1 Preface

1.1 Purpose of this document

This preface document provides an overview of the Bass Strait Environment Plan (EP) and incorporates the summary table required by regulation 11(4). It is designed to assist the reader to navigate the four volumes which make up the Bass Strait EP.

1.2 Overview of the Environment Plan Structure

1.2.1 Structure of the Environment Plan

Esso Australia Resources Pty Ltd (Esso), a wholly owned subsidiary of ExxonMobil Australia Pty Ltd, is the operator for the Gippsland Basin Joint Venture (Esso and BHP Billiton Petroleum (Bass Strait) Pty Ltd (BHP)) and the Kipper Unit Joint Venture (Esso, BHP, and MEPAU A Pty Ltd). In connection with these joint ventures, Esso operates 23 offshore platforms and installations in the Bass Strait and 600 km of subsea pipelines. Esso receives services, including personnel, from Esso Australia Pty Ltd (EAPL), which is also a wholly owned subsidiary of ExxonMobil Australia Pty Ltd.

Esso also undertakes project work across its offshore assets and permit areas, including those owned jointly by the Gippsland Basin Joint Venture participants and the Kipper Unit Joint Venture participants. Exploration and development drilling or other project activities are also planned or may be undertaken in the future.

All offshore activities as defined by the Offshore Petroleum and Greenhouse Gas Storage Act, 2006 (OPGGS Act) and the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations, 2009 (OPGGS(E)R), require an accepted Environment Plan to enable them to proceed. All of these activities take place in the Bass Strait and are operated by Esso using the same management systems and processes. Therefore there is direct replication of processes, information and systems across facilities and within facility specific Environment Plans. In an effort to minimse replication and streamline the administrative process, Esso has standardised the sections of the Environment Plans that are identical between activities. The Environment Plan is now presented in four separate volumes which should be read as one volume however can be maintained individually as nessecary.

Esso Bass Strait Offshore Environment Plan Structure

VOLUME 1 - DESCRIPTION OF THE ENVIRONMENT

APPLIES TO All Esso ACTIVITIES

Describes the total combined geographic area which may be affected by all and any of the activities undertaken by Esso

Section 1	Introduction
Section 2	Description of the Environment (Reg 13(2) and Reg 13(3))
Section 3	Legislative and other requirements (Reg 13(4))
Appendix A	Environmental Policy (Reg 16(a))
Appendix B	References
Appendix C	EPBC Act Search Reports
Appendix D	Current Roses

VOLUME 2 - DESCRIPTION OF THE ACTIVITY, IMPACTS AND RISKS

ACTIVITY SPECIFIC

- Provides activity specific scope
- Describes activity specific impacts and risks and measures taken to manage the impacts and risks

Section 1	Details of Titleholder (Reg 15)
Section 2	Description of Activity (Reg 13(1))
Section 3	Future Planning (OPGGSA Section 572)
Section 4	Impact and Risk Assessment Methodology
Section 5	Activity Specific Description of Environment (Reg 13(2) and Reg 13(3))
Section 6	Impact Assessment (Reg 13(5), Reg 6(a) & Reg 6(b))
Section 7	Risk Assessment (Reg 13(5), Reg 6(a) & Reg 6(b))
Appendix A	Bass Strait Operations Inventory
Appendix B	Inventory Maintenance and Planning End State
Appendix C	EPBC Act Listed Species PEA
Appendix D	EPBC Act Listed Species by OA and EPBC Reports
Appendix E	Bass Strait Facilities Survey Data
Appendix F	PFW Data File
Appendix G	PFW Breakout Boxes

VOLUME 3 - EMERGENCY PREPAREDNESS AND RESPONSE

APPLIES TO ALL ESSO ACTIVITIES

Describes Esso's Emergency Preparedness and Response activities and arrangements as they apply to all activities

Section 1-9	Description of Emergency Response Activities (Reg 13(1)) Potential Impact Assessment of Response Activities (Reg 13(5b), Reg 13(6)) Arrangements for responding to and monitoring oil pollution (Reg 14(8AA)) Arrangements and capability for monitoring oil pollution and inform response activities (Reg 14(8AAd), Reg 14(8D))
Appendix A	Oil Pollution Emergency Plan
Appendix B	Oil Spill Monitoring Plan

VOLUME 4-IMPLEMENTATION STRATEGY

ACTIVITY SPECIFIC

Describes activity specific implementation plan including performance monitoring, consultation and reporting

Section 1	Environmental Performance - Operations and Emergency Response Preparedness (Reg 13(7))
Section 2	Operations Integrity Management System (Reg 14(1), Reg 14(8A, 88 & 8C), Reg 10A(e) Reg 14(3))
Section 3	Platform Surveillance and Optimisation (Reg 14(3))
Section 4	Roles and Responsibilities (Reg 14(5))
Section 5	Training (Reg 14(5))
Section 6	Monitoring of performance outcomes and standards (Reg 14(3))
Section 7	Monitoring of emissions and discharges
Section 8	Reporting (Reg 14(2), Reg 26C)
Section 9	Emergency Response (Reg 14(4))
Section 10	Stakeholder Consultation and Community Engagement (Reg 11, Reg 16(b)) Environmental legislative compliance
Appendix A	Relevant Stakeholders
Appendix B	Stakeholder Consultation Reports

Figure 1-1 Environment Plan Structure for Esso activity submissions under OPGGS(E)R

1.2.2 Standardised information across all activities

The standardised sections of the Environment Plans that are identical between activities are described below:

Volume 1 - Description of the Environment

Volume 1 describes the environment within a geographic area (henceforth called the Described Area (DA)) which encompasses the combined breadth of all credibly conceivable worst case discharge scenarios (WCDS) that could arise from any activity undertaken by Esso.

Each project will have a different WCDS. Project specific stochastic oil spill modelling will be used to determine the geographic area potentially impacted by that particular project.

Volume 1 uses the combined geographic area from all the conceivable individual activities and is then used to determine the total DA.

Note that by definition, no single credible spill scenario could potentially impact the whole of the DA. Information contained in Volume 1 includes:

- Description of the Environment (Reg 13(2) and Reg 13(3))
- Legislative and other requirements (Reg 13(4))
- Describes the total combined geographic area which may be affected by all and any of the activities undertaken by Esso
- Esso's Corporate environmental policy (Reg 16(a))

Volume 3 - Emergency Preparedness and Response

Esso prepares for and manages emergency situations, including oil spills, under its safety management system, OIMS System 10-2 (refer Implementation Strategy). The purpose of OIMS System 10-2 is to ensure that Esso establishes effective response to emergencies and business disruptions that threaten the safety, security and health of the public, contractors and employees, the environment, asset integrity, and critical business operations. The system and its processes address all sites for which Esso has responsibility and are designed to respond to all emergency situations, regardless of the specific activity and is therefore applied consistently across all activities.

Information contained in Volume 3 includes:

- Description of the activities that may be undertaken in response to an oil spill, should one occur (Reg 13(1));
- Impact and Risk Assessment of the oil spill response activities (Reg 13(5) & Reg 13(6));
- A description of Esso's capability to respond to an oil spill, including arrangements with other organisations that can provide additional resources (Reg 14(8AA);
- An assessment of the adequacy of Esso's capability to respond in a timely manner to any oil spill arising from any and all of Esso's offshore petroleum activities (Reg 14(8AA).

The Oil Pollution Emergency Plan (OPEP) is included in Appendix A of Volume 3 and includes:

- Description of the specific arrangements in place for responding to and monitoring oil pollution arising from any of Esso's offshore petroleum activities (Reg 14(8AA).
- The Oil Spill Monitoring Plan (OSMP) is included in Appendix B of Volume 3 and includes:
- Description of the specific arrangements for monitoring oil pollution which also informs response activities (Reg 14(8AAd) & Reg 14(8D).

1.2.3 Activity specific information

The information which will vary between activities is the specific scope of work that will be undertaken, defined by the OPGGS(E)R as the description of the Activity (R13(1)), and its associated impacts and potential risks (R13(5), R13(6) and R13(7)). For each work scope, all activity specific information relating to these regulations will be provided in Volume 2, Description of the Activity, Impacts and Risks.

Volume 2 - Description of the Activity, Impacts and Risks

Information contained in Volume 2 includes:

- Details of Titleholder (Reg 15)
- Description of Activity (Reg 13(1))
- Description of the activity specific environment that may be affected (R13(2)a)
- Impact and Risk Assessment (Reg 13(5), Reg 6(a) & Reg 6(b))

Volume 4 - Implementation Strategy

Esso operates in accordance with the proprietary ExxonMobil Operations Integrity Management System (OIMS). OIMS consists of 11 Elements, each of which has globally defined corporate expectations. These are implemented through formally documented Management Systems. This provides for all the standard recognised requirements of safety management systems, beginning with Management Leadership, Commitment and Accountability (Element 1) and incorporating a continuous cycle of assessment and improvement (Element 11). Regardless of the specific activity, Esso will consistently use OIMS to implement all activities. However the activity specific organisation structure and roles and responsibilities of personnel in relation to the implementation, management and review of the environment plan defined by the OPGGS(E)R as the Implementation Strategy for the environment plan (R14), will vary for each project. This information will be provided in Volume 4, Implementaton Strategy.

Information contained in Volume 4 includes:

- Environmental Performance (Reg 13(7))
- Monitoring of performance outcomes and standards (Reg 14(3))
- Implementation Plan (Reg 14(1), Reg 10A(e) and Reg 14(8A, 8B & 8C)
- Environmental Management System (Reg 14(3))
- Roles and Responsibilities & Training (Reg 14(5))
- Incident reporting and recording requirements (Reg 26, 26A, 26AA & 26B) and Reporting (Reg 14(2) & 26C)
- Consultation (Reg 11 & Reg 16b)

1.3 EP Summary Requirement

This Bass Strait EP summary has been prepared from material provided in the EP. The summary consists of the following as required by regulation 11(4):

EP Summary material requirement	Relevant section of EP containing EP Summary material
The location of the activity	Volume 2 Section 2
A description of the receiving environment	Volume 1 Volume 2 Section 5
A description of the activity	Volume 2 Section 2 Volume 2 Section 3
Details of the environmental impacts and risks	Volume 2 Section 6 Volume 2 Section 7
The control measures for the activity	Volume 2 Section 6 Volume 2 Section 7 Volume 4 Section 1
The arrangements for ongoing monitoring of the titleholders environmental performance	Volume 4
Response arrangements in the oil pollution emergency plan	Volume 3, including appendices
Consultation already undertaken and plans for ongoing consultation	Volume 4 Section 10 Volume 4 Appendix B
Details of the titleholders nominated liaison person for the activity	Volume 2 Section 1

1.4 Summary of the Table of Contents of each Volume of the EP

This Bass Strait EP is comprised of four volumes. The table of contents of each volume is summarised here for convenience.

Table of Contents Volume 1 – Description of the Environment

Table of Contents Volume 2 – Impacts and Risks

Table of Contents Volume 3 – Emergency Response Impacts and Risks

Table of Contents Volume 4 – Environmental Performance and Implementation Strategy

1 Introduction

1.1 Overview

This Description of the Environment has been prepared in accordance with the requirements of the Commonwealth Offshore Petroleum and Greenhouse Gas Storage Act 2006 and the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations, 2009 (OPGGS(E)R) per the amended Act and Regulations as at 01 January 2015. The Environment Plan development has been guided by N04750-GN1344 Environment Plan Content Requirements (NOPSEMA 2016).

1.2 Regulatory Context

The OPGGS(E)R have prescribed requirements for the description of the environment. Table 1-1 lists the requirements of the regulations and identifies the sections in this description of the environment where the requirements are addressed.

Table 1-1 OPGGS(E)R requirements for the description of the activity with references to where these items are addressed

Regulation	Requirement	Relevant section where this is addressed
13(2)	The Environment plan must:	
13(2)(a)	Describe the existing environment that may be affected by the activity	1.4 Definition of Described Area 2 Description of the Environment
13(2)(b)	Include details of the particular relevant values and sensitivities (if any) of that environment’	2.2 Values and Sensitivities
13(3)	Particular relevant values and sensitivities may include	
13(3)(a)	the world heritage values of a declared World Heritage property within the meaning of the EPBC Act	2.2.1 World Heritage
13(2)(b)	the national heritage values of a National Heritage place within the meaning of that Act	2.2.2 National Heritage
13(2)(c)	the ecological character of a declared Ramsar wetland within the meaning of that Act	2.2.3 Wetlands of International Importance
13(2)(d)	the presence of a listed threatened species or listed threatened ecological community within the meaning of that Act	2.3.1 Fauna 2.2.4 Threatened Ecological Communities
13(2)(e)	the presence of a listed migratory species within the meaning of that Act	2.3.1 Fauna
13(2)(f)	any values and sensitivities that exist in, or in relation to, part or all of:	
13(2)(f)(i)	a Commonwealth marine area within the meaning of that Act; or	2.2.5 Commonwealth Marine Areas 2.2.6 Australian Marine Parks
13(2)(f)(ii)	(ii) Commonwealth land within the meaning of that Act	2.2.8 National Parks and Reserves

The OPGGS(E)R define 'environment' as 'the ecosystems and their constituent parts, natural and physical resources, qualities and characteristics of areas, the heritage value of places and includes the social, economic and cultural features of those matters'. In accordance with Regulation 13(2) of the OPGGS(E)R, this document describes the physical setting, ecological receptors, and social receptors, of the receiving environment.

A greater level of detail is provided for those particular receptors as defined by Regulation 13(3) of the OPGGS(E)R which states that particular relevant values and sensitivities may include any of the following:

(a) the world heritage values of a declared World Heritage property within the meaning of the EPBC Act;

(b) the national heritage values of a National Heritage place within the meaning of that Act;

(c) the ecological character of a declared Ramsar wetland within the meaning of that Act;

(d) the presence of a listed threatened species or listed threatened ecological community within the meaning of that Act;

(e) the presence of a listed migratory species within the meaning of that Act;

(f) any values and sensitivities that exist in, or in relation to, part or all of:

(g) a Commonwealth marine area within the meaning of that Act; or

(h) Commonwealth land within the meaning of that Act.

1.3 Environmental Policy

It is Esso's policy to conduct its business in a manner that is compatible with the balanced environmental and economic needs of the communities in which it operates. Esso is committed to continuous efforts to improve environmental performance throughout its operations.

Accordingly, Esso's policy is to:

- Comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist;
- Encourage concern and respect for the environment, emphasize every employee's responsibility in environmental performance, and ensure appropriate operating practices and training;
- Work with government and industry groups to foster timely development of effective environmental laws and regulations based on sound science and considering risks, costs and benefits, including effects on energy and product supply;
- Manage its business with the goal of preventing incidents and of controlling emissions and wastes to below harmful levels and design, operate, and maintain facilities to this end;
- Respond quickly and effectively to incidents resulting from its operations, cooperating with industry organizations and authorized government agencies;
- Conduct and support research to improve understanding of the impact of its business on the environment, to improve methods of environmental protection, and to enhance its capability to make operations and products compatible with the environment;
- Communicate with the public on environmental matters and share its experience with others to facilitate improvements in industry performance; and
- Undertake appropriate reviews and evaluations of its operations to measure progress and to ensure compliance with this environmental policy.

A copy of Esso's Environmental Policy is provided in Appendix A.

1.4 Definition of Described Area

In accordance with Regulation 13(2)a of the OPGGS(E)R and NOPSEMA A652993 (NOPSEMA, 2019), the Potentially Exposed Area (PEA) is defined as the outer edge of all simulations in stochastic modelling, using the worst case discharge scenario (WCDS) and the lowest relevant threshold for the furthest reaching fate of hydrocarbons. While modelling carries some inherent uncertainty, the Potentially Exposed Area (PEA) as defined:

- Represents the area that could be affected by any oil spill; and
- Is conservative, as the lowest threshold relevant to any receptor is used.

Each specific activity will define its own PEA in Volume 2 of the Environment Plan. The Described Area (DA) is the *combined* breadth of *all* credibly conceivable PEAs for specific operational activities and project activities to be undertaken by Esso. By definition:

- the limits of each specific PEA is expected to fall within the DA and therefore, all information required to describe the environment will be contained in this Volume 1; and
- no single activity is expected to potentially impact the entire DA.

In the event that the PEA for a future activity is found to reach beyond the edge of the DA, the DA will be expanded and the Description of Environment (this Volume 1) will be revised.

Using the criteria described above, the DA is shown in Figure 1-1. The DA encompasses the Southeast Marine Bioregion, the Temperate East Marine Bioregion and the Coral Sea Marine Bioregion. The IMCRA provincial bioregions encompassed by the DA are also shown in Figure 1-1.

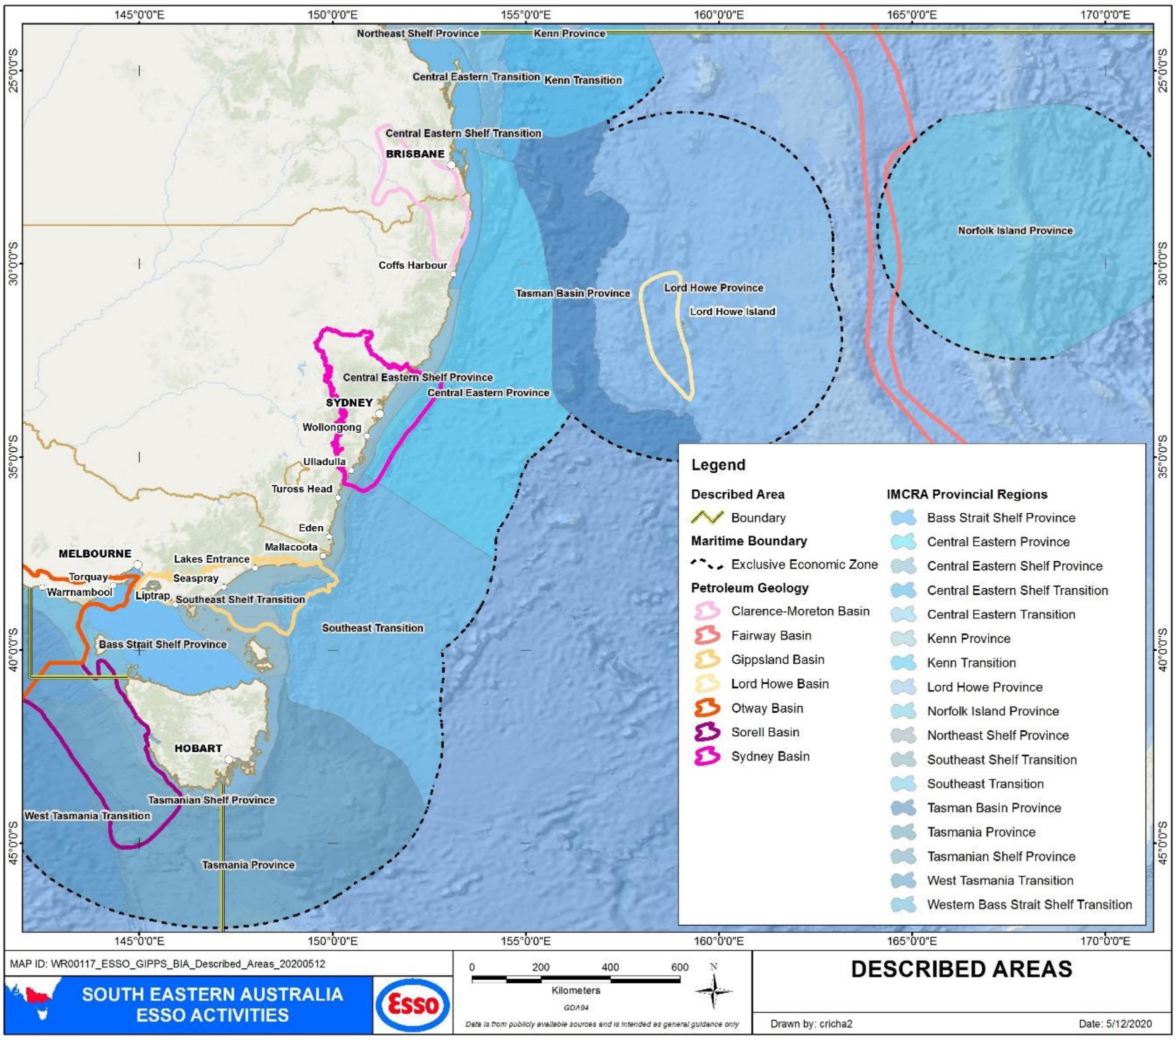

Figure 1-1 Described Area (DA)

1.5 Esso Bass Strait Permit Area

Esso's operations and project activities are undertaken within its permit areas in the Gippsland Basin in Bass Strait. Figure 1-2 shows the Esso Gippsland Basin Permit Areas (EGBPA) and Table 1-2 lists the location of the existing facilities and pipelines.

1 TWA subsea facility is located approximately 17 km to the south west of the BTA platform
2 The KFA platform is located approximately 3.5 km from the WKF platform and 4 km from the KFB platform.
3 The BMB platform is located approximately 7 km east of BMA
4 The SHA subsea facility is located approximately 11 km to the north of the BTA platform
5 KPA subsea facility is located approximately 18 km to the east of the WTN platform
6 The PCA and DPA platforms are 9 km apart, and approximately 40 km and 33 km west of BMA respectively
7 The BTW subsea facility is located approximately 6 km to the west of BTA platform

2 Description of the Environment

2.1 Physical Environment

Esso's operations are located in Bass Strait, the region of the continental shelf that separates mainland Australia from Tasmania. The physical environment of the Described Area (DA) is described in this section.

2.1.1 Climate and Meteorology

Average summer air temperatures in coastal Victoria (Yarram Airport) range from early morning lows of 11 to 13°C, to afternoon highs of 23 to 26°C (BOM, 2017). Average winter temperatures range from minimums of 5°C to maximums of 15°C in the afternoons. Offshore (on Deal Island in central Bass Strait), milder conditions occur with an average summer range of 13 to 21°C and an average winter range of 9 to 14°C (BOM, 2017).

Average monthly rainfall along the Gippsland coast (Yarram Airport) ranges from 36 mm in January (highest 112 mm) to 60 mm in June (highest 174 mm). Offshore (on Deal Island in central Bass Strait) monthly rainfall ranges from 41 mm in January (highest 162 mm) to 78 mm in June (highest 247 mm) and shows a similar pattern to the coastal region (Lakes Entrance) with slightly higher winter rainfall: 38 mm in January (highest 90 mm) to 101 mm in June (highest 298 mm) (BOM, 2017).

Wind speeds are in the range of 10 to 30 km per hour, with maximum gusts reaching 100 km per hour. The wind direction is predominately westerly during winter, westerly and easterly during spring and autumn (when wind speeds are highest) and easterly during summer. Strong south-easterly winds can be generated by low pressure systems known as 'east coast lows'. Although these occur relatively infrequently (once or twice per year), the longer fetch of these winds increases their potential for generating extreme wave conditions (BOM, 2017).

There are three main and one minor types of storm which can generate severe wave conditions in the study area of Bass Strait. These are (Esso, 1989 and Cardno, 2017):

South-east storms: are generally associated with what has become known as an "east-coast low". East-coast lows are generally associated with very strong east to south-east winds (speeds in excess of 80 knots have been measured off the New South Wales coastline) and high rainfall. South-east storms resulting from east-coast lows occur relatively infrequently (on average 1 to 2 per year), and not all travel far enough south to cause concern in Bass Strait. The waves they generate are however, unrestricted by fetch or water depth. As such they have the greatest potential for generating extreme wave conditions in eastern Bass Strait.

South-west storms: occur relatively frequently (typically several severe storms per year). Due to fetch and depth limitation, it is unlikely that extreme design-wave conditions will occur during a south-west storm.

South storms: are generally associated with low-pressure systems in the western part of the Tasman Sea. During the peak of the storm the Tasman Sea lows generate very strong south south-east through to south south-west winds in Bass Strait. During storm development however, the wind can have a significant south-east or south-west component, depending on the origin of the low. Southerly storms occur at about the same frequency as south-east storms. Southerly storms are considered to have a greater potential than the south-west storms for generating extreme wave conditions.

Small-scale Bass Strait Lows: can generate south east, south or south west waves, depending on their origin and location. These storms can be quite severe (e.g., the January 1986 storm), but due to fetch limitations are unlikely to be the cause of extreme design-wave conditions.

2.1.2 Oceanography

2.1.2.1 Currents and Tides

Currents in the Gippsland Basin are tide and wind driven. Tidal movements predominantly have a northeast–southwest orientation. Tidal flows come from the east and west during a rising (flood) tide, and flow out to the east and west during a falling (ebb) tide. Tidal streams are dominated by the lunar tidal constituent, which has a period of 12.4 hours. The main tidal components vary in phase by about three to four hours from east to west. Most of this phase change occurs between Lakes Entrance and Wilsons Promontory. Timing of the high tide, for example, can vary by up to three hours across this region. Tides in the area from Lakes Entrance to Gabo Island are, however, relatively weak in comparison to other areas of Bass Strait (GEMS, 2005).

Bass Strait is characterised by shallow water and tidal currents. While there is a slow easterly flow of waters in Bass Strait, there is also a large anticlockwise circulation. The shallowness of the water means that these waters more rapidly warm in summer and cool in winter than other waters of the Region.

Wind driven currents in Gippsland Basin can be caused by the direct influence of weather systems passing over Bass Strait (wind and pressure driven currents) and the indirect effects of weather systems passing over the Great Australian Bight (GEMS, 2005). Appendix D provides the current roses from six platforms in Bass Strait (SNA, TNA, FTA, HLA, CBA and MKA) (RPS, 2016). They show the monthly average ocean current rose plot derived from five-year current dataset at each location.

The colour keys shows the current speeds (m/s), the compass direction provides the current direction flowing *towards* and the length of the wedge gives the percentage of the record for a particular speed and direction combination.

The eastern parts of the Region are strongly influenced by the East Australian Current (EAC) that flows southward adjacent to the east coast of New South Wales, Victoria and Tasmania, carrying warm equatorial waters (Refer Figure 2-1 and Figure 2-2). The EAC is up to 500 m deep and 100 km wide, and is strongest in summer when it can flow at up to 5 knots. In winter it flows at 2–3 knots as the oceanographic and climatic drivers in the Coral Sea diminish. The EAC tends to form ocean eddies that rotate around warm, central cores that can be up to 200 km across, and may persist for months. Eddies form more frequently off the south coast of New South Wales than other areas, but are also common along the east coast of Tasmania. The eddies can cross the continental shelf, and when mixing with shelf break waters, create upwellings that form isolated areas of enhanced productivity 200–300 km in diameter. Seasonal and transient upwellings are important ecological features of the Region. The closest to the Bass Strait operations is the Upwelling East of Eden, a key ecological feature for the high productivity and aggregations of marine life (refer Section 4.6.2 for further details). The EAC also affects sea surface temperatures on the eastern Tasmanian shelf, which can vary substantially among years depending on the relative influence of subtropical waters.

At the shelf break east of Bass Strait, nutrient-rich waters rise to the surface in winter as part of the processes of the Bass Strait Water Cascade, where the eastward flushing of the shallow waters that are more saline and slightly warmer than surrounding Tasman Sea waters form an undercurrent that cascades down the continental slope (refer Section 4.6.4 for further details). The cascading water has a displacing effect causing nutrient rich waters to rise which in turn leads to increased primary productivity in those areas. The cascading water also concentrates nutrients and some fish and whales are known to aggregate along its leading edge.

Further offshore, in the south east part of the operational area, currents are driven by two parameters, the Sub-Antarctic Water movement, coming from the south, and the Bass Strait Water movement from the west (Tomczak, 1985; Rochford, 1975; in Gibbs et al, 1991). The presence of deepwater currents is documented in the Blackback Oceanographic Study (Lawson & Treloar 1996), Kingfish B Wave, Current and Wind data (Lawson & Treloar 1987 1990) and Metocean Design Criteria for Bass Strait Fixed Platforms (Esso 1990).

Esso undertook a comprehensive current measurement program in the Blackback study area using seven current meters moored three metres above the seabed over a 12 month period (Lawson & Treloar 1996) to provide an understanding of the regional oceanography of the Bass Strait shelf and continental slope, particularly the relative importance of tidal, wind-driven and density-generated currents and the influence of regional topography on currents in the study area.

Tidal current analysis indicated general seabed current alignment normal to the bathymetry, at speeds of around 0.2 to 0.3 m/s. The dominance of the bathymetry was most evident at the current meter sites located within a clearly defined valley.

Analysis of residual, non-tidal current vectors during significant storm periods has confirmed that wind driven currents are the strongest currents in the continental shelf areas but are of progressively lesser significance lower down the continental slope. The study has also provided evidence of flow of water from the continental shelf down the continental slope, conforming to the Bass Strait Cascade, as evidenced by high easterly currents and minimum vertical variation in temperature from the shelf to depths of 500 m (Refer to Section 2.2.7.4 for detail on the Bass Cascade). Currents during these cascade flows were stronger than background tidal currents and were the strongest currents recorded lower down the continental slope.

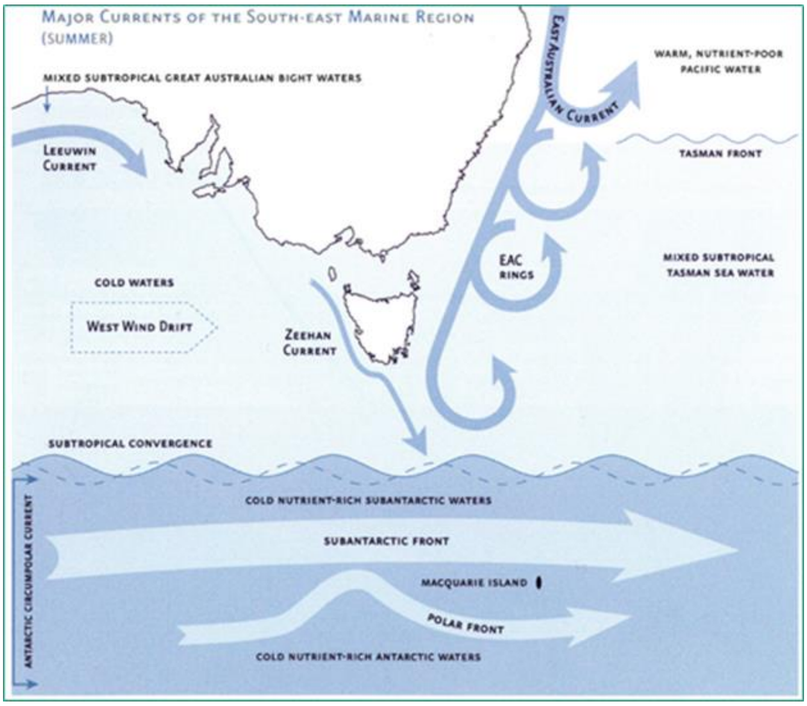

Figure 2-1 Major ocean currents in south-eastern Australian waters summer

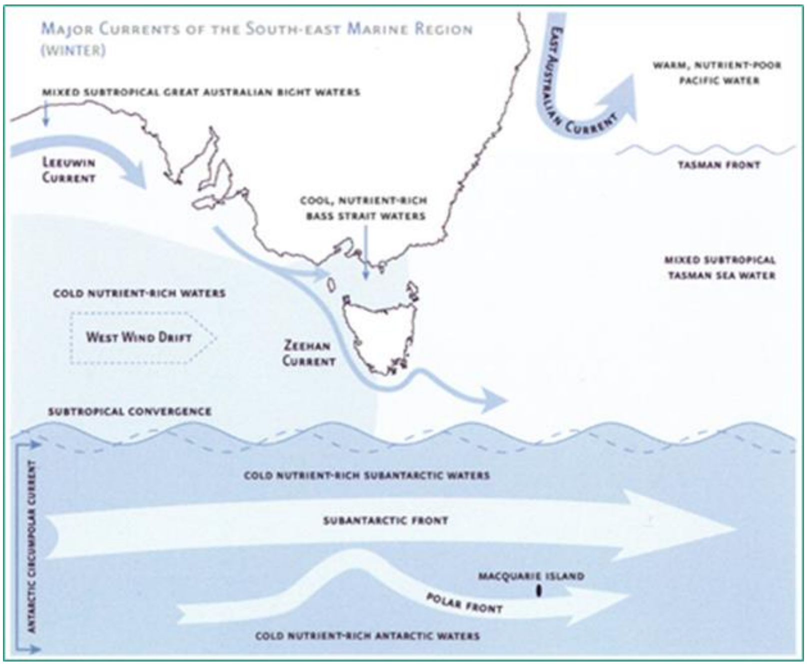

Figure 2-2 Major ocean currents in south-eastern Australian waters winter

2.1.2.2 Water Temperatures and Density Stratification

Temperatures in the subsurface waters of Bass Strait range from about 13°C in August/September to 16°C in February/March. Surface temperatures can exceed 20°C at times in late summer due to the warmer waters of the East Australia Current entering the strait. Water temperatures in the operational area are expected to follow this pattern (Jones 1980). Table 2-1 shows the monthly average sea surface temperatures and salinity as obtained from the World Ocean Atlas 2013 database which shows the same range of temperatures as those previously recorded. Monthly average sea surface temperatures were shown to range from 14°C (August, September) and 20°C (March). Salinity remained consistent throughout the year ranging from 35 to 36 psu (RPS, 2018a).

Table 2-1 Average monthly sea surface temperature and salinity nearby Blackback well location within the 0-5m water depth.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Temperature (°C)	19	20	20	19	18	16	15	15	14	15	16	18
Salinity (psu)	35	35	36	36	35	36	36	36	35	36	36	36

Waters are generally well mixed, but surface warming sometimes causes weak stratification in calm summer conditions. During these times, mixing and interaction between varying water masses leads to variations in horizontal water temperature and a thermocline (temperature profile) develops. The thermocline acts as a low friction layer separating the wind driven motions of the upper well mixed layer from the bottom well mixed layer. As a result, upwelling of cold water on the northern shores of Bass Strait can occur (Jones 1980).

Information on density and temperature profiles of the deeper area of the Blackback field has been obtained by Lawson and Treloar (1996a). Temperatures measured at the seabed confirmed a decrease in temperature with depth of measurement. The survey also showed a period (July to September) of uniformity of temperature at all measured depths, indicating flow down the continental slope (Bass Strait Cascade). The range of water temperatures observed at the seabed is from a maximum of 17°C at 93 m to a minimum of 7°C at 480 m. The minimum temperatures at depth were recorded in summer, possibly because of stronger stabilising stratification and absence of the cascade of relatively warmer water during winter.

2.1.2.3 Waves

Bass Strait is a high energy environment exposed to frequent storms and significant wave heights. High wave conditions are generally associated with strong west to southwest winds caused by the eastward passage of low pressure systems across Bass Strait. Storms may occur several times a month resulting in wave heights of 3 to 4 m or more. In severe cases, southwest storms can result in significant wave heights of greater than 6 m (Jones 1980).

Wave data have been analysed for the ten year period from 1977 to 1987 (Lawson & Treloar 1987). Wave conditions at Blackback exhibit an increased wave climate, in excess of those experienced at further inshore facilities due to the increased fetch length of waves approaching from the south west. Higher wave conditions are generally associated with strong west to south west winds caused by the eastward passage of low pressure systems across Bass Strait. These may occur several times per month and can result in significant wave heights of three to four metres or more. In severe cases, south west storms can result in significant wave heights of up to six to seven metres.

Extreme design wave conditions are associated with east coast low pressure systems. These can result in very strong east to south east winds in eastern Bass Strait. The 1989 Metocean Design Criteria Report (Esso 1990) gives a design significant wave height of 9.0 m and a corresponding maximum wave height of 17.5 m.

2.1.2.4 Bathymetry

The EGBPA is located in Bass Strait, the region of the continental shelf that separates mainland Australia from Tasmania. The bathymetry in the EGBPA is concave shaped, with a shallower rim on the eastern and western end of the EGBPA and a deeper centre. The seabed bathymetry across the region is highly variable. A steep nearshore profile (0 to 20 m water depth) extends to a less steep inner (20 to 60 m water depth) and moderate profile (60 to 120 m water depth), concluding with a flat outer shelf plain (greater than 120 m water depth) in the western part (central Bass Strait) and a steep slope into the Bass Canyon in the east. The Esso Bass Strait Operations are distributed across this area from the Dolphin platform located closest to the coast at approximately 21 km and in approximately 38 m water depth out to the VIC/P70 permit area that extends out to 90-100 km offshore in water depths of approximately 2,300m. Refer to Figure 1-2 which shows the bathymetry in the EGBPA.

