scenario that map the number of personnel required for each module at different intervals after the spill event to ensure that resource needs can be fulfilled within the required timeframes.

The Third Party OSMP Consultant has available the resources of its Victorian Environment Team which are highly experienced in the collection of water and sediment quality samples, and also in flora and fauna survey and marine environmental survey. In all the Third Party OSMP Consultant has, in Victoria, 45 people with extensive experience in water quality and sediment sampling and an addition 26 who are flora and fauna specialists. After one day these can be supplemented by additional staff from outside Victoria which will allow access to over 150 staff with water and sediment quality experience and over 100 staff with flora and fauna expertise. Supplementing the local experience there are the resources of three subconsultants (Table 2-3).

In summary the Third Party OSMP Consultant team has the resources available to choose from to deploy:

First Response (immediate):

- 29 water and sediment quality specialists
- 26 flora and fauna specialists
- 16 marine scientists

After 24 hours:

- 150 water and sediment quality specialists
- 100 flora and fauna specialists
- 42 marine scientists

An annual test of the capability of the Third Party OSMP Consultant to provide these resources is conducted. The Third Party OSMP Consultant maintains a register of the available resources, updated quarterly, including:

- Role in OSMP implementation
- Provider (company name)
- Provider contact details
- Contractual arrangement status
- Resource (name(s)) identified
- Minimum qualification and experience requirements
- Whether qualification and experience requirements are met
- Completion of OSMP familiarisation training

2.7.4. Awareness of role in OSMP implementation

The approach to the OSMP implementation summarised in Table 2-4 shows the activities for the Third Party OSMP Consultant that includes phases prior to and after OSMP activation. The outputs of the Readiness Phase includes the awareness of staff and resources through OSMP familiarisation training.

Table 2-4 OSMP implementation phases

Phase	Period	Activity	Purpose	Output
Readiness	Prior to spill	Personnel, contractors and equipment providers prepare for and continue to be prepared for activation of OSMP. Register of OSMP implementation personnel is maintained and updated quarterly	'Readiness' for timely response to implement OSMP.	Register of OSMP implementation personnel Awareness by all participants that they are to be available and ready for OSMP implementation OSMP familiarisation
Mobilising	Notification of a Level 2 or 3 spill	Third Party OSMP Consultant Project Manager and Initial Field Team mobilise onsite) Water and sediment sampling teams report to surveillance vessel(s) for deployment to site. Mobilise monitoring teams based on initiation criteria: Mobilise, personnel equipment and vessels to port Load equipment/ supplies on vessel and depart port	Initiate modules as quickly as possible and within timeframes required by OSMP.	Timely mobilisation of monitoring program.
Monitoring during Spill response	During a spill, before shoreline contact.	Implement relevant OM modules	Inform response planning and manage early stages of spill.	Operational data reported regularly throughout response
		Implement relevant SM modules Collect reactive baseline data. Collate and assess existing baseline data.	Establish baselines and analyse behaviour of spill hydrocarbons	Baseline data reports for each monitoring study.
	During a spill after shore line contact.	Continue to implement modules.	Inform response planning and management	Operational data reported regularly throughout response
Spill Response Termination	At end of spill response	Terminate modules when criteria met	Discontinue modules linked specifically to spill response phase.	Consolidated data on spill response to IMT IC. Consolidated data to inform later Scientific studies.

Monitoring Post-spill response	From termination of spill response until termination criteria met	Update SAPs for long-term monitoring.	Modify frequency /number of long-term monitoring sites. (Not if termination criteria met during spill response phase).	Approval of long-term monitoring SAPs

2.7.5. Staff availability for deployment in initial response

The following table lists staff that are available for deployment to respond to the requirements of the OSMP after the initial confirmation of a Tier 2 or Tier 3 spill. Many staff are capable of performing tasks in a number of modules and as such have been shown in these modules.

TL – Task Leader, FS – Field Staff,

Team Member	Personnel Contract Classification	Yrs Exp	O1- Oil Spill Surveillance	O2- Water and Oil Sampling	O3- - Shoreline Assessment	O4- Fauna Observations	O5- Air Quality	O6 Sediment sampling	S1- Hydrocarbons in intertidal sediments and water	S2- Hydrocarbons in offshore sediments and water	S3- Fish and shellfish taint and toxicity for human consumption	S4- Short term impacts to oiled flora and fauna	S5- Recovery of commercial/recreational fisheries	S6- Recovery of fauna	S7- Recovery of subtidal and intertidal benthic habitat	S8- Recovery of Coastal Flora	S9- Recovery of Ramsar values

2.7.6. Non-personnel resources

A summary of the likely key non-personnel resource requirements for each module is shown below in Table 2-5. Further information on the resources identified in this table is provided below and detailed equipment lists are provided in the supporting implementation guide for each module. Number of resources required will depend on the number of field teams for each module as well as efficiencies where one field team may collect data/samples for multiple modules.

Table 2-5: Non-personnel resource requirements

Equipment	O1	O2	O3	O4	O5	O6	S1	S2	S3	S4	S5	S6	S7	S8	S9
Fixed wing aircraft	✓		✓	✓											
Helicopter	✓		✓	✓											
Vehicles		✓	✓	✓	✓	✓	✓			✓		✓	✓	✓	
Vessels	✓	✓	✓	✓		✓		✓	✓	✓		✓	✓		
UAV	✓			✓						✓					
Sampling equipment		✓	✓			✓	✓	✓	✓	✓					
ROV	✓					✓	✓	✓		✓			✓		
Fluorometer		✓													
NATA accredited lab		✓	✓		✓	✓	✓	✓	✓	✓					
Oil Spill Trajectory Modelling services	✓														
Satellite imagery services	✓														

Aircraft

There may be a requirement for aircraft to support spill surveillance, shoreline assessment and fauna observations. There is access to helicopters through the Esso owned and operated helicopter fleet based out of Longford. An agreement is in place with a third party supplier to provide a fixed wing aircraft.

Vehicles

The Third Party OSMP Consultant has sufficient resources to meet the vehicle needs of the monitoring program in both the immediate and longer term. The Third Party OSMP Consultant has 4WD vehicles at its offices in Melbourne and these can be supplemented with 4WD drive vehicles from each of the subconsultants. The Third Party OSMP Consultant has Australia-wide contracts with rental car providers so that within 24 hours these vehicles can be supplemented with as many 4WD as needed for the duration of the monitoring programs. In addition to these vehicles which are set up for field work Third Party OSMP Consultant also has agreements with its staff to use their own personal vehicles should the need arise.

In summary the Third Party OSMP Consultant has available:

First Response (immediate):

- 4 - 10 4WD vehicles suitable for field work

After 24 hours

- As many 4WD vehicles as would be needed

Vessels

There is requirement for both large and small vessels to allow the monitoring to be completed as per the program.

Four inshore vessels from the Third Party OSMP Consultant which can operate in daylight hours only are immediately available.

The Third Party OSMP Consultant has an in principal agreement that the following vessels capable of operating offshore 24 hours per day can be used.

- *RV Orca II*
  - A trailerable 8 metre aluminium Oceaneer powered by twin 150 hp Yamaha four stroke engines. It is in Class 2C commercial survey, licensed to carry 12 passengers and 2 crew. We have two in-house coxswains with endorsements for operating in Port Phillip Heads. RV Orca II has a dry cabin for electronics and instrumentation as well as a large deck space for diving and instrument deployments.
- *Bass Rover*
  - 17 m long
  - Aluminium offshore twin screw patrol vessel
  - Speed of 22 knots
  - Max fuel consumption 120 litres per hour
  - Deck load carrying capacity of 5 tonnes
- *Silver Star*
  - Alloy aluminium catamaran
  - 20 tonne extendable A frame
  - 8 tonne Hiab crane
  - Max speed of 12 knots
  - Clear deck area of 15 m x 10 m
  - Length of 33.4 m
  - Beam of 11 m
  - Draught of 1.8 m
- *Calypso Star*
  - Twin hull, alloy aluminium catamaran
  - Two upper decks, a bulbous bow, transom stern and transverse and longitudinal framing
  - 3 tonne crane
  - Max speed of 12 knots
  - Clear deck area of 100 m^2
  - Length of 23.8 m
  - Beam of 11 m
  - Draught of 2.2 m
- *Turning Point MSV 11642*

  - Westcoaster 68’, 20’ beam. Powered by two 480HP diesel motors
  - Cruise speed 13 –14 knots, top speed 17 knots
  - 8 m x 5 m flush work deck to accommodate cargo bins plus 132 m of covered deck
  - Cargo to 8 tonnes
  - Water desalinator, sullage tanks and generous below-deck storage
  - Line hauler and 1.9 tonne crane with winch and 70 m spectra-rope available
  - Towing bollards to 5 tonne
  - Large transom doors opening onto dive platform
  - Vessel surveyed for: 2C - 22 passengers to 30 mile off shore and 2B – 12 overnight passengers to 100
- *Seapride MB883*
  - Steber 47’, 16’ beam
  - Powered by two 450HP diesel motors
  - Cruise speed 16 knots, top speed 20 knots
  - Large, stable work deck – 6 m x 3.8 m
  - 6.5 kva gen set
  - 2.2 tonne Hiab seacrane with 14’ reach. 400 kg lift capstan side hauler
  - 400 kg pull drum reel over transom or from vessel’s side
  - Cargo to 3 tonnes
  - Vessel fitted with radar, differential GPS giving accuracy to 2-3 metres
  - Large DGPS plotter incorporating details of Ninety Mile Beach reef system
  - Vessel surveyed for: 2C - 10 passengers to 30 mile off shore and 2B – five overnight passengers to 100 miles offshore intrastate

In addition to the vessels available through the Third Party OSMP Consultant identified above, the Esso support vessel used for ongoing operations may be used for surveillance and monitoring in the event of a spill. Esso also has an agreement in place with a third party supplier for the provision of additional vessels for surveillance and monitoring.

Sampling Equipment

The Third Party OSMP Consultant has its own wet laboratory in Victoria and has available the required sampling equipment for water quality and sediment quality. The Third Party OSMP Consultant also has a suite of ROVs, an automated underwater vehicle (AUV) and drones (with CASA certified operators) for rapid survey of intertidal reefs. The Third Party OSMP Consultant has fully certified divers with all required equipment including a suite of underwater cameras as well as side scan sonar units for mapping undersea habitats. All these resources are available for immediate deployment pending other commitments.

A flow-through fluorometer is not immediately available and this would be sourced by the Third Party OSMP Consultant as soon as possible following notification of the spill.

<u>Initial response sampling kits</u>

Given the short implementation time for sub-module O2.1, Esso has identified the following locations as stocking initial response spill sampling kits:

- Longford Plants Laboratory

- Long Island Point Laboratory
- Esso's contracted supply vessel
- Longford Heliport
- Sale Office (stored for deployment on inspection vessel when being used)
- Pipelines Warehouse - Sale
- Westbury Pumping Station

The initial response kits contain the equipment to obtain and store an oil sample from the water surface or from land.

Personnel should familiarise themselves with the sampling procedure (see Implementation Guide for O2: Water and Oil Sampling); but otherwise no specific training or qualifications are required to use the initial response kits to collect an oil sample.

Laboratory Access

Esso has identified the following NATA accredited laboratories within the region to support the various operational and scientific monitoring modules. Laboratories with the appropriate capabilities to support specific modules have been identified within the relevant modules.

Table 2-6: NATA accredited laboratories

Laboratory	Contact Details
Australian Laboratory Services (Melbourne)	4 Westall Road, Springvale VIC 3171 Ph: 03 8549 9600
Australian Laboratory Services (Traralgon)	Hazelwood Road, Traralgon VIC 3844 Ph: 03 5176 4170
Ecotox Services Australia	27/2 Chaplin Drive, Lane Cove NSW 2066 Ph: 02 9420 9481
Eurofins MGT	25 Kingston Town Close, Oakleigh VIC 3166 Ph: 03 8564 5000
Intertek Geotechnical	41-45 Furnace Road, Welshpool WA 6106 Ph: 08 9458 8877
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167
Longford Plants Laboratory	Garretts Road, Longford VIC 3851 Ph: 03 5149 6259
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Ph: 03 9644 4888

Modelling and Imagery Services

Esso (via ExxonMobil) is a member of the AMOSC. AMOSC membership allows access to RPS to provide predictive modelling capabilities in the event of an oil spill. Alternatively, modelling may also be requested from:

- Oil Spill Response Limited (OSRL);
- Exxon Mobil's in-house service (EMBSI).
- Australian Maritime Safety Authority (AMSA), noting that requests for modelling under the National Plan can only be made by Commonwealth or State/Territory spill response control agencies, or by AMOSC

Esso Australia has tracking buoys available, and additional buoys are available for hire from AMOSC. Esso also has agreements in place to allow access to satellite imagery services for remote observation of the spill.

2.8 Communication Management

Stakeholder (including regulators) consultation and external reporting requirements are described in the activity-specific EPs. This includes the requirement to consult with the:

- Department of Transport (DoT) in the event that a hydrocarbon spill is likely to impact Victorian waters;
- Department of Agriculture, Water and Environment (DAWE) in the event that a hydrocarbon spill is likely to impact matters of national environmental significance;
- Parks Australia, Director of National Parks, in the event that a hydrocarbon spill and/or response activity are likely to impact an Australian Marine Park.

If the spill may impact Tasmanian waters then consultation will occur with:

- The Environment Protection Authority Division of the Department of Primary Industries, Parks, Water, and Environment.

If the spill may impact New South Wales waters then consultation will occur with:

- NSW Environment Protection Authority;
- Transport for NSW

2.9 Review and Revision

Regulation 19 of the OPGGS (E) Regulations provides for the revision of this OSMP. Review and update of the OSMP may be initiated through findings from drills/exercises, actual events, internal or external assessments, audits, changes to regulation, or via planned periodic review. As per the EP&R Guide, this document is subject to:

- an annual review
- a mid-cycle (i.e. 2.5 – 3 years) comprehensive update
- 5 yearly revision and resubmission (in accordance with resubmission of Environment Plans)

Any changes made during review and revision must be tracked and documented in order to demonstrate continued compliance with regulatory accepted versions of this document. Changes made to the OSMP should be reviewed against *OPGGS (Environment) Regulations 2009* (Reg 7, Reg 8, Reg 17) to determine if a resubmission is required.

The annual review should be a general review of the OSMP to ensure it remains applicable to current operations. The annual review of the OSMP will include the annual test of the Third Party OSMP Consultants' capability to provide resources to fulfil the requirements of this OSMP (Section 2.7).

Table 2-7 describes the topics that should be considered when completing a mid-cycle update of the OSMP.

Table 2-7: Scope of revision of OSMP

3. Operational Monitoring

The following sections outline the individual operational monitoring modules that may be implemented in the event of a hydrocarbon spill to the marine or coastal environment. The tables describe the key aims, initiation and termination criteria, implementation times, and provide a high-level description of monitoring, reporting and resources. The studies are presented separately below; however, in practice they may be undertaken simultaneously.

These overviews are supported by internal implementation guides for each of the operational monitoring modules. The implementation guides have been prepared to provide Esso and their monitoring providers' sufficient information to efficiently finalise a monitoring design of an appropriate nature and scale in the event of a hydrocarbon spill.

Six operational monitoring modules have been identified:

- O1: Oil Spill Surveillance;
- O2: Water and Oil Sampling;
- O3: Shoreline Assessment;
- O4: Fauna Observations;
- O5: Air Quality;
- O6: Sediment Sampling.

3.1 O1: Oil Spill Surveillance

3.1.1. Purpose

The development and implementation of effective responses to oil spills depends critically on the knowledge of the extent and likely fate and behaviour of oil once exposed to ambient weather and sea state conditions. The purpose of this module is to:

- Track the location, extent and thickness of the surface oil slick to gain situational awareness of the incident and validate and inform forecasting and Oil Spill Trajectory Modelling (OSTM);
- Collect and collate relevant weather and sea state conditions to inform OSTM and response actions;
- Predict sensitivities at risk and fate/behaviour of the spill to inform response actions and scientific monitoring;
- Provide location of slick to O2 (water and oil sampling) monitoring team;
- Provide feedback on the extent, location, appearance and thickness of a dispersed slick (applicable only if dispersants used).

3.1.2. Initiation and termination criteria

Initiation Criteria	O1.1 Weather and sea state; O1.2 Trajectory estimation; and O1.3 Aerial or underwater observation;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred
	O1.4 Remote observation;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms the event as a Level 2 or Level 3 hydrocarbon spill.

	O1.5 Satellite imagery;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms the event as a Level 3 hydrocarbon spill;
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O1 is to commence.
Termination Criteria	✓ The IMT IC (or delegate) considers that continuation of monitoring under O1[1] will not result in a change to the scale or location of active response options; **or** ✓ Two consecutive aerial or underwater observations show that oil has weathered and dissipated to <0.3 g/m^2; or Bonn appearance code 1; or ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O1[1] may increase overall environmental impact.	

Notes:

1. Decision to terminate monitoring can be made for each individual sub-module independently.

3.1.3. Implementation

implementation time[1]	✓ O1.1, O1.2 and O1.3 within 4 hours of initiation criteria being met; ✓ O1.4 and O1.5 within 24 hours of initiation criteria being met.
Implementation Plan	✓ Refer to *Implementation Guide for O1: Oil Spill Surveillance*
Reporting	✓ Results from data collation, visual/remote surveillance, modelling and/or image analysis reported daily to PSC; ✓ Final report prepared within one-week of termination criteria being met; report provided to PSC.

Notes:

1. A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.

3.1.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during operational module O1. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- Aerial Observation of Marine Oil Spills (ITOPF 2014);
- SMART Protocols (NOAA 2006).

Sub-module	Sampling technique	Data collection and/or analysis
O1.1 Weather and sea state	• Data records collation; • Visual surveillance	• Data records sourced from Bureau of Meteorology (BoM) or local weather stations; • Sea state observations manually recorded from vessels, offshore platform or shore.
O1.2 Trajectory estimation	• Manual estimation; • OSTM.	• Manual estimation can be completed quickly and with limited data (wind and currents, spill origin and/or present location) • OSTM is generally completed by specialist consultants.
O1.3	• Visual surveillance; • Remote sensing.	• Visual observations of the location, extent, and appearance of the spill.

Sub-module	Sampling technique	Data collection and/or analysis
Aerial or underwater observation		• Estimates of volume based on percentage cover and oil thickness.
O1.4 Remote observation	• Satellite tracking	• Buoys are deployed and position can be tracked via satellite.
O1.5 Satellite imagery	• Satellite imagery analysis	• Remote sensing and image analysis to determine presence of oil slicks.

3.1.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation and termination of this operational monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for the initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the EP.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement operational module O1. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for O1 in the event of a spill; • Implement O1; • Review and/or carry out reporting requirements; • Compliance with the requirements of O1 and the OSMP; • Provide advice with respect to environmental issues as required.	• Level 1 - Familiarisation with relevant requirements of the OSMP and OPEP. • Level 2/3 – Relevant experience in coordination of operational monitoring
Field Teams (2 to 3 people)	• Conduct visual observations; • Completing field data sheets; • QA/QC data quality.	• Lead observer to be experienced in surveillance techniques; • All team members to be familiar with the relevant spill observation, estimation and recording techniques.

Resources

The key resources required for implementation of Module O1 include a fixed wing aircraft and/or helicopter for aerial surveillance. UAVs may be utilised to support aerial surveillance. Vessels may also be required for on-water surveillance of the spill and observations of weather and sea state. Use of a ROV may be required for subsea activities such as detection or tracking of the spill. Access to Oil Spill Trajectory Modelling services and satellite imagery services may be required for spill modelling and remote surveillance. Further information on access to these resources is provided in Section 2.7.6.

3.2 O2: Water and Oil Sampling

3.2.1. Purpose

The purpose of this module is to provide quantitative measures of water quality and oil (hydrocarbon) characteristics to:

- Determine the physical and chemical characteristics of the spilled oil to validate trajectory forecasts or models (i.e. provide information regarding the spill source characterisation);
- Obtain samples of spilled oil for retention or additional analysis (e.g. fingerprinting);
- Establish background concentrations of total petroleum hydrocarbon (TPH) and polyaromatic hydrocarbons (PAH), and non-hydrocarbon constituents in sea water;
- Determine concentrations of TPH and PAH within the spill plume to validate and enhance OSTM and support assessment of environmental and social impacts;
- Determine the concentrations of non-hydrocarbon constituents (e.g. heavy metals) within the spill plume;
- Determine the effectiveness of dispersants in reducing concentrations of oil in the water column (applicable only if dispersants used);
- To inform scientific monitoring.

3.2.2. Initiation and termination criteria

Initiation Criteria	O2.1 Collection of an oil sample	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred
	O2.2 Fluorometry O2.3 Water samples;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms the event as a Level 2 or Level 3 hydrocarbon spill; **or** ✓ Application of dispersant has been selected as a response option by the IMT IC (or delegate).
	O2.4 Dispersant Monitoring	✓ Application of dispersant has been selected as a response option by the IMT IC (or delegate).
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O2 is to commence.
Termination Criteria	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response **and** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O2[1] may increase overall environmental impact.	

Notes:

1. Decision to terminate monitoring can be made for each individual sub-module independently.

3.2.3. Implementation

Minimum time to implement[1]	✓ O2.1: as soon as practicable following initiation criteria being met; ✓ O2.2, O2.3, O2.4: within 24 hours of initiation criteria being met.
Implementation Plan	✓ Refer to *Implementation Guide for O2: Water and Oil Sampling*
Reporting	✓ Results from in-situ analysis of samples reported daily to PSC; ✓ Results from laboratory analysis of samples reported as available to PSC; ✓ Final report prepared within one-week of termination criteria being met; report provided to PSC.

Notes:

1. A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.

3.2.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during operational module O2. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- SMART Protocols (NOAA 2006);
- ASTM D4489 2017 Standard Practices for Sampling of Waterborne Oils.

Sub-module	Sampling technique	Data collection and/or analysis
O2.1 Collection of an oil sample	• Surface oil sample collection[1]	• Physical characteristics (e.g. wax content, dynamic viscosity, density, volatiles); • Chemical characteristics (e.g. PAH)
O2.2 Fluorometry	• Water column profiling	• TPH
O2.3 Water samples	• Surface and sub-surface water sample collection	• Laboratory analysis for hydrocarbons (e.g. TPH, PAH); • Laboratory analysis for non-hydrocarbon parameters (e.g. heavy metals); • Dispersant (e.g. DOSS).
O2.4 Dispersant Monitoring	• Surface and sub-surface water sample collection	• Laboratory analysis for hydrocarbons (e.g. TPH, PAH); • Laboratory analysis for non-hydrocarbon parameters (e.g. heavy metals); • Dispersant (e.g. DOSS).

Notes:

1. The location of Initial response sampling kits has been identified to facilitate the sampling required under O2.1.

3.2.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation and termination of this operational monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement operational module O2. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for O2 in the event of a spill; • Implement O2; • Review and/or carry out reporting requirements; • Compliance with the requirements of O2 and the OSMP; • Provide advice with respect to environmental issues as required.	• Level 1 - Familiarisation with relevant requirements of the OSMP and OPEP. • A least 10 years' experience in the collection and analysis of water quality samples. • Level 2/3 – Relevant experience or training in coordination of operational monitoring
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Familiarisation with oil and water sampling and recording techniques.

Resources

The key resources required for implementation of Module O2 include vessels for on-water sampling and monitoring as well as vehicles for coastal water sampling. A flow-through fluorometer may be required for monitoring oil in water concentrations. Sampling equipment will be required for sampling of the oil slick itself and sampling of water from both inside and outside the spill area. Further information on access to these resources is provided in Section 2.7.6.

Esso has also identified the following NATA accredited laboratories within the region with the capabilities to support the analysis for operational module O2:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	Main Melbourne Laboratory 4 Westall Road, Springvale VIC 3171 Phone: 03 8549 9600
Australian Laboratory Services (Traralgon)	Hazelwood Road, Traralgon VIC 3844 Phone: 03 5176 4170
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Phone: 03 9644 4888
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167

3.3 O3: Shoreline Assessment

3.3.1. Purpose

This module outlines a Shoreline Clean-up Assessment Technique (SCAT) to be used to directly inform shoreline clean-up, provide recommendations to operations, and ensure the clean-up is completed. The purpose of this module is to:

- Determine the physical, biological and dynamic properties of shorelines at risk, in order to:
  - Predict the oil behaviour and distribution;
  - Determine the most appropriate clean-up methods;
  - Identify sensitive or vulnerable areas or resources;
  - Determine whether any pre-impact actions are warranted;
- Determine the characteristics and distribution of oil on the shoreline in order to predict the potential for oil persistence and / or natural removal;
- Determine the effectiveness of shoreline response strategies and provide feedback to the IMT.

3.3.2. Initiation and termination criteria

Initiation Criteria	O3.1 Shoreline segmentation O3.2 Shoreline character O3.3 Oil on shorelines	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred
	O3.4 Shoreline profile	✓ Modification of the shoreline profile is identified as a recommended strategy (e.g. through mechanical construction of pits, berms, or bulk waste removal)
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O3 is to commence.
Termination Criteria	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response **and** ✓ Results of Module O1 monitoring demonstrate that shorelines will not be impacted; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O3[1] may increase overall environmental impact.	

Notes:

1. *Decision to terminate monitoring can be made for each individual sub-module independently.*

3.3.3. Implementation

Implementation Time [1]	✓ O3.1, O3.2, O3.3, O3.4: within 24 hours of initiation criteria being met.
Implementation Plan	✓ Refer to *Implementation Guide for O3: Shoreline Assessment*
Reporting	✓ Results from data collation, visual surveillance, in-situ monitoring reported daily to PSC; ✓ Final report prepared within one-week of termination criteria being met; report provided to PSC.

Notes:

1. *A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.*

3.3.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during operational module O3. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- SMART Protocols (NOAA 2006);
- Shoreline Assessment Job Aid (NOAA 2007)
- Shoreline Clean up Assessment Technique (SCAT) Oil Spill Response Limited (updated)
- The Open Water Oil Identification Job Aid for Aerial Observation (NOAA 2016)

Sub-module	Sampling technique	Data collection and/or analysis
O3.1 Shoreline character	• Visual surveillance	• Physical and biological characteristics (e.g. shoreline dimensions, habitat type, substrate type, wind/wave energy etc.).
O3.2 Oil on shorelines	• Visual surveillance; • Surface and sub-surface water sample collection	• Visual assessment of oil extent, percent cover, thickness etc.; • In-situ or laboratory analysis for hydrocarbon content (e.g. TPH). • Assessment of endpoints from clean-up, identification of suggested clean-up techniques

3.3.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation and termination of this operational monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement operational module O3. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for O3 in the event of a spill; • Implement O3; • Review and/or carry out reporting requirements; • Compliance with the requirements of O3 and the OSMP; • Provide advice with respect to environmental issues as required.	• Familiarisation with relevant requirements of the OSMP and OPEP. • A least 10 years' experience in shoreline survey including the analysis of data. • Relevant experience or training in coordination of operational monitoring
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories; • Completing field data sheets; • QA/QC data quality.	• Familiarisation with relevant observation and recording techniques • Zoologist for fauna observations.

Resources

Depending on the size and location of the spill, fixed wing aircraft or helicopters may be required for aerial surveys to help cover a broader area and to quickly assess remote or difficult to access locations. Similarly, vessels may be required for shoreline assessment to conduct vessel-based surveys or allow access to the shoreline. Vehicles will be required to support ground surveys. Sampling equipment is required for taking water and sediment samples to support visual observations of oil on shorelines.

Esso has also identified the following NATA accredited laboratories within the region with the capabilities to support the analysis for operational module O3:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	Main Melbourne Laboratory 4 Westall Road, Springvale VIC 3171 Phone: 03 8549 9600
Australian Laboratory Services (Traralgon)	Hazelwood Road, Traralgon VIC 3844 Phone: 03 5176 4170
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Phone: 03 9644 4888
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167

3.4 O4: Fauna Observations

3.4.1. Purpose

This module is designed to inform responses to spills where there is the potential for exposure to fauna either onshore (e.g. seals or birds on the shoreline) or offshore (e.g. whales or birds either in/on the water). The purpose of this module is to:

- Identify the presence of onshore and offshore fauna, including marine mammals and seabirds, in the response area (i.e. near the oil slick, response vessels or aircraft) in order to implement mitigation strategies, such as reduce vessel speeds, halt operations, move vessels or aircraft from the area, increase flight altitude or consider “hazing” strategies.
- Locate potentially oiled fauna for recovery (i.e. by government agencies (Department of Environment, Land, Water and Planning (DELWP) and Parks Victoria or as directed).

3.4.2. Initiation and termination criteria

Initiation Criteria	O4.1 Fauna observation (at sea)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred
	O4.2 Fauna observations (onshore)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms that data from Modules O1 and/or O3 predicted/confirmed shoreline exposure.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O4 is to commence.
Termination Criteria	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response **or** ✓ Results of Module O1 monitoring demonstrate that shorelines will not be impacted; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O4[1] may increase overall environmental impact.	

Notes:

1. Decision to terminate monitoring can be made for each individual sub-module independently.

3.4.3. Implementation

Implementation time [1]	✓ O4.1: within 4 hours of initiation criteria being met; ✓ O4.2: within 24 hours of initiation criteria being met.
Implementation Plan	✓ Refer to *Implementation Guide for O4: Fauna Observations*
Reporting	✓ Results from visual surveillance reported daily to PSC; ✓ Final report prepared within one-week of termination criteria being met; report provided to PSC.

Notes:

1. *A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.*

3.4.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during operational module O4. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- Australian National Guidelines for Whale and Dolphin (DoEE 2017).

Sub-module	Sampling technique	Data collection and/or analysis
O4.1 Fauna observations (at sea)	• Visual surveillance	• Regular observations of the location, species, activity, evidence of oiling etc.
O4.2 Fauna observations (onshore)	• Visual surveillance	• Regular observations of the location, species, activity, evidence of oiling etc.

3.4.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation and termination of this operational monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for the initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement operational module O4. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for O4 in the event of a spill; • Implement O4; • Review and/or carry out reporting requirements; • Compliance with the requirements of O4 and the OSMP; • Provide advice with respect to environmental issues as required.	• Level 1 - Familiarisation with relevant requirements of the OSMP and OPEP. • At least 10 years' experience in the collection and analysis of fauna data. • Level 2/3 - Doctorate in environmental science

Personnel	Responsibilities	Competencies
Field Teams (1 to 2 people)	• Conduct sampling and record data; • Completing field data sheets; • QA/QC data quality.	• Familiarisation with the fauna identification and recording techniques.

Resources

Fixed wing aircraft and/or helicopters may be required for aerial surveillance of fauna with fixed wing aircraft typically utilised for extensive offshore areas and helicopters used for slow speed near shore surveys. This would likely be an extension of surveillance and observation undertaken as part of Module O1. Vessels may also be used to support at sea fauna observations. Vehicles will be required to support onshore fauna observations. UAVs could be used for rapid data collection about faunal colonies via video or photographs.

3.5 O5: Air Quality

3.5.1. Purpose

In the event of a hydrocarbon spill, people will need to be deployed on site for monitoring and/or response and clean-up operations. Monitoring of air quality is necessary to ensure the protection and safety of human health. The purpose of this module is to:

- Establish a safe perimeter prior to any response operations being conducted where personnel may be exposed to hazards of airborne gases and vapours
- Identify any hazards from airborne gases and vapours;
- Determine the need for respiratory protection for environmental monitoring and clean-up workers; and
- Comply with occupational health regulatory requirements.

3.5.2. Initiation and termination criteria

Initiation Criteria	O5.1 Personnel and area monitoring O5.2 Laboratory analysis	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Confirmation by the Safety Officer (SO) (or delegate) a health and safety risk to personnel is present
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or ✓ Partial implementation of O5 is to commence.
Termination Criteria	✓ The SO (or delegate) has determined that there is no longer a health and safety risk; **or** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response.	

Notes:
1. *Decision to terminate monitoring can be made for each individual sub-module independently.*

3.5.3. Implementation

Implementation time [1]	✓ O5.1 and O5.2: within 12 hours of initiation criteria being met.
Implementation Plan	✓ Refer to *Implementation Guide for O5: Air Quality*
Reporting	✓ Results from personnel monitoring reported daily to SO; ✓ Results from laboratory sampling reported as available to SO; ✓ Final report prepared within one-week of termination criteria being met; report provided to SO.

Notes:
1. *A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.*

3.5.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during operational module O4. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Occupational Health Monitoring Plan (Centre for Toxicology and Environmental Health 2011);
- Oil Spill Response Field Manual (ExxonMobil 2008).

Sub-module	Sampling technique	Data collection and/or analysis
O5.1 Personnel and area monitoring	• Direct-read personal or area gas monitoring	• In-situ data collected and compared against known guideline levels.
O5.2 Laboratory analysis	• Laboratory analysis of vapour monitors	• Laboratory analysis for hydrocarbons (e.g. BTEX, TPH).

3.5.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation and termination of this operational monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for the initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement operational module O5. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for O5 in the event of a spill; • Implement O5; • Review and/or carry out reporting requirements; • Compliance with the requirements of O5 and the OSMP; • Provide advice with respect to environmental issues as required.	• Level 1 – Experience in implementation of safety or industrial hygiene programs in the oil & gas industry • A least 10 years' experience in the collection and analysis of air quality measurements and data. • Level 2/3 - Qualifications in Occupational Health & Safety, or Industrial Hygiene from a recognised institution or equivalent tertiary study in technical area; • Familiarisation with relevant requirements of the OSMP and OPEP.
Monitoring personnel	• To conduct air quality monitoring to determine safe exposure levels in operating environment	• Trained in use of personnel air monitoring equipment

Resources

It is expected that vehicles will be required to support onshore air quality monitoring through both personnel and area monitoring. Laboratory analysis of vapour monitors comprises part of this module. Esso has also identified the following NATA accredited laboratories within the region with the capabilities to support the analysis for operational module O5:

NATA accredited laboratory	Details
Australian Laboratory Services (Traralgon)	Hazelwood Road, Traralgon VIC 3844 Phone: 03 5176 4170
Longford Plants Laboratory	Garretts Road, Longford VIC 3851 Phone: 03 5149 6259

3.6 O6: Sediment Sampling

3.6.1. Purpose

The purpose of this module is to provide quantitative measures of sediment quality to:

- Establish background concentrations of TPH and PAH, and non-hydrocarbon constituents in sediment;
- Determine concentrations of TPH, PAH and non-hydrocarbon constituents (e.g. heavy metals) within exposed sediments to inform response strategies;
- Determine the effectiveness of clean-up operations;
- To inform scientific monitoring.

3.6.2. Initiation and termination criteria

Initiation Criteria	O6.1 Sediment samples (intertidal)	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms that data from Modules O1, O2 and/or O3 have predicted/confirmed exposure of intertidal benthic substrate.
	O6.2 Sediment samples (offshore);	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ IMT IC (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure of offshore benthic substrate.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of O6 is to commence.
Termination Criteria	✓ The IMT IC (or delegate) has determined that continuation of monitoring under the module is not necessary to meet the objectives of the response **and** ✓ The IMT IC (or delegate) has advised that agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the response; **or** ✓ The Principal Investigator through the EUL (or delegate) has advised that continuation of monitoring under O6[1] may increase overall environmental impact.	

Notes:

1. *Decision to terminate monitoring can be made for each individual sub-module independently.*

3.6.3. Implementation

Implementation time [1]	✓ O6.1 and O6.2: within 24 hours of initiation criteria being met.
Implementation Plan	✓ Refer to *Implementation Guide for O6: Sediment Sampling*
Reporting	✓ Results from in-situ sampling reported daily to EUL; ✓ Results from laboratory sampling reported as available to EUL; ✓ Final report prepared within one-week of termination criteria being met; report provided to EUL.

Notes:

1. *A module is considered implemented when Esso have (i) confirmed initiation criteria have been met, (ii) the monitoring providers have been notified, (iii) sampling and analysis plans (where required) have been completed, and (iv) mobilisation has commenced.*

3.6.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during operational module O6. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al.* 2016).

Sub-module	Sampling technique	Data collection and/or analysis
O6.1 Sediment samples (intertidal)	• Surface and sub-surface sediment sample collection	• Laboratory analysis for hydrocarbons (e.g. TPH, TRH, PAH, BTEX); • Laboratory analysis for non-hydrocarbon parameters (e.g. TOC, PSD, heavy metals, nutrients).
O6.2 Sediment samples (offshore)	• Surface sediment sample collection	• Laboratory analysis for hydrocarbons (e.g. TPH, TRH, PAH, BTEX); • Laboratory analysis for non-hydrocarbon parameters (e.g. TOC, PSD, heavy metals, nutrients).

3.6.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation and termination of this operational monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for the initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement operational module O6. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for O6 in the event of a spill; • Implement O6; • Review and/or carry out reporting requirements; • Compliance with the requirements of O6 and the OSMP; • Provide advice with respect to environmental issues as required.	• Level 1 - Familiarisation with relevant requirements of the OSMP and OPEP. • A least 10 years' experience in the collection and analysis of sediment quality samples. • Level 2/3 - Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area;
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Familiarisation with sediment sampling and recording techniques.

Resources

Sediment sampling will be conducted on both intertidal and offshore sediments with vehicles required to support the intertidal sediment sampling and vessels required to support the offshore sediment sampling. Sediment sampling equipment such as corers and grab samplers will be required to collect sediment samples. Offshore sediment sampling may utilise ROVs. A NATA accredited laboratory will be required to analyse sediment samples. Esso has identified the following NATA accredited laboratories within the region with the capabilities to support the analysis for operational module O6:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	Main Melbourne Laboratory 4 Westall Road, Springvale VIC 3171 Phone: 03 8549 9600
Australian Laboratory Services (Traralgon)	Hazelwood Road, Traralgon VIC 3844 Phone: 03 5176 4170
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Phone: 03 9644 4888
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167

4. Scientific Monitoring

The following sections outline the individual scientific monitoring modules that may be implemented in the event of a hydrocarbon spill to the marine or coastal environment. The sections describe the purpose, initiation and termination criteria, implementation timing, and provide a high-level description of monitoring, reporting and resources required. The modules are presented separately below; however, in practice they may be undertaken simultaneously.

These overviews are supported by internal implementation guides for each of the scientific monitoring modules. The implementation guides have been prepared to provide Esso and their monitoring providers sufficient information to efficiently finalise a monitoring design of an appropriate nature and scale in the event of a hydrocarbon spill.

Scientific monitoring generally has objectives relating to attributing cause-effect interactions of the spill with changes to the surrounding environment. Consequently, such studies are required to account for natural or sampling variation, and study designs must be robust and produce defensible data. Scientific monitoring is typically conducted over a wider study area taking into account the potentially exposed area, extending beyond the spill footprint, and a longer time period, extending beyond the spill response.

Nine scientific monitoring modules have been identified:

- S1: Hydrocarbons in Intertidal Sediments and Water;
- S2: Hydrocarbons in Offshore Sediments and Water;
- S3: Fish and Shellfish Taint and Toxicity for Human Consumption;
- S4: Short-Term Impacts to Oiled Fauna and Flora;
- S5: Recovery of Commercial and Recreational Fisheries;
- S6: Recovery of Fauna;
- S7: Recovery of Subtidal and Intertidal Benthic Habitat;
- S8: Recovery of Coastal Flora;
- S9: Recovery of Ramsar Values.

Guidance on various experimental monitoring approaches for scientific monitoring (e.g. use of baseline data in 'before versus after' analyses, and alternative approaches such as 'control versus impact' and 'gradient approach') is provided in Appendix A. Appendix B describes an approach to utilising baseline data where and when available; and a list of known regional studies and/or data sources. Specific guidance and sampling approaches are described within the implementation guides for each scientific monitoring module.

Guidance documents which provide information such as key locations, receptors and values will be used to inform monitoring design. The management plans for both Commonwealth and State Protected Areas that may be impacted by a spill do not provide guidance as to the levels of acceptable change nor do they state acceptable levels of contaminants including hydrocarbons, however aspects such as key values will be taken into account. Esso will also take into account information from other documents that provide guidance for protected areas such as Corner Inlet and the Gippsland Lakes and in addition will undertake consultation with relevant asset managers of protected areas as well as asset managers responsible for natural assets that are not protected such as commercial and recreational fishery managers. There are also other sources of guidance for the levels of acceptable change such as the Victorian State Environment Protection Policies (Waters) which gives guidance as to levels of change that are considered acceptable for various bodies of water within the state jurisdiction. In addition the conservation advices / recovery plans for Matters of National Environmental Significance (MNES) listed under the EPBC Act also provide guidance on levels of acceptable change and the actions that may be required to ensure protection / recovery of listed species and communities including aspects such as spatial and temporal distribution.

Initiation and/or termination criteria for some of the scientific monitoring modules require the use of 'accepted guidelines and/or benchmark values'. Where available, Australian guidelines (e.g. ANZECC

& ARMCANZ 2000) or regionally relevant data is used. Where these are unavailable or inappropriate for a selected parameter, toxicity screening benchmarks developed by the USEPA in response to the Deepwater Horizon incident (e.g. USEPA 2015), or other international guidelines (e.g. USEPA 2017) may be adopted. Specific guidance on benchmark values are described within the overviews below, and in the implementation guides, for each individual scientific monitoring module.

4.1 S1: Hydrocarbons in Intertidal Sediments and Water

4.1.1. Purpose

The purpose of this module is to provide quantitative measures of intertidal sediment and water quality. Scientific module S1 will assess and monitor concentrations of hydrocarbons and metals in intertidal sediments and water by:

- Establishing the baseline concentrations of hydrocarbons and metals in water and sediment at identified pre-impact (if practicable) or control (i.e. un-impacted) intertidal sites;
- Monitoring concentrations of hydrocarbons, metals and nutrients (if bioremediation techniques used as part of response operations) in intertidal water and sediments at identified control and impact sites.

4.1.2. Initiation and termination criteria

Initiation Criteria	S1.1 Water samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure of intertidal waters
	S1.2 Sediment samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure of intertidal or shoreline sediments
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S1 is to commence.
Termination Criteria	S1.1 Water samples	✓ Ambient hydrocarbon concentrations in intertidal waters have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Ambient hydrocarbon concentrations in intertidal waters are below relevant ANZECC & ARMCANZ (2000) 99% species protection levels; **or** ✓ There has been no demonstrable impact on intertidal water quality from hydrocarbons.
	S1.2 Sediment samples	✓ Ambient hydrocarbon concentrations in intertidal sediments have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Ambient hydrocarbon concentrations in intertidal sediments are below relevant ANZECC & ARMCANZ SQGV (Simpson *et al*. 2013) or NAGD (CoA 2009) trigger levels
	All sub-modules	✓ **Or** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.1.3. Implementation

Activation Time[1]	✓ S1 to be activated within 24 hours of initiation criteria being met;
Implementation Time	✓ Sampling and analysis plan to be ready within 24 hours of initiation criteria being met; ✓ Mobilisation and monitoring to commence within 24 hours of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S1: Hydrocarbons in intertidal sediments and water*
Reporting	✓ Summary report to be provided to Esso Environment Unit Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.1.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S1. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC & ARMCANZ 2000)
- Revision of the ANZECC/ARMCANZ Sediment Quality Guidelines (Simpson *et al*. 2013);
- National Assessment Guidelines for Dredging (CoA 2009).

Sub-module	Sampling technique	Data collection and/or analysis
S1.1 Water samples	• Surface and sub-surface water sample collection[1]	• Laboratory analysis for hydrocarbons (e.g. TPH, TRH, PAH, BTEX); • Laboratory analysis for non-hydrocarbon parameters (e.g. metals, nutrients).
S1.2 Sediment samples	• Surface and sub-surface sediment sample collection[2]	• Laboratory analysis for hydrocarbons (e.g. TPH, TRH, PAH, BTEX); • Laboratory analysis for non-hydrocarbon parameters (e.g. TOC, PSD, metals, nutrients).

Notes:

1. *Sampling techniques as per operational module O2.3.*
2. *Sampling techniques as per operational module O6.1.*

4.1.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S1. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S1 in the event of a spill; • Implement S1; • Review and/or carry out reporting requirements; • Compliance with the requirements of S1 and the OSMP; • Provide advice with respect to environmental issues as required.	• Doctorate in environmental science, • At least 10 years' experience in the collection of environmental samples from water and sediments; • Familiarisation with relevant requirements of the OSMP and OPEP.
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories; • Completing field data sheets; • QA/QC data quality.	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area; • Experienced in sediment and water quality sampling and recording techniques.

Resources

Vehicles will be required to support sampling of intertidal sediments and water. Sampling equipment for both sediment and water sampling will be required. Some resources for Module S1 can likely be shared with Modules O6 and S2. A NATA accredited laboratory will be required for analysis of the intertidal sediment and water samples. Esso has identified NATA accredited laboratories with the capabilities to support the analysis for scientific module S1, including but not limited to:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	4 Westall Road, Springvale VIC 3171 Ph: 03 8549 9600
Eurofins MGT	25 Kingston Town Close, Oakleigh VIC 3166 Ph: 03 8564 5000
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Ph: 03 9644 4888
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167

4.2 S2: Hydrocarbons in Offshore Sediments and Water

4.2.1. Purpose

The purpose of this module is to provide quantitative measures of offshore sediment and water quality. Scientific module S2 will assess and monitor concentrations of hydrocarbons and metals in offshore sediments and water by:

- Establishing the baseline concentrations of hydrocarbons and metals in water and sediment at identified pre-impact (if practicable) or control (i.e. un-impacted) offshore sites;
- Monitoring concentrations of hydrocarbons, metals and nutrients (if bioremediation techniques used as part of response operations) in offshore sediments and water at identified control and impact sites.

4.2.2. Initiation and termination criteria

Initiation Criteria	S2.1 Water samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) confirms that data from Modules O1 and/or O2 have predicted/confirmed exposure to offshore waters
	S2.2 Sediment samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O1, O2 or O6 has confirmed exposure to either benthic substrate or waters within bottom 1 m of seabed
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S2 is to commence.
Termination Criteria	S2.1 Water samples	✓ Ambient hydrocarbon concentrations in offshore waters have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Ambient hydrocarbon concentrations in offshore waters are below relevant ANZECC/ARMCANZ (2000) 99% species protection levels.
	S2.2 Sediment samples	✓ Hydrocarbon concentrations in offshore sediments have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ Hydrocarbon concentrations in offshore sediments are below relevant ANZECC/ARMCANZ SQGV (Simpson *et al*. 2013) or NAGD (CoA 2009) trigger levels.
	All sub-modules	✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.2.3. Implementation

Activation Time[1]	✓ S2 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Sampling and analysis plan to be ready within 24 hours of initiation criteria being met; ✓ Mobilisation and monitoring to commence within 24 hours of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S2: Hydrocarbons in offshore sediments and water*
Reporting	✓ Summary report to be provided to Esso Environment Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.2.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S2. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC & ARMCANZ 2000)
- Revision of the ANZECC/ARMCANZ Sediment Quality Guidelines (Simpson *et al*. 2013);
- National Assessment Guidelines for Dredging (CoA 2009).

Sub-module	Sampling technique	Data collection and/or analysis
S2.1 Water samples	• Surface and sub-surface water sample collection[1]	• Laboratory analysis for hydrocarbons (e.g. TPH, TRH, PAH, BTEX); • Laboratory analysis for non-hydrocarbon parameters (e.g. metals, nutrients)
S2.2 Sediment samples	• Surface sediment sample collection[2]	• Laboratory analysis for hydrocarbons (e.g. TPH, TRH, PAH, BTEX); • Laboratory analysis for non-hydrocarbon parameters (e.g. TOC, PSD, metals, nutrients).

Notes:

1. *Sampling techniques as per operational module O2.3.*
2. *Sampling techniques as per operational module O6.2.*

4.2.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S2. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S2 in the event of a spill • Implement S2 • Review and/or carry out reporting requirements • Compliance with the requirements of S2 and the OSMP • Provide advice with respect to environmental issues as required	• Doctorate in environmental science, • At least 10 years' experience in the collection of environmental samples from water and sediments; • Familiarisation with relevant requirements of the OSMP and OPEP
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area • Experienced in the relevant sampling and/or recording techniques.

Resources

Vessels and ROVs will be required to support sampling of offshore sediments and water. Sampling equipment for both sediment and water sampling will be required. Some resources for Module S2 can likely be shared with Modules O6 and S1. A NATA accredited laboratory will be required for analysis of the offshore sediment and water samples. Esso has identified NATA accredited laboratories with the capabilities to support the analysis for scientific module S2, including but not limited to:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	4 Westall Road, Springvale VIC 3171 Phone: 03 8549 9600

NATA accredited laboratory	Details
Eurofins MGT	25 Kingston Town Close, Oakleigh VIC 3166 Phone: 03 8564 5000
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Phone: 03 9644 4888
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167

4.3 S3: Fish and Shellfish Taint and Toxicity for Human Consumption

4.3.1. Purpose

The purpose of this module is to:

- Provide an understanding of the levels of taint in commercial and recreational fish and/or shellfish species;
- Undertake a chemical analysis of the level of PAH and non-hydrocarbon constituents (e.g. metals) in fish and/or shellfish tissue to assess the level of risk for human consumption;
- Determine if differences exist in concentration of PAH and non-hydrocarbon constituents (e.g. metals) in fish and/or shellfish samples collected from impact and control sites.
- Determine if differences exist in the olfactory status of fish and/or shellfish samples collected from areas exposed to an oil spill (impact) and from control sites;
- Assess possible sources of specific odours via qualitative evaluation;
- Determine the persistence of taint over a specified time period;

4.3.2. Initiation and termination criteria

Initiation Criteria	S3 Fish/shellfish tissue samples	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O2/O6 or scientific modules S1/S2 has confirmed either: (a) in-water hydrocarbon concentrations are above guideline levels known to cause tainting (Table 4.4.5 in ANZECC & ARMCANZ 2000); or (b) sediment hydrocarbon concentrations are above SQGV levels (Simpson *et al*. 2013) ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O2/O6 or scientific modules S1/S2 has confirmed either: (a) in-water non-hydrocarbon constituent concentrations are above guideline levels known to cause tainting (Table 4.4.5 in ANZECC & ARMCANZ 2000); or (b) sediment hydrocarbon concentrations are above SQGV levels (Simpson *et al*. 2013) **and** ✓ Agreement has been reached with the Jurisdictional Authority relevant to the spill to initiate the monitoring
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S3 is to commence.
Termination Criteria	S3 Fish/shellfish tissue samples	✓ Two sequential sample sets show ambient hydrocarbon concentrations are below guideline levels for tainting in ANZECC & ARMCANZ 2000); **and either** ✓ PAH and non-hydrocarbon constituent levels in fish and shellfish tissue have returned to within the expected natural dynamics of baseline state and/or control sites; **or** ✓ PAH and non-hydrocarbon constituent levels in fish and shellfish tissue are at or below levels specified by Food Standards Australia New Zealand (FSANZ).

	All sub-modules	✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.3.3. Implementation

Activation Time[1]	✓ S3 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Sampling and analysis plan to be ready within 7 days of initiation criteria being met; ✓ Mobilisation and monitoring to commence within 7 days of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S3: Fish and shellfish taint and toxicity for human consumption*
Reporting	✓ Summary report to be provided to Esso Environment Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.3.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S3. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016);
- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC & ARMCANZ 2000)
- Protocol for Interpretation and Use of Sensory Testing and Analytical Chemistry Results for Re-Opening Oil-Impacted Areas Closed to Seafood Harvesting Due to The Deepwater Horizon Oil Spill (USFDA 2010)

Sub-module	Sampling technique	Data collection and/or analysis
S3 Fish/shellfish tissue samples	• Fish and/or shellfish collection; • Biological tissue sampling	• Physical specimen characteristics (e.g. length, sex, visible lesions etc.); • Laboratory analysis of tissue samples for hydrocarbons (e.g. PAH); • Olfactory analysis.

4.3.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S3. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S3 in the event of a spill; • Implement S3;	• Doctorate in environmental science;

Personnel	Responsibilities	Competencies
	• Review and/or carry out reporting requirements; • Compliance with the requirements of S3 and the OSMP; • Provide advice with respect to environmental issues as required.	• At least 10 years' experience in the collection of fish and shellfish for laboratory analysis; • Familiarisation with relevant requirements of the OSMP and OPEP.
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories; • Completing field data sheets; • QA/QC data quality.	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area; • Experienced in the fish/shellfish collection, sampling and recording techniques.
Olfactory Analysis Panel (2 to 3 people)	• Conduct sensory evaluation of fish and/or shellfish samples.	• Bachelor degree in degree environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area; • Experienced in olfactory analysis.

Resources

Vessels will be required to support collection of fish and shellfish samples. Equipment required for collection of samples may include baited traps and lure lines. A NATA accredited laboratory will be required for analysis of the fish and shellfish samples. Esso has identified NATA accredited laboratories with the capabilities to support the analysis for scientific module S3, including but not limited to:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	4 Westall Road, Springvale VIC 3171 Ph: 03 8549 9600
Intertek Geotechnical	41-45 Furnace Road, Welshpool WA 6106 Ph: 08 9458 8877
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Ph: 03 9644 4888
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167

4.4 S4: Short-Term Impacts to Oiled Fauna and Flora

4.4.1. Purpose

For the purposes of this module 'fauna' is defined as avifauna (seabirds and shorebirds) and marine megafauna (predominately pinnipeds). 'Flora' is defined as both aquatic flora (e.g. kelp present on subtidal reefs) and coastal flora (e.g. mangroves and saltmarsh).

The purpose of this module is to assess any short-term effects of oiling on marine fauna and flora which may have resulted from an oil spill. Module S5 is designed to conduct:

- Visual inspections of wildlife in the near shore marine environment and assess the number and species of oiled fauna and their health;
- Visual inspections of wildlife on shoreline environments, including at breeding areas and determine the number and species of oiled wildlife, and their general health;
- Surveys of coastal, subtidal and intertidal flora populations to identify the species present and record health condition parameters; and
- Fingerprint analysis of oil samples taken from oiled fauna to provide quantitative measures on the composition, type, estimated age and weathering and degradation of the product.

4.4.2. Initiation and termination criteria

Initiation Criteria	S4.1 Fauna surveys (vessel-based) S4.2 Fauna surveys (land-based) S4.3 Oiled fauna hydrocarbon testing;	✓ Confirmation by the IMT IC (or delegate) that a hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O4 has confirmed the presence of oiled fauna.
	S4.4 Flora surveys	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational modules O3 has confirmed the presence of oiled shorelines
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S4 is to commence.
Termination Criteria	S4.1 Fauna surveys (vessel-based) S4.2 Fauna surveys (land-based) S4.3 Oiled fauna hydrocarbon testing;	✓ Disturbance parameters (e.g. mortality, percentage oiled fauna/flora) have returned to within the expected natural dynamics of baseline state and/or control sites; and ✓ Hydrocarbon concentrations from fauna samples have returned to within the expected natural dynamics of baseline state and/or control sites.
	All sub-modules	✓ Or, agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.4.3. Implementation

Activation Time[1]	✓ S4 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Sampling and analysis plan to be ready within 24 hours of initiation criteria being met ✓ Mobilisation and monitoring to commence within 24 hours of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S4: Short-term impacts to oiled fauna and flora*
Reporting	✓ Summary report to be provided to Esso Environment Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.4.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S4. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016).

Sub-module	Sampling technique	Data collection and/or analysis
S4.1 Fauna surveys (vessel-based)	• Visual surveillance	• Quantitative observation records (e.g. presence, abundance, behaviour etc.).

Sub-module	Sampling technique	Data collection and/or analysis
S4.2 Fauna surveys (land-based)	• Visual surveillance	• Quantitative observation records (e.g. presence, abundance, behaviour etc.).
S4.3 Oiled fauna hydrocarbon testing	• Oil sample collection	• Physical characteristics (e.g. wax content, dynamic viscosity, density, volatiles); • Chemical characteristics (e.g. PAH)
S4.4 Flora surveys	• Coastal vegetation surveys • Subtidal and intertidal benthic habitat surveys	• Quantitative observation records (e.g. vegetation type, percent cover, health parameters etc.).

4.4.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S4. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S4 in the event of a spill • Implement S4 • Review and/or carry out reporting requirements • Compliance with the requirements of S4 and the OSMP • Provide advice with respect to environmental issues as required	• Doctorate in environmental science; • At least 10 years' experience infauna survey including the survey of marine fauna; • Familiarisation with relevant requirements of the OSMP and OPEP
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area • Experienced in the relevant sampling and/or recording techniques.

Resources

Vehicles will be required to support land-based fauna surveys and flora surveys. Vessels will be required for implementation of vessel-based fauna surveys and may be supported by the use of UAVs for rapid collection of data via video or photographs of colonies. ROVs may be required for surveys of subtidal flora. Sampling equipment may be used by trained animal handlers to sample oil found on oiled wildlife and will require a NATA accredited laboratory to analyse the oil samples. Esso has identified NATA accredited laboratories with the capabilities to support the analysis for scientific module S4, including but not limited to:

NATA accredited laboratory	Details
Australian Laboratory Services (Melbourne)	4 Westall Road, Springvale VIC 3171 Ph: 03 8549 9600
Intertek Geotechnical	41-45 Furnace Road, Welshpool WA 6106 Ph: 08 9458 8877
Leeder Analytical Pty Ltd	33 Steane St, Fairfield, VIC, 3078 Phone: 03 9481 4167
National Measurement Institute	1/153 Bertie Street, Port Melbourne VIC 3207 Ph: 03 9644 4888

4.5 S5: Recovery of Commercial and Recreational Fisheries

4.5.1. Purpose

This module provides a semi-quantitative longer-term assessment of whether commercial and recreational fisheries have been impacted by a spill and the level of that impact pertaining to fish catch volume and effort rates. Module S5 will assess changes to fishery stocks due to oil exposure by:

- Determining the catch composition of species in each of the main fisheries following exposure to the spill;
- Summarise commercial catch volume and effort data post-oil spill and compare to pre-existing (baseline) information provided by the Victorian Fisheries Authority (VFA), the New South Wales Department of Primary Industries (NSW DPI)), Tasmanian Department of Primary Industries, Parks, Water and Environment (DPIPWE), and/or Australian Fisheries Management Authority (AFMA); and,
- Calculate catch-per-unit effort for fish/shellfish species to determine any change in abundance.