2.2 Values and Sensitivities in the DA

This sections summarises the relevant values and sensitivities in the DA as required by regulation 13(2)(b) of the OPGGS(E)R.

The OPGGS(E)R require petroleum activities to be carried out in a manner; consistent with the principles of ecologically sustainable development as set out in section 3A of the Environment Protection and Biodiversity Conservation Act (EPBC Act). Protected matters, or matters of national environmental significance (MNES) must be described and considered.

Table 2-2 provides a summary of the relevant MNES that have been identified as existing in the DA, or in the case of floral and faunal species, may exist within the DA. Additional detail of each MNES is provided in other parts of this volume as indicated in the table. Table 2-3 summarises the values and sensitivities of other protected matters within the DA.

2.2.1 World Heritage

There are three relevant World Heritage listings which occur in or near the DA. Darlington Probation Station and Port Arthur Historic Site are also on the Australian Convict Sites World Heritage list.

2.2.1.1 Australian Convict Sites

2.2.1.1.1 Darlington Probation Station

Darlington Probation Station, located on Maria Island National Park (Section 2.2.8.35) off the east coast of Tasmania is the only declared World Heritage place in the DA. It offers a glimpse into our convict past and the probation system that was unique to Tasmania. The precinct has 13 intact structures that remain and are set amongst a relatively unchanged landscape along the cove, uniquely demonstrating the philosophy behind the probation system (DoEE, 2019d).

2.2.1.1.1 Port Arthur Historic Site

Located in the south-west on the Tasman Peninsula is the Port Arthur Historic Site. Port Arthur was inscribed on the Australian Convict Sites World Heritage serial listing on 31 July 2010. Port Arthur was established in the 1830s as a penal settlement. It remains a physical chronicle of a dramatic part of Australia's history and together with its 60 or so buildings and picturesque landscape has become Tasmania's most popular tourist destination (DoEE, 2019c).

2.2.1.1.1 Kingston and Arthur's Vale Historic Area

The Kingston and Arthur’s Vale Historic Area (KAVHA), on Norfolk Island, is of outstanding significance to the nation as a convict settlement spanning the era of transportation to eastern Australia from 1788 to 1855. The punishment, living and working conditions for the convicts were extremely harsh and brutal making it infamous as a 'hell on earth' with 'no hope of return'. KAVHA includes more than 40 buildings, groups of buildings, ruins and archaeological remains within 225 hectares of relatively undisturbed land. All structures were built by convicts from limestone quarried on the island or with local timber. There was an exceptional phase of penal reform to rehabilitate convicts under Commandant Maconochie between 1840 and 1844. His penal regime had an impact and was partly adopted in Fremantle Prison, Britain and America (DAWE, 2020g).

2.2.1.2 Lord Howe Island Group

Located 700 kilometres north-east of Sydney and covering an area of 1,463 km^2, the Lord Howe Island Group comprises Lord Howe Island, Admiralty Islands, Mutton Bird Islands, Ball's Pyramid, and associated coral reefs and marine environments. The justification criteria for its World Heritage listing are its exceptional diversity of spectacular and scenic landscapes within a small area, including sheer mountain slopes, a broad arc of hills enclosing the lagoon and Balls Pyramid rising abruptly from the ocean. It is considered to be an outstanding example of an island system developed from submarine volcanic activity and demonstrates the nearly complete stage in the destruction of a large shield volcano. Having the most southerly coral reef in the world, it demonstrates a rare example of a zone of transition between algal and coral reefs. Many species are at their ecological limits, endemism is high, and unique assemblages of temperate and tropical forms cohabit. The second criteria is it’s an outstanding example of the development of a characteristic insular biota that has adapted to the island environment through speciation. A significant number of endemic species or subspecies of plants and animals have evolved in a very limited area. The diversity of landscapes and biota and the high number of threatened and endemic species make these islands an outstanding example of independent evolutionary processes (DoEE, 2019s). Endemic species occur in the flora and invertebrate fauna; 60% of invertebrate fauna are endemic with discovery of new species still occurring. Of the endemic flora, more is known about the vascular plants of which 113 of the 239 species are endemic. Whilst less is known about the non-vascular plants, they are also thought to be highly diverse and include endemic species (DECCW, 2007). Lord Howe Island Group is within the Lord Howe Marine Park, refer Section 2.2.6.11 for information on this park.

2.2.1.3 Gondwana Rainforests of Australia

Gondwana Rainforests of Australia, comprising eight blocks of protected areas (366,703 ha), is situated predominantly along the Great Escarpment on Australia's east coast. The outstanding geological features displayed around shield volcanic craters and the high number of rare and threatened rainforest species are of international significance for science and conservation. One of the protected areas (136 ha) is within the Iluka Nature Reserve (refer Section 2.2.8.38). The reserve is located on the north coast of NSW, approximately 750 km north of Sydney and 150 km south of the NSW/QLD border. The coastal reserve contains the largest single stand in New South Wales of littoral rainforest, a distinctive coastal variant of sub-tropical rainforest, and the least extensive of all New South Wales rainforest types (DoEE, 2019an).

2.2.1.4 Fraser Island

Fraser Island World Heritage site covers 181,851 hectares and includes all of Fraser Island and several small islands off the island's west coast. It is the world's largest sand island, with long sweeps of ocean beach, 40 kms of sand cliffs and inland remnants of tall rainforest growing on sand dunes, a phenomenon believed to be unique in the world because it requires significant biological adaptation. Fraser Island also represents significant biological evolution (such as the development of rare and biogeographically significant species of plants and animals). Vegetation associations and succession display an unusual level of complexity, with major changes in floristic and structural composition occurring over very short distances. Evolution and specialised adaptation to low fertility, fire, waterlogging and aridity is continuing in the ancient angiosperm flora of the heathlands and the associated vertebrate and invertebrate fauna. The site also represents an outstanding example of significant ongoing geological processes including longshore drift. Fraser Island also has a variety of freshwater dune lakes which are exceptional in terms of number (half of the all the world's perched lakes), diversity and age (DAWE, 2020d).

2.2.2 National Heritage

The National Heritage List is Australia's list of natural, historic and Indigenous places which are classified to have outstanding heritage value to the nation. There are three classes for National Heritage listings; natural, historic and indigenous. The declared World Heritage properties noted in Section 2.2.1 above are also listed on Australia's National Heritage list. Other relevant National Heritage places occurring in the DA are described below.

2.2.2.1 The Great Ocean Road and Scenic Environs – Historic Heritage

The Great Ocean Road and Scenic Environs is a 242 km road located on the west coast of Victoria, commencing at Torquay and ending in Allansford, just east of Warrnambool which as well as following the spectacular coast, passes inland through the forests of the Great Otway National Park and the rural landscape west of the Otway Ranges. The site includes all the coastline between the two towns where coastline abuts the dynamic ocean swells of Bass Strait, and the hinterland displays a diverse natural environment including temperate rainforest, heathlands, wetlands, sheer cliffs, ancient rock stacks and stunning beaches, which combined, provide a magnificent aesthetic landscape and seascape which support a diverse range of flora and fauna, including threatened coastal and migratory birds.

The project to build the road was created to provide work and continuing welfare for First World War returned servicemen over the 13 years it took to build, and also to provide a utilitarian memorial to all Australian First World War servicemen. This accounts for its listing under the historic classification on the database. It also provided the residents and tourists a means of accessing the spectacular coastal landscape, for which it is most well-known now. The limestone at Port Campbell is significant for the diversity of geomorphical features found in a single lithological unit giving rise to the distinctive rock formations of the twelve Apostles, Bay of Island and Bay of Martyrs. The Otway Ranges Coastal Cretaceous site is one of only two places in Australia where polar dinosaur fossils are found and illustrates the environment prior to the separation of Australia from Antarctica. These features contribute to the scientific and educational values of the place. The place includes a large part of the Great Otway

National Park (refer Section 2.2.8.21) where a diverse range of ecosystems including wet and dry sclerophyll forests, cool temperate rainforest and near the coast, shrublands and coastal heaths (DoEE, 2019p).

2.2.2.2 Ku-ring-gai Chase National Park, Lion, Long and Spectacle Island Nature Reserves – Natural Heritage

Located at the entry to Broken Bay and the mouth of the Hawksbury River, Ku-ring-gai Chase National Park, Lion, Long and Spectacle Island Nature Reserves span 15,000 ha, approximately 20 km north of Sydney. The park and reserves contain an outstanding representation of the species that contribute to the high endemism value of the Sydney region with high species richness across many groups and a representative range of ecosystems. The complex pattern of 24 plant communities contribute species richness with over 1000 native plant species present and an outstanding array of birds and other plant species. Rock art can be seen cross the entire sandstone landscape and a small number of engravings found on vertical boulders in close proximity to major waterways. Section 2.2.8.52 provides additional information on the National Park (DoEE, 2019).

2.2.2.3 North Head – Historic Heritage

The northern, seaward entrance to Port Jackson, more commonly known as Sydney Harbour, is important as it played a major role in the cultural and military life of the colony of New South Wales, following the arrival of the First Fleet in 1788. The 'Heads', have signified arrival and departure at Port Jackson since 1788 and are recognised as important, iconic, national landmarks. The North Head Quarantine Station is important for its association with the establishment of the colony of NSW and with Australia's development as an island-nation, susceptible to ship-borne disease. The quarantine station has the longest history (1828-1977) of quarantine use in Australia. Existing structures at the North Head Quarantine Station include hospital and isolation ward, cemeteries and memorials, wharf area, separation facilities for first, second and third class passengers and an administration area. The area comprises the entire headland of approximately 277 ha at Manly DoEE, 2019i).

2.2.2.4 Bondi Beach – Historic Heritage

Bondi Beach is significant in the course of Australia's cultural history as the site of the foundation of Australia's first recognised surf lifesaving club in 1907. It is also has significant social value for being having a central place in the development of Australia's beach culture and it's way of life and leisure (DoEE, 2019j).

2.2.2.5 Kurnell Peninsula Headland – Historic Heritage

The site of first recorded contact between Indigenous people and Britain in eastern Australia (The Meeting Place) representing the birthplace of a nation and the dispossession of Indigenous people is on Kurnell Peninsula. The first landfall on continental Australia made by Captain James Cook, Commander of the Endeavour at Kurnell Peninsula was a precursor of the colonisation of Australia by Britain. On this voyage in 1770, Cook mapped Australia's eastern coastline. The listed place occupies approximately 325 hectares on the southern headland at the entrance to Botany Bay. It includes the Meeting Place Precinct, including Captain Cook's Landing Place, the coastal, landmark, sandstone, areas of Kurnell Headland between Sutherland Point in the north and Doughboy Head in the south, Endeavour Heights and sand dunes, including Botany Cone, in the south-west. The boundaries are defined by Botany Bay National Park (Kurnell Section) and a small Sydney Water inholding at Potter Point (DoEE, 2019f).

2.2.2.6 Kamay Botany Bay: botanical collection sites – Historic Heritage

Accompanying Captain James Cook on the 1770 voyage to Australia (refer 2.2.2.5 above) were botanist Sir Joseph Banks and naturalist Dr Daniel Solander. Upon the first landing plants collected by Banks and Solander included a large number of iconic Australian plant species, including some that later became type-specimens which have important scientific and research value. The plant collection sites at Kamay Botany Bay, together with the collected plant material, represent the symbolic and actual integration of Australian flora into western science. Banks and Solander used ideas from Swedish scientist Carl Linnaeus newly developed and revolutionary biological classification system (known as the Linnaean System) to collect the plants for scientific study. This plant collection made a significant contribution in revolutionising the international systematic biology discipline, shaped European perceptions of Australia and provided a benchmark for the Australian environment as well as catalysing and informing subsequent botanical studies of Australia (DoEE, 2019h). The place is broadly comprised of three areas: the Kurnell Peninsula and La Perouse Headland which are located within Kamay Botany Bay National Park (refer Section 2.2.8.68) and the Towra Point Nature Reserve (refer Section 2.2.8.67).

Figure 2-3 shows the location of the National Heritage places and Ramsar Wetland in Botany Bay.

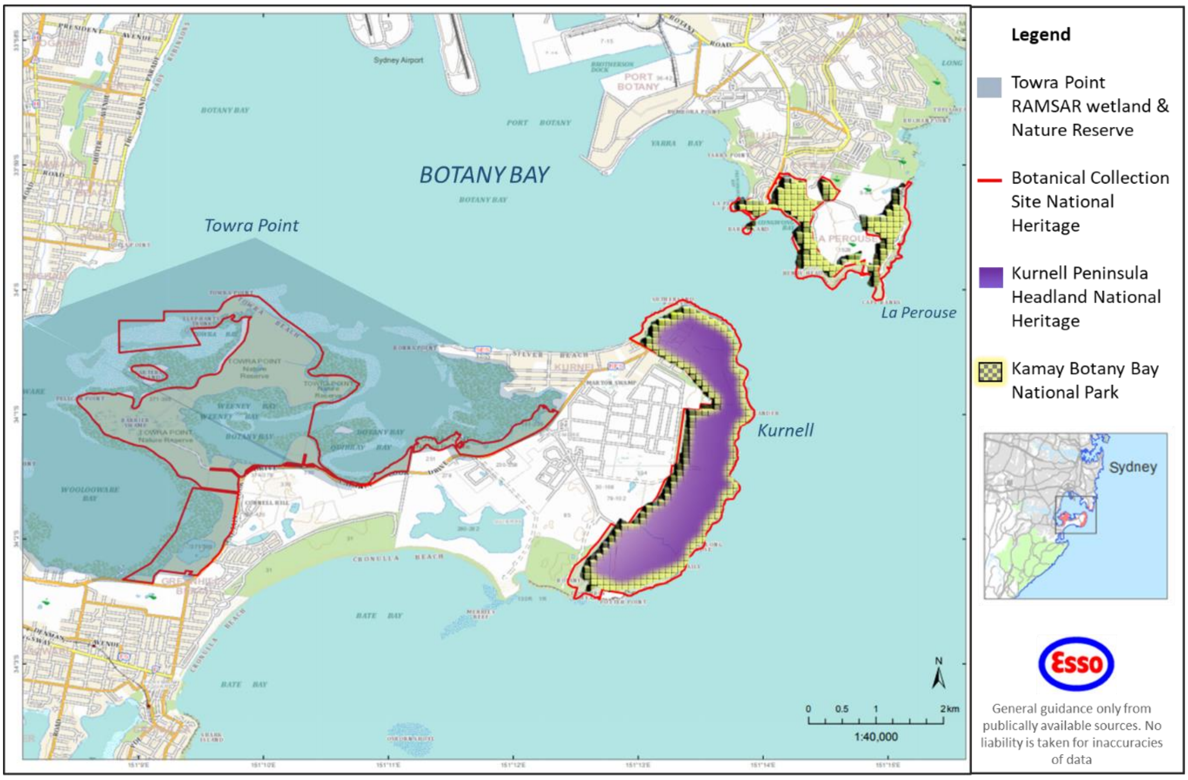

Figure 2-3 National Heritage Places, RAMSAR wetland, National Parks and Reserves in Botany Bay

2.2.2.7 Royal National Park and Garawarra State Conservation Area – Natural Heritage

Bounded by the Pacific Ocean to the east, Port Hacking to the north, the 15,968 ha area of the Royal National Park (15068 ha) and Garawarra State Conservation Area (900 ha) in NSW (south of Cronulla) was the second National Park to be established in the world after Yellowstone. Its declaration in 1879 marked the beginning of the development of Australia's National Park system of protected areas. With greater access to and use of natural areas for recreation, the public's concern for the natural environment and its conservation grew. The establishment of Royal NP is considered to be the beginning of the Australian conservation movement (DoEE, 2019e).

Royal National Park (Royal NP) and Garawarra State Conservation Area (Garawarra SCA) constitute a major centre of temperate plant species richness in Australia, with more than 1000 species recorded. The place is also extremely rich in perching birds, reptiles and butterflies and can be regarded as exemplifying the biodiverse Hawkesbury Sandstone environment.

The park's historical significance and species richness account for the official values of its National Heritage listing. However this area has many other values which are described in the National Parks and Reserves, Section 2.2.8.69.

2.2.2.8 Nepean Island Reserve and Phillip Island

Nepean Island Reserve and Phillip Island are part of the Norfolk Island group protected area system located in the External Territories of Australia. Nepean Island Reserve is listed for its natural values and is the main breeding site within the Norfolk Island Group for the masked booby Sula dactylatra. The masked booby is one of eight seabird species known to breed on the island. Seven of these are protected under Commonwealth legislation, and three are also protected under International treaties.

The reserve supports populations of the nationally vulnerable nocturnal marbled gecko, Christinus guentheri. This species is no longer found on Norfolk Island but remains on Nepean Island mainly due to the absence of predation pressure from black rats. Nepean Island is historically significant for its association with quarrying and timber-getting during the Second Settlement period (1825-55) (refer Section 2.2.6.18) (DAWE, 2020h).

Phillip Island is important as several vascular plant species have survived there and are re-establishing what were thought to be extinct including the endemic Norfolk Island abutilon Abutilon julianae, Phillip Island wheat grass Elymus multiflorus var. kingianus and the endemic Phillip Island hibiscus Hibiscus insularis. Phillip Island is the northern most breeding habitat for the Australasian gannet Morus serrator and also supports one of the largest breeding populations of the red-tailed tropicbird Phaethon rubricauda roseotincta (DAWE, 2020i).

2.2.2.9 HMAS Sirius Shipwreck

The shipwreck site of HMS Sirius has outstanding heritage value to the nation because of its importance in defining events in Australia's cultural history and for its part in development of the processes of Australian migration and defence. It also possesses rare and uncommon aspects of Australia's cultural history relating to early European settlement. The archaeological remains of HMS Sirius are the only known remains of a vessel of the first fleet that sailed to Australia. The primary shipwreck site of HMS Sirius is located east of Kingston Pier in Slaughter Bay, Norfolk Island (COA, 2011).

2.2.3 Wetlands of International Importance

Under the Ramsar Convention, wetland types have been defined to identify the main wetland habitats represented at each site. The classification system uses three categories (with a number of wetland types within each): (i) Marine/Coastal Wetlands; (ii) Inland Wetlands; and (iii) Human-made Wetlands. The wetlands are selected on account of their international significance in terms of the biodiversity and uniqueness of their ecology, botany, zoology or other natural process. A set of nine criteria have been developed to identify and classify wetlands, these are shown in Table 2-4 below. Two Ramsar wetlands are located inshore of Esso's permit areas and several others occur in the DA (Figure 2-4).

Table 2-4 Criteria for identifying Wetlands of International Importance (DoEE, 2019u)

Group	Ramsar Criteria
A Sites containing representative, rare or unique wetland types	**Criterion 1:** A wetland should be considered internationally important if it contains a representative, rare, or unique example of a natural or near-natural wetland type found within the appropriate biogeographic region.
B Sites of international importance for conserving biological diversity	Criteria based on species and ecological communities **Criterion 2:** A wetland should be considered internationally important if it supports vulnerable, endangered, or critically endangered species or threatened ecological communities. **Criterion 3:** A wetland should be considered internationally important if it supports populations of plant and/or animal species important for maintaining the biological diversity of a particular biogeographic region. **Criterion 4**: A wetland should be considered internationally important if it supports plant and/or animal species at a critical stage in their life cycles, or provides refuge during adverse conditions.
	Specific criteria based on waterbirds **Criterion 5:** A wetland should be considered internationally important if it regularly supports 20,000 or more waterbirds. **Criterion 6:** A wetland should be considered internationally important if it regularly supports 1% of the individuals in a population of one species or subspecies of waterbird.
	Specific criteria based on fish

	Criterion 7: A wetland should be considered internationally important if it supports a significant proportion of indigenous fish subspecies, species or families, life-history stages, species interactions and/or populations that are representative of wetland benefits and/or values and thereby contributes to global biological diversity. **Criterion 8:** A wetland should be considered internationally important if it is an important source of food for fishes, spawning ground, nursery and/or migration path on which fish stocks, either within the wetland or elsewhere, depend.
	Specific criteria based on other taxa **Criterion 9:** A wetland should be considered internationally important if it regularly supports 1% of the individuals in a population of one species or subspecies of wetland-dependent non-avian animal species.

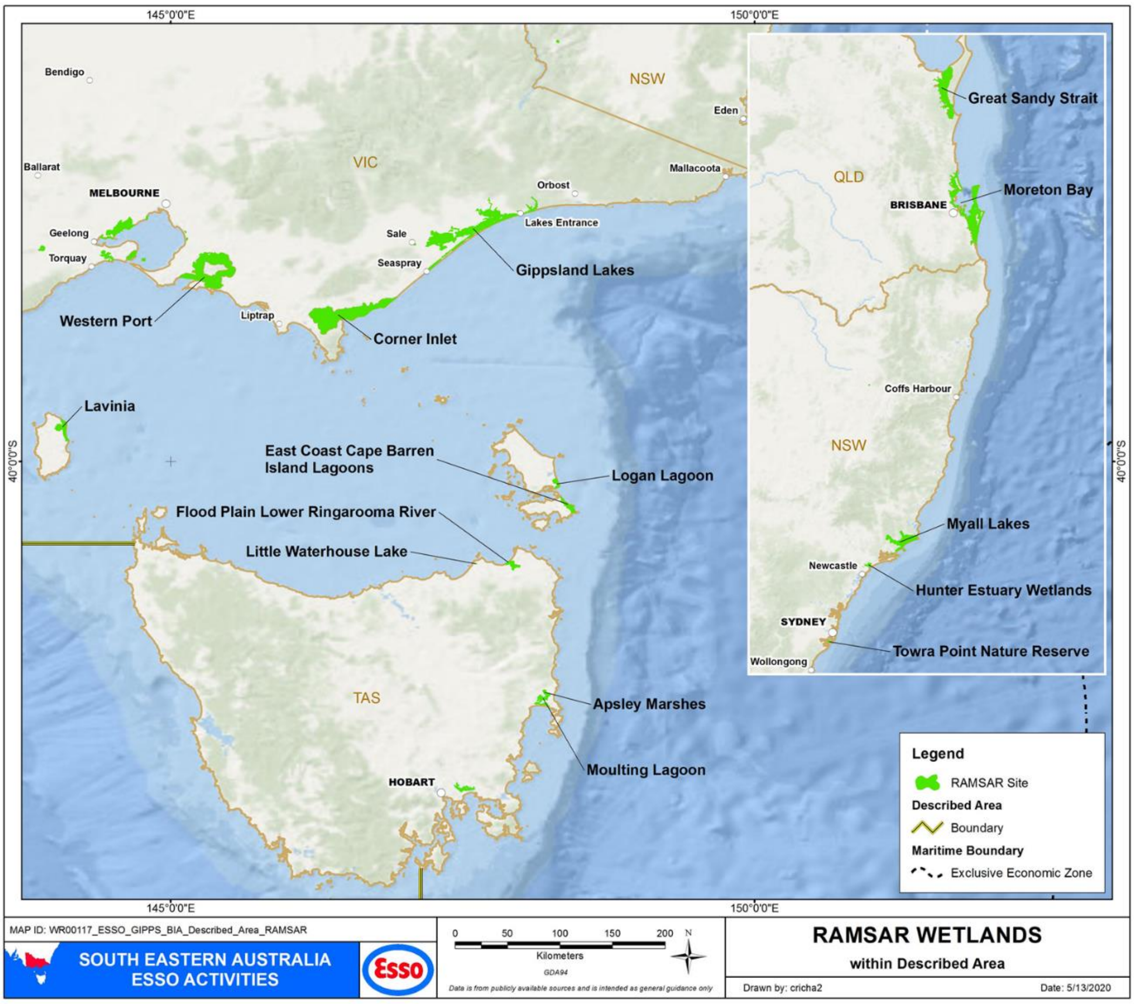

Figure 2-4 Wetlands of International Importance within the DA

2.2.3.1 Gippsland Lakes Ramsar Site

The Gippsland Lakes Ramsar Site is located in Victoria, south of the Eastern Highlands and to the east of the La Trobe Valley. Covering a vast area, the lakes are a series of large, shallow, coastal lagoons approximately 70 km in length and 10 km wide, separated from the sea by sand dunes. The surface area of the lakes is approximately 364 km2 and the three main water bodies are Lakes Wellington, Victoria and King.

The Gippsland Lakes Ramsar Site meets six of the Ramsar criteria:1, 2, 4, 6 & 8 (DoEE 2017s).

The Gippsland Lakes is a particularly good representative example of a natural or near-natural wetland, characteristic of the biogeographical region. It forms one of the largest coastal lagoon systems in the Drainage Division and contains a distinctive landscape of wetlands and flat coastal plains. The site supports a broad range of wetland types in close proximity to each other, including periodically inundated palustrine marshes, permanently inundated palustrine marshes, shallow lacustrine (lake) features, deep lacustrine features, lagoons with narrow inlets, and broad embayments.

The site supports several nationally threatened wetland fauna species at various stages of their life-cycle including two nationally threatened frog species (green and golden bell frogs and growling grass frogs), the vulnerable Australian painted snipe, a vulnerable fish species (the Australian grayling) and three nationally vulnerable and endangered wetland-associated flora species (dwarf kerrawang, swamp everlasting and metallic sun-orchid).

The site supports habitat and conditions that are important for critical life cycle stages of a variety of wetland-dependent fauna species. The permanence of the main lakes and the relatively regular flooding of the adjacent wetlands mean that this wetland is an important drought refuge for many water birds and other aquatic species, including as permanent refuges and breeding sites for two threatened frog species.

The Gippsland Lakes have been identified as being of outstanding importance for waterbirds, regularly supporting more than 20,000 waterfowl. Waterbird species which are considered to have met the one per cent population threshold are: Red-necked stint, Black swan, Sharp-tailed sandpiper, Chestnut teal, Musk duck, Fairy tern and Little tern.

Gippsland Lakes provides important habitats, feeding areas, dispersal and migratory pathways, and spawning sites for numerous fish species of direct and indirect fisheries significance. These fish have important fisheries resource values both within and external to the site.

Currently, parts of the Lakes system are heavily used for commercial and recreational fisheries and boating activities, while the immediate hinterland has been developed for agricultural use, and limited residential and tourism purposes (DoEE, 2017q).

The Lakes are protected as a Ramsar site by the Lakes National Park and the Gippsland Lakes Coastal Park (Refer Section 2.2.8.9). The locality of the Ramsar site is shown in Figure 2-5.

The ecological character description (ECD) of the Gippsland Lakes Ramsar Site as developed under the requirements of the National Framework and Guidance for Describing the Ecological Character of Australia's Ramsar Wetlands (DEWHA, 2008), is summarised in Table 2-5. The information on the limits of acceptable change, also required by the National Framework for describing the wetlands, are summarised in Table 2-6 (DSEWPAC 2010).

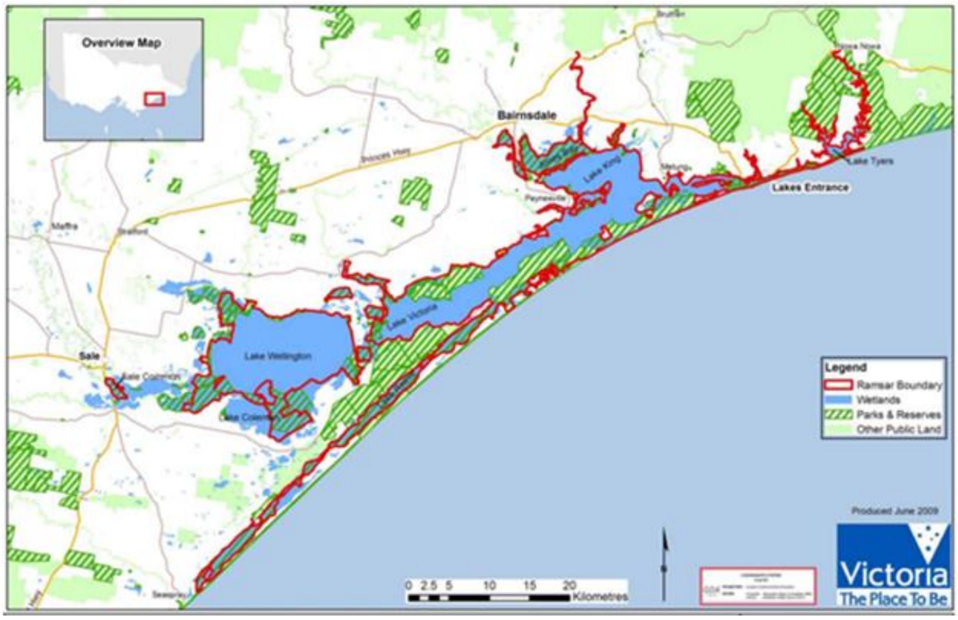

Figure 2-5 Locality of Gippsland lakes Ramsar Site (DSEWPAC, 2010)

Table 2-5 Summary of critical components, processes and services/benefits for the Gippsland Lakes Ramsar site (DSEWPAC 2010)

Critical components	Critical processes	Critical services/benefits
Wetland habitats: grouped as follows • (C1) marine subtidal aquatic beds (seagrass/aquatic plants). • (C2) coastal brackish or saline lagoons (open water phytoplankton-dominated habitats). • fringing wetlands that can occur within the site as– • (C3) predominantly freshwater wetlands • (C4) brackish wetlands • (C5) saltmarsh/ hypersaline wetlands. **Wetland flora and fauna:** • (C6) abundance and diversity of waterbirds. • (C7) presence of threatened frog species (green and golden bell frog; growling grass frog). • (C8) presence of threatened wetland flora species.	Hydrological regime: (P1) patterns of inundation and freshwater flows into the wetland system, groundwater influences and marine inflows that affect habitat structure and condition. Waterbird breeding functions: (P2) critical breeding habitats for a variety of waterbird species.	Threatened species: (S1) the site supports an assemblage of vulnerable or endangered wetland flora and fauna that contribute to biodiversity. Fisheries resource values: (S2) the site supports key fisheries habitats and stocks of commercial and recreational significance.
Supporting Components	**Supporting Processes**	**Supporting services/benefits**
Other wetland habitats: supported by the site (sand/pebble shores, estuarine waters, etc.). Other wetland fauna: supported by the site (for example, fish, aquatic invertebrates).	Climate: patterns of temperature, rainfall and evaporation. Geomorphology: key geomorphologic/ topographic features of the site. Coastal and shoreline processes: hydrodynamic controls on coasts and shorelines through tides, currents, wind, erosion and accretion. Water quality: water quality influences aquatic ecosystem values, noting the key water quality variables for Gippsland Lakes are salinity, dissolved oxygen, nutrients and sediments. Nutrient cycling, sediment processes and algal blooms: primary productivity and the natural functioning of nutrient cycling/flux processes in waterbodies. Biological processes: important biological processes such as primary productivity.	Tourism and recreation: the site provides and supports a range of tourism and recreational activities that are significant to the regional economy. Scientific research: the site supports and contains features important for scientific research.

Table 2-6 Limits of acceptable change (LAC) – Gippsland Lakes Ramsar site (DSEWPAC 2010)

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
Critical components						
C1	Marine sub-tidal aquatic beds (for example, within Lake King, Lake Victoria, Lake Tyers, Bunga Arm and Lake Bunga)	Long Term	Total seagrass extent will not decline by greater than 50 per cent of the baseline value of Roob and Ball 1997 (that is, 50 per cent of 4330 hectares = 2165 hectares) in two successive decades at a whole of site scale. Total mapped extent of dense and moderate *Zostera* will not decline by greater than 80 per cent of the baseline values determined by Roob and Ball (1997) in two successive decades at any of the following locations: Fraser Island Point Fullerton, Lake King Point King, Raymond Island, Lake King Gorcrow Point – Steel Bay, Lake Victoria Waddy Island, Lake Victoria	Sampling to occur at least twice within the decade under consideration. Baseline mapping against which this LAC can be tested is within Roob and Ball 1997. Note that the seagrass assessment by Hindell (2008) did not produce mapping but did use similar sampling sites to Roob and Ball.	Level B – Recent quantitative data describes seagrass condition at various sites but over a limited timeframe. There is no available seagrass condition data prior to listing.	P1
C2	Coastal brackish or saline lagoons (for example, Lake King, Lake Victoria, Lake Wellington, Lake Tyers)	Long Term	No change in wetland typology from the 1980 classification of Corrick and Norman (1980), as presented in Figure 2-3.	To be determined based on expert review.	Level B – VMCS mapping data describes wetland extent. This is coarse scale mapping and should be considered as indicative only.	P1, S2
		Long Term	A long-term change in ecosystem state at Lake King, Lake Victoria or Lake Tyers from relatively clear, seagrass- dominated estuarine lagoons to turbid, algae dominated system (characteristic of Lake Wellington) will represent a change in ecological character.	To be determined based on expert review.		