4.5.2. Initiation and termination criteria

Initiation Criteria	S5 Desktop review of fishery stock;	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has confirmed that either: (a) data from S3 confirms tainting in fish or shellfish tissue; or (b) in response from government / State IC advice
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S5 is to commence.
Termination Criteria	S5 Desktop review of fishery stock;	✓ Catch per Unit Effort (CPUE) for fishery stock assessments have returned to within the expected natural dynamics of baseline state and/or control sites.
	All sub-modules	✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.5.3. Implementation

Activation Time[1]	✓ S5 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Desktop assessment to commence within 24 hours of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S5: Long-term impacts to commercial and recreational fisheries*
Reporting	✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.5.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S5. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Sub-module	Sampling technique	Data collection and/or analysis
S5.1 Desktop review of fishery stock	• Desktop review.	• Stakeholder liaison and data collation; • CPUE analyses.

4.5.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S5. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Implement S5; • Review and/or carry out reporting requirements; • Compliance with the requirements of S5 and the OSMP; • Provide advice with respect to environmental issues as required • QA/QC data quality.	• Doctorate in environmental science; • At least 10 years' experience in the collection and analysis of fishery data; • Familiarisation with relevant requirements of the OSMP and OPEP; • Experienced in fisheries data analysis.

Resources

Module S5 is a desktop review and does not require mobilisation of non-personnel resources.

4.6 S6: Recovery of Fauna

4.6.1. Purpose

The purpose of this module is to provide semi-quantitative measures of changes to population dynamics of indicator fauna to assess long-term environmental effects on these species which may result from a hydrocarbon spill (i.e. assess the extent of damage and measure the degree of recovery, where possible). Module S6 will assess and monitor oil impacts to fauna populations by:

- Monitoring changes in population dynamics (pup counts, breeding success, population changes over time) at identified control and impact sites;
- Assessing the impact of a hydrocarbon spill on indicator fauna by analysing pre and post-impact data on population sizes at control and impact (where existing baseline data is available) sites.

4.6.2. Initiation and termination criteria

Initiation Criteria	S6 Fauna surveys	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred, **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational module O4 or scientific module S4 has confirmed the exposure of fauna
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S6 is to commence.
Termination Criteria	S6 Fauna surveys	✓ Disturbance parameters (e.g. estimated population) have returned to within the expected natural dynamics of baseline state and/or control sites.
	All sub-modules	✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.6.3. Implementation

Activation Time[1]	✓ S6 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Sampling and analysis plan to be ready within 7 days of initiation criteria being met; ✓ Mobilisation and monitoring to commence within 7 days of activation
Implementation Plan	✓ Refer to *Implementation Guide for S6: Long-term impacts to fauna*
Reporting	✓ Summary report to be provided to Esso Environment Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.

4.6.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S6. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016).

Or other related scientific studies (e.g. Kirkwood *et al*. 2005; Goldsworth *et al*. 2000).

Sub-module	Sampling technique	Data collection and/or analysis
S6.1 Fauna surveys	• Visual surveillance	• Quantitative observation records (e.g. population, chicks/pups abundance, behaviour etc.).

4.6.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S6. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S6 in the event of a spill • Implement S6 • Review and/or carry out reporting requirements • Compliance with the requirements of S6 and the OSMP • Provide advice with respect to environmental issues as required	• Doctorate in environmental science; • At least 10 years' experience in the survey and analysis of fauna data; • Familiarisation with relevant requirements of the OSMP and OPEP
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area • Experienced in the relevant sampling and/or recording techniques.

Resources

Vessels and vehicles will likely be required to access sites for ongoing monitoring of fauna at sea and on land.

4.7 S7: Recovery of Subtidal and Intertidal Benthic Habitat

4.7.1. Purpose

The purpose of this module is to assess long-term environmental effects on subtidal and intertidal benthic communities which may have resulted from an oil spill or response (i.e. assesses the extent of damage and measure the degree of recovery in benthic communities, where possible). Module S7 will assess and monitor long-term impacts to subtidal and intertidal benthic communities by:

- Undertaking habitat extent analysis to rapidly collect and process real-time data on abiotic and biotic parameters to determine subtidal and intertidal habitat classifications;
- Monitoring seagrass at impact and reference sites to determine extent of change (if any) in biomass and estimated cover due to oil impacts;

- Monitoring macroalgae and sponge at impact and reference sites to determine extent of change (if any) in biomass and estimated cover due to oil impacts;
- Monitoring benthic infauna at impact and reference sites to determine extent of change (if any) to species composition and abundance; and
- Monitoring fish at impact and reference sites to determine extent of change (if any) to species composition and abundance.

4.7.2. Initiation and termination criteria

Initiation Criteria	S7.1 Habitat mapping; S7.2 Macroalgae and sponges S7.3 Benthic infauna monitoring; S7.4 Intertidal and subtidal fish monitoring	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational module O2/O6 or scientific module S1/S2/S4 has confirmed the exposure of either benthic substrate or waters within bottom 1 m of seabed
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S7 is to commence.
Termination Criteria	S7.1 Habitat mapping; S7.2 Macroalgae and sponges S7.3 Benthic infauna monitoring; S7.4 Intertidal and subtidal fish monitoring	✓ Disturbance parameters (e.g. species composition, percent cover) and health parameters (e.g. leaf condition) have returned to within the expected natural dynamics of baseline state and/or control sites.
	All sub-modules	✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring

4.7.3. Implementation

Activation Time[1]	✓ S7 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Sampling and analysis plan to be ready within 7 days of initiation criteria being met; ✓ Mobilisation and monitoring to commence within 7 days of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S7: Long-term impacts to subtidal and intertidal benthic habitat*
Reporting	✓ Summary report to be provided to Esso Environment Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.7.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S7. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016).

Or other related scientific studies (e.g. Anderson *et al*. 2009; English *et al*. 1997; Brown *et al*. 2004; Cappo *et al*. 2006).

Sub-module	Sampling technique	Data collection and/or analysis
S7.1 Habitat mapping	• Visual and/or remote sensing surveillance (e.g. towed camera, tagging, side-scanning sonar etc.)	• Identification of habitat type and composition; • Mapping of habitat extent.
S7.2 Macroalgae and sponge	• Visual and/or remote sensing surveillance (e.g. towed camera, tagging, side-scanning sonar etc.)	• Population and community parameters (composition, cover, abundance, diversity)
S7.3 Benthic Infauna monitoring	• Infauna sample collection (e.g. sediment grab sampling)	• Population parameters (abundance, composition etc.).
S7.4 Intertidal and subtidal fish or monitoring	• Visual and/or remote sensing surveillance (e.g. divers, BRUVS etc.)	• Population parameters (abundance, composition etc.).

4.7.5. Responsibilities, competencies, and resources

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S7. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S7 in the event of a spill • Implement S7 • Review and/or carry out reporting requirements • Compliance with the requirements of S7 and the OSMP • Provide advice with respect to environmental issues as required	• Doctorate in environmental science; • At least 10 years' experience in the collection and analysis of data relating to marine infauna; • Familiarisation with relevant requirements of the OSMP and OPEP
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area • Experienced in the relevant sampling and/or recording techniques.

Resources

Vehicles and vessels will be required to support monitoring of nearshore and offshore benthic habitats and communities respectively. ROVs may be required for remote surveillance of benthic habitats and communities.

4.8 S8: Recovery of Coastal Flora

4.8.1. Purpose

The purpose of this module is to assess potential long-term environmental effects on the extent, composition and health of coastal flora communities which may have resulted from an oil spill (i.e. assess the extent of damage and measure the degree of recovery in coastal flora populations, where possible). Module S8 assesses and monitors long-term impacts to coastal flora by:

- Establishing the baseline (background) data on coastal flora community composition, structure and health at identified control and impact sites. Post-spill, pre-impact (reactive baseline) sampling will be undertaken if practicable e.g. if timing permits. This data will augment existing baseline information);
- Monitoring coastal flora communities over time at identified control and impact sites by assessing community extent, composition, structure and health; and
- Assessing the impact of a hydrocarbon spill on coastal flora communities by analysing long-term pre- and post-impact data at control and impact sites.

4.8.2. Initiation and termination criteria

Initiation Criteria	S8.1 Habitat mapping; S8.2 Condition monitoring	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that data from operational module O3 or scientific module S4 has confirmed the exposure of coastal flora
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S8 is to commence.
Termination Criteria	S8.1 Habitat mapping; S8.2 Condition monitoring	✓ Disturbance parameters (e.g. abundance, percent cover) and health parameters (e.g. leaf condition) have returned to within the expected natural dynamics of baseline state and/or control sites.
	All sub-modules	✓ **Or,** agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

4.8.3. Implementation

Activation Time[1]	✓ S8 to be activated within 24 hours of initiation criteria being met
Implementation Time	✓ Sampling and analysis plan to be ready within 7 days of initiation criteria being met; ✓ Mobilisation and monitoring to commence within 7 days of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S8: Long-term impacts to coastal fauna*
Reporting	✓ Summary report to be provided to Esso Environment Lead following completion of each field survey event; ✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.8.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S8. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, sampling and analysis will be undertaken in line with relevant guidance documents, such as:

- Oil Spill Monitoring Handbook (Hook *et al*. 2016).

Or other related scientific studies (e.g. English *et al*. 1997).

Sub-module	Sampling technique	Data collection and/or analysis
S8.1 Habitat mapping	• Remote sensing surveillance (e.g. multispectral imagery)	• Identification of habitat type and composition; • Mapping of habitat extent.
S8.2 Condition monitoring	• Visual (e.g. quadrats, photographs)	• Population parameters (e.g. abundance, percent cover etc.). • Health parameters (e.g. leaf cover, leaf damage, etc.)

4.8.5. Responsibilities, competencies, and resources

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for the initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S8. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Finalise the sampling and analysis design for S8 in the event of a spill • Implement S8 • Review and/or carry out reporting requirements • Compliance with the requirements of S8 and the OSMP • Provide advice with respect to environmental issues as required	• Doctorate in environmental science; • At least 10 years' experience in the collection and analysis of data on flora including coastal flora; • Familiarisation with relevant requirements of the OSMP and OPEP
Field Teams (2 to 3 people)	• Conduct sampling, record data and arrange transfer of samples to laboratories • Completing field data sheets • QA/QC data quality	• Bachelor degree in environmental science or an engineering degree from a recognised institution or equivalent tertiary study in technical area • Experienced in the relevant sampling and/or recording techniques.

Resources

Vehicles will be required to support the visual surveys involved in monitoring of coastal flora.

4.9 S9: Recovery of Ramsar Values

4.9.1. Purpose

This module is aimed at establishing whether oil entering Ramsar wetland has resulted in an alteration to the ecological character of the system. The purpose of this module is to:

- Assess long-term impacts of an oil spill on the ecological character of Ramsar sites.

4.9.2. Initiation and termination criteria

Initiation Criteria	S9 Desktop review of wetland values	✓ Confirmation by the IMT IC (or delegate) that Level 2 or Level 3 hydrocarbon spill to marine or coastal waters has occurred; **and** ✓ Principal Investigator through the EUL (or delegate) has determined that (a) data from operational module O3 has confirmed the exposure of a Ramsar wetland; and (b) data from scientific modules S1, S4, S6, S7 or S8 confirm an impact to water/sediment quality, flora or fauna in the wetland.
	All sub-modules	✓ The IMT IC (or delegate) has advised that either full or partial implementation of S9 is to commence.
Termination Criteria	S9 Desktop review of wetland values	✓ Wetland values that are important to the ECD* have returned to within the expected natural dynamics of baseline state and/or control sites.
	All sub-modules	✓ **Or**, agreement has been reached with the Jurisdictional Authority relevant to the spill to terminate the monitoring.

* as described in relevant Ramsar site documents prepared per the National ECD Framework

4.9.3. Implementation

Activation Time[1]	✓ S9 to be activated[1] within 24 hours of initiation criteria being met
Implementation Time	✓ Desktop assessment to commence within 24 hours of activation.
Implementation Plan	✓ Refer to *Implementation Guide for S9: Long-term impacts to Ramsar values*
Reporting	✓ Final report (including all data and associated interpretation and analysis) prepared following the termination criteria for the module being met.

Notes:

1. *A module is considered activated when Esso have confirmed initiation criteria have been met and the monitoring providers have been notified to initiate planning and implementation tasks.*

4.9.4. Monitoring overview

The below table provides an indication of the type of sampling techniques and analysis that may be undertaken during scientific module S9. The final sampling design, including methods and analysis, will be determined by Esso in conjunction with their monitoring providers in the event of a spill.

Where practicable, desktop reviews will be undertaken in line with relevant guidance documents, such as:

- National Framework and Guidance for Describing the Ecological Character of Australian Ramsar Wetlands (DEWHA 2008).

Sub-module	Sampling technique	Data collection and/or analysis
S9 Desktop review of wetland values	• Desktop review.	• Data collation (including relevant information from scientific modules S1, S4, S6, S7 and S8 where relevant). • Comparison to known ecological character descriptions of Ramsar wetlands.

4.9.5. Responsibilities, competencies, and resources

Emergency response team

The IMT IC and EUL have responsibilities relating to the initiation of this scientific monitoring module. These roles may delegate responsibilities as appropriate; e.g. the ERT VM/OIM may be responsible for the initiation if the IMT has not yet been established. Roles, responsibilities and competencies of the ERT and IMT teams are as detailed in the OPEP.

Esso environmental team

Termination of this scientific monitoring module is the responsibility of Esso Environment Lead.

Monitoring team

The below table lists the minimum personnel requirements from the monitoring provider to implement scientific module S9. The numbers of teams and final number of personnel may vary depending on the nature and scale of the spill.

Personnel	Responsibilities	Competencies
Principal Investigator (1 person)	• Implement S9 • Review and/or carry out reporting requirements • Compliance with the requirements of S9 and the OSMP • Provide advice with respect to environmental issues as required • QA/QC data quality	• Doctorate in environmental science; • At least 10 years' experience in dealing with Ramsar values including the analysis of changes to those values; • Familiarisation with relevant requirements of the OSMP and OPEP • Experienced in wetland ecology.

Resources

Module S9 is a desktop review and will not require mobilisation of non-personnel resources.

Appendix A: General guidance and approaches for scientific monitoring design

This appendix provides guidance on survey design approaches that are likely to be utilised for the scientific monitoring modules:

- Impact versus Control (IvC);
- Gradient of Impacts;
- Before-After-Control-Impact (BACI);
- Control Chart;
- Lines of Evidence.

The design of monitoring studies should ensure, as far as possible, that the planned monitoring activities are practicable and that the objectives of the study will be met. The design must result in the collection of meaningful data and, where practicable, data that are sufficiently powerful to detect ecologically relevant changes.

The final survey design(s) can depend on a variety of factors, included but not limited to:

- Scale and pattern of potential effects of the spill;
- Availability of baseline data and/or ability to rapidly obtain baseline data;
- Time frame available to gather pre- and post-spill data;
- Availability of operational monitoring data;
- Availability of appropriate control sites;
- Statistical approach proposed for data analysis;
- Range of possible chronic and acute effects on the parameters of concern, based on the characteristics of the spill;
- Monitoring frequency required to ensure short-and long-term impacts are detected;
- Legislative requirements;
- Available resources and equipment to conduct the work in terms of personnel, logistics, and access.

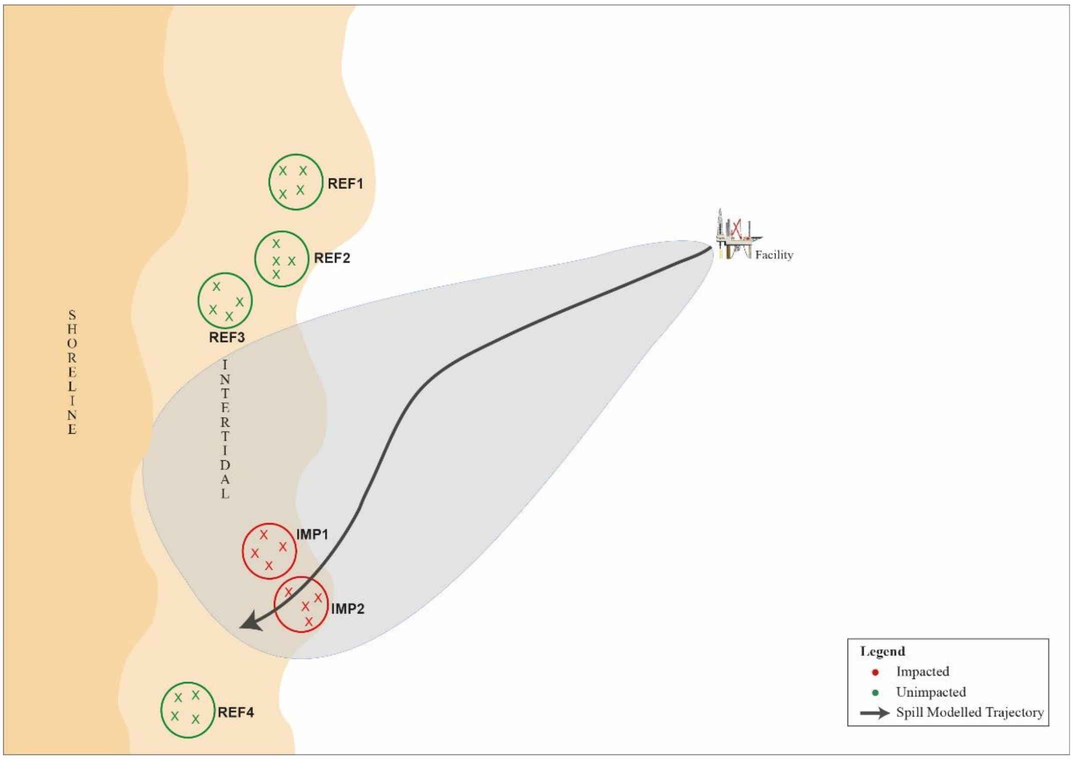
Note: data collection can depend on several constraints (as outlined above) and on access given logistical and safety constraints applicable to a particular spill event. Therefore, the survey designs recommended within the implementation guides for each scientific monitoring module, may not be able to be implemented exactly as intended. For example, there may be inadequate number of control sites because of the size of the spill and therefore data collected from an expected BACI design may need to be analysed as a gradient approach etc.

Before-After-Control-Impact (BACI) approach

Where appropriate baseline data are available, consideration should be given to developing a beyond BACI monitoring program design (Underwood 1991; 1994) or similar extended BACI design (mBACI), which monitors a range of control and impact sites, and can do so over time (Figure A-1). Where robust, appropriate baseline data for exposure sites are not available, pre-exposure sampling of locations that lie within the hydrocarbon spill trajectory should be prioritised to obtain baseline data prior to hydrocarbon exposure.

Exposure sites should be selected first, encompassing a representative selection of locations within the area affected by hydrocarbons. Where practicable, the monitoring program design may consider stratified sampling along environmental gradients (e.g. level of hydrocarbon exposure etc.). Comparable control sites beyond the area affected by hydrocarbons should then be selected, with monitoring conducted at all sites. Clearly obtaining control sites pre-exposure can be challenging and is heavily reliant on predicting the extent of hydrocarbon movement.

The suggested statistical analysis of data collected using the BACI approach includes a univariate or multi-factorial analysis of variance (ANOVA) and equivalent non-parametric tests, all of which will compare between treatment (impact versus reference) and time (before versus after). Components of variation may help partition a sum of squares into different sources and describe the importance of factors within tests.



Notes:

1. *A modification to the beyond BACI design, is known as an MBACI design. MBACI designs incorporate multiple impact locations, whereas beyond BACI designs include only one impact location.*
2. *The above design consists of four reference/control locations and two impact locations, with four nested sites in each. The number of replicates (e.g. quadrats or transects) per site should be set based on resourcing, and /or the results of the power analysis (if applicable).*
3. *The area affected by the spill is indicated by the grey shaded area, or the area of influence.*
4. *Design assumes the area of influence has been affected equally.*

Figure A-1: Example of an MBACI design for shoreline and/or intertidal communities

Impact versus Control (IvC) approach

For some locations and receptors, baseline data may not exist, may not be recent and applicable, or was collected using methods that are unrepeatable in the current study. If there is a lack of baseline information that can feed into a BACI design, an IvC approach can be used to assess impacts. However, due to the unknown status of the parameter before impact, there is a higher likelihood of encountering Type I error (falsely concluding that an impact has occurred) with this approach. For example, if the status of the parameter to be measured was already naturally lower at impact sites than control sites before the impact occurred, but this was not measured, a conclusion may be reached using the IvC approach that an impact has occurred when it may be natural variation. For this reason, sampling designs should always try to collect or use baseline data (i.e. aim for a BACI design), and if an IvC design is used, it is important to ensure that the control sites are comparable to the impact sites in every way possible except for the presence or absence of the studied effect (hydrocarbon). This may include, but not be limited to: site physical aspect, substrate, current regimes, and community composition.

Because of the higher likelihood of Type I error, it is also useful to collect additional data on relevant physical environmental parameters that are likely to be different at impact and control sites and may affect the conclusion of the assessment. Biological information may also be relevant, such as degree of sub-lethal and lethal impacts to populations. These parameters can be examined later for any potential co-variance with the observed changes in the parameter of interest, to understand whether hydrocarbons or natural variation affected the outcome. The physical and biological information can therefore augment and act as additional evidence to help interpret conclusions from any IvC analyses. As with the BACI approach, when using the IvC approach it is important to understand the scale of natural variation that may affect the outcome of the assessment by replicating sites within sampling locations and replicating samples within each site.

The suggested statistical approach for analysing the data collected using the IvC approach is a multi-factorial ANOVA (to account for nested data), including PERMANOVA and non-parametric tests, to test whether the level of variation among treatments (IvC) is greater than the level of variation within treatments. Components of variation may help partition variance into different sources and help infer whether the effect of hydrocarbons or spatial variation was responsible for any detected change in the receptors.

Gradient approach

The gradient approach can be used in some instances where a lack of suitable control sites prohibits using a BACI or IvC approach. Sampling should be established along a gradient of predicted effect (based on input of data from operational monitoring, surveillance or modelling), with sites established at various distances from the source of impact or along a gradient of magnitudes of concentrations of hydrocarbons. The gradient approach can also be used in combination with a BACI or IvC approach to help infer the cause of a detected impact and describe thresholds of impacts at which a response appears to have occurred. The gradient approach also provides a ‘line of evidence’ that the source of potential impact (hydrocarbons) was responsible for the observed effect, rather than natural variation. However, care should be taken to ensure awareness of any natural gradients in the parameter measured and take these into account when interpreting the data.

When designing a study using a gradient approach, relevant Oil Spill monitoring data (e.g. water and sediment quality), and modelling should be considered. Prior knowledge or prediction of the likely gradient of effect will greatly improve the efficiency of the sampling design by minimising the collection of data points that provide no additional information in the analysis (e.g. data points showing similar or no effects that do not help to characterise the gradient of effect), though noting these may aid in statistical power of gradient description so shouldn’t necessarily be discouraged.

Typically, the level of observed impact will decline at distance from the source of a hydrocarbon release, with this decline likely to be exponential (i.e. large changes close to a release that quickly decrease in severity); therefore, sampling effort can be distributed along the gradient of effect in a way that best characterises the changes in the parameter measured.

If possible, multiple (> two) sites could be sampled at each distance along the gradient (if logistics and time permit) to provide an understanding of small-scale variation. Sites should also be sampled at distances where no environmental effect is predicted or observed, if possible, to characterise the full extent of the effect’s gradient.

The suggested statistical analysis for the gradient approach includes correlation analysis between impact (measurements of hydrocarbon/stress; x-axis) and measurement parameter (biological response; y-axis), and associated regression analyses, may include least-squares regression line and hypotheses testing to determine if the trend is significantly different from zero.

Control chart approach

The control chart approach is applicable in the following circumstances:

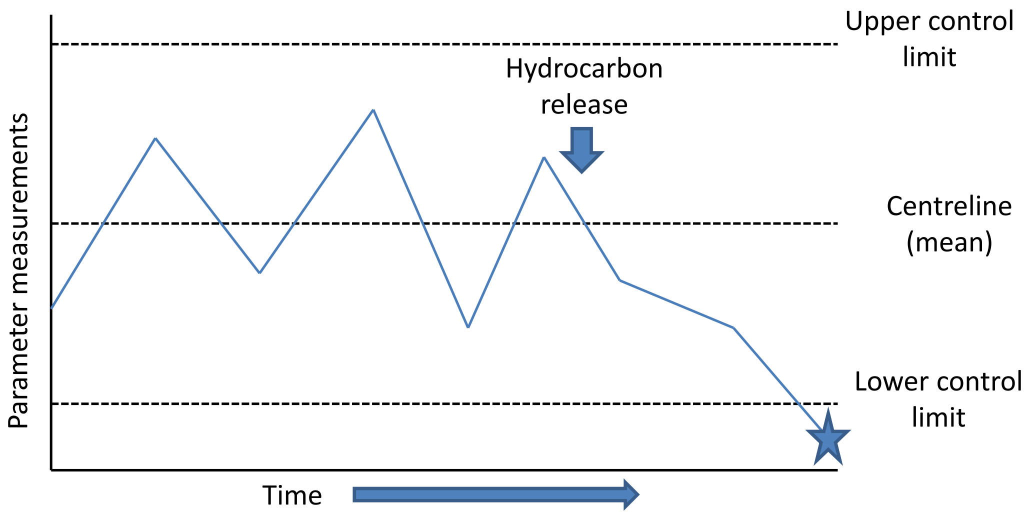
- When long-term (multi-year) datasets exist for the measured parameter;
- When a large amount of natural variation exists in the measured parameter;
- When predicting the expected range of outcomes from an impact.

One of the causal criteria described in the lines of evidence approach is ‘strength of association’ (Hill 1965), exemplified by a ‘larger decline in individuals in areas affected by hydrocarbon than in control areas’. The control chart approach takes this causal criterion a step further and uses rules to establish whether a detected change in a parameter at impact sites is outside what would be expected to occur naturally. This technique requires tracking a parameter over time and determining whether an observed change is within the bounds of what has been observed to occur naturally at that impact site or at control sites.

A control chart has a central line for the mean, an upper control limit (UCL; e.g. typically 3 standard deviations [SD] above the mean), and a lower control limit (LCL; e.g. typically 3SD below the mean), which are typically all determined from historical data (Gotelli and Ellison 2004). The mean line can be constructed using data from i) historical data of an impact site prior to it being affected by hydrocarbons (i.e. what the mean used to be), or ii) control locations, whereby either historical or recent data is used for comparison to other sites (i.e. a control site historical data compared to impact site). The approach is then based on calculating the mean (ongoing) for an impact site to compare against the control chart. Any observations outside the UCL and LCL suggest that increased variation has been observed that are inconsistent with other data and may post a simple way to detect change in a system (Figure A-2).

In addition, if ongoing data collection is possible following a potential impact, the control chart approach can be used to examine the direction of change and whether this is consistent or inconsistent with other data. These data and interpretation may provide a weight of evidence of a directional change in a given parameter.

The control chart approach is only useful if there is an adequate knowledge of natural variability in a given parameter whether from historical sources or similar sites/locations. Control chart approaches can be a powerful tool for detecting impacts for systems that are naturally highly variable.



Note: The star represents a measurement beyond the likely anticipated variation, which needs to be investigated.

Figure A-2: Example Control Chart showing Centreline (mean), Upper Control Limit (3 SD above mean), Lower Control Limit (3 SD below mean), and Measurements

Lines of evidence approach

The lines of evidence approach is applicable in the following circumstances:

- Can be combined with any of the above monitoring designs to provide inferential evidence of an effect;
- Are useful to support evidence of effect if there are limited (or only one) impact locations;
- Are useful to support evidence of effect if the effect radiates outward from source;
- Are useful to infer cause of change if limited or no baseline data exist;
- Are useful to infer cause of change if limited or no control sites exist.

When a sampling design is suboptimal, or if conclusions from more formal tests are inconclusive, a lines of evidence approach can be used to help infer the cause of an observed change (i.e. attribute change to the hydrocarbon release or to other causes, such as natural variation). Within the lines of evidence approach, inference is developed based on carefully structured arguments. A weakness of this method is that the evidence may be largely circumstantial because it is based on correlations (Downes *et al*. 2002), which does not necessarily imply causation. Each causal argument may be weak when considered independently but combined they may provide strong circumstantial evidence and support for a conclusion (Downes *et al*. 2002).

This approach was originally developed in medicine (Hill 1965) but has been used more recently in ecological studies (e.g. Downes *et al*. 2002; McArdle 1996; Suter 1996; Beyers 1998; Fabricius 2004).

Causal criteria have been developed for categorizing arguments from studies on disease on humans (Hill 1965), and these can be applied to ecological arguments (Hill 1965). With lines of evidence, there is a need to seek evidence not only to support the impact prediction, but evidence to rule out plausible alternative predictions, such as that the observed difference was due to natural processes (Downes *et al*. 2002; Beyers 1998).

In the lines of evidence approach, a set of descriptions should be developed for all or some of the causal criteria listed in Table A-1 before the survey is undertaken (see Downes *et al*. 2002 for further criteria and examples). Data would then be collected that allows each line of evidence to be tested or objectively questioned. The final assessment of whether an impact is likely to have occurred should be based on the 'weight of evidence' from examining multiple lines of evidence.

Example generalised lines of evidence descriptions are provided in Table A-2. These should be modified and tailored to individual scientific monitoring module, as required and each parameter investigated.

Table A-1: Hills (1965) causal criteria and description in the context of ecological impact Assessment

Causal Criterion	Description
Strength of association	A large proportion of individuals are affected in the impact area relative to control areas
Consistency of association	The association was observed by other investigators at other times and places
Specificity of association	The effect is diagnostic of exposure
Temporality	Exposure must precede the effect in time
Biological gradient	The risk of effect is a function of magnitude of exposure
Biological plausibility	A plausible mechanism of action links cause and effect
Experimental evidence	A valid experiment provides strong evidence of causation
Coherence	Similar stressors cause similar effects
Analogy	The causal hypothesis does not conflict with existing knowledge of natural history and biology

Table A-2: Causal criteria and example lines of evidence descriptions that could be used to assess whether a change in a measured parameter was due to the effects of a hydrocarbon release

Causal Criterion	Evidence Supportive of a Hydrocarbon Release Impact	Evidence Unsupportive of a Hydrocarbon Release Impact
Strength of association	Larger decline in individuals in areas affected by hydrocarbon than in control areas	Similar declines in individuals in areas affected by hydrocarbon and control areas
Consistency of association	Consistent finding of declines in a range of biota in areas affected by hydrocarbon	Inconsistent declines in biota in areas affected by hydrocarbon (e.g. declines in one species but not in other similar species)
Specificity of association	Number of individuals affected correlates with hydrocarbon concentrations	No correlation between number of individuals affected and hydrocarbon concentration
Temporality	Decline in individuals immediately preceded by contact with hydrocarbon	Decline in individuals occurred before or long after hydrocarbon contact
Biological gradient	Changes in individuals aligned with exposure to hydrocarbon spills or concentrations	Decline in individuals occurs with increasing distance from a hydrocarbon spill or hydrocarbon concentrations
Biological plausibility	Evidence from literature of sensitivity to detected hydrocarbon concentration for species where declines are observed	Evidence from literature suggests lack of sensitivity to detected hydrocarbon concentration for species where declines are observed

Causal Criterion	Evidence Supportive of a Hydrocarbon Release Impact	Evidence Unsupportive of a Hydrocarbon Release Impact
Experimental evidence	A valid experiment provides strong evidence of causation	Not applicable (N/A)
Coherence	Evidence of a decline in species abundance, habitat, and food source with increasing hydrocarbon exposure	Evidence of a decline in species abundance, but no other evidence of expected declines associated with exposure
Analogy	Apparent declines in hatchling numbers despite no apparent decline in numbers of adults	Apparent declines in hatchling numbers associated with decreased numbers of adults

Appendix B: Baseline data

Rationale and approach

Scientific monitoring provides for the quantitative assessment of the environmental impacts associated with a Level 2 or Level 3 spill. The primary goal of the scientific monitoring program is to document the overall impact (short and long term) of the spill on habitats, species and ecosystems and the subsequent post spill recovery.

In the event of a Level 2 or Level 3 spill, scientific monitoring will be activated and individual modules selected and implemented appropriate to the nature, scale and duration of the spill. Activation of these scientific modules during the spill operational response phase may be required to collect pre-contact baseline data or spill impact data at identified receptors. The appropriate scientific modules will be implemented to assess the extent, severity and persistence of environmental impacts associated with the oil spill event.

Baseline monitoring provides information on the condition of ecological receptors prior to, or spatially independent (e.g. if used in control chart analyses) of, a spill event and is used for comparison with the post-impact scientific monitoring where required. This is particularly important for scientific monitoring where the ability to detect changes between pre-impact and post-impact conditions is necessary.

The design of the scientific monitoring program adopts the following framework:

- Where adequate and appropriate baseline data exists, then scientific modules for species and habitats will commence if and when initiation triggers are reached. In this instance given the adequacy of baseline, the scientific modules will not document the decline of the habitat or species, but will quantify impacts and monitor post-spill recovery;
- Where adequate and appropriate baseline data is not available, the options which will be considered include the following:
    - Collect baseline data prior to hydrocarbon contact and meet the requirements for a Before/After Assessment[1]; or
    - Collect environmental data during the spill event, if practicable, to determine potential impacts[2];
- In all cases, undertake post-spill scientific monitoring to determine the overall impact of the spill and document post-spill recovery.

An assessment of available baseline data for environmental receptors within the DA is contained in each of the scientific modules. Within each of those modules there is a description of the scientific monitoring approach which respect to baseline, obtaining data and determining impacts.

There are Oil Spill monitoring modules that are suited to pre-impact baseline monitoring. In the event of a spill to marine or coastal waters, reactive pre-impact monitoring should, where practicable, be implemented to gather additional data on the current state of the environment. Note: the collection of ongoing baseline data (i.e. under regular operational conditions) is not planned or considered to be practicable.

Understanding priority areas for reactive pre-impact baseline monitoring is important. Stochastic modelling may be used to determine areas likely to be contacted with fresh hydrocarbons above impact thresholds within a specified timeframe. For example, stochastic modelling may indicate a number of shoreline receptors have a high probability of contact with fresh hydrocarbons; these areas would then

[1] Application of the simple BACI sampling design and data analysis programs can be applied to the quantification of oil spill related impacts. See Appendix A

[2] Spill impact and post impact monitoring data will be collected following 'beyond-BACI' principles which is amenable to statistical techniques that can detect significant difference in recorded parameters (i.e. asymmetrical analysis of variance) following procedures described by Underwood (1994).

provide an initial focus for reactive pre-impact monitoring. A summary of activity specific modelling data identifying priority monitoring sites is provided in the OPEP Appendix D Quick Reference Information.

Control sites (i.e. similar to the impact or disturbance location) are sometimes more relevant than reference sites (undisturbed or natural sites) for determining the impact of a hydrocarbon spill as separate from other human or natural stressors (Downes *et al*. 2002). In the event of a spill, existing baseline information should be used to select relevant control sites outside the impact area of a single spill. It is expected that most control sites will be within the predicted environment that may be affected, but outside the impacted area for any given single spill. As all possible permutations or combination of sites cannot be realistically assessed in advance, control sites should be selected post-spill. The number of samples and/or sampling sites for a particular spill should depend on the extent of the spill, and the statistical power necessary to determine whether there is an impact and the ability of the monitoring program to determine recovery and termination criteria.

Baseline monitoring

Baseline information for the environment has been sourced from existing data and is summarised in each scientific monitoring module. In the event of a spill, where insufficient baseline exists information will be augmented with 'reactive' baseline studies at control sites or using pre-impact data at the receptor site where appropriate.

Control sites (i.e. similar to the impact or disturbance location) are often more relevant than reference sites (undisturbed or natural sites) for determining the impact of an oil spill as separate from other human or natural stressors (Downes *et al.* 2002). In the event of a spill existing baseline information will be used to select relevant control sites outside the impact area of a single spill. It is expected that most control sites will be within the DA, but outside the impacted area for any given single spill and will be selected post spill event on the basis of their representativeness to the potentially impacted site and their ability to provide a reliable comparison against which to compare the potentially impacted environmental values that are being measured.

The number of samples and/or sampling locations for a particular spill will depend on the extent of the spill, and the statistical power necessary to determine whether there has been an impact and the ability of the monitoring program to determine recovery and termination criteria.

Existing data

Baseline data characterises the existing environment and its variability both in affected sites and unaffected (control or reference) sites.

The EP contains desk study baseline environmental, social and economic values within the DA at a level deemed suitable for risk assessment and identification of mitigation and contingency planning measures as set out in the EP and OPEP. A summary of known baseline data from the Gippsland region and beyond, including New South Wales is shown in Table B-2.

In the event of a Level 2 or 3 spill relevant specific existing data will be obtained as the starting point to scientific monitoring, by the following process:

- Relevant scientific monitoring studies are catalogued for identified sensitive locations along with the custodian's contact details;
- The monitoring methodology, monitoring sites, and sampling duration and frequency of monitoring studies are provided when appropriate in a tabular format to identify methodological differences, and spatial and temporal gaps in accrued baseline data information;
- In the event of a spill data custodians will be contacted and datasets requested. As a contingency, 'data mining' from publically available information will occur simultaneously for baseline database establishment; and
- Data gaps will be used by the PI to refine the SAP to further optimise the design of the study.

Within each module is a summary of the available baseline information together with implementation strategy to address the assessment of impacts is provided.

The methods used to collect the existing baseline data will be assessed and, where possible, the methods used in the implementation of the monitoring will be consistent with the baseline data methods such that comparisons can be made. The design of the modules has already drawn upon the information contained within the existing baseline studies that were used to inform both the preparation of the EP and the OSMP and its modules, and as such there is already a degree of conformity between the methods proposed in the modules and that used for the collection of the published baseline data.

Monitoring survey type

Establishment of baseline is conducted according to Table B-1.

Table B-1: Baseline data types

Type	Description
Baseline field surveys	Field surveys undertaken in advance of the full implementation of the investigations in the modules where baseline information is required. Since the DA is very large and actual spill trajectory dependent on many variables, it is not possible to devise a study programme in advance of a spill that would provide a useful, representative baseline that would cover all spill scenarios.
Reactive baseline surveys	Monitoring surveys mobilised rapidly after a spill to assess baseline conditions at sensitive locations potentially affected by the spill but before spill contact. Esso recognises that reactive baseline monitoring surveys alone may not be sufficient to serve as a baseline dataset, but can provide an important contribution to augment existing 'baseline' with a 'current pre-exposure' condition.
Baseline studies at control sites	Monitoring at sites chosen from within the DA but where spill trajectory estimation predicts no contact.

Impact surveys

Impact surveys examine the immediate aftermath of a spill on specific receptors.

Recovery surveys

Recovery surveys examine the long term effects on specific receptors following the spill recovery.

Use of operational monitoring data

Findings of operational monitoring will be incorporated into the datasets gathered by scientific monitoring.

Monitoring methods

Survey and analytical methods are specific to the environmental value or receptor to be monitored. Methods selected for each module are set out in the relevant subsection of each module.

Monitoring sites

Reactive baseline monitoring sites may be required where there is insufficient existing baseline data against which to compare data collected following exposure to a hydrocarbon spill.

Selection of reactive baseline survey sites will need to be flexible and will depend on a range of site-specific, scientific criteria depending on the module. However in general sites must be:

- Representative of the area that is potentially impacted by the hydrocarbon spill;
- Coincide in proximity to locations with long-term (or recent) monitoring (notably in Victorian Marine Conservation Areas); and
- Be free from obvious anthropogenic impacts.

Reference sites

Reference sites are those that are representative of undisturbed / natural conditions of similar type, habitat, community etc. to those affected. Although reference sites for most types of affected environment will exist within the DA, control sites may be more representative in many cases.

Control sites

Control sites (i.e. unaffected sites similar to those affected by the spill) are used to determine the impact of an oil spill as separate from other human or natural stressors. In the event of a spill existing baseline information will be used to select relevant control sites outside the impact area of a single spill and must be selected post spill. Control sites will be selected and details of distribution and number of replicates will be decided after detailed appraisal of baseline data such that an understanding of the variability of the data can be obtained.

Monitoring indicators

Indicators are specific species, communities or habitats where changes reflect impacts on the wider environment. Indicators for scientific monitoring were identified and chosen based on the following criteria.

Typical – representative of ecological characteristics of the DA

Monitoring of spill impacts is focussed on species that are known to regularly occur within the DA and for which the DA provides vital habitat. This accords with the ecological principle of 'regularly supports' (United Nations 1971).

Sensitive – are sensitive to the impacts of oil spills

Species and communities can be impacted by both the oil spill and by associated response actions. The mechanisms and cumulative impacts to species and communities have been explored using a stressor model. This does not cover the entire myriad of complexities and pathways associated with oil and response actions in marine, coastal and estuarine environments but provides an overview of the main linkages (Gross 2003).

Determining impacts

Data on impacted sites will be compared with baseline data from reference or control locations to determine impacts. Multiple reference / control locations will be selected to provide a robust assessment of the impacts.

If there is sufficient statistical power in the data collected then post-impact monitoring will be analysed using statistical models such as Analysis of Variance (ANOVA). The data collected during the monitoring may be too variable to establish statistical trends. Such a situation is not uncommon in monitoring programs where limited 'before' data are available.

Generally determination of an impact involves an experimental approach with sampling before and after the purported impact at both potentially impacted and control (non-impacted) sites – the BACI (Before – After – Control – Impact) approach. The BACI approach allows for the detection of impacts that can be identified as statistically separable from the background natural variation that could be causing the observed phenomenon. The soundness of the approach stems from the ability to combine a range of design elements (an assessment of the before situation, replication, use of controls) to ensure the robustness of the assessment.

In many cases, and this situation pertains to an oil spill is one of them, where there is an inability to be able to collect information about the pre-impact situation. This may be as a result of adverse weather conditions not allowing a reactive baseline survey to be conducted safely. Thus a situation can arise there is insufficient information available as to what the before situation was and indeed what the situation was at any control location either before or after the action. There is also potentially no replication. In such cases an evaluation of the available evidence can be undertaken to see whether there is support for a particular hypothesis or not. Downes *et al*. (2002) in their book on monitoring of aquatic environments present a detailed review of this technique, the Weight (Levels) of Evidence approach. The use of multiple lines of evidence consistent with the integrated assessment philosophy of the revised ANZECC/ARMCANZ (2000a) guidelines as discussed in the CSIRO Handbook for

Sediment Quality Assessment (Simpson *et al*., 2005). A weight of evidence approach can be taken when there is no definitive experimental evidence available to support or not support a hypothesis.

Table B-2: Regional environmental studies and available baseline data

Reference	Description	Summary	Relevant Location/s	Relevant scientific module

Appendix C: Environmental Values and Sensitivities

Environmental values and sensitivities

The monitoring program responding to a spill is dependent on the types of environmental, social and economic values potentially affected by a spill. Those sensitivities identified by in the Environment Plan (EP) as being present in the Potentially Exposed Area (PEA) are summarised in Table C-1. Linkages between environmental sensitivities, their location, oil spill response options for spill scenarios and OSMP studies are also shown in this table.

Scope of the monitoring program

The OSMP modules provide for the rapid assessment of the extent of spread of hydrocarbons from a Level 2 or Level 3 spill and effects on the environment of the spilt hydrocarbons as well as any spill response activities that may be used in the clean-up of the spill. The modules provide for the rapid assessment of impacted and potentially affected wildlife including those listed as Matters of National Environmental Significance (MNES) und the EPBC Act (1999). These modules were based on the spill impact assessment in the EP and probable exposure pathways and the likelihood of contact with the identified sensitive receptors.

Table C-1: Sensitivities within Level 3 Hydrocarbon Spill PEA with Monitoring Strategies and Potential OSMP Response Measures to be adopted

Environment	Legislative category	Location	Marine Receptors											Coastal Receptors

OPERATIONS ENVIRONMENTAL PERFORMANCE AND IMPLEMENTATION STRATEGY

BASS STRAIT ENVIRONMENT PLAN

Volume 4

Document Number: AUGO-EV-EMM-004

OIMS MANUAL - DOCUMENT CONTROL DETAILS

TITLE:	Bass Strait Operations Environment Plan Environmental Performance and Implementation Strategy Volume 4
REVISION:	3
REVISION STATUS:	Response to NOPSEMA RFFWI
DATE OF ISSUE:	26 March 2021
DOCUMENT ADMINISTRATOR:	Environment & Regulatory Advisor
OIMS DOCUMENT CATEGORY:	Special Controls Mandatory
MPI CLASSIFICATION:	None
RETENTION PERIOD:	IND, MIN ACT+10+LC (Indefinite, Retain while current + 10 years, then obtain Law Clearance prior to disposal)
MASTER STORAGE LOCATION:	UDocs (OIMS 6-5 Environmental Management)

APPROVALS:

Rev 3	Name	Position	Signature	Date
Document Owner:	Hena Kalam	Offshore Risk, Env. & Regulatory Supervisor	On file	23 Mar 2020
Endorsed By:	Hena Kalam	Offshore Risk, Env. & Regulatory Supervisor	On file	23 Mar 2020
Approved By:	Simon Kemp	Offshore Asset Manager	On file	23 Mar 2020

Endorsed / approved by Esso Australia Pty Ltd, for and on behalf of Esso Australia Resources Pty Ltd.

REVISION HISTORY

Rev	Revision / Status	Date	Prepared by	Approved By
3	Response to NOPSEMA RFFWI	23 March 2021	Lucy Levecke	Simon Kemp
2	Response to NOPSEMA OMR	15 Dec 2020	Sarah McCarthy	Simon Kemp
1	Response to NOPSEMA RFFWI	10 June 2020	Sarah McCarthy	Simon Kemp
0	Issued for NOPSEMA acceptance as part of the Bass Strait Operations EP	10 September 2019	Sarah McCarthy	Simon Kemp

DOCUMENT REVIEW AND UPDATE:

The Document Owner is responsible for maintaining and controlling changes to this document in accordance with the Document Management Manual (AUGO-PO-DMM-001). In the course of using this document, users may identify opportunities to improve its content. They are requested to provide suggestions to the Document Owner.

This document should be reviewed for accuracy and currency on a 5 yearly basis commencing from the original formal issue date. Major revisions to this manual are to comply with the OIMS System Manual/Process Management of Change procedures.

DISTRIBUTION:

An electronic copy of this document is lodged on U-Docs. Any updates to this document will be communicated to the relevant personnel in accordance with the Document Management Manual (AUGO-PO-DMM-001).

SMS	Short Message Service
SOPEP	Shipboard Oil Pollution Emergency Plan

TMoA	Toxic Mode of Action, refers to the exertion of similar effects based on concentration addition by certain substances within the same group
TRH	Total Recoverable Hydrocarbons
TU	Toxic Units, refers to the number of times that the predicted exposure concentration is above the corresponding concentration causing toxicity at the median species sensitivity
UK	United Kingdom
US	United States
WA	Western Australia
WET	Whole Effluent Toxicity
WIMS	Well Integrity Management System
WMM	Waste Management Manual
WMS	Work Management System
WOMP	Well Operations Management Plan
WWC	Wild Well Control

1 Environmental Performance

1.1 Environmental Performance Outcomes and Standards

This chapter presents the environmental performance outcomes (EPO), environmental performance standards (EPS) and measurement criteria required to manage the impacts and risks identified in Bass Strait Environment Plan Volumes 2 and 3.

The following definitions are used in this section, as defined in Regulation 4 of the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009 (OPGGS(E)R):

- EPO – a measurable level of performance required for the management of environmental aspects of an activity to ensure that environmental impacts and risks will be of an acceptable level (i.e. a statement of the environmental objective);
- EPS – a statement of the performance required of a control measure; and
- Measurement criteria (not defined in the regulations) – defines how environmental performance will be measured such that the measurement can be used to determine whether the EPS and EPO have been met.

1.2 Environment Performance – Operations

1.2.1 Operations

Table 1-1 Environmental Performance - Operations

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Platform Operations Pipeline Operations Subsea facility operations	Physical Presence	Change to the function, interests or activities of other users	Limit interference with other marine users to the extent necessary for the reasonable exercise of the right conferred by the titles granted. Property is removed as soon as reasonably practicable, taking into account environmental and safety risks, cost efficiency and execution planning. Property is maintained so as not to preclude its removal.	**CM6:** Temporary Storage Assessment	Facilities, pipelines and equipment that have reached the CoP stage of operations (or are deemed 'out of service' during production operations) and where removal is not reasonably practicable prior to a Heavy Lift Vessel campaign will be subject to a Temporary Storage Assessment to ensure that environmental and safety risks continue to be reduced to ALARP and acceptable levels.	Temporary storage assessment which demonstrates environmental and safety risks continue to be reduced to ALARP and acceptable levels.
				CM70: The Subsea Material Register (SMR) will be reviewed by the Marine Group against the scope, location and operational capability of each vessel as they become available.	The Marine Group incorporates the recovery of property/material into the Vessel Synergies Planner to identify opportunities for the removal of subsea property (where possible).	The planned recovery of property/material is documented in the Integrated Marine Schedule Planner for execution. Documentation of recovery is recorded in the SMR.
				CM1: Maintenance activities for facilities already at CoP are implemented in accordance with s572 (2) requirements.	A review of decommissioning critical inspection and maintenance controls will be undertaken and implemented by 1Q, 2022 retrospectively for facilities already in CoP to ensure property is maintained to reduce environmental risks to ALARP and acceptable levels and so as not to preclude its future removal.	Documented Section 572 (2) Maintenance review for all facilities already in CoP.
				CM1a: Post CoP maintenance activities are implemented for facilities as they are assessed prior to reaching CoP stage in accordance with s572 (2) requirements	A Section 572 (2) maintenance review is undertaken to identify decommissioning critical inspection and maintenance activities (post CoP) for all facilities as part of the preparation prior to moving into CoP stage to ensure property is maintained to reduce environmental risks to ALARP and acceptable levels and so as not to preclude its future removal. This process will be in place by 1Q 2021.	Documented Section 572 (2) Maintenance review for all facilities prior to reaching CoP.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Platform Operations	Emissions to Air	Change in air quality Injury / mortality to fauna	Limit emissions to air so that impacts to air quality will be localised to the source. Limit injury or harm to fauna from air emissions.	**CM30:** Offshore Technical Monitoring Program	Monthly surveillance of fuel and flare trends identifies abnormalities and response actions taken to address abnormalities.	PS&O Technical Monitoring report documents the identification and significance of abnormalities and any action items required to address abnormalities or potential improvement opportunities.
Platform Operations Subsea facilities operations	Planned Discharge - Operational Fluids	Change in water quality Injury / mortality to fauna	Limit operational fluids discharge to water so that impacts to water will be localised to the source (e.g. pile window, subsea wellhead). Limit injury or harm to fauna from operational discharges to water.	**CM3:** Chemical Discharge Assessment Process	Chemicals planned for discharge are evaluated as acceptable in accordance with the Chemical Discharge Assessment Process.	Chemicals approved for use and discharge list confirms the fluids meet criteria for discharge.
				CM47: Monitoring of chemical use in accordance with Corrosion Control & Chemical Injection program	Chemical Injection, including exceptions or anomalies, is monitored in accordance with the Corrosion Control & Chemical Injection Program.	OFC report shows any exceptions or anomalies to chemical injection, is prepared monthly and is signed-off by the appropriate level of management.
				CM46: Maintenance and testing of Open and Closed Skimmer Piles	Maintenance and inspection of open and closed skimmer pile equipment will occur in accordance with the FIMS equipment strategies and as scheduled in IPES. Pile equipment includes pumps, level indicators and instrumentation. • Maintenance and inspection plans for open and closed skimmer pile equipment which are in exception must be reviewed and endorsed by the Offshore Risk, Environment and Regulatory Supervisor to ensure that potential risk posed by the deferral is mitigated or alternate controls are in place to prevent potential environmental incidents	Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management. Offshore Risk, Environment and Regulatory Supervisor endorsement provided for the Environment section of report.
				CM36: Pre Start notifications	Relevant stakeholders are notified of scheduled Pipeline and Subsea IMR activities each quarter and again one week prior to commencement.	Stakeholder consultation records confirm that information regarding Gippsland Basin scheduled Pipeline and Subsea IMR activities was conveyed to relevant stakeholders in required timeframes.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
				CM68: Environmental Sampling	Sediment and water sampling will be designed and executed in accordance with relevant guidelines and will occur within 2 years from acceptance of this Environment Plan at the following facilities: • CBA • HLA • SNA Sediment and water sampling will occur within 2 years from commissioning of the water handling system at MLB	Sediment and water sampling report
				CM69: Sampling of KPA Gas to monitor mercury concentrations	Bi monthly sampling results demonstrate mercury in KPA gas remains below spec. Should sampling return results above spec, additional sampling is implemented and offshore discharges cease (as required)	Bi-monthly sampling results.
Platform Operations	Produced Formation Water	Change in water quality Change in sediment quality Injury / mortality to fauna Change in habitat Change to the function, interests or activities of other users	At the edge of and beyond the mixing zone, ANZECC 99% species protection water quality and ISQL 'low' sediment quality criteria and/or be within natural variation or background concentrations PFW discharge (within and beyond the mixing zone) will have: - no significant impacts to MNES (per Significant Impact Guidelines [DOE, 2013]) - no direct impact to benthic habitat - no taint of fisheries stock	**CM43:** PFW processed though secondary separation equipment	PFW is processed through secondary separation equipment before being discharged overboard. The online monitor reads <30 mg/L using UV fluorescence for the OIW 24 hour average.	Records demonstrate that the online monitor or substitute manual sampling was reading <30 mg/L 24 hour average OIW levels
				CM67: Surveillance of the treatment system	Monthly surveillance of water handling trends reviews that operation of facilities is within design envelope, identifies abnormalities and response actions taken to address abnormalities as required, as well as potential improvement opportunities.	PS&O Technical Monitoring report documents the identification and significance of abnormalities and any action items required to address abnormalities or potential improvement opportunities
				CM3: Chemical Discharge Assessment Process	Chemicals discharged through the water handling system will be evaluated as acceptable in accordance with the Chemical Discharge Assessment Process (as defined in Section 2.7.2).	Chemicals approved for use and discharge list confirms the fluids meet criteria for discharge.
				CM10a: OIW levels of the discharge stream is continuously monitored and maintained at concentrations below 30 mg/L 24 hour average	Monitoring of the water overboard is per procedure GEN-100-102. This includes: a. Online monitor reads <30 mg/L OIW 24 hour average using UV fluorescence b. The 24 hour average of the on-platform verification checks (InfraCal) using infrared	Records demonstrate that the online monitor or substitute manual sampling was reading <30 mg/L 24 hour average OIW levels

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
			- no seafood is unsafe for human consumption - no interference with commercial fishing operations		spectrophotometry methods also read <30 mg/L c. If an online monitor is not available, then hourly samples using infrared spectrophotometry methods is taken d. Daily oil load is limited to loadings specified in Table F-69 in Volume 2 Appendix F.7, as calculated by either the online oil-in-water monitor or the on-platform verification checks (6-hourly) using infrared spectrophotometry methods e. Discharges of 24 hour average OIW 25-30 mg/L (not inclusive) or daily oil load in the actionable range (specified in Table F-69 in Volume 2 Appendix F.7) are flagged on a daily basis	Records demonstrate that an online monitor was available, or manual sampling was performed Records demonstrate that the platform specific oil load was met Morning report shows a yellow traffic light if platform discharges are within the ranges specified.
				CM10b: Online monitor is calibrated	Calibration is undertaken per procedure GEN-100-102 and lab procedure *GL3 Oil and Grease Analysis*. This includes: a. Acid is added to samples for effective preservation b. A monthly crosscheck sample within the tolerance limits of +/- 6 mg/L compared to the Sigrist and InfraCal must be obtained within a given calendar month for any discharge occurring within that month of >48 hrs total duration c. If monthly lab test is not within expected tolerance limits or is >36 mg/L, a second sample is taken, the Sigrist is serviced and a calibration check performed using a calibration rod d. Turnaround time of the laboratory tests is within 7 days of platform sampling in order to facilitate timely response e. 6 hourly InfraCal results are within +/- 6 mg/L of the Sigrist reading and if not, the Sigrist is cleaned and another InfraCal sample taken and analysed. If the retest difference is still >6 mg/L, the Sigrist is	Records of pH at LFD Lab demonstrate that acid has been added to all samples Records demonstrate cross-check of the online OIW analyser with the onshore laboratory is undertaken each month where a discharge of >48 hours total duration occurred. Records demonstrate that the tolerance limits were met, or another sample was taken and a service and calibration was performed Records demonstrate samples were assessed and notice sent back to the platform within 7 day of platform sampling Records demonstrate that the tolerance limits were met, or the unit was cleaned and reanalysed and passed;