		Short Term	No single cyanobacteria algal bloom event will cover greater than 10 per cent of the combined area of coastal brackish/saline lagoons (that is, Lake King, Victoria, Wellington and Tyers) in two successive years.	Algal bloom extent (per cent lakes area and location) and number should be reported annually, but assessed on an ongoing basis.	Level A – The occurrence of cyanobacteria algal blooms are well documented. The extent of algal blooms historically has not been assessed, including at the time of site declaration.	
C3	Fringing wetlands – predominantly freshwater marsh at Macleod Morass and Sale Common	Long Term	No change in wetland typology from the 1980 classification (Corrick and Norman 1980; See Figure 2-3). In this regard, the conversion of vegetation communities at Sale Common and Macleod Morass from a predominantly freshwater character (for example, giant rush, common reed, cumbungi) to those of a brackish water character (brackish or swamp scrub/saltmarsh species) will represent a change in ecological character.	To be determined based on expert review.	Level B – VMCS mapping data describes wetland extent during 1980. This is coarse scale mapping and should be considered as indicative only. There is no available community data prior to listing.	P1, P2, C6, C7, C8
			The total mapped area of freshwater marshes (shrubs and reed wetland types) at Sale Common and Macleod Morass will not decline by greater than 50 per cent of the baseline value outlined in VMCS for 1980 (that is, 50 per cent of 402 hectares = 201 hectares) in two successive decades.	Sampling to occur at least twice within the decade under consideration.		
		Short Term	In existing freshwater wetland areas, the annual median salinity should not be greater than one grams per litre in two successive years. Note that where ambient water quality characteristics fall outside the range of these baseline levels, and ecosystem health indicators shows no signs of impairment, the LAC may need to be adjusted accordingly.	Annual median based on at least eight sampling periods per year, encompassing wet and dry periods.	Level C – No available baseline data. Value based on species salinity tolerances.	
C4	Fringing wetlands – brackish marsh (for example, Dowd	Long Term	For all fringing brackish wetlands: No change in wetland typology from the 1980 classification (Corrick and Norman 1980).	To be determined based on expert review.	As for C3.	P1, P2, C6, C7, C8

	Morass; The Heart Morass; Clydebank Morass, Lake Coleman {Tucker Swamp})	Medium Term	For Dowd Morass and the Heart Morass: The annual median salinity will be less than four grams per litre in five successive years. Note that where ambient water quality characteristics fall outside the range of these baseline levels, and ecosystem health indicators shows no signs of impairment, LAC may need to be adjusted accordingly.	Annual median based on at least eight sampling periods per year, encompassing wet and dry periods.	Level C – No available baseline data. This value is based on species tolerances and requirement for salinity to be less than four grams per litre to allow reproduction (refer Tilleard and Ladson 2010).	
		Long Term	The total area of common reed at Dowd Morass will not decline by greater than 50 per cent of the 1982 baseline value (that is, 50 per cent of 480 hectares = 245 hectares) outlined in Boon et al. (2007) in two successive decades.	Sampling to occur at least twice within the decade under consideration.	Level A – Boon et al. (2007) provides good quality mapping data relevant to time of listing.	
C5	Fringing wetlands – saltmarsh/hypersaline marsh (for example, Lake Reeve)	Medium Term	No change in wetland typology from the 1980 classification (Corrick and Norman 1980). The total mapped area of salt flat, saltpan and salt meadow habitat at Lake Reeve Reserve will not decline by greater than 50 per cent of the baseline value outlined in VMCS for 1980 (that is, 50 per cent of 5035 hectares = 2517 hectares) in two successive decades.	To be determined based on expert review. Sampling to occur at least twice within the decade under consideration.	As for C3.	P1, C6

C6	Abundance and diversity of waterbirds	Medium Term	The number of standard 20 minute searches (within any ten year period) where waterbird abundance is less than 50 individuals will not fall below 50 per cent of the 'baseline' value (based on Birds Australia count data – 1987-2010), for the following species: black swan = 15 per cent of surveys chestnut teal = 10 per cent of surveys Eurasian coot = 11 per cent of surveys. The absence of records in any of the following species in five successive years will represent a change in character: red- necked stint, sharp-tailed sandpiper, black swan, chestnut teal, fairy tern, little tern, musk duck, Australasian grebe, grey teal, Eurasian coot, great cormorant, red knot, curlew sandpiper. Median abundance (derived from at least three annual surveys {summer counts} over a 10-year period) falls below the 20th percentile baseline value. *Note: An adequate baseline will need to be established to assess this LAC (for example, at least three annual surveys (summer counts) over a 10-year period).*	Sampling to be undertaken at least twice a year over any 10 year period at stations containing favourable habitat for these species (see Table E8 for locations). Surveys should consist of standardised 20 minute counts. Sampling to be undertaken at least twice a year (during summer) at stations containing favourable habitat for these species (see section 3.4.1 for important locations). Recommended baseline monitoring program should include: A combination of aerial and ground surveys. Representative coverage of primary habitats within the site.	Level A – Birds Australia data, while standardised in terms of sampling effort per site, is not standardised in terms of frequency of sampling events at any given sampling location. Data should be considered indicative only. Level A – Records for these species are reliable. Birds Australia and DSE data can be used to assess this qualitative LAC. There are no baseline data available for this LAC.	P1, P2

C7	Presence of threatened frogs	Medium Term	The site will continue to support suitable habitat for growling grass frog and green and golden bell frog. In this regard, the LAC for Component 3 applies. There is insufficient data to develop a LAC relating directly to site usage by these species, which represents a critical information gap. Should baseline data become available in the future, the following LAC will apply: a significant reduction (greater than 25 per cent over a period of 5 years) in the local adult population within the site, especially for important local populations (for example, within Macleod Morass, Sale Common, Ewings Marsh, Roseneath wetlands (Morley Swamp and Victoria Lagoon), the Heart Morass and freshwater pools on Rotamah Island).	Refer to C3. Recommended baseline monitoring program should comprise a minimum two annual sampling periods separated by at least one year (and within a 5 year period).	Level C – Surveys for these species have been opportunistic. The most recent record for growling grass frog is 2007, whereas the green and golden bell frog was recorded at the site in 1998. There are no empirical data describing abundances at the site.	P1
C8	Presence of threatened wetland flora species	Long Term	The three threatened flora species (*Rulingia prostrata*, *Thelymitra epipactoides* and *Xerochrysum palustre*) continue to be supported within the boundaries of the Gippsland Lakes Ramsar site.	Based on opportunistic searches.	Level C – Setting of empirical limits of acceptable change is not possible at present, given the absence of quantitative estimates of population size of threatened species within the site, and more importantly the viability of populations (and their key controls) within the site.	P1

<table>
<tr><th colspan="7">Critical processes</th></tr>
<tr>
<td>P1</td>
<td>Hydrological regime</td>
<td>Short Term – Medium Term</td>
<td>Wetland wetting frequency, flushing frequency and flushing volume are maintained as follows:
<table>
<tr><th>Wetland</th><th>Wetting Frequency</th><th>Flushing Frequency</th><th>Required Flushing Volume</th></tr>
<tr><td>Sale Common</td><td>Annual with 100 per cent reliability</td><td>2-3 times/decade</td><td>4 GL</td></tr>
<tr><td>Dowd Morass</td><td>5-7 times/decade</td><td>2-3 times/decade</td><td>15GL</td></tr>
<tr><td>The Heart Morass</td><td>5-7 times/decade</td><td>2-3 times/decade</td><td>15GL</td></tr>
</table>
From Tilleard and Ladson (2010); note that larger flushing volumes (~20GL) are identified as being needed for Dowd and the Heart Morasses following saline flood events in the Lake Wellington system (for example, when the wetlands are filled with saline water from Lake Wellington and this corresponds with low flows in the Latrobe River).</td>
<td>Refer to LAC for details. Values measured at existing gauging stations in the lower reaches of the Rivers or otherwise in the wetlands themselves.</td>
<td>LAC have been identified for these wetlands on the basis that they are the best indicators of freshwater flows into the broader Gippsland Lakes system.

Level C – LAC based on Tilleard and Ladson (2010) 'Hydrological Analyses to Support Determination of Environmental Water Requirements in the Gippsland Lakes'. This is a threshold-based LAC that is based on modelling and ecological assessments.

Note that these values should be considered as indicative only at this stage, and should be constantly reviewed.

Tilleard and Ladson (2010) indicate no work has been done for wetlands on the Mitchell (Macleod Morass); McLennan Straits (Morley Swamp, Lake Betsy); or Jones Bay.</td>
<td>C1 – C8
S1, S2</td>
</tr>
</table>

P2	Waterbird breeding	Short Term	Abandonment or significant decline (greater than 50 per cent) in the productivity of two or more representative breeding sites (based on two sampling episodes over a five year period) within any of the following site groupings: Lake Coleman, Tucker Swamp and Albifrons Island – Australian pelican. Bunga Arm and Lake Tyers – little tern and fairy tern. Macleod Morass, Sale Common and Dowd Morass – black swan, Australian white ibis, straw-necked ibis, and little black cormorant.	Recommended baseline monitoring program should comprise a minimum two annual sampling periods separated by at least one year (and within a 5 year period).	Level C – The use of the site by these species is well documented. However, there are no empirical data describing breeding rates. Baseline data will need to be collected to assess this LAC.	C6
Critical services/benefits						
S1	Threatened species	N/A	No LAC are proposed for painted snipe and Australasian bittern at the current time until greater information is available about patterns of usage and populations in the Ramsar site. Other threatened species are dealt with in the critical components above.	N/A	Level C – Site records are not recent, uncommon and the location within the Ramsar boundary not known.	P1, C3
		Long Term	Australian grayling continues to be supported in one or more of the catchments draining into the Gippsland Lakes.	Setting of more empirical limits of acceptable change not possible at present, given the absence of quantitative population data for this species for any of the rivers and creeks that drain into the site.	Level C – This species has been recorded in the major drainages that drain into the site. Juveniles have an apparent obligate estuarine phase, and therefore must use the site in order for this species to persist in these drainages. There are no data describing the population status of this species in these drainages.	P1, C1, C2
S2	Fisheries resource values	Medium Term	Total annual black bream commercial fishing catch per unit effort will not fall below the 10th percentile historical baseline value of 6.1 (see Section 3.8.2) in a five successive year period.	Median measured over five years.	Level B – While some commercial fish data has been accessed and	C1, C2, C3, C4, C5

			Sub-optimal black bream spawning conditions should not occur in any successive five year period within key spawning grounds (that is, mid-lower estuaries and adjacent waters of main lakes) during the peak spawning period (October to December). Based on Tilleard (2009), optimal conditions are as follows:	Annual median value for the period October to December.	reviewed as part of the current study, the abundance and usage of the Gippsland Lakes by key fish species of commercial and recreational significance is not well quantified. The baseline data used in this LAC has limited duration (five years), and is unlikely to be representative of patterns in abundance over longer timeframes. This LAC will need to reviewed and refined.	
			Water column salinity is maintained in brackish condition (for example, between 17-21 grams per litre median value) in the middle of the water column in the mid-lower estuaries and adjacent waters of the main lakes	As above.		
			The salt wedge is located within the mid-lower section of the estuarine river reaches or just out into the main lakes as opposed to far upstream or well-out into the Lakes.		Level C – based on conditions outlined in Tilleard (2009).	

C – component, P – process , S/B – service/benefit

2.2.3.2 Corner Inlet Ramsar Site

The Corner Inlet Ramsar Site is located on the south-east coast of Victoria. It is bounded to the west and north by the South Gippsland coastline, in the south-east by a series of barrier islands and sandy spits lying end to end and separated by narrow entrances, and to the south by the hills of Wilsons Promontory.

The Corner Inlet Ramsar Site also meets six of the Ramsar criteria (DoEE 2017o): 1, 2, 4, 5, 6 and 8 (as described above).

Corner Inlet is a very good example of a wetland enclosed by barrier islands in Victoria and contains the most extensive intertidal mudflats in Victoria. The area contains the only extensive bed of the Broad-leafed seagrass in Victoria. The islands of Corner Inlet, although not rich in plant diversity, are of high biogeographical significance as a result of their geological history and connectivity to the mainland during ice ages. The islands also contain significant areas of saltmarsh and mangroves, both of which are communities of very limited distribution. These communities filter pollutants, stabilize sediments and protect the shoreline from erosion.

Corner Inlet provides breeding habitat for a variety of waterbirds, including several species listed as threatened at the State level and/or occurring in significant numbers and habitat for significant aggregations of waterbirds during post-breeding, and as a refuge during adverse environmental conditions. Corner Inlet regularly supports well over 20,000 waterbirds including species such as the Eastern curlew, Curlew sandpiper, Bar-tailed godwit, and Double-banded plover.

The Corner Inlet Ramsar Site has regularly supported more than one per cent of the population of the Pied oystercatcher, Sooty oystercatcher, Pacific gull, Fairy tern, Red knot, Red necked stint and Chestnut teal.

Corner Inlet supports the nationally critically endangered Orange bellied parrot as well as several other vulnerable and endangered species, including the growling grass frog and Australian grayling. The Southern right whale, Leathery turtle, Swift parrot and Shy albatross have all also been recorded at the site.

Corner Inlet provides important habitats, feeding areas, dispersal and migratory pathways, and spawning sites for numerous fish species. Some of these include King George whiting, Australian salmon, greenback flounder, southern garfish, leatherjackets (several species), short-finned eel and gummy shark.

Corner Inlet was used traditionally by Indigenous people and many archaeological sites including scarred trees, burial sites, artefact scatters, shell middens and camps have been found. Currently, the Ramsar site is used for biological conservation, ports with servicing facilities for off-shore oil and natural gas exploration, commercial fishing, recreational fishing, and other recreational activities. Diving is popular around the numerous shipwreck sites in Corner Inlet and around the barrier islands (DoEE, 2017o).

The site is protected as a Ramsar site by the Nooramunga and Corner Inlet Marine and Coastal Parks, and by part of it lying within the Corner Inlet Marine National Park (Section 2.2.8.11). The locality of the Ramsar site is shown in Figure 2-6.

The ecological character description (ECD) of the Corner Inlet Ramsar Site is summarised in Table 2-7 with limits of acceptable change summarised in Table 2-8 (DSEWPAC, 2011b).

In the context of the Bass Strait Operations and predicted extent of the DA, critical components that may be affected by a major spill event include Seagrass, mangroves, saltmarshes and intertidal and subtidal waters (C1), Waterbird breeding (P1), Threatened species (S1) and Fish abundance (S2).

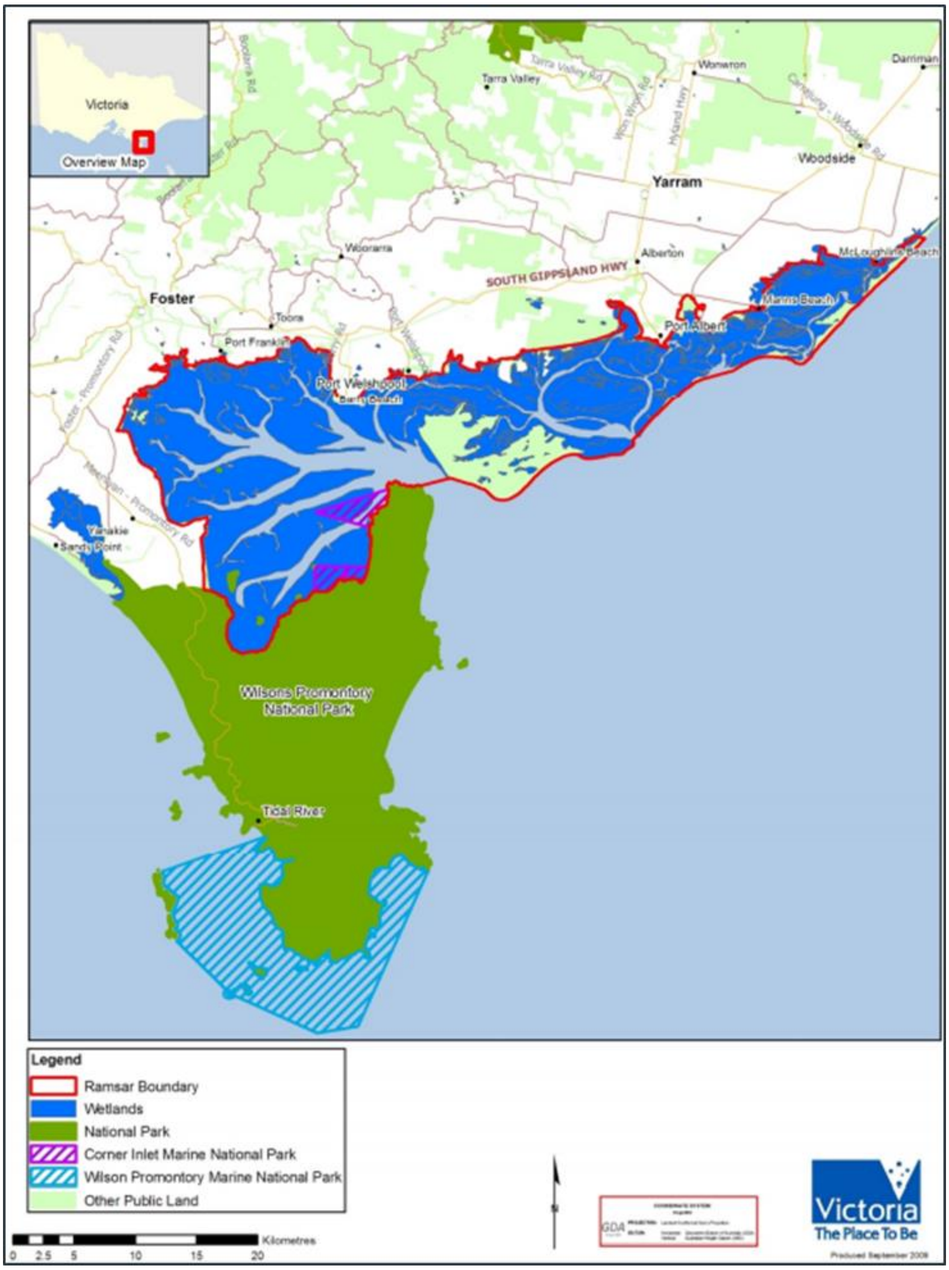

Figure 2-6 Locality of Corner Inlet Ramsar Site (DSEWPAC, 2011b)

Table 2-7 Summary of critical components, processes and services/benefits for the Corner Inlet Ramsar site (DSEWPAC, 2011b)

Critical Components	Critical Processes	Critical Services/Benefits
C1. Several key wetland mega-habitat types are present: • seagrass • intertidal sand or mud flats • mangroves • saltmarshes • permanent shallow marine water **C2.** Abundance and diversity of **waterbirds**	**P1. Waterbird breeding** is a key life history function in the context of maintaining the ecological character of the site, with important sites present on the sand barrier islands	S1. The site supports nationally threatened fauna species including: • orange-bellied parrot • growling grass frog • fairy tern • Australian grayling **S2.** The site supports **outstanding fish habitat values** that contribute to the health and sustainability of the bioregion
Supporting Components	**Supporting Processes**	**Supporting Services/Benefits**
Important **geomorphological features** that control habitat extent and types include: • sand barrier island and associated tidal delta system • the extensive tidal channel network • mudflats and sandflats. **Invertebrate megafauna** in seagrass beds and subtidal channels are important elements of biodiversity and control a range of ecosystem functions. The **diverse fish communities** underpin the biodiversity values of the site	**Climate**, particularly patterns in temperature and rainfall, control a range of physical processes and ecosystem functions Important **hydraulic and hydrological processes** that support the ecological character of the site includes**:** • Fluvial hydrology. Patterns of inundation and freshwater flows to wetland systems • Physical coastal processes. • Hydrodynamic controls and marine inflows that affect habitats through tides, currents, wind, erosion and accretion. • Groundwater. For those wetlands influenced by groundwater interaction, the level of the groundwater table and groundwater quality. **Water quality** underpins aquatic ecosystem values within wetland habitats. The key water quality parameters for the site are salinity, turbidity, dissolved oxygen and nutrients. Important **biological processes** include nutrient cycling and food webs.	The site supports **recreation and tourism values** (scenic values, boating, recreational fishing, camping, etc.) that have important flow-on economic effects for the region. The site provides a range of values important for **scientific research**, including a valuable reference site for future monitoring.

Table 2-8 Limits of acceptable change (LAC) – Corner Inlet Ramsar site (DSEWPAC, 2011b)

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
Critical Components						
C1	Seagrass extent	Long Term	• Total mapped extent of dense *Posidonia* will not decline by greater than 10 percent of the baseline value outlined by Roob *et al.* (1998) at a whole of site scale (baseline = 3050 hectares; LAC = mapped area less than 2745 hectares) on any occasion. (Note: the small degree of allowable change recognises that this seagrass species is a critical habitat resource and generally shows low natural variability.) • Total mapped extent of the dense and medium density Zosteraceae will not decline by greater than 25 percent of the baseline values outlined by Roob *et al.* (1998) at a whole of site scale on two sampling occasions within any decade. • Dense *Zostera* - Baseline = 5743 hectares (LAC = mapped area less than 4307 hectares) • Medium *Zostera* - Baseline = 1077 hectares (LAC = mapped area less than 807 hectares) (Note: the moderate degree of allowable change recognises that these seagrass species generally show moderate degrees of natural variability)	Sampling to occur at least twice within the decade under consideration. Note that the seagrass assessment by Hindell (2008) did not produce mapping but did use similar sampling sites to Roob *et al*.	Recent quantitative data describes seagrass condition at various sites but over a limited timeframe. It is thought that the Roob *et al*. (1998) study under-estimated the total available seagrass habitat (J. Stevenson, Parks Victoria, pers. comm. February 2011), hence a 10 per cent change from this baseline value would represent a larger actual change from the true baseline. ***Note***: Prior to declaration, *Posidonia* covered approximately 44 per cent (11,900 hectares) of the site (Poore 1978). Morgan (1986) estimated that *Posidonia* meadows covered 11,900 hectares in 1965 and 9,000 to 9,500 square kilometres in 1983–84. There is uncertainty regarding these mapping data and therefore empirical LACs	S2

[1] *Short Term – measured in years; Medium Term – five to 10 year intervals; Long term – 10+ year intervals.*

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
					have not been developed from these data.	
	Mangrove forest extent	Long term	• Based on EVC mapping, it is estimated that mangroves presently cover an area of 2137 hectares within the site (see Section 3.3.1). A 10 percent reduction in the total mapped mangrove area, observed on two sampling occasions within any decade, is an unacceptable change. (LAC – mapped area less than 1924 hectares). (Note: the small degree of allowable change recognises that mangroves are a critical habitat resource and generally shows low natural variability)	Sampling to occur at least twice within the decade under consideration.	No available data to determine changes in extent over time. It is unlikely that this has changed markedly since Ramsar listing. Note that there are uncertainties regarding the quality of existing mapping, and therefore the baseline value should be considered as indicative only.	S2
	Saltmarsh extent	Long term	• Based on EVC mapping, it is estimated that intertidal saltmarsh presently covers an area of 6500 hectares within the site (see Section 3.3.1). A 10 percent reduction in the total mapped saltmarsh area, observed on two sampling occasions within any decade, is an unacceptable change (LAC – mapped area less than 5850 hectares). (Note: the small degree of allowable change recognises that saltmarsh is a critical habitat resource and generally show low natural variability)	Sampling to occur at least twice within the decade under consideration.	No available data to determine changes in extent over time. It is unlikely that this has changed markedly since Ramsar listing. The note regarding data quality for mangroves applies also to saltmarsh.	S2
	Shallow subtidal waters	Long term	• A greater than 20 percent reduction in the extent of subtidal channel (areas mapped by NLWRA = 16 349 hectares), observed on two sampling occasions within any decade, will represent a change in ecological character (LAC – mapped area less than 13 079 hectares). (Note: the moderate degree of allowable change recognises that shallow subtidal waters represent a critical	Sampling to occur at least twice within the decade under consideration.	NLWRA mapping data describes wetland extent. This is coarse scale mapping and should be considered as indicative only. ***Note***: there is a need to develop a condition-based LAC for this critical component. While some water quality data	S2

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
			habitat resource, generally show low natural variability, but data reliability is low)		exists, this is presently insufficient to derive a LAC (i.e. whether a change in water quality represents a true change in ecological character of the wetland)	
	Inlet waters (intertidal flats)	Long term	• A greater than 20 percent reduction in the extent of permanent saline wetland – intertidal flats (areas mapped by DSE = 40 479 hectares, see Figure 3-1), observed on two sampling occasions within any decade, will represent a change in ecological character (LAC – mapped area less than 36 431 hectares). (Note: the moderate degree of allowable change recognises that intertidal flats represent a critical habitat resource and generally show low natural variability. A loss of intertidal flat would also result in changes in seagrass)	Sampling to occur at least twice within the decade under consideration.	VMCS mapping data describes wetland extent. This is coarse scale mapping and should be considered as indicative only. ***Note***: there is a need to develop a condition-based LAC for this critical component. While some water quality data exists, this is presently insufficient to derive a LAC (i.e. whether a change in water quality represents a true change in ecological character of the wetland)	S2
C2	Abundance and of waterbirds	Short term (All species)	• Mean annual abundance of migratory bird species - Birds Australia (2009c) notes that there is a maximum annual abundance of migratory species of 42 811 birds, with a mean annual abundance of migratory species being 31 487 birds (deriving from 28 years of data collection to September 2008). The annual abundance of migratory shorebirds will not decline by 50 per cent of the long-term annual mean value (that is, must not fall below 15 743 individuals) in three consecutive years. (Note: the large degree of allowable change recognises that these species can show high	At least four annual surveys (summer counts) within the decade under consideration.	Bird count data are available from a variety of programs, most notably Birds Australia monitoring programs	P2

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
			levels of natural variability, and that limitations of existing baseline data)change recognises that these species can show high levels of natural variability, and that limitations of existing baseline data)			
		Short term (individual species)	• Mean annual abundance of migratory species that meet the one per cent criterion will not be less than 50 per cent of the long-term annual mean value in five years of any ten year period. These values are follows: • curlew sandpiper – baseline = 2588 birds, LAC = 1294 birds • bar tailed godwit – baseline = 9727 birds, LAC = 4863 birds • eastern curlew – baseline = 1971 birds, LAC = 985 birds • pied oystercatcher – baseline = 893 birds, LAC = 446 birds • sooty oystercatcher – baseline = 285 birds, LAC = 142 birds • double-banded plover– baseline = 523 birds, LAC = 261 birds There are insufficient baseline data to determine long-term average abundance of fairy tern and Pacific gull. (Note: the large degree of allowable change recognises that these species can show high levels of natural variability, and that limitations of existing baseline data)	At least five annual surveys (summer counts) within the decade under consideration.	Bird count data are available from a variety of programs, most notably Birds Australia monitoring programs	P2
Critical Processes						
P1	Waterbird breeding	Short Term	A greater than 50 per cent decrease in nest production at two or more monitoring stations (based on two sampling	Recommended baseline monitoring	The use of the site by these species is well documented.	C2

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
			episodes over a five year period) within any of the following locations and species: • Clomel Island - fairy tern, hooded plover, Caspian tern, crested tern • Dream Island - fairy tern, hooded plover, crested tern • Snake Island and Little Snake Island - pied oystercatcher	program should comprise a minimum two annual sampling periods separated by at least one year (and within a five year period).	However, there are no empirical data describing nest or egg production rates. Baseline data will need to be collected to assess this LAC.	
Critical Services/Benefits						
S1	Threatened Species	N/A	For orange-bellied parrot and growling grass frog, an unacceptable change will have occurred should the site no longer support these species.	Based on multiple targeted surveys at appropriate levels of spatial and temporal replication (at least four annual surveys in preferred habitats) over a 10 year period.	Most site records are based on opportunistic surveys	P1, C3
		Short Term	For Australian grayling, an unacceptable change will have occurred should all of the drainages that drain into Corner Inlet no longer support this species.	Based on four annual surveys in a 10 year period at multiple sites located in all major catchments.	This species has been recorded in the major drainages that drain into the site. There are no data describing the population status of this species in the site. Abundance data are available for drainages that discharge into the site (Ecowise 2007; O'Connor *et al*. 2009). O'Connor *et al*. (2009) notes that collection of this species is difficult and requires targeted survey techniques. Few targeted empirical surveys have	P1, C1, C2

Number	Indicator for Critical Component / Process/Service for the LAC	Relevant timescale[1]	Limit(s) of Acceptable Change	Spatial scale/temporal scale of measurements	Underpinning baseline data	Secondary critical C,P,S addressed through LAC
					been undertaken in the site's drainages to date	
S2	Fish abundance (using fish catch of key species as a surrogate)	Medium term	An unacceptable change will have occurred if the long term (greater than five years) median catch falls below the 20th percentile historical baseline values in standardised abundance or catch-per unit effort of five or more commercially significant species (relative to baseline) due to altered habitat conditions within the site. The 25th percentile pre-listing baseline commercial catch per unit effort values for the site are as follows (units are tonnes per annum per number of boats): Australian salmon 379 rock flathead 316 southern sand flathead 373 greenback flounder 514 southern garfish 1452 yelloweye mullet 740 gummy shark 167 King George whiting 1347	Annual fish catch measured over a greater than five year period.	Commercial fish catch data. Note that there are presently no fisheries-independent baseline data (collected using empirical, systematic methods) describing patterns in the distribution and abundance of key species. Therefore, the limits of acceptable change should be treated with caution, noting socio-economic factors should be taken into account when assessing catch data underpinning this LAC.	S2

2.2.3.3 Logan Lagoon Ramsar Site

The site is an excellent, regionally representative example of a coastal estuarine wetland system and includes Logan, Syndicate and Wilsons Lagoons, Pot Boil Point and part of Planters Beach.

The Logan Lagoon Ramsar site is enclosed within the Logan Lagoon Conservation Area and is located on the south-east corner of Flinders Island in Bass Strait, Tasmania.

Logan Lagoon meets five of the Ramsar Criteria: 1, 2, 3, 4 and 6.

The Logan Lagoon Ramsar site is in the Tasmanian Australian Drainage Division. It contains two sites listed on the Tasmanian Geoconservation Database; Logan Lagoon Holocene Shorelines and Planter Beach Coastal Barrier System. Logan Lagoon, with other lagoons and dunes in the area, provides a representative and outstanding example of the development of Holocene shorelines for the local region. Planter Beach Coastal Barrier System, partly within the site, is a representative and outstanding example of how offshore bars formed with Holocene sea level rise and barrier growth has enclosed the coast, forming large lagoons. Logan Lagoon is recognised as a wetland in near pristine condition.

The nationally threatened Northern leek orchid occurs within the Logan Lagoon Ramsar site (DoEE, 2017v). The nationally threatened subspecies of the Common wombat (Bass Strait) also occurs on the site and is restricted to Flinders Island.

Logan Lagoon supports species and communities threatened in the Tasmania Drainage Division, particularly Callitris rhomboidea forest and the rayless starwort. The site provides breeding habitat for two beach nesting shorebirds that are threatened in the region, the Fairy tern and Little tern.

The Logan Lagoon Ramsar site is an important area for birds migrating between south-eastern Australia and Tasmania. The lagoon supports five migratory bird species, the Red-necked stint, Curlew sandpiper, Sharp-tailed sandpiper, Common greenshank, and Little tern. The site also regularly supports one percent of the global or regional populations of: Hooded plover, Fairy tern, Musk duck, and Chestnut teal (DoEE 2017v).

In the context of the Bass Strait Operations and predicted geographical extent of the DA, critical components that may be affected by a major spill event include water quality (should tidal exchange occur), threatened wetland-dependent plant species, threatened saline plant communities and shorebird and waterbird species.

The locality of the Ramsar site is shown in Figure 2-7. The critical components and processes of the Logan Lagoon Ramsar site and its limits of acceptable change are shown in Table 2-9.

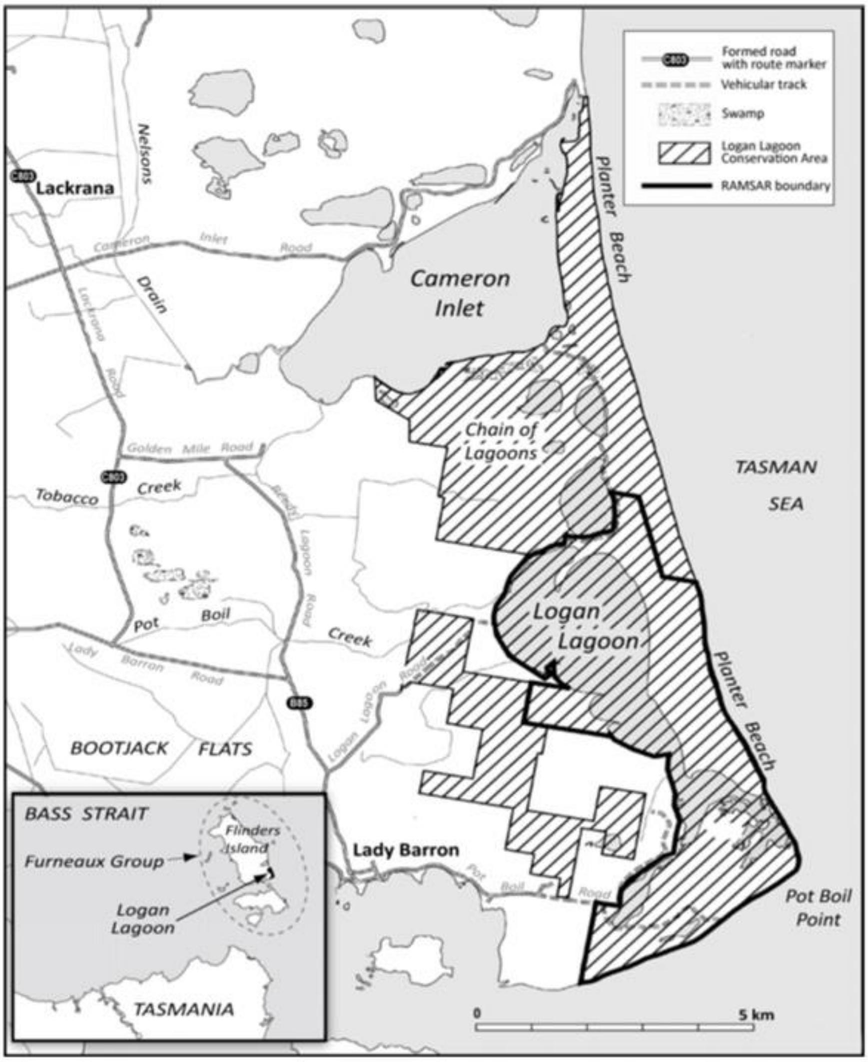

Figure 2-7 Locality Logan Lagoon Ramsar Site (Finley and Roberts, 2010)

Table 2-9 Limits of acceptable change for critical components and processes of the Logan Lagoon Ramsar site (Finley and Roberts, 2010).

Critical Component/Process / Service	Baseline / supporting evidence	Limit of acceptable change
Climate: Understanding the interactions between the physical conditions at the site and its subsequent use by flora and fauna is important. For example, waterbirds may use the site for breeding only in years when water levels are moderate and there is adequate area for nesting on the shores.		
Climate	The particular attributes of climate that are important in maintaining the ecological character of the site are rainfall, temperature, wind and evaporation. Climate predictions for north-eastern Tasmania suggest a generally warmer climate which is wetter in all seasons. Mean daily temperatures are projected to be warmer (both minimum and maximum temperatures) with increased solar radiation, relative humidity in summer, and increased evaporation (ACE CRC 2010).	The links between climatic conditions, the hydrological responses to such conditions, and their impact on the biological components are poorly understood and should be further investigated. No LAC can be determined due to a lack of understanding of the impact of climatic processes on other critical components, processes and services, such as, hydrology, geomorphology, flora and fauna.
Geomorphology: Protecting the geological features, including the integrity and structure of the dunes, is important for the purposes of geoconservation and maintaining the ecological character which contributes to the site's listing under Criterion 1.		
Holocene Shorelines and dune systems	There are approximately 54 hectares of shorelines, spits and dune systems that are important for maintaining the geoconservation value of the site under Criterion 1. The area of shorelines, spits and dunes defined in the TASVEG mapping layers require ground-truthing.	Currently there are 54 hectares of high quality shorelines, dune systems and spits mapped within the site. In the absence of studies detailing impacts from human disturbance, a common-sense approach has been adopted, setting a limit of acceptable change at not more than 3 hectares (2 percent) of the area of the Holocene shoreline and dune systems showing evidence of human disturbance through vehicle use or foot traffic. Because the wetland map was made without proper ground-truthing, verification of areas will be required.
Hydrology: The hydrological regime is a major driver in the vegetation communities at the site, particularly for wetland-dependent communities. The availability of water plays a key role in the attractiveness of the site for resting and breeding of resident and migratory fauna, especially birds.		
Surface water flow	Flow regimes are poorly understood: Historically, the lagoon mouth has been artificially breached by local landowners. Alterations to the natural hydrological regime impacts on other components such as geomorphology, water quality, vegetation and fauna. Surrounding farmland drains into the lagoon via a series of channels. High water levels in the lagoon have previously been blamed for inundated pasture on surrounding farms. The link between climate and hydrology is poorly understood. For example, the amount of rainfall required to maintain the natural hydrology.	No unnatural opening of the lagoon mouth. Site observations indicate that fluvial inflows are a significant input of surface water to the lagoon. Whilst this inflow is beneficial in maintaining water in the lagoon, poor water quality in inflow waters could offset this benefit. Site specific hydrology data and further water quality data is therefore required before LAC can be set that takes into account these factors.