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					serviced and a calibration check performed using a calibration rod f. The lab conducting the calibration is qualified to conduct the GL3 Oil and Grease analysis procedure	Records show on the third fail test appropriate corrective action was taken. Monthly sample proforma indicates that GL3 Oil and Grease analysis was followed
				CM10c: Online monitor is serviced	The online monitor is serviced routinely as per the frequency defined in IPES equipment strategy.	Records in IPES show the servicing of the online monitor were performed.
				CM38: Sigrist alarm and shutdown function is tested	Sigrist oil in water monitor shutdown function tested in accordance with Critical Function Test Manual and as scheduled in IPES • Sigrist and oil-in-water monitor shutdown function tests to be marked as environmental critical tasks • Tests for Sigrist alarm and function testing which are in exception must be reviewed and endorsed by the Offshore Risk, Environment and Regulatory Supervisor to ensure that: - any risk posed by the deferral is mitigated; or - alternate controls are in place to prevent potential environmental incidents	Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management. Offshore Risk, Environment and Regulatory Supervisor endorsement provided for the Environment section of report.
				CM10d: Discharge of water on start-up is controlled	Competent operators manage startup which is controlled according to procedure XXX-100-302 (where XXX is the platform name). Qualification required is Offshore Operations Technician 1 competency.	Records show operators are competent to manage water handling startup and discharge overboard.
				CM11: Apply the PFW monitoring and management framework procedure	The adaptive management regime is implemented to monitor and manage ongoing discharge of PFW. It is described in 2.7.5.1 and consists of: • Annual compositional sampling and analysis • Annual microtox testing • Three yearly WET testing sampling and analysis • Implementation of management measures as required • Additional sampling/modelling as required	Routine monitoring has been conducted as per frequencies defined in this. Monitoring, modelling, adaptive management and/or other assessments demonstrate that the EPS is met.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					• For MLB platform, should overboard water discharge be required, six-monthly composition testing for the first two years from the platform PFW stream will also be applied. • For MLB platform, should overboard water discharge be required, WET testing is performed within 6 months of commissioning.	
				CM68: Environmental Sampling	Sediment and water sampling will be designed and executed in accordance with relevant guidelines and will occur within 2 years from acceptance of this Environment Plan at the following facilities: • CBA • HLA • SNA Sediment and water sampling will occur within 2 years from commissioning of the water handling system at MLB.	Sediment and water sampling report
Platform Operations	Accidental Release - Dropped Objects	Change in habitat	Limit impacts to habitat caused by dropped objects to a localised area.	**CM41**: Crane maintenance and inspection programs developed and actioned per FIMS process	Crane maintenance and inspection is carried out within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Maintenance and inspection plans are developed per Crane Operations, Maintenance and Inspection Manual (COMI) and are scheduled in IPES This includes maintenance and inspection of: • Cranes • Rigging and lifting gear • Testing of equipment Integrity Program compliance is monitored and managed through the IPES Exception Reporting process	IPES – computerised maintenance management system status reviewed and reported monthly. Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management as defined by FIMS process. IMPACT database record of incidents shows no crane integrity failure related incidents
				CM42: Crane Operations, Maintenance and Inspection Manual	All lifting operations to be conducted in accordance with the Lifting Procedures. This includes requirements for: • Qualification of crane operators/ doggers/riggers	PTW records for lifting operations

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
				(COMI) - Lifting Procedures	• Checking that equipment is in test • Load weights / safe working loads	
Platform Operations Subsea facilities Operations Pipeline Operations	Accidental Release – LOC (chemicals / hydraulic fluids)	Change in water quality Injury / mortality to fauna	No spills to the environment	**CM66:** PTW system	Operations conducted under PTW (including JSA) • May include operations procedures where they exist for the task	PTW records
				CM44: Bunding	Oil and chemical stores are located within a deck bund, and water-soluble chemicals not approved for discharge are stored in a bund that is isolated from drain/pile.	Operator first day on checks
				CM13: Platform induction process (Greencard)	All personnel are aware of spill clean-up requirements and have access to spill kits.	Greencard demonstrates that spill clean-up requirements and location of spill kits are communicated to all offshore personnel.
				CM3: Chemical Discharge Assessment Process	Firefighting foams planned for discharge are evaluated as PFAS free and acceptable in accordance with the Chemical Discharge Assessment Process.	Chemicals approved for use and discharge list confirms the foams meet criteria for discharge.
				CM12: OPEP	Emergency response activities will be implemented in accordance with the OPEP.	Records confirm that emergency response activities have been implemented in accordance with the OPEP.
Platform Operations	Accidental Release - Waste	Change in habitat Injury / mortality to fauna	Limit impacts to habitat caused by accidental release of waste to a localised area.	**CM13:** Platform induction process (Greencard)	All personnel are aware of waste management requirements and have access to relevant waste receptacles.	Greencard demonstrates that waste management requirements and location of receptacles are communicated to all offshore personnel.
				CM45: Waste Management Manual	Waste is stored and handled in accordance with the Waste Management Manual which includes measures to prevent overboard release of waste: • Prohibition of discharge of waste to the sea • Storage and handling procedures for each type of waste generated including documentation requirements for handling,	IMPACT database records show there have been no incidences of waste managed in a way that is not in accordance with waste management procedures.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					storage, and disposal of hazardous materials. • Receptacles on deck or areas exposed to the weather should be secured and have lids that are tight and securely fixed.	
Platform Operations	Accidental Release - Bulk Transfer	Injury / mortality to fauna	No spills to the environment	**CM14:** Procedures for bulk transfer of fluids from supply vessels.	Transfers of fluids from supply vessels to be undertaken in accordance with bulk transfer procedures • Handling of hoses - Liquid Loading Hose Transfer Procedure • Liquid Loading ex supply vessel procedure (diesel, glycol & methanol)	PTW records for liquid bulk transfers.
Pipeline Operations	Accidental Release – LOC (pipeline)	Change in water quality Injury / mortality of fauna	No spills to the environment	**CM27**: Support vessel approach procedure	The 500m approach checklist and DP Checklist are completed prior to the vessel entering the 500m PSZ.	Records of the facility 500 m PSZ and DP operational checklists.
				CM28: ASOG / CAMO procedures	Activity Specific Operating Guidelines (ASOG) / Critical Activity Mode (CAMO) procedures developed to IMCA Standard.	Implementation (AFI) procedures signed by Vessel Master.
				CM29: Support vessel DP system	All support vessels engaged in DP operations have Class recognised DP 2/3 notation.	Records of IACS member DP Notation, Failure Mode and Effects Analysis (FMEA), proving trials and Annual Trials.
					Watchkeepers in charge of watch hold DP certification.	Records of watchkeepers DP certificates.
				CM34: NOPSEMA accepted Safety Case	Development and application of Bass Strait Pipeline Network Safety Case including: • identification of a) potential pathways and b) response measures for major accident events from topsides and subsea • identification of critical controls (both preventative and mitigative) for each MAE • development of performance standards for each critical control	Pipeline Network Safety Case Key Performance Indicators

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
				CM55: Corrosion monitoring and control plans for pipelines developed and actioned per FIMS process	Corrosion monitoring and control plans occur within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Maintenance and inspection plans are developed for pipelines per the Equipment and Structural Integrity Manual and are scheduled in IPES Corrosion monitoring may be done via • Fluid sampling • Corrosion probes • Inspection (refer inspection below) Corrosion control plans include: • Sand management • Cathodic protection • Corrosion inhibition Integrity Program compliance is monitored and approved through the IPES Exception Reporting process	IPES – computerised maintenance management system status reviewed and reported monthly Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management as defined by FIMS process IMPACT database record of incidents shows no pipeline equipment integrity failure incidents.
				CM56: Pipeline inspection and monitoring program developed and actioned per FIMS process	Pipeline inspection and monitoring plans occur within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Plans are developed in accordance with the Pipeline Management Plan and Pipeline Integrity Manual and are scheduled in IPES. This includes: • Underwater pipeline inspection • Leak detection • In-line metal loss surveys Pipeline equipment includes: • Pipelines • Risers • Pipeline launchers and receivers Integrity Program compliance is monitored and approved through the IPES Exception Reporting process	

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
				CM42: Crane Operations, Maintenance and Inspection Manual (COMI) - Lifting Procedures	All lifting operations to be conducted in accordance with the Lifting Procedures. This includes requirements for: • Qualification of crane operators/ doggers/riggers • Checking that equipment is in test • Load weights / safe working loads	PTW records for lifting operations
				CM40: Flag State lifting requirements	Vessel lifting equipment maintenance standards and procedures undertaken in accordance with vessel Flag state requirements (e.g. Australia: Marine Order 32 - Cargo handling equipment).	Vessel lifting gear register confirms compliance with relevant Flag State requirements. Vessel SMS includes lifting standards and procedures consistent with the relevant Flag State.
				CM58: Navigational Chart	Location of pipelines and facilities is plotted on navigational chart AU357	Navigational chart AUS357 shows locations of pipelines and facilities.
				CM59: Observation during helicopter flights	Helicopters pilots are required to immediately report spills /sheens seen during flights	Incident records describe how spills/sheens were detected.
			Minimise the impact on the environment from a LOC	**CM12**: OPEP	Emergency response activities will be implemented in accordance with the OPEP.	Records confirm that emergency response activities have been implemented in accordance with the OPEP.
				CM35: OSMP	Operational and scientific monitoring will be implemented in accordance with the OSMP.	Records confirm that operational and scientific monitoring have been implemented in accordance with the OSMP.
				CM57: Isolation test plan for pipeline isolation valves developed and actioned per FIMS process	Pipeline isolation mechanisms tested within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Plans are developed in accordance with Critical	IPES – computerised maintenance management system status reviewed and reported monthly Monthly exception reports shows any overdue

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					Function Testing Management and are scheduled in IPES Integrity Program compliance is monitored and approved through the IPES Exception Reporting process.	maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management per FIMS process IMPACT database record of incidents shows no pipeline equipment integrity failure incidents.
			Minimise the impact on commercial fisheries from a LOC	**CM51:** Utilisation of idle fishing vessels	Opportunities to utilise idle fishing vessels, if deemed suitable, for oil spill response and monitoring activities will be taken where there is agreement of the vessel owner and where a risk assessment shows that there are no additional risks to vessels and crew.	IMT records reflect communications with fishing industry looking for opportunities to utilise idle fishing vessels
				CM52: Communication with fisheries	Updates on oil spill response and monitoring provided to fishery representative bodies (through SETFIA) to enable accurate information on spill status, impacts and effects of spilled hydrocarbons on seafood safety to be provided to fishing industry members and the public. Daily updates provided in the first week until the modelling is completed and then as needed, until source control has been achieved (and beyond if there is ongoing concern).	IMT records reflect communications with SETFIA.
Platform Operations	Accidental Release - LOC (bulk storage topside)	Change in water quality Injury / mortality to fauna	No spills to the environment	**CM39:** Equipment strategies for pressure equipment developed and actioned per FIMS process	Inspection and condition monitoring occurs within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Plans are developed in accordance with requirements of Pressure Equipment Inspection Program Manual. Equipment strategies for pressure equipment and are scheduled in IPES. This may include • PSV function checks • Corrosion inspection • Piping (external and internal) • Vessel inspection	IPES – computerised maintenance management system status reviewed and reported monthly Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management per FIMS process

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					Pressure equipment includes: • Tanks (DGI) (atmospheric including jacket leg storage) • Pressure vessels Integrity Program compliance is monitored and approved through the IPES Exception Reporting process	IMPACT database record of incidents shows no pressure equipment integrity failure incidents.
				CM54: Change out of IBC operating procedures	Change out of IBC conducted in accordance with relevant operating procedure • Changing Out Diesel Bulky Packs • Change out of Chemical Bulk containers	PTW records for liquid bulk transfers
				CM12: OPEP	Emergency response activities will be implemented in accordance with the OPEP.	Records confirm that emergency response activities have been implemented in accordance with the OPEP.
Platform Operations	Accidental Release – LOC from drain system	Change in water quality Injury / mortality to fauna Change to the function, interests or activities of other users.	No spills to the environment	**CM46**: Maintenance and testing of Open and Closed Skimmer Piles	Maintenance and inspection of open and closed skimmer pile equipment will occur in accordance with the FIMS equipment strategies and as scheduled in IPES. Pile equipment includes pumps, level indicators and instrumentation. Maintenance and inspection plans for open and closed skimmer pile equipment which are in exception must be reviewed and endorsed by the Offshore Risk, Environment and Regulatory Supervisor to ensure that potential risk posed by the deferral is mitigated or alternate controls are in place to prevent potential environmental incidents	Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management. Offshore Risk, Environment and Regulatory Supervisor endorsement provided for the Environment section of report.
				CM49: Equipment strategies for equipment with protective instruments developed and actioned per FIMS process	Testing program for protective instruments occurs per requirements of FIMS Critical Function Testing Management Manual and are scheduled in IPES This includes tests for: • Pump shutdowns • Discharge valve closures • Surface shutdown Testing programs which are in exception must be reviewed and endorsed by the Offshore Risk,	

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					Environment and Regulatory Supervisor to ensure that potential risk posed by the deferral is mitigated or alternate controls are in place to prevent potential environmental incidents	
				CM50: Closed Drain and Open Drain Piles procedures.	Monitor and respond to Central Control Panel (CCP) indicators for pile operation in accordance with pile procedures to manage operational changes and prevent incidents.	Impact database records incidents associated with piles.
				CM30: Offshore Technical Monitoring Program	Quarterly monitoring of pile trends identifies abnormalities and response actions taken to address abnormalities as required.	PS&O Technical Monitoring report documents the identification and significance of abnormalities and any action items required to address abnormalities.
				CM71: Dosing of piles with emulsion breaker	Where potential for emulsion in piles is identified (either through Offshore Technical Monitoring Program or Testing of Pile systems), application of emulsion breaker is implemented. Effectiveness of emulsion breaker dosing is monitored (per procedure GEN-110-201)	PS&O Technical Monitoring reports or FIMS testing records identify potential presence of emulsions (as required) Platform logs demonstrate effectiveness of emulsion dosing was monitored

1.2.2 Wellwork

Table 1-2 Environmental Performance – Wellwork

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Wireline / Workover Activities (general)	Emissions to Air	Change in air quality Injury / mortality to fauna	Limit emissions to air so that impacts to air quality will be localised to the source. Limit injury or harm to fauna from air emissions.	**CM4:** Wireline / Workover work scope or plan.	Gas will be flared / vented as per Wireline / Workover work scope or plan.	Workover program shows a plan for flaring / venting is in place, as needed Daily records demonstrate that workover program has been followed.
Wireline / Workover Activities (general) Conductor cutting and pulling Conductor Clean-out Sandwash	Planned Discharge – Operational Fluids	Change in water quality Change in sediment quality Injury / mortality to fauna	Limit operational fluids discharge to water and sediment so that impacts will be localised to the source. Limit injury or harm to fauna from operational discharges to water.	**CM3:** Chemical Discharge Assessment Process	Chemicals planned for discharge are evaluated as acceptable in accordance with the Chemical Discharge Assessment Process.	Chemicals approved for use and discharge list confirms the fluids meet criteria for discharge.
Cementing	Planned Discharge – Cement	Change in water quality Change in sediment quality	Limit impacts to water and sediment caused by discharge of cement to a localised area.	**CM3:** Chemical Discharge Assessment Process	Chemicals planned for discharge are evaluated as acceptable in accordance with the Chemical Discharge Assessment Process.	Chemicals approved for use and discharge list confirms the fluids meet criteria for discharge.
Conductor Clean-out Sandwash	Planned Discharge – Solids	Change in water quality	Limit impacts to water quality from wellwork solids discharges to a localised area.	**CM5:** Collection and onshore disposal of solids.	Solid collection equipment (such as filters, sieves and settling vessels) is used when completing wellwork activities in order to capture solids for onshore disposal, so far as reasonably practicable, as per Wireline / Workover work scope or plan	Workover program shows a plan for the collection of solids as needed. Daily records demonstrate that workover program has been followed.
Wireline / Workover	Accidental Release -	Change in habitat	Limit impacts to habitat caused by	**CM41**: Crane maintenance and	Crane maintenance and inspection is carried out within the parameters defined in FIMS to prevent serious SHE	IPES – computerised maintenance management

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Activities (general) Conductor cutting and pulling	Dropped Objects		dropped objects to a localised area.	inspection programs developed and actioned per FIMS process	risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Maintenance and inspection plans are developed per Crane Operations, Maintenance and Inspection Manual (COMI) and are scheduled in IPES This includes maintenance and inspection of: • Cranes • Rigging and lifting gear • Testing of equipment Integrity Program compliance is monitored and approved through the IPES Exception Reporting process	system status reviewed and reported monthly. Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management as defined by FIMS process. IMPACT database record of incidents shows no crane integrity failure related incidents
				CM42: Crane Operations, Maintenance and Inspection Manual (COMI) - Lifting Procedures	All lifting operations to be conducted in accordance with the Lifting Procedures Includes requirements for • Qualification of crane operators/ doggers/riggers • Checking that equipment is in test • Load weights / safe working loads	PTW records for lifting operations
Wireline / Workover Activities (general)	Accidental Release - LOC (chemicals / hydraulic fluids)	Change in water quality Injury / mortality to fauna	No spills to the environment	**CM15:** Preventative Maintenance System	Equipment used for wellwork activities is maintained in accordance with the relevant PMS (contractor or Esso dependent on equipment).	Records demonstrate maintenance has been conducted in accordance with the relevant PMS.
Wireline / Workover Activities (general)	Accidental Release - Loss of Well Control	Change in water quality Injury / mortality to fauna	No spills to the environment	**CM32:** NOPSEMA accepted Well Operations Management Plan (WOMP)	The NOPSEMA accepted WOMP demonstrates how the risks to the integrity of the wells will be reduced to as low as reasonably practicable (ALARP). This includes: • Two barriers have been maintained	Records confirm a NOPSEMA-accepted WOMP was in place before operations commenced.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Platform Operations Subsea Facility Operations		Change in habitat Change to the function, interests or activities of other users.			• Barrier integrity is tested and verified. • And that suspended wells are left in a safe state.	Records demonstrate that operations take place in accordance with processes described in the WOMP.
				CM33: Wellwork Execution Manual (WEM)	Wellwork procedures are prepared in accordance with the WEM for each wellwork activity and consider: • well design; • fluid selection; and • formation pressures, to ensure that there are two barriers in the well at any time. Procedures are signed off at appropriate level of management	Records demonstrate that a wellwork procedure has been prepared and signed off by the appropriate level of management before wellwork operations have commenced. Records demonstrate that operations take place in accordance with processes described in the procedure.
					The workover program outlines the well control equipment to be used.	Records demonstrate that well control equipment was tested prior to wellwork operations
				CM34: NOPSEMA accepted Safety Case	The NOPSEMA accepted Safety Case demonstrates how the risks to the integrity of the wells will be reduced to as low as reasonably practicable (ALARP). This includes: • Planned maintenance of pressure well control equipment • Testing of well control equipment • Validation of activity specific safety critical equipment	Records confirm a NOPSEMA-accepted safety case was in place before operations commenced. Records demonstrate that operations have taken place in accordance with processes described in the Safety Case.
				CM48: Well Integrity Management System (WIMS)	Periodic pressure monitoring, testing, preventative maintenance and downhole corrosion control is conducted in accordance with the Well Integrity Management System to ensure no loss of containment due to wellbore integrity failure or wellbore equipment failure.	The Wellbore Integrity Testing Exception Report shows any overdue testing and potentially increased wellbore integrity risks, is prepared ~~monthly~~ and is signed-off by the appropriate level of management.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
			Minimise the impact on the environment from a LOWC	**CM12:** OPEP	Emergency response activities will be implemented in accordance with the OPEP.	Records confirm that emergency response activities have been implemented in accordance with the OPEP.
				CM35: OSMP	Operational and scientific monitoring will be implemented in accordance with the OSMP.	Records confirm that operational and scientific monitoring have been implemented in accordance with the OSMP.
				CM60: Isolation test plan for platform shutdowns and subsurface isolation valves developed and actioned per FIMS process	Subsurface isolation mechanisms tests carried out within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Isolation test plan developed in accordance with Critical Function Testing Management Manual and are scheduled in IPES Integrity Program compliance is monitored and approved through the IPES Exception Reporting process.	IPES – computerised maintenance management system status reviewed and reported monthly. Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management as defined by FIMS process. IMPACT database record of incidents shows no subsurface isolation valve incidents
				CM61: Well Kill Contingency Plan	A Well Kill Contingency Plan has been prepared to ensure emergency response activities can be implemented in the event of a LOWC.	Records demonstrate that a Well Kill Contingency Plan is in place.
				CM62: Drilling Emergency Preparedness and Response (EP&R) Manual	Incident specific Emergency Response Plan (ERP) is prepared prior to relief well being drilled in accordance with the Drilling EP&R Manual, Appendix C2 which includes details of: • Relief well planning	Records demonstrate an incident specific ERP is prepared in the event of an incident which requires drilling a relief well.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					• Sourcing available rigs • Required resources • Notification • First Action checklists	Records demonstrate response activities have been implemented as described in the incident specific response plan.
				CM63: Monitoring relief well rig availability.	A register of the status and location of suitable rigs to drill relief wells will be maintained to ensure availability of rigs to meet committed relief well drilling timeframes (98 days as per Volume 2 Section 7.7).	A register of suitable rigs to drill relief wells is maintained and updated on a quarterly basis.
			Minimise the impact on commercial fisheries from a LOWC	**CM51:** Utilisation of idle fishing vessels	Opportunities to utilise idle fishing vessels, if deemed suitable, for oil spill response and monitoring activities will be taken where there is agreement of the vessel owner and where a risk assessment shows that there are no additional risks to vessels and crew.	IMT records reflect communications with fishing industry looking for opportunities to utilise idle fishing vessels
				CM52: Communication with fisheries	Updates on oil spill response and monitoring provided to fishery representative bodies (through SETFIA) to enable accurate information on spill status, impacts and effects of spilled hydrocarbons on seafood safety to be provided to fishing industry members and the public. Daily updates provided in the first week until the modelling is completed and then as needed, until source control has been achieved (and beyond if there is ongoing concern).	Stakeholder consultation records show communication with SETFIA per the performance standard.

1.2.3 Inspection, Maintenance and Repair

Table 1-3 Environmental Performance – Inspection, Maintenance and Repair (IMR)

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Pipeline and Subsea IMR	Physical Presence - Interference with Other Marine Users	Change to the function, interests or activities of other users	Limit interference with other marine users to the extent necessary for the reasonable exercise of the right conferred by the titles granted.	**CM31:** Temporary storage will occur within an existing PSZ or 200m operational zone around pipelines	Equipment or infrastructure temporary stored on the seabed within PSZ or 200m operational zone around pipelines.	Subsea Material Register showing locations of temporary stored equipment.
				CM36: Pre Start notifications	Pipeline and Subsea IMR activities occurring outside platform designated PSZs will notify AMSA JRCC before operations commence to enable AMSA to distribute an AUSCOAST warning.	Records confirm that information to distribute an AUSCOAST warning was provided to the JRCC before operations commenced.
					Relevant stakeholders are notified of scheduled Pipeline and Subsea IMR activities each quarter and again one week prior to commencement.	Stakeholder consultation records confirm that information regarding Gippsland Basin scheduled Pipeline and Subsea IMR activities was conveyed to relevant stakeholders in required timeframes.
Pipeline and Subsea IMR	Physical Presence – NORM	Change in habitat	Limit impacts to habitat caused by presence of NORM to a localised area.	**CM6:** Temporary Storage Assessment	A Temporary Storage Assessment will be undertaken which will assess technical and environmental considerations associated with management of NORM.	Temporary Storage Assessment
	Physical Presence – Seabed disturbance	Change in habitat	Avoid physical damage to habitats (i.e. benthic features such as epifauna).	**CMP37:** Post campaign ROV inspection	ROVs will inspect the seafloor post pipeline or Subsea IMR campaigns to confirm that no unplanned equipment has been left on the seabed and that it is removed where practicable.	ROV campaign reports note that any identified dropped objects, debris or equipment that was not planned to be left has been removed where practicable

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Facility IMR Pipeline and Subsea IMR	Planned Discharge - Operational Fluids	Change in water quality Injury / mortality to fauna	Limit operational fluids discharge to water so that impacts to water will be localised to the source. Limit injury or harm to fauna from operational discharges to water.	**CM3:** Chemical Discharge Assessment Process	Chemicals planned for discharge are evaluated as acceptable in accordance with the Chemical Discharge Assessment Process.	Chemicals approved for use and discharge list confirms the fluids meet criteria for discharge.
Facility IMR Pipeline and Subsea IMR	Planned Discharge – Solids	Change in water quality	Limit impacts to water quality caused by discharge of solids to a localised area.	**CM7:** Abrasive blasting SWP 50.101	Abrasive blasting area is contained to capture solids and fines as far as practicable. Captured material is sent to shore for disposal.	PTW records demonstrates solids have been contained as far as practicable.
Facility IMR	Unplanned interaction with fauna	Change in fauna behaviour	No substantial adverse effect to the population of a listed species caused by unplanned interaction with fauna.	**CM16:** SWP 50.139.A1 – Drone Operation Offshore	Drone operators must check for presence of wildlife in the work area to ensure suitable flight route planning and positioning of drone.	PTW records demonstrate that Inspection Drone Operation Checklist has been completed.
				CM17: SWP 50.313 – Sea Deck Access	Access to sea deck is restricted and approval from the supervisor must be sought prior to accessing the area. Access is only allowed in pairs and personnel must communicate with supervisors upon entry to and exit from the area	IMPACT database records show that there has been no unauthorised access to sea deck that resulted in injury or death of wildlife.
				CM13: Platform Induction Process (Greencard)	All personnel are aware of platform restricted areas, including sea deck.	Greencard demonstrates that platform restricted areas have been communicated to all offshore personnel.
				CM53: Onboarding process	All personnel pass through an on boarding process, and placement takes into account a background check.	Records show all personnel have been through the applicable on boarding process.
Facility IMR Pipeline and	Accidental Release – Dropped Objects	Change in habitat	Limit impacts to habitat caused by dropped objects to a localised area.	**CM41**: Crane maintenance and inspection programs developed and actioned per FIMS process	Crane maintenance and inspection is carried out within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Maintenance and inspection plans are developed per	IPES – computerised maintenance management system status reviewed and reported monthly.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Subsea IMR					Crane Operations, Maintenance and Inspection Manual (COMI) and are scheduled in IPES This includes maintenance and inspection of: • Cranes • Rigging and lifting gear • Testing of equipment Integrity Program compliance is monitored and approved through the IPES Exception Reporting process	Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate level of Operations Management as defined by FIMS process. IMPACT database record of incidents shows no crane integrity failure related incidents
				CM42: Crane Operations, Maintenance and Inspection Manual (COMI) - Lifting Procedures	All lifting operations to be conducted in accordance with the Lifting Procedures. Includes requirements for • Qualification of crane operators/ doggers/riggers • Checking that equipment is in test • Load weights / safe working loads	PTW records for lifting operations
				CM40: Flag State lifting requirements	Vessel lifting standards and procedures undertaken in accordance with the Flag state requirements (e.g. Australia: Marine Order 32 - Cargo handling equipment).	Vessel lifting gear register confirms compliance with relevant Flag State requirements. Vessel SMS contain lifting procedures consistent with the standard required of the Flag State.
Facility IMR Pipeline and Subsea IMR	Accidental Release – LOC (chemicals / hydraulic fluids)	Change in water quality Change in habitat Injury / mortality to fauna	No spills to the environment	**CM64** Equipment Strategies for subsea facilities developed and actioned per FIMS process.	Inspection and condition monitoring is carried out within the parameters defined in FIMS to prevent serious SHE risks (Consequence Category 1 or 2), including a process for managing plans that are in exception. Equipment strategies developed in accordance with requirements of Subsea Equipment Integrity manual and are scheduled in IPES. Subsea facilities includes: ○ Wellhead ○ Tie-in spools	IPES – computerised maintenance management system status reviewed and reported monthly. Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with action signed-off by the appropriate

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					○ Umbilicals, terminations and flying leads ○ Subsea control modules ○ Subsea topside controls ○ Instrumentation ○ Hydraulic and utility chemical system Integrity Program compliance is monitored and approved through the IPES Exception Reporting process	level of Operations Management as defined by FIMS process. IMPACT database record of incidents shows no subsea facility incidents
				CM44: Bunding	Oil and chemical stores are located within a deck bund, and water-soluble chemicals not approved for discharge are stored in a bund that is isolated from drain/pile.	Operator first day on checks
				CM13: Platform induction process (Greencard)	All personnel are aware of spill clean-up requirements and have access to spill kits.	Greencard demonstrates that spill clean-up requirements and location of spill kits are communicated to all offshore personnel.
				CM66: PTW system	Maintenance works conducted under PTW (including JSA) • May include maintenance procedures where they exist for the task	PTW records

1.2.4 Support Operations

Table 1-4 Environmental Performance – Support Operations

<table>
<tr><th>Activity</th><th>Aspect</th><th>Impact</th><th>Environmental Performance Outcome (EPO)</th><th>Control</th><th>Environmental Performance Standard (EPS)</th><th>Measurement Criteria</th></tr>
<tr><td rowspan="4">Vessel Operations
Helicopter Operations</td><td rowspan="4">Underwater Sound Emissions</td><td rowspan="4">Change in ambient noise
Change in fauna behaviour</td><td rowspan="4">Prevent injury, harm or interference to cetaceans from sound emissions during vessel operations</td><td>CM8: Vessel Master</td><td>Vessel Master is aware and implements EPBC interaction management actions consistent with the EPBC Regulations 2000 – Part 8 Division 8.1
• Vessels will not knowingly travel faster than 6 knots within 300m of a whale or 150 m of a dolphin
• Vessels will not knowingly get closer than 100m of a whale or 50m of a dolphin
• If a cetacean approaches the vessel within the above zones, the vessel will avoid rapid changes in engine speed or direction.</td><td>Daily operations reports record when cetaceans were sighted in the caution zone and interaction management actions implemented.</td></tr>
<tr><td rowspan="2">CMP26: Fauna Observations</td><td>Vessel bridge watch officers will undertake noise mitigation training for whales which will include
a. requirements of noise management procedure (CMP33).
b. whale observation and identification and distance measurement and reporting</td><td>Training records confirm that vessel bridge watch officers are trained in the noise management procedure (CMP33).</td></tr>
<tr><td>Crew members on active duty will report observations of megafauna to bridge watch officers as soon as it is safe to do so.</td><td>Daily reports confirm recordings of cetacean sightings</td></tr>
<tr><td>CMP33:
Noise Management</td><td>During the peak Southern Right Whale (SRW) period of May to October inclusive and during daylight hours:
A. vessel bridge watch officers will observe* for whales within a radius of the vessel; and
B. When safe to do so, the activities listed below will not commence unless no</td><td>Daily reports confirm recordings of SRW sightings, and actions taken as a result of sightings are consistent with the noise management procedure</td></tr>
</table>

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					SRW are observed for a continuous 30 minutes: i. Bringing supply vessel alongside platform during conductor cutting ii. Subsea IMR activities with noise e.g., cutting, grinding **observations can reasonably be made within a range of 0 to 6 km dependent on conditions (DEWHA, 2008)* C. If supply vessel is alongside a platform during conductor cutting, or If Subsea IMR activities with noise are underway, and If a SRW whale is sighted, and Where safe to do so: i. The vessel which is alongside the platform will move to a safe position away from the platform and away from the direction of the SRW or ii. Subsea IMR noise generating activities will be stopped, until the SRW whale moves out of sight or when 30 mins have lapsed since the last sighting. D. During night-time or at times of when visibility is limited to less than 3 km: i. Vessel operations alongside a platform or Subsea IMR activities with noise may proceed provided that there have not been any SRW observations during the preceding 24 hour period.	

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
			Prevent injury or harm to marine mammals from sound emissions during helicopter operations	**CMP4**: Helicopter Pilot	Interaction between helicopters and cetaceans within the operational area will be consistent with EPBC Regulations 2000 – Part 8 Division 8.1: Helicopters will not fly lower than 1650ft when within 500m horizontal distance of a cetacean except when landing or taking off and will not approach a cetacean from head on.	Flight reports note when cetaceans were sighted in the caution zone and interaction management actions implemented.
Vessel Operations ROV Operations	Light Emissions	Change in fauna behaviour	Lighting will be limited to that required for safe navigation and work requirements	**CMP30:** Lighting will be limited	Lighting will be limited to that required for safe navigation and work requirements and light spill to sea will be minimised.	Inspection confirms light spill to sea is minimised, except where required for safe work/navigation.
Vessel Operations	Emissions to Air	Change in air quality Injury / mortality to fauna	Fuel combustion equipment complies with the requirements of MARPOL Annex VI	**CM9:** Class certification	Fuel combustion equipment complies with the requirements of MARPOL Annex VI.	Vessels have class certification verified and issued by IACS member.
Vessel Operations	Planned Discharge - Deck Drainage & Bilge	Change in water quality	Bilge discharges from vessels comply with MARPOL Annex I requirements.	**CM9:** Class certification	Bilge discharges from vessels comply with MARPOL Annex I requirements.	Vessels have class certification verified and issued by IACS member.
			Deck drainage discharges comply with MARPOL Annex V requirements.	**CM9:** Class certification	Deck drainage discharges comply with MARPOL Annex V requirements.	Vessels have class certification verified and issued by IACS member.
Vessel Operations	Planned Discharge - Sewage and Grey water	Change in water quality Injury / mortality to fauna	Sewage discharges comply with MARPOL Annex IV requirements.	**CM9:** Class certification	Sewage discharges comply with MARPOL Annex IV requirements.	Vessels have class certification verified and issued by IACS member.
Vessel Operations	Planned Discharge – Food waste	Change in fauna behaviour	Food waste discharges comply with MARPOL Annex V requirements.	**CM9:** Class certification	Food waste discharges comply with MARPOL Annex V requirements.	Vessels have class certification verified and issued by IACS member.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
Vessel Operations	Unplanned Interaction with Fauna	Injury / mortality to fauna	No substantial adverse effect to the population of a listed species caused by unplanned interaction with fauna.	**CM8:** Vessel Master	Vessel Master is aware and implements EPBC interaction management actions consistent with the EPBC Regulations 2000 – Part 8 Division 8.1 • Vessels will not knowingly travel faster than 6 knots within 300m of a whale or 150 m of a dolphin • Vessels will not knowingly get closer than 100m of a whale or 50m of a dolphin • If a cetacean approach the vessel within the above zones, the vessel will avoid rapid changes in engine speed or direction.	Daily operations reports record when cetaceans were sighted in the caution zone and interaction management actions implemented
				CMP25: Tunnel thruster guards	Grills are fitted to forward (tunnel) thrusters of the DSV to prevent suction / entrapment.	Inspection or drawings confirm vessel forward (tunnel) thrusters fitted with grills.
Vessel Operations ROV Operations	Accidental Release - Dropped Objects	Change in habitat	Limit impacts to habitat caused by dropped objects to a localised area.	**CM18:** Preventative Maintenance System	Visual inspection of lifting gear is undertaken every quarter by a qualified competent person (e.g. maritime officer) and lifting gear is tested regularly in line with the Vessel PMS.	Records verify that inspections and testing have been conducted to schedule.
				CM19: Cargo Securing Manual	All cargo secured in accordance with approved Cargo Securing Manual to prevent loss to sea.	Pre-departure checklist verifies that cargo is securely sea-fastened.
				CM40: Flag State lifting requirements	Vessel lifting standards and procedures undertaken in accordance with the Flag state requirements (e.g. Australia: Marine Order 32 - Cargo handling equipment).	Vessel lifting gear register confirms compliance with relevant Flag State requirements. Vessel SMS contain lifting procedures consistent with the standard required of the Flag State.
Vessel Operations	Unplanned Introduction of IMS	Change in ecosystem dynamics	No introduction and establishment of IMS Limit interference with other marine users to the extent	**CM23:** Ballast Water Management Plan	Ballast Water Management Plan approved in accordance with IMO Ballast Water Management Convention – Australian Guidelines for Ballast Water Management	Ballast Water Management Plan.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
		Change in the functions, interests or activities of other users	necessary for the reasonable exercise of the right conferred by the titles granted.		and Development of Ballast Water Management Plans.	
				CM24: Ballast Water Certificate	Ballast Water Management Certificate approved in accordance with the IMO Ballast Water Convention, including implementation of the D-2 standard per the agreed timeline.	Ballast Water Management Certificate.
				CM25: Biosecurity clearance when entering Australian territory	Vessel Master to obtain biosecurity clearance to enter Australian territory through pre-arrival information reported through Maritime Arrivals Reporting System (MARS).	Records confirm biosecurity clearance obtained.
				CM8: Vessel Master	Vessel Master to adhere to Australian Ballast Water Management Requirements and IMO Ballast Water Management Convention.	Ballast water records show location of ballast water uptake and discharge.
				CM26: IMS Risk Assessment Procedure (IMS-RAP).	Biofouling risk assessment conducted in accordance with IMS RAP shows low risk.	Biofouling risk assessment record confirms vessel poses low risk of introducing IMS.
Vessel Operations ROV Operations	Accidental Release – LOC (chemicals / hydraulic fluids)	Change in water quality Injury / mortality to fauna	No spills to the environment	**CM20:** SMPEP	MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require that a SMPEP (or equivalent, according to class) is in place.	Vessels have class certification verified and issued by IACS member.
				CM21: ROV pre-post dive checks	A ROV pre and post dive inspection visually check for leaks.	Records of ROV pre and post dive inspection checklist.
				CM22: ROV IMCA Audit	ROV installation inspected against IMCA Guideline.	Audit report - corrective action managed in accordance with IMC A category rating.
Vessel Operations	Accidental Release - Waste	Change in habitat Injury / mortality to fauna	Limit impacts to habitat caused by accidental release of waste to a localised area.	**CM9:** Class certification	Vessel compliant with MARPOL Annex V which includes measures to prevent loss of waste to the ocean such as: • Prohibition of discharge of garbage to the sea (other than as permitted for bilge, sewage and food waste). • Separation of garbage by recommended types	Vessels have class certification verified and issued by IACS member.

Activity	Aspect	Impact	Environmental Performance Outcome (EPO)	Control	Environmental Performance Standard (EPS)	Measurement Criteria
					• Any receptacles on deck areas, poop decks or areas exposed to the weather should be secured on the ship and have lids that are tight and securely fixed • All garbage receptacles should be secured to prevent loss, spillage	
Vessel Operations	Accidental Release - LOC (vessels)	Change in water quality Injury / mortality to fauna Change in habitat Change to the function, interests or activities of other users	No spills to the environment	**CM27:** Support vessel approach procedure	The 500m approach checklist and DP Checklist are completed prior to the vessel entering the 500 m PSZ.	Records of the facility 500 m PSZ and DP operational checklists.
				CM28: ASOG / CAMO procedures	Activity Specific Operating Guidelines (ASOG) / Critical Activity Mode (CAMO) procedures developed to IMCA Standard.	Implementation (AFI) procedures signed by Vessel Master.
				CM29: Support vessel DP system	All support vessels engaged in DP operations have Class recognised DP 2/3 notation.	Records of IACS member DP Notation, Failure Mode and Effects Analysis (FMEA), proving trials and Annual Trials.
					Watchkeepers in charge of watch hold DP certification.	Records of watchkeepers DP certificates.
				CM20: SMPEP	MARPOL Annex I Regulations for the Prevention of Pollution by Oil specifically require that a SMPEP (or equivalent, according to class) is in place.	Vessels have class certification verified and issued by IACS member.
				CM36: Pre Start notifications	Pipeline and Subsea IMR activities occurring outside platform designated PSZs will notify AMSA JRCC before operations commence to enable AMSA to distribute an AUSCOAST warning.	Records confirm that information to distribute an AUSCOAST warning was provided to the JRCC before operations commenced.
					Relevant stakeholders are notified of scheduled Pipeline and Subsea IMR activities each quarter and again one week prior to commencement.	Stakeholder consultation records confirm that information regarding Gippsland basin scheduled Pipeline and Subsea IMR activities was conveyed to relevant stakeholders in required timeframes.

1.3 Environmental Performance – Emergency Response Capability

Table 1-5 Environmental Performance – Emergency Response Capability

Performance Outcome	Control	Performance Standard	Measurement Criteria
Esso Incident Management Team is available to respond as required to coordinate spill response operations in a timely manner to minimise impact to the environment.	Esso Incident Management Team (IMT)	Trained personnel are available to fulfil Incident Commander, Operations Section Chief, Planning Section Chief, Logistics Section Chief, Safety Officer and Environmental Unit Lead roles with 1 hour of IMT activation.	Capability is demonstrated during test / drill and is documented in test/drill report Training records.
		RRT support is available for a Tier III response in: • <12 hours from notification for remote support • <72 hours for in country support	Capability is demonstrated during test / drill and is documented in test/drill report
		Emergency response capability is maintained for the duration of the activities.	IMT call out tests conducted and recorded per test schedule
Source Control equipment is available when required to prevent further uncontrolled release of hydrocarbons into the marine environment.	Agreements in place with ROV specialist	Current global agreements state that a ROV appropriate to the task will be available. Estimated 5 days from call out request to arrive in Victoria.	Current global agreement document.
	Support vessel identification process	Suitable support vessels and their location during the activity will be identified prior to rig activities.	Completed register in the Tier II/III Emergency Response Plan (ERP).
	Agreements with AMOSC for Subsea First Response Toolkit (SFRT)	Current agreements with AMOSC state SFRT will be available to deploy to field <7 days.	Annual review of agreement document.
	MoU with APPEA	Current APPEA MoU states that signatories will make best endeavours to make drilling units available for transfer between operators when requested for emergency response.	MoU document.
	Well Kill Skid	Well Kill Skid is maintained and available for use within 48 hours	Maintenance records
	Pipeline repair	Pipeline repair equipment is available for mobilisation and use within 45 days.	Capability is demonstrated during test / drill and is documented in test/drill report
	Pipeline de-pressuring and watering out	Procedures are in place for pipeline de-pressuring and watering out.	Procedures are in place for pipeline de-pressuring and watering out

Performance Outcome	Control	Performance Standard	Measurement Criteria
Equipment and third party services are available to complete oil spill surveillance and monitoring when required to gather information on the extent, severity & persistence of the oil and potential sensitivities at risk.	Helicopter fleet	A helicopter is available to complete surveillance and monitoring in <4 hours of request, subject to safe flying conditions. (Note: Assumes good visibility, daylight hours and suitable flying conditions).	Capability is demonstrated during test / drill and is documented in test/drill report
	Arrangements with third party for provision of fixed wing aircraft	Third party fixed wing aircraft will be available <24 hours from request of service.	Capability is demonstrated during test / drill and is documented in test/drill report
	Support vessel	Support vessel is available to complete surveillance and monitoring in <24 hours from request of service.	Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement with third party suppliers for provision of additional vessels.	Current agreement states additional vessels will be available when requested.	Agreement document.
	Agreement with AMOSC for trajectory modelling	Trajectory modelling is through AMOSC within <4 hours of service request.	Agreement document
	Tracking buoys	Tracking buoy is available to complete surveillance and monitoring within 12 hours of spill occurring subject to safe conditions.	Functionality is demonstrated during test / drill and is documented in test/drill report
	Contract with satellite imagery provider	Current agreement with satellite imagery provides 24/7 emergency response support.	Agreement document.
	Esso initial response sampling kits	Esso initial response sampling kit with required equipment is available when required. Samples obtained within <24 hours of spill occurring subject to safe conditions.	Functionality is demonstrated during test / drill and is documented in test/drill report
	Agreement with service provider for monitoring and sampling	Monitoring and sampling service provider has capability to implement OSMP.	Annual capability review.
Dispersant and equipment for applying dispersant is available when required to reduce consequences to surface and shoreline values and sensitivities.	Esso owned Dispersant stocks	Sufficient dispersant volume (estimated 12 m^3) is available to mobilise for the first 24 hours of the response.	Annual dispersant testing report.
	Dispersant application equipment	Equipment is maintained in response ready condition.	Annual equipment inspection report.

Performance Outcome	Control	Performance Standard	Measurement Criteria
	Agreement with AMOSC for dispersant capabilities	Response capabilities maintained per service level statement including access to mutual aid and the National Plan (which provides dispersant stockpiles within 24 hours of request).	Annual assurance assessment report.
	Agreement with OSRL for dispersant capabilities	Response capabilities maintained per service level statement including access to OSRL Global Dispersant Stockpile (GDS) within 48 hours.	Annual assurance assessment report.
	Support vessel	Support vessel is available to complete surface dispersant application in <24 hours from request of service.	Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement with third party suppliers for provision of additional vessels.	Current agreement states additional vessels will be available when requested.	Agreement document.
Containment and recovery equipment is available when required to recover spilt oil before shoreline or other sensitivity contact.	Containment & Recovery Vessels	Esso will have access to containment and recovery vessels per Table 6-5 of Volume 3.	Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement in place with AMOSC	Esso will have required contracts, agreements and memberships with AMOSC in place to provide oil spill response equipment and personnel per Table 6-5 of Volume 3 within 72 hours.	Contracts, agreements or memberships that demonstrate access to spill response equipment and personnel
	Annual assurance assessment of AMOSC capabilities	Response capabilities maintained per AMOSC Service Level Statement.	Annual assurance assessment report.
	Personnel trained for containment and recovery activities	Personnel trained in OSR equipment operation per Table 6-5 of Volume 3 within <24 hour of request of service.	Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement with waste management contractor	Current contract in place for onshore waste management in timeframe described in Table 9-6 of Volume 3.	Agreement document.
Equipment and personnel available to support shoreline protection and clean-up when requested to reduce oil impact on shoreline environmental sensitivities.	Agreement with third party OSMP consultant.	Esso will have required contract in place to enable access to personnel and resources required for implementation of OSMP in the timeframe described in Table 7-10 of Volume 3.	Current agreement in place for OSMP consultant Capability testing conducted and recorded.
	Annual review of agreement with third party	Esso will have required contracts in place to enable access to vessels needed for shoreline protection in the timeframe described in Table 7-10 of Volume 3.	Current agreement in place for vessels which meets standard.

Performance Outcome	Control	Performance Standard	Measurement Criteria
	suppliers for provision of vessels.		Capability testing conducted and recorded.
	Esso/AMOSC response equipment	Equipment is maintained in accordance with maintenance strategy. Equipment is available for deployment within 24 hours.	Monthly exception reports shows any overdue maintenance, inspection, and/or testing tasks with actions signed-off by the appropriate level of Operations Management. Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement in place with AMOSC	Esso will have required contracts, agreements and memberships with AMOSC in place to provide oil spill response equipment and personnel in timeframe described in Table 7-10 of Volume 3.	Contracts, agreements or memberships that demonstrate access to spill response equipment and personnel
	Annual assurance assessment of AMOSC capabilities	Response capabilities maintained per AMOSC Service Level Statement.	Annual assurance assessment report.
	Personnel hiring agreements	Current agreements in place with labour hiring companies.	Agreement documents.
	Agreement with waste management contractor	Current contract in place for onshore waste management in timeframe described in Table 9-6 of Volume 3.	Agreement Contract. Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement with contractor for Heavy Plant Equipment	Current agreement in place with contractor for Heavy Plant Equipment. Equipment is available for deployment within 48 hours.	Agreement documents. Capability is demonstrated during test / drill and is documented in test/drill report
Equipment and personnel to support oiled wildlife response are available when requested to monitor, evaluate and reduce environmental impact on fauna	Agreement in place with AMOSC	Esso will have required contracts, agreements and memberships with AMOSC in place to provide oiled wildlife response equipment and personnel per Table 8-6 of Volume 3 for deployment within 24 hours.	Contracts, agreements or memberships that demonstrate access to oiled wildlife response equipment and personnel
	Annual assurance assessment of AMOSC capabilities	Response capabilities maintained per AMOSC Service Level Statement.	Annual assurance assessment report.

Performance Outcome	Control	Performance Standard	Measurement Criteria
	Agreement in place with OSRL	Esso will have required contracts, agreements and memberships with OSRL in place to provide oiled wildlife response equipment per Table 8-6 of Volume 3 for mobilisation to Melbourne within 72 hours.	Contracts, agreements or memberships that demonstrate access to oiled wildlife response equipment and personnel
	ExxonMobil Regional Response Team (RRT)	ExxonMobil RRT OWR Core Team personnel are available for remote support within 12 hours and in country support within 72 hours.	Capability is demonstrated during test / drill and is documented in test/drill report
	Agreement with waste management contractor	Current contract in place for onshore waste management. Equipment is available for deployment within 48 hours.	Contract agreement. Capability is demonstrated during test / drill and is documented in test/drill report
Equipment and personnel to manage waste are available when requested to reduce secondary contamination impacts on shoreline environmental sensitivities	Annual review of agreement with third party suppliers for provision of vessels.	Esso will have required contracts in place to enable access to vessels needed for waste management in the timeframe described in Table 7-10 of Volume 3.	Current agreement in place for vessels which meets standard. Capability testing conducted and recorded.
	Agreement in place with AMOSC	Esso will have required contracts, agreements and memberships with AMOSC in place to provide oil spill response equipment and personnel, and waste management resources in timeframe described in Table 9-8 of Volume 3.	Contracts, agreements or memberships that demonstrate access to spill response equipment and personnel
	Annual assurance assessment of AMOSC capabilities	Response capabilities maintained per AMOSC Service Level Statement.	Annual assurance assessment report.
	Agreement with waste management contractor	Current contract in place for onshore waste management in timeframe described in Section 9.3.1 of Volume 3	Agreement Contract. Capability is demonstrated during test / drill and is documented in test/drill report
	Personnel hiring agreements	Current agreements in place with labour hiring companies.	Agreement documents.
	Agreement with contractor for Heavy Plant Equipment	Current agreement in place with contractor for Heavy Plant Equipment. Equipment is available for deployment within 48 hours.	Agreement documents. Capability is demonstrated during test / drill and is documented in test/drill report

Note: Capability and functionality testing is conducted in accordance with Section 2.5.3 and the schedule outlined in Table 2.7. These tests are also further detailed in the annual EP&R Activity Plan.

2 Operations Integrity Management System (OIMS)

The OPGGS(E)R 14(3) requires that the implementation strategy must contain a description of the environmental management system for the activity, including specific measures to be used to ensure that for the duration of the activity:

a) the environmental impacts and risks of the activity continue to be identified and reduced to a level that is as low as reasonably practicable (ALARP); and

b) control measures detailed in the environment plan are effective in reducing the environmental impacts and risks of the activity to as low as reasonably practicable and an acceptable level; and

c) environmental performance outcomes and standards set out in the environment plan are being met.

The Environmental Management System (EMS) is the method by which environmental impacts and risks are managed to ensure they are reduced to ALARP and an acceptable level for the duration of the activity. The Environmental Management System on Esso facilities is called OIMS (Operations Integrity Management System). Lloyd's Register Quality Assurance Inc. has assessed OIMS and concluded that it is consistent with the intent and meets the requirements of ISO 14001 (Environmental Management Systems).

In practice OIMS comprises of a number of separate systems each designed to meet specific expectations, which are set out within a framework of 11 separate elements. ExxonMobil's OIMS Framework (Figure 2-1) establishes common worldwide expectations for addressing risks inherent in the business. The term Operations Integrity is used by ExxonMobil to address all aspects of its business that can impact personnel and process safety, security, health and environmental (SSHE) performance.

The 11 elements of OIMS interact within a hierarchy as shown in Figure 2-1. The visible leadership and commitment of management required by Element 1 is the driver for the effective implementation of OIMS. Elements 2 to 10 provide the operations of OIMS to control the hazards associated with the operation of all facilities. Element 11 provides evaluation of the effective implementation of Elements 1 to 10 through a process of periodic audits and assessments. Element 11 also drives the feedback loop within OIMS.

Key aspects of OIMS relevant to the implementation of this Environment Plan are described in further detail below. All OIMS Management Systems contribute to the effective management of the environmental impacts and risks identified in this EP.

Figure 2-1 OIMS Framework

2.1 Compliance with Laws, Regulations and Permits (OIMS System 4-2)

OIMS System 4-2: Compliance with Laws, Regulations and Permits, addresses regulatory compliance activities during all phases of operations. Several mechanisms are in place to identify new or amended requirements that may or may not have an impact on the environment:

- Active participation in industry organisations or cooperatives (e.g. APPEA);
- Active participation in local or international trade organisations;
- Subscriptions to specialist consultants, commercial publications and government provided subscriptions (e.g. SAI Global, Environment Essentials, COMLAW);
- Engagement with government agencies and review of government publications of laws and regulations; and
- Participation in government-sanctioned working committees.

If new, amended or existing requirements are identified, an assessment is made as to their applicability and possible impact on Esso operations and the environment. Environmentally relevant changes could include:

- Changes to existing legislation or introduction of new legislation
- Changes to the existing environment including (but not limited to) fisheries, tourism and other commercial and recreational uses, and any changes to protective matter requirements;
- Changes to the requirements of an existing external approval (e.g. changes to conditions of environmental licences);
- New information or changes in information from research, stakeholders, legal and other requirements, and any other sources used to inform the EP; and
- Changes or updates identified from incident investigations, emergency response activities or emergency response exercises.

Changes to legislation are screened by the Esso Regulatory Advisor before being forwarded to an appropriate Subject Matter Contact (SMC) for their determination on applicability. A tracking list of emerging / amending regulation and associated current review status is maintained by the Esso SSHE Group.

Relevant changes to protected matter management are assessed on an periodic basis by the Offshore Environmental Advisor, and incorporated into the risk assessments, control measures, EPOs and EPSs and implementation strategy in the EP where required.

Changes assessed by the Offshore Environmental Advisor are reviewed and assessed in accordance with the process outlined in Section 2.8 (Management of Change (OIMS System 7-1)).

2.2 Occupational Health (OIMS System 5-2)

The purpose of Occupational Health Management is to:

- Identify health hazards (physical, chemical and biological) in the offshore working environment, evaluate risks, control the risks and communicate health hazard information.
- Manage employee health by determining their fitness to work, assessing potentially exposed personnel and provide clinical treatment.
- Identify and communicate information on the health hazards of products.

A risk-based approach is used to ensure occupational health hazards that may exist in the workplace environment are identified and, as far as practicable, eliminated or reduced.

The Medicine and Occupational Health (MOH) Department supports offshore operations and consists of Doctors, Industrial Hygienists and other health professionals.

EAPL's first aid service ensures that emergency first aid and medical advice is provided to offshore facilities in a timely and efficient manner, 24 hours per day, year round. This includes treatment on the Platform and transfer via a medivac flight to an onshore doctor or hospital.

All major changes to first aid medication, equipment, supplies and producers are reviewed by the First Aid Review Group (FARG). This group is a committee comprising key stakeholders including offshore representatives and HSRs.

A confidential Employee Assistance program is in place to provide a range of counselling to employees and their families.

The First Aid Procedures (FAP) Manual (OIMS System 5-2) documents procedures, policies, and processes for the delivery of first aid services offshore. The Manual also details policies regarding inventory control.

Esso Australia manages infectious diseases in line with the ExxonMobil Infectious Disease Outbreak Management (IDOM) Program Manual, with Business Lines also taking guidance from individualised Pandemic Flu Management plans, which are applicable to COVID19, as they are to pandemic influenza.

These documents provide guidance for local management and operations personnel to prevent, quickly identify and interrupt infectious disease outbreaks in locations where personnel live and work together in close quarters, such as offshore installations, ships, and remote camps. The IDOM also identifies external organizations that can support management and operations personnel experiencing infectious disease outbreaks.

The purpose of these are to:

- Provide basic guidance on controls needed to prevent disease outbreaks.
- Recommend surveillance practices to quickly identify potential outbreaks.
- Recommend steps to take to limit or interrupt infectious disease transmission among the workforce when an outbreak is suspect or an outbreak occurs.
- Provide guidance on sharing lessons learned with management and Medical and Occupational Health (MOH).

The hazards and risks associated with infectious diseases are monitored by the local MOH department who recommend the controls and mitigations that are required depending on the level of risk. The local MOH department are supported by the ExxonMobil MOH group that has over 400 personnel worldwide monitoring health risks and providing international support.

2.3 Operations and Maintenance Procedures (OIMS System 6-1)

Esso has a comprehensive library of operations and maintenance procedures (managed by OIMS System 6-1) that cover the full range of activities that are undertaken throughout the Bass Strait operation. Key manuals or procedure types are:

- Platform Operating Procedures detail procedures for operating the platform, including start up procedures, critical function test procedures, process or platform shut down procedures, managing the flare, vent and drain system, and managing the produced water handling system (CM10).
- Offshore Maintenance Procedures cover inspection and maintenance related activities on offshore platforms, pipelines and subsea facilities and include: vessel tanks and exchangers; pumps; compressors; generators and turbines; piping and valves; instrumentation and electrical systems; fire, safety and protective equipment; as well as maintenance and calibration of the produced water online analysers.
- Crane Operation, Maintenance and Inspection (COMI) procedures define the responsibilities for Crane Operators, Maintenance Technicians and the Maintenance Reliability Group (CM42). COMI procedures are available for lifts including diesel, glycol and for methanol bulk transfer from supply vessels (CM14).
- The Lifting Equipment Manual (LEM) includes guidelines for use, storage, maintenance, inspection and purchase of cargo lifting gear (such as winches, jacks, hoists and rigging) used for routine cargo handling.
- Underwater Operations Manual contains marine operations procedures, although some platform based marine operations procedures are also found in the Work Management System.

Procedures are stored and accessed via a globally mandated electronic system known as the Procedures Management Electronic Tool (PMeT). This ensures that the most recent version of a procedure is readily available for use. PMeT is supplemented by physical back-up copies of many of the manuals listed above including procedures and other documents, for situations where the PMeT system is unavailable.

Risk assessment processes are used to identify when procedures are needed to mitigate a risk, and to categorise the procedures as critical procedures, normal procedures or work aids (dependent on the level of risk when completing the work described in the procedure). This assessment process establishes the approval authority, deviation authority, review period and compliance expectations.

2.3.1 Water Handling System (CM10)

Monitoring and management of the water handling process system (refer Volume 2, Figure 5-36 [Routine Monitoring, Water handling system performance]) and the oil in water monitoring system (refer Volume 2, Figure 5-36 Routine Monitoring, OIW monitoring]) consist of operations and maintenance actions, further described here; and surveillance and optimisation actions (described under CM67). Both these management controls act in concert in order to ensure the oil in water is kept at minimum levels during overboard discharge.

Water handling system - *Operations and Maintenance*

Operations procedures outline how to establish control of the process on the platform, start-up the water handling system, and troubleshoot the system. For example:

- *Water handling startup* procedures e.g. XXX-100-302 details how to perform a hot or cold restart (where XXX is platform name, e.g. TNA). In order to ensure that discharge of water on start-up is controlled (CM10d), implementation of the procedure requires:
    - Correct valve line-up/operation, auto controller function and separator levels/flow, ratios across hydrocyclones
    - Implementation of troubleshooting guides as required (i.e. poor water quality at separator or poor water quality post separator).
- *Vortoil operating principles* work aid GEN-100-101 details service troubleshooting to ensure that secondary separation equipment for managing produced water are operating optimally (CM43). This could include troubleshooting of internal blockages, wear or deterioration, general operating principles. I.e. start up, normal operation and shutdown, start up after normal shutdown, shutdown for vessel inspection.
- *Water handling matrix & bypass controls* procedure GEN-100-201 is used in conjunction with GEN-100-102 to ensure OIW levels of the discharge stream are monitored and are below the 30 mg/L 24 hour average (CM10a). Implementation of the procedure requires:
    - backup protective devices must be in operation should a piece of equipment be bypassed or isolated. In particular, if the online OIW monitor is down for maintenance, low flow, spurious, or out of service, then an hourly Spec 21 must be conducted.