Critical Component/Process / Service	Baseline / supporting evidence	Limit of acceptable change
Tidal exchange	Historical information on lagoon mouth opening is anecdotal. Future monitoring should include the status of the lagoon entrance (open/closed) because parameters such as salinity may be highly variable when the lagoon is open to the ocean.	No unnatural opening of the lagoon mouth. The lagoon is rarely open to the ocean. However, when the hydrological regime shifts to a marine system, advice on appropriate parameters should be sought.
Water Quality: provides suitable water quality to support the persistence of wetland dependent flora and fauna. The ecological character of the site currently depends on the quality of water entering and being retained within the lagoon. Baselines need to be set before LAC can be set.		
Water quality	Only two water samples recorded from the site. pH: Limited data indicates pH of 7.2-7.7 in Logan Lagoon waters. Potential for acid sulphate soils to impact on pH of lagoon waters. Salinity: Limited data indicates salinity (as Total Dissolved Solids) ranging between 2,600-35,700 mg/L: Salinity highly variable depending on seasonal climatic and hydrological processes. Dissolved Oxygen: No data available. Turbidity: Limited data indicates range between 0.5 and 4.9 NTU: Turbidity varies with freshwater inflows, wind and tidal influences. Nutrients: Limited site data indicates Total P (0.09 – 0.2 mg/L and Total N (1.4-1.5 mg/L).	Cannot determine LAC due to insufficient data.
Vegetation: the hydrology, climate, water quality and soil quality of Logan Lagoon influence the vegetation that is supported at the site. The threatened wetland-dependent vegetation communities contribute to the regional biodiversity and selection of Criterion 1 and 3.		
Holocene Shorelines and dune systems	There are currently three threatened wetland-dependent plant species mapped at the site.	In the absence of accurate mapping, a common sense approach has been adopted, setting a limit of acceptable change as the persistence of the following threatened species within the Logan Lagoon boundary: Swamp fireweed (*Senecio psilocarpus*) Large-fruit seatassel *(Ruppia megacarpa*) Northern leek orchid (*Prasophyllum secutum*) These three species are cryptic and therefore seasonally specific surveying will be required to identify them. Species should be observed during two out of every three surveys.
Threatened plant communities	Poor quality information on the current distribution and abundance of threatened plant communities because maps based on TASVEG	There are 14.22 hectares of threatened wetland-dependent vegetation communities at the site. Common sense would suggest no loss greater than 10 percent for each wetland type

Critical Component/Process / Service	Baseline / supporting evidence	Limit of acceptable change
	Mapping Layers have not been ground-truthed. The areas of threatened wetland-dependent vegetation communities are: Saline aquatic herbland = 9.23 hectares Freshwater aquatic herbland = 1.28 hectares Lacustrine herbland = 3.71 hectares.	based on TASVEG mapping layers. Because the wetland map was made without proper ground-truthing, verification of areas will be required. Based on current estimates made for this ECD, the maximum areas of threatened wetland vegetation that could be lost before causing unacceptable change to the site are: Saline aquatic herbland: 0.9 hectares Freshwater aquatic herbland: 0.5 hectares Lacustrine herbland: 4 hectares.
Fauna: Logan Lagoon supports and large number of birds, many with conservation significance locally, nationally, and internationally which justifies the selection of Ramsar criteria 3, 4 and 6.		
Number of waterbird species counted at the site annually	Annual counts of waterfowl carried out at Logan Lagoon during February 1985 - 2009, excluding 1987, 1989, 1994 and 2008. The area counted varied among years and data are not comparable, making it difficult to detect population trends.	No LAC can be determined due to insufficient data. To be defined once population trends for waterfowl are clear from systematic annual counts.
Number of shorebirds recorded in annual surveys	There has been no systematic, long term monitoring of shorebirds within the Ramsar site to enable a numerical baseline to be set, although Birds Tasmania conducted counts along the ocean coastline of the site in 2008 and 2010, and is planning future work.	No LAC can be determined due to insufficient data. To be defined once population trends for shorebirds are clear from systematic annual counts.
Threatened mammals, reptiles, amphibians	Very little systematic data. Poor information on the current distribution and abundance of threatened species.	No LAC can be determined due to insufficient data. To be defined once systematic surveys undertaken for a range of species.

2.2.3.4 East Coast Cape Barren Islands Lagoons Ramsar Site

The East Coast Cape Barren Island Lagoons Ramsar site is located on the east coast of Cape Barren Island, one of the Furneaux Group of islands which lie in Bass Strait to the north-east of Tasmania. The site extends from just north of Tar Point down to Jamieson's Bay and extends westwards from the coast for a distance varying from one to four kilometres. The site meets two of the Ramsar Criteria: 1 and 3.

The East Coast Cape Barren Island Lagoons site is significant as it forms a representative sample of coastal lagoons in the Flinders Biogeographic Region and is relatively undisturbed. The Cape Barren Dunes, within the site, are a geoconservation site in Tasmania. Thirsty Lagoon is a hypersaline lagoon and is a Tasmanian estuary of critical conservation significance. Three of the lagoons within the site, Flyover Lagoon 1, Flyover Lagoon 2 and Little Thirsty Lagoon, have been assessed as near pristine wetlands for Tasmania.

The critical components and processes for the site at the time of listing in 1982 have been determined to be geomorphology, hydrology and vegetation types. While there is some anecdotal evidence that this site is important for shorebirds, there is insufficient data to evaluate whether they are a critical component (DSEWPAC, 2008).

The Ramsar site is an important habitat for a number of plant species and vegetation communities. Thirteen threatened species listed in Tasmania occur on the site, including the Furze hakea and horny cone bush. The site represents the only known reserve in Tasmania for the threatened pink bladderwort. The White-bellied sea eagle, listed as vulnerable in Tasmania, and the Ruddy turnstone, listed under international migratory conservation agreements, also occur within the site.

This area is of cultural importance to the local Indigenous community, who manage the freehold title to part of Cape Barren Island, including the Ramsar site. Access is currently restricted, keeping the site largely undisturbed (DSEWPAC, 2008).

In the context of the Bass Strait Operations and predicted geographical extent of the DA, critical components that may be affected by a major spill event include estuarine waters, coastal brackish or saline lagoons, intertidal marshes, intertidal mud sand or salt flat and, threatened flora species.

The locality of the Ramsar site is shown in Figure 2-8. The critical components and processes of the East Coast Cape Barren Island Lagoons Ramsar and its limits of acceptable change are shown in Table 2-10.

Figure 2-8 Locality of East Coast Cape Barren Island Lagoons Ramsar site (DSEWPAC, 2008)

Table 2-10 Summary of limits of acceptable change for the East Coast Cape Barren Island Lagoons Ramsar site (DSEWPAC, 2008)

Critical ecological components, processes and services	Baseline condition and range of natural variation where known	Limit(s) of Acceptable Change* (based on baseline and natural variability)	Basis of LAC	Level of confidence
Critical component and process: Geomorphology and Hydrology *Critical service:* Natural or near-natural wetland ecosystem	There is a diversity and range of Ramsar wetland types which are defined by their geomorphology and hydrology. There is an absence of information relating to the variability in extent and types of wetland around the time of listing	The areal extent of Ramsar wetland types does not change by ±20%, i.e. • estuarine waters ± 20% from 200 hectares • intertidal marshes ± 20% from 44 hectares • coastal brackish/saline lagoons ± 20% from 375 hectares • intertidal mud sand or salt flats ± 20% from 55 hectares.	Based on aerial photograph interpretation and geomorphological mapping by Mowling (2007).	Low: Limited confidence in estimates of aerial extent. Limited data on changes to geomorphology, hydrology and vegetation types since time of listing (refer to Chapter 7 of ECD).
Critical component and process: Hydrology *Critical service:* Natural or near-natural wetland ecosystem	Hydrology as a critical component and service is linked to the geomorphology of the wetland.	As above, this LAC is linked to the geomorphology of the wetland.	As above	As above
Critical component Vegetation types *Critical service*: Natural or near-natural wetland ecosystem	Thirteen different Tasmanian wetland vegetation communities were identified within site which corresponds to six TASVEG communities. Sixteen flora species have been recorded on site that are threatened in Tasmania. Vegetation succession is an integral component of the ECCBIL wetlands such that some changes in vegetation communities are normal.	Maintenance of the extant TASVEG vegetation communities on site at time of listing i.e. • lacustrine herbland (AHL) • freshwater aquatic sedgeland and rushland (ASF) • freshwater aquatic herbland (AHF) • saline aquatic herbland (AHS) • saline sedgeland/rushland (ARS)	Based on the limited available vegetation data i.e. TASVEG mapping, the Kirkpatrick and Harwood (1981) survey and expert opinion.	Low: Not confident in the data and not confident that this will represent a change in ecological character. Limited information about the variability in extent and condition of the vegetation types since the time of listing is available. Difficult to describe baseline condition and variability (refer to Chapter 7 of ECD).

Critical ecological components, processes and services	Baseline condition and range of natural variation where known	Limit(s) of Acceptable Change* (based on baseline and natural variability)	Basis of LAC	Level of confidence
		• succulent saline herbland (ASS).		

*Exceeding or not meeting a LAC does not automatically indicate that there has been a change in ecological character

2.2.3.5 Flood Plain Lower Ringarooma

The Flood Plain Lower Ringarooma River Ramsar site is located on the far north-east coast of Tasmania, between Cape Portland and Waterhouse Point and covers an area of 3519 hectares.

The Flood Plain Lower Ringarooma River Ramsar site is rare within the Drainage Division, as it is rare for large rivers in Tasmania to be flowing through flood plains and forming the mosaic of wetlands that the Ringarooma River does. The site contains good condition, regionally representative examples of wetland systems within a flood plain, with a mosaic of permanent and seasonal marshlands and a large river estuary (Boobyalla Inlet). Boobyalla Inlet is recognised as a Tasmanian estuary with high conservation significance.

The site meets Ramsar Criteria 1, 2, 3 and 4. It supports six fauna species listed as nationally threatened including four wetland dependant species. : green and gold frog (Litoria raniformis-Vulnerable) , dwarf galaxias (Galaxiella pusilla - Vulnerable), fairy tern (Sterna nereis- Vulnerable), Australian grayling (Prototroctes maraena - Vulnerable), Australasian bittern (Botaurus poiciloptilus - Endangered) and shiny grasstree (Xanthorrhoea bracteata - Endangered) (Newall and Lloyd, 2012a). The series of shallow freshwater lagoons at the site are an important feeding and nesting place for many species of waterbirds. A number of migratory birds have been recorded from the site, including eleven listed species.

The locality of the Ramsar site is shown in Figure 2-9. The critical components and processes of the Flood Plain Lower Ringarooma River site and its limits of acceptable change are shown in Table 2-11.

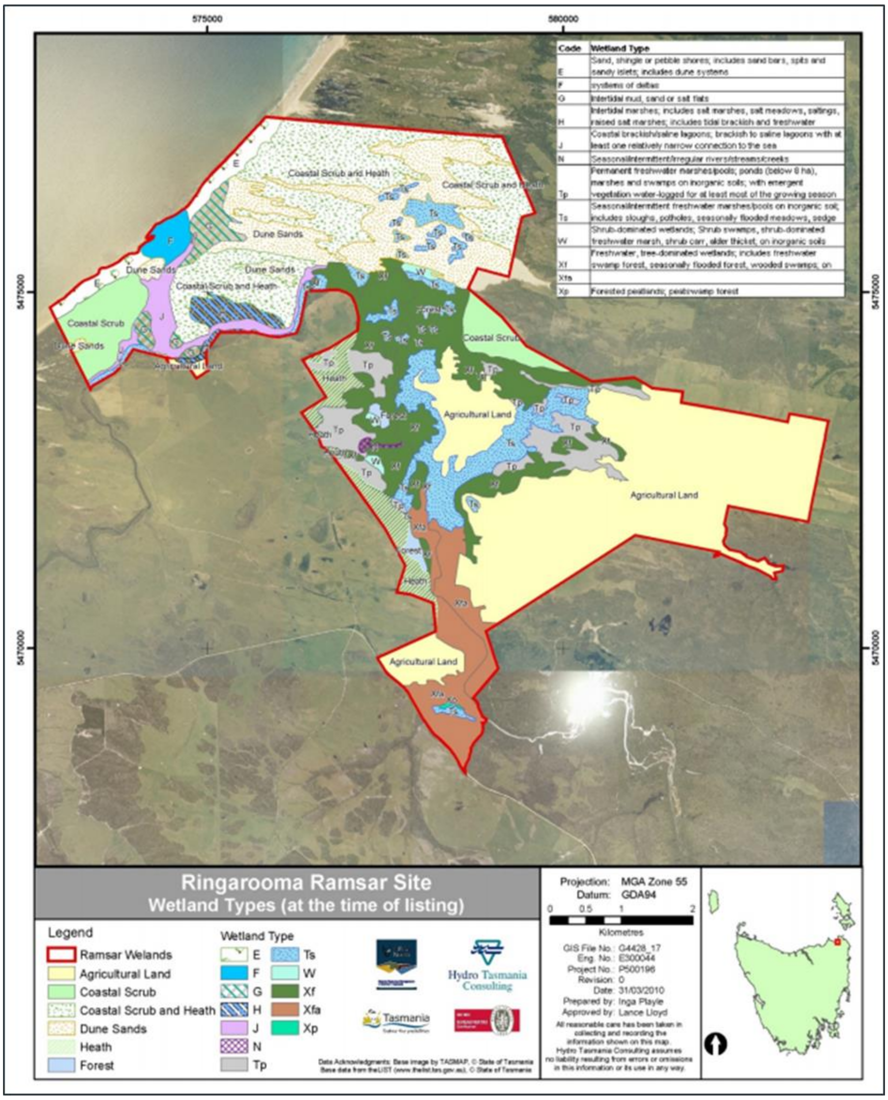

Figure 2-9 Locality and wetland type of Ringarooma Ramsar Site

Table 2-11 Critical Components and Limits of Acceptable Change for the Flood Plain Lower Ringarooma River Ramsar Site.

Critical Component, Process or Service	Baseline Information	Limits of acceptable change*	Confidence level	Justification and Comments
All Ramsar wetland types identified as being present at time of listing except Freshwater aquatic sedgeland and rushland (Ts) (service = supports Ramsar wetland types).	Using a vegetation survey (DPIW 2006), aerial photographs, and a site inspection, the following areas were identified for each wetland type (hectares): E = 74, F = 33 G = 58, H = 44 J = 74, N = 5 Tp= 169, W = 13 Xf = 614, Xp = 1	Not more than a 20 percent loss in area of any wetland type in nine out of 10 years. So that is, no more than: • 15 hectares for E • 6.5 hectares for F o 12 hectares for G • 9 hectares for H • 15 hectares for J • 1 hectare for N • 34 hectares for xp • 2.5 hectares for W • 123 hectares for Xf • 0.2 hectares for Xp	Medium – site specific measures of area are used: however, the 20 percent change is not quantitatively derived.	There are no data on the variability of the wetland habitat types and, until this ECD, there was no mapping of the wetland types. These limits have been set as a common sense approach to defining a significant change in the area of each wetland type. Monitoring into the future should incorporate changes to wetland type over time to refine this LAC.
Freshwater aquatic sedgeland and rushland (Ts) (service = supports Ramsar wetland types).	Using a vegetation survey (DPIW 2006), aerial photographs and a site inspection, an area of 257 hectares was identified as freshwater aquatic sedgeland and rushland at the time of listing.	No less than 298 hectares of freshwater aquatic sedgeland and rushland should be present at the site in nine out of 10 years. This represents 80 percent (for example a 20 percent loss) of the current area of this wetland type (373 hectares).	Medium – site specific measures of area are used: however, the 20 percent change is not quantitatively derived.	At listing, the site contained a large area of agricultural land (rough grazing) in Fosters Swamp. Grazing has subsequently ceased and the area allowed to regenerate into sedgeland and rushland, increasing the total area of this vegetation type to 373 hectares. There are no data on the variability of the wetland habitat type at the site and, until this ECD, there was no mapping of the wetland types. A limit of 20 percent has been set as a common sense approach to defining a significant change in the area of each wetland type. Monitoring into the future will refine this LAC.
Rare plant species (service = supporting populations important for regional biodiversity).	The only baseline information available is that four rare wetland dependent species were recorded as being at the site at the time of designation.	Presence in nine out of 10 years of: • native gypsywort • erect marshflower • purple loosestrife • ribbon weed	Low	There is no quantitative information on these species within the site. Therefore quantitative limits of acceptable change cannot be set and a qualitative LAC based on presence / absence of these four species is provided. Based on lack of data for the site, confidence in the LAC representing

Critical Component, Process or Service	Baseline Information	Limits of acceptable change*	Confidence level	Justification and Comments
				good indicator of change in ecological character is low.
Australian grayling and dwarf galaxias (service = support for rare or threatened species).	The only baseline information available is that these species were recorded as being at the site at the time of designation.	Presence in nine out of 10 years of: • Australian grayling • dwarf galaxias	Low	There is no quantitative information on any fish species at the site. Therefore quantitative limits of acceptable change cannot be set and a qualitative LAC based on presence / absence of the species is provided. Based on lack of data for the site, confidence in the LAC representing good indicator of change in ecological character is low.
Green and gold frog (service = support for rare or threatened species).	This species has been seen and heard at the site on different occasions. There are no quantitative data for this species.	Presence in nine out of 10 years of the green and gold frog	Low	There is no quantitative information on *Litoria raniformis* at the site. Therefore quantitative limits of acceptable change cannot be set and a qualitative LAC based on presence / absence of the species is provided. Based on lack of data for the site, confidence in the LAC representing good indicator of change in ecological character is low.
Migratory bird species (service = support for a population at a critical stage of its life cycle), and regionally rare bird species (service = supporting populations important for regional biodiversity).	The only baseline information available is that these eleven species were recorded as using the site at the time of designation.	Presence in 2 out of 3 years of: • Latham's snipe • curlew sandpiper • red-necked stint • ruddy turnstone • bar-tailed godwit • caspian tern • little tern • greenshank • cattle egret • great egret • white-bellied sea eagle	Low	There is no quantitative information on these species at the site. Therefore quantitative limits of acceptable change cannot be set and a qualitative LAC based on presence / absence of the species is provided. Based on lack of data for the site, confidence in the LAC representing good indicator of change in ecological character is low.
Nesting shorebird species (service = support for a population at a critical stage of its life cycle), and	The only baseline information available is that five species of shorebirds nest at the site, one of which (fairy	The presence of nesting populations in 2 out of 3 years for: • little tern • hooded plover	Low	There is no quantitative information on these species at the site. Therefore quantitative limits of acceptable change cannot be set and a qualitative LAC based on presence / absence of the species is provided. Based on lack of data for the site,

Critical Component, Process or Service	Baseline Information	Limits of acceptable change*	Confidence level	Justification and Comments
rare bird species (service = support for rare or threatened species).	tern) is listed on the IUCN redlist.	• fairy tern • pied oystercatcher • red-capped plover		confidence in the LAC representing good indicator of change in ecological character is low.
Migratory fish species (service = support for a population at a critical stage of its life cycle).	The only baseline information available is that three migratory fish species occur at the site, one of which is the rare Australian grayling.	Presence in 2 out of 3 years of: • Tasmanian mudfish • Tasmanian whitebait • Australian grayling	Low	Again, no quantitative information on these species at the site. Therefore quantitative limits of acceptable change cannot be set and a qualitative LAC based on presence / absence of the species is provided. Based on lack of data for the site, confidence in the LAC representing good indicator of change in ecological character is low.

2.2.3.6 Moulting Lagoon Ramsar Site

Moulting Lagoon Ramsar site comprises of an estuarine and marine waters system and is influenced by freshwater inflows from two permanent fresh water rivers which are not within the site boundary. Moulting Lagoon is located on the east coast of Tasmania, between the townships of Bicheno and Swansea and 6 kilometres north-west of Coles Bay and the Freycinet Peninsular. The site covers approximately 4507 hectares and lies within the municipality of Glamorgan-Spring Bay. The entire area of the site is Crown Land and is contiguous with the Apsley Marshes Ramsar site. The site, plus several sections of coastal reserve surrounding it and an additional area of land to the north, is located within the Moulting Lagoon Game Reserve, under the management of the Tasmanian Parks and Wildlife Service. Moulting Lagoon discharges into Great Oyster Bay via a narrow entrance at the end of a long sand spit (DoEE, 2019a).

Moulting Lagoon meets Ramsar Criteria 1, 2, 3, 4 & 8. It supports large numbers and a high diversity of waterbirds including shorebirds and waders. Twenty-two species of resident and migratory waders have been recorded onsite, with nine species regularly using the area. The site supports a number of threatened species listed under the Tasmanian Threatened Species Protection Act 1995 (TSPA) including the white-bellied sea eagle (Haliaeetus leucogaster; vulnerable); eastern curlew (Numenius madagascariensis, endangered); and great-crested grebe (Podiceps cristatus vulnerable); 13 plant species and a number of saltmarsh communities. The estuary also supports substantial populations of fish and diverse floristic communities. Wetland vegetation is dominated by two key types: saltmarsh and seagrass. These vegetation associations are critical components of the site's ecological character playing central roles in the provision of physical habitat for aquatic species as well providing key food resources, particularly for the waterbirds including migratory species. Moulting Lagoon and the Apsley Marshes provide a linkage between the inland waters of the Apsley River and the Southern Ocean. Regular migrations of short-finned eels (Anguilla australis), both on their seaward migration to breed as well as returning juveniles, are reported (Hale and Butcher 2011). In addition, black bream (Acanthopagrus butcheri) are known to travel up the drains, via Moulting Lagoon into the Apsley Marshes Ramsar site in order to spawn. Australian grayling (vulnerable, EPBC Act and TSPA) have also been recorded in the river upstream and presumably would use the site as a migratory route during breeding (DoSEWPaC, 2011).

Moulting Lagoon has indigenous cultural significance as part of the lands were occupied by the Oyster Bay Tribe, which included most of the east coast from the Derwent estuary to the Fingal Valley and west inland to the Midlands. Currently only eight sites have been registered on the Tasmanian Aboriginal Site Index.

The locality of the Ramsar site is shown in Figure 2-10. The critical components and processes of the Moulting Lagoon site and its limits of acceptable change are shown in Table 2-12.

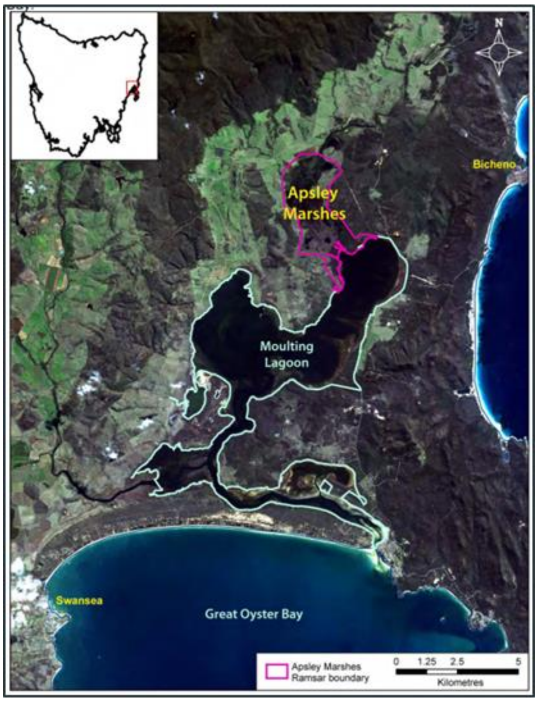

Figure 2-10 Locality of Moulting Lagoon and Apsley Marches Ramsar Sites (Hale &Butcher, 2011).

Table 2-12 Limits of Acceptable Change for the Moulting Lagoon Ramsar site

Critical Component/ Process / Service	Baseline Information and Justification	Limit of acceptable change*	Confidence level
Hydrology	Moulting Lagoon receives freshwater inflows from the Swan and Apsley Rivers. The Department of Primary Industries, Parks, Water and Environment, Tasmania monitor flow events into Moulting Lagoon at stream gauges located at Swansea Grange and Apsley upstream at Coles Bay Road. This information is stored and accessible via WIST (The Water Information System of Tasmania). There is a relatively high degree of inter annual variability in inflows. For example, from 1968 to 1992 average daily flow during winter ranged from less than 10 megalitres a day to over 5000 megalitres a day (data from State of Tasmania 2010). The tidal influence and estuarine conditions that prevail in the site are critical to the character of the site. However, there is limited information other than tide heights for this source of water. The site supports a range of estuarine wetland types including intertidal mud and sand flats, and sea grass beds. However mapping and other information is insufficient to determine extent and variability at the time of listing. In the absence of sufficient data LAC are based on no change in hydrological wetland types.	No change in wetland hydrological types present within the site. That is, the following hydrological wetland types are maintained: • • Dominance of estuarine waters; • • Presence of marine subtidal aquatic beds - seagrass beds; • • Presence of sand bars, spits, dune systems; • • Presence of intertidal mud, sand and salt flats; • • Presence of intertidal saltmarsh and salt meadows; and • • Presence of brackish to saline lagoons.	M
Wetland vegetation-saltmarsh	Some mapping of plant communities has been undertaken as part of the TASVEG program; however extent of saltmarsh vegetation within the Ramsar site is considered a knowledge gap. As such a quantitative LAC for this component cannot be set and will require revision should such information become available.	No less than 90 percent of the extent of saltmarsh communities within the Ramsar site.	L
Wetland vegetation – seagrass	Detailed mapping of seagrass was completed by Mount et al. (2005) (for the Great Swanport estuary part of the site) and Lucieer et al. (2009) for Moulting Lagoon. The combined figures from these studies indicate 2200 hectares of Ruppia; 940 hectares of seagrass (mixed Heterozostera tasmanica and Zostera muelleri) and 50 hectares of macroalgae. The mapping is a single snap shot in time and does not provide an indication in variability. The LAC has therefore been based on an arbitrary figure of 25 percent reduction from baseline mapping.	No less than 1650 hectares of Ruppia and 700 hectares of seagrass (*Heterozostera tasmanica* and *Zostera muelleri*).	H
Wetland vegetation – threatened species	The Management Plan for the Moulting Lagoon Game Reserve (PWS 2007), which covers a larger area than the Ramsar site, indicates that 13 plant species listed under the Tasmanian Threatened Species Protection Act 1995 occur “in and around” the game reserve (Appendix 2). Moulting Lagoon is recognised as being important for the conservation of some of these species such as: large fruit sea tassel Ruppia megacarpa (rare) and the spreading watermat Lepilaena patentifolia (rare) both of which are marine angiosperms; southern swampgrass Amphibromus neesii (rare), which is found at Charlie Diglers Hole; and native broom Viminaria juncea, for which Moulting Lagoon is the only known Tasmanian population.	Continued presence of the following species within the Ramsar site: *Ruppia megacarpa;* *Lepilaena patentifolia Amphibromus neesii and* *Viminaria juncea*	M

Critical Component/ Process / Service	Baseline Information and Justification	Limit of acceptable change*	Confidence level
	However, how many of the 13 species occur within the Ramsar site and are important to the ecological character of the site remains unknown. The LAC is based on continued presence of those species currently known to occur in the site and for which the site has been recognised as important for their conservation.		
Fish	Last (1993) recorded 36 fish species from Great Swanport estuary. Last also described habitat preferences for these species.	No less than 28 of recorded fish species (Last 1983) are present at least once every 10 years.	H
Waterbirds – abundance	Three waterbird species have greater than one percent of their population occurring at the site on a regular basis. These species are a major reason for the site's Ramsar listing. Further reductions in population numbers may be beyond site management control, but it is vital to the site's ecological character that it still retains the quality and quantity of habitat required by waterbirds for foraging and breeding. Long-term regional trends for these species can be used to underpin the LAC. If trends in species counts move opposite to regional trends, this may indicate issues at the site, and might be used as a management trigger for these LAC. The LAC for individual species are provided for the intrinsic value of the species but also in part as a surrogate for the waterbird community as a whole. For black swan the 20th percentile+ as a minima of the current data (1992 to 2009, S. Blackhall data) has been used to derive the LAC as the species move into and out of the site on a seasonal basis. For pied oystercatcher and Pacific gull the 80th percentile+ of the current data (1992 to 2009, S. Blackhall data) has been used to derive the LAC.	No less than 7000 black swan (*Cygnus atratus*) in eight out of 10 years.	H
		No less than 200 pied oystercatcher (*Haematopus longirostris*) in five out of 10 years.	H
		No less than 80 Pacific gull (*Larus pacificus*) in five out of 10 years	H
Waterbirds - breeding	Of the waterbirds which breed at the site, the most significant in terms of occurrence and abundance is the black swan, which breeds annually within the site.	Presence of black swan (Cygnus atratus) breeding within the site on an annual basis.	H
Supports near natural wetland types	Wetland types are maintained by hydrology and vegetation.	See LAC for hydrology and vegetation communities.	N/A
Physical habitat for waterbird (breeding, roosting and feeding).	Physical habitat for waterbirds is maintained through wetland types and can be indicated by the numbers of waterbirds supported by the site.	See LAC for hydrology, vegetation and waterbirds.	N/A
Provides drought refuge	Drought refuge is maintained by hydrology.	See LAC for hydrology.	N/A

Critical Component/ Process / Service	Baseline Information and Justification	Limit of acceptable change*	Confidence level
Supports biodiversity including threatened species	Biodiversity values of the site lie predominantly with the high diversity of wetland flora, waterbirds and fish and can be indicated by the species richness of these groups.	See LAC for vegetation, fish and waterbirds.	N/A
Ecological connectivity	Connectivity for fish migration is maintained through hydrological connections from Moulting Lagoon to inland freshwater wetlands via the Aspley River. While the LAC for hydrology partially addresses this service, it is important that physical connectivity is also retained and that obstructions to water flow are not introduced to the site	No barriers to hydrological connectivity between Moulting Lagoon and the Aspley River.	H

2.2.3.7 Apsley Marshes Ramsar Site

The Apsley Marshes Ramsar site is located on the east coast of Tasmania, within the Tasmanian Drainage Division (bioregion), 14 kilometres south west of the town of Bicheno (population in 2007; 640). The site covers approximately 880 hectares and lies within the municipality of Glamorgan-Spring Bay. The site is situated almost entirely within private (freehold) land and is contiguous with and inland of Moulting Lagoon Ramsar site (Refer Section 2.2.3.6, Figure 2-10 above). It meets Ramsar Criteria 1, 2, 3, 4 & 8. The wetland has 82 native species of wetland plant; including six species that are considered rare or threatened within the bioregion and the nationally vulnerable swamp everlasting (Xerochrysum palustre) and ten wetland vegetation associations. There are 26 species of waterbird recorded including the internationally endangered Australasian bittern (Botaurus poiciloptilus). It is also a significant breeding site for black swans (Cygnus atratus); confirmed breeding of three additional species including the white-bellied sea-eagle and potential breeding of three more waterbird species (Hale &Butcher, 2011).

2.2.3.8 Western Port Ramsar Site

The Western Port Ramsar site situated in south-eastern Australia, approximately 60 km south-east of Melbourne, Victoria, occupies approximately 59,950 ha and consists of large shallow intertidal areas dissected by deeper channels, and a narrow strip of adjacent coastal land in some areas. The Ramsar site has long been recognised for its diversity of native flora and fauna, particularly for its ability to support diverse assemblages of waterbirds and wetland vegetation, including seagrass, saltmarsh and mangroves. As such, the site as listed in 1982 satisfies criteria 1a, 1b, 2, 3a, 3b, 3c, 4 and 8.

2.2.3.9 Little Waterhouse Lake Ramsar Site

Little Waterhouse Lake, part of the Waterhouse Point wetlands complex, is located seven kilometres south-west of Waterhouse Point, and lies between the towns of Bridport and Tomahawk on the north-east coast of Tasmania.

Little Waterhouse Lake is a good example of a coastal freshwater body in good condition in the Flinders Biogeographic Region. The site forms part of the Waterhouse Dunefield Geoconservation site, a system of current, active dunes moving over the top of much older longitudinal dunes, which developed at the height of the last glacial stage when Bass Strait was dry and arid.

2.2.3.10 Lavinia Ramsar Site

Lavinia Ramsar Site (7,034 ha) is situated on the northeast coast of King Island in Bass Strait. King Island lies between the north-west tip of Tasmania and Cape Otway in Victoria. The site is listed under Ramsar criteria 1, 2, 3 and 4 (Newall and Lloyd, 2012b). The site has 4 ecosystem units and the coastal components include estuarine waters, intertidal mud and marshes, saline/brackish lagoons and rocky/sand/shingle shores. The site is important for supporting regionally rare flora and fauna and providing habitat for ten migratory bird species listed under international agreements. It provides nesting habitat for waterbirds and seabirds including the threatened fairy tern and orange-bellied parrot. The vulnerable green and gold frog are also found at the site (Newall and Lloyd, 2012b).

2.2.3.11 Myall Lakes Ramsar site

The large area of 44,612 ha making up the Myall Lakes Ramsar site is entirely within the Port Stephens Great Lakes Marine Park (NSW) just to the north of Newcastle city on the NSW central coast. It supports a rich biodiversity, containing a range of undisturbed terrestrial and wetland vegetation communities with a large number of plant and animal species. The site's vegetation is particularly diverse, with 968 species of terrestrial and aquatic plants recorded, and vegetation communities ranging from littoral rainforest to forest, heath, grassland, swamp, mangrove, seagrass, submerged aquatic vegetation and emergent freshwater vegetation. It is listed under Ramsar criterion 1a, 1c, 2a and 3b. There are 22 species of shorebirds listed under migratory bird agreements (JAMBA, CAMBA and ROKAMBA) which use the site as roosting, feeding, nesting and breeding habitat. The lakes support 5 wetland dependent threatened species including the endangered, Australasian bittern, 3 vulnerable frog species and 1 endangered frog species (NSW OEH, 2012a).

2.2.3.12 Hunter Estuary Wetlands Ramsar site

The Hunter Estuary Wetlands Ramsar site is comprised of two components, Kooragang is located in the estuary of the Hunter River, 7km north of Newcastle comprising of 3,388 ha and Hunter Wetlands Centre is a small, 42 ha complex approximately 2.5 km south west of the Kooragang (NSW OEH, 2012b). The site meets Ramsar criteria 2, 4 and 6. The site is extremely important as both a feeding and roosting site for a large seasonal population of shorebirds and as a waylay site for transient migrants. Over 250 species of birds have been recorded within the Ramsar site, including 45 species listed under international migratory conservation agreements. In addition, the Ramsar site provides habitat for the nationally threatened Green and Golden Bell Frog, Red Goshawk and Australasian Bittern (Brereton et al., 2010).

2.2.3.13 Towra Point Nature Reserve Ramsar Site

Towra Point Nature Reserve Ramsar site consists of 386.5 hectares of wetlands that lie on the southern shore of Botany Bay, approximately 16 kilometres from Sydney city centre. The entire Ramsar site lies within Towra Point Nature Reserve (Refer Section 2.2.8.67). The site meets Ramsar criteria 2, 3, 4 & 8. Towra Point is a critical roosting and feeding habitat for large numbers of migratory shorebird species and a significant nesting site for the endangered little tern (Sterna albifrons). The mangroves and seagrass provide protection and food for juvenile fish species. Studies have shown that a higher abundance and diversity of fish species are found in areas of mangrove and saltmarsh which are adjacent to seagrass than are found in isolated communities. The release of crab larvae from saltmarsh areas during spring ebb tides provides a reliable source of food for a variety of fish species and a critical link in the estuary's food web. Towra Point is important in providing ecological connectivity for itinerant species, and is important for maintaining biodiversity in the greater Sydney region. Threats to the site include its proximity to one of the largest ports in eastern Australia; alterations to the shoreline, hydrology and bathymetry of Botany Bay causing increased wave energy on the southern side of the bay; residential and industrial development within the catchment; invasive species; and the impacts of climate change including sea level rise (DECCW, 2010).

2.2.3.14 Elizabeth and Middleton Reefs Ramsar Site

Elizabeth and Middleton Reefs are located in the northern Tasman Sea, 630 km east of Coffs Harbour (NSW); 690 km east-southeast of Brisbane (Queensland); and 150 km north of Lord Howe Island. Elizabeth and Middleton Reefs are a pair of isolated oceanic platform reefs separated from one another by 45 km of deep oceanic waters and together they represent the southern-most platform reefs in the world. Elizabeth Reef measures 8.2 km by 5.5 km and Middleton Reef, slightly larger but of a similar shape, at 8.9 km by 6.3 km. The site is listed under Ramsar criteria 1, 2, 3, 4 and 8.

Critical Services provided by this site are:

- It is representative of a unique ecosystem in the bioregion: southern-most open ocean coral reef platform in the world;
- It supports threatened species: Green turtle (Chelonia mydas) (feeding habitat only, no nesting);
- It supports regionally high species diversity: fish; coral communities; molluscs; and sea cucumbers (beche-de-mer).
- It supports animal taxa at a vulnerable or critical stage of their lifecycle, particularly the Galapagos Shark (Carcharinus galapagensis)(likely nursery ground); and,
- It supports the last known large population of Black Cod (Epinephelus daemelii).

The threats to this site are the Crown of Thorns starfish which is present at the reefs however its distribution and abundance is not well known. Other threats are illegal fishing of Black Cod and other species (including for the aquarium trade), coral bleaching due to thermal changes in temperature and also water quality changes form pollution (DEWHA, 2006).

2.2.3.15 Moreton Bay Ramsar Site

The Moreton Bay Ramsar site is located in and around Moreton Bay, north-east, east and south-east of the city of Brisbane, in the state of Queensland. The site is 1,206 km^2 and includes most of Moreton Island, and parts of North and South Stradbroke Islands, Bribie Island, the southern Bay Islands, inclusive of the National Parks and Marine Parks in those areas. It is notable for its large size, diversity of wetland habitats, connectivity between wetland types, as well as diverse flora and fauna that includes threatened species and ecological communities. It contains seagrass, sandy and muddy tidal flats and subtidal areas, saltmarsh, mangroves and coral communities, freshwater wetlands, as well as ocean beaches and dunes. The site is listed under all nine of the Ramsar criteria (RSIS, 2019).

Critical Services provided by this site are:

- It includes one of the most extensive intertidal areas of seagrass, mangrove and saltmarsh communities on the eastern coast of Australia, and is valuable for supporting fisheries resources, waterbirds and marine megafauna of conservation significance.
- It regularly supports more than 50,000 waterbirds, representing at least 43 species of shorebirds and at least 28 migratory shorebird species. The site is recognised as a network site under the East Asian Australasian Flyway Partnership and supports at least nine migratory shorebird species, including the critically endangered eastern curlew (Numenius madagascariensis) and curlew sandpiper (Calidris ferruginea).
- It supports a range of internationally, nationally, state and locally significant species including the Oxleyan pygmy perch fish, four species of acid frogs, the water mouse, Illidge’s ant-blue butterfly, and several freshwater invertebrates.
- The site provides important cultural, social, economic and recreational values

Conservation measures focus on managing water quality from human, agricultural, industrial and commercial threats.

2.2.3.16 Great Sandy Strait Ramsar Site

Great Sandy Strait (including Great Sandy Strait, Tin Can Bay and Tin Can Inlet) is a sand passage estuary between the mainland and the World Heritage-listed Fraser Island. It covers an area of approximately 837 km2. The site is listed under Ramsar criteria 1, 2, 3, 5, 6 and 8 (RIS, 1999).

Critical Services provided by this site are (DAWE, 2020a):

- It is an outstanding example of a sand passage estuary and is in a relatively undisturbed state. Large, well developed expanses of sand and mud flats, salt flats, mangroves and seagrass beds are widespread along the Strait.
- It provides feeding grounds that are frequently or occasionally used by six species of threatened marine turtle, the Green Turtle, Loggerhead Turtle, Hawksbill Turtle, Flatback Turtle, Leatherback Turtle and Pacific Ridley Turtle. Other threatened species that occur in the site include the Dugong, Humpback Whale, Water Mouse, Illidge's Ant Blue Butterfly, and the Oxleyan Pygmy Perch
- It supports at least 38 species of shorebirds, 104 species of fish, 27 species of molluscs, hard & soft coral species, 11 species of mangrove, and seven species of seagrass. The mangrove communities within the Strait represent a transition between essentially temperate and tropical species
- Wetlands along Great Sandy Strait regularly support in excess of 20,000 migratory shorebirds and support more than 1% the total world population of the Eastern Curlews, Grey-tailed Tattlers, Lesser Sand Plovers, Terek Sandpipers, Whimbrels, Bar-tailed Godwits, Pied Oystercatchers, Greenshanks, and Grey Plovers
- The tidal wetlands are extremely important for protection of, and source of food for, juvenile and adult fish, prawns and other crustaceans. It is highly valued for commercial and recreational fishing.

Great Sandy Strait is located close to regional population centres (Maryborough and Hervey Bay) that are rapidly growing and causing development pressures to the site including increased water extraction, clearing of land and seagrass disturbance, landfill and dredging and pressures from expanding agriculture (RIS, 1999).

2.2.4 Threatened Ecological Communities

Ecological communities are a group of native flora, fauna and other organisms that naturally occur together and interact in a unique habitat. Their structure, composition and distribution are determined by environmental factors such as soil type, location (e.g. altitude/depth), climate, and water availability, chemistry and movement (e.g. oceanic currents) and thereby changes to any one or a combination of these factors threatens the viability of the community. Species within each ecological community interact with and depend on each other for survival. Ecological communities are important because of their unique combination of native biodiversity, distinctive landscape/seascape values, vital habitat qualities and for the ecosystem services they provide. There are three types of listed threatened ecological communities (TEC) within the DA.

2.2.4.1 Giant Kelp Marine Forests of South East Australia

The 'Giant Kelp Marine Forests of South East Australia' is listed as an endangered TEC under the EPBC Act. Kelps are very large brown algae that grow on hard sub tidal substrates in cold temperate regions. Kelps have a holdfast that attaches to the substrate, a stem-like or trunk-like stipe, and large, flattened, leaf-like blades called fronds. Because kelps require constant water motion to provide nutrients, they are located in relatively high-energy settings. Kelp forests support a diverse animal community of fish, invertebrates, and marine mammals as well as important algal communities (NOAA 2010). The ecological community is characterised by a closed to semi-closed surface or subsurface canopy of Macrocystis pyrifera, and extends between the ocean floor and ocean surface, exhibiting a 'forest-like' structure with a diverse range of organisms occupying its benthic, pelagic and upper-canopy layers (TSSC 2012). M. pyrifera is the only species of kelp to provide this three-dimensional structure from the sea floor to the sea surface (TSSC 2012). This ecological community occurs on rocky substrate along the east and south coastlines of Tasmania; some patches may also occur in the coastal waters of western and northern Tasmania, south eastern South Australia, and Victoria (TSSC 2012).

The high primary and secondary productivity of the giant kelp forests create and provide a number of ecosystem services to the local environment including settlement habitat for juvenile life stages of commercially important fisheries, improvements in local water quality conditions and coastal protection via buffering strong wave conditions from reaching the shore (TSSC 2012).

The key threats affecting the ecological community include increasing sea surface temperatures, changes in nutrient availability in warmer waters, changes in weather patterns and large scale oceanographic conditions, and associated range expansion of invasive species (TSSC 2012). Other threats include impacts on water quality from land-based activities and aquaculture and potential loss from catastrophic storm events (TSSC 2012). Figure 2-11 shows the distribution of the Giant Kelp Marine Forests of south east Australia.

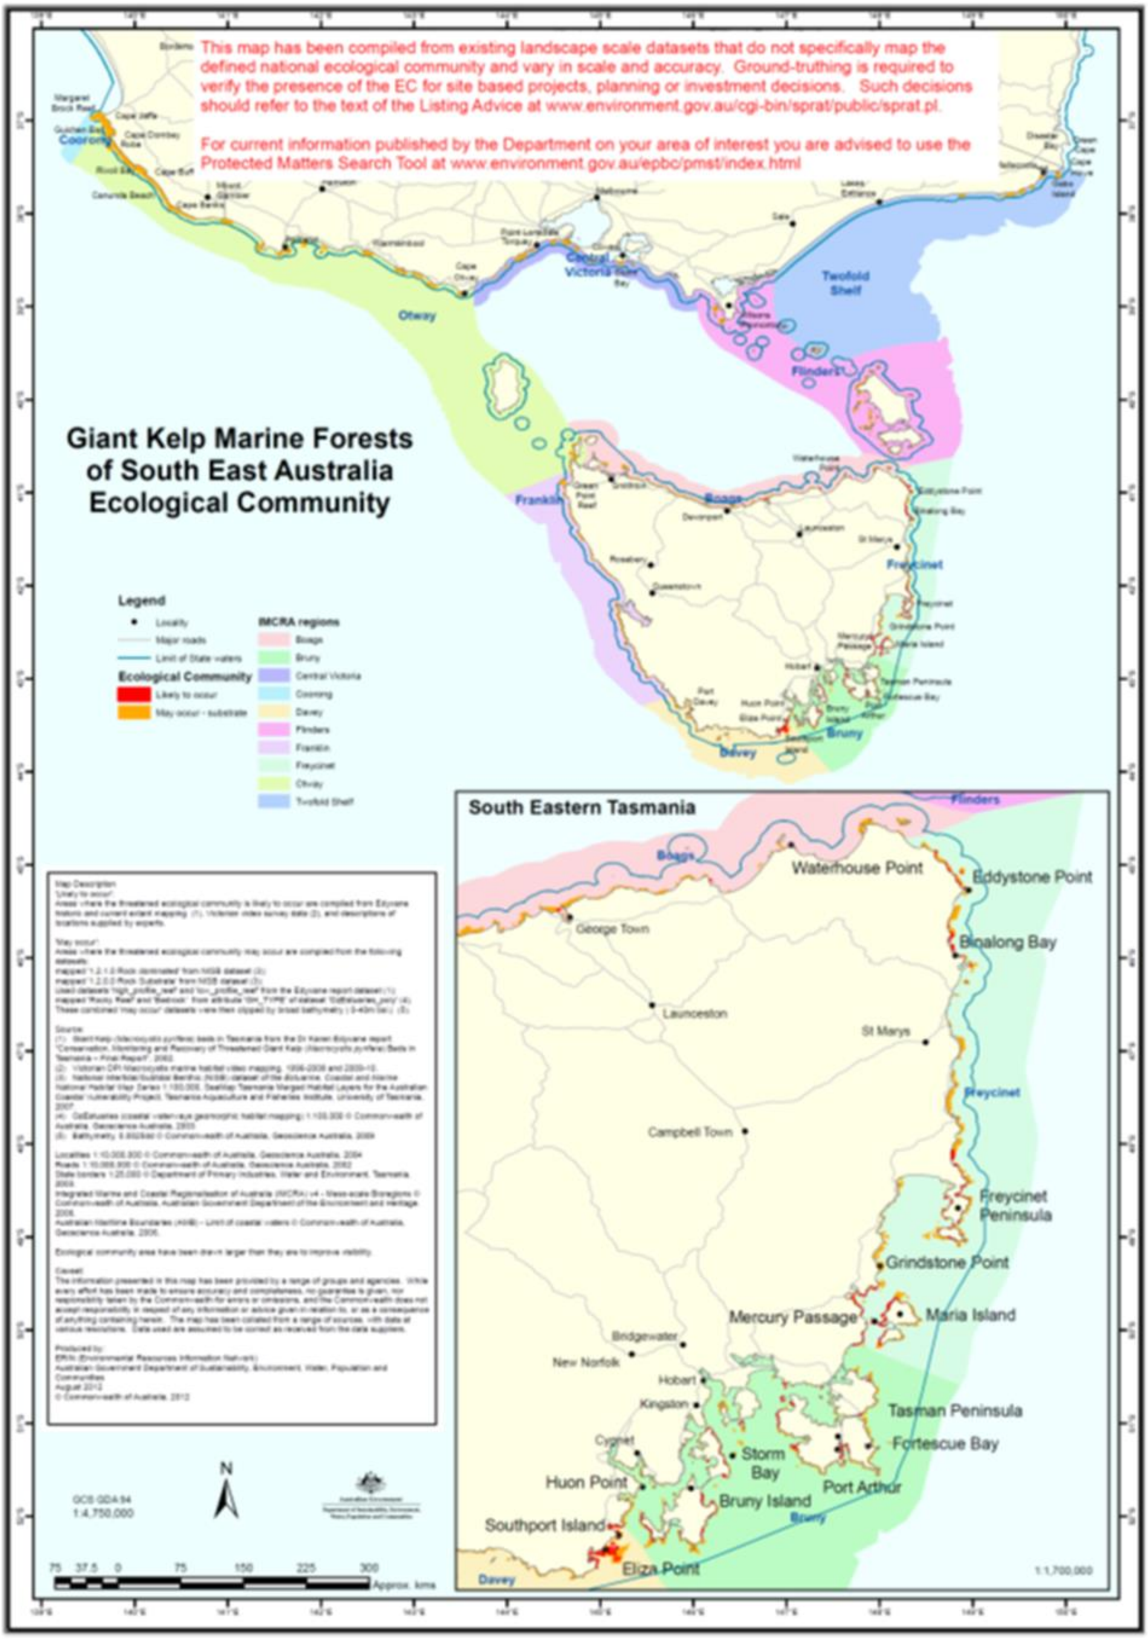

Figure 2-11 Distribution of Threatened Ecological Communities - Giant Kelp Marine Forests of South East Australia

2.2.4.2 Littoral Rainforest and Coastal Vine Thicket

The 'Littoral Rainforest and Coastal Vine Thickets of Eastern Australia' is listed as a critically endangered TEC under the EPBC Act. The ecological community is a complex of rainforest and coastal vine thickets on the east coast of Australia influenced by its proximity to the sea; and provides habitat for over 70 threatened plants and animals and provides important stepping stones along the eastern Australian coast for various migratory and marine birds (DoE&PI, 2014). It also provides an important buffer to coastal erosion and wind damage (TSSC, 2015a; DoEE, 2017s).

The ecological community occurs as a series of naturally disjunct and localised stands within two kilometres of the eastern coastline of Australia or adjacent to a large saltwater body, such as an estuary on a range of landforms including dunes and flats, headlands and sea-cliffs, including offshore islands, from Princess Charlotte Bay, Cape York Peninsula to the Gippsland Lakes in Victoria (TSSC, 2015a). Figure 2-12 shows the detailed distribution of Littoral Rainforest within East Gippsland. Figure 2-13 shows the distribution of Littoral Rainforest in New South Wales.

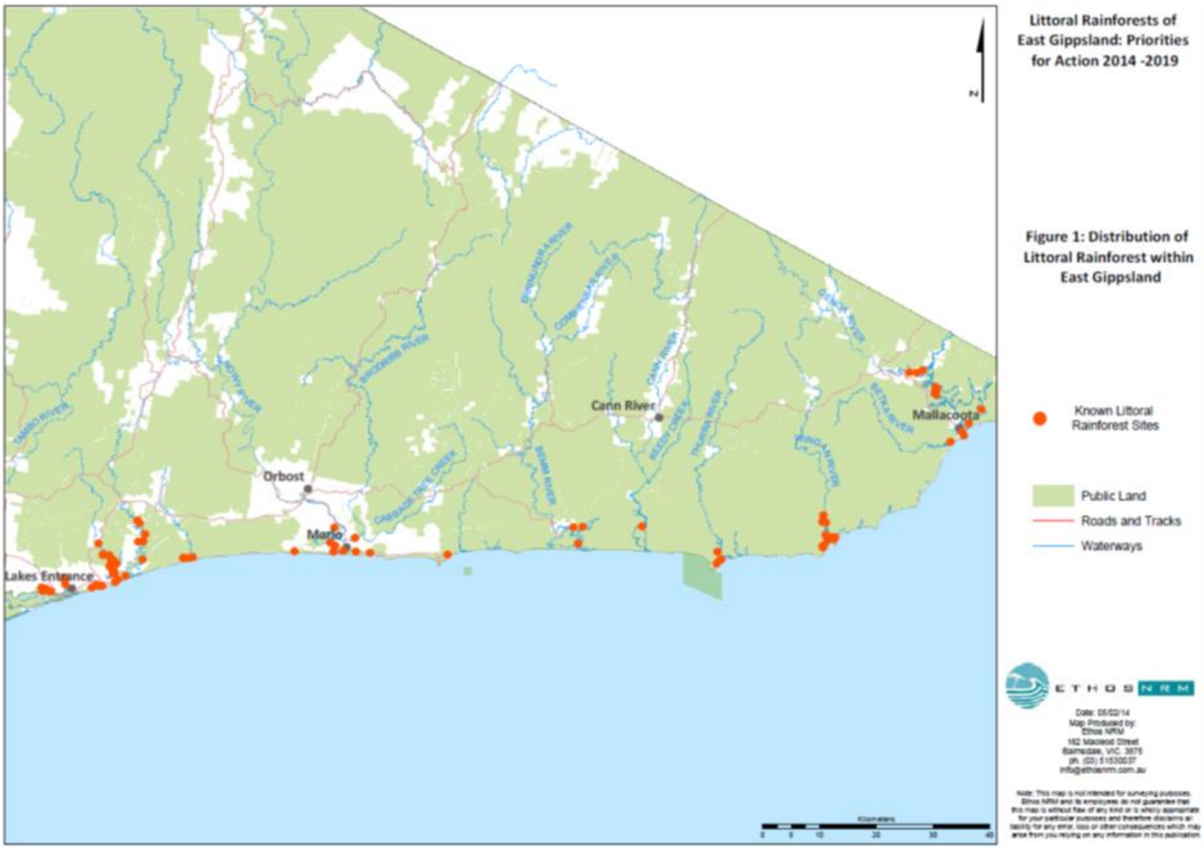

Figure 2-12 Distribution of Threatened Ecological Communities - Littoral Rainforest within East Gippsland (Vic DoE&PI, 2014 Littoral Rainforests of East Gippsland: Priorities for Action 2014-2019)

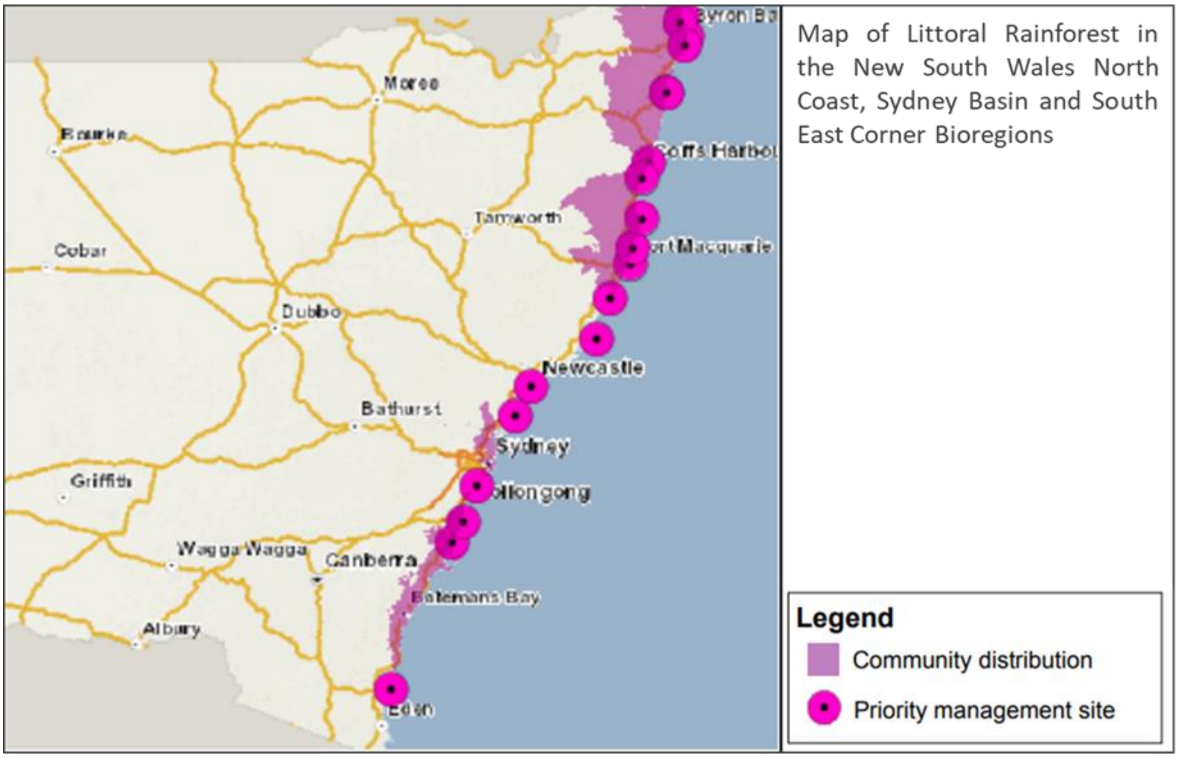

Figure 2-13 Distribution of Threatened Ecological Communities - Littoral Rainforest in NSW (NSW OEH, 2017)

2.2.4.3 Subtropical and Temperate Coastal Saltmarsh

The 'Subtropical and Temperate Coastal Saltmarsh' is listed as a vulnerable Threatened Ecological Community (TEC) under the EPBC Act, and its known distribution includes the southern and eastern coasts of Australia (Figure 2-14). The Subtropical and Temperate Coastal Saltmarsh ecological community occurs within a relatively narrow margin along the Australian coast, within the subtropical and temperate climatic zones; and includes coastal saltmarsh occurring on islands within these climatic zones (TSSC, 2013a). The physical environment for the ecological community is coastal areas under regular or intermittent tidal influence (TSSC, 2013a).

The ecological community consists mainly of salt-tolerant vegetation (halophytes) including: grasses, herbs, sedges, rushes and shrubs (TSSC, 2013a). Many species of non-vascular plants are also found in saltmarsh, including epiphytic algae, diatoms and cyanobacterial mats (TSSC, 2013a). The ecological community is inhabited by a wide range of infaunal and epifaunal invertebrates, and temporary inhabitants such as prawns, fish and birds (and can often constitute important nursery habitat for fish and prawn species) (TSSC, 2013a). Insects are also abundant and an important food source for other fauna, with some species being important pollinators (TSSC, 2013a). The dominant marine residents are benthic invertebrates, including molluscs and crabs that rely on the sediments, vascular plants, and algae, as providers of food and habitat across the intertidal landscape (TSSC, 2013a).

The key threats affecting the ecological community include: clearing and fragmentation, infilling, altered hydrology/tidal restriction, invasive species, climate change, mangrove encroachment, damage from recreational activities, pollution (including oil spills), eutrophication, acid sulphate soils, grazing, insect control, salt and other mining activities, and inappropriate fire regimes (TSSC, 2013a).

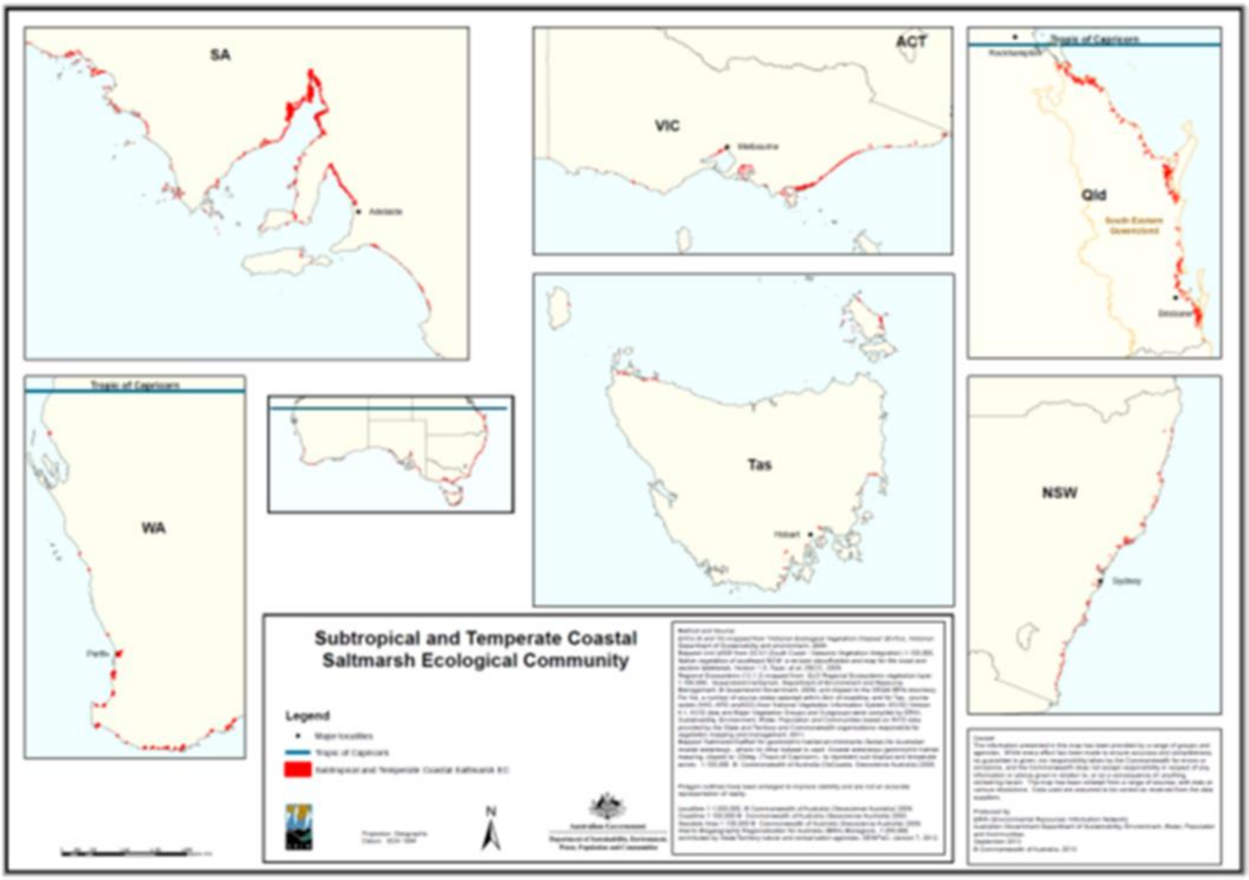

Figure 2-14 Distribution of the TEC Subtropical and Temperate Coastal Saltmarsh

2.2.5 Commonwealth Marine Areas

Six marine regions have been identified in Commonwealth waters around Australia. Marine bioregional planning is designed to better protect marine environments, conserve biodiversity and deliver greater certainty to resource users and decision-makers about the marine conservation priorities of the Australian Government. The majority of the DA lies within the South-east Marine Region. A portion of the north-eastern section of the DA overlaps with the Temperate East Marine Region (Refer Figure 2-15 in Section 2.2.6 below).

The key conservation values of the South-east Marine Region are:

- Features with high biodiversity and productivity, such as the east Tasmania subtropical convergence zone, Bass Cascade, Upwelling east of Eden, Seamounts south and east of Tasmania and Bonney coast upwelling.
- Breeding and resting areas for Southern right whale.
- Migration areas for Blue, Fin, Sei, Southern right and Humpback whales.
- Foraging areas for Australian sea-lion, White shark, Harrison's dogfish, Killer and Sei whales, Australasian gannet, Fairy prion, Black-faced cormorant, Little penguin, Crested tern, and several species of seal, penguin, albatross, petrel, shearwater and gulls.
- Wrecks of MV City of Rayville, SS Cambridge and ketch Eliza Davies.
- 10 provincial bioregions and 17 seafloor types are represented in the network (DoEE, 2015a)

The Temperate East Marine Region spans an area of approximately 1.4 million square kilometres from the southern boundary of the Great Barrier Reef in Queensland to Bermagui in Southern New South Wales. The key conservation values of the Temperate East Marine Region relevant to the DA are:

- Features with high biodiversity and productivity such as the Canyons of the Eastern Continental Slope and Shelf rocky reefs

- Nesting sites for listed seabirds on islands along the NSW coast, including Montague Island (Short-tailed shearwater, Sooty shearwater)
- Breeding sites for Little penguin, shearwater, Wilson's storm petrel, Crested tern
- Migration areas for Humpback whale
- Breeding sites for Indo-Pacific Bottlenose Dolphin
- Foraging sites for several species of petrel, albatross, shearwater
- 3 provincial bioregions

2.2.6 Australian Marine Parks

Australian Marine Parks have been established in Commonwealth waters for to contribute to the long term conservation of marine ecosystems and protect marine biodiversity found in them, while also allowing for sustainable use of natural resources. The Australian Marine Parks are protected areas.

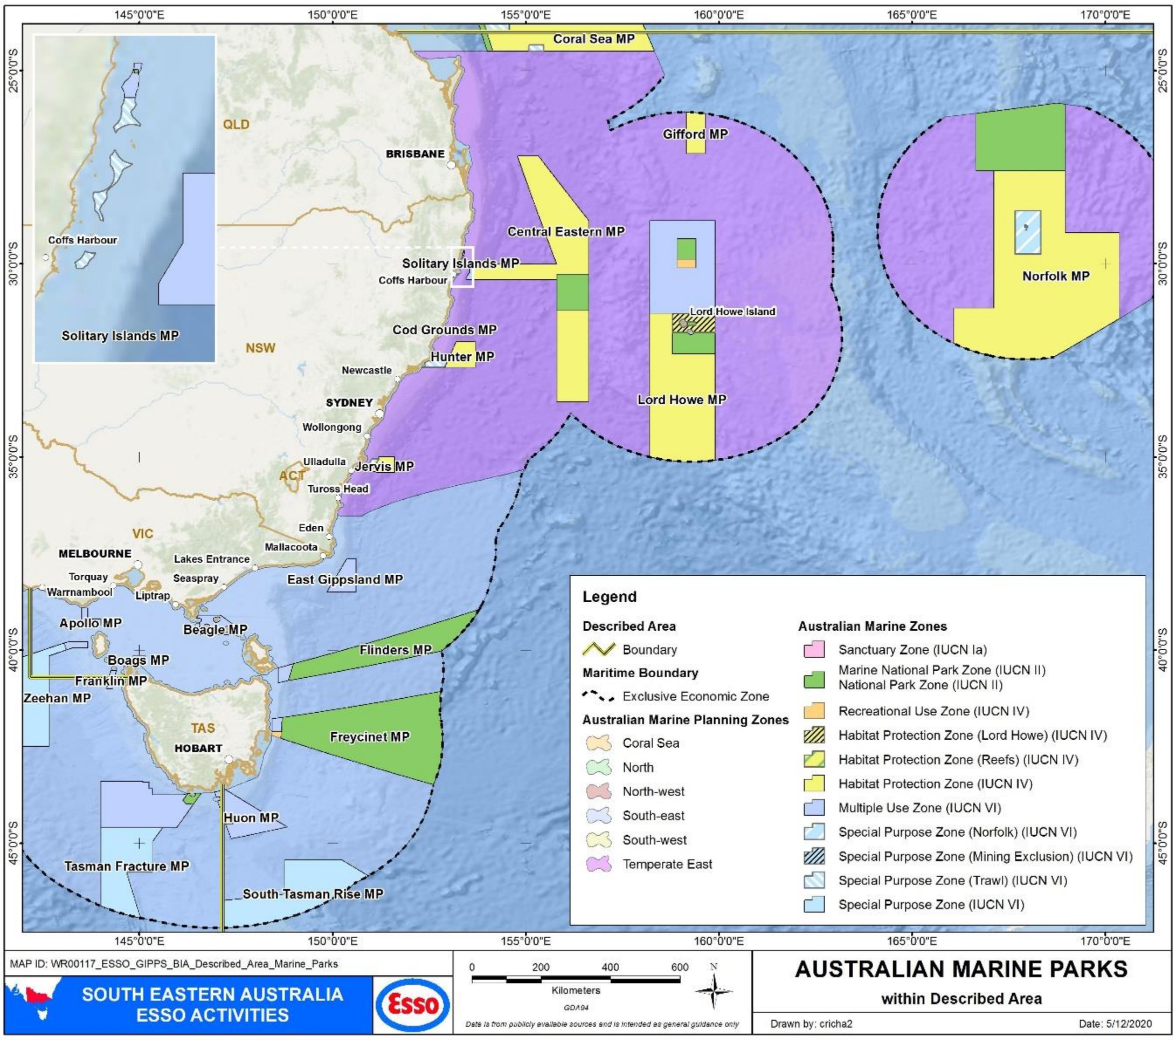

Figure 2-15 Australian Marine Parks within the DA

2.2.6.1 East Gippsland Marine Park

The East Gippsland Marine Park (4,137 km2) is off the north-east corner of Victoria, on the continental slope and escarpment and the closest of the Marine Parks to the EGBPA. The full area of the Marine Park is designated as a multiple use zone (IUCN VI).

The East Australian Current funnels warm waters through the marine park over the complex seafloor features causing eddies to form off Cape Howe. This results in conditions in which phytoplankton flourish, thereby attracting and supporting an abundance of marine life. The main features of the seafloor are the continental shelf, the steep escarpments and deep canyons.

Details of the East Gippsland Marine Park are listed in Table 2-13 (DNP, 2013). The full extent of the East Gippsland Marine Park occurs within the DA (Figure 2-15); as such all conservation values identified above are considered applicable to this region.

Table 2-13 East Gippsland CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP, 2013)

Important migration area for:
• Humpback whale</td></tr>
<tr><td>Location</td><td colspan="4">The East Gippsland Commonwealth Marine Reserve is off the north-east corner of Victoria, on the continental slope and escarpment.</td></tr>
<tr><td>General description of the reserve</td><td colspan="4">The East Gippsland Commonwealth Marine Reserve contains representative samples of an extensive network of canyons, continental slope and escarpment at depths from 600 m to more than 4000 m.

The geomorphic features of this reserve include rocky-substrate habitat, submarine canyons, escarpments and a knoll, which juts out from the base of the continental slope.

The reserve includes both warm and temperate waters, which create habitat for free-floating aquatic plants or microscopic plants (i.e. phytoplankton) communities. Complex seasonality in oceanographic patterns influences the biodiversity and local productivity.

The East Australian Current brings subtropical water from the north, and around Cape Howe the current forms large eddies, with a central core of warm water. Around the outside of the eddies, cooler, nutrient-rich waters mix with the warm water creating conditions for highly productive phytoplankton growth, which supports a rich abundance</td></tr>
</table>

	of marine life. During winter, upwellings of cold water may occur and bring nutrient-rich waters to the surface, boosting productivity. Many oceanic seabirds forage in these waters, including albatrosses (e.g. Wandering, Black-browed, Yellow-nosed and Shy albatrosses), the Great- winged petrel, Wedge-tailed shearwater and Cape petrel. Humpback whales pass by during their migrations north and south along the eastern seaboard.

2.2.6.2 Beagle Marine Park

The Beagle Marine Park (2,928 km2) lies entirely within Bass Strait, encompassing Tasmania's Kent Group Marine Reserve and the Hogan and Curtis Island groups; and is nearby to the north-east is Victoria's Wilsons Promontory Marine National Park. The full area of the Marine Park is designated as a multiple use zone (IUCN VI).

The Beagle Marine Park was once dry land which connected mainland Australia to Tasmania. After the ending of the last ice-age, the melting glaciers caused sea levels to rise and the connection to Tasmania was lost leaving the Bass Strait islands and an area of shallow waters 50-70m depth. Further information on the Hogan Group of islands, the Kent Group and other protected areas is described in Section 2.2.8, National Parks and Reserves. Detailed information on the Beagle Marine Park is presented in Table 2-14 (DNP, 2013).

The full extent of the Beagle Marine Park occurs within the DA (Figure 2-15); as such all conservation values identified in the park are considered applicable to this region.

Table 2-14 Beagle CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP, 2013)

Proclaimed	28 June 2007			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN VI—Multiple Use Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
				Multiple Use Zone
Depth of reserve below seabed	100 m			
Total area	2,928 km^2 (292 800 ha)			
Major conservation values	Ecosystems, habitats and communities associated with: • the Southeast Shelf Transition. and associated with sea-floor features: • basin • plateau • shelf • sill Important migration and resting on migration area for: • southern right whale Important foraging area for: • Australian fur seal • Killer whale • Shy albatross, Australasian gannet, Short-tailed shearwater, Pacific and Silver gulls, • Crested tern, Common diving petrel, Fairy prion, Black-faced cormorant and Little penguin			

	• White shark Cultural and heritage sites: • the wreck of the steamship SS Cambridge • the wreck of the ketch Eliza Davies
Location	The Beagle Commonwealth Marine Reserve lies entirely within Bass Strait, with its north-western edge abutting Victorian waters south-east of Wilson's Promontory. It is a shallow-water reserve surrounding a collection of Bass Strait islands.
General description of the reserve	The Beagle Commonwealth Marine Reserve represents an area of shallow continental shelf ecosystems in depths of about 50–70 m that extends around south-eastern Australia to the east of Tasmania. The sea floor that it covers formed a land bridge between Tasmania and Victoria during the last ice age 10 000 years ago. Its boundary encloses Tasmania's Kent Group Marine Reserve and the Hogan and Curtis Island groups. Nearby to the north-east is Victoria's Wilsons Promontory Marine National Park. The reserve encompasses the fauna of central Bass Strait, which is expected to be especially rich based on studies of several sea floor–dwelling animal groups. Its ecosystems are similar to those documented for the deeper sections of the Kent Group Marine Reserve, especially those based around habitats of rocky reefs supporting beds of encrusting, erect and branching sponges, and sediment composed of shell grit with patches of large sponges and sparse sponge habitats. Islands encompassed by the reserve and nearby islands support important breeding colonies for many seabirds and for the Australian fur seal. The waters of the reserve provide an important foraging area for those species breeding nearby. The rich marine life also attracts top predators, such as the great white shark and killer whales. The SS Cambridge, a British freighter, which lies in the reserve to the east of Wilson's Promontory, was sunk in 1940 by a WWII mine. The trading ketch Eliza Davies, which lies in the reserve to the east of Wilson's Promontory, sunk under tow in 1924.