Maintenance is performed to keep the system working properly. For example:

- *Vortoil service* procedure e.g. OFS MP XXX 110 (where XXX is platform name, e.g. TNA) details the cleaning and inspection of [platform] Vortoils [hydrocyclones], including removal and replacement of liners, gaskets, o-rings, inspection for wall thickness and cleaning of vessel internals.

Oil in Water monitoring - *Operations and Maintenance*

Instantaneous monitoring of oil in water is available on the platform and a comparison of platform results with the LFD Laboratory takes place on a regular basis to cross-check the platform’s online monitor. For example:

- *System Monitoring, Recording & Reporting work aid* GEN-100-102 is implemented:
    - Primarily to ensure that OIW levels of the discharge stream is continuously monitored and maintained at concentrations below 30 mg/L 24 hour average (CM10a). Implementation of the procedure requires:
        - Sigrist alarms to be set correctly,
        - daily reporting of OIW sampling results,

- Secondly, to ensure the 24 hour average of online monitor is verified via:
    - the requirement that a 'Spec' reading using an infrared Spectrophotometer ("Infracal" unit) be taken every six hours;
- Thirdly, to ensure that the online monitor is calibrated (CM10b). This requires:
    - that a verification sample be sent to the shore laboratory every month for cross-check.
    - *Oil In Water Monitor Cleaning & Lamp Replacement* procedure GEN-100-503 details Sigrist shutdown, start up and general troubleshooting, Sigrist cleaning (including cleaning of the degasser pot and sample conditioning pot as well as lenses and air eductor) and Spectrophotometer lamp replacement
- *Determination of Oil In Formation Water* GEN-100-701 procedure details correct methodology to accurately determine oil in formation water to ensure that the online monitor is calibrated (CM10b). This requires:
    - Execution of the correct sample and extraction method including:
        - Extraction with the use of acid and Horiba via a solvent extraction method;
        - Recycling of contaminated Horiba Solvent S-316 in order to purify it for reuse; and
        - Testing and calibration of the InfraCal spectrophotometer unit.

Maintenance and calibration is performed on the online OIW monitoring unit, and alarms are functional in order to initiate water handling shutdown if required based on the OIW monitor.

- *Oil In Water Monitor Service* procedure OFS MP ALL 512 is implemented to ensure the online monitor accuracy is maintained through servicing (CM10c). Implementation of this procedure requires:
    - checking the accuracy and maintaining the condition of oil in water monitor;
    - cleaning of lenses, use of a calibration rod to system-calibrate the online oil in water monitor, air dryer maintenance, electrical maintenance, UV lamp replacement, testing the oscillating mirror in SIPRO units and troubleshooting common problems.
- *Critical function testing* tests ensures the alarm and shutdown functionality at the online OIW monitor are working. For the system to be considered functional:
    - The water handling system to shutdown after 30 mins where online oil in water monitor readings exceed 50 mg/L and 15 seconds where readings exceed 100 mg/L, and water is either directed to the onshore pipeline or the platform is shut down.

2.4 Facility Integrity (OIMS System 6-2)

The Facility Integrity Management System (FIMS), defines the key processes, standards and tools to be applied to the integrity management of critical equipment. Critical equipment is defined as equipment where failures could pose a serious threat to people (safety and health), the environment, property, security or have a significant business impact. Criticality categories are assigned based on these threats through a formal Consequence Assessment Process. FIMS provides a structured approach to managing facility integrity by developing barriers to *prevent* facility integrity incidents from occurring, *detect* facility integrity threats before an event occurs and to *respond* and *recover* effectively and efficiently by limiting consequence escalation.

Changes in the status of a facility from producing to non-producing does not alter the fundamental approach to the maintenance of equipment within FIMS. A Section 572(2) Maintenance Review mechanism will be developed as part of the initial activities undertaken as a facility begins to approach the CoP stage, while a review of critical inspection and maintenance controls for facilities already in CoP will be undertaken. Until such time as the Section 572 (2) Maintenance Review is undertaken, equipment will continue to be managed in accordance with existing FIMS processes, regardless of operating status. These processes are discussed further in Volume 2, Section 2.4.4.3 of this EP.

FIMS has three key steps in its process, these are:

- Program Design
  - identifying critical equipment through risk assessments
  - developing equipment strategies (for high complexity critical equipment) and maintenance plans (for low complexity critical equipment)

  The criticality categories drive the requirements of the Equipment Strategies which are designed to prevent incidents that pose a threat to people (safety and health), the environment, property, and security or have a significant business impact. The Equipment Strategies and Maintenance Plans are designed to be fit-for-risk and consider regulatory requirements, applicable industry codes, and recommended practices.
- Program Execution
  - developing plans and scheduling into the computerised maintenance management system (IPES)
  - monitoring of schedule
  - executing and assessing the data
  - analysing facility integrity incidents (root-cause failure analysis)
- Program Stewardship and Improvement
  - management reporting and review
  - continuous improvement and program redesign

FIMS has a number of Individual Integrity Programs which document the process applied to manage the ongoing integrity of specific equipment and/or asset covered by that program and all follow the system objectives and process steps described above. Each FIMS program has a Program Owner who oversees and is responsible for, the programmed work on the equipment. Each item of equipment has an overall Program Owner even though several programs may apply to that one item. These programs are:

- Corrosion Control & Chemical Injection;
- Pressure Equipment;
- Pipelines;
- Structures and structural equipment;
- Machinery;
- Subsea Equipment;
- Critical Instrumentation, Controls & Alarms;
- Electrical Systems;
- Cranes & Lifting Gear;
- Emergency Communications;
- Gas & Fire Detection/Safety Equipment;
- Oil Spill Response Equipment; and
- Personnel Protection Equipment

Note: Well integrity is managed under OIMS System 6-3.

Computerised Maintenance Management System

Maintenance and inspection program tasks and requirements are contained within a computerised maintenance management system (IPES). Planners, Supervisors and Technicians use IPES and other tools to generate work requests and work orders, plan and schedule work, order parts & materials, write technical reports and record failure mode and other useful data.

Execution

Maintenance and inspection program tasks are undertaken in accordance with the Maintenance System Manual which describes the requirements and procedures for implementation of all planned maintenance work and for the treatment of new work which has been identified. Reporting of maintenance work is done by the person who completed the work and this includes information such as, as found and as left condition of the equipment, test and inspection results, updating of documentation and also has a process for notification of any additional work or corrective actions identified as a result of the maintenance or inspection task. The results may also be used to determine whether a review of the integrity program (which may result in a change to the condition monitoring or inspection program and schedule) is appropriate.

New work notifications are categorised and recorded through IPES Work Notifications and have a defined process for assessment and implementation. The notification categories include Break-in (Corrective Work that is urgent enough to "break in" to the weekly work schedule) and Emergency work (Corrective Work that needs attention within 24 hours because of significant SSHE or business need, breakdown or shutdown) to address urgency and criticality of the new task.

A Risk Based Work Selection (RBWS) process is used to assess work notifications. Operations, maintenance and technical (where required) personnel (OMT Forum) screen the notifications and use the risk based selection tools (Work Selection Matrix, Work Selection Worksheet and interpretive guidance document) to validate and approve new work notifications including the timeframe in which the task is required to be performed. The Work Selection Worksheet assesses the unmitigated and mitigated safety, health, environmental, economic and business disruption risk (each is assessed separately) based on the proposed task. Any corrective tasks consider the *prevention, detection* and *response/recovery* opportunities used per the initial development of the maintenance or inspection activity (refer above).

Equipment that is found to be inoperable, faulty or out of service is managed in the field through the Work Management System (OIMS System 6-4, refer Section 2.6) and includes controlled processes such as isolation systems (locking and tagging), temporary defeat and shutdown, which must be approved and recorded in the electronic Permit to Work system (ePTW) and reviewed at every change of shift. The Work Permit process is designed to identify and safely manage all work that occurs on facilities including on or around effected equipment.

Details of the process for maintenance of non-producing equipment is included within Volume 2, Section 2.4.4.3 of this EP.

Stewardship and Reporting

Integrity Program compliance is monitored through the IPES Exception Reporting process which monitors if tasks associated with integrity critical equipment ("A" and/or "B" critical equipment) are carried out per the approved work plans. Integrity critical equipment is that which if deferred and/or not performed could pose a serious threat to people (safety and health), property, the environment, and/or significant business impact. Serious threat is defined as those events that could lead to a consequence 1 or 2 risk per the ExxonMobil risk matrix. Potential work plan schedule deviations are subject to risk-based analysis to allow for rescheduling, or developing and implementing corrective action plans through the MOC process. Program tasks are analysed on a monthly basis to identify maintenance, inspection or testing tasks that were due during the month but not completed. Figure 2-3 describes the guidance for integrity threat identification and use of the MOC process. The process flow for critical preventative maintenance in exception which is shown in Figure 2-3 which shows how risk analysis (RBWS) is used to inform the review process.

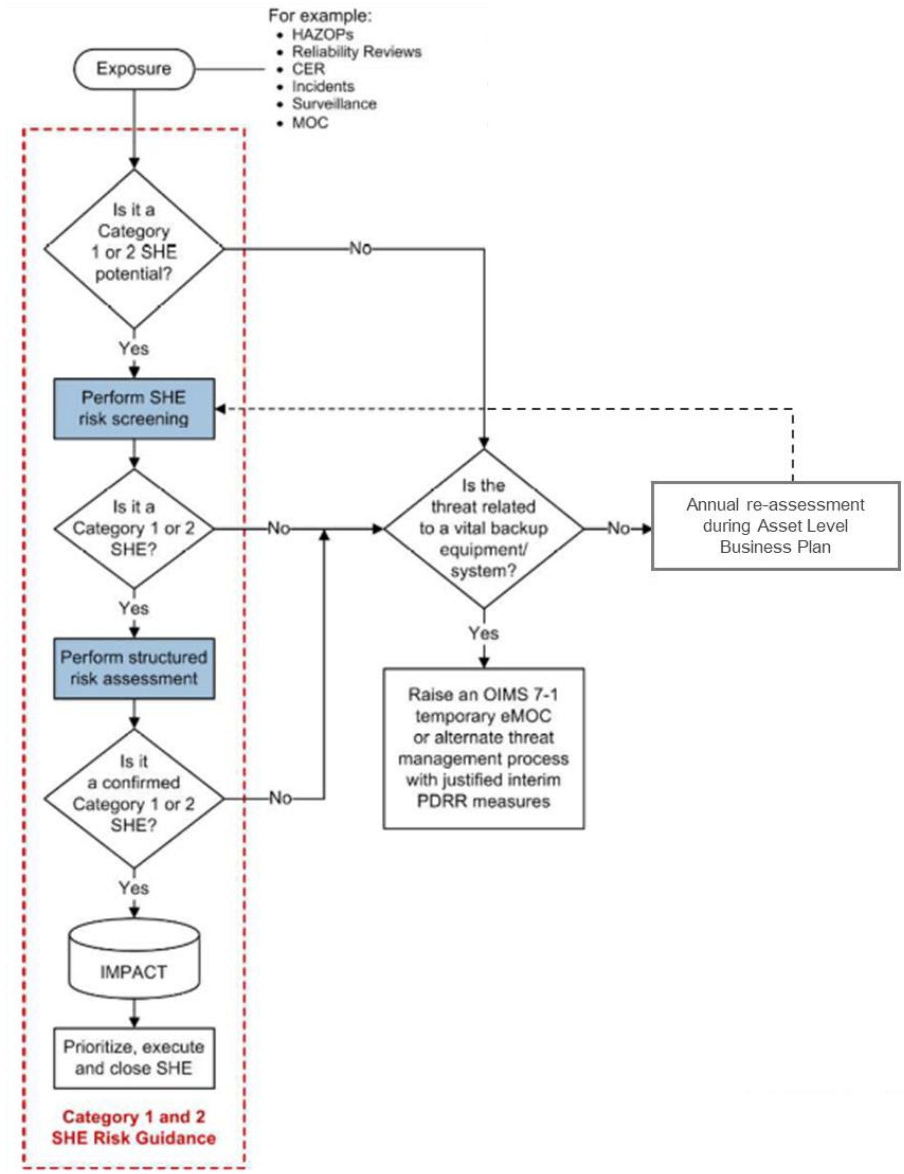

Figure 2-2 Guidance for Integrity Threat Identification: Category 1 and 2 SHE Risks Evaluation

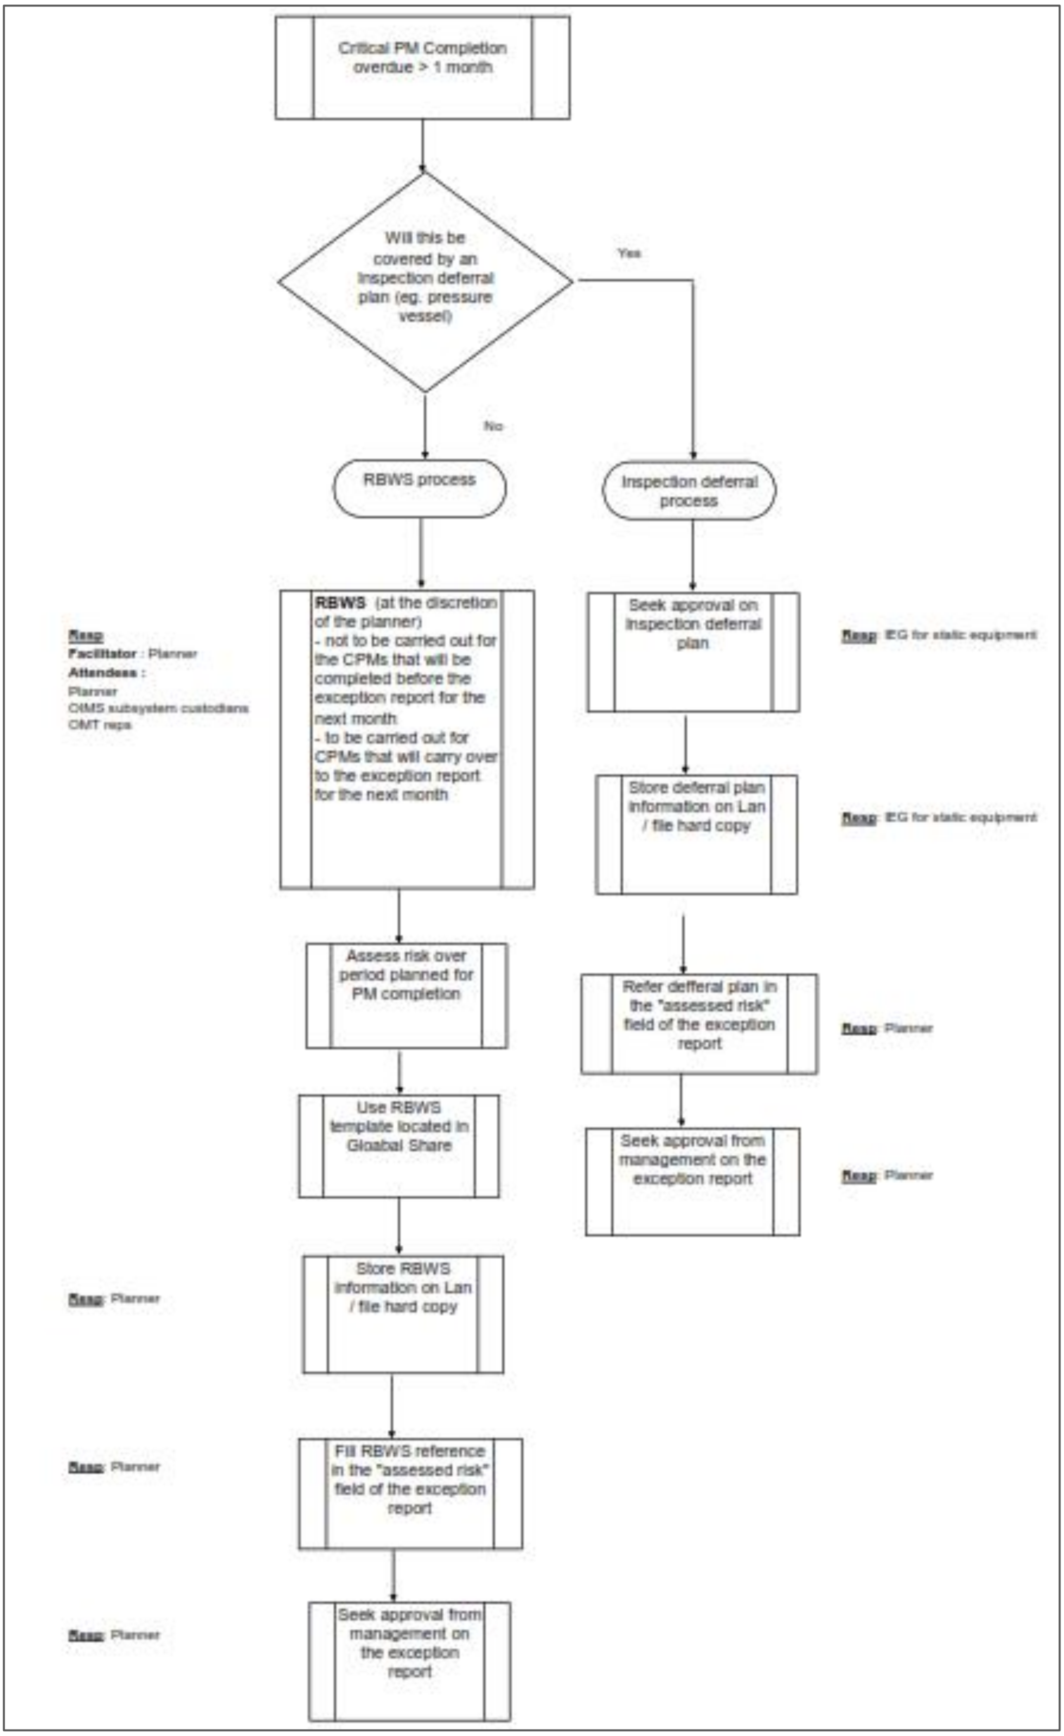

Figure 2-3 Critical PM Exception Process

An exception report is prepared for the Operations Superintendent to review at the end of each month detailing all agreed Key Performance Indicators that measure the effectiveness of the system and includes integrity critical equipment program tasks past their expected due date.

The Operations Superintendent, with appropriate technical and operations staff assistance, evaluates the risk to the operation. At the end of each month critical equipment program tasks that have exceeded their latest acceptable completion date must be reviewed by the Operation Superintendent. The Operations Superintendent, in consultation with technical and operational staff, evaluate the risk to the operation and take one or more of the following actions:

- Request that the task be conducted immediately
- Implement special precautions for continued operations
- Shuts down the critical equipment (or protected equipment) until the tasks are executed
- When regulations address maintenance, inspection, or testing task frequency, arrange for the task to be undertaken or obtain an appropriate extension from the regulatory body, if allowed.

Extension of integrity critical equipment program tasks by more than 30 days past the latest acceptable completion date (referred to as exceptions >30 days) requires a plan to perform the task within a timeframe that meets the asset's safety and reliability objectives, and requires approval by the Operations Superintendent. Exceptions > 90 days requires endorsement by the Operations Superintendent and approval by the Production Manager, allowing use of each individual's judgement to trigger a formal risk assessment to inform their decision if required.

Environment Critical Equipment

The exception report includes a section which reports on environment critical plans which have passed their scheduled completion date. Specific equipment which directly monitor or are designed for planned discharges, has been identified as environment critical and currently includes all oil in water monitors for platforms that discharge produced formation water and the pile systems on producing platforms. All maintenance and inspection programs associated with this equipment appear in the exception report if they are not completed by their scheduled date. The Offshore Risk, Environment and Regulatory Supervisor is required to review the environment section of the exception report and provide endorsement if satisfied that the risk posed by the deferral is mitigated or alternate controls are in place to prevent potential environmental incidents and thereby breaches in environmental commitments associated with discharges from this equipment.

MOC – Equipment Strategies

Revisions or changes to equipment strategies occur through a formal process and are initiated through the Triggered Equipment Strategy Review Request Form. Examples of triggers include:

- change in a process condition or
- change or deviation in performing a mitigation task
- near miss or incident where the level of maintenance is a root cause or a contributing factor
- it is proposed to change the scope or frequency of a PM task
- circumstances change in such a way as to significantly alter the risk of equipment failure

The nature of the critical equipment and the type of change request will determine the level of review and approval necessary before the change can be made. This may include a full workshop risk review. The reviews take into consideration the purpose of the criticality classification (threat to people (safety and health), property, the environment, security or business impact) and also whether the proposed change will impact these or on the regulatory requirements, applicable industry codes, and recommended practices.

Deviations to the Equipment Strategy program must be endorsed by the Program Supervisor and approved by respective Site Operations and Maintenance Superintendents and must still meet the initial objectives and considerations of the strategy with regard to the criticality classification.

MOC – Computerised Maintenance Management System

Change requests can also be triggered through IPES which has an electronic workflow of approval steps to allow changes. These are based on the type of change requested (8 types of change are considered including equipment type, maintenance frequency, parameters etc.). Each type of change must follow the requirements of the IPES Change Request approval matrix which defines the level of endorsement and approved needed from the IPES Lead through to the FIMS Program Supervisor approval with Maintenance Superintendent endorsement. If the change involves a change to an equipment strategy, IPES rejects the request (requiring the requester to use the Triggered Equipment Strategy Review Request Form, as above).

2.5 Well Management System (OIMS System 6-3)

The Well Management System (OIMS System 6-3) provides the structure for wellwork planning and operations as well as ongoing well integrity activities. The Well Integrity Manual provides guidelines to comply with OIMS System 6-3, Well Management, and country specific regulations. The Manual describes policy, management principles, performance standards, assurance processes, procedures and practices that exist to ensure well integrity and to minimise the risk of unplanned or uncontrolled release of wellbore fluids. Monitoring and maintenance of well integrity is completed on a regular basis and includes:

- Annulus pressure monitoring and bleed down test;
- Subsurface safety valve testing;
- Wellhead and tree testing and maintenance;
- Regulatory required tests; and
- Downhole corrosion control.

The Well Integrity Management System (WIMS) (CM 48), which is described in the Well Integrity Manual, is used to ensure that well integrity tasks are scheduled for completion and the results are documented. A risk-based approach is used to determine well monitoring, testing and maintenance requirements and frequencies.

When determining these requirements consideration is given to

- well type and status,
- production method,
- mechanical condition,
- critical equipment installed,
- environmental sensitivity,
- well stream composition,
- wellhead pressure,
- regulatory requirements.

Monitoring and testing acceptance criteria are also established and routine testing or surveillance activities may identify potential issues that require further analysis.

Risk assessment processes are used during Wellwork planning and execution to identify procedures needed to prevent or mitigate risk and to categorise the criticality of the well activity procedure. The Wellwork Execution Manual (CM33) provides a process for assessing the overall risk of Wellwork operations.

Active and shut in wells equipment maintenance, well integrity and annulus integrity are conducted at the following frequency (see also Volume 2, Section 2.4.3.1)

- SSSV testing: 3 – 6 months depending on type of valve
- Annulus pressure monitoring: 6 – 12 months depending on type of well
- Wellhead and tree testing: 6 monthly

Wells that have been suspended, temporarily abandoned or abandoned (until removed from the WOMP as per *OPPGS Regulations (Well Operations) 2015. s5.17)* undergo 6 - 12 monthly pressure and fluid checks on the tubing, PA and SA (depending on the type of well) to ensure that the wells are standing full of inhibited sea water and that the down hole isolations maintain integrity.

Additional requirements for subsea wells (including old exploration wells) includes aerial inspection of subsea wells and ROV visual subsea inspection of the subsea facilities, every 3 or 6 years (depending on the risk characterisation of the well or subsea facility). This is considered to be an appropriate methodology for the following reasons:

- This monitoring / surveillance method allows the wellhead to be inspected for oil seepage, gas bubbles, for signs of extensive corrosion, damage or excessive debris and confirmation of well status (debris cap position). The debris cap protects the wellhead sealing surfaces. This cap is not removed during ROV inspections as this would increase the risk of damage to the wellhead.
- This methodology is consistent with practices adopted by other operators and ExxonMobil worldwide practice with regard to monitoring of exploration wells.
- The methodology and frequency of these inspections is consistent with the accepted Bass Strait WOMP.

Any changes to the frequencies or the testing criteria are subject to MOC approval.

All well integrity testing is done in accordance with the Platform Operating Procedures which outline specific steps to ensure the accuracy of tests while minimising the risk of spills or incidents. Testing results are reported to Wells Engineers for review. If any issues are identified during WIMS testing, appropriate mitigations are considered which may include shutting in the well until appropriate maintenance activities can be completed.

The schedule of well integrity tasks is reviewed each month and an exception report prepared for Operations Management detailing all wells for which any tasks are past due. These exception reports require the appropriate level of management approval, as defined in OIMS System 6-3, Well Management, depending on the nature and duration of the exception.

Overdue tests >3 months require a justification and action plan. Wells with known integrity issues are identified and actions are put in place to manage safety and environmental risks. This could include actions ranging from minor wireline workovers through to abandonment of wells where repair is not reasonably practicable.

2.6 Work Management (OIMS System 6-4)

The OIMS 6-4 Work Management System has two parts: the Work Management System and Safe Work Practices.

The Work Management System (WMS) describes the different types of permits and the process for work planning, authorisation, execution and re-instatement. The WMS provides a framework for identifying hazards, planning work, actively managing the risks associated with the work and confirming that interfaces with the work activity are considered appropriately. This ensures that the activities are undertaken in a structured and controlled manner to reduce the risk of incidents.

The WMS defines controls and restrictions required when simultaneous activities are planned. In particular, simultaneous operations includes helicopter procedures and communication as they relate to platform operations and vessel authorisation to enter the 500m petroleum safety zone.

The WMS also includes the electronic Permit to Work System (ePTW). The Permit to Work System requires proposed work to be planned and reviewed by the team before starting work. It includes the use of tools to identify and mitigate possible safety and environmental risks. Permits must be reviewed and approved by the person in charge before work can commence, and must be closed out once work is complete. Permits are archived electronically for a minimum period of 3 years.

The Safe Work Practices describe additional requirements for a range of specific work activities and hazards. Safe Work Practices can be referenced when preparing permits to ensure site specific risks and requirements are addressed. Examples include guidance for accessing seadeck (CM17), abrasive blasting (CM7) and the use of drones (CM16).

2.7 Environmental Management (OIMS System 6-5)

OIMS System 6-5, Environmental Management, specifically addresses corporate requirements for environmental management, including socioeconomic and community health aspects. This includes the fundamental requirement to develop Environmental Management Plans which identify and assess all environmental aspects, impacts and risks associated with Esso's activities, facilities and ongoing operations. The Environmental Management Plans must also describe how the impacts and risks are addressed and controlled. As such, this EP meets the System 6-5 requirement for an Environment Management Plan for offshore operations and is an integral part of Esso's System 6-5 documents.

In addition, System 6-5 Environmental Management, includes processes and procedures for managing environmental impacts. Processes have been developed for waste management, chemical discharge assessment, invasive marine species risk assessment, produced water adaptive monitoring and management as well as processes for calculating and reporting greenhouse gas emissions based on fuel use and flare volumes.

2.7.1 Waste Management

The Waste Management Manual (WMM) (CM 45) describes the process for labelling, storing, transporting and tracking waste. Waste is clearly labelled with the relevant EPA Victoria waste category and/or Dangerous Goods category. The WMM also details requirements for storage in accordance with EPA Victoria and/or Dangerous Goods bunding guidelines and requirements for transport to onshore including material dispatch advice (MDA).

2.7.2 Chemical Discharge Assessment Process (CM3)

Esso assesses all chemicals that are likely to be discharged during the activities described in this EP. The chemical discharge assessment process is triggered by the (Management of Change) MOC process. The introduction of a new chemical to Esso's facilities requires assessment for environmental and safety suitability in accordance with the Workplace Substances Manual.

In the absence of Australian standards regarding the suitability of chemical additives, the Offshore Chemical Notification Scheme (OCNS) is generally used as a basis for selecting environmentally-acceptable chemicals in the Australian offshore petroleum industry. The OCNS manages chemical use and discharge by the UK and Netherlands offshore petroleum industries. The scheme is regulated in the UK by the Department of Energy and Climate Change using scientific and environmental advice from the UK's Centre for Environment, Fisheries and Aquaculture Science (CEFAS) and Marine Scotland.

The OCNS uses the Harmonised Mandatory Control Scheme (HMCS) developed through the OSPAR Convention 1992. This ranks chemical products according to Hazard Quotient (HQ), calculated using the Chemical Hazard and Risk Management (CHARM) model. The CHARM model requires the biodegradation, bioaccumulation and toxicity data of the product to be provided.

Under the OSPAR Convention, organic-based compounds used in production, completion and workovers, drilling and cementing are subject to the CHARM model. The CHARM model calculates the ratio of the 'Predicted Effect Concentration' against the 'No Effect Concentration' expressed as a HQ, which is then used to rank the product. The HQ is converted to a colour banding to denote its environmental hazard, which is then published on the Definitive Ranked Lists of Approved Products (by the OCNS on its website, https://www.cefas.co.uk/cefas-data-hub/offshore-chemical-notification-scheme/). Gold has the lowest hazard, followed by silver, white, blue, orange and purple (having the highest hazard).

Products not amenable to assessment under the CHARM model (i.e. inorganic substances, synthetic based muds, hydraulic fluids or chemicals used only in pipelines) are assigned an OCNS grouping A – E, with 'A' having the greatest potential environmental hazard and 'E' having the least. Products that only contain substances termed PLONORs (Pose Little or No Risk to the environment) are given the OCNS 'E' grouping. Data used for the assessment includes toxicity, biodegradation and bioaccumulation.

Chemicals that are hazardous to the marine environment are subject to substitution warnings under the HMCS. The UK follows and applies the OSPAR harmonised pre-screening scheme and complies with the REACH recommendation to replace chemical substances identified as candidates for substitution. These substances are flagged with a substitution warning on the product template and CEFAS encourages operators to select products without a substitution warning.

The chemical pre-assessment process is the process referred to that manages a variety of operational discharges, including produced formation water (purple box in Volume 2, Figure 5-36).

The following are criteria for discharge as part of the evaluation:

- Only chemicals ranked under the OCNS rating system (i.e. 'Gold' or 'Silver' [CHARM] and 'E' or 'D' [non-CHARM], or equivalent) with no substitution warning will be approved for discharge without further assessment.
- Where no OCNS ranking is available for a chemical but ecotox data is available, an equivalence check can be completed to establish if it would have a substitution warning. The equivalence check will be completed in accordance with the assessment process outlined by CEFAS for the OCNS scheme. A chemical will be considered to be 'equivalent' if it is assessed to *not* have a substitution warning according to the criteria defined by OCNS (https://www.cefas.co.uk/data-and-publications/ocns/substitution-warning/).
- If a chemical is not on the OCNS list, has a substitution warning (or equivalent) or has limited ecotoxicity data available, then further assessment is required to determine if the chemical is suitable for discharge to the marine environment. This assessment can include:
    - For firefighting foams, that they are PFAS-free
    - Calculation of CHARM ranking in accordance with the CHARM User Guide
    - Details of the technical requirement for this product and review of any possible alternative chemicals
    - Assessment of impacts to the receiving environment from discharge in the relevant scenario
    - Consideration of additional restrictions or controls to the approval e.g. timeframes for use, periodic reassessment.

2.7.3 Vessel Management

Vessels are managed under maritime regulations e.g. MARPOL and Marine orders to minimise environmental impacts and minimise environmental risks associated with operations. A number of vessel controls have been detailed in the EP:

CM18: Preventative Maintenance System (Vessel)

Vessel have software-based system which allows ship owners or operators to carry out maintenance in intervals according to manufacturers and class/Classification society requirements

CM19: Cargo Securing Manual

The Cargo Securing Manual is a regulatory plan which ensures all cargoes other than solid and liquid bulk cargoes shall be loaded, stowed and secured throughout the voyage.

CM20: SMPEP

The SMPEP is available to assist the ship's personnel in dealing with an unexpected discharge of oil or noxious liquids, its primary purpose is to set in motion the necessary actions to stop or minimize the discharge and to mitigate its effects.

CM21: ROV pre-post dive checks:

The pre/post dive checks are conducted each time an ROV is in the water. They include visual checks of hydraulic systems to look for wear and tears to minimise the potential for hydraulic leaks.

CM22: ROV IMCA Audit

The auditing of ROV systems is usually undertaken to either ensure the equipment is fit for purpose or as part of an ongoing internal process.

CM23: Ballast Water Management Plan and **CM24:** Ballast Water Certificate

Ballast Water Management Plans and Certificates are in place in order to reduce the harmful effects on the marine environment that are spread through aquatic micro-organisms transferred from one area to another through ballasting operations of the ship.

CM25: Biosecurity clearance when entering Australian territory

The Department of Agriculture, Water and the Environment conduct an assessment on the vessel prior to entry to Australia to prevent the risks associated with international vessels, which may include rabies, foot and mouth disease, or avian flu. This could be introduced by infected animals or in food purchased overseas or from trading with overseas vessels. International vessels can bring in unwanted pests and disease.

CM27: Support vessel approach procedure

Prior to entering the 500m Platform Safety Zone, vessels complete a checklist to verify safety systems, communications and environmental conditions are in place and or acceptable.

CM28: ASOG / CAMO procedures

Critical Activity Mode (CAMO)) and Activity Specific Operating Guidelines (ASOG) set out the operational, environmental and equipment performance limits and procedures for the location and the specific activity the vessel is undertaking, including SIMOPS.

CM29: Support vessel DP system

Prior to entering the 500m Platform Safety Zone, vessels complete a DP checklist to verify systems are in place and functioning correctly.

A pre-mobilisation inspection is undertaken (Section 6.3.1) of the EP for all vessels to ensure all controls are in place.

Where a control requires ongoing compliance, it is monitored through an ongoing monthly checklist which is completed by the vessel and submitted to the Environmental Adviser with evidence.

Any breaches of vessel controls will be recorded in IMPACT and included in the monthly recordable incident report. Breaches and are reviewed with contractor management during the quarterly management review.

2.7.4 IMS Risk Assessment Process (CM26)

Esso's IMS Risk Assessment Process was developed to complement Australian IMS prevention efforts in the context of Esso's operations offshore in Bass Strait. The assessment is undertaken prior to the mobilisation of all vessels to an Esso Operational Area (as defined under the EP for the activity). The IMS Risk Assessment incorporates key considerations from other established risk assessment processes.

The IMS-RAP is to be applied to all contracted non-trading vessels undertaking petroleum activities in the Gippsland Basin.

Consistent with the 'best practice' approach set out in the IMO Guidelines for the Management of Ships Biofouling (IMO Guidelines) (IMO, 2012) the risk assessment considers many parameters of the vessel or rig including (where relevant):

- Transport method (dry versus wet haulage)
- Presence and age of antifouling coating (AFC)
- Evidence of in-water inspection by divers or inspection in dry dock and cleaning of hull
- Presence and operation of internal seawater treatment systems if applicable
- Duration of stay in overseas or interstate coastal waters
- Location of operations (operational area), timings and durations.

Where the initial indicative assessment (conducted by an IMS Expert and/or via the online Vessel Check tool www.vessel-check.com)) results in 'Low Risk', the risk assessment is provided to the Principal Officer Invasive Marine Species, DJPR. If the Principal Officer is satisfied that no further action is necessary following this consultation the vessel or rig is deemed acceptable for use.

If the risk assessment result is uncertain or high risk, or further action is recommended by the Principal Officer, an IMS Expert is consulted to determine whether additional controls can be implemented to reduce the vessel risk status to 'Low Risk'.

Examples of potential control/mitigation measures to reduce risk that may be proposed are consistent with the NBMG and the IMO Guidelines. The control measures proposed must meet the standard of performance described in IMS-RAP.

Following implementation of these mitigation measures, the IMS Expert is consulted to reassess the level of risk for the activity and determine whether the level of risk for the activity is 'Low Risk' and meets the ALARP and Acceptability criteria (Sections 3.7 and 3.8).

If this process still results in an uncertain or high risk then an alternative vessel or rig must be sought for the activity.

2.7.5 Produced Formation Water Management

2.7.5.1 PFW Adaptive Monitoring and Management Framework (CM11)

Figure 2-4 to Figure 2-7 provide a summary of Esso's Adaptive Monitoring and Management Framework. The framework consists of both routine and non-routine monitoring and/or modelling. Routine monitoring consists of:

- Annual detailed composition sampling
- Annual microtox testing
- Three yearly Whole Effluent Toxicity (WET) testing

In-sea and other types of non-routine monitoring or modelling, are proposed to be triggered if required based on certain trigger factors that may indicate that the ability to maintain the designated mixing zone could have, or may be compromised. Increased frequency routine, or non-routine monitoring/modelling can be triggered by a relevant trigger in the adaptive management process.

Note that composition sampling, microtox testing and/or WET testing or other non-routine monitoring/modelling could be triggered through other changes, such as changes to chemical additives (this section), legislation (Section 2.1, for example changes in ANZECC/ARMCANZ guidance) or changes to process conditions (e.g. via MOC, Section 2.8).

Non-routine monitoring may involve:

- Non-routine WET testing
- Dispersion modelling
- Sediment sampling
- Water sampling
- Biological sampling

A description of each component of the framework, along with associated trigger points, is provided below.

Statistical Analysis of Composition

- Results outside the existing 95% confidence interval for chemical characterization (see data file for confidence interval)
- Increasing trends of potential contaminants of concern over 3 years
- Presence of contaminant of concern not previously detected in that platform's discharge

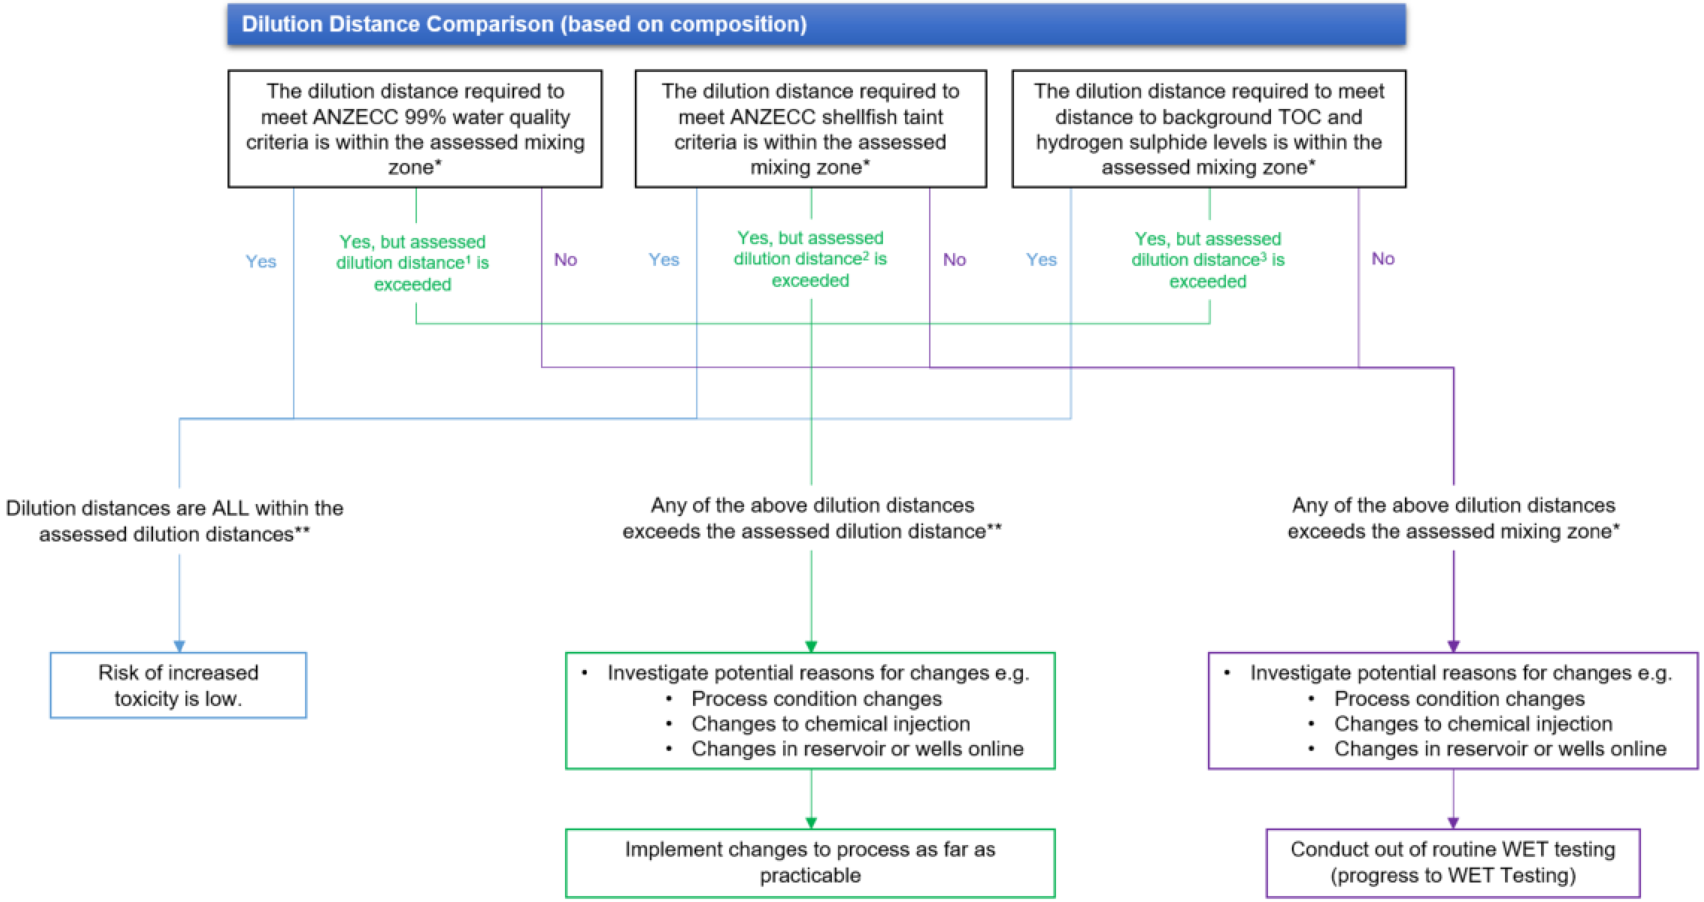
↓

- Investigate potential reasons for changes e.g.
    - Process condition changes
    - Changes to chemical injection
    - Changes in reservoir or wells online

↓

Implement changes to process as far as practicable

Figure 2-4 Line of evidence 1 – Statistical analysis of composition



** "Assessed mixing zone" refers to the "Mixing zone extent (m)" identified in Table 6-5 of Volume 2*
[1] "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet ANZECC 99% water quality criteria
[2] "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet ANZECC shellfish taint criteria
[3] "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet background levels of TOC and hydrogen sulphide

*"Assessed mixing zone" refers to the "Mixing zone extent (m)" identified in Table 6-5 of Volume 2

** "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet whole effluent ecotoxicity 99% species protection criteria

Figure 2-7 Line of evidence 4 – WET testing

2.7.5.2 Detailed compositional samples

Samples are collected in order to understand each individual platform's PFW composition and to identify changes in composition that may require management actions. Annual sampling is targeted to be completed in third quarter each year. A recurring work order directs operators to complete annual sampling before the end of the calendar year for each platform that is discharging produced water to the marine environment. Samples are sent to a third party laboratory for compositional analysis using a comprehensive suite of tests. An Environmental Advisor analyses the composition results for changes and trends, and compares the results to relevant guideline criteria.

Statistical Analysis of Composition

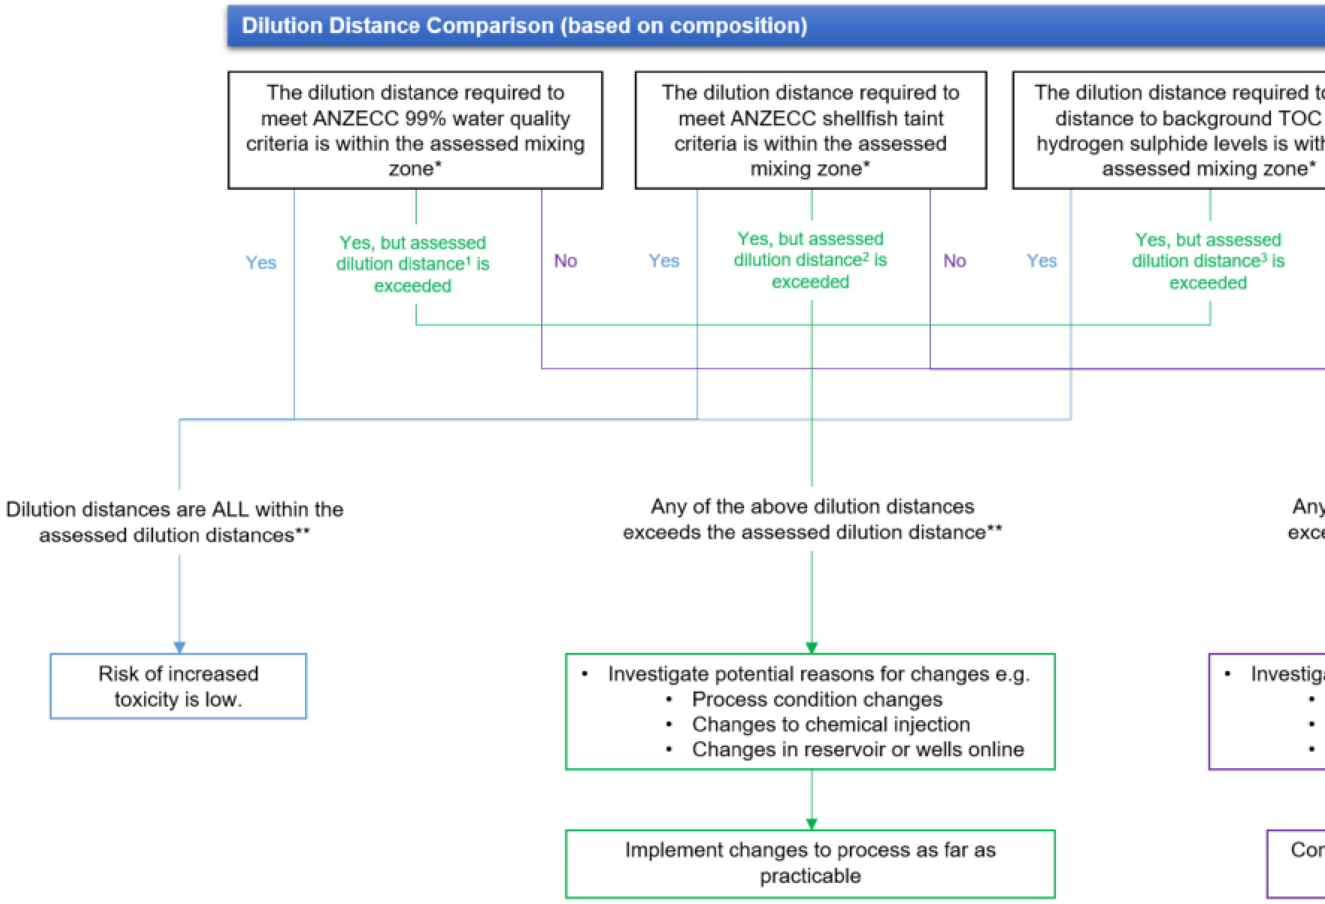
A statistical analysis of the compositional data is conducted to capture any changes that may not be detected through changes to dilution distances or microtox testing. The following will act as triggers for further investigation when analysing the results for changes and trends:

- Results that fall outside of the existing 95% confidence interval (see Volume 2 Appendix F – PFW Data File for confidence intervals)
- Increasing trends of potential contaminant of concern over 3 years
- Presence of a contaminant of concern not previously detected in that platform's discharge

If any of the above triggers are met, investigation will be undertaken to identify possible reasons for the change. The investigation will consider:

- Process condition changes
- Changes to chemical injection
- Changes in reservoir or well mix

Changes to the process will be considered as a means for reducing or preventing further increase in contaminant levels as far as practicable. If changes are not sufficient to prevent an exceedance of the assessed dilution distance or mixing zone in the following round of sampling, this will be managed via the process shown in



** "Assessed mixing zone" refers to the "Mixing zone extent (m)" identified in Table 6-5 of Volume 2*
[1] "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet ANZECC 99% water quality criteria
[2] "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet ANZECC shellfish taint criteria
[3] "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet background levels of TOC and hydrogen sulphide
*** "Assessed dilution distance" refers to the distances identified in Table 6-5 in Volume 2 required to meet ANZECC 99% water quality criteria, ANZECC shellfish taint criteria a*

Figure 2-5 and described in under the "Dilution Distance Comparison" section below.

Dilution Distance Comparison

In parallel to analysis of changes or trends, dilution distances required to meet the following will be calculated from the results:

1. ANZECC 99% species protection water quality criteria
2. ANZECC shellfish taint criteria
3. Background TOC and H_2S levels

If the dilution distances for all of the above three criteria are within the assessed dilution distances for each (provided in Table 6-5 in Volume 2), the risk of increased toxicity is low and no further action is required based on these results. However, further sampling may be required based on the outcomes of microtox testing (see Section 2.7.5.3).

If any of the dilution distances for the above three criteria exceeds the applicable assessed dilution distance but does not exceed the mixing zone for that facility (see "Mixing zone extent" in Volume 2 Table 6-5), potential reasons for the change will be investigated. This will involve investigation into:

- Process condition changes
- Changes to chemical injection
- Changes in reservoir or well mix
- Presence of a contaminant of concern which has not previously been detected at that facility

Changes to the process will be considered as a means for reducing or preventing further increase in contaminant levels as far as practicable.

If any of the dilution distances for the above three criteria exceeds the mixing zone, potential reasons for the change will be investigated and out of routine WET testing will be triggered.

2.7.5.3 Microtox testing

Microtox testing is a single species toxicity test which will be collected at the same time as the annual chemical characterisation and, when applicable, at the same time as WET testing sampling. The single species toxicity test to be undertaken is the Acute Microtox test which measures the decreased light output (luminescence) of the marine bacterium *Viberio fischeri* after exposure to PFW. The toxicity is expressed as the concentration of the PFW sample that causes a 50% reduction in the light output of the bacteria (EC50). These samples will be statistically compared over time to determine if there is a statistically significant change in single species toxicity. It must be noted that there are limitations to these statistical tests until enough sample points have been taken.

If the change in toxicity is not statistically significant, the risk of increased toxicity is low and no further actions are required on the basis of microtox testing.

If the toxicity of the single species toxicity test has shown a statistically significantly increase, then the trigger has been exceeded and non-routine whole effluent toxicity (WET) testing will be undertaken.

2.7.5.4 Whole Effluent Toxicity (WET) testing

Routine WET testing is also performed every three years with the reasoning behind this frequency explained in the Engineering Risk Assessment in Section 6.3.10 of Volume 2. WET testing quantitatively takes into account the bioavailability and interactions of known and unknown substances.

In WET testing, toxicity tests (bioassays) determine the potential toxicity of the sample. Such tests allow for interactions between toxicants and take into account toxicants which cannot readily be measured or are not known to be present in the sample. The toxicity of the sample to temperate marine organisms is determined using chronic bioassays with species that cover a range of trophic levels.

Multiple (8+) tests are used in the WET testing. This number ensures that a range of species and endpoints can be measured with sufficient toxicity data available to establish a species sensitivity distribution (SSD) curve with 50% confidence. From the SSD, the predicted no-effect concentration (PNEC) will be extrapolated; a valuable estimate to compare the toxicity of different samples to a range of biota.

Test species are selected based on their known sensitivity to contaminants, availability of species with standardised test protocols, and, known reproducibility as surrogate test species for assessing contaminants in marine environments. Temperate species are selected in preference to tropical species, where possible, for the toxicity assessment. Toxicity tests with temperate species are carried out at their respective standardised temperatures and fall within the range of 18-20˚C.

Toxicity data generated from these toxicity tests will be utilised to determine a 95% species protection level equivalent per the guidance given in ANZECC (2000).

Species sensitivity distribution (SSD) can also be plotted to derive the concentration that protects (i.e. not harms) 95% and 99% of species with 50% confidence (the PNEC). Species protection values derived from ≥ 8 chronic toxicity values are defined as having a high reliability provided there is an acceptable fit of the data in the SSD. Toxicity data from at least eight toxicity tests is required to ensure that a Burr Type III curve fit is utilised to extrapolate species protection values however eight data points does not necessarily guarantee a good curve fit from which the species protection values are derived. The species protection values (PC95 and PC99) will be derived using the methods described in the Revised Method for Deriving Australian and New Zealand Water Quality Guideline Values for Toxicants (Warne et al., 2014).

The results of both routine and non-routine WET testing will be used to determine the dilution distance required to meet 99% species protection. This distance will be compared to the assessed dilution distance for WET testing and the mixing zone distance for each facility in Table 6-5 in Volume 2.

If the dilution distance determined based on the WET test results is within the assessed dilution distance, the risk of toxicity is low and no further analysis is required.

If the distance is greater than the assessed dilution distance but within the mixing zone in (Volume 2 Table 6-5), investigation into potential reasons for the change will occur. This will involve investigation into:

- Process condition changes
- Changes to chemical injection
- Changes in reservoir or well mix
- Presence of a contaminant of concern which has not previously been detected at that facility

If the dilution distance determined based on the WET test results exceeds the mixing zone defined in Volume 2 Table 6-5, potential reasons for the change will be investigated and updated dispersion modelling will be conducted. Based on the updated dispersion modelling, an impact assessment will be conducted to determine whether the potential change in impact is ALARP and acceptable in accordance with the OPGGS(E) Regulations. This impact assessment will be facilitated by the Environmental MOC process described in Section 2.8.1. If the change in impact is assessed to be ALARP and acceptable, the risk of increased toxicity is considered to be low and no further analysis is required.

If the impact assessment determines that the impact is either not ALARP or not acceptable, in-field monitoring will be triggered. The scope of in-field monitoring will consider sediment sampling, water sampling and biological sampling. Monitoring programs will be designed in consultation with relevant guidance (e.g. *Australian and New Zealand Guidelines for Fresh and Marine Water Quality*) to ensure the program will be appropriate for demonstrating that the environmental performance outcomes have been met (per CM68).

Following in-field monitoring, if the change in impact is unacceptable or cannot be reduced to ALARP, PFW discharge from that facility must cease until a new EP has been submitted and accepted by NOPSEMA.

2.7.6 Greenhouse Gas Calculation and Reporting

Esso calculates and reports its greenhouse gas emissions under the National Greenhouse and Energy Reporting (NGER) scheme, established by the National Greenhouse and Energy Act 2007 and administered by the Clean Energy Regulator. Esso's National Greenhouse and Energy Reporting Management Manual describes the process for tracking and collecting data for greenhouse gas emission calculation and energy reporting across Esso's operations. Esso submits a report of the total amount of greenhouse gas emissions (both emissions released as a direct result of facility activities and emissions released from indirect consumption of energy), energy consumption (including fuel gas, natural gas, electricity) and energy production (crude and condensate, LPG, natural gas, ethane) from its operations via the online Emissions and Energy Reporting System on an annual basis.

2.8 Management of Change (OIMS System 7-1)

Esso's management of change process is documented in the Management of Change Manual which sits under OIMS System 7-1 Management of Change (MOC). The objective of OIMS System 7-1 is to manage permanent or temporary changes that arise during operations and ensure that additional impacts and risks are not introduced by changes that could increase the risk of harm to people, assets or the environment.

OIMS System 7-1 is a structured process, involving relevant engineers, technicians, operations and maintenance personnel and SSHE specialists to evaluate the potential positive and negative consequences of the proposed change, and to seek the endorsement of all potentially impacted parties.

The MOC process is implemented electronically and requires a number of assessments which include technical, regulatory, safety and environmental assessments. A mandatory screening checklist is undertaken for all work being assessed under the MOC process to identify the potential for a change to or increase in environmental impacts. A mandatory regulatory checklist is completed to identify if proposed activities will result in a change to the Environment Plan, this process may trigger an Environmental MOC (detailed below). MOCs where potential environmental impacts are also identified, will also need the environmental checklist completed. Environmental and Regulatory checklists are reviewed and approved by an Environmental and Regulatory Advisor.

2.8.1 Environmental MOC Process

Esso have developed and environmental MOC process that will requires any changes to an existing or new activity against OPGGS(E)Rs. This environmental assessment has been developed to align with NOPSEMAs guidance on when a change is likely to trigger the requirement to submit a proposed revision of an EP. This testing criteria is based on NOPSEMA Guideline A515816 – When to submit a proposed revision of an EP.

As soon as a change from existing approved EP has been identified, through MOC process or HAZID risk screening the Offshore Environment Advisor will complete the assessment.

The Environmental and Regulatory Advisor assesses the Environmental MOC in accordance with OPGGS(E)R 17. A revision of the EP will be required under OPGGS(E)R 17 in the event that a proposed change:

- constitutes a new stage or significant modification; or
- introduces a significant new environmental impact or risk; or
- Significantly increases an existing environmental impact or risk.

The environmental MOC also considers the following:

- Regulation 7 – Activity contrary to the Environment Plan Sub-regulation 17(1) – New activity
- Regulation 8 – Significant new or increased environmental impact or risk
- Sub-Regulation 14(3)(a) – Have the impacts and risks been reduced to as low as reasonably practicable
- OPPGS Act (2006), Section 572 – Maintenance and removal or property etc. by titleholder
- Regulation 14(8) – maintenance of oil spill response arrangements

Minor changes (which do not trigger a resubmission under OPGGS(E)R 17) may result in administrative updates to this Environment Plan which are documented in a change register. If outcome of the assessment concludes the activity is not provided for by current EP, a revision or new EP will be submitted for assessment by NOPSEMA.