2.2.6.3 Flinders Marine Park

The Flinders Marine Park (27,043 km2) is east of the north-east tip of Tasmania and Flinders Island, and extends over 400 km eastward. The Marine Park has two management zones: Marine National Park (IUCN II), and a multiple use zone (IUCN VI).

Seafloor habitats found in this marine park are the continental shelf, and a long section of steep continental slope cut through by a series of deep canyons, a large seamount and areas of sandy and muddy sediments. As per the East Gippsland Marine Park, Flinders Marine Park is influenced by the East Australian Current forming large-scale eddies which ultimately result in an abundance of marine fauna. Detailed information on the Beagle Marine Park is presented in Table 2-15 ((DNP, 2013)).

The full extent of the Flinders Marine Park occurs within the DA (Figure 2-15); as such all conservation values identified above are considered applicable to this region.

Table 2-15 Flinders CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP, 2013)

IUCN category assigned by this Management Plan and reserve management zone name	IUCN II—Marine National Park zone			
	IUCN Ia	IUCN II	IUCN IV	IUCN VI

Assigned zones in reserve: **2**		Marine National Park Zone		Multiple Use Zone
Depth of reserve below seabed	100 m			
Total area	27 043 km^2 (2 704 300 ha)			
Major conservation values	Examples of ecosystems, habitats and communities associated with: • the Tasmania Province • the Tasmanian Shelf Province • the Southeast Transition • the Southeast Shelf Transition And associated with sea-floor features: • abyssal plain/deep ocean floor • canyon • plateau • seamount/guyot • shelf slope Features with high biodiversity and productivity: • east Tasmania subtropical convergence zone Important foraging area for: • wandering, black-browed, yellow-nosed and shy albatrosses, northern giant petrel, Gould's petrel and cape petrel • killer whale • white shark • Harrison's dogfish Important migration area for: • humpback whale			
Location	The Flinders Commonwealth Marine Reserve is east of the north-east tip of Tasmania and Flinders Island, and extends over 400 km eastward.			
General description of the reserve	The Flinders Commonwealth Marine Reserve covers a depth range from about 40 m on the shallow continental shelf to abyssal depths of 3000 m or more near the edge of Australia's exclusive economic zone. Key features of this area are the continental shelf, and a long section of steep continental slope, incised by a series of deep submarine canyons. Sea bottom habitats include sheer rocky walls and large rocky outcrops that support a rich diversity of small seabed animals, such as lace corals and sponges. These and the large expanses of sandy and muddy sediments are habitats to a wide variety of fishes and to populations of the giant crab. Areas between 400 m and 600 m of the continental slope sea floor are habitat for dogfish and gulper sharks, and Harrison's dogfish has been recently recorded in the reserve. The biodiversity of the reserve is influenced by summer incursions of the warm East Australian Current and associated large-scale eddies. Another prominent feature is a large offshore seamount believed to be too deep to have been fished. Seamounts are generally considered to be important centres of deep ocean biodiversity, offering a wide range of habitats at different depths and			

	orientations to currents. The large seamounts to the east of Tasmania are believed to be individually important, providing habitat to species that may be unique to each seamount and to a range of more widely occurring species that make their homes only on their rocky slopes. Presently, little is known about the fauna of these seamounts, but based on information from other better known offshore seamounts, seabed animals are expected to include endemic species.

2.2.6.4 Freycinet Marine Park

The Freycinet Commonwealth Marine Park (57,942 km2) is east of Tasmania, offshore from the Freycinet Peninsula. The Marine Park has three management zones: Marine National Park (IUCN II), recreational use zone (IUCN IV) and a multiple use zone (IUCN VI).

The Freycinet Marine Park begins offshore from Bicheno and Freycinet National Park on the east coast of Tasmania and extends out to over 3,000 m depth covering seafloor features such as seamounts, deep sea (abyssal) plains, canyons and deep granite reefs. Detailed information on the Freycinet Marine Park is presented in Table 2-16 (DNP, 2013).

The offshore region of the Freycinet Marine Park occurs within the DA (Figure 2-15); as such all conservation values relevant to the deeper offshore waters are considered applicable to this region.

Table 2-16 Freycinet CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP, 2013)

Depth of reserve below seabed	100 m			
Total area	57 942 km^2 (5 794 200 ha)			
Major conservation values	Examples of ecosystems, habitats and communities associated with: • the Tasmania Province • the Tasmanian Shelf Province • the Southeast Transition And associated with sea-floor features: • abyssal plain/deep ocean floor • canyon • escarpment • knoll/abyssal hill • saddle • seamount/guyot • shelf			

	• terrace Features with high biodiversity and productivity: • east Tasmania subtropical convergence zone Important foraging area for: • wandering, black-browed and shy albatrosses, cape petrel and fairy prion • sei whales and killer whales Important migration and resting on migration area for: • southern right whale Important migration area for: • humpback whale
Location	The Freycinet Commonwealth Marine Reserve is east of Tasmania, offshore from the Freycinet Peninsula.
General description of the reserve	The Freycinet Commonwealth Marine Reserve covers a depth range from about 40 m on the shallow continental shelf, to abyssal depths of 3000 m or more at the edge of Australia's exclusive economic zone. The reserve spans the continental shelf and deeper water ecosystems that extend around south-eastern Australia to the east of Tasmania. The shelf is adjoined to a large offshore saddle. The reserve also includes large offshore seamounts, which are believed to be too deep to have been fished. Seamounts are generally considered to be important centres of biodiversity. They offer a wide range of habitats at different depths and orientations to currents. The seamounts east of Tasmania are also believed to be individually important, providing habitat to species that may be unique to each seamount. The shallower part of the reserve includes habitat important to seabirds. White shark also forage in the reserve.

2.2.6.5 Boags Marine Park

The Boags Marine Park is north of Three Hummock Island off Tasmania's north-west coast. It covers 537 square kilometres, with depths mostly between 40 metres and 80 metres.

The shallow waters of central Bass Strait are home to rich arrays of animals that live on the seafloor and in the sediment, including crustaceans, molluscs and polychaete worms. Seabirds from colonies on nearby islands forage also in the area (DNP, 2013).

The marine park is a Multiple Use Zone.

Table 2-17 Boags CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP, 2013)

Proclaimed	28 June 2007			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN VI—Multiple Use Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
				Multiple Use Zone

Depth of reserve below seabed	100 m
Total area	537 km2 (53 700 ha).
Major conservation values	Ecosystems, habitats and communities associated with:: • the Bass Strait Shelf Province And associated with sea-floor features: • plateau • tidal sandwave/sandbank Important foraging area for: • shy albatross, Australasian gannet, short-tailed shearwater, fairy prion, black-faced cormorant, common diving petrel and little penguin
Location	The Boags Commonwealth Marine Reserve is off the north-west tip of Tasmania, north of Three Hummock Island. The reserve is wholly contained within western Bass Strait.
General description of the reserve	The Boags Commonwealth Marine Reserve represents an area of shallow ecosystems that has a depth range mostly between 40m and 80 m. It encompasses the fauna of central Bass Strait, which is expected to be especially rich based on studies of several sea floor–dwelling animal groups. The Boags Marine Reserve contains a rich array of life, particularly bottom-dwelling animals and animals living in the sea-floor sediments and muds, such as crustaceans, polychaete worms and molluscs, as is common for the Bass Strait seabed. The reserve is adjacent to the important seabird breeding colonies of Tasmania's north-west, particularly the Hunter group of islands (Three Hummock Island, Hunter Island, Steep Island, Bird Island, Stack Island and Penguin Islet), and so is an important foraging area for a variety of seabirds. White shark also forage in the reserve.

2.2.6.6 Apollo Marine Park

The Apollo Commonwealth Marine Reserve (118,400 ha) is representative of the continental shelf that extends from South Australia to the west of Tasmania. The park is located off the southern tip of Cape Otway just beyond the Victorian state boundary down to the north of King Island in Tasmania. The waters of the reserve are exposed to large swell waves generated from the south-west and strong tidal flows. Detailed information on the Apollo Marine Park is presented in Table 2-18 (PA, 2019c).

Table 2-18 Apollo CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (PA, 2019c)

Proclaimed	28 June 2007			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN VI—Multiple Use Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
				Multiple Use Zone
Depth of reserve below seabed	100 m			
Total area	1184 km2 (118 400 ha).			
Major conservation values	Ecosystems, habitats and communities associated with:: • the Western Bass Strait Shelf Transition • Bass Strait Shelf Province And associated with sea-floor features: • deep hole valley			

	• shelf Important migration area for: • blue, fin, sei and humpback whales Important foraging area for: • black-browed and shy albatross, Australasian gannet, short-tailed shearwater, and crested tern
Location	The Apollo Commonwealth Marine Reserve is in Bass Strait south of Cape Otway and Apollo Bay in western Victoria, and north-west of King Island.
General description of the reserve	The Apollo Commonwealth Marine Reserve represents the continental shelf that extends from South Australia to the west of Tasmania. The cool waters of the reserve are less than 50 m deep near Cape Otway. The reserve includes the Otway Depression, a 100 m deep undersea valley joining the Bass Basin to the open ocean. This valley was an outlet channel for the ancient Bass Lake and mainland river systems, which existed during the last ice age. The waters of the reserve are exposed to large swell waves generated from the southwest and strong tidal flows. The sea floor has many rocky reef patches interspersed with areas of sediment and, in places, has rich, benthic fauna dominated by sponges. Seabirds, dolphins, seals and white shark forage in the reserve, and blue whales migrate through Bass Strait. The MV City of Rayville, a United States of America freighter, which lies in the reserve south of Cape Otway, was sunk in 1940 by a mine.

2.2.6.7 Zeehan Marine Park

The Zeehan marine park is south-west of King Island. It covers 19,897 km^2 with depths from about 50 metres to over 3000 metres. The park has four undersea canyons cutting into the continental shelf. The Zeehan current, an extension of the Leeuwin current from the west runs along the west coast of Tasmania and reaches the southern tip at its strongest point in winter. Zeehan Marine Park is a nursery ground for blue warehou and ocean perch. Concentrations of larval fish of these species are found in the marine park as well as the commercially fished species of Tasmanian giant (PA, 2019e).

Table 2-19 Zeehan CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (PA, 2019e)

</table>

	• Bass Strait Shelf Province And associated with sea-floor features: • abyssal plain/dep ocean floor • canyon • deep hole valley • knoll/abyssal hill • shelf • slope Important migration area for: • blue and humpback whales Important foraging area for: • black-browed, wandering and shy albatross and great-winged and cape petrels
Location	The Zeehan Commonwealth Marine Reserve is north-west of Tasmania.
General description of the reserve	The Zeehan Commonwealth Marine Reserve covers a broad depth range, from the shallow continental shelf at a depth of about 50 m to the abyssal plain, which is over 3000 m deep. A significant feature of this reserve is a series of four submarine canyons that incise the continental slope, extending from the shelf edge to the abyssal plain. Biodiversity and productivity on the outer shelf and upper slope in this reserve are influenced by the Zeehan Current and its interactions with the canyons. The reserve includes a variety of seabed habitats, including exposed limestone, that support rich animal communities of large sponges and other, permanently fixed, invertebrates on the continental shelf. There are also extensive 'thickets' of low invertebrate animals, such as lace corals and sponges, on the continental slope. These communities are exceptionally diverse and include species new to science. The rocky limestone provides important habitats for a variety of commercial fish species, including Australia's giant crab. Concentrations of larval blue warehou and ocean perch indicate the area is a nursery ground. It is also a foraging area for a variety of seabirds and white shark.

2.2.6.8 Franklin Marine Park

The Franklin Marine Park is located off the north-western point of Tasmania, south of King Island. It mostly comprises of water depths of approximately 40 m except for a deep valley in the southern end of the reserve which drops to 150m depth. Seabirds from the numerous breeding colonies on nearby islands including Albatross Island, Black Pyramid Rock and other Hunter Group islands forage in the park (PA, 2019d). Detailed information on the Franklin Marine Park is presented in Table 2-20 (PA, 2019d).

Table 2-20 Franklin CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (PA, 2019d))

Proclaimed	28 June 2007			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN VI—Multiple Use Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
				Multiple Use Zone
Depth of reserve below seabed	100 m			
Total area	671 km2 (67 100 ha).			
Major conservation values	Ecosystems, habitats and communities associated with:: • The Tasmanian Shelf province • the Western Bass Strait Shelf Transition			

	And associated with sea-floor features: • shelf • deep hole valley • escarpment • plateau Important foraging area for: • shy albatross, short-tailed shearwater, Australasian gannet, fairy prion, little penguin, common diving petrel, black-faced cormorant and silver gull
Location	The Franklin Commonwealth Marine Reserve is west of the north-western corner of Tasmania and south-east of King Island.
General description of the reserve	The Franklin Commonwealth Marine Reserve represents an area of shallow continental shelf ecosystems and incorporates areas of two major bioregions: western Bass Strait and the Tasmanian shelf. Its cool temperate waters are exposed to large swells driven by westerly gales. At its northern end, the waters are only 40 m deep, and in much of the reserve the sea floor slopes gently and is covered by fine and coarse sediments. At the southern end of the reserve there is a valley where the water is up to 150 m deep. The reserve provides a feeding ground for a variety of seabirds, such as the fairy prion, shy albatross, silver gull, short-tailed shearwater, black-faced cormorant and common diving petrel that have breeding colonies on the nearby Hunter group of islands. Black Pyramid Rock, 6 km north of the reserve supports the largest breeding colony of the Australasian gannet in Tasmania, and one of only eight breeding sites for this species in Australia. White shark also forage in the reserve

2.2.6.9 Huon Marine Park

The Huon Commonwealth Marine Park off Southern Tasmania covers approximately 991 square kilometres of outer continental shelf, continental slope and deeper seabed, ranging from 70 metres to over 3000 metres. It has more than 120 seamounts within the marine park, the largest cluster in Australia. The seamounts are cone-shaped remnants of extinct volcanoes rising from the seafloor, up to 25km across at the base and rising 200 to 500 m from the seabed. Some 'summits' are over 1000 metres below the surface. In an otherwise bare substrate, seamounts provide hard, elevated and current swept attachment sites for communities of filter feeding fauna such as corals, sponges, sea stars and anemones (CSIRO, 2007). Their structural form made of massive accumulations of the reef building stony coral also provides habitat for a smaller mobile fauna such as crustaceans, brittle stars, urchins and molluscs. The marine park protects spawning grounds for basketwork eels and commercial fish species, including ocean perch. Details of the Huon Marine Park are listed in Table 2-21 (PA, 2019a).

The marine park has Habitat Protection and Multiple Use zones. The Tasmanian seamounts are also on the Commonwealth Heritage List and are also listed as a key ecological feature (refer Section 2.2.7.5).

Table 2-21 Huon CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (PA, 2019a)

Proclaimed	28 June 2007			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN VI—Multiple Use Zone			
Assigned zones in reserve:			IUCN IV	IUCN VI
2			Habitat Protection Zone (389 km2)	Multiple Use Zone (9602 km2)

Depth of reserve below seabed	100 m
Total area	9991 km2 (999 100 ha)
Major conservation values	Examples of ecosystems, habitats and communities associated with: • the Tasmanian Shelf Province • the Tasmania Province And associated with sea-floor features: • canyon • knoll/abyssal hill (seamount) • pinnacle • saddle • shelf • terrace Features with high biodiversity and productivity: • seamounts south and east of Tasmania Important foraging area for: • black-browed, Buller's and shy albatrosses, great-winged petrel, short-tail shearwater and fairy prion • Australian fur seal and killer whale • Important migration area for: • humpback whale
Location	The Huon Commonwealth Marine Reserve is south-east of Tasmania.
General description	The Huon Commonwealth Marine Reserve covers a broad depth range from the inner continental shelf at about 70 m, to abyssal depths of more than 3000 m. The majority of the area is in deep water. The Tasman Seamounts Marine Reserve that was proclaimed in 1999 has been wholly incorporated into the Huon Commonwealth marine reserve. The reserve contains a cluster of seamounts that appear as cone-shaped submerged mountains, which provide a range of depths for a diversity of plants and animals. The peaks of many of the reserve's seamounts are between 750 m and 1000m below the sea surface and support endemic species, including large erect corals and sponges. Some of the flora and fauna are hundreds and possibly thousands of years old, making them some of the longest-lived animals on Earth. The reserve also provides an important connection between seamounts of the Indian Ocean and the Tasman Sea. Seamounts are regarded as areas of increased productivity in the otherwise nutrient-poor open ocean. Their topography accelerates water currents to provide a consistent and relatively rich food source for filter feeders, and which sweeps the seamounts clear of fine sediments, exposing rocks for animals, such as corals, to attach to. Seamounts are generally considered to be important stepping stones in the transoceanic dispersal of larvae of bottom-dwelling species. The habitat protection zone was established to protect the unique and vulnerable benthic communities of the reserve's seamounts. The zone includes seamounts rising 650–1000 m above the sea floor, which have been subject to commercial fishing. Deeper seamounts, peaking at 1150–1700 m above the sea floor, have not been fished, and are in pristine condition. Benthic communities include coral dominated communities found at depths less than 1400 m. The hard coral Solensomilia variabilis forms a dense matrix that provides a platform for hydroids and sponges; stone corals; and black, gold and bamboo corals. Benthic communities deeper than 1400 m are urchin dominated. The reserve is a foraging area for white shark and seabirds and a spawning or nursery area for important commercial fish, including ocean perch and blue warehou.

2.2.6.10 Solitary Islands Marine Park

Solitary Islands Marine Park offshore northern NSW is a place where many species occur at the limits of their range as the East Australian Current meets cooler waters from the south. The marine park includes Pimpernel Rock, a submerged pinnacle rising to within a few metres of the surface. Also, the critically endangered grey nurse sharks gather here, making it a popular dive spot. Details of the park are described in Table 2-22 (DNP, 2018).

</table>

Location	Located approximately 5.5 km offshore of New South Wales, adjacent to the NSW Solitary Islands Marine Park (adjacent to the north coast, NSW).
General description of the reserve	The Solitary Islands Marine Park is significant because it contains habitats, species and ecological communities associated with the Central Eastern Shelf Transition. The Marine Park contains habitat for species of special conservation interest such as grey nurse sharks, and biologically important areas for humpback whale, white shark and a number of migratory seabirds. The Marine Park includes habitats connecting to and complementing the adjacent New South Wales Solitary Islands Marine Park. The Marine Park includes habitats connecting to and complementing the adjacent New South Wales Lord Howe Island Marine Park.

2.2.6.11 Lord Howe Marine Park

The Lord Howe Marine Park surrounds the NSW Lord Howe Island Marine Park (refer Section 2.2.8.37) and extends further seaward to 12 nautical miles. The waters – a unique mix of warm tropical and cool temperate ocean currents – are home to over 500 fish species, more than 90 coral species and countless other marine species, many only found in the immediate area. A wide range of habitats include a barrier coral reef and lagoon, and fringing reefs dominated either by coral or macroalgal communities. Details of the park are described in Table 2-23 (DNP, 2018).

Table 2-23 Lord Howe Marine Park CMR: Temperate East Marine Parks Network Management Plan 2018 (DNP, 2018)

Proclaimed	14 December 2013			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN category IV - Habitat Protection Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
		National Park Zone	Habitat Protection Zone Habitat Protection Zone (Lord Howe) Recreation Zone	Special Purpose Zone (Trawl)
Depth of reserve below seabed	between 15 m and 6000 m.			
Total area	110,126 km ²			
Major conservation values	Ecosystems, habitats and communities associated with:: • Lord Howe Province—due to the convergence of warm, tropical and cooler temperate waters in the area, the Marine Park supports a unique mix of tropical, subtropical and temperate species, many found at the northern or southern extent of their range. • Tasman Basin Province—interactions between currents, eddies and seamounts and the movements of the deep sub-Antarctic water mass influence biological productivity in this area. Important area for: • Foraging and breeding of seabirds • Migrating humpback whales			

	Key ecological features of the Marine Park are: • Lord Howe Seamount Chain—a chain of submerged volcanoes running 1000 km north–south, the seamount chain includes Lord Howe Island and Elizabeth and Middleton Reefs. These isolated, oceanic reefs support a diverse range of tropical and temperate marine life, including both warm-water and cold-water corals and an abundance of fish species. This diversity is a result of the effect of the East Australian Current on the reefs as it exposes the area to its warm waters, in contrast to the surrounding cooler ocean. • Elizabeth and Middleton Reefs—small, isolated, oceanic platforms reefs that occur on top of the volcanic seamounts of the Lord Howe seamount chain. The lagoons of both reefs are important areas for populations of black cod and the Galapagos shark. • Tasman Front and eddy field—a region that separates the warm, nutrient-poor waters of the Coral Sea from the cold, nutrient-rich waters of the Tasman Sea, providing increased nutrients and plankton aggregations, and enhanced productivity that attracts mobile species such as turtles, cetaceans, tuna and billfish. Culture • The marine environment around Lord Howe Island has long held significance among Lord Howe Islanders. A unique community and culture has developed by those who have visited and settled the island over time Sea country is valued for Indigenous cultural identity, health and wellbeing. • Across Australia, Indigenous people have been sustainably managing their sea country for tens of thousands of years. At the commencement of this plan, there is limited information about the cultural significance of this Marine Park due to its remote location World Heritage • Parts of the Marine Park are within the world heritage-listed Lord Howe Island Group, which was listed as an area of outstanding universal value under the World Heritage Convention in 1982. The Lord Howe Island Group comprises Lord Howe Island, Admiralty Islands, Mutton Bird Islands, Ball's Pyramid, and associated coral reefs and marine environments. It includes spectacular landscapes, volcanic mountains, and diverse low-lying rainforests, palm forests and grasslands. There are a large number of species of native plants, of which many are endemic to Lord Howe Island, and colonies of endangered seabirds. National Heritage • The Lord Howe Island Group was included in the National Heritage List in 2007. Historic shipwrecks • The Marine Park contains over 25 known shipwrecks listed under the Historic Shipwrecks Act 1976. Social and economic values • Tourism, commercial fishing, recreation, including fishing, and scientific research, are important activities in the Marine Park. These activities contribute to the wellbeing of regional communities and the prosperity of the nation.
Location	The Lord Howe Marine Park is located approximately 550 km offshore of New South Wales, adjacent to the New South Wales Lord Howe Island Marine Park and World Heritage Area.
General description of the reserve	The Lord Howe Marine Park is significant because it includes habitats, species and ecological communities associated with the Lord Howe Province and the Tasman Basin Province. It includes three key ecological features: the Lord Howe Seamount Chain; Elizabeth and Middleton Reefs (the southernmost coral reefs in the world); and the Tasman Front and eddy field, all valued for high productivity, aggregations of marine life, biodiversity and endemism. The Elizabeth and Middleton Reefs Ramsar site is located within the Marine Park. The site was listed under the Ramsar Convention in 2002 and is a wetland of

	international importance under the EPBC Act, due to its unique nature as the southernmost open-ocean coral-reef platform in the world. The Marine Park includes habitats connecting to and complementing the adjacent New South Wales Lord Howe Island Marine Park.

2.2.6.12 Central Eastern Marine Park

Central Eastern Marine Park begins 30 kilometres east of Coffs Harbour. It covers 70,054 km², with depths from 120 m to 6000 m. It has National Park, Habitat Protection and Multiple Use zones. And is located between the Hunter and the Lord Howe Commonwealth Marine Parks. Details of the park are described in Table 2-24 (DNP, 2018).

Table 2-24 Central Eastern Marine Park CMR: Temperate East Marine Parks Network Management Plan 2018 (DNP, 2018)

<table>
<tr><td>Proclaimed</td><td colspan="4">14 December 2013</td></tr>

<tr><td>Depth of reserve below seabed</td><td colspan="4">between 120 m and 6000 m.</td></tr>
<tr><td>Total area</td><td colspan="4">70,054 km ²</td></tr>
<tr><td>Major conservation values</td><td colspan="4">Ecosystems, habitats and communities associated with:
• Central Eastern Province—includes canyons along the shelf that interact with currents and ocean gyres resulting in upwellings that influence biological productivity. Plankton blooms associated with the upwellings attract aggregations of tuna, whale and albatross and support over 50 fish species endemic to the area.
• Central Eastern Shelf Transition—upwellings caused by the East Australian Current crossing the continental shelf, and river sediment influence biological productivity
• Tasman Basin Province—interactions between currents, eddies and seamounts and the movements of the deep sub-Antarctic water mass influence biological productivity in this area. The deep-reef coral communities on seamounts are dominated by filter feeders and provide stepping stones for large oceanic species moving between breeding, nesting, calving and foraging sites.
Important area for:
• Foraging and breeding of seabirds
• Migrating humpback whales

Key ecological features of the Marine Park are:
• Tasmantid Seamount Chain—a series of underwater volcanic mountains comprised of guyots, seamounts, tablemounts, banks, plateaux and terraces that runs in a north–south direction, and extends into the Tasman Basin. The feature rises from approximately 4800 m deep to 125 m from the surface at Taupo Seamount in the south, approximately 280 m from the surface at Derwent–Hunter Seamount in the centre of the Marine Park, and to approximately 350 m from the surface at Queensland Guyot in the north of the</td></tr>
</table>

	Marine Park. The seamounts support a diverse range of habitats in temperate and subtropical waters • Canyons on the eastern continental slope—canyons enhance diversity and abundance of species, driven by the combined effects of steep and rugged topography, ocean currents, seafloor types and nutrient availability. Canyons also create localised changes in productivity in the water column above them, providing feeding opportunities for a range of species. • Tasman Front and eddy field—a region that separates the warm, nutrient-poor waters of the Coral Sea from the cold, nutrient-rich waters of the Tasman Sea, providing increased nutrients and plankton aggregations, and enhanced productivity that attracts mobile species such as turtles, cetaceans, tuna and billfish. Culture Sea country is valued for Indigenous cultural identity, health and wellbeing. Across Australia, Indigenous people have been sustainably managing their sea country for tens of thousands of years. At the commencement of this plan, there is limited information about the cultural significance of this Marine Park. Heritage • The Marine Park contains two known shipwrecks listed under the Historic Shipwrecks Act 1976— Amelia (wrecked in 1816) and Illagong (wrecked in 1872). Social and economic values • Tourism, commercial fishing, and recreation, including fishing, are important activities in the Marine Park. These activities contribute to the wellbeing of regional communities and the prosperity of the nation.
Location	The Central Eastern Marine Park is located approximately 30 km east of Coffs Harbour at the edge of the continental shelf. It extends to deep ocean waters approximately 200 km offshore of New South Wales.
General description of the reserve	The Central Eastern Marine Park is significant because it includes habitats, species and ecological communities associated with the Central Eastern Province, the Central Eastern Shelf Transition and the Tasman Basin Province. It includes three key ecological features: canyons on the eastern continental slope (valued as a unique seafloor feature with ecological properties of regional significance); the Tasmantid Seamount Chain; and the Tasman Front and eddy field (both valued for high productivity, aggregations of marine life, biodiversity and endemism).

2.2.6.13 Hunter Marine Park

Encompassing three key ecological features, the Hunter Marine Park is located offshore from Port Stephens in NSW and extends out approximately 100km. Details of the Hunter Marine Park are described in Table 2-25 (DNP, 2018).

Table 2-25 Hunter CMR: Temperate East Marine Parks Network Management Plan 2018 (DNP, 2018)

Proclaimed	14 December 2013			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN category IV - Habitat Protection Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
			Habitat Protection Zone	Special Purpose Zone (Trawl)

Depth of reserve below seabed	between 15 m and 6000 m.
Total area	6257 km²
Major conservation values	Ecosystems, habitats and communities associated with:: • Central Eastern Province—includes canyons along the shelf that interact with currents and ocean gyres resulting in upwellings that influence biological productivity. Plankton blooms associated with the upwellings attract aggregations of tuna, whale and albatross and support over 50 fish species endemic to the area. • Central Eastern Shelf Province—upwellings caused by the East Australian Current crossing the continental shelf, and river sediment influence biological productivity in this provincial bioregion that extends south over the continental shelf from the boundary of the Great Barrier Reef Marine Park to offshore Coffs Harbour. Important area for: • Foraging seabirds and humpback whales • Migrating humpback whales • Aggregation of grey nurse sharks Key ecological features of the Marine Park are: • Canyons on the eastern continental slope—canyons enhance diversity and abundance of species, driven by the combined effects of steep and rugged topography, ocean currents, seafloor types and nutrient availability. Canyons also create localised changes in productivity in the water column above them, providing feeding opportunities for a range of species. • Shelf rocky reefs—which have a complex range of benthic habitat that supports diverse benthic communities. • Tasman Front and eddy field—a region that separates the warm, nutrient-poor waters of the Coral Sea from the cold, nutrient-rich waters of the Tasman Sea, providing increased nutrients and plankton aggregations, and enhanced productivity that attracts mobile species such as turtles, cetaceans, tuna and billfish. Heritage • The Marine Park contains one known shipwreck listed under the Historic Shipwrecks Act 1976— India (wrecked in 1884). Social and economic values • Commercial fishing, tourism and recreation, including fishing, are important activities in the Marine Park. These activities contribute to the wellbeing of regional communities and the prosperity of the nation
Location	The Hunter Marine Park extends from the New South Wales state water boundary to approximately 100 km offshore, and adjacent to the New South Wales Port Stephens–Great Lakes Marine Park.
General description of the reserve	The Hunter Marine Park is significant because it contains habitats, species and ecological communities, representative of the Central Eastern Province and the Central Eastern Shelf Province. It includes three key ecological features: canyons on the eastern continental slope (valued for a unique seafloor feature with ecological properties of regional significance); shelf rocky reefs (valued for a unique seafloor feature with ecological properties of regional significance); and the Tasman Front and eddy field (valued for high productivity, aggregations of marine life, biodiversity and endemism). The Marine Park supports a range of species, including species listed as threatened, migratory, marine or cetacean under the EPBC Act. The Marine Park includes habitats connecting to and complementing the adjacent New South Wales Port Stephens–Great Lakes Marine Park.

2.2.6.14 Cod Grounds Marine Park

Cod Grounds covers a small, 4km2 area, 5.5 km offshore, NSW (south of Port Macquarie). It is an important aggregation ground for grey nurse sharks (DNP, 2018). Details of the Cod Ground Marine Park are described in Table 2-26 (DNP, 2018).

Table 2-26 Cod Grounds CMR: Temperate East Marine Parks Network Management Plan 2018 (DNP, 2018)

Proclaimed	14 December 2013			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN category II – National Park Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
		National Park Zone		
Depth of reserve below seabed	between 21 m and 46 m.			
Total area	4 km²			
Major conservation values	Ecosystems, habitats and communities associated with:: • Central Eastern Shelf Transition— ecosystems in this area are influenced by tropical waters of the Eastern Australian Current meeting temperate waters, creating a combination of topical and temperate environments. Many species found within the marine park are at or close to, either their southern or northern geographical limits. Important area for: • Migratory pathway and aggregation area for grey nurse sharks • Migratory and foraging habitat for humpback whales • Foraging habitat for seabirds Key ecological features of the Marine Park are: • Shelf rocky reefs— predominantly rocky reef surrounded by boulder and cobble slopes that support diverse and abundant marine communities. The reefs are interlaced with sand and cobble gutters. Cultural • Sea country is valued for Indigenous cultural identity, health and wellbeing. Across Australia. There is limited, other information about the cultural significance of this Marine Park. Social and economic values • Tourism, scientific research and recreation activities are important in the Marine Park. These activities contribute to the wellbeing of regional communities and the prosperity of the nation			
Location	The Cod Grounds Marine Park is 5.5 km offshore, NSW (south of Port Macquarie).			
General description of the reserve	The Cod Grounds Marine Park is significant because it contains habitats, species and ecological communities representative of the Central Eastern Shelf Transition. It provides habitat for grey nurse sharks.			

2.2.6.15 Jervis Marine Park

Jervis Marine Park comprises an area of 2473 square kilometres and covers a depth range from 120 m to 5000 m approximately.

Seafloor features represented in the reserve include abyssal-plain/deep ocean floor, canyons, shelf and slope. The reserve include two key ecological features, it is one of three shelf incising canyons occurring within the region (unique sea-floor feature with ecological properties of regional significance) and shelf rocky reefs. Details of the Jervis Marine Park are described in Table 2-27 (DNP, 2018).

<tr><td>Major conservation values</td><td colspan="4">Ecosystems, habitats and communities associated with::
• the Central Eastern Province and Southeast Shelf Transition

Important foraging area for:
• seabirds, grey nurse sharks and humpback whales

Key ecological features of the Marine Park are:
• Canyons on the eastern continental slope—canyons enhance diversity and abundance of species, driven by the combined effects of steep and rugged topography, ocean currents, seafloor types and nutrient availability. Canyons also create localised changes in productivity in the water column above them, providing feeding opportunities for a range of species.
• Shelf rocky reefs—which have a complex range of benthic habitat that supports diverse benthic communities.
Heritage
The Marine Park contains one known shipwreck listed under the Historic Shipwrecks Act 1976—HMAS Tattoo (wrecked in 1939).</td></tr>
<tr><td>Location</td><td colspan="4">The Jervis Marine Park is located approximately 20 km offshore, adjacent to the New South Wales Jervis Bay Marine Park and Commonwealth Booderee National Park.</td></tr>
<tr><td>General description of the reserve</td><td colspan="4">The Marine Park supports a range of species, including species listed as threatened, migratory, marine or cetacean under the EPBC Act. Biologically important areas within the Marine Park include foraging habitat for seabirds, grey nurse sharks and humpback whales.</td></tr>
</table>

	Tourism, commercial fishing, and recreation are important activities in the Marine Park. These activities contribute to the wellbeing of regional communities and the prosperity of the nation. Sea country is valued for Indigenous cultural identity, health and wellbeing. Across Australia, Indigenous people have been sustainably managing their sea country for tens of thousands of years. At the commencement of this plan (Temperate East Management Plan), there was limited information about the cultural significance of this Marine Park. The Native Title Services Corporation is the Native Title Service Provider for the New South Wales region.

2.2.6.16 South Tasman Rise Marine Park

The South Tasman Rise is an area of seafloor that lies 550 km south of Hobart, Tasmania in the Southern Ocean where water depths are about 1,500 metres. This deep ocean park covers 27,704 square kilometres. It is designated as a Special Purpose zone.

The reserve supports unique environments for marine life and is an area of significant scientific interest. The seamounts here have flat tops, evidence they were once above the ocean's surface where they were shaped by wind and wave erosion. The rise most probably originates from subsided continental crust that fragmented as Australia and Antarctica separated (AMP, 2019). Australia and New Zealand agreed that there would be no fishing in 2007-08 and indefinitely thereafter. No permits have been issued for this fishery since 2007 (AFMA, 2019). Details of the South Tasman Rise Marine Park are listed in Table 2-28 (DNP, 2013).

Table 2-28 South Tasman Rise CMR: SE Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP, 2013)

Proclaimed	28 June 2007			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN VI—Special Purpose Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
				Special Purpose Zone
Depth of reserve below seabed	100 m			
Total area	27,704 km^2 (27 704 00 ha)			
Major conservation values	Ecosystems, habitats and communities associated with: • Tasman Province and associated with sea-floor features: • Abyssal plain/deep ocean floor • canyon • plateau • seamount/guyot • slope Important foraging area for: • wandering and black-browed albatrosses, Short-tailed shearwater • white-headed and white-chinned petrels			

Location	The South Tasman Rise Commonwealth Marine Reserve is south-east of Tasmania, with its southern edge following the boundary of the Australian exclusive economic zone, 200 nm from land.
General description of the reserve	The South Tasman Rise Commonwealth Marine Reserve occurs in the deep ocean and includes a section of the mid-continental slope at depths of 1200–3000 m. It encloses a submerged plateau of continental rock that stands as the last remnant of the link between Australia and Antarctica. The sea floor in this reserve was deformed by the massive rifting process when the Australian continental block moved north. The reserve supports unique environments for marine life and is an area of significant scientific interest. It contains several seamounts, some of which have flat summits, which indicates that they were exposed above the surface at some time.