Assessments are prepared by an Offshore Environmental Advisor with relevant technical support. Dependent on their level of complexity, assessments are signed off by the Offshore Risk, Environment and Regulatory Supervisor.

Records of these assessment are stored on file. Any changes made to Environment Plans as a result of these assessments must be documented in the relevant Environment Plan's change register.

2.8.2 Temporary Storage Assessment

The Management of Change process includes a 'Temporary Storage Assessment' which is completed when there is the requirement to store property on the seabed temporarily as planning for its removal is being undertaken, or a proposed deviation to complete removal is being prepared or assessed. This process is further described in Volume 2, Section 2.4.4.3.

2.9 Contractor Management (OIMS System 8-1)

OIMS System 8-1 Third Party Services, provides a systematic approach for the selection and management of third parties doing work on the company's (Esso's) behalf. Third parties, or third party service providers, referred to here as contractors, can influence Esso's operations and reputation and therefore it is essential that they perform in a manner that is consistent with Esso's policies and business objectives. OIMS System 8-1 defines processes for contractor selection including the establishment of agreements (pre job stage) and all aspects of managing interfaces between Esso and contractors to ensure work meets Esso's expectations and is performed in a safe, secure, and environmentally sound manner (during job execution). This System applies to all contractors whether they are providing a service (including marine operations, wireline and workover operations, crane services and aviation services) or whether they are providing goods such as suppliers of critical equipment (e.g., valves, seals, gaskets, lifting equipment and cranes). Contractors are prioritised based on the environment in which they will operate, their potential SSHE impact, exposure hours/frequency of work and, once job execution has commenced, SSHE performance (categorisation can be adjusted based on SSHE performance). The prioritisation category in which the contractor is placed determines the scale/level/intensity/frequency of interface activities required for that contractor as determined by the Contractor Interface Management program.

The contractor selection and management processes are established to support two different stages of a contract life cycle:

- The first stages include requisitioning for contractor services, pre-qualifying contractors, selecting the contractor, and conducting pre-mobilisation activities associated with subsequent contractor interface management.
- The later stages occur during job execution and involve ongoing interface management to
    - ensure contractor crew understands EAPL's culture and expectations, along with the hazards at the job site;
    - communicate EAPL requirements to take proactive measures to prevent incidents;
    - maintain crew competency; and
    - monitor and steward activities to confirm that the contractor is meeting the Operations Integrity requirements of the agreement.

The pre-qualification process includes review of recent contractor performance results, reviews of contractor SSHE programs, and site visits to the contractor's facilities to validate reported performance results and evaluate a contractor's capability for effective work execution. The Esso SSHE Group participates in the pre-qualification screening and bid evaluation process including contractor site assessments, as required. OIMS System 8-1 specifies that all contractors conducting activities with potential high SSHE impact must submit a SSHE execution plan or a bridging document for the scope of work. High SSHE impacts are activities which if poorly executed could cause significant safety or environmental impacts. These may include aviation, construction, wellwork, subsea activities and vessels.

The Contractor's SSHE execution plan is required to address:

- Communication of SSHE expectations and requirements to Contractor crews and Subcontractors;
- Compliance with relevant regulatory obligations (including Environmental Management Plans, Safety Cases, relevant laws and regulations);
- Reporting of leading and lagging indicators;
- Incident investigation and management processes;
- Other specific requirements as dictated by the scope of the assignment or local site characteristics.

Esso appoints a Contract Owner and a Contract Administrator for each contractor agreement, who together with other Esso personnel, deliver the requirements of the Contractor Interface Management program. The Contract Administrator has responsibilities specific to the contractor activities in this EP. These are listed in Table 4-1.

2.10 Incident Management (OIMS System 9-1)

The purpose of OIMS System 9-1 Incident Management is to provide the requirements for proper management of SSHE incidents including initial response and notifications, investigation and analysis, documentation, communication of lessons learned, corrective actions management and the analysis of trends. In the context of this System, incidents (including near misses) are related to personnel safety, process safety, security, occupational health, equipment reliability (with SSHE consequences), environmental impact and regulatory compliance.

OIMS System 9-1 requires that:

- The incident is reported in the IMPACT database;
- An investigation occurs, if triggered by an evaluation of actual or potential incident severity; and

- The incident is correctly documented, lessons learned are communicated, and corrective actions are followed up and tracked in the IMPACT database.

The triggers and expected deliverables for incident investigations are based on incident severity (actual and potential) and are documented in the Incident Investigation and Sharing Guideline. The triggers for an investigation of an environmental incident are a significant spill to the environment, a community complaint or a regulatory reportable incident (see Table 8-2) (or other incident at the discretion of the Asset Manager).

Corrective actions that address the root cause(s) of the incident are identified and implemented to prevent the recurrence of similar incidents. Corrective actions can be improvements to facilities, programs, processes or procedures that are identified to reduce the impact or risk, and enhance the integrity of operations. Once corrective actions have been identified from incident reports (including audit and inspection reports), the implementation process is systematically managed to completion via IMPACT. This ensures results are achieved and that the improvement is documented and sustained.

Esso utilises the IMPACT incident database as the single, centralised tool for capturing data, tracking, sharing and analysing incidents, assessment findings, lessons learned and follow-up actions.

3 Platform Surveillance and Optimisation

Engineers and technical specialists support the ongoing operation of Esso's Bass Strait activities by providing technical oversight, advice and direction to offshore operators. A variety of engineers and technical specialists are responsible for monitoring and optimising the production process through surveillance of a variety of aspects of the platforms including reservoir performance, production rates, facility efficiency, and flaring rates. In addition, they are responsible for safely and effectively implementing changes and improvements to the facilities.

Operations Technical Monitoring Program (CM30)

The technical monitoring program provides a structure for undertaking process and equipment surveillance. The aims of technical monitoring are to ensure operation within the design envelope. A variety of parameters throughout the process are monitored on a monthly basis.

Technical monitoring continues once platforms suspend oil and gas production, commensurate with the platform services which are still operating.

Pile level trends are monitored on a quarterly basis. The level trends are analysed to identify if there has been any extended period of operation outside the expected operating envelope. Deviations require investigation to establish the cause and develop a corrective plan where required.

Monitoring and management of the water handling process system (red boxes in Volume 2, Figure 5-36) and the oil in water monitoring system (yellow boxes in Volume 2, Figure 5-36) consist partly of operations and maintenance actions (described under CM10); and surveillance and optimisation actions (further described here). Both these management controls act in concert in order to ensure the oil in water is kept at minimum levels during overboard discharge.

Water handling system - *Surveillance and Optimisation*

Checks are performance for the system against key operating limits/bounds and that the control system parameters are stable and functional. Chemical use to aid water and oil separation is monitored according to set targets. Trends are reviewed to make adjustments to enhance the water handling process including to reduce oil-in-water levels.

Engineers/specialists:

- Review the oil in water performance during period.
- Consider whether hydrocyclones have been operating in preferred range.
- Review pressure ratio to ensure it is appropriate.
- Review maintenance history of equipment and suggests improvements as required.
- Where performance issues are identified, review with Platform Operations. Consideration is given to adjusting operating parameters, degassing of the hydrocyclone, more frequent backflushing of the hydrocyclone, and scheduling of clean-up to clear deposits and checking for liner wear.
- Consider separator residence time, DGF gas feed rate per design (where applicable) and chemical injection rates

OIW monitoring - Surveillance and Optimisation

Trends are reviewed to make adjustments to the OIW monitor to enhance monitoring effectiveness.

Engineers/specialists:

- Consider reliability of online OIW monitor – shore laboratory trends and long term OIW trends
- Review performance against OIW discharge limits to ensure discharges remain below limits and to allow for identification of opportunities for improvement

4 Roles and Responsibilities

As required by OPGGS(E)R 14(4), this section sets out the roles and responsibilities of personnel in relation to the implementation, management and review of this EP.

4.1 OIMS Management Committee

The OIMS Management Committee (OIMS MC) has overall accountability for the implementation, execution and continuous improvement of OIMS within Esso.

Key responsibilities of the OIMS MC include:

- Demonstrate commitment to OIMS through active and visible participation in OIMS implementation, execution and improvement;
- Ensure that Annual System Reviews are conducted;
- Review key Operations Integrity performance indicators that show the status and effectiveness of OIMS implementation and execution; and
- Periodically review Operations Integrity incidents for learning and continuous improvements to OIMS.

4.2 Environment Plan Key Roles and Responsibilities

Key roles and responsibilities for Esso and Contractor personnel relating to implementing, managing and reviewing this EP are described in Table 4-1.

The organisation structure for the activities described in this EP is illustrated in Figure 4-1.

Table 4-1 Key Roles and Responsibilities

Role	Responsibility
Operations	
All site personnel	• Follow procedures and safe work practices • Comply with requirements and expectations of the Permit to Work system, including completing JSAs • Store equipment, chemicals and oils in designated areas to prevent spills to the environment • Dispose of waste in appropriate containers • Notify relevant person in charge of all environmental incidents immediately • Record and report environmental hazards
Offshore Installation Managers (OIM) / Designated person in charge	• Encourage active employee and contractor involvement in hazard identification and risk assessment processes including Job Safety Analysis and Step Back 5x5 • Ensure platform inductions (Greencards) are completed as required • Ensure waste is managed on platforms and that it is stored and sent to shore as per relevant Waste Management Plan • Review and approve Permits to Work • Review and approve daily operations performance data (e.g. water discharge, fuel and flare volumes) • Ensure periodic environmental compliance reviews are completed • Develop, track and close out corrective actions from inspections, audits or environmental monitoring in a timely manner • Ensure production operations are conducted in accordance with this EP and approval conditions • Report environmental incidents • Complete verbal notifications of Reportable incidents to NOPSEMA

Role	Responsibility
Platform Services Operator	• Deliver Platform Induction Card "Green Card" • Ensure waste is transported with correct labelling • Oversee general platform housekeeping • Correspondence with helicopters and vessels from platform

Offshore Producing Field Superintendent / Offshore Decommissioning Superintendent	• Assist Environment and Regulatory advisors to
	  ○ engage with OIMs on environmental matters
	  ○ communicate environmental expectations and guidance materials
	  ○ communicate environmental learnings
	• Ensure all personnel (including third party service contractors) on platforms complete an HSE induction
	• Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately
	• Ensure personnel are competent to perform the work they have been assigned.
	• Ensure production operations are conducted as per this EP and approval conditions
	• Stewardship and sustainability of OIMS on platforms
	• Encourage active employee and contractor involvement in hazard identification and risk assessment processes including Job Safety Analysis and Step Back 5x5
	• Manage change requests for the activity and submit MOC to notify the Offshore Environmental Adviser of any scope changes in a timely manner

Offshore Producing Asset Manager / Offshore Decommissioning Asset Manager	• Ensure sufficient competent staff to operate the platform and pipelines under normal and emergency conditions • Ensure production operations are conducted as per this EP and approval conditions • Liaise with regulatory authorities as required • Manage change requests for the activity and submit MOC to notify the Offshore Environmental Adviser of any scope changes in a timely manner • Monitor and steward close out of corrective actions identified during environmental monitoring or audits • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Review this EP as necessary and manage change requests • Verify relevant Environmental Approvals for petroleum activities exist prior to commencing an activity
Decommissioning Supervisor	• Steward development of Decommissioning activities • Manage change requests for the activity and submit MOC to the Offshore Environmental Adviser for assessment of implications for this EP • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor
Marine Field Superintendent	• Responsible for sourcing and contracting vessels • Liaise with *Contractor Representative – Vessel Services* • Ensure Vessel Management Team completes an Environmental Familiarisation
Wellwork	
Well Operations Supervisor	• Manages work activities in accordance with Operations, Maintenance, Wellwork and Work Management procedures

Role	Responsibility
	• Steward wellwork and contractor management requirements on Workover/Wireline Rig and Marine Operations while servicing Esso operations • Manage change requests for the activity and submit MOC to the Offshore Environmental Adviser for assessment of implications for this EP • Submit notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Verify relevant Environmental Approvals have been obtained prior to commencing activity • Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported
Well Operations Superintendent	• Monitor and steward close out of corrective actions identified during environmental monitoring or audits • Manage change requests for the activity and submit MOC to the Offshore Environmental Adviser for assessment of implications for this EP • Submit notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Verify relevant Environmental Approvals have been obtained prior to commencing activity
Maintenance, Reliability and Integrity	
Emergency Preparedness & Response (EP&R) Advisor	• Ensure emergency drills are conducted as per the OPEP schedule • Maintain Production OPEP and ERM • Verify, maintain and monitor changes in oil spill capabilities (EPOs and EPSs)
IMT Duty Manager	• Establish and take control of the Incident Management Team (IMT) and establish an appropriate command structure for the incident. Implement Emergency Response Activities as required and as outlined in the OPEP
Maintenance Reliability and Integrity (MR&I) Manager	• Ensure maintenance and testing activities are carried out in accordance with OIMS 6-4 requirements • Ensure that a SSHE Execution plan is in place as required • Review current operations and maintenance issues with the Production Manager and the Operations Superintendent • Monitor and steward close out of corrective actions identified during environmental monitoring or audits • Manage change requests for the activity and submit MOC to the Offshore Environmental Adviser for assessment of implications for this EP • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Ensure subsea installation activities are conducted as per this EP and approval conditions • Track and report compliance with performance outcomes and performance standards as per the requirements of this EP • Verify relevant Environmental Approvals for all petroleum activities exist prior to commencing activity • Submit MOC to notify the Offshore Environmental Adviser of any scope changes in a timely manner
Production Chemist	• Ensure all chemicals proposed to be discharged are communicated to the Offshore Environment Advisor, assessed and approved prior to discharge • Ensure all production chemicals are used in approved concentrations

Role	Responsibility
	• Provide relevant documentation and assist Offshore Environmental Advisor in assessment of chemicals proposed to be discharged
Production Surveillance and Optimisation	
Production Surveillance & Optimization (PS&O) Engineers / CoP Engineers	• Close out corrective actions identified during environmental monitoring or audits. • Ensure all chemicals proposed to be discharged are communicated to, assessed and approved prior to discharge • Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately • Ensure production operations are conducted as per this EP and approval conditions • Surveillance and optimisation of production systems listed in this EP • Manage change requests for the activity and submit MOC to notify the Offshore Environmental Adviser of any scope changes in a timely manner. • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Verify relevant Environmental Approvals for petroleum activities exist prior to commencing activity
Third Party Services	
Contractor Representative – Vessel Services	• Develop and maintain a SSHE Execution Plan which details Esso EP obligations and HSE requirements • Track and report compliance with performance outcomes and performance standards as per the requirements of this EP • Verify that contractors meet environmental-related contractual obligations • Ensure personnel are competent to perform the work they have been assigned • Ensure the vessel management system and procedures are implemented • Maintain Vessel ERP • Ensure all chemicals proposed to be discharged are communicated to, assessed and approved prior to discharge • Ensure periodic environmental compliance reviews are completed. Corrective actions from inspections must be developed, tracked and closed out in a timely manner • Monitor and steward close out of corrective actions identified during environmental monitoring or audits • Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately • Ensure emergency drills are conducted as per the Shipboard Marine Pollution Emergency Plan (SMPEP) schedule. • Manage change requests for the activity and submit MOC to notify the Offshore Environmental Adviser of any scope changes in a timely manner • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Verify relevant Environmental Approvals for the activities exist prior to commencing activity
Contractor Representative – (for all contractors except for contractor providing vessel services)	• Develop and maintain a SSHE Execution Plan (if required) which details Esso EP obligations and HSE requirements • Track and report compliance with performance outcomes and performance standards as per the requirements of this EP

Role	Responsibility
	• Ensure periodic environmental compliance reviews are completed. Corrective actions from inspections must be developed, tracked and closed out in a timely manner • Verify that contractors meet environmental-related contractual obligations • Ensure personnel are competent to perform the work they have been assigned. • Ensure all chemicals proposed to be discharged are communicated to, assessed and approved prior to discharge • Close out corrective actions identified during environmental monitoring or audits • Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately • Ensure emergency drills are conducted as per the SMPEP schedule • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Verify relevant Environmental Approvals for all petroleum activities exist prior to commencing activity
Contract Administrator (Esso)	• Confirm that activities are conducted in accordance with this EP, as detailed in the approved Contactor SSHE Execution Plan (or equivalent) • Ensure contracted personnel are competent to perform the work they have been assigned • Track and report compliance with performance outcomes and performance standards in accordance with requirements in this EP • Ensure that a SSHE Execution plan is in place where required • Verify that contractors meet environmental-related contractual obligations
Safety, Security, Health and Environment (SSHE)	
Offshore Environmental Advisor(s)	• Provide day-to-day environmental support and advice • Assist with reviewing, investigating and reporting environmental incidents. • Confirm environmental incident reporting meets regulatory requirements • Compile and review environmental compliance documentation • Communicate Environmental Plan obligations to relevant personnel (including contractors) • Prepare environmental component of relevant Induction Packages • Provide material and advice to relevant personnel and contractors to assist them to understand their environment responsibilities • Confirm that activities are conducted in accordance with this EP, as detailed in the approved Contactor SSHE Execution Plan (or equivalent) • Track and report compliance with performance outcomes and performance standards as per the requirements of this EP • Ensure environmental monitoring and inspections/audits are conducted as per the requirements of the EP • Monitor and steward close out of corrective actions identified during environmental monitoring or audits • Assess change requests against the scope of the Environment Plan to ensure it meets regulatory requirements using Environmental Management of Change process (See Section 2.8) • Conduct assessment of chemicals proposed to be discharged • Assist in preparing external regulatory reports, in line with environmental approval requirements and ExxonMobil external regulatory reporting obligations • Liaise with regulatory authorities as required

Role	Responsibility
	• Verify relevant Environmental Approvals for all petroleum activities exist prior to commencing an activity
Offshore OIMS Coordinator	• Confirm environmental incident reporting meets ExxonMobil internal event recording, investigation and learning requirements
Stakeholder Engagement Advisor	• Perform ongoing liaison and notification as outlined in the EP • Prepare and implement the Stakeholder Consultation Plan Report on stakeholder consultation
Offshore Risk, Environment and Regulatory Supervisor	• Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately • Ensure ongoing engagement with government agencies and other relevant external stakeholders • Liaise with regulatory authorities as required • Monitor and steward close out of corrective actions identified during environmental monitoring or audits • Review environmental performance at Asset Leadership Team meetings. • Verify relevant Environmental Approvals for petroleum activities exist prior to commencing activity
Management	
SSHE Manager	• Hold personnel accountable for ensuring operations are conducted as per the relevant standards and commitments in this EP • Review environmental performance at Business Unit Leadership meetings.
Production Manager	• Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately • Ensure an effective organisational structure is in place, with defined roles and responsibilities to ensure the implementation of OIMS for offshore facilities and associated pipeline operations • Hold personnel accountable for ensuring operations are conducted as per the relevant standards and commitments in this EP • Verify relevant Environmental Approvals for petroleum activities exist prior to commencing activity
Projects Manager	• Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP are reported immediately. • Provide notification of potential new activity/modification of existing activity/change in stage of activity for new or increased risk to the Offshore Environmental Advisor • Verify relevant Environmental Approvals for petroleum activities exist prior to commencing activity

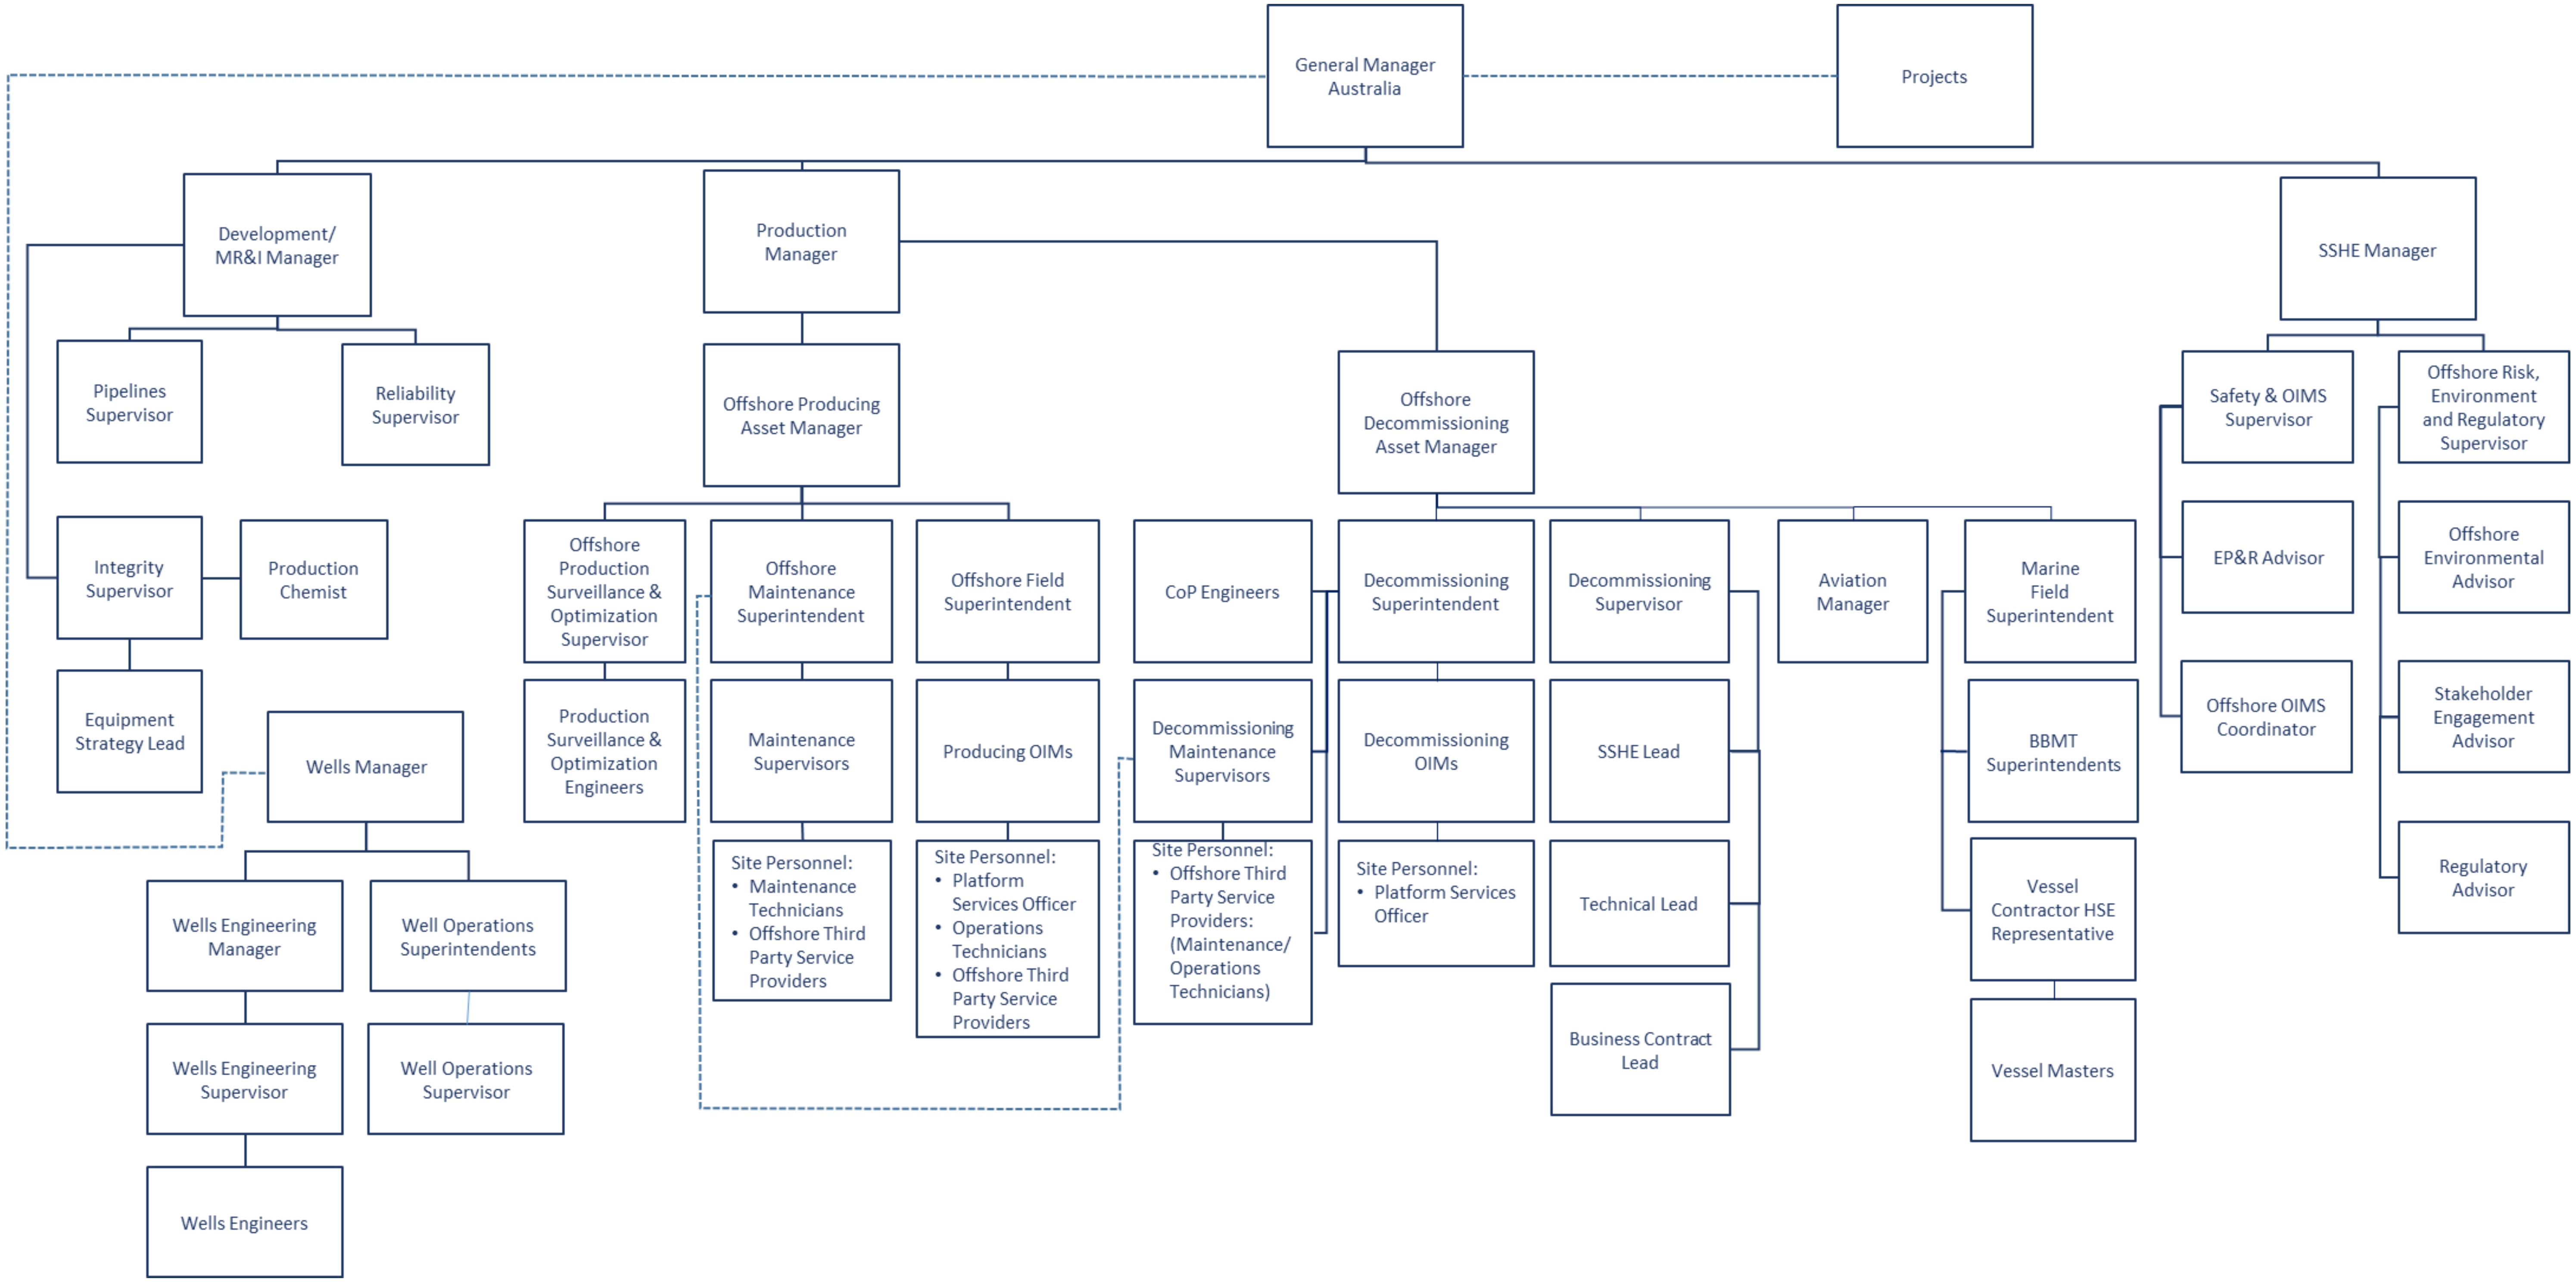


Chart current at time of writing. Subject to change

Figure 4-1 Organisational Chart

5 Training and Awareness

OPGGS(E)R 14(5) requires that the implementation strategy must include measures to ensure that each employee and contractor working on, or in connection with, the activity is aware of their roles and responsibilities in relation to the EP.

All personnel are required to be competent to perform their assigned positions. The Training and Procedures group are responsible for identifying training needs, keeping records of training undertaken, and identifying minimum training requirements of personnel. Personnel Competency is managed through OIMS System 5-1.

As part of the contracting process, Esso Procurement ensures all contractors have the appropriate qualifications, job skills and training. Additional training and familiarisation may be delivered by the Training and Procedures group or environmental and regulatory adviser.

5.1 Environmental Training

5.1.1 Environment Plan Awareness

All personnel with roles and responsibilities (as defined in Table 4-1) will complete general environmental awareness training which outlines Environment Plan importance, structure, implementation and roles and responsibilities. This training will define reportable environmental incidents and highlight the associated reporting requirements. Personnel receiving the training will be made aware of all environmental performance outcomes and standards relating to their area of work and that a breach of any outcome or standard constitutes a recordable environmental incident. This training will also cover reporting of recordable incidents.

Guidance documents exist for identifying and reporting environmental reportable incidents, identifying environmental recordable incidents and incidents involving wildlife. These documents will be reviewed, updated as required and distributed to the relevant personnel on an annual basis or if triggered earlier (e.g. following an update to this EP).

5.1.2 Offshore Induction

The Offshore Induction is compulsory for anyone accessing Esso's offshore facilities. The Offshore Induction describes basic requirements including identifying and reporting incidents to the OIM, work permits and waste management practices. Records of inductions are maintained by the Training and Procedures group.

5.1.3 Platform Induction Card "Green Card"

The Platform Induction or 'Green Card' (CM 13) is provided to all personnel that have not visited a platform before, or have not been to the platform in more than a year. The induction includes platform-specific information about environmental awareness, including reporting oil/chemical spills or potential spills and locating emergency spill kits. A record is kept of all completed inductions on the platform for a minimum of one year.

5.1.4 Vessel Management Environmental Familiarisation

Vessel Management personnel receive Esso environmental familiarisation. The familiarisation material includes specific Environmental Plan vessel requirements and definitions of an environmental incident. The familiarisation material will ensure Vessel Management personnel are aware of all environmental performance outcomes and standards relating to their work and that a breach of any outcome or standard constitutes a recordable environmental incident. This familiarisation material will also cover the requirements of the vessel contractor in relation to reporting of recordable incidents. The environmental familiarisation material will be delivered on newly contracted vessels and to new crew members when they board the vessel for the first time. The familiarisation material will be reviewed, updated as required and distributed to the relevant personnel on an annual basis or if triggered earlier (e.g. following an update to this EP).

5.2 Competency and Training

5.2.1 Esso Personnel

OIMS System 5-1 Personnel Selection, Placement and Competency Verification addresses the selection, placement, training and ongoing verification of competency of employees and contractors to meet specific job requirements

Position descriptions for Key Positions, which could have a significant impact on OI (personnel and process safety, security, health or environment), document required OI related competencies and/or experience. This provides the basis for ensuring personnel selection and placement decisions meet specific job requirements. Personnel performing tasks with environmental aspects and impacts / risks will have the knowledge and skills necessary to perform their work in a manner consistent with the environmental policy and the requirements of OIMS System 6-5 Environmental Management.

The placement of personnel is subject to verification of completion of any needed training and/or experience, and demonstration of the required competencies for the performance of the job. The extent of initial, ongoing and refresher training provided is based on established requirements for OI related training and an individual's competency and/or experience gaps. These training requirements are documented in a training plan. The requirements may be met through training and/or developmental activities (i.e. training assignments).

Learning management systems are used for competency tracking, e-learning, training, scheduling and tracking of re-qualification requirements. Training progress is reviewed periodically by an individual's Supervisor. Any new training requirements are completed per the training plan.

In addition to the process of assuring that a person is competent in the knowledge and skills necessary to perform in a position, an assessment of the individual's performance and behaviours in that position is conducted annually. The performance assessment process includes OI aspects and behaviours such as compliance with OIMS systems and associated procedures.

5.2.2 Third Party Service Providers

Third party services contractor requirements are addressed in OIMS System 8-1 Third Party Services. Job specific requirements are defined and communicated to contractors during the contracting process and all contractor personnel are screened, trained and suitably qualified.

Each contractor is required to maintain training files for their personnel. Esso verifies these records as part of the initial contracting process and at least annually for OIMS Critical contractors.

Table 5-1 Overview of Offshore Personnel Environment Plan Induction and Training

Component	Esso Office Based Personnel (inc. engineers, contractors)	Esso Facilities		Vessels
		Esso Offshore Personnel (field staff)	Third Party Service Providers (Contractors)	Vessel Personnel
Environmental Plan / environmental incident definition	Environment Plan Awareness	Environment Plan Awareness	Environment Plan Awareness	Vessel management environmental familiarisation
Work Management Systems (Risk Assessments, JSA, Stepback 5x5) to manage environmental risks	Offshore Induction (where relevant)	Work Management Systems Fundamentals Training Offshore Induction Stepback 5x5 and Job Safety Analysis competency (non-Visitors)	Work Management Systems Fundamentals Training (where relevant) Offshore Induction Stepback 5x5 and Job Safety Analysis competency (non-Visitors)	Contractor Management System SSHE Execution Plan
Identification and reporting of environmental hazards and incidents	Platform Induction Card "Green Card" (where relevant)	Platform Induction Card "Green Card"	Platform Induction Card "Green Card" SSHE Execution Plan	SSHE Execution Plan Vessel management environmental familiarisation
Overview of oil spill response procedures	Green Card (where relevant) Included in Esso Offshore Induction Specific training for those with a response position in an emergency	Green Card Included in Esso Offshore Induction Specific training for those with a response position in an emergency	Green Card Included in Esso Offshore Induction Specific training for those with a response position in an emergency	SSHE Execution Plan Contractor Vessel Induction Vessel management environmental familiarisation
MOC	Via use of Procedures & MOC electronic Tool (P/MeT) which includes MOC training	Via use of Procedures & MOC electronic Tool (P/MeT) which includes MOC training	MOC for work completed by Third Party Service Providers on Esso Facilities is managed by Esso Personnel.	Via implementation of contractor MOC system. Vessel management environmental familiarisation

6 Monitoring of Environmental Performance

In accordance with OPGGS(E)R 14(6) the implementation strategy must include monitoring, recording, audit, management of non-conformance and review of environmental performance and the implementation strategy to ensure that the environmental performance outcomes and standards in the environment plan are being met.

6.1 Monthly Review of the Environmental Plan

Esso conducts a monthly review of activities against the EPOs and the EPSs in the EP to ensure they are continually being met. The process involves reviewing a number of reports including the FIMS equipment exception list, vessel monthly compliance checklists, incident records from IMPACT, produced formation water monthly report, Required Competency exception reports and Wellbore Risk Management Test Exceptions reports. The review also includes tracking of open and overdue action items.

The purpose of this review is to monitor and confirm that all EPOs and EPSs are being met and that the effectiveness of the controls is acceptable. This review ensures the correct level of environmental performance is continuously being achieved and prompts action where EPOs or EPSs may not be met.

This review is recorded and if there any breaches of EPOs or EPS, these are detailed and provided to NOPSEMA through the monthly recordable incident report. This monthly review allows for comparison of compliance against EPOs and EPSs with previous months and provides a foundation for the identification of trends in environmental compliance. Trends identified may form focus areas for the audits against this EP described below.

The review is distributed to the Offshore Asset Managers each month.

6.2 Audits, Assessments and Inspections

Environmental performance assurance for the activity will be undertaken to ensure that:

- Controls are implemented in accordance with EPSs to achieve the EPOs;
- Non-compliances and opportunities for improvement are identified; and
- Environmental monitoring and reporting requirements are met.

6.3 Offshore Audit and Inspections

Esso undertakes audits against this EP periodically which may consist of both desktop audits and offshore site audits. Audits are conducted in accordance with the Esso Internal Audit Protocol. This protocol describes the EAPL risk-based approach to environmental plan (or monitoring plan, license conditions) audits and assessments. The risk-based approach considers the environmental impacts and risks associated with the activities, previous environmental performance of the activity (informed by NOPSEMA inspections, incident history and other environmental performance factors), trends in environmental recordable/reportable incident notifications and the nature and scale of the activity.

The primary objective of each audit is to verify activities are undertaken in accordance with EPOs and EPSs in this EP and that the controls are in place and effective in reducing the environmental impacts and risks of the activity to ALARP and acceptable levels. However, the audit may also consider the following secondary objectives:

- Verify that environmental risks are identified, assessed and managed adequately;
- Training and competency verification and communication of roles and responsibilities;
- Evaluate the effectiveness of environmental management systems; and
- Recommendations for improvement opportunities for environmental performance.

Across the lifetime of the EP, the implementation strategy as well as all impacts and risks identified in Volume 2 will be audited. Learnings from audits will be applied to all applicable facilities. Table 6-1 and Table 6-2 are used as the coversheet for all internal audits to ensure the scope of the audit is clearly linked to impacts, risks and elements of the implementation strategy in the EP. The environmental management system described in this plan is common to all EAPL facilities in Bass Strait. Therefore audits of the environmental management system are applicable to all facilities. Verification (field or desktop) will be conducted on a minimum of three facilities per audit and these facilities will be selected to give a varied representation of Esso's Bass Strait facilities (e.g. CoP, wellwork/wireline, older facility, newer facility). As a minimum, an annual offshore audit will be completed against this EP and each facility covered by this EP will be subject to verification once over the lifetime of the EP.

The Offshore Environmental Advisor(s) is responsible for planning and coordinating audits. The Offshore Environmental Advisor(s) may perform the role of auditor for particular components of the audit where they are independent from the work being conducted. To maintain the independence of the auditor, another auditor will be selected to audit work which the Offshore Environmental Advisor(s) has been directly involved in such as environment plan awareness training, monitoring of environmental performance and reporting.

Periodic environmental inspections will be completed. These inspections may focus on aspects of activities assessed to be of a higher consequence level or risk category, or key focus areas, or specific EPOs.

Opportunities for improvement or non-compliances observed are documented and communicated to the OIM at the time of the audit, who in turn is responsible for communicating this information to all relevant platform personnel. Findings and actions are provided in an audit report and documented in the IMPACT database to facilitate the tracking of the actions until closed out.

Table 6-1 Audit Coversheet – Implementation Strategy

Implementation Strategy	
☐	4-2 Compliance with Law, Regulations and Permits

6.3.1 Vessel Inspections

In addition to the third party services contractor OIMS evaluation (see Section 2.8), a pre-mobilisation inspection is undertaken for all vessels to communicate specific EP requirements and to ensure that procedures and equipment for managing routine discharges and emissions are in place to enable compliance with this EP.

Vessels will conduct their own HSE inspections, which will be provided to Esso for ongoing compliance monitoring. These will be discussed in the quarterly review and any findings/actions discussed.

Table 6-3 Summary of Audits, Inspections and Assessments

Audit/Inspection/Assessment	Frequency	Responsibility
EP Compliance Audit / Inspection	Once for contracts <1 year Annually for contracts >1 year	Environment & Regulatory Advisor
EP Compliance ongoing monitoring	Monthly report	Vessel Master /HSE
OIMS Assessment	Annually for contracts >1 year	Contract Manager

6.3.2 Marine Assurance

The ExxonMobil Marine Quality Assurance Best Practice (MQABP) is developed by the ExxonMobil Logistics Upstream Centre of Excellence and administered locally by each affiliate. The MQABP is based on a recognised marine quality process and standards framework developed and administered by the Oil Companies International Marine Forum.

The MQABP determines the level of assessment required, based on the term of hire, or repeated terms of hire. The Best Practice assesses both the vessel, and vessel operator, against a recognised industry standard:

- Offshore Vessel Safety Management System Assessment (OVMSA); and
- Offshore Vessel Inspection Questionnaire (OVIQ).

The OVIQ is customised by the selection of appropriate variants designed to examine the specific capabilities of the subject vessel in the specific tasks that will be undertaken by the vessel. An OCIMF accredited inspector completes the OVIQ and provides the observations in the form of the OVIQ report which is uploaded to the OCIMF database. The ExxonMobil Global Marine Quality Assurance group provides feedback on the OVIQ completed, or where less than 12 months old, provides a review of the existing OVIQ. OVIQ observations are ranked in priority by the Global Marine group, and the affiliate is responsible for ensuring the closeout of observations.

Esso's marine/logistics group is responsible for engaging with the vessel owner to develop a closeout target for high priority items, and the effective closeout of observations is reviewed quarterly by the Global Upstream Logistics Centre of Excellence. The assessment of OVMSA is determined by the length of engagement of each specific vessel operator, and is defined within the MQABP. Where OVMSA's are to be verified, they are verified at the site responsible for the day to day management of the vessel. ExxonMobil's Global Upstream Logistics Centre of Excellence assigns OCIMF accredited inspectors to complete on site OVMSA verifications.

Other inspections which are complimentary to the OVIQ, such as Condition and Suitability Surveys, and assessments against International Marine Contractor (IMCA) guidelines may also be conducted.

Where an OVIQ inspection and/or OVMSA Verification Review is not available and all reasonable efforts based on time and resource availability to complete an OVID inspection and/or OVMSA Verification Review are exhausted (i.e. short term vessel hire), the affiliate may approve the use of an alternate means of inspection.

6.3.3 Annual OIMS Assessment

OIMS Assessments (OIMS System 11-1) are carried out annually to determine if Esso is meeting the ExxonMobil OIMS Expectations and Guidelines.

OIMS System 11-1 describes the following OIMS assessments:

- External Assessment - An ExxonMobil team, composed of persons external to Esso operations, conduct an assessment of all of the Systems every 4 years. The External Assessment provides an independent evaluation of compliance with OIMS Expectations.
- OIMS Internal Assessment - This assessment is conducted in a similar manner to that of the external assessment. It is undertaken annually by a local team, except in the years in which an external assessment is conducted.

The findings and recommendations of assessments are documented in the IMPACT database to facilitate the tracking of all OIMS actions until closed out. Annual OIMS assessments do not look specifically at compliance with EPOs and EPSs in the EP and instead evaluate compliance at the system level. This allows for continual and systematic identification of deficiencies and improvements in the environmental management system.

6.3.4 Ongoing Stewardship

6.3.4.1 Business Unit Leadership

Business Unit Leadership meetings (attendees include the Production Manager, the SSHE Manager and the Production Projects Manager, among others) cover issues relating to management of the upstream business and involve a review of key performance indicators. These meetings do not review compliance against all EPOs and EPSs but do involve periodic reviews of environmental KPIs.

6.3.4.2 OIMS Management Committee

OIMS Management Committee Review meetings (attendees include the Production Manager, the SSHE Manager, the Maintenance, Reliability & Integrity Manager, Asset Managers, OIMS Supervisor and OIMS Coordinator) are held quarterly to review the OIMS system. These reviews may include regulatory submissions, enforcement notices and current regulator focus areas driving activity.

OIMS Management Committee meetings also involve an annual review of OIMS System 6-5 Environmental Management. The annual OIMS System 6-5 review does not focus specifically on performance against EPOs and EPSs in this EP. The annual review looks at system KPIs including trends in environmental spills and corporate environmental compliance incidents. The review may include a discussion on opportunities for continuous improvement including areas for environmental performance improvement from the previous year.

6.3.4.3 Asset Managers Environment Meeting

These meetings are held quarterly between the Offshore Environmental Advisors, Offshore Asset Managers and the Offshore Field Superintendents. These meetings are aimed at giving an overview of offshore environmental monitoring and management and to compare the environmental performance from the current quarter to previous quarters. Agenda items may include a discussion of current and upcoming work fronts in the environmental space and discussions on trends in environmental compliance and performance. Trends by facility or type of non-compliance may be identified and discussed in these meetings. Asset Managers also receive a Monthly Environmental Compliance Monitoring Report which includes:

- Recordable Environmental Incident Report for the month
- Monthly EP compliance check against performance standards and outcomes
- Monthly PFW performance summary

6.3.4.4 Red Box

The Red Box Team (which includes OIMs and Offshore Field Superintendents) reviews platform performance fortnightly for each platform covering production, cost, engineering safety and environment. Each meeting reviews overdue action items including those from NOPSEMA Environmental Inspections and those arising from internal environmental audits. Red Box meetings also include a summary of environmental non-compliances against EPOs and EPSs in the EP which is generated from the IMPACT database.

6.3.4.5 Incident Reviews

Offshore Incident Reviews are held at the start of each week with a team which includes Offshore Asset Managers, Field Superintendents, the Offshore Safety Coordinator and the Offshore OIMS Coordinator. The meeting involves a review of all incidents and near misses that were entered into IMPACT the previous week, including environmental incidents and near misses against this EP. This review verifies that the environmental team has been engaged for any environmental incidents. The review also involves a check for any internal or external triggers that have been met to report or investigate the incident further.

6.3.4.6 Toolbox

Toolbox meetings are conducted at the start of each shift to plan for activities being undertaken during the shift. This allows for relevant permits and Job Safety Analyses to be completed and to make sure that personnel undertaking the tasks understand all associated safety and environmental risks. Toolbox meetings involve a review of IMPACT entries from the previous day, including environmental incidents against this EP.

6.3.4.7 Vessel

Daily vessel reports are prepared by project vessels and issued to Esso. The report provides updates on project activities and HSE performance. Vessel HSE meetings are also used to transfer information, discuss environmental incidents and hazards and provide updates on environmental performance.

6.3.4.8 Third Party Services Contractor Performance

In accordance with the Third Party Services Management Manual, third parties' performance monitoring plans are established prior to a contractor mobilising to a work site location.

The Esso Contract Administrator is engaged in the contract life cycle management and the SSHE Group assists in the assessment and monitoring of contractor performance, as required. Providers of OIMS-critical services such as aviation, vessels, construction, subsea activities and wellwork are subject to a Quarterly Performance Review and Annual Performance Assessment.

Performance reporting consists of documented reports and verbal communications appropriate to the impacts and risks involved with the services provided. Written reports can include:

- Non-conformance reports;
- SSHE performance statistics, including environmental incidents/ EP breaches;
- Assessments of the adequacy of actions taken to address performance gaps / incidents;
- Deficiencies with SSHE requirements and recommended corrective actions; and
- Review of contractor HSE inspections and findings.

Report findings and recommendations are reviewed with contractor management and follow-up actions implemented to address deficiencies.

7 Monitoring of Emissions and Discharges

In accordance with OPGGS (E) Reg 14 (7) the implementation strategy must provide for sufficient monitoring of, and maintain quantitative records of, emissions and discharges (whether occurring during normal operations or otherwise), such that the record can be used to assess whether the environmental performance outcomes and standards in the environment plan are being met. Measurement and recording of emissions and discharges are completed under OIMS System 6-5 Environmental Management. Table 7-1 summarises the monitoring requirements for routine operations in this EP.

Table 7-1 Summary of monitoring of emissions and discharges

Activity / Aspect	Platform Operations Subsea facilities operation Pipeline Operations Facility IMR Pipeline and Subsea IMR	Wellwork	Vessel Operations ROV Operations
Planned Discharges			
Emissions to air	Platform fuel and flare volumes recorded and reported (including wellwork emissions) - *daily*. Monthly tech monitoring to identify anomalies – *monthly*		Recorded by vessel contractor. Anomalies or abnormalities provided - *by exception, quarterly*
Planned Discharge - Brine	Number of persons on board (monthly average)	Monitored and recorded in Wellview - *daily*	Recorded by vessel contractor. Anomalies or abnormalities provided - *by exception, quarterly*
Planned Discharge - Cooling Water			Recorded by vessel contractor. Anomalies or abnormalities provided - *by exception, quarterly*
Planned Discharge - Deck Drainage & Bilge			Recorded by vessel contractor. Anomalies or abnormalities provided - *by exception, quarterly*
Planned Discharge - Sewage and Greywater	Number of persons on board (monthly average)		Recorded by vessel contractor. Anomalies or abnormalities provided - *by exception, quarterly*
Planned Discharge - Food waste	Number of persons on board (monthly average)		Recorded by vessel contractor. Anomalies or abnormalities provided - *by exception, quarterly*
Planned Discharge - Operational Fluids	Monitored in accordance with Corrosion Control & Chemical Injection program – *ongoing* Oil Field Chemicals Exception Report - *monthly*	Monitored and recorded in Wellview - *daily*	

Aspect / Activity	Platform Operations Subsea facilities operation Pipeline Operations Facility IMR Pipeline and Subsea IMR	Wellwork	Vessel Operations ROV Operations
Planned Release – Gas (subsea)	Intermittent discharge. Volume and frequency monitored by PS&O Engineers - *as required*.		
Planned Discharge - Cement		Monitored and recorded in Wellview - *daily*	
Planned Discharge – Solids	During facility IMR solids are collected. Residual solids may be discharged via the drain system. Sediment sampling and water program to be completed (per CM68).	Monitored and recorded in Wellview - *daily*	
Produced Water Discharge	Monitored and reported as per Section 2.3 and Section 2.7.		
Accidental / Unplanned Discharges			
Accidental Release - Cement	Spill volumes estimated/calculated. Documented via incident records – *as required*	Spill volumes estimated/calculated. Monitored and recorded in Wellview. Documented via incident records – *as required.*	
Accidental Release - LOC (chemicals / hydraulic fluids)	Spill volumes estimated/calculated. Documented via incident records – *as required*	Spill volumes estimated/calculated. Monitored and recorded in Wellview. Documented via incident records – *as required.*	Spill volumes estimated/calculated. Recorded by vessel contractor. Documented via incident records – *as required* Incident records provided by vessel contractor- *monthly*.
Accidental Release - Bulk Transfer	Spill volumes estimated/calculated. Documented via incident records – *as required*		
Accidental Release - LOC (pipelines)	Spill volumes estimated/calculated. Documented via incident records – *as required*		
Accidental Release - LOC (bulk storage)	Spill volumes estimated/calculated. Documented via incident records – *as required*		

Aspect \ Activity	Platform Operations Subsea facilities operation Pipeline Operations Facility IMR Pipeline and Subsea IMR	Wellwork	Vessel Operations ROV Operations
Accidental Release - LOC (vessels)			Spill volumes estimated/calculated. Recorded by vessel contractor. Documented via incident records – *as required* Incident records provided by vessel contractor- *monthly*.
Accidental Release - Hydrocarbon from the piles	Spill volumes estimated/calculated. Documented via incident records – *as required*		
Accidental Release - Loss of Well Integrity / Loss of Well Control	Spill volumes estimated/calculated. Documented via incident records – *as required*	Spill volumes estimated/calculated. Monitored and recorded in Wellview. Documented via incident records – *as required.*	

8 Reporting

8.1.1 Annual Environmental Performance Reporting

The OPGGS (E) R 14(2) states that the implementation strategy must:

a) state when the titleholder will report to the Regulator in relation to the titleholder's environmental performance for the activity; and
b) Provide that the interval between reports will not be more than 1 year.

Note: Regulation 26C requires a titleholder to report on environmental performance in accordance with the timetable set out in the environment plan.

Table 8-1 NOPSEMA annual environmental performance reporting timetable

Requirement	Timing	Contact
Submit an annual EP environmental performance report to NOPSEMA.	The annual report for the calendar year (January – December) will be submitted to NOPSEMA by the end of February of the following year.	NOPSEMA – submissions@nopsema.gov.au

8.1.2 Incident Notification and Reporting

The OPGGS(E)R define "*recordable incidents*" and "*reportable incidents*", and also describe reporting requirements for each type of incident. The reporting requirements under the OPGGS(E)R are managed under OIMS System 4-2 Compliance with Laws Regulations and Permits.

Incidents are managed internally in accordance with OIMS System 9-1 Incident Management to ensure valuable information and lessons learned are available to improve operations and prevent the recurrence of similar incidents.

The requirements for reporting environmental incidents to external agencies are listed in Table 8-2.

Table 8-2 External incident notification and reporting requirements

Requirement	Timing	Contact
Recordable Incidents		
Recordable incident, for an activity, means a breach of an EPO or EPS, in the environment plan that applies to the activity that is not a reportable incident. As a minimum, the written monthly recordable incident report must include a description of: • All recordable incidents which occurred during the calendar month; • All material facts and circumstances concerning the incidents that the titleholder knows or is able, by reasonable search or enquiry, to find out; • Any action taken to avoid or mitigate any adverse environmental impacts of the recordable incidents; and • The action that has been taken, or is proposed to be taken, to prevent a similar incident occurring in the future.	As soon as possible but before the 15th day of the following calendar month.	NOPSEMA – submissions@nopsema.gov.au

Requirement	Timing	Contact
• Monthly reports will utilise the NOPSEMA Incident Monthly Summary Report template.		
Reportable Incidents		
Reportable incidents are those that have caused, or have the potential to cause, moderate to significant environmental damage. Esso has interpreted this to mean: • Unplanned release of hydrocarbon liquid or chemicals exceeding 80 L into the marine environment caused by, or suspected to have been caused by, petroleum activities (as defined as a Significant Spill in the ExxonMobil EPI Reporting Guidelines); and • Injury or death of a listed threatened / migratory / marine species caused by, or suspected to have been caused by, petroleum activities. The notification must contain: • All material facts and circumstances concerning the reportable incident that the titleholder knows or is able, by reasonable search or enquiry, to find out; • Any action taken to avoid or mitigate the adverse environmental impact of the reportable incident; and • The corrective action that has been taken or is proposed to be taken to stop, control or remedy the reportable incident.	• **Verbally ASAP but within 2 hours of incident,** or, if the reportable incident was not detected by the Titleholder at the time of the first occurrence – the time the titleholder becomes aware of the reportable incident, then • **Written notification as soon as practicable** (copy to NOPTA and DJPR) • **Written report as soon as practicable but within 3 days** including specifying if a further written report will be provided (then copy to NOPTA and DJPR within 7 days) • **If formal investigation is triggered, a further written report within 30 days**	NOPSEMA - 1300 674 472 submissions@nopsema.gov.au DJPR - marine.pollution@ecodev.vic.gov.au (0409 858 715) NOPTA – reporting@nopta.gov.au
Other Reporting Requirements		
Mandatory vessel MARPOL pollution notification reporting, Vessel Master to provide AMSA with the following information: • name of ship/s involved; • time, type and location of incident; • quantity and type of harmful substance; • assistance and salvage measures; and • any other relevant information. A POLREP form should be submitted by Vessel Master • Harmful substances report (POLREP) form 197 (Marine	Notification Immediately POLREP (pollution report). <24 hours	AMSA – Notification 1800 641 792 (Maritime) 1800 815 257 (Aviation) or +612 6230 6811 (Maritime) +612 6230 6899 (Aviation) AMSA POLREP Report rccaus@amsa.gov.au

Requirement	Timing	Contact
Order 91—Marine Pollution—Oil); • Harmful substances report (POLREP) form 196 (Marine Order 93—Marine Pollution Prevention—Noxious Liquid Substances); and • Marine Order 94 (Marine pollution prevention—packaged harmful substances) 2014 (Schedule 1—Marine pollutants report form).		
Suspected or known IMS introduction	Immediately	Report a pest (as per marinepests.gov.au website): DELWP – 136 186
Oiled wildlife	Immediately	DJPR – 1300 134 444
Wildlife emergency	Immediately	DELWP – 136 186 DELWP Whale & Dolphin Emergency Hotline - 1300 136 017 Seals, Penguins or Marine Turtles 136 186 (Mon-Fri 8am to 6pm) or AGL Marine Response Unit 1300 245 678.
Notification of activities affecting listed species or ecological communities in or on a Commonwealth area (specifically unintentional injury or death of a cetacean or listed threatened / migratory / marine species caused by, or suspected to have been caused by petroleum activity)	Within 7 days	DoEE – 1800 803 772 EPBC.Permits@environment.gov.au
Cetacean vessel strike	Within 3 days	DoEE – https://data.marinemammals.gov.au/report/shipstrike

9 Emergency Response

The process to prepare emergency preparedness and response plans, including procedures to prevent and mitigate potential environmental impacts associated with accidents and emergency situations, is addressed through OIMS System 10-2 Emergency Preparedness and Response.

The purpose of OIMS 10-2 is to ensure that Esso establishes effective response to emergencies and business disruptions that threaten: the safety, security and health of the public, contractors and employees; the environment; asset integrity; and critical business operations. This System addresses all sites for which Esso has responsibility and includes emergencies, disruptions to critical business operations, and security threats that could occur throughout the business line's sphere of influence (e.g. processing, drilling, transportation, and office).

The System objectives are as follows:

- Emergency response plan(s) and business continuity plan(s) are documented, resourced with qualified personnel, accessible, current, and clearly communicated; and
- Required training, exercises, simulations, and/or drills are conducted to determine the adequacy of the emergency response and business continuity plans.

9.1 Emergency Response Documentation

The Emergency Response Manual (ERM) consists of concise information that may be required immediately in the event of an incident. Information contained in the ERM includes emergency response organisational structures, emergency response procedures relevant to specific emergency events, personnel role and responsibility checklists, emergency response call-out procedures and contact directories.

Copies of the ERM are held on each platform and other Esso onshore sites.

9.2 Oil Pollution Emergency Plan

In accordance with OPGGS(E)R 14(8) and 14(8A), the implementation strategy must contain an OPEP and provide for updating the plan, and include arrangements for testing the response arrangements in the OPEP.

Esso has in place the Bass Strait OPEP (see Appendix A of Volume 3) for all its offshore assets and operations in Bass Strait. The OPEP describes how Level 1, 2 and 3 spills will be managed and defines the lead organisations, responders, and notification requirements.

9.2.1 Oil Spill Monitoring Program

In accordance with OPGGS(E)R 14(8D), the implementation strategy must provide for monitoring of impacts to the environment from oil pollution and response activities. This is provided for in Esso's Bass Strait Oil Spill Monitoring Program (OSMP). The OSMP guides monitoring of extent, severity and persistence of environmental impacts from a hydrocarbon spill and associated response activities.

The OSMP is subject to annual reviews as well as a mid-cycle comprehensive update. A register of OSMP implementation resources is updated quarterly. Testing of the OSMP comprises of an annual desktop capability review as well as 2 yearly detailed testing of the ability to implement the OSMP.

The Bass Strait OSMP exists as Appendix B to Volume 3 and applies to all of Esso's offshore assets and operations in Bass Strait. The OSMP is supported by a set of internal implementation guides for each monitoring module which are designed to provide Esso and its monitoring providers with information to finalise a monitoring design appropriate to the nature and scale of the spill.

9.3 Testing of Oil Spill Response Arrangements

In accordance with OPGGS(E)R 14(8C) and requirements of OIMS System 10-2 Emergency Preparedness and Response, the response arrangements within the OPEP will be tested:

- When they are introduced;
- Prior to the commencement of the activity;
- When they are significantly amended;
- Not later than 12 months after the most recent test;
- If a new location for the activity is added to the EP after the response arrangements have been tested, and before the next test is conducted—testing the response arrangements in relation to the new location as soon as practicable after it is added to the plan; and
- If a facility becomes operational after the response arrangements have been tested and before the next test is conducted—testing the response arrangements in relation to the facility when it becomes operational.
- In accordance with the schedule outlined in Table 9-1, and as further detailed in the annual EP&R Activity Plan.

The EP&R Activity Plan includes some additional guidance on how to organise a test, test types, duration and recommended participants, to assist in meeting preparedness and response performance standards outlined in Table 1-5 and the OPEP.

Testing may be externally or internally facilitated. Tests will be documented and any corrective actions/recommendations arising from the tests will be managed in accordance with the Emergency Preparedness & Response Programs Guide. Emergency response training records will be maintained in accordance with OIMS System 10-2: Emergency Preparedness and Response.

Where changes are required to the OPEP, resulting from testing / exercise outcomes, altered contractual arrangements, corrective actions, routine information updates (e.g. contact detail change), or other items; the OIMS System 10-2 Administrator is responsible for ensuring changes are assessed against OPGGS(E)R 17 revision criteria and where necessary, the EP and / or OPEP is submitted to NOPSEMA as a formal revision, in accordance with the Management of Change (MOC) process (OIMS System 7-1 Management of Change). For changes which do not trigger a formal revision, internal revisions to the OPEP will also be in accordance with the MOC process with any change justified.

Table 9-1 Testing of oil spill response arrangements

Test	Objective	Parties Involved	Schedule
Emergency Response contact lists	To ensure that current emergency response contact details are available.	Esso and Third party service providers	6 Monthly
Incident Management Team (IMT) availability	To test the availability of personnel to staff the Esso Incident Management Team	Esso IMT	Quarterly
NEBA	To test the NEBA decision making process	Esso IMT – Environmental Unit	6 Monthly
Dispersant	To test efficacy of Esso owned dispersant stockpile	Esso AMOSC	Annual
Dispersant	To test arrangements to implement dispersant application	Esso IMT AMOSC	Annual
Shoreline response	To test ability to undertake SCAT and execute Shoreline Tactical Response Plans and/or Shoreline Treatment Recommendations	Esso IMT AMOSC	Annual
Waste management	To test ability to implement waste management plans	Esso Waste Contractor	2 yearly
Oil Spill Monitoring Plan (OSMP)	To test availability of qualified personnel to implement OSMP	Esso / OSMP service provider	Annual

Test	Objective	Parties Involved	Schedule
OSMP	To test ability to implement OSMP	Esso OSMP service provider	2 yearly
Regional Response Team (RRT)	To test the integration of the ExxonMobil RRT to support a Level II IMT	Esso ExxonMobil RRT	3 yearly
Oil Spill Response (OSR) Equipment	To test availability of third party OSR equipment.	Esso AMOSC OSRL	Quarterly
OSR Equipment	To test readiness of Esso owned OSR equipment.	Esso	Annual
OSR Equipment	To maintain familiarity with use of OSR equipment through field equipment deployment.	Field response teams	Annual
OSR Equipment	To test field deployment of an offshore containment and recovery with a third party	Esso 3rd party	Every 3 years
Level II/III response arrangements	To test Level II/III response arrangements included within OPEPs including activation of external service providers and OSROs To test interface and communication/reporting arrangements with regulatory authorities and controlling agencies	Esso IMT & ESG State govt. agencies ExxonMobil RRT AMOSC	Every 5 years
Oiled Wildlife Response	To test availability of OWR resources to assist a State led oiled wildlife response	Esso AMOSC OSRL DELWP	Every 3 years
OSRO preparedness	To assess preparedness of AMOSC	Esso AMOSC APPEA	Annual
OSRO preparedness	To assess preparedness of OSRL	Esso / ExxonMobil	Annual

9.4 Oil Spill Response Competency and Training

In accordance with OPGGS(E)R 14(5), the implementation strategy must ensure personnel have the appropriate competencies and training to undertake their roles and responsibilities in emergency situations.

Esso implements incident management based on the Incident Command System (ICS). The ICS is a system designed to provide a consistent organisation to respond to emergency situations. Positions within the ICS are fixed and have specific functions, ensuring that all responders know what to do and where they report in the organisation structure. The ICS is based on the US National Incident Management System 2006 ICS Structure, with slight modifications for industry. ICS is the primary emergency response framework for an oil spill response from all offshore activities. Typical incident management roles and training requirements are outlined in Table 9-2.

IMT members are selected by their supervisors based on skills and experience. Nominations are reviewed by the OIMS 10-2 system owner (to ensure training and competency requirements have been met or appropriate management measures have been put in place) and approved by the asset manager, An Emergency Preparedness and Response required competency road map is assigned to the new incumbent. A training plan is put in place and the OIMS System 5-1 mitigation approval process applies.

IMT key members have 6 months to complete the required training once listed on the IMT. In the event of an incident, additional resources will be used to fill IMT key roles. These additional IMT members will be required to meet the relevant training and competency requirements.

The selection of the Environmental Unit Lead is based on relevant experience as an Environment Advisor, with experience and/or training in the implementation of scientific monitoring. Minimum requirements include involvement in drills and spill exercises, management of marine monitoring programmes, such as produced formation water monitoring, and monitoring of parameters relating to offshore operations. In addition, the minimum requirement includes a relevant tertiary degree in engineering, environmental science, environmental management or similar.

Table 9-2 Oil spill response competency and training

Section	Role	Training and competency
Command	Incident Commander	• Incident Management Training (PMAOMIR418). • IMO III - Command & Control Training (for Level II/III incidents)
	Safety Officer	• Incident Management Training (PMAOMIR320). • Experience in implementing safety management systems
	Liaison Officer	• Incident Management Training (PMAOMIR320).
Planning Section	Planning Section Chief (PSC)	• Incident Management Training (PMAOMIR320). • IMO II - Oil Spill Response Management Training (for Level II/III incidents) • Familiarity with PSC role
	Environment Unit Lead*	• Incident Management Training (PMAOMIR320). • IMO II - Oil Spill Management • Familiarity with OSMP
	All other roles	• ICS 200
Operations Section	Operations Section Chief (OSC)	• Incident Management Training (PMAOMIR320). • IMO II - Oil Spill Response Management Training (for Level II/III incidents) • Familiarity with OSC role
	Maritime Unit	• ICS 200 • Experience in marine operations
	Aviation Unit	• ICS 200 • Experience in aviation operations
	Aerial Observer	• Aerial Surveillance Course
	Source Control Branch Director / Deputy Director (for loss of well control incidents)	• ICS 300
	Source Control Branch – team member	• ICS 100/200

Section	Role	Training and competency
Logistics Section	Logistics Section Chief (LSC)	• Incident Management Training (PMAOMIR320). • IMO II - Oil Spill Response Management Training (for Level II/III incidents) • Familiarity with LSC role
	All other roles	• ICS 200
Finance & Admin Section	Finance & Admin Section Chief	• ICS 200
	All other roles	• ICS 200

**When the IMT is activated, the Environmental Unit Lead becomes responsible for managing implementation of the OSMP modules, as directed by the Planning Section Chief.*

9.4.1 Incident Management Training

The training program has been designed to meet the PMA08 Chemical, Hydrocarbons and Refining training standard. Personnel with an oil spill response role undertake Incident Management Training including ICS and oil spill response specific training, as defined by their role and in accordance with the Emergency Response Training Plan.

ICS 100 & 200 Training

ICS 100 & 200 Training consists of computer based training IMT which addresses fundamental principles of the ICS including key roles and functions.

ICS 300

ICS 300 training is instructor led training that expands upon the information covered in the ICS 200 course. ICS 300 training may be obtained through completion of the ExxonMobil University of Spill Management course where the training provider is accredited to provide the certification.

IMO II/II Oil Spill Response Training

To supplement Incident Management Training, identified IMT members must also complete IMO II/III - Oil Spill Response Management or Command and Control Training. Oil Spill Response Training may be completed through participation in a training program, completion of training delivered by AMOSC (or another training provider). Key aspects that must be addressed in this training include:

1. Understand different oil spill response objectives and strategies;
2. Understand the different environmental, sociological and economic considerations of oil spill response;
3. Learn and undertake an oil spill incident action planning process;
4. Understand how to effectively monitor and evaluate oil spill strategies; and
5. Understand jurisdictional control arrangements.

9.4.2 Oil Spill Response Equipment Operation

Selected operations and maintenance personnel at Esso's onshore facilities are familiarized with oil spill equipment operation, deployment and shoreline clean up techniques through dedicated training sessions and/or through participation in exercises. Training and exercises may be supported by AMOSC, Oil Response Company of Australia (ORCA) or another training provider. Selected personnel may also be nominated to attend IMO I - Oil Spill Response Operations.

9.4.3 Additional Specialist Training

Additional specialist training may be made available to specific personnel required to undertake a role in oil spill response. This training has been summarised in Table 9-3 and discussed further below.

Table 9-3 Specialist training

Typical Attendees	Course
Members of the AMOSC Core Group	IMO I - Oil Spill Response Operations AMOSC Core Group Workshop
Select IMT members	IMO II - Oil Spill Response Management or IMO III - Command and Control Oiled Wildlife Response
Aerial observers	Aerial Surveillance Course
Regional Response Team (RRT) members and select IMT members	ExxonMobil University of Spill Management (or equivalent) RRT Training Workshop
Emergency Support Group (ESG) members and select IMT members	ESG Training

AMOSC Core Group

Selected ExxonMobil personnel have been identified as members of the AMOSC Core Group and may be called upon to respond under the AMOSplan and National Plan arrangements. These personnel receive training through AMOSC in accordance with the AMOSC Core Group agreement. They also participate in bi-annual training, exercise or response activities in order to maintain their competency.

ExxonMobil University of Spill Management

ExxonMobil has developed an oil spill response training program which presents the fundamentals of oil spill response and provides a broad overview of response activities with a focus on the practicality and limits when responding to an oil spill. This course is aimed at personnel who fulfil a role within the IMT. The course combines theory, desktop exercises and field deployment of response equipment. The course is jointly run by ExxonMobil personnel along with specialist contractors and the local oil spill response organisation. The course is generally run over four days.

The course content covers:

- Oil spill response concepts;
- Decision processes;
- Corporate policies and preferences;
- Fate, behaviour, tracking and surveillance;
- Response options: Mechanical, In-situ burning, Dispersants, Monitor & Surveillance;
- Response components;
- Practical realities;
- Common misconceptions;
- Hands-on equipment deployment; and

On completion of the course, participants are certified in ICS 100-200.

Regional Response Team

Esso, along with other ExxonMobil business units, contribute personnel to ExxonMobil's RRT. All RRT members in Europe, Africa, Middle East, Asia Pacific RRT complete University of Spill Management training (or equivalent) as base training. RRT Members in the Americas RRT complete a minimum of ICS 300. Selected RRT members also participate in additional role specific training. The RRT conducts annual RRT Training Workshops which are typically combined with a response exercise.

The ExxonMobil Regional Response Team includes personnel (currently 10) with experience and/or training in oiled wildlife response. These personnel are able to provide above field support to an oiled wildlife response through development of response plans and coordination of specialist resources.

Emergency Support Group

Members of the ESG provide strategic support in event of an oil spill or other emergency event. ExxonMobil's ESG course is used to train ESG members in the ESG process as well as provide an overview of ExxonMobil's emergency response structure. This is an internally run course which combines theory and a number of simulation exercises. The course is typically run over 2.5 days. Course objectives are to:

- Increase awareness of the ExxonMobil emergency response system and the underpinning principles;
- Assist in achieving a consistent approach to the ESG response process across the Corporation
- Familiarise participants with roles and responsibilities within the ESG and the interface with other responders and stakeholders;
- Provide an opportunity for participants to practice roles;
- Improve ESG leadership and communication skills;
- Build confidence of participants in responding as a team and individually; and
- Enhance ExxonMobil's commitment to a consistent approach to emergency response.

Personnel new to the ESG may initially complete ESG Overview training (2 hours) and/or ESG CBT which provides an overview of ESG processes and roles and responsibilities.

Aerial Surveillance Course

Aerial Observers complete an Aerial Surveillance Course, which is provided by AMOSC and OSRL. The course is typically run over two days and includes theory and practical activities including:

- Basic hydrocarbon theory and its relevance to aerial surveillance;
- Basic understanding of how to work in an aviation crew environment;
- How to effectively plan and coordinate an aerial surveillance flight;
- How to carry out the plotting and recording of oil spill information; and
- How to present oil spill information back through the IMT in a clear and coherent manner.

9.4.4 Source Control Branch

ExxonMobil have a source control branch who specialise in source control in relation to a well blowout scenario. Personnel involved in Source Control Branch (SCB) management (i.e. Branch Director / Deputy Branch Director) will have the minimum competencies and training or meet requirements recognition of prior learning and experience.

10 Stakeholder Engagement and Community Consultation

OIMS System 10-1 Community Awareness and Public Affairs is in place to establish and maintain community confidence and trust in Esso activities through consultative and collaborative interactions and relationships that establish Esso as a responsible corporate citizen and good neighbour. This System addresses all forms of communication and interaction with employees, contractors, government and law enforcement officials, non-governmental organisations (NGOs), the media and local communities where Esso's offices and operations could have an impact on the communities.

The System objectives are:

- Recognise and respond to community concerns and impacts so as to establish and maintain public trust and confidence in the Operations Integrity of Esso operations and facilities;
- Anticipate community concerns and develop response plans, as appropriate; and
- Stakeholder consultation contributes to Esso's understanding of the impacts and risks of the activity and is undertaken with a genuine desire to further understand the environments in which we operate.

Esso maintains a database of relevant stakeholders potentially affected by offshore production and drilling operations and records of consultation for each stakeholder (Appendix A).

10.1 Activity-based Consultation with Relevant Stakeholders

To consult with relevant stakeholders and assist with preparing EPs, Esso provides Campaign Information Sheets to all relevant stakeholders. These information sheets include a description of the activity to be undertaken, impacts and risks and control measures to be implemented, as appropriate to the stakeholders' functions, activities or interests.

Relevant stakeholders are invited to correspond with Esso if they have concerns or require clarification. Follow up verbal discussions with relevant stakeholders occur if and when requested. All phone discussions are followed up with an email summarising the discussion and included in the SSHE consultation database.

10.2 Discussions with Relevant Stakeholders in the Immediate Vicinity of Esso's Activities

Esso has regular meetings with SETFIA and Cooper Energy (approximately every quarter) to discuss proposed and current Bass Strait offshore activities in detail and to communicate associated impacts and risks that may affect relevant stakeholders. SETFIA then assists in identifying fisheries stakeholders who may be affected by an activity and consults with these stakeholders on Esso's behalf. All consultation between SETFIA and identified stakeholders is documented and provided to Esso, and any identified issues or concerns are followed up by Esso with a phone call and/or emails.

Esso also includes Offshore Fact Sheets and Campaign Information Sheets (including impacts and risks) in the SETFIA quarterly newsletter as necessary.

During times of major project activity, regular meetings with interested relevant stakeholders are considered. Esso had a monthly phone hook-up with SETFIA and Lakes Entrance Fishermen's Cooperative Society Limited (LEFCOL) throughout 2018 and 2019 to discuss Esso's activities. Details of these meetings are recorded in the SSHE consultation database.

In February 2020 Esso held a consultation session in Lakes Entrance for the Eastern Fishing Fleet in conjunction with SETFIA. The session was held to discuss current and proposed offshore activities, including impacts and risks, and offer the opportunity for stakeholders to raise any questions or concerns about any of Esso's activities. Stakeholders were also asked how the consultation process could be improved.

Following on from the session, Esso's environmental representatives spent time at the Lakes Entrance wharf with the stakeholders to gain a deeper insight into how the fishing activities are undertaken, including the use of plotter systems and trawling equipment.

Esso have offered to hold more of these consultation sessions as requested by the fisheries stakeholders.

A six-monthly meeting occurs with the fishing industry to negotiate compensation claims (Compensation Tribunal). A fisheries subject matter expert also attends the meeting together with fisheries claimants. The last tribunal meetings occurred in August 2019 and February 2020 and an overview of Esso's current projects was outlined.

Throughout 2020, Esso has also been consulting with relevant stakeholder on other activities (jack up activities and P&A campaigns).

10.3 Consultation with State Departments and Agencies

The following consultation / review process was agreed with the following state departments and agencies - Victorian Department of Transport (DoT), Tasmanian Department of Primary Industries, Parks, Water and Environment (DEPIPWE) - Environment Protection Authority (EPA) and NSW Transport for NSW:

- 30 days to review a new OPEP
- 14 days to review OPEP changes, by exception only
- 14 days to review Quick Reference Guides or similar smaller documents

The DoT will be the main contact for Victorian government department and agency stakeholders. Esso will consult with DoT who will then distribute relevant consultation to the following stakeholders:

- Victorian Fisheries Authority
- Department of Environment, Land, Water and Planning
- Department of Jobs Precincts and Regions (DJTR) – Earth Resources Regulation
- Environment Protection Authority
- Transport Safety Victoria - Maritime Safety
- Parks Victoria

10.4 Periodic Updates

To assist relevant stakeholders in their general understanding of the industry and Esso's overall operations, Esso provides an annual fact sheet or email to relevant stakeholders. This communication contains updates about Esso's offshore operations, including information such as environmental performance data.

Esso also works with Seafood Industry Victoria (SIV) to include a copy of Offshore Fact Sheets and Campaign Information Sheets in the SIV quarterly newsletter, PROFISH when practical.

10.5 Ongoing Community Engagement

Esso is committed to supporting and engaging with the communities in which we operate and consider community relationships an essential element of our business. The process for receiving, documenting and responding to relevant environmental, socioeconomic, and community health information requests from external interested parties is addressed through OIMS System 10-1 Community Awareness and Public Affairs.

10.5.1 Public Forums

Esso currently conducts public engagement sessions approximately every one to two years to engage with the broader community. The purpose of these sessions is to enable face-to-face discussions with relevant stakeholders and also to enable other persons and organisations to learn about Esso's activities.

The last two public engagement sessions were conducted on 17 November 2017 and 5 December 2018 and included information on Esso's offshore projects and ongoing operational activity. Invitations were sent to all Lakes Entrance local stakeholders, including fishers and both sessions were advertised in the local newspaper. The next public engagement session is planned for 2H 2021.

10.5.2 Esso Webpage

Esso's webpage is an information portal providing the community with access to fact sheets and EP summaries and provides an opportunity for stakeholders to make enquiries about our offshore activities and projects. Information on current major project activity can be accessed at https://www.exxonmobil.com.au/Energy-and-environment/Energy-resources/Upstream-operations/Bass-Strait

Appendix A – Relevant Stakeholders

Stakeholder Consultation

The OPGGS(E)R establish that titleholders (and those with access authority) must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person.

To address this, Esso has undertaken consultation during the preparation of this EP to identify stakeholders; share sufficient information; and allow reasonable time for consideration of this information (and feedback to Esso).

Categories of relevant persons

As described in the OPSGG(E)R, there are five categories of relevant persons with whom Esso will consult:

- Each department or agency of the Commonwealth to which the activities to be carried out under the EP may be relevant.
    - This is taken to mean a Commonwealth Government department or agency that has responsibility for managing or protecting the marine environment from pollution. This may include those with responsibilities for environmental and fisheries management, oil pollution management and response, defence and communications, maritime / navigational safety, marine parks and native title.
- Each department or agency of a State or the Northern Territory to which the activities to be carried out under the EP may be relevant.
    - This is taken to mean a State or the Northern Territory Government department or agency that has responsibility for managing or protecting the marine environment from pollution. This may include those with responsibilities for environmental and fisheries management, oil pollution management and response, defence and communications, maritime / navigational safety, marine parks and native title.
- The department of the responsible State Minister or the responsible Northern Territory Minister.
    - This is taken to mean the department that has responsibilities for offshore petroleum or energy resources in the adjacent State or Northern Territory.
- Persons or organisations whose functions, interests or activities may be affected by the activities to be carried out under the EP.
    - This is taken to mean a person or organisation that may be affected by the petroleum activity.
- Any other persons or organisation that it considers relevant.
    - Any other identified stakeholders based on existing environmental knowledge, past experience, internet research, initial campaign emails, existing networks and forums, or social media.

Definition of relevant persons' functions, interests and activities

Relevant persons' functions, interests and activities have been defined in Table 1 below.

Table A0-1 Definitions of relevant persons' functions, interests and activities

Function	Person or organisation's power, duty, authority or responsibilities
Activity	Thing or things that a person or group does or has done
Interest	Person or organisation's rights, advantages, duties and liabilities; or a group or organisation having a common concern

Definition of sufficient information

Providing 'sufficient information' includes:

- Sharing information that is targeted to relevant persons' needs;
- Detailing the proposed activity and any impacts and risks that may be relevant to them;

- Putting forward information on how an impact or risk may affect that relevant person; and
- Describing the control measures proposed to manage the potential impacts to that relevant person.

Reasonable consultation period

The time required for consultation varies depending on the individual circumstances of the relevant person, the proposed activity, the extent of impact and risks on that relevant person and the level of information that has been provided.

Esso understands that some relevant persons may require longer timeframes than others, such as those that do not have resources dedicated specifically to liaise with the petroleum industry.

A reasonable consultation period will allow:

- A relevant person to assess information and provide a response detailing any 'objections or claims'
- Esso to consider responses in developing the EP; and
- Esso to reply back to the relevant person addressing any 'objections or claims' in the EP.

Addressing objections / claims

Esso will clearly identify and address each *specific* objection or claim raised by relevant persons and if applicable:

- Demonstrate that the risk or impact in question has been reduced to ALARP and will be of an acceptable level;
- Provide a statement that addresses each element of the objection or claim made by a relevant person and where control measures are implemented to resolve objections and claims, will clearly communicate this to the relevant person; and
- Provide copies of all written responses provided by a relevant person to NOPSEMA.

In the event that Esso and a relevant person are unable to reach agreement on an activity, or there is a broad objection (e.g. to resource exploitation) or differing views (e.g. on the significance of an environmental impact or risk) the consultation report will demonstrate that:

- Reasonable attempts have been made;
- Reasonably available options have been explored for resolving or mitigating the degree to which a person may be affected, particularly through control measures;
- The relevant person has been informed about how their objections or claims have been addressed; and
- The relevant person has been made aware of how their objections or claims are going to be represented to NOPSEMA.

Stakeholder Categorisation

Table A0-2 Category 1 Stakeholders – Commonwealth department or agency

Commonwealth Department or Agency	Relevance
Department of Agriculture, Water and Environment - fisheries, biosecurity and marine pests	Responsible for the implementation of Australia's marine pest and biosecurity management requirements when bringing in diving or installation vessels, MODUs and support vessels.
Department of Agriculture, Water and Environment Parks Australia- Director of National Parks	Responsible for managing Commonwealth reserves and conservation zones. Esso reports death / injury of EPBC listed species and notifies oil pollution if it impacts, or potentially impacts, Australian Marine Parks.
Department of Defence Australian Hydrographic Office (AHO)	Responsible for publication of nautical charts and other information for safety of ships navigating in Australian waters (including Notices to mariners)
Department of Foreign Affairs and Trade	Relevant where proposed activity, or oil spill/other environmental risk, could result in impacts in international jurisdictions or on foreign individuals/governments

Commonwealth Department or Agency	Relevance
Australian Maritime Safety Authority	Commonwealth government agency responsible for maritime safety, protection of the marine environment including marine pollution and maritime aviation search and rescue.
Australian Fisheries Management Authority	Responsible for management of Commonwealth commercial fisheries from 3NM to 200NM. Esso titles and areas of operations overlap with a number of these fisheries.
National Offshore Petroleum Titles Administrator (NOPTA)	Advises on and administers the OPGGS Act, provides regulation and management of offshore petroleum resources in Commonwealth waters.

Table A0-3 Category 2 Stakeholders – State or Northern Territory department or agency

State	State or Northern Territory Department or Agency	Relevance
VIC	Victorian Fisheries Authority	An independent statutory authority established to effectively manage Victoria's fisheries resources. Bay and inlet fishery license holders overlap with Esso's operational areas and further fisheries could potentially be affected by an unplanned event.
VIC	Department of Environment, Land, Water and Planning	Relevant for unplanned events as a response agency for responding to wildlife impacted by marine pollution.
VIC	Department of Transport (DOT) (formerly DJPR and DEDJTR)	Relevant for unplanned events as a control agency in Victorian state waters.
VIC	Department of Jobs Precincts and Regions (DJTR) – Biosecurity and agricultural services	Relevant for planned events. Responsible for marine biosecurity.
VIC	Environment Protection Authority	Relevant for unplanned events as they have jurisdiction over environmental matters in Victoria, including environmental protection and may advise on pollution and waste management in a response scenario.
VIC	Transport Safety Victoria - Maritime Safety	Relevant for unplanned events. A branch of Transport Safety Victoria, working closely with vessel operators and waterway and port managers to provide expert knowledge, education, support and direction
VIC	Parks Victoria	Relevant for unplanned events. They manage significant stretches of land along the Gippsland coastline and some maritime infrastructure in the Gippsland area (e.g. some piers, jetties, berths)
NSW	Transport for NSW	Relevant for unplanned events. The control agency for marine pollution incidents impacting NSW state waters. NSW waters could potentially be affected by an extended duration unplanned event.
NSW	Department of Primary Industries	Relevant for unplanned events. Is responsible for the administration and development for agriculture, fisheries, aquaculture, forestry, and biosecurity in NSW.
TAS	Department of Primary Industries, Parks, Water and Environment – Environment Protection Authority (EPA)	Relevant for unplanned events as the control agency for marine pollution in Tasmanian state waters.
TAS	Parks and Wildlife Service	Relevant for unplanned events. The managing authority of Tasmania's nature reserve system which could potentially be affected by an unplanned event.

Table A0-4 Category 3 Stakeholders – Department of the responsible State Minister

Department of the responsible State Minister	Relevance
Department of Jobs Precincts and Regions - Earth Resources Regulation (VIC)	Victoria's regulator of exploration, mining, quarrying, petroleum, recreational prospecting and other earth resources activities. Assesses and authorises earth resource projects and enforces laws to ensure those projects are conducted such that the community and environment are safeguarded.

Category 4 (and 5) Stakeholders - Persons or organisations with functions, interests or activities that could be potentially affected by the activities (sub-divided into planned activities and unplanned events) to be carried out under the EP.

During the planning of each activity Esso reviews the current list of stakeholders maintained in the SSHE database and uses a checklist to assess which stakeholders are relevant based on the definitions in Table 1.

Table A0-5 Category 4 & 5 Stakeholders – Other relevant persons or organisations

Stakeholder ID	Relevant stakeholders (planned activities)	Relevance
17	Lakes Entrance Fishermen's Co-operative Limited	The largest (fleet and throughput) fishing co-operative in Australia.
33	Seafood Industry Victoria	The peak body representing professional fishing, seafood processors and exporters in Victoria.
37	South East Trawl Fishing Industry Association	Represents the interests of Commonwealth-licensed trawl fishermen in the South East Trawl Fishery.
15	Gippsland Ports	Potentially affected function or activity
18	Lakes Entrance Scallop Fishing Industry Association	Potentially affected function or activity
24	Seven Group Holdings (formerly Nexus)	Potentially affected function or activity
26	Beach Energy	Potentially affected function or activity
34	Cooper Energy (Formerly Santos)	Potentially affected during activity
40	Sustainable Shark Fishing Association	Potentially affected during activity
52	Victorian Scallop Industry Association	Potentially affected during activity
58	Emperor Energy (formerly Oil Basins)	Potentially affected function or activity
70	Victorian Bays and Inlets Fisheries Association	Potentially affected during activity
73	Victorian Rock Lobster Association	Potentially affected during activity
76	Commonwealth Fisheries Association	Potentially affected during activity
77	Southern Shark Industry Alliance	Potentially affected during activity
79	Eastern Victorian Sea Urchin Divers Association	Potentially affected during activity
81	Australian Oceanographic Services	Potentially affected during activity
83	Corner Inlet Fisheries Habitat Association	Potentially affected during activity
87	Bass Oil	Potentially affected during activity
100	CarbonNet	Potentially affected during activity

Stakeholder ID	Relevant stakeholders (planned activities)	Relevance
121	Australian Southern Bluefin Tuna Industry Association	Potentially affected during activity
123	Panama II Octopus fishing vessel	Potentially affected during activity
128	Fishermans Tribunal	Potentially affected during activity
10	East Gippsland Catchment Management Authority	Potentially relevant in an unplanned event
11	East Gippsland Shire Council	Potentially relevant in an unplanned event
20	Wellington Shire Council	Potentially relevant in an unplanned event
29	Phillip Island Nature Park	Potentially relevant in an unplanned event
30	Port Franklin Fisherman's Association	Potentially relevant in an unplanned event
38	South Gippsland Shire Council	Potentially relevant in an unplanned event
41	Tasmanian Seafood Industry Council	Potentially relevant in an unplanned event
51	VR Fish - Victorian Recreational Fishing Peak Body	Potentially relevant in an unplanned event
66	Apollo Bay Fishermen's Co-op	Potentially relevant in an unplanned event
71	Victorian Fishery Association in Research Management (VFARM)	Potentially relevant in an unplanned event
82	East Gippsland Estuarine Fishermen's Association	Potentially relevant in an unplanned event
112	Victorian Regional Channels Authority	Potentially relevant in an unplanned event

Appendix B – Stakeholder Consultation Reports

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response

Category: 1 - Commonwealth Department or Agency

ID: 4 Organisation: Australian Fisheries Management Authority

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
09-Oct-17	136	To Stakeholder	Email	Fact sheet #1 outlining Esso Australia's upcoming activities in Bass Strait.	No objections, claims or issues raised	N/A
13-Oct-17	137	From Stakeholder	Email	Request to update contact details	No objections, claims or issues raised	EAPL stakeholder database updated.
26-Oct-17	138	From Stakeholder	Email	Invitation to December 2017 Community Session in Lakes Entrance to discuss offshore activities in Bass Strait	No objections, claims or issues raised	Stakeholder requested invitation be resent
09-Nov-17	140	To Stakeholder	Phone	Stakeholder requested invitation to Community Session be resent.	No objections, claims or issues raised	EAPL resent invitation.
21-Dec-17	1178	To Stakeholder	Email	Fact sheet #2 outlining Esso Australia's upcoming activities in Bass Strait.	No objections, claims or issues raised	N/A
16-Jul-18	1995	To Stakeholder	Phone	Called to check if contact details are current	No objections, claims or issues raised	N/A
06-Aug-18	2013	To Stakeholder	Email	Fact sheet #4 outlining Esso Australia's upcoming activities in Bass Strait including: - Baldfish and Hairtail drilling program - Blackback wells - West Barracouta drilling - Seabed surveys - Cobia pipeline project - Mackerel wells - Kipper and Pilchard drilling - Environments Plans - Produced Water Formation	No objections, claims or issues raised	N/A
20-Nov-18	2143	To Stakeholder	Email	Invitation to December 2018 Community Session in Lakes Entrance to discuss offshore activities in Bass Strait	No objections, claims or issues raised	Stakeholder requested invitation be resent
06-May-19	2956	To Stakeholder	Email	JUR campaign sheet #1 detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline	No objections, claims or issues raised	N/A
24-Jul-19	3077	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	No objections, claims or issues raised	N/A
11-Dec-19	3188	To Stakeholder	Email	2020 JUR Campaign Sheet #2: campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A

24-Jul-19	3079	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	24/07/19 RESPONSE: Thank you for contacting the Australian Maritime Safety Authority. The Master should notify AMSA's Joint Rescue Coordination Centre (JRCC) by e-mail to rccaus@amsa.gov.au (Phone: 1800 641 792 or +61 2 6230 6811) for promulgation of radio-navigation warnings at least 24-48 hours before operations commence. AMSA's JRCC will require the vessel details (including name, callsign and Maritime Mobile Service Identity (MMSI)), satellite communications details (including INMARSAT-C and satellite telephone numbers), area of operation, requested clearance from other vessels and any other information that may contribute to safety at sea. JRCC will also need to be advised when operations start and end. Contact the Australian Hydrographic Office at datacentre@hydro.gov.au no less than four working weeks before operations, with details relevant to the operations. The AHO will promulgate the appropriate Notice to Mariners (NTM), which will ensure other vessels are informed of your activities. To obtain a vessel traffic plot showing Automatic Identification System (AIS) traffic data for your area of interest, please visit AMSA's spatial data gateway and Spatial@AMSA portal to download digital data sets and maps. A form for requesting customised information and data is also available via the portal (fees and charges may apply).	Email from stakeholder advising they received our update. No objections, claims or issues raised

06-May-19	3049	To Stakeholder	Email	JUR campaign sheet #1 detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline	No objections, claims or issues raised	the planned activities do not overlap any Australian Marine Parks, therefore there are no authorisation requirements from the DNP.

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
24-Jul-19	3107	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	No issues, objections or claims	Thank you for providing the Director of National Parks (DNP) with an update on Geotechnical Investigation at Proposed West Barracouta Well Site (VIC/L1) as approved under the accepted Gippsland Basin Geophysical and Geotechnical Investigations Environment Plan (EP), as well the additional works associated with Sweetlips and Wirrah. Based on the information provided in this email and previous correspondence, we note that the planned activities are a minimum of approximately 80 km from the closest Australian Marine Park. Therefore there are no authorisation requirements from the DNP. As mentioned in our previous comments sent 13 June 2019, I can confirm that we do not require further notification of progress made in relation to this activity unless details regarding the activity change and result in an overlap with, or may impact, a marine park or for emergency responses (please see our previous correspondence for details on emergency response notifications). Please don't hesitate to contact marineparks@environment.gov.au if you have any further questions.

20-Nov-18	2165	To Stakeholder	Email	Invitation to Community Session in Lakes Entrance to discuss offshore activities in Bass Strait	No objections, claims or issues raised	No objections, claims or issues raised
24-Jul-19	3082	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	No objections, claims or issues raised	N/A
10-Dec-19	3273	To Stakeholder	Email	EAPL emailed stakeholder to enquire if the WA vessel check is being reworked and may evolve into a more Australia wide tool for assessing IMS issues	No objections, claims or issues raised	Stakeholder confirmed that the Vessel Check system has been reworked. It is already live and can be accessed at www.vessel-check.com. The portal does not rely on any specific questions (unlike the previous WA questionnaire process) – it effectively seeks what vessel biofouling management is being undertaken for a vessel and assesses whether the outlined management is sufficient to mitigate the transfer of invasive marine species (IMS) to as low as reasonably practicable (ALARP) (it is NOT assessing whether a vessel has an IMS on it).
11-Dec-19	3199	To Stakeholder	Email	2020 JUR Campaign Sheet #2: campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
24-Jul-19	3087	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	No objections, claims or issues raised	N/A
09-Dec-19	3150	To Stakeholder	Email	Stakeholder provided with Esso Australia Bass Strait Oil Pollution Emergency Plan and Quick Reference Guides for review and comment.	No objections, claims or issues raised	N/A
11-Dec-19	3206	To Stakeholder	Email	2020 JUR Campaign Sheet #2: campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
13-Dec-19	3242	To Stakeholder	Email	2020 JUR Campaign Sheet #2: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
19-Dec-19	3158	To Stakeholder	Email	Stakeholder provided with Quick Reference Guides containing the specific information and potential risks related to worst case discharge scenario from the West Barracouta (BTW), Kipper (KPA) and Whiting (WTA) activities under the Jack Up Rig campaign and requested stakeholder feedback on the Quick Reference Guides.	Stakeholder raised some queries relating to the Condensate QRG and low resolution of maps provided	Stakeholder has reviewed the OPEP and QRGs and provided feedback: - maps require higher resolution - question regarding oiled wildlife response and what the percentage contact is considered for a response to be likely.
20-Feb-20	3278	To Stakeholder	Email	EAPL repsonse to stakeholder re review and feedback on OPEP and quick reference guides. Regarding clarity of maps, we are including higher resolution images in future quick reference guides. Your question regarding the thresholds for wildlife response is a one that we need to give more consideration to, particularly in regards to open water foraging areas where ability to conduct oiled wildlife response activities is difficult. Esso will conduct some additional OWR preparedness activities and we will consider this in the scope of that work. From a practical response perspective, fauna observations are included as part of our operational and scientific monitoring program and would be used to inform the IMT of potential impacts to wildlife. The Esso IMT would engage with relevant State response agencies regarding OWR activities.	No objections, claims or issues raised	N/A
07-Mar-20	3390	To Stakeholder	Email	2020 JUR Campaign Sheet #3: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the West Barracouta Installation programme including activity description, location and timing.	No objections, claims or issues raised	N/A
11-Mar-20	3343	To Stakeholder	Email	2020 JUR Campaign Sheet #4: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Seahorse/Tarwhine P&A programme including activity description, location and timing.	No objections, claims or issues raised	N/A
12-Mar-20	3420	To Stakeholder	Email	Further to the West Barracouta installation campaign sheet #3 we sent last week, below is a link to view a 2 minute video outlining how this complex project will come together.	No objections, claims or issues raised	N/A
09-Apr-20	3310	To Stakeholder	Email	The following activities will be postponed after the completion of drilling at West Barracouta by approximately 13 April 2020: • Whiting plug and abandonment • Seahorse / Tarwhine plug and abandonment • Kipper drilling • Mulloway / Whiptail plug and abandonment	No objections, claims or issues raised	N/A
25-May-20	3479	To Stakeholder	Email	EAPL proposing a process defining adequate timing for reviewing documents	No objections, claims or issues raised	N/A
27-May-20	3480	To Stakeholder	Email	EAPL requesting stakeholder to review Quick Reference Guides Part 1	No objections, claims or issues raised	N/A
27-May-20	3481	To Stakeholder	Email	EAPL requesting stakeholder to review Quick Reference Guides Part 2	No objections, claims or issues raised	N/A
27-May-20	3482	To Stakeholder	Email	EAPL requesting stakeholder to review Quick Reference Guides Part 3	No objections, claims or issues raised	N/A
01-Jun-20	3500	To Stakeholder	Email	Updated Quick Reference Guides with changes to Shoreline clean up resources for Seahorse, Cobia, Halibut and Tuna	Request for further discussion on expectations of the state.	N/A
04-Jun-20	3499	To Stakeholder	Phone	EAPL called stakeholder to follow up on the Quick Reference Guides. Stakeholder advised they are satisified with the QRGs and requested a higher quality map and further discussion on expectations of the state.	Stakeholder requested further discussion on expectations of the state during a response. EAPL will call on 9 June 2020 to discuss.	EAPL advised stakeholder how to enlarge maps for higher quality.
09-Jun-20	3509	To Stakeholder	Email	EAPL contacted stakeholder to discuss OPEP and IMT arrangements.	No objections, claims or issues raised	N/A

26-Aug-19	3129	To Stakeholder	Email	Email discussing titleholders Oil Pollution Emergency Plans and confirming scheduled meeting	No objections, claims or issues raised	N/A
09-Sep-19	3132	To Stakeholder	Email	Resent draft of the Esso Australia Bass Strait Oil Pollution Emergency Plan for review and comment by the Victorian Department of Transport and other State agencies.	No objections, claims or issues raised	Acknowlegement of receipt
09-Sep-19	3133	To Stakeholder	Email	Provided stakeholder with titleholders Bass Strait Oil Spill Monitoring Program	No objections, claims or issues raised	Stakeholder requested minor changes to OPEP
09-Dec-19	3145	To Stakeholder	Email	Stakeholder provided with Esso Australia Bass Strait Oil Pollution Emergency Plan and Quick Reference Guides for West Barracouta, Kipper and Whiting for review and comment.	No objections, claims or issues raised	N/A
11-Dec-19	3172	To Stakeholder	Email	2020 JUR Campaign Sheet #2: campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
13-Dec-19	3231	To Stakeholder	Email	2020 JUR Campaign Sheet #2: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
19-Dec-19	3152	To Stakeholder	Email	Stakeholder provided with additional information regarding oil spill response risks and capabilities related to West Barracouta and Kipper programs which are scheduled to commence in January 2020. Stakeholder provided with updated Quick Reference Information sheets for these facilities for both MDO and condensate including revised worst case scenario modelling.	No objections, claims or issues raised	Stakeholder responded that the OPEP and Quick Reference Guides look ok.
19-Dec-19	3164	To Stakeholder	Email	Stakeholder provided with Quick Reference Guides containing the specific information and potential risks related to worst case discharge scenario from the West Barracouta (BTW), Kipper (KPA) and Whiting (WTA) activities under the Jack Up Rig campaign and requested stakeholder feedback on the Quick Reference Guides.	No objections, claims or issues raised	Stakeholder responded no further comment. If marine mammals and sharks are impacted in the ocean, there is little that can be done from a response point of view.
07-Mar-20	3378	To Stakeholder	Email	2020 JUR Campaign Sheet #3: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. 11-Dec-19	3207	To Stakeholder	Email	2020 JUR Campaign Sheet #2: campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
13-Dec-19	3241	To Stakeholder	Email	2020 JUR Campaign Sheet #2: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
19-Dec-19	3153	To Stakeholder	Email	Stakeholder provided with Quick Reference Guides containing the specific information and potential risks related to worst case discharge scenario from the West Barracouta (BTW), Kipper (KPA) and Whiting (WTA) activities under the Jack Up Rig campaign and requested stakeholder feedback on the Quick Reference Guides.	No objections, claims or issues raised	N/A
23-Dec-19	3165	To Stakeholder	Email	Stakeholder provided with additional information regarding oil spill response risks and capabilities related to West Barracouta and Kipper programs which are scheduled to commence in January 2020. Stakeholder provided with updated Quick Reference Information sheets for these facilities for both MDO and condensate including revised worst case scenario modelling.	No objections, claims or issues raised	N/A
20-Feb-20	3283	To Stakeholder	Email	EAPL following up if stakeholder has any feedback on the OPEP or QRGs.	1. Names of state control agencies for both NSW and Victoria have been updated in the latest revision of the OPEP (version 5) COMPLETE 2. Discussed that NSW would send a Liaison Officer into IMT for a Level 2/3 incident early within a response to understand and plan for potential impacts to NSW State waters - COMPLETE 3. Nadgie Lake and Nadgie River are of highest protection priority to NSW due to unique ecosystems in these areas. Esso to add these locations to QRG and/or EP. IN PROGRESS - No tactical response plans have been developed for these locations. Refer to NSW South Coast Marine Oil & Chemical Spill Contingency Plan (Jan 2017) for details on arrangements for this area. - Nadgie Lake is intermittently open to the sea. No vehicle access. All resources would need to be brought in by vessel or helicopter. - Nadgie River is accessible by vehicle. 4. Cross border marine pollution exercise to be conducted later in 2020. Esso to be kept in the loop with planning	Stakeholder advised of name change, advising of action in the event of a tier 2/3 incident and of a couple of extreme sensitive areas in Victoria

01-Jun-20	3502	To Stakeholder	Email	Updated Quick Reference Guides with changes to Shoreline clean up resources for Seahorse, Cobia, Halibut and Tuna	No objections, claims or issues raised	N/A
04-Jun-20	3501	To Stakeholder	Phone	EAPL called stakeholder to follow up review of the Quick Reference Guides.	No objections, claims or issues raised	Stakeholder advised they will be reviewing EAPL Quick Reference Guides.
08-Jun-20	3510	From Stakeholder	Email	Stakeholder provided feedback on Quick Reference Guides, namely additional areas to be referenced for TRPs.	No objections, claims or issues raised	EAPL will include 'significant wilderness area' as suggested by stakeholder. EAPL explained that suggested additional estuaries won't be includedas the current list includes all locations that we have an existing Tactical Response Plan (TRP), rather than it being a list of all estuaries. If the State has developed any tactical response plans that should be referenced, EAPL can add reference to those in the plans.

15-Feb-18	1571	To Stakeholder	In Person	Meeting to discuss degree of consultation and update on offshore activities	ISSUE: Amount and degree of consluation - too much MERIT: Yes and acknowledged however the regulatory regime requires it and Esso need to be able to demonstrate that they have consulted. Esso consultation will continue to be scheduled and managed to try and co-ordinate and minimise the amount. No further action required - closed.	During a meeting the stakeholder raised the item of the amount and degree of consultation between key fishing representatives and EAPL. EAPL will coordinate consultation to try and minimise the amount and degree, whilst still meeting community needs and regulatory requirements. Monthly phone call with key stakeholders to discuss EAPL offshore activities.
06-Aug-18	2022	To Stakeholder	Email	Fact sheet #4 outlining Esso Australia's upcoming activities in Bass Strait including: - Baldfish and Hairtail drilling program - Blackback wells - West Barracouta drilling - Seabed surveys - Cobia pipeline project - Mackerel wells - Kipper and Pilchard drilling - Environments Plans - Produced Water Formation	No objections, claims or issues raised	N/A

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
21-May-19	3043	To Stakeholder	Minutes	Meeting with stakeholder to discuss: - increased workload from the Oil and Gas industry to SETFIA - West Barracouta and Kipper projects (including the Geotechnical & Geophysical campaign), potential plugging and abandonment at Blackback, Seahorse, Tarwhine, Whiting, Perch and Dolphin and drilling at Sculpin, East Pilchard, Wirrah & Sweetlips. - Work at Seahorse, Tarwhine, Perch and Dolphin would also be within PSZs and that decommissioning options and potential removal of their PSZs was being considered. - The Geotechnical & Geophysical EP has been revised to cover potential advance work at these locations to confirm the sea bed is suitable for a jack-up rig. - Drilling at Wirrah, Sweetlips, and East Pilchard would require temporary PSZs - Drilling at Sculpin is expected to start Q3/Q4 this year this is very deep water (2400m) and there is no known commercial fishing effort at this depth.	No objections, claims or issues raised	N/A
24-Jul-19	3056	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	No objections, claims or issues raised	N/A

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
16-Dec-19	3160	To Stakeholder	Email	Esso requested key stakeholder to identify relevant stakeholders who fish in the area of the Whiting P&A and discuss with them the key potential impacts relating to the Whiting jack up rig campaign to assist them making an informed assessment on possible impacts to their interests, functions or activities.	Issue: Stakeholder has concerns regarding various discharges, release of materials/waste and whether the site will be fish-overable.	Stakeholder responded with concerns regarding various discharges, release of materials/waste and whether the site will be fish-overable. Stakeholder requested further information regarding the Whiting plug and abandon campaign.
20-Dec-19	3213	From Stakeholder	Email	Esso explained the aim of the P&A campaigns is to permanently plug and abandon the wells. This process provides multiple barriers to prevent the release of any hydrocarbons from these wells in the future. The remaining infrastructure, such as platforms may be removed as part of a separate, future campaign and will be the subject of further consultation. Until that occurs, access to the area around platforms will remain unchanged in accordance with NOPSEMA policy.	No objections, claims or issues raised	Stakeholder sent email advising they now understand the P&A activity.
07-Jan-20	3261	To Stakeholder	Email	Request to call stakeholder to: • Discuss online portal for stakeholders • Visit a commercial fishing boat and view the plotters, etc • Discuss the impacts and risks that are included in our EPs • General update on EAPL activities in Bass Strait	No objections, claims or issues raised	N/A
12-Feb-20	3280	To Stakeholder	Email	Calendar invite sent to stakeholders for a meeting in Lakes Entrance as an opportunity to discuss: - Impacts and risks that are included in the Environment Plans - Decommissioning - EAPL bushfire relief and assistance - Online stakeholder portal -Upcoming activities in Bass Strait	No objections, claims or issues raised	N/A
24-Feb-20	3282	To Stakeholder	SMS	SMS sent to Eastern Fishing Fleet: Esso will be in Lakes Entrance on Thurs at 10am at SEAMEC to speak with fishers about their plans, decommissioning of assets and the roll-over of their approvals in eastern Bass Strait. If anyone is interested please let me know.	No objections, claims or issues raised	N/A
27-Feb-20	3463	To Stakeholder	Community Session	Meeting held at SEAMAC (Lakes Entrance) for Eastern Fishing Fleet as an opportunity to discuss: - Impacts and risks that are included in the Environment Plans - Decommissioning - EAPL bushfire relief and assistance - proposed Online stakeholder portal Approximately 15 commercial fishermen attended the session along with fishing rep SETFIA Following on from the information session, EAPL reps went on board several fishing vessels to better understand the plotter systems and how the Eastern Fishing Fleet operate and how to improve the consulation process.	Stakeholder enquiring about fishing activities around West Barracouta	
07-Mar-20	3404	To Stakeholder	Email	2020 JUR Campaign Sheet #3: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the West Barracouta Installation programme including activity description, location and timing.	No objections, claims or issues raised	N/A
11-Mar-20	3357	To Stakeholder	Email	2020 JUR Campaign Sheet #4: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Seahorse/Tarwhine P&A programme including activity description, location and timing.	No objections, claims or issues raised	N/A

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
12-Mar-20	3371	From Stakeholder	Email	Stakeholder enquiring about fishing activities around West Barracouta	Queries have been answered	Email sent to stakeholder responding to the following questions: QUESTIONS: 1. Regarding the hot tap tie in on Barracouta: is that inside the PSZ? 2. Regarding the flow line skid: does this run up and down the pipe or is it fixed? Is this fish-over-able? 3. Are there any other flowline skids? 4. Where are concrete mats going to be positioned? RESPONSE: The hot tap tie in and the flowline skid, located in close proximity are planned to be within the Barracouta PSZ. The flowline skid is the termination assembly to the flexible pipeline and is fixed in position. It is a steel structure about 8m long, 3m wide and 3m high and is not designed to be over-fishable, given its location within the Platform PSZ. The other end of the pipeline is contained within another structure called the Pipeline End Manifold (PLEM) located within the BTW PSZ. There are no other skids along the pipeline. The concrete mattresses will be placed over the electrical and hydraulic flying leads, between the umbilical termination assembly and the two wells, within the BTW PSZ. Mattresses will also be placed on the jumpers connecting the wells to the PLEM and on the end of the pipeline before the PLEM again all within the BTW PSZ. At the platform end additional concrete mattresses may be used at the hot tap location, on the pipeline before the flowline skid, on the jumper between the skid and the hot tap and at the end of the umbilical near the platform, all these are planned to be in the platform PSZ. The flexible pipeline consists of 6 sections, the ends of each pipeline section are bolted together with a shroud installed to minimise snag points. Whilst there are no anode sleds there are low profile bracelet style anodes at each end next to the shroud, the design of these bracelet anodes shouldn't pose a significant snag risk. The ends of each flexible section will also be restrained by a number of low profile concrete mattresses.
12-Mar-20	3426	To Stakeholder	Email	Further to the West Barracouta installation campaign sheet #3 we sent last week, below is a link to view a 2 minute video outlining how this complex project will come together.	No objections, claims or issues raised	N/A
12-Mar-20	3438	To Stakeholder	Email	Further to the West Barracouta installation campaign sheet #3 we sent last week, below is a link to view a 2 minute video outlining how this complex project will come together.	No objections, claims or issues raised	N/A
09-Apr-20	3296	To Stakeholder	Email	The following activities will be postponed after the completion of drilling at West Barracouta by approximately 13 April 2020: • Whiting plug and abandonment • Seahorse / Tarwhine plug and abandonment • Kipper drilling • Mulloway / Whiptail plug and abandonment	No objections, claims or issues raised	N/A
28-Apr-20	3464	To Stakeholder	Phone	EAPL called Fishing Representative to discuss the postponment of all JUR activities offshore and see if Stakeholders / Eastern Fishing Fleet had an queries or concerns. Fishing Represetative confirmed there are currently no concerns or queries from the fishing stakeholders.	No objections, claims or issues raised	N/A
25-May-20	3471	To Stakeholder	Phone	EAPL called stakeholder to review minutes from stakeholder consultation session in February 2020.	No objections, claims or issues raised	N/A

20-Nov-18	2174	To Stakeholder	Email	Invitation to Community Session in Lakes Entrance to discuss offshore activities in Bass Strait	No objections, claims or issues raised	N/A
06-May-19	2978	To Stakeholder	Email	JUR campaign sheet #1 detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline	No objections, claims or issues raised	Acknowledgement of receipt
24-Jul-19	3062	To Stakeholder	Email	Advising of geotechnical investigation at the proposed West Barracouta well site to confirm the suitability of locations for the use of a jack-up rig to drill new wells at West Barracouta, Kipper, Sweetlips and Wirrah and to workover the existing wells at Tarwhine and Seahorse with a view to plugging and abandoning them.	No objections, claims or issues raised	Email from stakeholder advising they have received our email. No objections, claims or issues raised
11-Dec-19	3209	To Stakeholder	Email	2020 JUR Campaign Sheet #2: campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
13-Dec-19	3239	To Stakeholder	Email	2020 JUR Campaign Sheet #2: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Whiting Plug and Abandonment programme including activity description, location, timing, impacts and risks.	No objections, claims or issues raised	N/A
07-Mar-20	3393	To Stakeholder	Email	2020 JUR Campaign Sheet #3: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the West Barracouta Installation programme including activity description, location and timing.	No objections, claims or issues raised	Acknowledgement of receipt
11-Mar-20	3346	To Stakeholder	Email	2020 JUR Campaign Sheet #4: updated campaign information sheet detailing a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign. This campaign sheet contains details of the Seahorse/Tarwhine P&A programme including activity description, location and timing.	No objections, claims or issues raised	N/A
12-Mar-20	3447	To Stakeholder	Email	Further to the West Barracouta installation campaign sheet #3 we sent last week, below is a link to view a 2 minute video outlining how this complex project will come together.	No objections, claims or issues raised	Acknowledgement of receipt
09-Apr-20	3307	To Stakeholder	Email	The following activities will be postponed after the completion of drilling at West Barracouta by approximately 13 April 2020: • Whiting plug and abandonment • Seahorse / Tarwhine plug and abandonment • Kipper drilling • Mulloway / Whiptail plug and abandonment	No objections, claims or issues raised	Acknowledgement of receipt

ExxonMobil

Esso offshore projects

Introduction

Esso Australia, a subsidiary of ExxonMobil Australia, is planning on undertaking a program of work across some of its offshore assets, including those owned jointly by the Gippsland Basin Joint Venture, in 2018 and 2019. This program forms part of Esso's ongoing investment in exploring domestic gas development opportunities to ensure that we can continue to meet Australia's energy needs.

This fact sheet provides high level details about the projects, regulatory requirements and consultation which will be occurring to facilitate information sharing and stakeholder engagement.

Hairtail Latitude 38° 36′ south, Longitude 148° 31′ east

Esso

An ExxonMobil Brand

ExxonMobil

VIC/P70 drilling program

Esso Australia is planning to undertake an exploration drilling program in the VIC/P70 block, approximately 90km off the East Gippsland Victorian coast. The program will involve drilling two exploration wells, known as Baldfish and Hairtail, with the activity planned to commence in mid 2018. The drilling program is expected to last approximately 60 days.

The exploration wells will determine the extent of any gas reserves contained within the field and support any subsequent development. If successful, this development has the potential to bring online much needed new gas supplies from Bass Strait fields, which have been producing for more than 40 years.

Offshore Environment Regulations

Esso is preparing an Environment Plan and associated Oil Pollution Emergency Plan to identify, assess and manage environmental risks for the exploration drilling program. These plans will be submitted to the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA), the offshore environment regulator, for review and acceptance in accordance with the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* and *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009*.

In developing the Environment Plans, Esso will conduct an environmental risk assessment to evaluate environmental risks associated with the activities being planned, and will incorporate prevention and mitigation measures that reduce these risks to As Low as Reasonably Practicable (ALARP).

Key impacts and environmental risks

As part of development of the VIC/P70 Environment Plan, the key impacts and environmental risks of the project will be identified and controls implemented to reduce the risks to ALARP. These include:

Temporary displacement of shipping/fishing

The Baldfish and Hairtail wells are located outside the "*Bass Strait Area to be Avoided*" as defined on marine chart AUS357. Esso will seek to have a temporary petroleum safety zone created around the drill rig will for the duration of the drilling program, to ensure drilling activities can be completed safely and other marine users are protected. Esso will be working with stakeholders, including the Australian Marine Safety Authority, to manage the impact and communicate with marine users.