2.2.6.17 Gifford Marine Park

Gifford Marine Park is located in the norther region of the Temperate East Marine Region. Details of the Gifford Marine Park are listed in Table 2-29 (DNP, 2018)

Table 2-29 Gifford CMR: Temperate East Marine Parks Network Management Plan 2018 (DNP, 2018)

Proclaimed	14 December 2014, renamed Gifford Marine Park on 9 October 2017			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN IV—Special Purpose Zone			
Assigned zones in reserve:	IUCN Ia	IUCN II	IUCN IV	IUCN VI
			Habitat Protection Zone	
Depth of reserve below seabed	Depth range of 220 and 4000 m			
Total area	5,828 km^2			
Major conservation values	Ecosystems, habitats and communities associated with: • Ecosystems representative of Lord Howe Province • Abyssal plain/deep ocean floor • canyon • plateau • Lord Howe Seamount Chain • slope Important area for: • a range of threatened species including migratory, marine and cetacean species • foraging habitat for seabirds • migratory pathway for humpback whales Commercial fishing is an important activity in the marine park			
Location	The Gifford Marine Park located approximately 480 km north of Lord Howe Island and borders on the limit of Australia's exclusive economic zone.			
General description of the reserve	The Gifford Marine Park is significant because it contains habitats, species and ecological communities associated with the Lord Howe Province. It includes one key ecological feature: the Lord Howe Seamount Chain, valued for high productivity, aggregations of marine life, biodiversity and endemism.			

2.2.6.18 Norfolk Marine Park

Norfolk Island Marine Park is around Norfolk Island in the External Territories, over 1500 km from mainland Australia. Details of the Norfolk Marine Park are listed in Table 2-30 (DNP, 2018)

Table 2-30 Norfolk Island CMR: Temperate East Marine Parks Network Management Plan 2018 (DNP, 2018)

<table>
<tr><td>Proclaimed</td><td colspan="4">14 December 2013, renamed Norfolk Marine Park on 9 October 2017.</td></tr>

<tr><td></td><td>National Park Zone</td><td>Habitat Protection Zone</td><td>Special Purpose Zone (Norfolk)</td></tr>
<tr><td>Depth of reserve below seabed</td><td colspan="4">5000 m</td></tr>
<tr><td>Total area</td><td colspan="4">188,444 km^2</td></tr>
<tr><td>Major conservation values</td><td colspan="4">Natural Values:
• ecosystems representative of the Norfolk Island Province:
• mixing of warm-water and cold-water currents and eddies, and their interactions with seamounts influence biological productivity
• Tasman Front transports Coral Sea biota including corals, crustaceans and molluscs to the area
• The shallow-water habitats of Norfolk Island support diverse tropical and temperate species of fish, corals and other marine organisms similar to those found in the reefs surrounding Lord Howe Island, but with a unique reef fish assemblage of endemic, sub-tropical and temperate species.
KEFs:
• Tasman Front and eddy field
• Norfolk Ridge
Important area for:
• a range of threatened species including migratory, marine and cetacean species
• foraging habitat for seabirds
• migratory pathway for humpback whales
Cultural
The marine environment around Norfolk Island has long held significance among Norfolk Islanders. A unique community and culture has developed by those who have visited and settled the island over time. The Polynesians were the first inhabitants before the island was made a penal settlement and then the settlers from Pitcairn Island who constituted the third settlement.
Heritage
• Kingston and Arthur's Vale Historic Area World Heritage Australian Convict Site (ref Section 2.2.1.1)
• Norfolk Island, Nepean Island Reserve and Phillip Island providing important breeding habitat for at least eight species of seabird that also forage in the Marine Park.
• With Captain James Cook discovering Norfolk Island in 1774 – it is also important for European Heritage
Social and Economic</td></tr>
</table>

	• Fishing, boating and shipping, tourism and recreation are important activities contributing to the economy and wellbeing of the island community
Location	The Norfolk Marine Park is around Norfolk Island, including Nepean Island Reserve and Phillip Island, approximately 1400 km offshore from Evans Head in New South Wales.
General description of the reserve	The Norfolk Marine Park is significant because it contains habitats, species and ecological communities associated with the Norfolk Island Province. It includes two key ecological features: Norfolk Ridge, and the Tasman Front and eddy field, both valued for high productivity, aggregations of marine life, biodiversity and endemism.

2.2.6.19 Coral Sea Marine Park

The Coral Sea Marine Park southern boundary commences at latitude 24º 30’ 00” and extends north for over 1400 kms. The southern end of the park intersects with the limits of the DA by approximately 75 kms. Details of the Coral Sea Marine Park are listed in Table 2-31 (DNP, 2018b)

Table 2-31 Coral Sea CMR: Coral Sea Marine Park Management Plan 2018 (DNP, 2018b)

Proclaimed	14 December 2013, renamed on 9 October 2017			
IUCN category assigned by this Management Plan and reserve management zone name	IUCN IV—Habitat Protection Zone			
Assigned zones in reserve:	IUCN II	IUCN IV	IUCN IV	IUCN VI
	National Park Zone	Habitat Protection Zone	Habitat Protection Zone (reefs)	Special Purpose Zone
Depth of reserve below seabed	From 15 m to depths of 6,000 m			
Total area	989,836 km²			
Major conservation values	Ecosystems representative of: • Cape Province, Northern Transition and Province, Central Eastern Transition, Kenn Province and Transition KEFs: • Tasmantid Seamount Chain • Reefs, cays and herbivorous fish of the Queensland and Marion Plateau Important area for: • the only known spawning aggregation of black marlin in the Pacific Ocean (occurs near Osprey Reef) • breeding and or foraging habitat for seabirds, internesting habitat for marine turtles, and a migratory pathway for humpback whales • Supporting migratory birds • Coringa-Herald and Lihou Reefs and Cays Ramsar site (beyond the DA) Historic, social and economic values • Tourism, commercial fishing, and recreation, including fishing contribute to the wellbeing of regional communities and the prosperity of the nation • 45 historic shipwrecks are found in the park			
Location	The Coral Sea Marine Park extends from Cape York Peninsula to an east–west line approximately 40 km north of Bundaberg in Queensland. The nearest point of the Marine Park to mainland Australia is approximately 60 km and it extends to approximately 1100 km from the coast. It lies immediately to the east of the Great Barrier Reef Marine Park.			

General description of the reserve	The marine environment of the Coral Sea Marine Park is characterised by shallow-water tropical marine ecosystems, a large area of continental shelf and continental slope, two areas of abyssal plain with depths to 6000 m, high incidence of cyclones, high, mostly tropical species diversity and globally significant populations of internationally threatened species. There are approximately 34 reefs, and 56 cays and islets in the Marine Park, with a total reef area of approximately 15,024 km^2. It is influenced by a complex system of ocean currents that change seasonally and between years. Currents have also influenced the composition of reef species. The east–west-flowing South Equatorial Current cuts through the centre of the Marine Park before dividing to form the north-flowing Hiri Current and the south-flowing East Australian Current. These currents create a barrier reducing the mixing of species between the north and south of the Marine Park, forming distinct communities. The southern part of the Marine Park transitions between tropical and temperate waters and includes the northern extent of the range of some temperate species typical of the Temperate East Marine Region.

2.2.7 Key Ecological Features (KEF)

Key Ecological Features (KEF) are elements of the Commonwealth marine environment that are considered to be of regional importance for either a region's biodiversity or its ecosystem function and integrity. KEFs are not matters of national environmental significance and have no legal status in their own right. However, they are components of the Commonwealth marine area. Fourteen KEFs occur in the DA as identified in the Conservation Values Atlas (DoEE 2015b). The eleven KEFs that have been spatially defined are shown in Figure 2-16.

The location of the three KEFs that are not spatially defined (Bass Cascade, shelf rocky reefs and hard substrates (South East Marine Region) and the East Tasmania subtropical convergence zone) are described below.

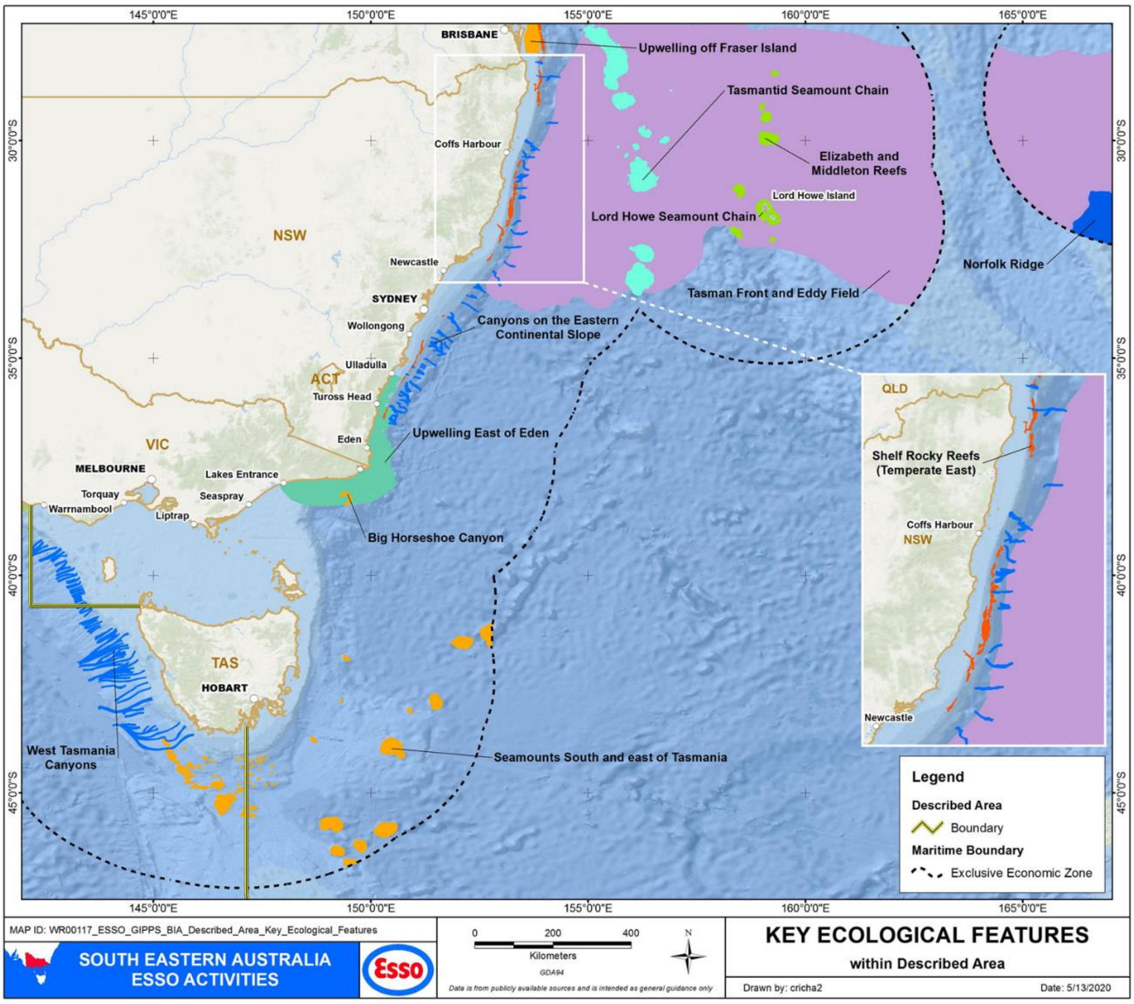

Figure 2-16 Spatially defined Key Ecological Features within the DA

2.2.7.1 Big Horseshoe Canyon

Big Horseshoe Canyon is defined as a key ecological feature as it is an area of high productivity and aggregations of marine life.

The steep, rocky slopes of the Big Horseshoe Canyon provide hard substrate habitat for attached large epifauna. Sponges and other habitat forming species provide structural refuges for benthic fishes, including the commercially important pink ling.

The Big Horseshoe Canyon is the largest south eastern canyon sampled for benthic biodiversity (Williams et al., 2009). It has a total area of 319 km2 in 1500-m depth that supports a rich, abundant, filter-feeding benthic megafauna, including large sponges in dense beds of large individuals at 120 m and at 300–400 m, dense stands of the stalked crinoid Metacrinus cyaneus in 200–300 m, and many species of octocoral (especially gold corals) at depths >700 m (Kloser et al., 2001). It is the only known temperate location of the stalked crinoid Metacrinus cyaneu.

Big Horseshoe Canyon lies south of the coast of eastern Victoria. This feature is the eastern most arm of the Bass Canyon system (DoEE 2015a).

2.2.7.2 Upwelling East of Eden:

The Upwelling east of Eden is defined as a key ecological feature as it is an area of high productivity and aggregations of marine life.

Dynamic eddies of the East Australian Current cause episodic productivity events when they interact with the continental shelf and headlands. The episodic mixing and nutrient enrichment events drive phytoplankton blooms that are the basis of productive food chains including zooplankton, copepods, krill and small pelagic fish.

The upwelling supports regionally high primary productivity that supports fisheries and biodiversity, including top order predators, marine mammals and seabirds. This area is one of two feeding areas for blue whales and humpback whales, known to arrive when significant krill aggregations form. The area is also important for seals, other cetaceans, sharks and seabirds.

This feature displays seasonal and annual variation, and is present along the eastern Victorian and southern NSW coasts.

2.2.7.3 East Tasmania subtropical convergence zone (East coast of Tasmania):

A zone of enhanced pelagic productivity where eddies of the East Australian Current interact with subantarctic waters driven by westerly winds. This is a complex feature that is characterised by autumn and spring phytoplankton blooms that form the basis of a productive food chain which supports cetaceans, seals, sharks and seabirds. The phytoplankton blooms attract migratory commercial fish stocks such as Southern bluefin tuna, barracouta, and jack mackerel, and are also important for krill, which in turn form an important component of the diet of many pelagic species. This KEF has not been spatially defined and hence is not shown in Figure 2-16 however it is not expected to occur within the DA. The northern and southern extent of the feature are approximately level with the north-east tip of Tasmania and the Tasman Peninsula.

2.2.7.4 The Bass Cascade (along the Bass Canyon System)

The Bass Cascade refers to the "underwater waterfall" effect brought about by the northward flow of Bass Strait waters in winter which are more saline and slightly warmer than surrounding Tasman Sea waters. As the water approaches the mainland in the area of the Bass Canyon group it forms an undercurrent that flows down the continental slope. The cascading water has a displacing effect causing nutrient rich waters to rise, which in turn leads to increased primary productivity in those areas. The cascading water also concentrates nutrients and some fish and whales are known to aggregate along its leading edge. The Bass Cascade occurs during winter months only.

This KEF has not been spatially defined and hence is not shown in Figure 2-16, however it is expected to occur within the DA.

2.2.7.5 Seamounts south and east of Tasmania (south and east of Tasmania):

The Seamounts south and east of Tasmania are defined as a key ecological feature as they are an area of high productivity and aggregations of marine life.

These seamounts are a chain or cluster of seamounts rising from the abyssal plain, continental rise or plateau situated 200 km or more from shore (east of Flinders Island to south east of southern Tasmania). Seamounts with hard substrate summits and slopes provide attachment points for sessile invertebrates, while the soft sediments can be habitat for species that burrow into the sediments.

The Seamounts south and east of Tasmania extend into the southern offshore waters of the DA (Figure 2-16).These seamounts create localised upwellings of nutrient rich waters from the seafloor. The hard substrate support sessile invertebrates.

2.2.7.6 Shelf rocky reefs and hard substrates (Southeast Marine Region)

Rocky reefs and hard grounds are located in all areas of the South-east Marine Region continental shelf including Bass Strait, in 50 m to 150–220 m water depth. They support macroalgae and sessile invertebrates and provide habitat and shelter for fish and are important for aggregations of biodiversity and enhanced productivity. This KEF has not been spatially defined and hence do not appear on Figure 2-16 however it is expected to occur along the continental shelf of Bass Strait within the DA.

2.2.7.7 West Tasmania Canyons

The West Tasmania Canyons are located in the Southeast Marine Bioregion on the edge of the continental shelf offshore of the north-west corner of Tasmania and they extend down as far south as Macquarie Harbour. The northern section of the canyons intersect the DA. These canyons can influence currents, act as sinks for rich organic sediments and debris, and can trap waters or create upwellings that result in productivity and biodiversity hotspots. For example, plumes of sediment and nutrient-rich water can be seen at or near the heads of canyons. Sponges are concentrated near the canyon heads, with the greatest diversity between 200 m and 350 m depth. Sponges are associated with abundance of fishes and the canyons support a diversity of sponges comparable to that of seamounts (refer Section 2.2.7.5 above) (DoEE, 2015a).

2.2.7.8 Tasmantid Seamount Chain

Just 150-600 km east of the Australian mainland is a 2000 km long chain of submerged volcanoes (from approximately Latitude 19ºdeg south to 33º deg south) are the Tasmantid Seamount Chain that rise over 4000 m above the seafloor - nearly twice the height of the highest mountain on the mainland. These undersea mountains, the Tasmantid Seamounts, are extinct volcanoes formed from around 40 to 6 million years ago above a mantle hotspot, similar to the Hawaiian Islands. The seamount chain includes Lord Howe Island and Elizabeth and Middleton Reefs. These isolated, oceanic reefs are thought to support a diverse range of tropical and temperate marine life, including both warm-water and cold-water corals and an abundance of fish species. This diversity is a result of the effect of the East Australian Current on the reefs as it exposes the area to its warm waters, in contrast to the surrounding cooler ocean. The information on the Tasmantid Seamounts has been based on observations from some seamounts in other locations, however for benthic ecosystems, the data for the Tasmantid seamount chain is poor (CSIRO, 2012). Thus the seamount chain's conservation values are defined in terms of containing feature scale geomorphic surrogates for biodiversity (basin, plateau, seamount and abyssal plain/deep ocean floor). In general what is known is that Taupo seamount supports a diverse and dense invertebrate megafauna and abundant sharks; a high diversity of demersal fishes is recorded in commercial fishery logbooks and fishery observers; individual seamounts vary greatly in size in shelf and upper/mid slope depths where benthic biodiversity is expected to be greatest (CSIRO, 2012).

2.2.7.9 Lord Howe Seamount Chain

Lord Howe Seamount Chain is a chain of submerged volcanoes running 1000 km north–south, the seamount chain includes Lord Howe Island and Elizabeth and Middleton Reefs. This seamount chain runs east of the Tasmantid Seamount discussed above (refer Section 2.2.7.8). These isolated, oceanic reefs support a diverse range of tropical and temperate marine life, including both warm-water and cold-water corals and an abundance of fish species. This diversity is a result of the effect of the East Australian Current on the reefs as it exposes the area to its warm waters, in contrast to the surrounding cooler ocean (DSEWPAC, 2012a).

2.2.7.10 Tasman Front and eddy field

The Tasman Front and eddy field occurs in the Temperate East Marine Region and is defined as a key ecological feature formed by complex and dynamic oceanographic processes supporting transient patches of enhanced productivity that, in turn, attract aggregations of species across trophic levels, including top predators such as tuna and sharks. This feature also supports biological connectivity with seamount habitats (Tasmantid Seamount Chain – refer Section 2.2.7.8 above) further offshore. The Tasman Front is formed by a current that moves to the north in winter and to the south in summer. The Front separates the warm, nutrient-poor waters of the Coral Sea from the nutrient-rich waters of the Tasman Sea and its boundary can and associated eddies vary in shape, strength and location. The front is formed between 27º S and 33º S. In the southern portion of the Temperate East Marine Region, the Tasman Front creates a complex oceanographic environment with vertical mixing causing enhanced productivity. Patches of productivity are important for mid-level consumers including turtles and top fish predators. This is supported by Fisheries oceanography studies that describe a positive relationship between fish catch rates and proximity to frontal features, and a predominance of bigeye tuna and swordfish associated with the Tasman Front (DoEE, 2019t).

2.2.7.11 Shelf rocky reefs (Temperate East Marine Region)

The Shelf Rocky Reefs habitat has been identified as a key ecological feature as it is considered a unique sea-floor feature which is associated with ecological properties of regional significance.

Shelf rocky reefs feature support a range of complex benthic habitats that, in turn, support diverse benthic communities. Along the continental shelf, south of the Great Barrier Reef, benthic communities on rock outcrops and boulder substrates shift from algae-dominated communities to those dominated by attached invertebrates, including dense populations of large sponges, with a mixed assemblage of moss animals and soft corals; this shift generally occurs at a depth of 45 m. Below wave-influenced areas, massive and branched growth forms of sponges are more prevalent, and sponge species richness and density generally increases with depth along the New South Wales coast.

Collectively, these invertebrates create a complex habitat-forming community that supports microorganisms and other invertebrates, such as crustaceans, molluscs, annelids and echinoderms. These habitats also contribute to increased survival of juvenile fish by providing refuge from predation. Rocky reef habitats on Australia's east coast support a diverse assemblage of demersal fish, which show distinct patterns of association with shelf-reef habitats; e.g. jackass morwong, barracouta, orange-spotted catshark, eastern orange perch, butterfly perch and warehou are species that distinguish rocky-reef habitats at depths greater than 45 m from those of soft sediments. Unlike the shelf rocky reef and hard substrate of the South East Marine Region, this KEF has been spatially defined and is shown in Figure 2-16.

2.2.7.12 Canyons on the eastern continental slope

The Canyons on the eastern continental slope are defined as a key ecological feature as they are a unique seafloor feature with enhanced ecological functioning and integrity, and biodiversity, which apply to both its benthic and pelagic habitats.

Canyon systems have a marked influence on diversity and abundance of species through their combined effects of topography, geology and localised currents, all of which act to funnel nutrients and sediments into the canyon. As such, these features are valued for their enhanced productivity and biological diversity properties. Canyons contribute to habitat diversity by providing a hard surface that offers anchoring points and vertical relief for filter feeder benthic species. Hard substrata support different species assemblages; particularly favouring large filter feeder–dominated benthic species (e.g. attached sponges and crinoids) that thrive in abundance in the enhanced current flow conditions. Large benthic animals such as sponges and feather stars are abundant, with particularly high diversity found in the upper slope regions (150–700 m). A range of higher trophic level species, including crustaceans, echinoderms, bivalves, cephalopods and fish are then attracted to these regions. Canyons are therefore significant contributors to overall biodiversity, particularly in terms of benthic organisms. Due to isolation, restricted dispersal and connectivity, it is also expected this diversity encompasses a high degree of endemism, further contributing to the social and biological values of these communities.

The Canyons on the eastern continental slope lie off the coast of NSW (Figure 2-16).

2.2.7.13 Upwelling off Fraser Island

In two areas near Fraser Island, upwellings of cold, deep waters mix with surface waters. Tides, wind and currents draw these nutrient-rich waters onto the shelf, where they generate blooms of phytoplankton that support animals higher in the food chain, including a number of commercially valuable and threatened species (DSEWPAC, 2012a). The spatial boundary for this KEF is an area of enhanced productivity (identified through areas of enhanced chlorophyll levels) spanning shelf-edge, slope and off-shelf areas running from the northwest to the southeast of Fraser Island. The feature also appears to be an important area of connectivity in migrations of small pelagic fish and top predators. The subtropical waters off Fraser Island are an important spawning area for temperate small pelagic fish (i.e. the sardine, round herring and Australian anchovy), the adults of which appear to migrate from the south and whose larvae are subsequently transported back into temperate nursery areas by the East Australian Current (DAWE, 2020b).

2.2.7.14 Norfolk Ridge

The Norfolk Ridge occurs in a region of remnant volcanic arcs, plateaux, troughs and basins (ranging from 50 m to 3,900 m). The ridge runs southward from New Caledonia to New Zealand, between the New Caledonia Trough to the west and the Norfolk Basin to the east (DSEWPAC, 2012a). There are likely to be high levels of diversity in seamount communities (1.24% is classed as pinnacles or seamount/guyot) including endemic species, caused by relatively productive seafloor habitats that support population densities far higher than surrounding areas. Benthic habitats along the Norfolk Ridge are also thought to act as ‘stepping stones’ for animal dispersal, connecting deep water species from New Caledonia to New Zealand (DSEWPAC, 2012a). Similar to the Lord Howe chain, the ridge also generates localised oceanographic changes which create sites of enhanced productivity and aggregate marine species (DAWE, 2020c).

2.2.8 National Parks and Reserves

National parks and reserves which include marine protected areas and terrestrial protected areas are declared under each individual state's legislation and are managed by state authorities. A number of state marine protected areas occur within the DA. The parks which are located within approximately 100 kms of the EGBPA are all on the Victorian coastline between Point Hicks National Park and Corner Inlet and Nooramunga Marine and Coastal Parks. Figure 2-17 shows National Parks and Reserves in the DA in Victoria. Figure 2-18 shows the Parks and Reserves in the DA in the islands of Tasmania in northern Bass Strait, Figure 2-19 shows the Parks and Reserves in the DA in Tasmania and Figure 2-20 shows the Parks and Reserves in the DA in NSW.

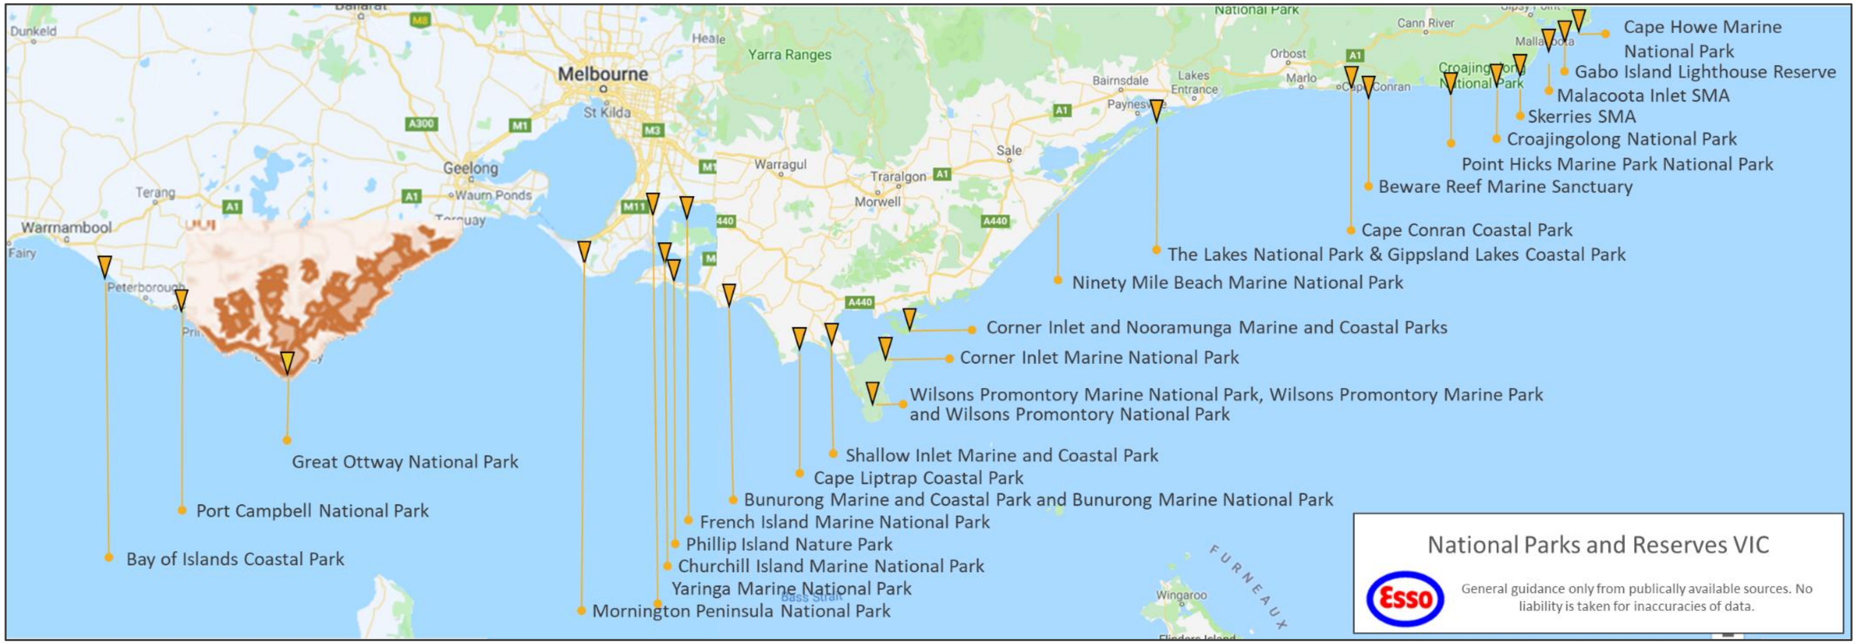

Figure 2-17 National Parks and reserves in the DA in Victoria

Figure 2-18 National Parks and reserves in the DA on the islands of Tasmania in northern Bass Strait

Figure 2-19 National Parks and Reserves in the DA on and around mainland Tasmania

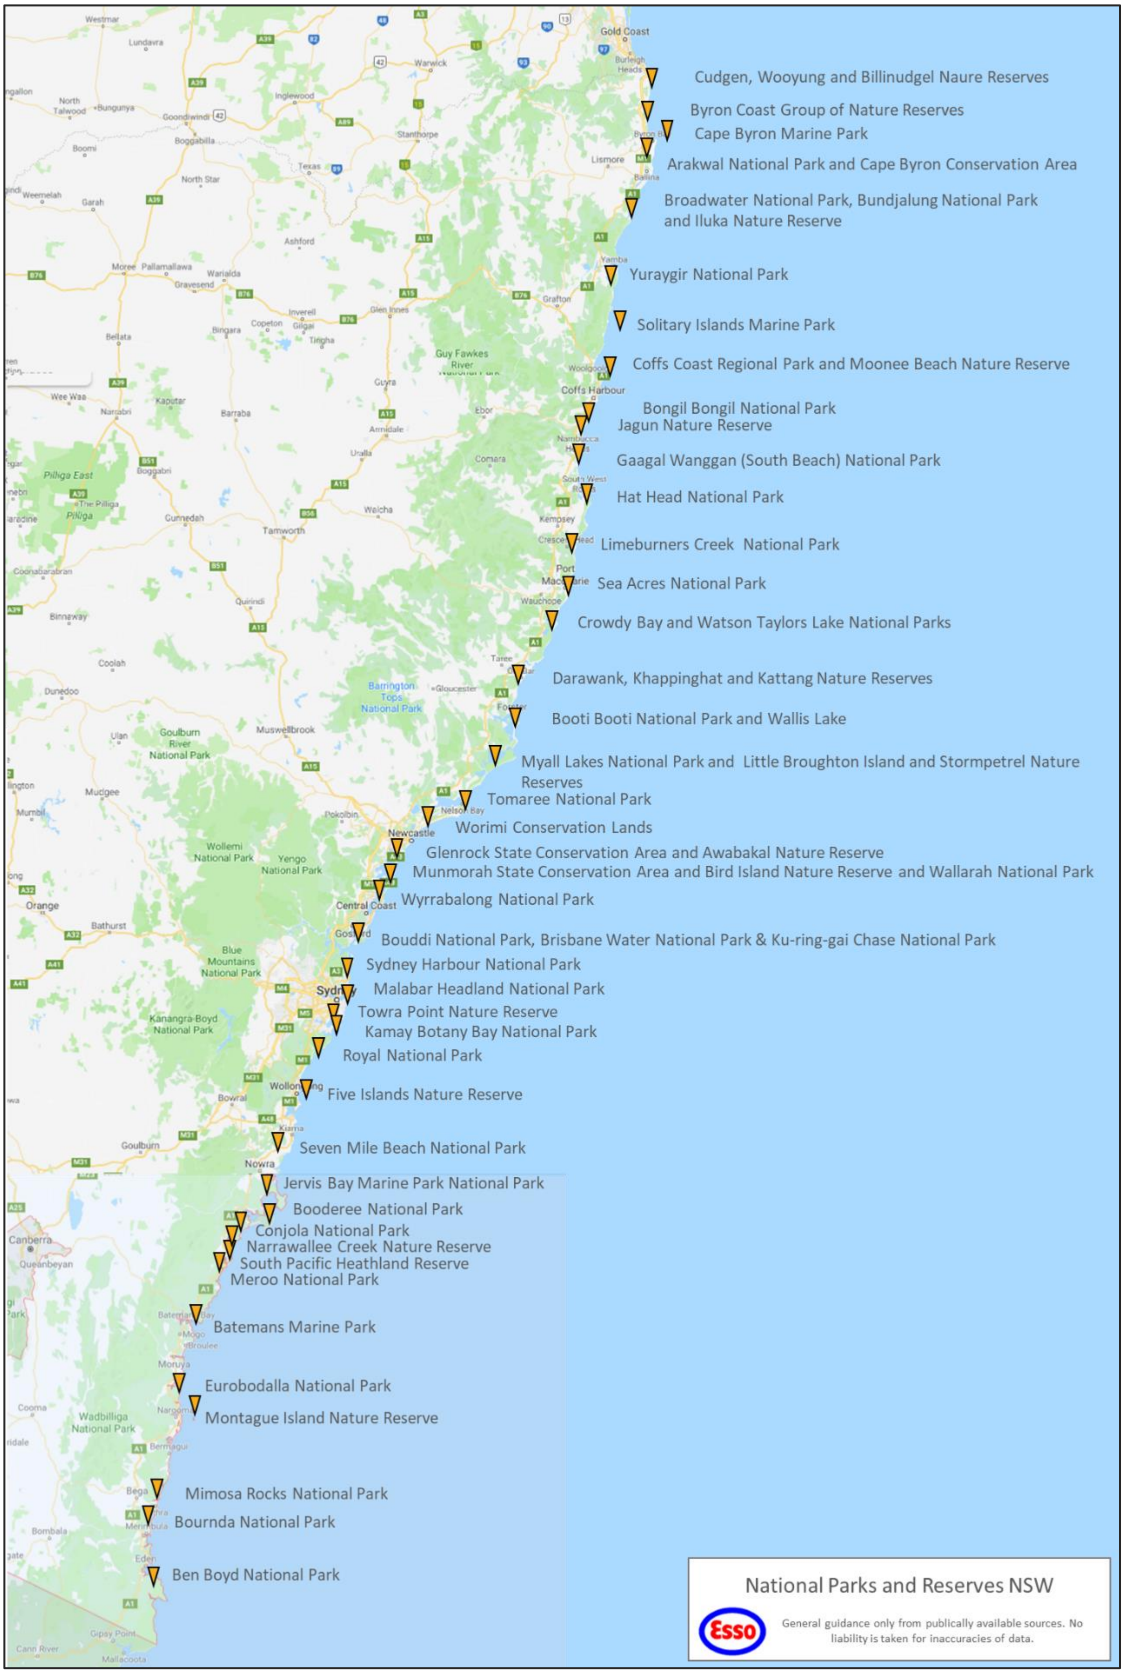

Figure 2-20 National Parks and reserves in the DA in New South Wales

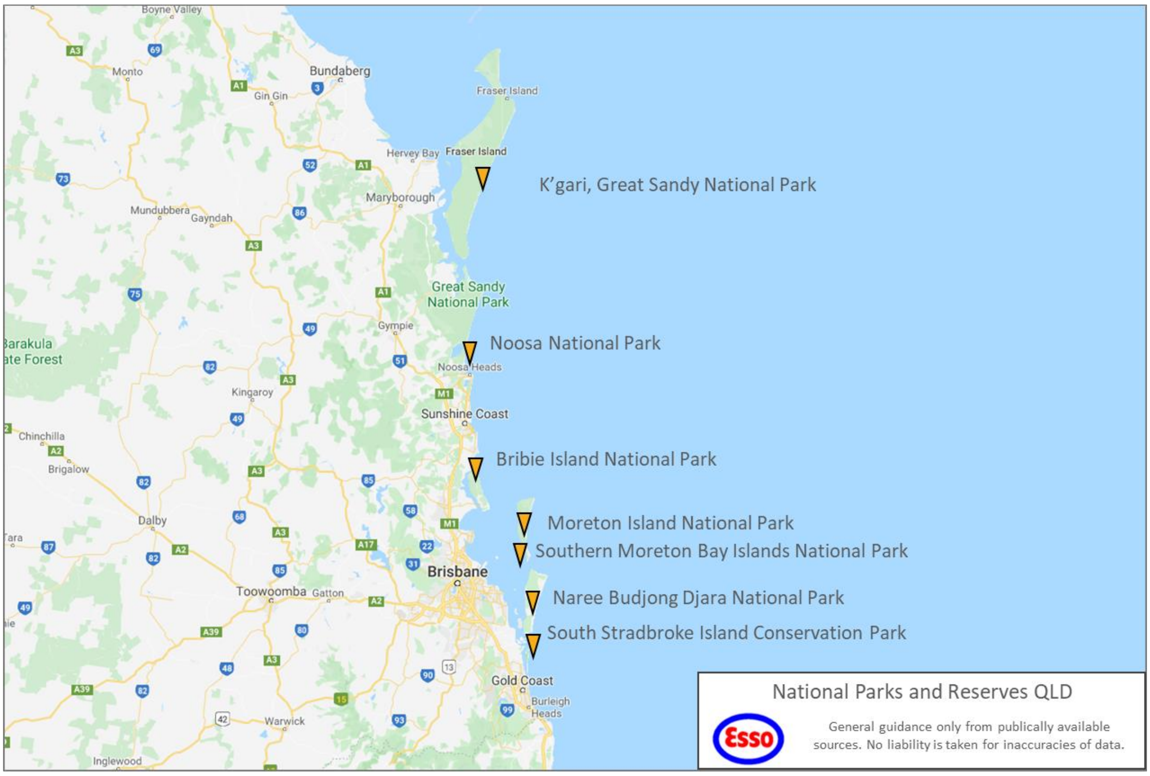

Figure 2-21 National Parks and reserves in the DA in Queensland

2.2.8.1 Cape Howe Marine National Park - VIC

The Cape Howe Marine National Park is situated in the far east of Victoria alongside the border with New South Wales. The habitats found in the park include kelp forests, granite and sandstone reefs, sandy beaches and soft sediments. The marine life of the area is particularly diverse because species of both warm and cool areas can reside here. Whales pass by Cape Howe on their migration from Antarctica and are sometimes followed by a pod of orcas. Little penguins also forage at the rook on Gabo Island. (ParksVic 2017l).