Drilling fluids and drill cuttings

As part of the drilling program, water-based mud (WBM) will be used to remove the cuttings from the wells to be drilled, cool the drill bits and maintain pressure control of the wells. WBM is mostly water and natural clays, with a small amount of low toxicity additives. The drill cuttings will be separated from the WBM and discharged overboard, while the WBM will be recycled and reused. Drill cuttings will settle in the local vicinity of the wells on the sea floor, which is predominantly sandy with limited bottom-dwelling marine fauna.

Esso
An ExxonMobil Brand

Other discharges and waste

Controls such as hose inspections and creation of bunded areas will be in place to prevent and mitigate the uncontrolled release of fluids to the marine environment. Any waste generated will be managed in accordance with correct segregation, handling and be returned for onshore disposal. Small amounts of residual fluid from cleaning the mud and cement equipment will be discharged overboard.

Hydrocarbon release

The VIC/P70 drilling program will be undertaken in a well understood geological area where the target reservoir is gas. This, in conjunction with preventative measures, including the application of appropriate well control barriers, procedures and equipment, means that a well blowout or loss of well control are very unlikely. In the unlikely event of a release, the impact is expected to be localized with no significant shore line impact. Third party oil spill modelling is being conducted with a range of scenarios being investigated which will form the basis of Oil Pollution Emergency Plans. The plans will outline the roles, responsibilities and response strategies to mitigate the impact of a potential spill from drilling activities.

Other projects

VIC/L1 development

Esso Australia is examining options to develop a gas field in block VIC/L1 known as West Barracouta, approximately 6km south west of the existing Barracouta platform. The project is likely to involve the drilling of a number of subsea wells which will be tied back to our existing Barracouta infrastructure in Bass Strait. This project will be undertaken within Esso's current "Bass Strait Area to be Avoided".

To support the project's development, Esso will be conducting environmental and seabed surveys commencing in early 2018 (duration approximately 20 days) to assess the location of potential well sites and flow line routes. As the project develops, additional consultation with stakeholders will be conducted.

Cobia Pipeline project

The Cobia Pipeline project will undertake maintenance and repair works on the Cobia pipeline, which runs from the Cobia platform to the Halibut platform in Bass Strait. This project will be undertaken within the existing Bass Strait "Area to be Avoided" and a temporary petroleum safety zone will be implemented to provide protection during the project.

The offshore work for this project is planned to be carried out by a dynamically positioned vessel in late 2018 and will take approximately two weeks.

The key impacts and environmental risks of the VIC/L1 development and Cobia pipeline project will be developed and shared with stakeholders as regulatory documentation is progressed.

Consultation

We are committed to engaging with the communities where we operate and helping our stakeholders to understand our business. Esso will be consulting with stakeholders potentially affected by these projects through a number of different channels.

This fact sheet provides information to allow stakeholders to make an informed assessment of the possible consequences of the proposed activities to their functions, interests or activities. We will address questions and consider feedback from stakeholders relating to these projects throughout this consultation process.

If you have any specific questions or feedback about any of these projects please contact Esso at consultation@exxonmobil.com.

A face to face session is being planned for 17 November 2017. To register your interest in attending, please RSVP to consultation@exxonmobil.com

About Esso

Esso Australia is a subsidiary of ExxonMobil Australia, the country's largest integrated oil and gas company. Esso's Longford Plants has processed more than four billion barrels of oil and eight trillion cubic feet of gas since production began in 1969.

We place the highest priority on operating flawlessly in all aspects of our business. All these offshore projects will be managed in accordance with all regulatory requirements, as well as Esso's Operational Integrity Management System to reduce risks to ALARP. Environment Plans detailing each program of work and how the risks of the program will be managed by Esso will be submitted to NOPSEMA for acceptance.

Esso is continuously striving to improve all aspects of our safety performance including for our people, our processes, security, health, and environmental performance.

Any waste generated will be managed in accordance with correct segregation, handling and be returned for onshore disposal. Small amounts of residual fluid from cleaning the mud and cement equipment will be discharged overboard.

Hydrocarbon release

The VIC/P70 drilling program will be undertaken in a well understood geological area where the target reservoir is gas. This, in conjunction with preventative measures, including the application of appropriate well control barriers, procedures and equipment, means that a well blowout or loss of well control are very unlikely. In the unlikely event of a release, the impact is expected to be localized with no significant shore line impact. Third party oil spill modelling is being conducted with a range of scenarios being investigated which will form the basis of Oil Pollution Emergency Plans. The plans will outline the roles, responsibilities and response strategies to mitigate the impact of a potential spill from drilling activities.

Other projects

VIC/L1 development

Esso Australia is examining options to develop a gas field in block VIC/L1 known as West Barracouta, approximately 6km south west of the existing Barracouta platform. The project is likely to involve the drilling of a number of subsea wells which will be tied back to our existing Barracouta infrastructure in Bass Strait. This project will be undertaken within Esso's current "Bass Strait Area to be Avoided".

To support the project's development, Esso will be conducting environmental and seabed surveys commencing in early 2018 (duration approximately 20 days) to assess the location of potential well sites and flow line routes. As the project develops, additional consultation with stakeholders will be conducted.

Cobia Pipeline project

The Cobia Pipeline project will undertake maintenance and repair works on the Cobia pipeline, which runs from the Cobia platform to the Halibut platform in Bass Strait. This project will be undertaken within the existing Bass Strait "Area to be Avoided" and a temporary petroleum safety zone will be implemented to provide protection during the project.

The offshore work for this project is planned to be carried out by a dynamically positioned vessel in late 2018 and will take approximately two weeks.

The key impacts and environmental risks of the VIC/L1 development and Cobia pipeline project will be developed and shared with stakeholders as regulatory documentation is progressed.

Seabed surveys

In addition to the environmental and seabed surveys to be conducted for the VIC/L1 development, in order to support a number of future developments, Esso will be conducting seabed surveys commencing in early 2018 (duration approximately 60 days over a 6 month period) to help inform potential drilling activities at Kipper and VIC/L9, as well as potential plug and abandonment activities at a number of existing licence areas as shown in the figure below.

The proposed surveys will involve collection of geophysical data (i.e. measurements of seabed characteristics, imaging and profiling), collection of water and sediment samples, and collection of subsea floor materials.

A range of measures will be implemented to reduce potential environmental impacts to acceptable levels:

- Survey vessels will not anchor or refuel during the activity
- Measures will be taken to protect marine fauna from noise and to prevent vessel collisions
- All discharges (e.g. sewage, grey water) will meet legal requirements
- Appropriate spill response plans will be established
- Survey vessels will be assessed and managed to prevent the introduction of invasive marine species

Consultation

We are committed to engaging with the communities where we operate and helping our stakeholders to understand our business. Esso has been consulting with stakeholders potentially affected by these projects through a number of different channels.

This fact sheet provides information to allow stakeholders to make an informed assessment of the possible consequences of the proposed activities to their functions, interests or activities. We will address questions and consider feedback from stakeholders relating to these projects throughout this consultation process. If you have any specific questions or feedback about any of these projects please contact Esso at consultation@exxonmobil.com or call 03 9261 0260.

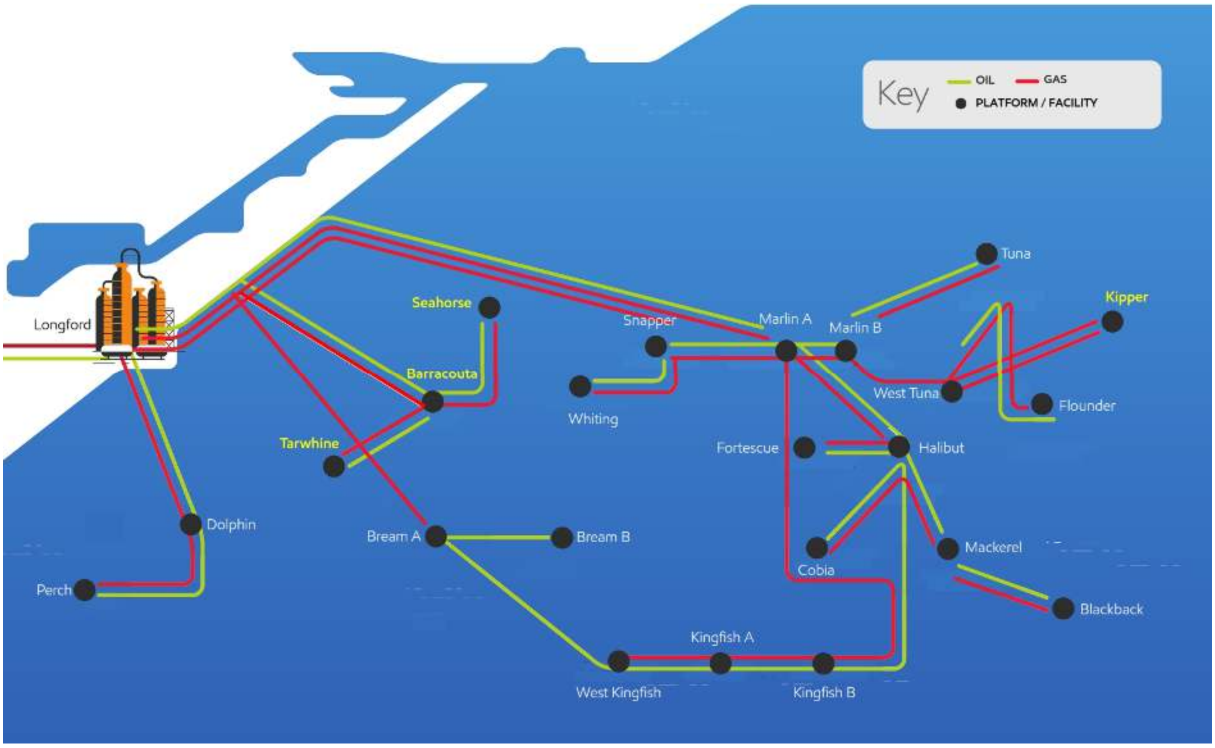
ExxonMobil

Esso Bass Strait 2020 Jack Up Rig Campaign



Esso Australia is planning to undertake a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign and includes:

- Well Plug and Abandonment (P&A)
  - Two subsea wells, Seahorse -1 and Tarwhine – 1
  - 5 wells at the Whiting platform
- Drilling
  - Two subsea gas production wells in the West Barracouta field.
  - Two subsea gas production wells in the Kipper field.

There will be no seismic activity as part of this campaign.

All well abandonment and drilling activities will be undertaken by the jack-up drilling rig “Tom Prosser”. The Tom Prosser was built in 2014 and operates to the latest international safety and environmental standards. The drilling rig will be supported by up to three support vessels.

Noble Tom Prosser Jack-Up Drilling Rig (Image courtesy of Noble Corporation)

The Tom Prosser does not have any propulsion capability and will be towed into position, then the legs lowered onto the seabed and the rig elevated above the sea surface.

Activity Description

Well Abandonment

The Seahorse-1, Tarwhine-1 and Whiting wells no longer produce a viable quantity of oil and gas, so permanent barriers will be installed to enable the wells to be safely abandoned in accordance with regulatory standards. Well ‘abandonment’ is a safe and long-standing practice.

For all wells, a Blowout Preventer (BOP) will be used to prevent the release of hydrocarbons during the plugging of the wells. Tubing and associated instruments and control valves will be removed, and permanent cement plugs / barriers installed to provide multiple physical barriers to prevent the release of any hydrocarbons that remain in the reservoir.

The Seahorse-1 and Tarwhine-1 wellheads will be cut at a depth of ~ 3 m beneath the seabed and removed. The remaining infrastructure, such as the Whiting platform jacket and topsides, well conductors, disconnected pipelines and umbilical control lines, will be removed as part of a separate campaign and will be the subject of further consultation.

Production Drilling

The drilling process uses a rotating bit attached to the end of a string of drill pipe to bore through the earth to reach the gas reservoirs. As the bit turns, it grinds off small pieces of rock, or drill cuttings, thus deepening the well.

In upper sections seawater-based fluids will be pumped down the drill string to remove the cuttings from the well, cool the drill bit, and maintain pressure control of the well. In lower sections, to assist well stability, low toxicity non-aqueous fluids (NAF) will be used. The NAF and cuttings are recirculated to the drilling rig where the fluids will be removed from the cuttings before being re-used. Once removed, drill cuttings will be discharged overboard where they will settle on the seabed near the rig.

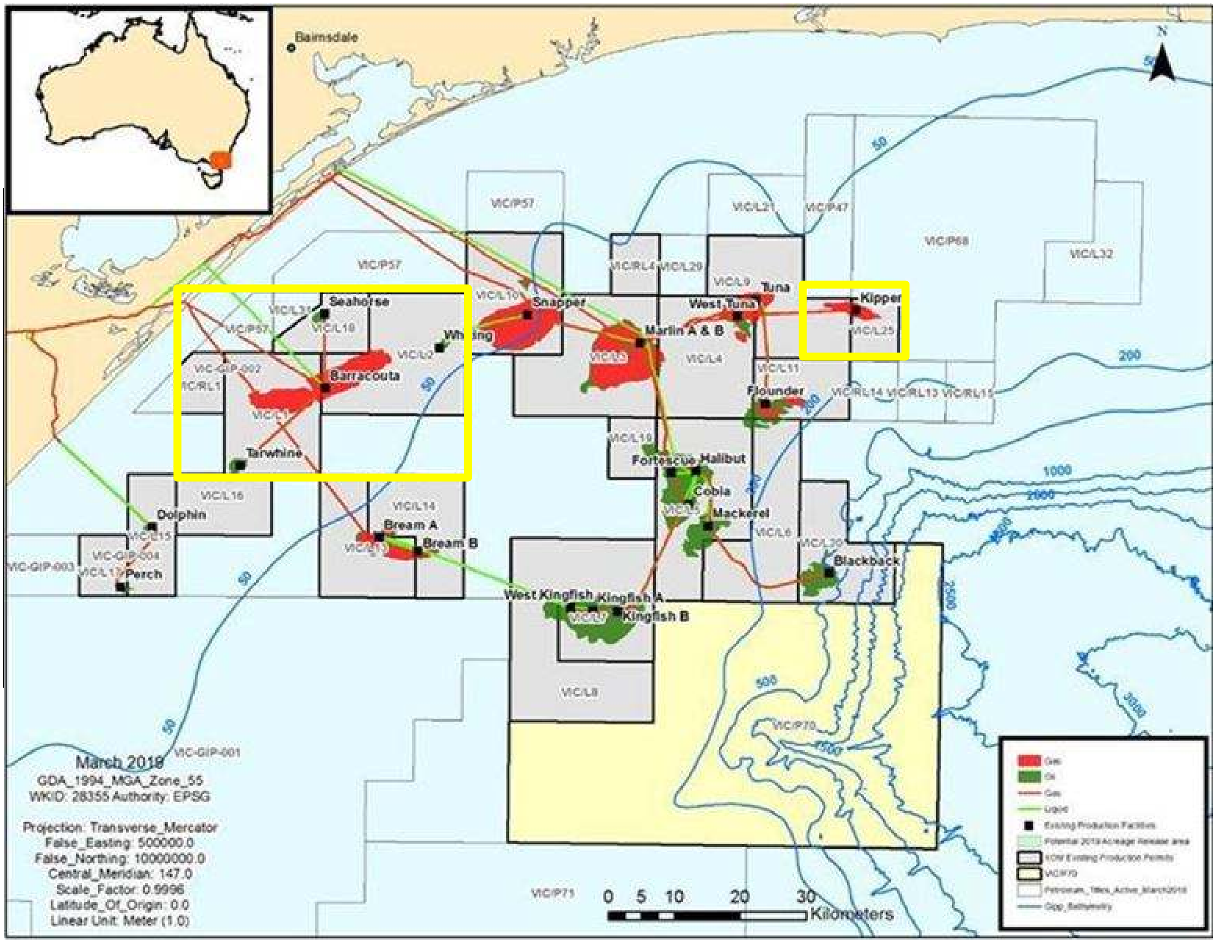
Once drilling has finished, steel casing will be installed in the wellbore and cemented in place. Then production tubing will be installed containing various instruments and flow control valves.

At Kipper the rig will also install the pipework and control valves attached to the top of the well on the seafloor called 'trees'. However, the West Barracouta wells will be suspended until the trees, which will sit ~ 5m above the seafloor, are installed in a separate campaign.

Activity Location

The Seahorse and Tarwhine wells and the proposed West Barracouta wells are located ~ 15km off the Gippsland coastline, south of Lakes Entrance in water depths of ~45m. The Whiting platform is located ~34km offshore in water depths of ~54m. The Kipper Subsea Facility is located ~45km east of Lakes Entrance in a water depth of ~95m.

The wells are not located within any established or proposed Commonwealth or State Marine Protected Areas, Critical Habitats or Threatened Ecological Communities, and are outside of established shipping fairways. It is recognised that the activities will overlap with existing fisheries.



Esso Bass Strait 2020 Jack Up Rig Campaign Activity Locations

Activity Timing

The following shows two indicative campaign timetables only. The earliest date of commencement of the campaign is January 2020 with all activity scheduled to be completed no later than December 2021.

Activities will be conducted 24 hours per day, seven days per week. It is expected to take ~30 days to plug and abandon each well and ~50 days to drill and complete each of the West Barracouta and Kipper wells.

The timing and order of activity may vary and is contingent on regulatory approvals, joint venture approvals, and weather and rig/vessel schedules.

Jack Up Rig Campaign ‘Early’ Activity Timeline

Jack Up Rig Campaign ‘Late’ Activity Timeline

Impacts and Risks

Provided in the table below are the key potential impacts relating to the Jack Up Rig Campaign to assist stakeholders in making an informed assessment on possible impacts to their activities, functions or interests in the area.

Potential Impacts	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
Drill Rig and Vessel-based impacts		
Drill rig leg placement	Temporary and localised seabed disturbance	Seabed survey completed to identify obstructions. Rig move procedures in place. Small area affected by leg placement, rapidly filled after removal. Area is sandy bottom with no sensitive seabed features.
Planned discharges to the marine environment - Sewage and food waste - Treated bilge and deck wash - Cooling water and brine	Temporary and localised reduction in water quality Temporary change to predator / prey dynamics	Routine discharges and vessel waste treatment systems will meet MARPOL requirements and are routinely maintained. Food-scraps will be macerated prior to discharge. Discharged bilge water will have less than 15 ppm oil in water content. Any chemicals planned for discharge undergo an environmental assessment to confirm suitability for discharge prior to use.
Sound emissions	Temporary displacement of sound sensitive fauna around active vessels	Support vessels and helicopters will comply with EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans.
Light emissions	Attraction of light sensitive species Change in fauna behaviour	Lighting will be kept to minimum while still meeting navigational and workplace safety requirements.
Air emissions	Temporary and localised reduction in air quality	Air emissions from marine engines will meet MARPOL requirements and are routinely maintained. Low sulphur content fuel will be used.
Unplanned interaction with marine fauna (vessel strike)	Injury or death of marine fauna	Support vessels will comply with EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans. Any injury/mortality of EPBC-listed fauna will be reported to the Department of the Environment and Energy
Unplanned introduction of invasive marine species (IMS)	Displacement of native species and habitat domination	Jack Up Rig and all support vessels will have a Ballast Water Management Plan and Certificate. Jack Up Rig and all support vessels will comply with Australian Ballast Water Management requirements.

		A Biofouling Risk Assessment will be completed to confirm a low risk of IMS introduction. Submersible equipment will be cleaned prior to commencement of activity.
Accidental release of materials and waste	Temporary and localised: - Increase in turbidity - Burial of benthic habitat in immediate seabed area - Potential toxicity impacts	Waste handling, storage and disposal will meet MARPOL requirements. Lifting equipment is certified and routinely maintained. Bulk transfer equipment is certified and routinely maintained. Dropped objects will be recovered where safe and practicable.
Accidental release of fuel (vessel collision)	Tainting of commercial fisheries species (e.g. shellfish). Injury and death of species such as fish, marine reptiles, seabirds, cetaceans. Pathological effects on fish larvae and plankton.	All operational locations are within gazetted exclusion zones. Commencement of activity and exclusion zone will be communicated to other marine users via Notice to Mariners and via AMSA. Vessel will hold Dynamic Positioning (DP) System II Notation and watchkeeper-in-charge will hold DP Certification. Vessels will only travel at slow speeds within 500m of Jack Up Rig. Vessels will comply with their approved Shipboard Oil Pollution Emergency Plan (SOPEP) including maintaining spill kits, emergency response procedures and conducting spill response exercises Esso has a comprehensive Oil Pollution Emergency Plan (OPEP) which will be used in the event of a spill.
Drilling and Abandonment Activity Impacts		
Discharge of cement	Localised and temporary: - Reduction in water quality - Smothering of benthic habitat	Low toxicity cement additives have been selected for use. Cement hose flushing and slurry releases will be rapidly diluted and dispersed by the dynamic marine environment.
Drilling fluid and cuttings discharges	Localised and temporary: - Increase in turbidity - Burial of benthic habitat in immediate seabed area - Potential toxicity impacts	Seawater-based fluids will be used where practicable. Low toxicity non-aqueous fluids (NAF) and additives will be used when required. Solids control equipment will be used to remove NAF on cuttings to minimal residues prior to discharge overboard Dynamic seabed and marine environment will rapidly disperse discharged cuttings and drilling fluids.
Well fluid discharges	Increased salinity Potential toxicity effects	Low toxicity chemical additives have been selected for use in abandonment and completion fluids.

		Chemicals used in well fluids undergo environmental assessment to confirm suitability for discharge prior to use. Dynamic seabed and marine environment will rapidly disperse discharged well fluids.
–Disconnection / cutting discharges	Localised and temporary: - Reduction in water quality - Smothering of benthic habitats	Chemicals planned for discharge undergo environmental assessment to confirm suitability prior to use. Discharge will rapidly disperse in dynamic seabed and marine environment.
Naturally Occurring Radioactive Materials (NORM)	Temporary exposure of marine fauna to radioactive materials	Open ends of disconnected pipelines plugged to prevent fauna entry and leave NORM in a contained system.
Loss of well control	Tainting of commercial fisheries species (e.g. shellfish). Injury and death of species such as fish, marine reptiles, seabirds, cetaceans. Pathological effects on fish larvae and plankton. Pollution of shoreline habitats such as sandy beaches and rocky shores	West Barracouta and Kipper are gas wells. A loss of well control event may release condensate, which is generally not persistent in the environment, but not oil. Seahorse and Tarwhine are depleted light crude wells that mainly produce water. An accepted Environment Plan (EP), OPEP and Emergency Response Plan (ERP) will be in place and implemented in the event of a loss of well control. An accepted Safety Case and Well Operations Management Plan will be in place.

Petroleum Safety Zones

The Seahorse and Tarwhine subsea wells, the Whiting platform and the Kipper Subsea Facility are located within existing 500m Petroleum Safety Zones (PSZ) and a new PSZ will be gazetted around the West Barracouta subsea drill location. The exact location of the drill rig while at each location will be communicated to other marine vessels via a Notice to Mariners issued by the Australian Hydrographic Service (AHS) and AUSCOAST warnings issued by the Australian Maritime Safety Authority (AMSA).

The existing PSZ around the Seahorse and Tarwhine wells will be removed once all well abandonment activities have been carried out and removal of seabed infrastructure is complete.

Interaction with Commercial Fishing

The well sites are located within existing designated Commonwealth and State fisheries that may be used by commercial fishers. The 500 m PSZ will be communicated to Lakes Entrance Fisherman's Co-op (LEFCOL), South East Trawl Fishing Industry Association (SETFIA) and Seafood Industry Victoria (SIV) as it is a legal requirement that the area should be avoided during drilling.

Environment Plans

Under the Offshore Petroleum and Greenhouse Gas Storage Act 2006, before any petroleum related activities in Commonwealth waters can commence, an Environment Plan (EP) must be accepted by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

In the course of preparing an EP, Esso Australia must consult with relevant authorities, persons and organisations whose functions, interests or activities may be affected by the proposed activities (i.e. a relevant person) and provide the opportunity for any issues or concerns to be raised.

Three separate Environment Plans (EPs) are proposed to be developed for these different activities, however, to improve efficiencies for stakeholders, a single consultation process is being undertaken.

The EP is a comprehensive document that describes the existing environment, including stakeholders, and how Esso Australia will undertake the activities to avoid, minimise or manage potential environmental impacts to the "As Low As Reasonable Practicable" standard (ALARP) and meet Esso Australia's acceptability criteria.

Oil Pollution Emergency Plan (OPEP)

Under Commonwealth environment legislation, Esso Australia must demonstrate and document oil spill response arrangements. The OPEP forms part of an EP submission and demonstrates our capability to respond in the unlikely event of an oil spill.

Esso Australia is a member of the Australian Marine Oil Spill Centre (AMOSC), a co-operative national oil spill response organisation, which provides access to additional oil spill response resources if required.

Esso Australia's OPEP interfaces with national, state and industry response plans prepared and implemented by the Australian Government via AMSA (NATPLAN), the Victorian Government (Maritime Emergencies (non-search and rescue) Plan), the Tasmanian Government (TASPLAN), the NSW Government (NSW Marine Oil and Chemical Spill Contingency Plan) and the Australian Oil industry's Australian Marine Oil Spill Plan (AMOSPLAN) administered by AMOSC.

The OPEP defines spill response options which may be applied to a spill event. The selected spill response option(s) would depend upon the size and type of spill; environmental sensitivities within the spill path; prevailing weather conditions; access restrictions and available resources. In all instances, a Net Environmental Benefits Assessment (NEBA) is undertaken, in consultation with relevant government agencies, to consider the advantages and disadvantages of the available spill response options.

Consultation

Esso Australia is committed to engaging with the communities where we operate and helping our stakeholders to understand our business.

Esso has been consulting with stakeholders potentially affected by this campaign through a number of different channels.

While some community consultations have occurred, Esso welcomes the opportunity for more face-to-face meetings and will continue to keep interested stakeholders informed of the proposed activities throughout the planning phase and into operational phase.

We will address questions and consider feedback from stakeholders throughout this campaign.

If you have any specific questions or feedback about any of these activities please contact Esso at consultation@exxonmobil.com or call 03 9261 0260.

Fact Sheet #3 - April 2018 (included in PROFISH)

ExxonMobil

Esso offshore projects

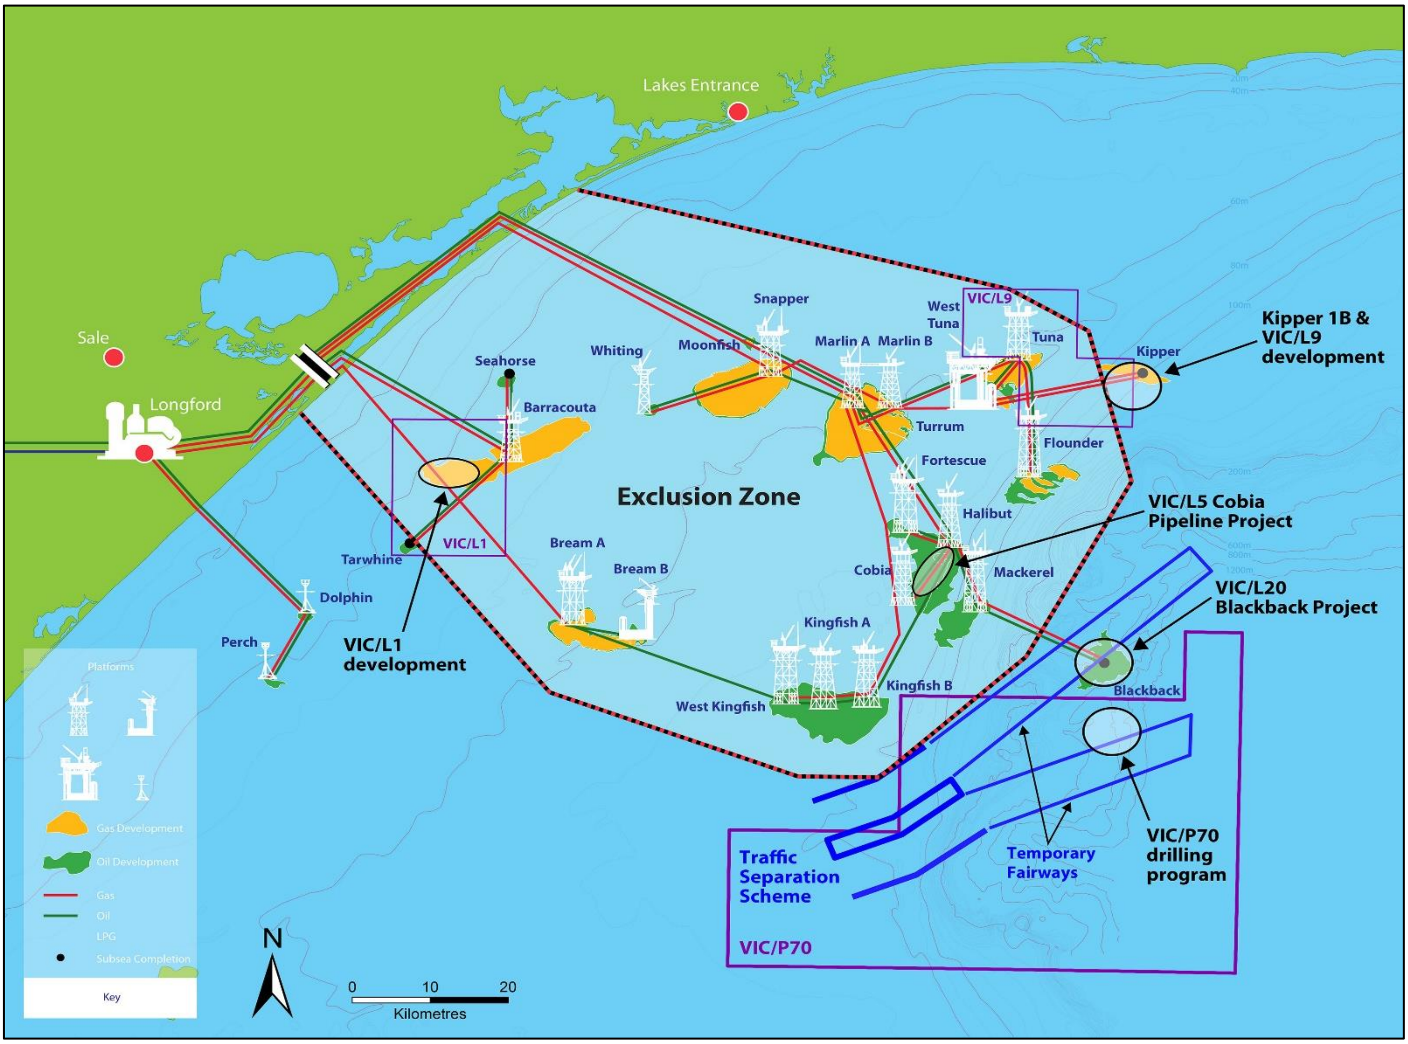
INTRODUCTION

Esso Australia, a subsidiary of ExxonMobil Australia, is planning on undertaking a program of work across some of its offshore assets, including those owned jointly by the Gippsland Basin and Kipper Unit Joint Ventures, in 2018 and 2019.

This program forms part of Esso's ongoing investment in exploring domestic gas development opportunities to ensure that we can continue to meet Australia's energy needs.

This fact sheet provides high level details about the projects, regulatory requirements and consultation which will be occurring to facilitate information sharing and stakeholder engagement.

Project Locations



PROJECTS

VIC/P70 drilling program

Esso Australia is planning to undertake an exploration drilling program in the VIC/P70 block, approximately 90km off the East Gippsland Victorian coast. The program will involve drilling two exploration wells, known as Baldfish and Hairtail. The drilling program is expected to last approximately 60 days starting mid-2018.

The exploration wells will determine the extent of any gas reserves contained within the field and has the potential to lead to development of much needed new gas supplies from The Gippsland Basin, which has been producing for more than 40 years.

The Baldfish and Hairtail wells are located outside the "Bass Strait Area to be Avoided" as defined on marine chart AUS357.

Esso will seek to have a temporary petroleum safety zone created around the drill rig for the duration of the drilling program, to ensure drilling activities can be completed safely and other marine users are protected. (VIC/P70 well coordinates: Baldfish Latitude 38° 36′ south, Longitude 148° 35′ east / Hairtail Latitude 38° 36′ south, Longitude 148° 31′ east)

Esso will be working with stakeholders, including the Australian Marine Safety Authority, to manage the impact and communicate with marine users.

Esso
An ExxonMobil Brand

Seabed surveys

Esso Australia is examining options to develop a gas field in block VIC/L1 known as West Barracouta, approximately 6km south west of the existing Barracouta platform. The project is likely to involve the drilling of a number of subsea wells which will be tied back to our existing Barracouta infrastructure in Bass Strait. This project will be undertaken within Esso's current "Bass Strait Area to be Avoided".

To support the project's development, Esso will be conducting environmental and seabed surveys commencing in early 2018 (duration approximately 20 days) to assess the location of potential well sites and flow line routes.

In addition to the environmental and seabed surveys to be conducted for the VIC/L1 development, in order to support a number of future developments, Esso will be conducting seabed surveys commencing in early 2018 (duration approximately 60 days over a 6 month period) to help inform potential drilling activities at Kipper and VIC/L9, as well other activities at a number of existing licence areas.

The proposed surveys will involve collection of geophysical data (i.e. measurements of seabed characteristics, imaging and profiling), collection of water and sediment samples, and collection of subsea floor materials. The Environment Plan for the seabed survey work was accepted in February 2018.

VIC/L5 Cobia Pipeline project

The Cobia Pipeline project will undertake maintenance and repair works on the Cobia pipeline, which runs from the Cobia platform to the Halibut platform in Bass Strait. This project will be undertaken within the existing Bass Strait "Area to be Avoided" and a temporary petroleum safety zone will be implemented to provide protection during the project.

The offshore work for this project is planned to be carried out by a dynamically positioned vessel in late 2018 and will take approximately two weeks.

VIC/L20 Blackback

Esso Australia is examining options to secure wells no longer in operation. (Well coordinates: Latitude 38° 32′ south, Longitude 148° 33′ east)

VIC/L25 and VIC/L9 Kipper 1B and Pilchard

Esso Australia and its Joint Venture partners are planning to drill a number of additional wells at Kipper. These will be tied into the existing infrastructure within the existing Kipper petroleum safety zone. The current schedule is for these to be drilled in 2019.

In addition to the Kipper infield drilling a similar gas field, Pilchard, is being assessed and may be drilled and developed in the same drilling campaign.
Pilchard may be drilled from Kipper or may require a new subsea location nearby. (Well coordinates: Latitude 38° 11′ south, Longitude 148° 36′ east)

OFFSHORE ENVIRONMENT REGULATIONS

Esso is preparing Environment Plans and associated Oil Pollution Emergency Plans to identify, assess and manage environmental risks for these projects. These plans will be submitted to the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA), the offshore environment regulator, for review and acceptance in accordance with the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* and *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009*.

In developing the Environment Plans, Esso will conduct an environmental risk assessment to evaluate environmental risks associated with the activities being planned, and will incorporate prevention and mitigation measures that reduce these risks to As Low as Reasonably Practicable (ALARP).

CONSULTATION

We are committed to engaging with the communities where we operate and helping our stakeholders to understand our business. Esso has been consulting with stakeholders potentially affected by these projects through a number of different channels.

As these projects develop, additional consultation with stakeholders will be conducted, including key impacts and environmental risks.

This fact sheet provides information to allow stakeholders to make an informed assessment of the possible consequences of the proposed activities to their functions, interests or activities. We will address questions and consider feedback from stakeholders relating to these projects throughout this consultation process. If you have any specific questions or feedback about any of these projects please contact Esso at consultation@exxonmobil.com or call 03 92610260

ABOUT ESSO

Esso Australia is a subsidiary of ExxonMobil Australia, the country's largest integrated oil and gas company. Esso's Longford Plants has processed more than four billion barrels of oil and eight trillion cubic feet of gas since production began in 1969.

We place the highest priority on operating flawlessly in all aspects of our business. All these offshore projects will be managed in accordance with all regulatory requirements, as well as Esso's Operational Integrity Management System to reduce risks to ALARP. Environment Plans detailing each program of work and how the risks of the program will be managed by Esso will be submitted to NOPSEMA for acceptance.

Esso is continuously striving to improve all aspects of our safety performance including for our people, our processes, security, health, and environmental performance.
For more information about our operations please visit www.exxonmobil.com.au

An ExxonMobil Brand

Fact Sheet #4 - August 2018

ExxonMobil

Esso offshore projects

Introduction

Esso Australia, a subsidiary of ExxonMobil Australia, is undertaking a program of work across some of its offshore assets, including those owned jointly by the Gippsland Basin Joint Venture and the Kipper Unit Joint Venture, in 2018 and 2019.

This program forms part of Esso's ongoing investment in exploring for domestic gas development opportunities to ensure that we can continue to meet Australia's energy needs.

This fact sheet provides high level details about the projects, regulatory requirements and consultation that is occurring to facilitate information sharing and stakeholder engagement.

Projects

VIC/P70 drilling program

Esso is undertaking an exploration drilling program in the VIC/P70 block, approximately 90km off the East Gippsland Victorian coast. The program will involve drilling two exploration wells, known as Baldfish and Hairtail.

All regulatory requirements are in place with the Environmental Plan accepted by NOPSEMA on 4 July 2018 (a summary is available on the NOPSEMA website and on the ExxonMobil Australia website www.exxonmobil.com.au).

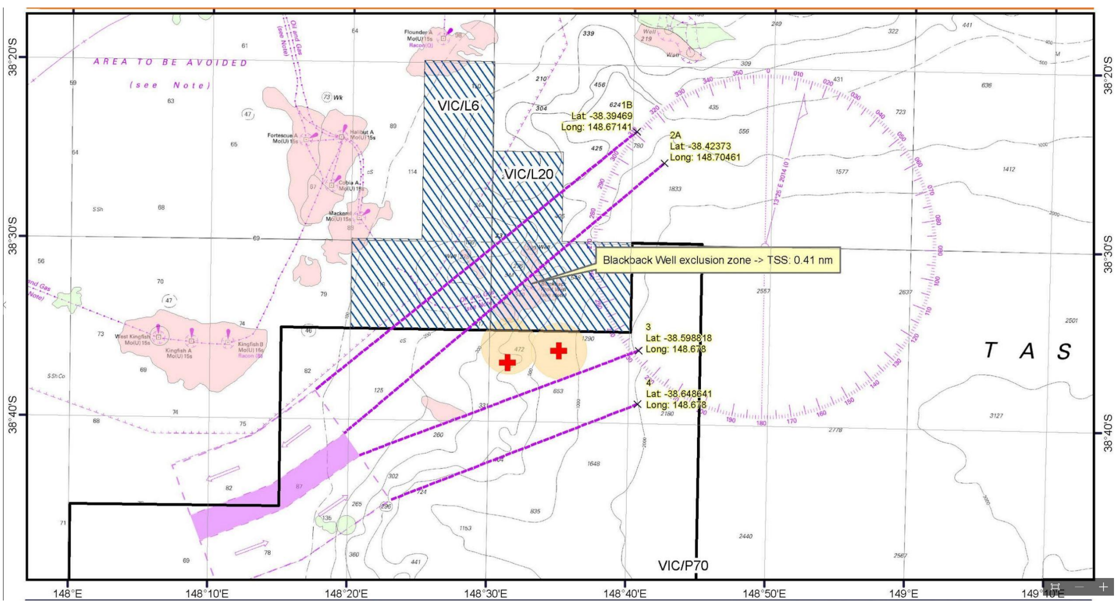
The drilling program is expected to start in the second half of 2018 and continue for approximately 60 days, using the Ocean Monarch mobile offshore drilling unit (MODU).

The exploration wells will determine the extent of any gas reserves contained within the field and the potential for development of much needed new gas supplies from the Gippsland Basin, which has been producing for more than 45 years.

The Baldfish and Hairtail wells are located outside the Bass Strait "Area to be Avoided" as defined on marine chart AUS357 and temporary fairways have been established to protect the rig and other marine users (see figure below).

Temporary petroleum safety zones will also be in place for the duration of the drilling program, to further provide protection. (VIC/P70 well coordinates: Baldfish Latitude 38° 36′ south, Longitude 148° 35′ east / Hairtail Latitude 38° 36′ south, Longitude 148° 31′ east).

Esso is working with stakeholders, including the Australian Marine Safety Authority, to manage the impact and communicate with marine users.



Temporary fairways

VIC/L20 Blackback

Esso is undertaking a project to work on the Blackback wells also using the Ocean Monarch MODU. The program is expected to start in the second half of 2018 and continue for approximately 60 days. (Well coordinates: Latitude 38° 32′ south, Longitude 148° 33′ east).

Ocean Monarch MODU

VIC/L1 development

Esso is examining options to develop a gas field in block VIC/L1 known as West Barracouta, approximately 6km south west of the existing Barracouta platform. The project is likely to involve the drilling of two subsea wells within one petroleum safety zone, which will be tied back to our existing Barracouta infrastructure in Bass Strait.

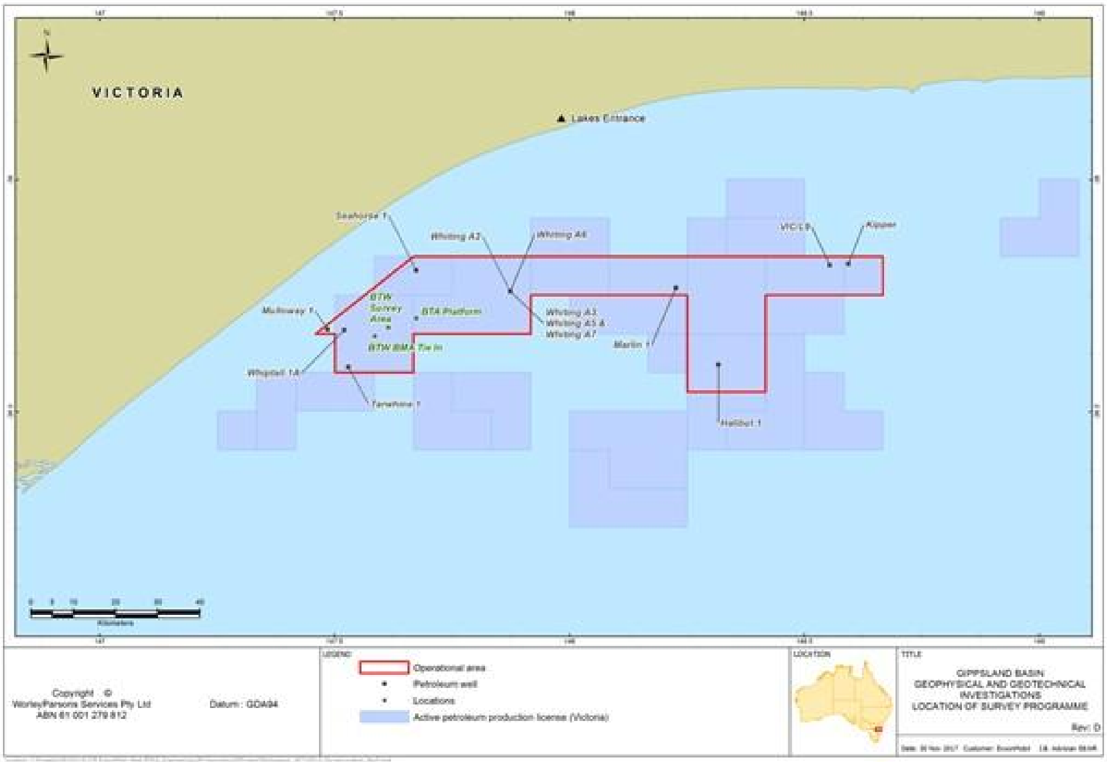
A subsea flowline approximately 6km in length connected via a subsea hot tap into the existing gas export pipeline and controls umbilical approximately 6.5 km in length to the Barracouta platform is planned to be installed. This project will be undertaken within Esso's current Bass Strait "Area to be Avoided".

To support the project's development, Esso has conducted environmental and seabed surveys and geotechnical surveys are planned to be completed the first half of 2019 (previously planned for 2018), subject to regulatory approval. The results of these surveys will be used to assess the location of the well sites and flowline and umbilical routes.

Seabed surveys

In addition to the seabed surveys to be conducted for the VIC/L1 development, Esso will be conducting seabed surveys to help inform potential drilling activities in VIC/L9, as well as potential plug and abandonment activities at a number of existing licence areas as shown in the figure below.

The proposed surveys will involve collection of geophysical data (i.e. measurements of seabed characteristics, imaging and profiling), collection of water and sediment samples, and collection of subsea floor materials. Geotechnical data will also be collected.



Map of proposed seabed surveys

ExxonMobil

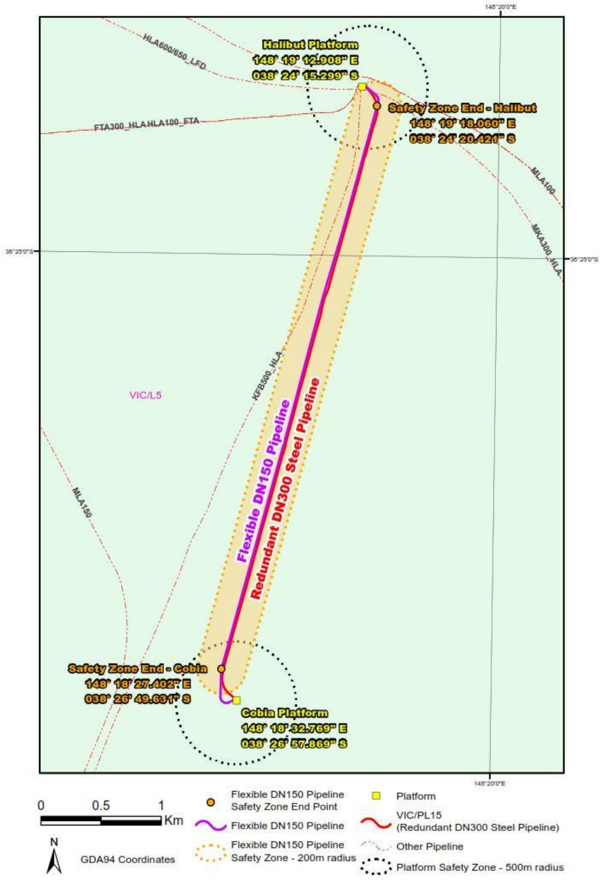
A range of measures will be implemented to reduce potential environmental impacts to acceptable levels:

- Survey vessels will not anchor or refuel during the activity
- Measures will be taken to protect marine fauna from noise and to prevent vessel collisions
- All discharges (e.g. sewage, grey water) will meet legal and environmental requirements
- Appropriate spill response plans will be established
- Survey vessels will be assessed and managed to prevent the introduction of invasive marine species

VIC/L05 Cobia Pipeline project

The Cobia Pipeline project will undertake maintenance and repair works on the Cobia pipeline, which runs from the Cobia platform to the Halibut platform in Bass Strait.

This project will be undertaken within the existing Bass Strait "Area to be Avoided" and a temporary petroleum safety zone will be implemented to provide protection during the project.



Temporary petroleum safety zone for Cobia Project

The offshore work for this project is planned to be carried out by the Seven Eagle, a dive support vessel, in December 2018 and will take approximately two weeks.

Dive support vessel 'Seven Eagle'

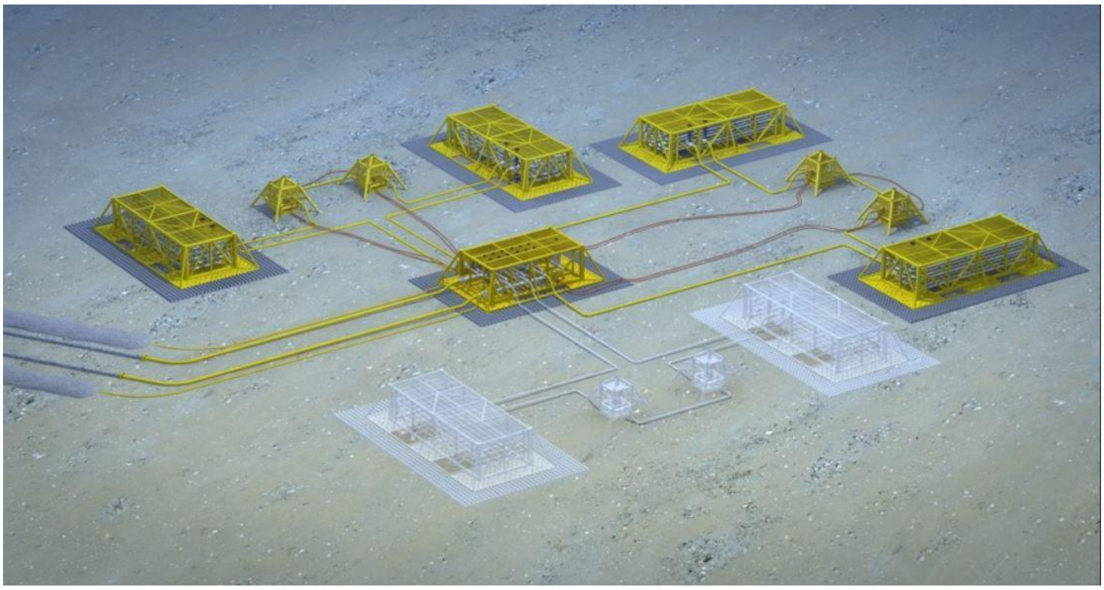
VIC/L05 Mackerel and other platform based activities

Esso is also considering work on the Mackerel wells with the program expected to begin in November 2018 and continue for approximately 10 months (Platform coordinates: Latitude 38° 27′ south, 148° 18′ east), with various platform based activities scheduled throughout 2019 to 2022.

VIC/L25 and VIC/L9 Kipper 1B and Pilchard

Esso and its Kipper Unit Joint Venture partners are planning to drill a number of additional wells at Kipper (Well coordinates: Latitude 38° 11′ south, Longitude 148° 36′ east). These wells were part of the original Kipper plan and are referred to as Stage 1B.

The wells will be tied into the existing subsea infrastructure within the current Kipper petroleum safety zone as shown in the following artist's impression. The current schedule is for the Kipper 1B wells to be drilled in 2020.



Artist's impression of Kipper Subsea Facilities

In addition to the Kipper infield drilling, a similar gas field, Pilchard, is being assessed by Esso and its Gippsland Basin Joint Venturers and may be drilled and developed in a future drilling campaign.

Offshore environment regulations

Esso is preparing Environment Plans and associated Oil Pollution Emergency Plans to identify, assess and manage environmental risks for these projects.

These plans will be submitted to the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA), the offshore environment regulator, for review and acceptance in accordance with the Offshore Petroleum and Greenhouse Gas Storage Act 2006 and Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009.

In addition, Esso will be conducting a five-yearly review of existing Environment Plans for platforms operating in Bass Strait commencing mid-2019, in accordance with the Offshore Petroleum and Greenhouse Gas Storage Act 2006 and Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009.

In developing the Environment Plans, Esso will conduct an environmental risk assessment to evaluate environmental risks associated with the activities being planned, and will incorporate prevention and mitigation measures that reduce these risks to As Low as Reasonably Practicable (ALARP).

Produced Formation Water (PFW)

As part of the accepted offshore Environment Plans, Esso committed to undertaking in-situ monitoring of the discharge of Produced Formation Water (PFW) to assess its potential impact on the Bass Strait environment, including impacts to seawater and marine sediments.

This in-situ sampling was conducted during the period 28 to 29 June 2018 in the vicinity of the Tuna platform (Latitude 38° 10′ south, Longitude 148° 25′ east).

The sampling involved adding fluorescent (FWT) red dye solution to the PFW stream as a tracer (prior to discharge) for two hours on 28 June and three hours on 29 June.

The dye allowed visual detection of the plume for accurate sampling. Dilution was also determined by towing a fluorometer in transects, a short distance behind the sampling vessel at both near field and far field locations.

This type of monitoring is commonly undertaken to provide dispersion and dilution parameters from discharge points such as sewage outfalls.

Produced Formation Water tracer dye study

Consultation

We are committed to engaging with the communities where we operate and helping our stakeholders to understand our business. Esso has been consulting with stakeholders potentially affected by these projects through a number of different channels.

As these projects develop, additional consultation with stakeholders will be conducted, including key impacts and environmental risks.

This fact sheet provides information to allow stakeholders to make an informed assessment of the possible consequences of the proposed activities to their functions, interests or activities. We will address questions and consider feedback from stakeholders relating to these projects throughout this consultation process.

If you have any specific questions or feedback about any of these projects please contact Esso at consultation@exxonmobil.com or call 03 9261 0260.

About Esso

Esso Australia is a subsidiary of ExxonMobil Australia, the country's largest integrated oil and gas company. Esso's Longford Plants has processed more than four billion barrels of oil and eight trillion cubic feet of gas since production began in 1969.

We place the highest priority on operating flawlessly in all aspects of our business. All of these offshore projects will be managed in accordance with all regulatory requirements, as well as Esso's Operational Integrity Management System to reduce risks to ALARP.

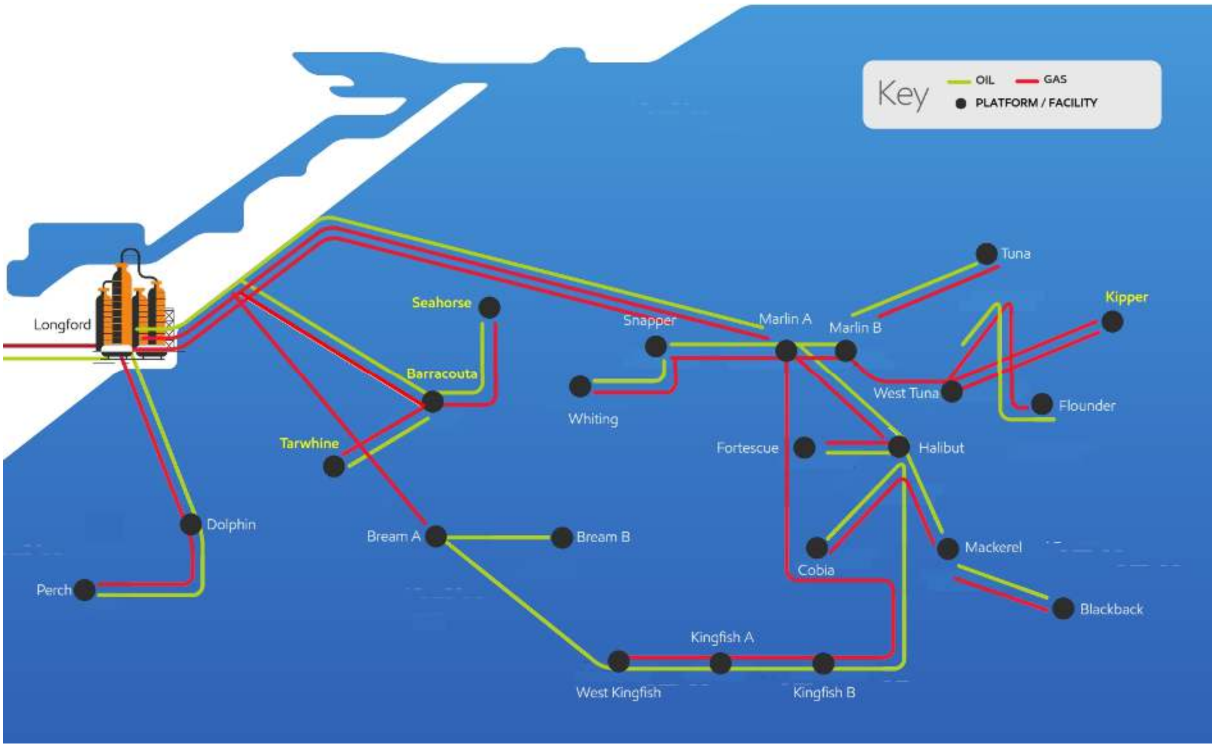
Environment Plans detailing each program of work and how the risks of the program will be managed by Esso will be submitted to NOPSEMA for acceptance.

Esso is continuously striving to improve all aspects of our safety performance including for our people, our processes, security, health, and environmental performance.
For more information about our operations please visit www.exxonmobil.com.au.

ExxonMobil

Esso Bass Strait 2020 Jack Up Rig Campaign – Update 1 (December 2019):

Whiting P&A programme



Esso Australia is planning to undertake a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign as advised in 2Q19. This programme includes:

- Drilling
    - Two subsea gas production wells in the West Barracouta field.
    - Two subsea gas production wells in the Kipper field.
- Well Plug and Abandonment (P&A)
    - Two subsea wells, Seahorse -1 and Tarwhine – 1
    - 5 wells at the Whiting platform (WTA)

There will be no seismic activity as part of this campaign.

Planning is well underway for the drilling activities to begin at Barracouta in January 2020 using the jack-up drilling rig "Tom Prosser", which is known as a jack-up offshore drilling rig (JUR). The Tom Prosser was built in 2014 and operates to the latest international safety and environmental standards. The drilling rig will be supported by up to three support vessels.

Noble Tom Prosser Jack-Up Drilling Rig (Image courtesy of Noble Corporation)

The Tom Prosser does not have any propulsion capability and will be towed into position, then the legs lowered onto the seabed and the rig elevated above the sea surface.

Following the BTW drilling activities the Tom Prosser will move to the Whiting platform to begin the plug and abandonment programme of the five Whiting wells.

This information sheet provides additional information on the Whiting Plug and Abandonment (WTA P&A) programme.

Activity Description

Well Abandonment

The Whiting platform has been shut in since 1997 after the five wells were temporarily suspended. Whiting wells no longer produce a viable quantity of oil and gas, so permanent barriers will be installed to enable the wells to be safely abandoned in accordance with regulatory standards. Well 'abandonment' is a safe and long-standing practice.

Once onsite, the JUR will be jacked-up and cantilevered over the wellheads on the Whiting platform. For all wells, a Blowout Preventer (BOP) will be used to prevent the release of hydrocarbons during the plugging of the wells. Tubing and associated instruments and control valves will be removed, and permanent cement plugs / barriers installed to provide multiple physical barriers to prevent the release of any hydrocarbons that remain in the reservoir.

The well casing and conductors will be cut at a depth of ~ 3 m below the mudline and removed. The remaining infrastructure, such as the Whiting platform jacket and topsides and disconnected pipelines will be removed as part of a separate campaign and will be the subject of further consultation.

Activity Location

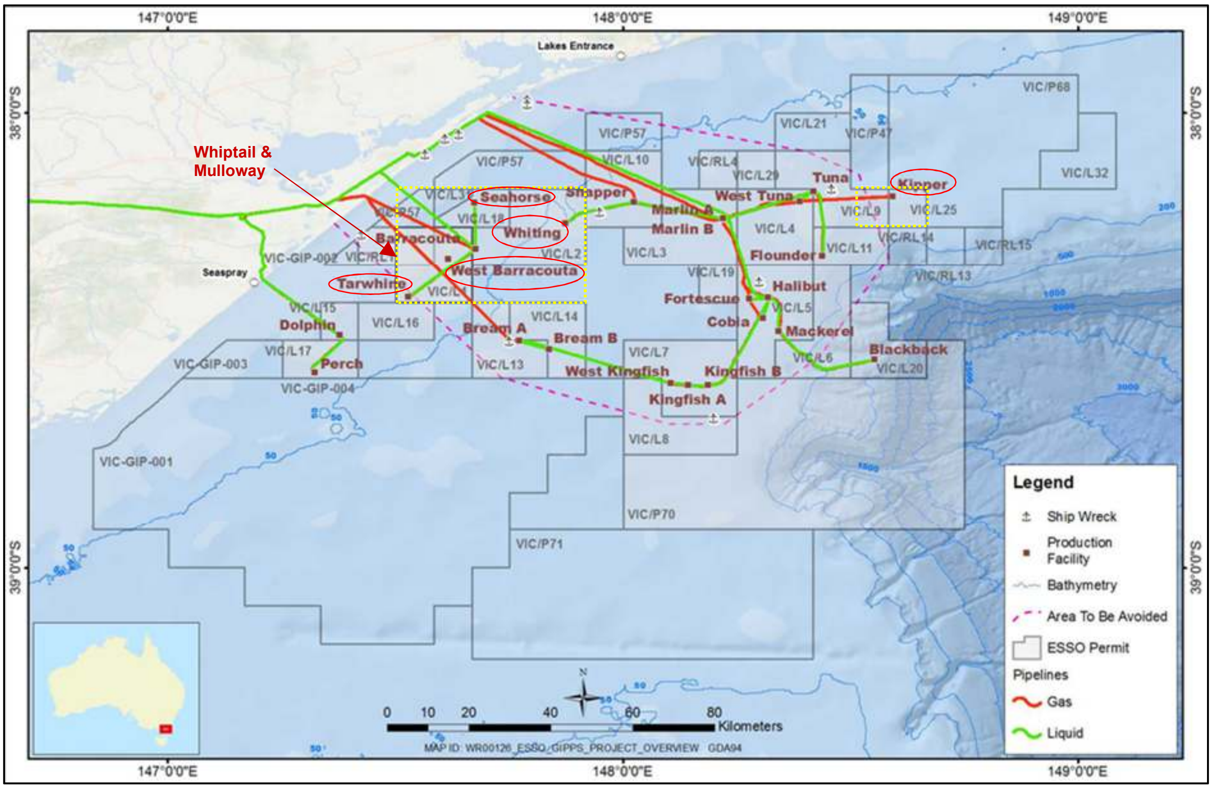
The Whiting platform is located ~ 34km off the Gippsland coastline, south of Lakes Entrance in water depths of ~54m.

All activities will occur in existing Commonwealth offshore petroleum licences.

The Whiting platform is not located within any established or proposed Commonwealth or State Marine Protected Areas, Critical Habitats or Threatened Ecological Communities, and is outside of established shipping fairways. It is recognised that the activities will overlap with existing fisheries.

ExxonMobil

Well Locations	Licence Area	Latitude/Longitude	Activity Type	Water depth (m)
Kipper Subsea Facility (KPA-A1, KPA-A3)	VIC/L25	38°10' 53" S 148° 35' 35" E	Drilling	95
West Barracouta Drill Centres (BTW-W1, BTW-W2)	VIC/L1	38° 19' 06" S 147° 36' 53" E	Drilling	46
Tarwhine (TWA-1)	VIC/L1	38° 24' 12" S 147° 31' 46" E	P&A	42
Seahorse (SHA-1)	VIC/L18	38° 11' 42" S 147° 40' 27" E	P&A	42
Whiting platform (WTA) (5 wells)	VIC/L2	38° 14' 29" S 147° 72' 20" E	P&A	54



Esso Bass Strait 2020 Jack Up Rig Campaign Activity Locations as circled

Activity Timing

The following shows an indicative campaign timetable only.

Activities will be conducted 24 hours per day, seven days per week. It is expected to take ~20 days to plug and abandon each well.

The timing of the activity may vary and is contingent on regulatory approvals, joint venture approvals, and weather and rig/vessel schedules.

January 2020	West Barracouta Drilling Commences
April 2020	Whiting Plug & Abandonment Commences
July 2020	Seahorse / Tarwhine Plug & Abandonment Commences
September 2020	Kipper Drilling Commences
December 2020	Mulloway / Whiptail Plug & Abandonment Commences (to be confirmed)

Indicative Jack Up Rig Campaign Activity Timeline

Impacts and Risks

Provided in the table below are the key potential impacts relating to the Whiting Jack Up Rig Campaign to assist stakeholders in making an informed assessment on possible impacts to their activities, functions or interests in the area.

Potential Impacts	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
Drill Rig and Vessel-based impacts		
Drill rig leg placement	Temporary and localised seabed disturbance	Seabed survey completed to identify obstructions. Rig move procedures in place. Small area affected by leg placement, rapidly filled after removal. Area is sandy bottom with no sensitive seabed features.
Planned discharges to the marine environment - Sewage and food waste - Treated bilge and deck wash	Temporary and localised reduction in water quality Temporary change to predator / prey dynamics	Routine discharges and vessel waste treatment systems will meet MARPOL requirements and are routinely maintained. Food-scraps will be macerated prior to discharge. Discharged bilge water will have less than 15 ppm oil in water content. Any chemicals planned for discharge undergo an environmental assessment to confirm suitability for discharge prior to use.
Sound emissions	Temporary displacement of sound sensitive fauna around active vessels	Support vessels and helicopters will comply with EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans.
Unplanned interaction with marine fauna (vessel strike)	Injury or death of marine fauna	Support vessels will comply with EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans. Any injury/mortality of EPBC-listed fauna will be reported to the Department of the Environment and Energy.
Unplanned introduction of invasive marine species (IMS)	Displacement of native species and habitat domination	Jack Up Rig and all support vessels will have a Ballast Water Management Plan and Certificate. Jack Up Rig and all support vessels will comply with Australian Ballast Water Management requirements. A Biofouling Risk Assessment will be completed to confirm a low risk of IMS introduction. Submersible equipment will be cleaned prior to commencement of activity. Spud cans on JUR legs will be jetted prior to moving location.
Accidental release of materials and waste	Temporary and localised:	Waste handling, storage and disposal will meet MARPOL requirements.

Potential Impacts	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
	- Increase in turbidity - Burial of benthic habitat in immediate seabed area - Potential toxicity impacts	Lifting equipment is certified and routinely maintained. Bulk transfer equipment is certified and routinely maintained. Dropped objects will be recovered where safe and practicable.
Accidental release of fuel (vessel collision)	Tainting of commercial fisheries species (e.g. shellfish). Injury and death of species such as fish, marine reptiles, seabirds, cetaceans. Pathological effects on fish larvae and plankton.	All operational locations are within gazetted exclusion zones. Commencement of activity and exclusion zone will be communicated to other marine users via Notice to Mariners and via AMSA. Vessel will hold Dynamic Positioning (DP) System II Notation and watchkeeper-in-charge will hold DP Certification. Vessels will only travel at slow speeds within 500m of Jack Up Rig. Vessels will comply with their approved Shipboard Oil Pollution Emergency Plan (SOPEP) including maintaining spill kits, emergency response procedures and conducting spill response exercises Esso has a comprehensive Oil Pollution Emergency Plan (OPEP) which will be used in the event of a spill.
Abandonment Activity Impacts		
Discharge of cement	Localised and temporary: - Reduction in water quality - Smothering of benthic habitat	Low toxicity cement additives have been selected for use. Cement hose flushing and slurry releases will be rapidly diluted and dispersed by the dynamic marine environment. Cement powder is also lost to the air as part of the transfer process.
Well fluid discharges	Increased salinity Potential toxicity effects	Low toxicity chemical additives have been selected for use in abandonment and completion fluids. Chemicals used in well fluids undergo environmental assessment to confirm suitability for discharge prior to use. Dynamic seabed and marine environment will rapidly disperse discharged well fluids.
Removal of Conductors	Localised and temporary: - Reduction in water quality - Change to local benthic habitat - Smothering of benthic fauna	Turbidity produced is akin to that that caused by natural currents and will be short term with no lasting impact. Impact is limited to the small, direct area under the platform. Once conductors are removed the benthic environment will be available for recolonisation. No long term on species diversity or abundance.

Potential Impacts	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
Potential Loss of well control	Tainting of commercial fisheries species (e.g. shellfish). Injury and death of species such as fish, marine reptiles, seabirds, cetaceans. Pathological effects on fish larvae and plankton. No pollution of shoreline habitats.	Whiting has one gas well and four condensate wells. A loss of well control event may release condensate, which is generally not persistent in the environment. No surface oil shoreline impact is predicted. An accepted Environment Plan (EP), OPEP and Emergency Response Plan (ERP) will be in place and implemented in the event of a loss of well control. An accepted Safety Case and Well Operations Management Plan will be in place.

Whiting produces a non-persistent light condensate. Spill assessment demonstrates that in the unlikely event of a loss of well control during P&A activities, no shoreline impact is predicted, with ecological impacts from surface oil (10 g/m^2) restricted to an area immediately around the release location (<1km).

Petroleum Safety Zones

The Whiting platform is located within existing 500m Petroleum Safety Zones (PSZ) which in turn is situated within the Gippsland Basin "Area To Be Avoided" (ATBA), as designated by the Australian Maritime Safety Authority (AMSA). The exact location of the drill rig while at location will be communicated to other marine vessels via a Notice to Mariners issued by the Australian Hydrographic Service (AHS) and AUSCOAST warnings issued by AMSA.

Interaction with Commercial Fishing

The Whiting Platform is located within existing designated Commonwealth and State fisheries that may be used by commercial fishers. The 500 m PSZ will be communicated to Lakes Entrance Fisherman's Co-op (LEFCOL), South East Trawl Fishing Industry Association (SETFIA) and Seafood Industry Victoria (SIV) as it is a legal requirement that the area should be avoided during the P&A Activities.

Environment Plans

Under the Offshore Petroleum and Greenhouse Gas Storage Act 2006, before any petroleum related activities in Commonwealth waters can commence, an Environment Plan (EP) must be accepted by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

In the course of preparing an EP, Esso Australia must consult with relevant authorities, persons and organisations whose functions, interests or activities may be affected by the proposed activities (i.e. a relevant person) and provide the opportunity for any issues or concerns to be raised.

Separate Environment Plans (EPs) are being developed for these different activities, however, to improve efficiencies for stakeholders, a single consultation process is being undertaken.

The EP is a comprehensive document that describes the existing environment, including stakeholders, and how Esso Australia will undertake the activities to avoid, minimise or manage potential environmental impacts to the "As Low As Reasonable Practicable" standard (ALARP) and meet Esso Australia's acceptability criteria.

Oil Pollution Emergency Plan (OPEP)

Under Commonwealth environment legislation, Esso Australia must demonstrate and document oil spill response arrangements. The OPEP forms part of an EP submission and demonstrates our capability to respond in the unlikely event of an oil spill.

Esso Australia is a member of the Australian Marine Oil Spill Centre (AMOSC), a co-operative national oil spill response organisation, which provides access to additional oil spill response resources if required.

Esso Australia's OPEP interfaces with national, state and industry response plans prepared and implemented by the Australian Government via AMSA (NATPLAN), the Victorian Government

(Maritime Emergencies (non-search and rescue) Plan), the Tasmanian Government (TASPLAN), the NSW Government (NSW Marine Oil and Chemical Spill Contingency Plan) and the Australian Oil industry's Australian Marine Oil Spill Plan (AMOSPLAN) administered by AMOSC.

The OPEP defines spill response options which may be applied to a spill event. The selected spill response option(s) would depend upon the size and type of spill; environmental sensitivities within the spill path; prevailing weather conditions; access restrictions and available resources. In all instances, a Net Environmental Benefits Assessment (NEBA) is undertaken, in consultation with relevant government agencies, to consider the advantages and disadvantages of the available spill response options.

Consultation

Esso Australia is committed to engaging with the communities where we operate and helping our stakeholders to understand our business.

Esso has been consulting with stakeholders potentially affected by this campaign through a number of different channels.

While some community consultations have occurred, Esso welcomes the opportunity for more face-to-face meetings and will continue to keep interested stakeholders informed of the proposed activities throughout the planning phase and into operational phase.

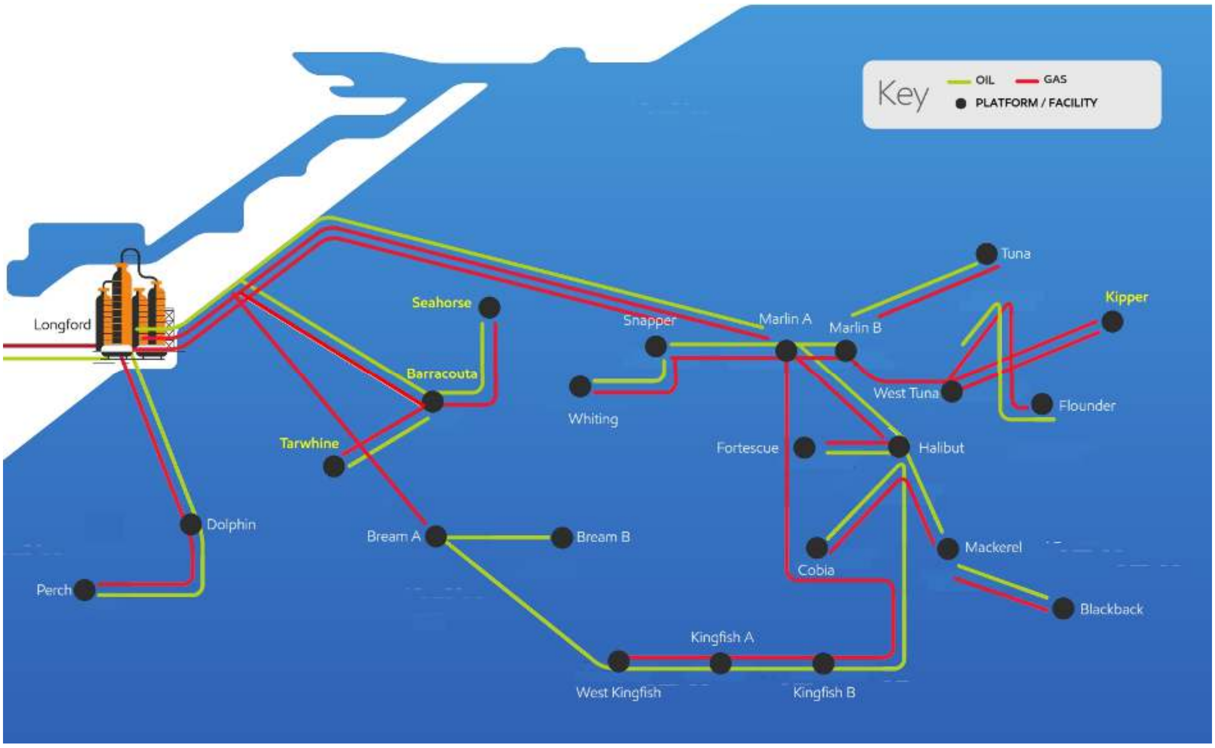
We will address questions and consider feedback from stakeholders throughout this campaign.

If you have any specific questions or feedback about any of these activities please contact Esso at consultation@exxonmobil.com or call 03 9261 0260.

Esso Bass Strait 2020 Jack Up Rig Campaign – Update 2

March 2020

Seahorse / Tarwhine P&A programme



Esso Australia is planning to undertake a number of offshore activities within the Gippsland Basin off the Victorian coastline collectively called the 2020 Jack Up Rig Campaign as advised in 2Q19. This programme includes:

- Drilling
  - Two subsea gas production wells in the West Barracouta field (BTW)
  - Two subsea gas production wells in the Kipper field
- Well Plug and Abandonment (P&A)
  - Subsea wells, Seahorse -1 and Tarwhine – 1 (SHA/TWA)
  - Whiting platform
  - Mulloway / Whiptail
  - Perch / Dolphin

There will be no seismic activity as part of this campaign.

Drilling activities began at Barracouta (BTA) in January 2020 using the jack-up drilling rig "Tom Prosser", which is known as a jack-up offshore drilling rig (JUR). The Tom Prosser was built in 2014 and operates to the latest international safety and environmental standards. The drilling rig will be supported by up to three support vessels.

Noble Tom Prosser Jack-Up Drilling Rig (Image courtesy of Noble Corporation)

The Tom Prosser does not have any propulsion capability and will be towed into position, then the legs lowered onto the seabed and the rig elevated above the sea surface.

Following the BTW drilling activities the Tom Prosser will move to the Whiting platform and then to Seahorse / Tarwhine to begin the plug and abandonment programme of the wells.

This information sheet provides additional information on the Seahorse/Tarwhine Plug and Abandonment (SHA/TWA P&A) programme.

Activity Description

Well Abandonment

The SHA subsea well was plugged with solids in 2014 and the wellbore was circulated to replace its contents with inhibited water.

The TWA chemical and hydraulic cores of the umbilical were also flushed with inhibited seawater prior to severing it at the BTA platform end in 2018.

Once the JUR is positioned over the wellhead, the tree cap will be removed and barrier testing will be completed.

For all wells, a Blowout Preventer (BOP) will be used to prevent the release of hydrocarbons during the plugging of the wells. Tubing and associated instruments and control valves will be removed, and permanent cement plugs / barriers installed to provide multiple physical barriers to prevent the release of any hydrocarbons that remain in the reservoir.

The well casing and conductors will be cut at a depth of ~ 3 m below the mudline and removed and the severed wellhead will be retrieved.

Activity Location

The Seahorse and Tarwhine wells are located 15 and 23 km off the Gippsland coastline respectively, south of Lakes Entrance in a water depth of ~43m.

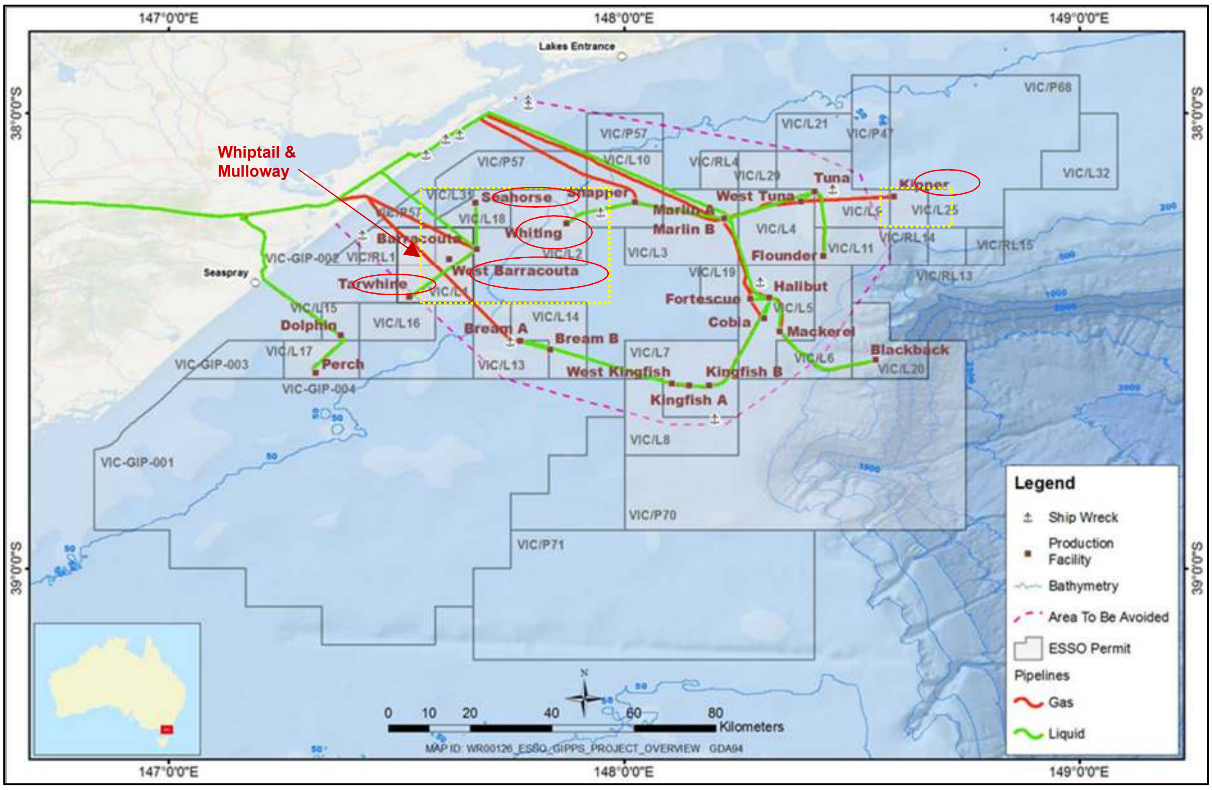
The BTA platform lies in-between the two subsea wells, ~11km from SHA and ~17km from TWA.

SHA activities will occur within the Bass Strait Area To Be Avoided (ATBA) for commercial shipping while TWA lies immediately outside the ATBA. Neither the existing subsea facilities nor the existing routes of the flexible flowline and control umbilical from BTA to SHA/TWA are located within any established or proposed Commonwealth or State Marine Protected Areas, Critical Habitats or Threatened Ecological Communities. It is recognised that the activities will overlap with existing fisheries.

Impacts and Risks

Impacts and risks from the JUR activities have been outlined in the campaign sheet sent out in 2Q19.

Well Locations	Licence Area	Latitude/Longitude	Activity Type	Water depth (m)
Kipper Subsea Facility (KPA-A1, KPA-A3)	VIC/L25	38°10' 53" S 148° 35' 35" E	Drilling	95
West Barracouta Drill Centres (BTW-W1, BTW-W2)	VIC/L1	38° 19' 06" S 147° 36' 53" E	Drilling	46
Tarwhine (TWA-1)	VIC/L1	38° 24' 12" S 147° 31' 46" E	P&A	42
Seahorse (SHA-1)	VIC/L18	38° 11' 42" S 147° 40' 27" E	P&A	42
Whiting platform (WTA) (5 wells)	VIC/L2	38° 14' 29" S 147° 72' 20" E	P&A	54



Esso Bass Strait 2020 Jack Up Rig Campaign Activity Locations as circled

Activity Timing

The following shows an indicative campaign timetable only.

Activities will be conducted 24 hours per day, seven days per week. It is expected to take ~30 days to plug and abandon each well.

The timing of the activity may vary and is contingent on regulatory approvals, joint venture approvals, and weather and rig/vessel schedules.

Indicative Jack Up Rig Campaign Activity Timeline

Petroleum Safety Zones

Seahorse / Tarwhine is located within existing 500m Petroleum Safety Zones (PSZ). The exact location of the drill rig while at location will be communicated to other marine vessels via a Notice to Mariners issued by the Australian Hydrographic Service (AHS) and AUSCOAST warnings issued by AMSA.

Interaction with Commercial Fishing

Seahorse / Tarwhine is located within existing designated Commonwealth and State fisheries that may be used by commercial fishers. The 500m PSZ will be communicated to South East Trawl Fishing Industry Association (SETFIA) as it is a legal requirement that the area should be avoided during the P&A Activities.

Environment Plans

Under the Offshore Petroleum and Greenhouse Gas Storage Act 2006, before any petroleum related activities in Commonwealth waters can commence, an Environment Plan (EP) must be accepted by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

In the course of preparing an EP, Esso Australia must consult with relevant authorities, persons and organisations whose functions, interests or activities may be affected by the proposed activities (i.e. a relevant person) and provide the opportunity for any issues or concerns to be raised.

Separate Environment Plans (EPs) are being developed for these different activities, however, to improve efficiencies for stakeholders, a single consultation process is being undertaken.

The EP is a comprehensive document that describes the existing environment, including stakeholders, and how Esso Australia will undertake the activities to avoid, minimise or manage potential environmental impacts to the "As Low As Reasonable Practicable" standard (ALARP) and meet Esso Australia's acceptability criteria.

Consultation

Esso Australia is committed to engaging with the communities where we operate and helping our stakeholders to understand our business.

Esso has been consulting with stakeholders potentially affected by this campaign through a number of different channels.

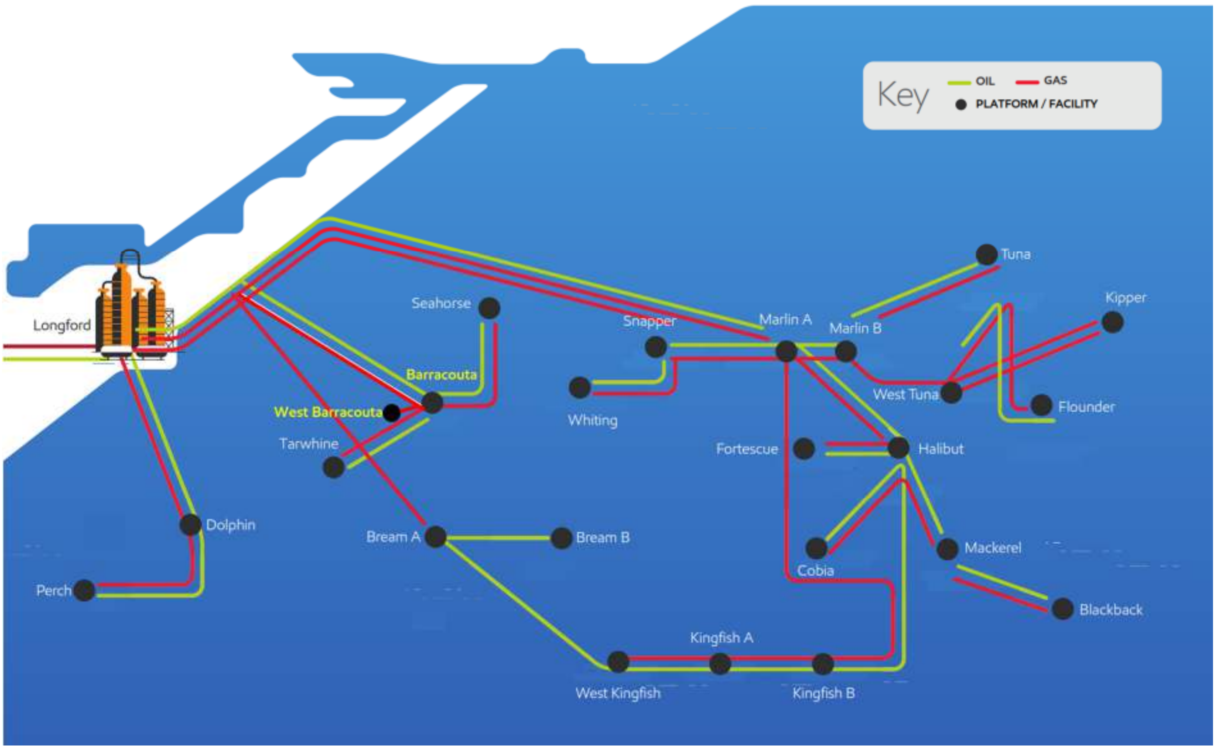
While some community consultations have occurred, Esso welcomes the opportunity for more face-to-face meetings and will continue to keep interested stakeholders informed of the proposed activities throughout the planning phase and into operational phase.

We will address questions and consider feedback from stakeholders throughout this campaign.

If you have any specific questions or feedback about any of these activities please contact Esso at consultation@exxonmobil.com or call 03 9261 0788.

ExxonMobil

West Barracouta Installation Campaign



Summary

In January 2020 Esso Australia Pty Ltd (Esso) commenced drilling of two subsea gas production wells in the West Barracouta field. The drilling activity is the subject of a separate Environment Plan and was subject to previous consultation.

At the completion of drilling, the two wells will be suspended. The subsequent West Barracouta installation campaign will be covered by a new Environment Plan and the work includes:

- Installation of two subsea trees on the West Barracouta wells.
- Laying a ~ 6km 12" flexible pipeline between the wells and the existing BTA450 pipeline to shore.
- Tie-in to the BTA450 pipeline via a Hot Tap.
- Laying and trenching a control umbilical from the wells to the Barracouta platform.
- Installation of associated subsea equipment including the Pipeline End Manifold (PLEM) and pipeline skid, Umbilical Termination Assembly (UTA) and jumpers and flying leads.
- Pre commissioning.

There will be no seismic activity as part of this campaign.

The activities will be undertaken by a Dive Support Vessel (DSV) the "Seven Eagle". The Seven Eagle operates to international safety and environmental standards. Diving operations from the Seven Eagle will be supported by a Hyperbaric Rescue Vessel stationed outside the West Barracouta Petroleum Safety Zone (PSZ).

The activities will be undertaken in multiple stages and it is expected that the DSV will travel between the onshore supply base and the West Barracouta field between each stage.

The operation of the West Barracouta wells and the pipeline are covered by the Esso Bass Strait Environment Plan.

Subsea 7 Seven Eagle Dive Support Vessel (Image courtesy of Subsea 7)

Activity Location

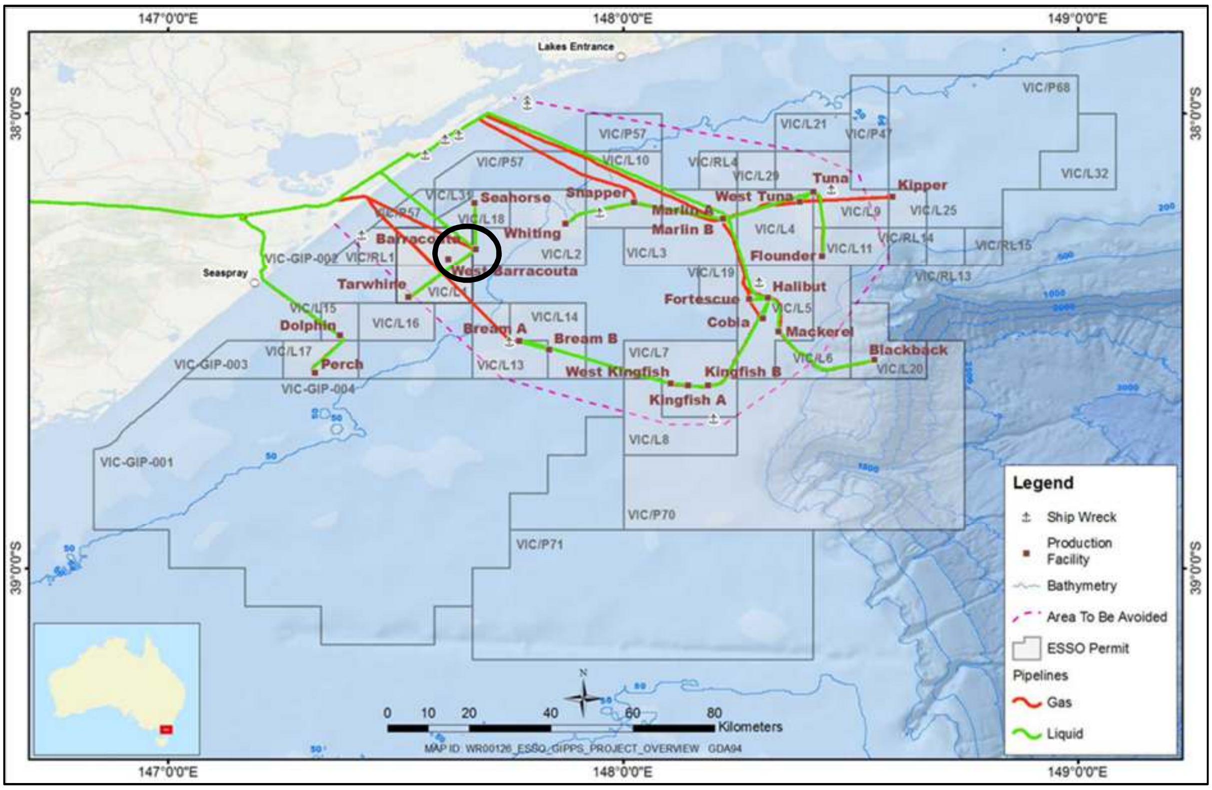
The West Barracouta wells are located ~ 15km off the Gippsland coastline, south of Lakes Entrance in a water depth of ~45m.

The DSV will be operating in the Barracouta platform PSZ when performing the hot tap operations and installing the umbilical to the platform. Activities around the West Barracouta Well Centre are located 6km distant from the platform and within the West Barracouta PSZ.

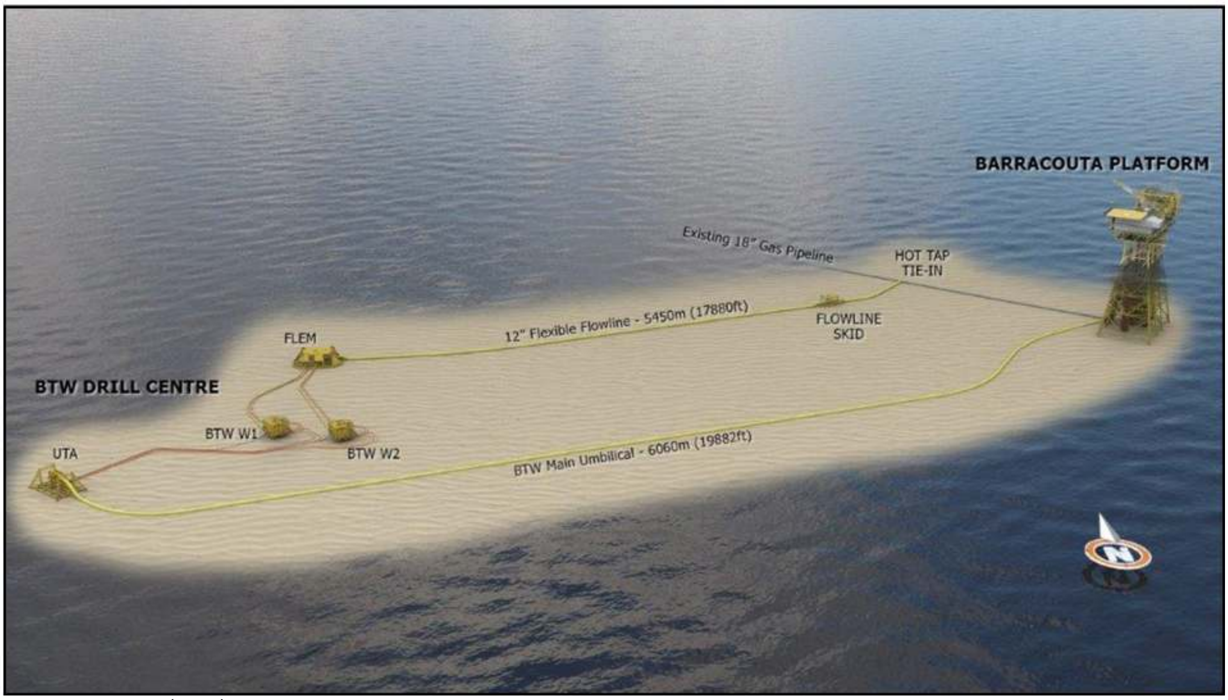
All activities will occur within the Bass Strait Area To Be Avoided for commercial shipping.

Neither the proposed West Barracouta subsea facilities nor the proposed routes of the flexible flowline and control umbilical are located within any established or proposed Commonwealth or State Marine Protected Areas, Critical Habitats or Threatened Ecological Communities. It is recognised that the activities will overlap with existing fisheries.

Locations	Licence Area	Latitude/ Longitude	Activity Type	Water depth (m)
Barracouta Platform	VIC/L2	38° 17.883′ S 147° 40.467′ E	Umbilical tie-in and Hot Tap	~45
West Barracouta Well Centre (BTW-W1, BTW-W2)	VIC/L1	38° 19.100′ S 147° 36.467′ E	Subsea trees, PLEM, UTA installation	~45



West Barracouta Installation Campaign Location



West Barracouta (BTW) Field Development Schematic

Activity Description

Tree installation

The DSV will install the subsea trees (pipework and control valves) that are approximately 5m x 5m x 4m and weigh over 50 tonnes. Once in position the trees and wells will be function tested using a Remotely Operated Vehicle (ROV) to confirm function and integrity.

Pipeline / umbilical installation

The flexible pipeline will be installed by the Seven Eagle, filled with Mono-ethylene Glycol (MEG) and water. The lay will be initiated from the PLEM and then laid along the seafloor towards the BTA450 hot tap tie-in location.

Connections between pipeline sections will be made on the back deck of the Seven Eagle. Stabilising concrete mattresses will be installed over the pipeline adjacent to the tie-in location, mid-line connections and at any crossings to ensure stability.

The Seven Eagle will install the umbilical through a J Tube onto the Barracouta platform. The umbilical will then be laid towards the Barracouta Well Centre near the pipeline. The umbilical will be trenched using either a water-jetting or mechanical trencher vehicle to mitigate the risk of impact and snagging from fishing vessels.

Hot tap tie-in

A hot tap tie-in enables a new connection to be safely made to an existing / operating piping. This means that a pipe, such as the BTA450 which transports gas to Longford Plants for distribution to consumers, can remain in service whilst modifications are being made to it. The hot tap installation will involve divers, a hot tap machine and support from an ROV.

Pre-commissioning

Once all new infrastructure is tied in it will be leak tested using dyed MEG to confirm the integrity of the pipeline and trees.

Activity Timing

The earliest date of commencement of the campaign is October 2020.

Activities will be conducted 24 hours per day, seven days per week. It is expected to take approximately 6 weeks to complete the activities, subject to weather conditions.

Impacts and Risks

Provided in the tables attached, are the key potential impacts / risks relating to the Installation Campaign. These are provided to assist stakeholders in making an informed assessment on possible impacts to their activities, functions or interests in the area.

Environment Plans

Under the Offshore Petroleum and Greenhouse Gas Storage Act 2006, before any petroleum related activities in Commonwealth waters can commence, an Environment Plan must be accepted by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

In the course of preparing an Environment Plan, Esso must consult with relevant authorities, persons and organisations whose functions, interests or activities may be affected by the proposed activities (i.e. a relevant person) and provide the opportunity for any issues or concerns to be raised.

This consultation is specifically for the West Barracouta Installation Environment Plan.

The Environment Plan is a comprehensive document that describes the existing environment, including stakeholders, and how Esso will undertake the activities to avoid, minimise or manage potential environmental impacts to the "As Low As Reasonable Practicable" standard (ALARP) and meet Esso's acceptability criteria.

Oil Pollution Emergency Plan (OPEP)

Under Commonwealth environment legislation, Esso must demonstrate and document oil spill response arrangements. The OPEP forms part of an Environment Plan submission and demonstrates our capability to respond in the unlikely event of an oil spill.

Esso is a member of the Australian Marine Oil Spill Centre (AMOSC), a co-operative national oil spill response organisation, which provides access to additional oil spill response resources if required.

Esso's OPEP interfaces with national, state and industry response plans prepared and implemented by the Australian Government via AMSA (NATPLAN), the Victorian Government (Maritime Emergencies (non-search and rescue) Plan), the Tasmanian Government (TASPLAN), the NSW Government (NSW Marine Oil and Chemical Spill Contingency Plan) and the Australian Oil industry's Australian Marine Oil Spill Plan (AMOSPLAN) administered by AMOSC.

The OPEP defines spill response options which may be applied to a spill event. The selected spill response option(s) would depend upon the size and type of spill; environmental sensitivities within the spill path; prevailing weather conditions; access restrictions and available resources. In all instances, a Net Environmental Benefits Assessment (NEBA) is undertaken, in consultation with relevant government agencies, to consider the advantages and disadvantages of the available spill response options.

Consultation

Esso is committed to engaging with the communities where we operate and helping our stakeholders to understand our business.

Esso has been consulting with stakeholders potentially affected by this campaign through a number of different channels.

While some community consultations have occurred, Esso welcomes the opportunity for more face-to-face meetings and will continue to keep interested stakeholders informed of the proposed activities throughout the planning phase and into operational phase.

We will address questions and consider feedback from stakeholders throughout this campaign.

If you have any specific questions or feedback about any of these activities please contact Esso at consultation@exxonmobil.com or call 03 9261 0260. If you require any of this consultation to be kept confidential or if you would like to be removed from our consultation list please advise us.

Aspect of Activities	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
Physical interaction with other marine users	Disruption to other marine users such as commercial fishing and shipping	Activity occurs within Bass Strait Area To Be Avoided. Existing PSZs shown on navigation charts. Communicate commencement of installation activities to relevant stakeholders via Notice to Mariners and via AMSA JRCC Installation activity outside of PSZs of relatively short duration. Umbilical is trenched. Pipeline tie-in and West Barracouta subsea facilities located within PSZs.
Vessel planned discharges to the marine environment - Sewage and food waste - Treated bilge and deck wash	Temporary and localised reduction in water quality Temporary change to predator / prey dynamics	Routine discharges and vessel waste treatment systems will meet MARPOL requirements. Food-scraps will be macerated prior to discharge. Discharged bilge water will have less than 15 ppm oil in water content. Any chemicals planned for discharge undergo an environmental assessment to confirm suitability for discharge prior to use.
Vessel sound emissions	Localised sound emissions Temporary disturbance / displacement of sound sensitive fauna around active vessels	Vessels will maintain 'caution' and 'no approach' zones consistent with EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans.
Vessel air emissions	Temporary and localised reduction in air quality	Air emissions from marine engines will meet MARPOL requirements. Low sulphur content fuel will be used.
Seabed disturbance	Localised and temporary increase in turbidity near the seabed. Localised disturbance / damage to benthic habitat and communities.	Seabed survey along flowline and umbilical routes completed to identify obstacles including benthic features. Procedures in place for activities with the potential to disturb the seabed such as pipeline / umbilical laydown, excavation for Hot Tap, umbilical trenching, concrete mattress installation. Area affected by trenching expected to be rapidly filled after laying of umbilical. Area affected by installation activities expected to be rapidly recolonised. No vessel anchoring except in an emergency. Area is a mobile sandy bottom with no sensitive seabed features.

Aspect of Activities	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
Planned subsea discharges from preparatory cleaning and function / leak testing	Localised and temporary reduction in water quality	Chemicals planned for discharge undergo environmental assessment to confirm suitability prior to use. Discharge will rapidly disperse in dynamic seabed and marine environment.
Unplanned vessel interaction with marine fauna (vessel strike)	Injury or death of marine fauna	Installation vessel will travel at low speed during installation activities. Vessels will maintain 'caution' and 'no approach' zones consistent with EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans.
Unplanned introduction of invasive marine species (IMS) from vessel ballast water / biofouling	Displacement of native species and habitat domination	Vessels will have a Ballast Water Management Plan and Certificate, and a Ballast Water Record System. Vessel clearance will be obtained to enter Australian territory through DAWR pre-arrival reporting system (MARS). Vessels will comply with Australian Ballast Water Management requirements. A Biofouling Risk Assessment will be completed to confirm a low risk of IMS introduction. Immersible, retrievable equipment will be cleaned prior to commencement of activity.
Accidental release of materials and waste	Temporary and localised reduction in water quality. Injury / death of marine fauna. Localised disturbance / damage to benthic habitat and communities.	Waste handling, storage and disposal will meet MARPOL requirements. Chemicals and oils will be stored with spill protection in place. Overboarding procedures will be developed and implemented including ROV surveillance. Lifting equipment is certified and routinely maintained and inspected. Bulk transfer equipment is certified and routinely maintained and inspected. Vessel cargo securing manual is adhered to. Vessels will comply with approved SOPEP, including maintaining spill kits, emergency response procedures and conducting spill response exercises.

Aspect of Activities	Potential Consequence	Impact/Risk Reduction & Mitigation Measures
Accidental release of fuel (vessel collision)	Reduction in water quality Injury / death of marine fauna Pollution of shorelines such as sandy beaches Disruption to other marine users such as commercial fisheries	Commencement of activity will be communicated to other marine users via Notice to Mariners and via AMSA JRCC. DSV will hold Dynamic Positioning (DP) System II Notation and watchkeeper-in-charge will hold DP Certification. DSV will only travel at slow speeds during installation activities. Activity occurs within Bass Strait Area To Be Avoided. Main installation work will take place within the existing PSZs shown on navigation charts. Installation activity outside of PSZs of relatively short duration. Platform approach procedures will be adhered to. Activity specific vessel operating procedures will be developed and implemented. Vessels will comply with their approved Shipboard Marine Pollution Emergency Plan (SMPEP) including maintaining spill kits, emergency response procedures and conducting oil spill response exercises Esso has a comprehensive and approved Oil Pollution Emergency Plan (OPEP) which will be used in the event of a spill. No offshore bunkering will take place.
Accidental release of gas from pipeline	Temporary and localised change in water and air quality	NOPSEMA accepted Dive Support Vessel Safety Case and Pipeline Safety Case Installation / Hot Tap procedures will be developed and implemented including ROV surveillance. Lifting equipment is certified and routinely maintained and inspected. Pipeline emergency shutdown / isolation facilities

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
12-Jan-21	3715	To Stakeholder	SMS	Providing stakeholder with updated information relating West Barracouta work location and timing	No objections, claims or issues raised	N/A
13-Jan-21	3716	To Stakeholder	Phone	Follow up phone call with stakeholder to check that message from previous day had been received. No answer, voicemail left.	No objections, claims or issues raised	N/A
13-Jan-21	3717	From Stakeholder	Phone	Stakeholder returned call and confirmed that he had received my text message with information relating to West Barracouta and that he would not be in the area. We briefly discussed that the timing was currently planned for 24/25 January but that this could change if government regulations regarding COVID restrictions changed and obviously if sea conditions did not permit. Stakeholder said he was well aware of the likelihood of changes. He also advised that he would send me a list of where his current strings were laid so that the vessels were aware. I agreed to pass this on to our vessels team. We also discussed how close Stakeholder lays his lines to our pipelines - he advised that sometimes he lays over the top of them but usually not closer than 0.2 of a mile. I advised that we had some ROV work planned for February starting 1st for about three weeks. The actual locations and timing yet to be confirmed and that once I had that I would let him know. He said given it was an ROV it was unlikely to impact him as it does go on the seabed. I did advise him though that on this ocassion we were likely be taking samples from the seabed so could impact. Once I have more information I will share it with him. He thanked me for the advice.	No objections, claims or issues raised in relation to the Barracouta work. ACTION: Provide stakeholder with information regarding ROV survey work to test if any impacts	N/A
21-Jan-21	3724	To Stakeholder	SMS	EAPL sent stakeholder SMS advising the following: Seven Eagle (call sign ELUB4) will commence work around the West Barracouta wells on Jan 24. Work involves pipeline installation, associated construction & diving activities in & between the West Barracouta PSZ & the Barracouta Platform PSZ. A box around this work is: SW 38° 19' 52"S 147° 36'42"E NW 38° 18'50"S 147° 36'02"E NE 38° 16' 59"S 147° 40'36"E SE 38° 18'01"S 147° 41'17"E	No objections, claims or issues raised	Stakeholder advised EAPL of locations of surface buoys.
29-Jan-21	3725	To Stakeholder	SMS	7 Eagle vessel advising has arrived in the area and confirming that stakeholder's pot locations are plotted on vessel's maps.	No objections, claims or issues raised	N/A
05-Feb-21	3726	To Stakeholder	SMS	Advice to stakeholder that 7 Eagle vessel is moving off site in next 24 hours but will be back in about a week. Vessel will advise when moving. Requested update from stakeholder on pot locations so that we can pass on to the vessel.	No objections, claims or issues raised	Stakeholder advised he has moved 3 lines but they are in same area so shouldn't be a problem
05-Feb-21	3727	To Stakeholder	SMS	SMS to Stakeholder from Vessel advising vessel was departing West Barrouta well site within next 24 hours to return to Melbourne and would be back approximately 11 Feb.	No objections, claims or issues raised	N/A
10-Feb-21	3728	To Stakeholder	SMS	Advice to stakeholder that Seven Eagle vessel will be heading back to West Barracouta wells next day; requested coordinates of gear locations so that the vessel can load to its navigation system.	No objections, claims or issues raised	Stakeholder provided coordinates of gear location and advised if more information needed to let him know
10-Feb-21	3729	From Stakeholder	SMS	Text message received from stakeholder advising he won't be moving any gear into the area until work completed	No objections, claims or issues raised	Acknowledged text message received
15-Feb-21	3730	From Stakeholder	SMS	Stakeholder seeking update on status of work at West Barracouta	ISSUE: work status query MERIT: provided update to which stakeholder responded no issues	Advised Stakeholder that work is expected to be complete around March 7th with divers expected in the water approximately February 27th Stakeholder responded No worries thanks for that
02-Mar-21	3736	To Stakeholder	SMS	Text message to stakeholder advising the Seven Eagle is currently in Melbourne and expecting to return to the Barracouta site on Thursday. This trip will involve divers for 2-3 weeks and you will see an additional vessel, the Dryden, for dive support.	No objections, claims or issues raised.	Stakeholder acknowledged message
16-Mar-21	3741	To Stakeholder	SMS	Text message to Stakeholder - 'Good afternoon the Seven Eagle has completed its work and is departing the Barracouta and West Barracouta area today'	ISSUE: will there be any other works or is it okay to deploy lines in the area MERIT: All work going forward will be within the PSZ's including another vessel	Stakeholder acknowledged advice and asked if okay to deploy lines. Upon our response, stakeholder advised no issues
16-Mar-21	3742	To Stakeholder	SMS	Text message to stakeholder advising that we will be installing a noise monitoring device outside the PSZs	No issues or concerns	No issues
17-Mar-21	3743	To Stakeholder	Email	Email to stakeholder confirming noise monitoring devices will be installed - provided timing and locations and a brief description of the activity.	No issues, concerns raised	N/A

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
ID: 37		**Organisation:**	**South East Trawl Fishing Industry Association**			
17-Dec-20	3712	To Stakeholder	Email	EAPL confirming West Barracouta installation SMS scheduled for 1/1/21	No objections, claims or issues raised	
02-Jan-21	3713	To Stakeholder	SMS	Dear Eastern Fleet, Esso will work around the West Barracouta wells from the Seven Eagle (call sign ELUB4) between 15 Jan & 20 Feb 2021. Work involves pipeline installation, construction & divin in & between the West Barracouta PSZ & the Barracouta platform PSZ. A box around this work is: SW 38° 19′ 52″S 147° 36′42 NW 38° 18′50″S 147° 36′02 NE 38° 16′ 59″S 147° 40′36 SE 38° 18′01″S 147° 41′17	No objections, claims or issues raised	
05-Jan-21	3714	To Stakeholder	Email	EAPL requested contact to be added to SMS distribution list.	No objections, claims or issues raised	Stakeholder confirmed contact has been added to distribution list.
21-Jan-21	3721	To Stakeholder	Email	EAPL requested SMS be sent to fisheries stakeholders: Seven Eagle (call sign ELUB4) will commence work around the West Barracouta wells on Jan 24. Work involves pipeline installation, associated construction & diving activities in & between the West Barracouta PSZ & the Barracouta Platform PSZ. A box around this work is: SW 38° 19′ 52″S 147° 36′42″E NW 38° 18′50″S 147° 36′02″E NE 38° 16′ 59″S 147° 40′36″E SE 38° 18′01″S 147° 41′17″E	No objections, claims or issues raised	Stakeholder asked what is requested?
22-Jan-21	3722	To Stakeholder	Phone	EAPL rang stakeholder and discussed the West Barracouta SMS and advised of upcoming ROV pipeline work.	No objections, claims or issues raised	N/A
22-Jan-21	3723	From Stakeholder	SMS	Dear Eastern Oil/Gas Fleet, Seven Eagle (call sign ELUB4) will commence work around the West Barracouta wells on Jan 24. Work involves pipeline installation, associated construction & diving activities in & between the West Barracouta PSZ & the Barracouta Platform PSZ. A box around this work is: SW 38° 19′ 52″S 147° 36′42″E NW 38° 18′50″S 147° 36′02″E NE 38° 16′ 59″S 147° 40′36″E SE 38° 18′01″S 147° 41′17″E Please make contact if you are fishing in that area.	No objections, claims or issues raised	N/A
25-Jan-21	3731	To Stakeholder	SMS	EAPL requested stakeholder to send SMS to fisheries: The Seven Eagle (call sign ELUB4) has been delayed & will now commence work around the West Barracouta wells on Jan 28. Work involves pipeline installation, associated construction & diving activities in & between the West Barracouta PSZ & the Barracouta Platform PSZ.	No objections, claims or issues raised	SMS sent to fisheries.
05-Feb-21	3732	To Stakeholder	SMS	EAPL requested stakeholder to send SMS to fisheries: The 7 Eagle will be departing the West Barracouta wells site in the next 24 hours to return to Melbourne. We expect the vessel to be back at the West Barracouta PSZ approx. 11 February. Vessel will advise when returning.	No objections, claims or issues raised	SMS sent to fisheries.
08-Feb-21	3733	From Stakeholder	Email	Stakeholder advising EAPL of increase of cost of SMS service.	No objections, claims or issues raised	Acceptance of increased rate.
10-Feb-21	3734	To Stakeholder	SMS	EAPL requested stakeholder to send SMS to fisheries: EAPL advises that the Seven Eagle is expected back at the West Barracouta well sites from 12 Jan for up to 2 weeks. Work continues involving the pipeline installation in & between the West Barracouta PSZ & the Barracouta Platform PSZ.	No objections, claims or issues raised	SMS sent to fisheries.
26-Feb-21	3735	To Stakeholder	Phone	General catchup with Stakeholder to discuss up and coming activities for EAPL. We discussed: 1. West Barracouta installation works - noting that slightly behind schedule but we expected the Seven Eagle to return to shore early next week, essentially to just pick up the divers and then back out again Thursday /Friday of same week. We will communicate when this is happening and ask Stakeholder to send out an SMS to his distribution list to let everyone know as an added safety precaution. 2. West Barracouta pipeline is located at the 400m mark with in the PSZ - will ask Stakeholder to advise his stakeholders so that they are aware that it is wihtin the PSZ and as a reminder to folks to stay out of it. 3. Noise Monitoring - we will be conducting some noise monitoring activities involving putting some equipment in the water; essentially all will be within the PSZs but some will be outside. Once we know detials (expected next week) we will reach out to him to see if we can identify anyone in particular it may impact and also will ask him to notify stakeholders to ensure awareness 4. Oil Spill Deployment Response exercise - we will be conducting an exercise on 23rd March at Corner Inlet; we do not expect it will immpact anyone, but would like to advise people so that they know it is just an exercise and not to be concerned 5. Discussed potential face to face meeting in Lakes Entrance on neither 15th March or 25th March.	No objections, claims or issues raised	N/A
28-Feb-21	3737	To Stakeholder	Email	Email requesting text advice to fleet be sent "The 7 Eagle will be departing the West Barracouta wells site in the next 24 hours to return to Melbourne. We expect the vessel to be back at the West Barracouta PSZ approx. 4/5 March. Vessel will advise when returning."	No objections or issues raised	Text message to fleet sent

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
02-Mar-21	3738	To Stakeholder	Email	Email requesting text advice to the fleet be sent "EAPL advises that the Seven Eagle is expected back at the West Barracouta wells site on Thursday 04 March. Work continues involving the pipeline installation in and between the West Barracouta PSZ & the Barracouta Platform PSZ. This trip will involve divers for 2-3 weeks and you will see an additional vessel, the Dryden, for dive support."	No objections or issues raised	Text message sent to fleet
16-Mar-21	3744	To Stakeholder	SMS	SMS sent to Eastern Fishing Fleet "Esso would like to advise that the Seven Eagle has completed its work and is currently demobilising from its current location at West Barracouta."	No objections, claims or issues raised	N/A
18-Mar-21	3745	To Stakeholder	Phone	EAPL called stakeholder to discuss the planned noise monitoring at Barracouta and Flounder.	No objections, claims or issues raised	N/A
18-Mar-21	3746	To Stakeholder	Email	EAPL sent stakeholder noise monitoring information including locations and photos	No objections, claims or issues raised	Stakeholder asked EAPL for additional info to send to Eastern Fishing Fleet
18-Mar-21	3747		SMS	EAPL requested stakeholder send SMS to Eastern Fishing Fleet: Esso will be conducting an oil spill field exercise in Corner Inlet on 23 March – it's expected to take 4-5 hours. An inflatable boom will be deployed from the DOF – Skandi Feisten and towed into formation by the MV Investigator. This exercise is only testing equipment deployment and its operations and there is no plan to spill oil into the water.	No objections, claims or issues raised	N/A
22-Mar-21	3748	To Stakeholder	SMS	EAPL requested stakeholder send out SMS to Eastern Fishing Fleet: Dear Eastern Fishers, Esso plan to place 4 noise monitors to measure noise levels from platform and vessel operations on the seafloor around Barracoutta platform at the following locations (link to table Facebook, also show image). One device is located outside the PSZ (38° 19.57643' S 147° 42.66622' E) and is not fisher-overable. The monitors will be deployed approx 26 Mar to 9 April (subject to change) and updates will follow.	No objections, claims or issues raised	N/A

ID: 38 Organisation: South Gippsland Shire Council

Date	ID	To / From	Method	Consultation	Assessment of Merit	Response
18-Mar-21	3749	To Stakeholder	Email	EAPL sent email to stakeholder advising of an oil spill field exercise in Corner Inlet on 23 March 2021.	No objections, claims or issues raised	N/A
19-Mar-21	3750	From Stakeholder	Phone	Stakeholder left a voice message for EAPL requesting a call back to discuss the OSR exercise.	No objections, claims or issues raised	EAPL returned stakeholders call and after a discussion about the exercise, there was no further questions or follow up.