2.2.8.2 Gabo Island Lighthouse Reserve - VIC

Gabo Island is considered to be of State zoological significance due to the presence of one of the largest breeding colonies of Little penguins in the world. Short-tailed shearwaters also breed on Gabo Island.

Common species of whale sighted from the island include Southern right whales, Humpback whales and Killer whales. Whales pass Gabo Island on their annual migration south to feed in Antarctic waters from late winter to early spring and then again during autumn on their northern migration to calve in tropical areas. Pods of dolphins are also regularly sighted from Gabo Island. Species include Common dolphins and Bottlenose dolphins. Australian and New Zealand Fur Seals are also often seen on the rocks surrounding the island.

The lighthouse was constructed from 1858 to 1862 and is the only operating island lighthouse in Victoria (ParksVic, 2017f).

2.2.8.3 Mallacoota Inlet Special Management Area (Victoria)

The Mallacoota Inlet Special Management Area is a special management area. Flora, fauna and areas of geomorphological significance are protected in this area.

2.2.8.4 The Skerries Special Management Area (Victoria)

The Skerries Special Management Area is a special management area. The Skerries is home to a major seal breeding colony with an estimated population of 11,500 representing approximately 12% of the national population.

2.2.8.5 Croajingolong National Park & Nadgee Nature Reserve - VIC

The Croajingolong National Park follows the far-eastern coastline of Victoria for 100 km and together with the adjoining Nadgee Nature Reserve in New South Wales is classified as a UNESCO World Biosphere Reserve. Over 1000 species of native plants have been recorded in the park including 90 species of orchids. The park also contains areas of cool temperate and warm temperate rainforest, eucalypt forest and coastal heathland.

Of the 52 mammal species recorded in the park, arboreal mammals, such as possums, gliders and bats are common. Seals, whales and dolphins occur in coastal waters adjacent to the park. The islands and ocean beaches attract migratory seabirds and waders, the wetlands are habitat for a diversity of waterfowl and the coastal woodlands are favoured habitat for birds of prey. Significant populations of reptiles and amphibians also occur within the park.

The park's secluded coastal camping locations make it popular for beach walks, bird watching, boating and fishing (ParksVic 2017h).

The Skerries, offshore from Wingan Inlet, is home to a major seal breeding colony with an estimated population of 11,500 representing approximately 12% of the national population.

Dry open forest areas occur widely throughout Nadgee Nature Reserve with patches of rainforest occurring in creek catchments and low shrubby heaths being encountered at Mt Nadgee and along the coast. Nadgee Nature Reserve also contains examples of both fresh and salt water wetlands.

The near-coastal areas are significant breeding and foraging habitat for the Eastern bristlebird and seabirds such as the Short-tailed shearwater, Crested tern and Gannet. Most of the park's beaches support a breeding pair of Hooded plovers. Sea caves support important invertebrate 'guano' communities.

The reserve is largely undisturbed by recreational development and contains the only coastal Wilderness Area in NSW (NPWS 2017a).

2.2.8.6 Point Hicks Marine National Park - VIC

The Point Hicks Marine National Park is located alongside Croajingolong National Park, East Gippsland. Many creatures found here are not found further west because the water is too cold, for example the large black sea urchin. The National Park is approximately 4,000 ha in area, with fauna including intertidal and shallow subtidal invertebrates, diverse sessile invertebrates living on subtidal reefs, kelps and small algae, and a high diversity of reef fish. In addition to the subtidal reef, the marine environment around Point Hicks includes intertidal rock operational areas and offshore sands (ParksVic 2017a). Point Hicks Marine National Park is also a popular location for recreational divers. Remains of two shipwrecks can be encountered in the National Park.

2.2.8.7 Beware Reef Marine Sanctuary - VIC

The Beware Reef Marine Sanctuary is a State marine protected area, IUCN Category II, located approximately 5 km southeast of Cape Conran and to the north-east of the operational area, comprises a granite outcrop covering an area of 220 ha and extending for a distance of approximately 500 m from the edge of the exposed reef. It rises from a depth of approximately 30 m and is exposed at low tide, providing a resting area for Australian fur seals. The reef is covered by outcrops of Bull kelp (Durvillaea sp.) and supports a range of marine life, including seahorses and leafy seadragons (ParksVic, 2017b). Beware Reef is a popular location for recreational divers and the remains of numerous shipwrecks can be encountered in the sanctuary.

2.2.8.8 Cape Conran Coastal Park - VIC

The Cape Conran Coastal Park extends from Sydenham Inlet in the east to Point Ricardo near Marlo. The park includes ocean beaches and is a popular park for water activities - swimming, diving, boating, fishing and rock pooling.

Many birds feed on the nectar rich plants of the heathlands and banksia woodlands including the threatened Ground parrot (Pezoporus wallicus wallicus). Lizards and large lace monitors are common around Cape Conran (Parks Victoria 2017i).

2.2.8.9 The Lakes National Park and Gippsland Lakes Coastal Park - VIC

The Gippsland Lakes are a group of large coastal lagoons in eastern Victoria, separated from the sea by sand dunes and fringed on the seaward side by Ninety Mile Beach. The main lakes - Wellington, Victoria and King cover an area of 340 km2 and have a shoreline of 320 km. The lakes are fed by a number of river systems. The largest of the rivers are the Latrobe River and the Avon River (flowing into Lake Wellington), and the Mitchell River, Nicholson River and Tambo River (flowing into Lake King). The system is linked to the sea by an artificial entrance near the eastern end, opened in 1889, where the town of Lakes Entrance is now situated (ParksVic, 2017j, ParksVic, 2017k).

The Lakes National Park covers 2390 ha bounded by Lake Victoria, Lake Reeve and the township of Loch Sport. Gippsland Lakes Coastal Park is a narrow coastal reserve covering 17,600 ha along approximately 90km of Ninety Mile Beach from Seaspray to Lakes Entrance. The Lakes National Park contains large areas of diverse and relatively undisturbed flora and fauna communities representative of the inner barrier of the Gippsland Lakes system. Gippsland Lakes Coastal Park takes in extensive coastal dune systems, woodlands and heathlands, as well as water bodies such as Lake Reeve and Bunga Arm (ParksVic 2017k).

The Gippsland Lakes system is listed under the Convention on Wetlands of International Importance (Ramsar). The Gippsland Lakes provide important feeding, resting and breeding habitat for approximately 80 waterbird species (ParksVic 2003, 2017j,k), and the lakes, and associated swamps and morasses, regularly support approximately 40,000 to 50,000 waterbirds.

Clydebank Morass, Macleod Morass and Jones Bay (within Lake King) support many species of migratory waders. Lake Wellington, Lake Victoria and Lake King support migratory seabirds, including the little tern and fairy tern, as well as a range of other waterfowl. Lake Reeve provides significant habitat for a large number of migratory waders, and is listed as one of the five most important areas for shorebirds in Victoria (Parks Victoria, 2003). Bunga Arm supports breeding populations of threatened species e.g. Little tern, Fairy tern, Hooded plover and White-bellied sea-eagle (ParksVic 2003, 2017k).

2.2.8.10 Ninety Mile Beach Marine National Park - VIC

Located 30 km south of Sale and adjacent to Gippsland Lakes Coastal Park, the Ninety Mile Beach Marine National Park covers 5 km of coastline. The huge subtidal sandy expanses characteristic of the area exhibit particularly high species diversity including tube building worms, small molluscs and many tiny crustaceans. Many pelagic fish species feed on the benthos, and young Great white sharks have also been observed feeding in the area (ParksVic 2017c).

2.2.8.11 Corner Inlet and Nooramunga Marine and Coastal Park - VIC

The Corner Inlet and Nooramunga Marine and Coastal Parks are protected from Bass Strait by sand barrier islands and Wilsons Promontory. Corner Inlet and Nooramunga consist of shallow marine waters, intertidal mudflats and a series of sand islands. Corner Inlet and Nooramunga Marine and Coastal Parks contain a diverse range of habitats including large stands of white mangrove and saltmarsh areas. Seaward of the mangroves are extensive areas of intertidal mud and sand flats which provide food for thousands of migratory wading birds each year.

Thirty two species of migratory waders have been recorded, including the largest concentrations of Bar tailed godwit and Great knot in south eastern Australia. In summer, the ocean beaches and sand spits are also used as nesting sites by shorebirds like the Pied oyster catcher, Crested tern, Caspian tern, Fairy tern, Hooded plover and the endangered Little tern. Fringing the saltmarshes and mangroves on the mainland and islands are stands of swamp paperbark and coast tea-tree, and further inland woodlands of coast banksia and manna gum. These are home for a variety of animals including the New Holland mouse, swamp antechinus, Orange-bellied parrot, Ground parrot and White-bellied sea eagle. The parks are recognised as wetlands of international importance under the Ramsar convention (Parks Victoria 2017d and 2017e).

2.2.8.12 Corner Inlet Marine National Park - VIC

Corner Inlet Marine National Park is located north and east of Wilson's Promontory adjacent to the southern shores of Corner Inlet. The National Park protects large areas of seagrass including the only extensive Posidonia australis meadow in southern Australia. Amongst the seagrass live over 300 marine invertebrates including crabs, seastars, sea snails, squid and many fish including pipefish, stingrays, flathead, whiting and flounder. The seagrass and surrounding marshes are particularly important for international migratory birds such as the Eastern curlew (Parks Victoria 2017e). The area has been listed as part of the Corner Inlet Ramsar Site.

2.2.8.13 Wilsons Promontory Marine National Park - VIC

Wilsons Promontory Marine National Park is Victoria's largest Marine Protected Area (MPA) at 15,550 ha and is located around the southern tip of Wilsons Promontory. There is a diversity of marine life including octopus, sharks and rays. It is a popular location for recreational divers particularly around the sponge gardens. The offshore islands support many colonies of fur seals and oceanic birds such as Little penguins, Fairy prions, Silver gulls and Pacific gulls (Parks Victoria 2017g).

Wilsons Promontory National Park is a popular tourist destination due to its coastal scenery and diverse natural environments. Tourist activities include walking, camping, sightseeing, viewing wildlife, fishing, boating, diving, sea kayaking and surfing.

The park is important for its range of plants and animals, including many threatened species including the New Holland mouse, Ground parrot and White-bellied sea eagle. Coastal features include expansive intertidal mudflats, sandy beaches and sheltered coves interrupted by prominent headlands and granite cliffs in the south, backed by coastal dunes and swamps.

The avifauna recorded for Wilsons Promontory includes around half of all Victorian bird species. Significant species of migratory wading birds feed on the tidal mudflats of Corner Inlet within and adjoining the park. The offshore islands have breeding and roosting sites for sea birds, including a large number of Short-tailed shearwaters (Parks Victoria 2017g).

2.2.8.14 Cape Liptrap Coastal Park - VIC

Cape Liptrap is a narrow peninsula formed by the spine of the Hoddle Range running out to sea. It consists of steep cliffs flanked by rock pinnacles and wave cut platforms. Between Venus Bay and Cape Liptrap the coast varies between cliffs of dune limestone and rock stacks and pebble beaches to broad sandy beaches backed by high dunes.

The Gunai/Kurnai and Boonwurry people have inhabited this area for over 6000 years. Middens mark the location of camps along the coast.

Along the coast Pacific Gulls, Silver gulls, Sooty oystercatchers and herons feed on the beach and rock platforms, and cormorants and Australian gannets forage for fish (ParksVic, 2018).

2.2.8.15 Bunurong Marine and Coastal Park and Bunurong Wilsons Promontory Marine National Park - VIC

The Bunurong group of parks stretches along 17 km of coastline. The Bunurong Marine National Park is 2,100 ha in size and adjoins the Bunurong Marine Park and Bunurong Coastal Reserve.

The coastal waters protect a remarkable range of habitats including intertidal reefs, subtidal rocky reefs, algal gardens and seagrass beds. The coastal waters share the cool waters of Victoria's central and western coasts but, unlike those shores, are relatively protected from the oceanic south-westerly swell by the position of distant King Island. The gently sloping rocky seafloor is also unusual in Victoria.

The marine life of the region is considered special due to the unusual set of environmental conditions. The intertidal sandstone reefs of the area boast the highest recorded diversity of intertidal and subtidal invertebrates in eastern Victoria. The range of seaweed species is also large and includes greens, blue-greens, browns and encrusting, coralline reds.

Seagrass meadows and sandy bays are also important habitats within the area. The diversity of habitats supports many marine animals including seastars, featherstars, crabs, snails, Port Jackson Sharks and up to 87 species of fish.

The coastal area is home to the Hooded plover which breeds on the beaches (ParksVic, 2018).

2.2.8.16 Phillip Island Nature Park - VIC

Phillip Island Nature Parks is part of the United Nations Scientific and Cultural Organisation (UNESCO) Western Port Biosphere Reserve, and abuts the Western Port Ramsar wetland. Phillip Island is part of Bunurong and Boonwurrung country, and the Nature Parks conserves important elements of the area's indigenous heritage, as well as historical sites of European settlement and agriculture. It is an important ecotourism site for Victoria and protects threatened flora and fauna and is a known breeding site for threatened marine species of Little Penguin and Short-Tailed Shearwaters, Hooded Plovers and has a population of Australian Fur Seals (PoV, 2013).

2.2.8.17 French Island Marine National Park - VIC

The park is 2,978 hectares in size and approximately 10 kilometres south of the township of Tooradin on the Victorian coast. The main ecological communities protected by the park include subtidal and intertidal soft sediments (including seagrasses, mangroves and a small area of saltmarsh), and the water column. Over 73 per cent of the park is intertidal. French Island Marine National Park provides important feeding and roosting habitat for forty listed bird species such as the grey-tailed tattler Heteroscelus brevipes and the intermediate egret Ardea intermedia and the critically endangered orange-bellied parrot Neophema chrysogaster. The park is also feeding habitat for twenty-seven internationally important migratory bird species. Syngnathids, the group that includes seahorses and pipefish, are protected and are found in the park (ParksVic, 2019c).

2.2.8.18 Churchill Island Marine National Park - VIC

Churchill Island Marine National Park covers 670 hectares and is located south of Rhyll on the eastern shore of Phillip Island. The main habitats protected by the park include intertidal and subtidal soft sediments (including small areas of mangroves and saltmarsh, and seagrasses), some shingle-cobble rock areas, and the water column. The park provides important feeding and roosting habitat for forty-one listed bird species including the critically endangered orange-bellied parrot Neophema chrysogaster. The park and surrounds is a feeding area for twenty-nine internationally important migratory bird species (ParksVic, 2019 a).

2.2.8.19 Yaringa Marine National Park - VIC

Yaringa Marine National Park covers 970 ha along the north of Western Port Bay in Victoria. It is typified by saltmarsh communities, coastal heaths and open woodlands and forms part of the Western Port Ramsar Site. The areas above high water mark are protected within Western Port Nature Conservation Reserve. The natural values include the seagrass, mangrove and saltmarsh communities that provide habitat for migratory wader and shorebird species. Extensive intertidal mudflats support a diverse range of invertebrate and fish species. The areas are also a place of Indigenous cultural significance. Boating, birdwatching and marine education are elements of its social value (ParksVic, 2007).

2.2.8.20 Mornington Peninsula National Park - VIC

Mornington Peninsula National Park covers 2,686-hectares along the coastline of the Mornington Peninsula situated approximately 90 km south of Melbourne. It contains important areas of native vegetation remaining on the Mornington Peninsula following depletion since European settlement. Of particular note are communities of coastal grassy forests, banksia woodlands and sand heathlands. The park has known breeding habitat in Victoria for the threatened Hooded Plover. The park's tourism values are important to Victoria (ParksVic, 2019 b).

2.2.8.21 Great Otway National Park - VIC

Great Otway National Park (103,185 ha) includes extensive forests and heathlands on much of the southern fall and many northern areas of the Otway Ranges, and much of the coastline between Torquay in the east and Princetown in the west. The area of the park is not continuous but contains large areas of public land, private and rural communities with larger towns nearby such as Anglesea, Lorne and Apollo Bay. The park is an integral element of Victoria's most popular regional tourism destination. The Great Ocean Road and Scenic Environs, also on Australia's National Heritage list (refer Section 2.2.2.1) intersects the park in many places. Covering a large area both on the coast and inland, the park has many values from European and Indigenous historic significance to educational and scientific significance for its geomorphic and geological forms. Its proximity to Melbourne and its past (logging) and present uses for rural and forestry are managed with the high demand for its scenic and recreational values including fishing, hunting and touring. Relevant to this plan are the conservation values of the park in the coastal regions and the numerous tourist and recreational values the coastline and beaches offer, primarily due to their natural beauty. The park supports several species of migratory birds and listed threatened species include the Shy Albatross, Wandering Albatross and Fairy Prion (ParksVic and DSE, 2009).

2.2.8.22 Port Campbell National Park and Bay of Islands Coastal Park - VIC

Port Campbell National Park and Bay of Islands Coastal Park combine to form a linear reserve along 65 km of Victoria's southern ocean coastline extending past the limits of the Great Otway National Park and covering a total area of 2,700 ha. The park extends to the limits of the National Heritage Great Ocean Road and Scenic Evirons place (refer Section 2.2.2.1). The Parks' geomorphical features including sheer cliffs and gorges, the arches and the off-shore stacks draw over five million visitors to the Great Ocean Road region each year. The park contains a wide range of remnant coastal vegetation types, including important coastal heathlands, which provide a valuable link between other patches of remnant vegetation in the area and contains a high diversity of plants. The area supports the endangered Australasian Bittern and listed marine species like the Great Egret and White-bellied sea-eagle (ParksVic, 1998).

2.2.8.23 Hogan Group - TAS

Hogan Island, the largest island in the Hogan Group, is a 232 ha granite island located in northern Bass Strait between the Furneaux Group and Wilsons Promontory. Recorded breeding seabird and wader species include Little penguin, Short-tailed shearwater, Pacific gull, Silver gull and Sooty oystercatcher (Brothers et al., 2001).

2.2.8.24 West Moncoeur Island and East Moncoeur Island - TAS

West Moncoeur Island and East Moncoeur Island are part of Tasmania's Rodondo Group lying in northern Bass Strait south of Wilsons Promontory. The islands are granite islands ringed by steep cliffs. Recorded breeding seabird and wader species include Little penguin, Short-tailed shearwater, Fairy prion, Common diving petrel, Pacific gull and Sooty oystercatcher. Both islands are considered important breeding sites for seabirds (Brothers et al., 2001). West Moncoeur Island holds an important breeding colony of Australian fur seals and is a nature reserve (DPIPWE, 2000).

2.2.8.25 Curtis Island Nature Reserve and Devils Tower Nature Reserve - TAS

Curtis Island, part of the Curtis Group, is a granite island with an area of 150 ha lying in northern Bass Strait between the Furneaux Group and Wilsons Promontory. It is a nature reserve and supports up to 390,000 breeding pairs of Short-tailed shearwaters. Other recorded breeding seabird and wader species include Little penguin, Fairy prion, Pacific gull and Sooty oystercatcher.

Other islands in the Curtis Group are Cone Islet, Sugarloaf Rock and Devils Tower. Devils Tower comprises two small granite islands with a combined area of 4.77 ha. It is a nature reserve and recorded breeding seabird species include Short-tailed shearwater, Fairy prion and Common diving-petrel. The island is also used as a regular haul-out site for Australian fur seals (Brothers et al., 2001)

2.2.8.26 Kent Group National Park and Kent Group Marine Reserve - TAS

The six islands and islets of the Kent Group comprise Tasmania's northernmost National Park. Surrounding the largest of the islands, the Kent Group Marine Reserve covers 29,000 ha of marine habitat including deep and shallow reefs as well as extensive sponge beds (TPWS 2017). The waters around the Kent Group include the southernmost strongholds of several fish species including the violet roughy, mosaic leatherjacket and Wilson's weedfish, and the southern limit of distribution of Maori wrasse, one spot puller and Bank's shovelnose. The Marine Protected Area (MPA) is made up of a sanctuary zone which is a 'no take' zone, and a habitat protection zone which allows for lower impact fishing (e.g. abalone and rock lobster fishing, hand line fishing).

The North East Isle is a 32.62 ha unpopulated granite island with a peak elevation of 125 m above sea level. Recorded breeding seabird and wader species include Little penguin, Short-tailed shearwater, Fairy prior, Common diving petrel, Pacific gull and Sooty oystercatcher (Brothers et al., 2001).

2.2.8.27 Logan Lagoon Conservation Area - TAS

Logan Lagoon Conservation Area is also a Ramsar wetland of international significance. Refer to Section 2.2.3.3 Logan Lagoon Ramsar Site for further information.

2.2.8.28 Strzelecki National Park - TAS

Strzelecki National Park covers 4216 hectares in the south-western corner of Flinders Island. Flinders is the main island in the Furneaux Group, a group of 54 islands in Bass Strait off the north-east coast of mainland Tasmania.

The national park protects rich and varied ecosystems as well as spectacular coastal and granite mountain landscapes. Strzelecki forms an area where plant and animal species found on mainland Australia and Tasmania overlap, making the park of important biogeographic significance. The park is also home to a high number of endemic species, rare flora and fauna and significant vegetation communities.

Flinders Island has particular significance as an important stop-over point for bird species migrating between the Australian mainland and Tasmania. A number of rare and threatened species occur in the park, including the Swift parrot, Forty-spotted pardalote, Grey-tailed tattler, and the Hooded plover (Tas Parks, 2018).

2.2.8.29 Lavinia State Reserve – TAS

Lavinia State Reserve located on the north-eastern side of King Island contains the Lavinia Ramsar wetland site which accounts for its primary values. Refer to Section 2.2.3.10 for information on this reserve.

2.2.8.30 Hunter Island Group – TAS

The Hunter Group of Islands is a group of 13 islands which lay off the north-west tip of Tasmania in Bass Strait. The two largest islands are Hunter Island and Three Hummock Island and they are surrounded by many smaller islands including Albatross Island, Kangaroo Island (Tasmania), Bird Island and Stack Island. The group supports large numbers of migratory and seabirds. The endangered Northern Royal Albatross, southern Giant Petrel and Grey- headed Albatross are only some of the listed migratory species. The Critically endangered Great Knot and endangered Sand Plover are known to roost on the islands. The Critically endangered Curlew Sandpiper and Eastern Curlew are known to occur in the area and the islands are breeding and feeding or foraging areas for many other threatened bird species (DoEE, 2019r). The Hunter Group of Island is listed as an Important Bird Area by Birdlife International, formerly the International Council for Bird Preservation.

2.2.8.31 Rocky Cape National Park - TAS

Rocky Cape National park has an area of about 3064 ha on the north coast of Tasmania. As the name suggests the park is valued for its geoheritage where the age of the rocks and the geomorphosis, movement and erosion over time has created a spectacular coastline, including caves which are now 20M above the waterline. Threatened species habitat for critically endangered Curlew Sandpiper, Swift Parrot, Bar-tailed Godwit, Far Eastern Curlew and a migration route for the critically endangered Orange-Bellied Parrot (TSSC, 2006).

2.2.8.32 Narawntapu National Park - TAS

The Park has a total area of about 4,500 hectares and stretches on the north coast of Tasmania along the coast of Bass Strait from the Port Sorell estuary in the west to the mouth of the Tamar River in the east. The Park includes the adjacent islands in the Port Sorell estuary and The Carbuncle, covers primarily land mass extending to the low water mark and the tidal flats but does not include marine or estuarine waters. Threatened ecological communities of saltmarsh occur in the area. Endemic flora species such as velvet bush, threatened species such as the grass tree, and several plant communities which are unreserved or poorly reserved elsewhere in the State reserve system make this park an area of high conservation value for Tasmania. Threatened fauna species recorded are the Green and Gold frog, Swift Parrot, Wedge Tail Eagle and Great Crested Grebe. Endemic species found here are the Tasmanian Pademelon and the Bettong (TPWS, 2016).

2.2.8.33 Mt William National Park - TAS

Mt William National Park located in the far north-east corner of Tasmania is an important area for the conservation of Tasmania's coastal heathlands and dry sclerophyll plants. Being a coastal park, Mt. William is an excellent area for observing sea birds. Gulls, terns, gannets, and albatrosses can be seen, as well as both the Pied and Sooty oystercatcher. Although not common, both the White-bellied sea eagle and the Wedge-tailed eagle can sometimes be spotted soaring overhead. Mt William is also the first and last stop off point for some migratory birds such as shearwaters (TPWS, 2014).

2.2.8.34 Freycinet National Park and Wye River State Reserve - TAS

Freycinet National Park on the east coast of Tasmania comprises a total area of some 16,803 hectares and includes Freycinet Peninsula, Schouten Island and nearby offshore islets and rocks extending in each case to the low water mark. The park has visitor, recreation and conservation zones which also include cultural and historical values. Freycinet National Park is important for the conservation of Tasmania's dry sclerophyll plant communities on granite and dolerite, and the conservation of a range of rare and endemic plant species, including several threatened species. The Park is important for wading birds due to its proximity to Moulting Lagoon, a wetland of international importance. All of the Park's offshore islands, islets and rocks are important breeding and resting sites for seabirds. Australian Fur Seals and Leopard Seals haul out to rest on the Islands. Vulnerable species include the Hooded Plover, Swift Parrot, Wedge Tail Eagle, White-bellied Sea Eagle, Shy Albatross and Black-browed Albatross, White-fronted Tern and Fairy Tern. With the wide diversity in habitats, the park is important for conservation of numerous native and endemic species of flora and fauna and together with its social values is a renowned Tasmanian recreation and tourist destination (TPWS, 2000).

2.2.8.35 Maria Island National Park and Ile des Phoques Nature Reserve - TAS

Maria Island lies off the south-east coast of Tasmania and has a total area of about 11,550 hectares which includes a marine area of 1878 hectares. Except for Lachlan Island in Mercury Passage, the Park includes all the islands, rocks, and reefs adjacent to the coastline, most notably Ile du Nord (Rabbit Island) and Ile des Phoques Nature Reserve located midpoint between Maria Island and Schouten Island (TPWS, 1998). Threatened ecological communities include Giant Kelp Marine Forests and subtropical and temperate coastal saltmarsh (EPBC, 2019a). The area includes 53 threatened species including the critically endangered Swift Parrot, Curlew Sandpiper, Eastern Curlew and Bar-tailed Godwit. The waters around Maria Island are known foraging and feeding areas for vulnerable Humpback Whales and other marine mammals may also feed in the area. The park is rich in poorly reserved flora species. The Australian Convict Site, Darlington Probation Station is listed in the world Heritage list and was a penal colony established by Governor Arthur.

The Maria Island Marine Reserve on the north and north-west coast of the island covers 1250 ha and extend out to 1km from shore (or 20m depth) and include a sanctuary zone for the protection of kelp species (TPWS, 2019).

2.2.8.36 Tasman National Park and Reserves - TAS

Tasman National Park in the south-east of Tasmania has an area of 10,755 hectares and includes the adjacent offshore rocks and islands and includes several reserves. As many of the national parks on the east coast, the Tasman Park has geoheritage significance. Due to the substantially undisturbed landscape it is significant for flora and fauna conservation. Threatened fauna include the endangered Wedge- Tailed Eagle, Shy Albatross, Swift Parrot, Live-Bearing Sea Star. Several threatened flora species also occur in the Park. Several historic sites have been recorded in the park and reserves, and include examples of historic heritage from the convict era, through to maritime history and timber harvesting (TPWS, 2011). Whilst it does not include the world heritage Port Arthur site, the park spans either site of the entry to the port.

2.2.8.37 South Bruny National Park - TAS

South Bruny National Park (5,059 ha) provides key habitat for a number of threatened species, particularly bird life. The hooded plover uses the sandy beaches and dunes to nest, and the critically endangered swift parrot depends on blue gums for its specialised diet. The marine environment surrounding the park is home to seals and whales. The Australian fur seal, the most common seal in Tasmanian waters, can be seen around The Friars. Bruny Island was home to the Nuenonne clan of the South East nation of Tasmanian Aboriginal people and the park contains a number of important Aboriginal sites, including middens, quarries and artefact scatters (TPWS, 2020a).

2.2.8.38 Southport Lagoon Conservation Area – TAS

Lying approximately 80 kms south of Hobart the 4,280 hectare Southport Lagoon Conservation Area possesses a wide diversity of significant natural, cultural and recreational values. The lagoons and fringing vegetation support many bird species and fish nurseries. The historically significant Bruni D'Entrecasteaux's 1792 expedition documented plants found at the time, all of which still remain, including the 25 species that were thought to be extinct. Whaling stations operated to the north of the lagoon in the early 1900's but became unviable by the late 1840s due to overfishing (TPWS, 2020b).

2.2.8.39 Lord Howe Island Permanent Park Preserve - NSW

Lord Howe Island Permanent Park Preserve includes a major part of the Lord Howe Island Group but excludes the settlement areas of the island (residential and tourist accommodation and agricultural lands). Whereas a National Park does not allow any harvesting, the management of the *Preserve* allows for sustainable harvesting of some natural resources, in this case mainly palm seeds. Lord Howe is listed as World Heritage (refer to Section 2.2.1.2) for its exceptional natural beauty and for a place which has habitats where populations of rare or endangered species of plants and animals still survive. The Lord Howe Island Group forms one of the major seabird breeding sites in the Tasman Sea and is thought to be home to the most diverse and largest number of seabirds in Australia, 34 bird species regularly breed on the island. The summit and slopes of Mt Lidgbird and Mt Gower support almost the entire breeding population of the marine bird, providence petrel (Pterodroma solandri); the only known breeding locality in Australasia of the grey ternlet (Procelsterna cerulea) and vulnerable Kermadec petrel (Pterodroma neglecta neglecta); and the southernmost breeding locality in the world for the threatened masked booby (Sula dactylatra tasmani), sooty tern (Sterna fuscata) and common noddy (Anous stolidus) (DECCW, 2010a).

2.2.8.40 Cudgen, Wooyung and Billinudgel Nature Reserves - NSW

Cudgen, Wooyung and Billinudgel Nature Reserves are located just south of the QLD/NSW border and collectively cover approximately 7km of coastline. All are characterised by high species diversity and contain an overlap of the tropical and subtropical species close to the extent of their range. The three reserves conserve important coastal landscapes, remnant vegetation, and wildlife habitat in a region subject to considerable pressures from agricultural, residential, infrastructure and tourism development (DECC, 2007).

Cudgen Nature Reserve is also significant for wetland conservation in a local, regional and state context (NPWS, 1998d).

2.2.8.41 Cape Byron Marine Park - NSW

The Cape Byron Marine (State) Park is situated off the far north coast of NSW, wrapping around Cape Byron headland at Byron Bay and covers approximately 220 km^2 of NSW waters from the mean high water mark to 3 nautical miles offshore. It includes the tidal waters of the Brunswick River and its tributaries and Belongil and Tallow Creeks. It has multiple zones including Sanctuary, Habitat Protection and General Use.

The marine park conserves many subtropical marine habitats which support high levels of biodiversity including some threatened and protected species. It is strongly influenced by the East Australian Current (EAC) as warm waters from the north come together with cooler waters from the south. Julian Rocks within the park is an aggregation site for the endangered Grey Nurse Sharks, Carcharias taurus, who visit in winter (DPI, 2019a).

2.2.8.42 Byron Coast Group of Nature Reserves - NSW

The Brunswick Heads, Tyagarah and Broken Head nature reserves, together form the Byron Coast Group of Nature Reserves and cover about 922 hectares to the north and south of Byron Bay, a major tourist location. Like many of the parks and reserves described in this region, their importance as a group of protected areas is greater than their importance individually for nature conservation. These reserves, together with the surrounding parks and reserves form a discontinuous chain that protect habitats which support a diverse range of wildlife and plant communities including refuges for animals of ecological significance and important links in the north-south migration of certain animal species. Protection of these reserves becomes increasingly important in the face of growing population and recreational use (NPWS, 1998c).

2.2.8.43 Arakwal National Park and Cape Byron Conservation Area- NSW

Arakwal National Park is a 185.2 ha area created under an Indigenous Land Use Agreement (ILUA) with the Arakwal people as part of resolving a native title claim. It is situated 2km south of Byron Bay which is a regional and international tourist destination. It is a core component of the protected areas in the Byron Coast Group of reserves discussed above and also has significant values to its aboriginal people, the Arakwal people, who have been associated with the coastal landscape for over 22,000 years. The Park protects significant coastal habitat including a large area of honeysuckle country (Banksia heathland) that is home to a range of native plants and animals including threatened ecological communities and species (DEC, 2007).

Situated on the most easterly point of the Australian mainland on the far north coast of NSW, Cape Byron Headland Reserve is a State Conservation Area of 98.5 ha. It adjoins the Arakwal National Park and is equally important to the Arakwal people. It has rich historical heritage symbolised by the Cape Byron Lighthouse and is a major tourist attraction in walking distance to the Byron Bay township, providing various recreational activities including hiking, hang-gliding and whale watching (CBT, 2002).

2.2.8.44 Broadwater National Park, Bundjalung National Park and Iluka Nature Reserve - NSW

Broadwater National Park, Bundjalung National Park and Iluka Nature Reserve collectively form part of a major conservation system covering much of the subtropical coast of northern NSW. They protect most of the coastline (over 20,000 ha of coastal land) from Ballina on the Richmond River to the north and Iluka on the Clarence River to the south. The parks are significant as they exhibit high levels of biodiversity and a range of faunal species, which reflects the diverse vegetation communities and climatic conditions within the three areas. They contain subtropical communities, being at the end of the southern range of the subtropics, as well as coastal communities and also support temperate species. The parks protect more than 280 species of reptiles, birds and mammals. Twenty-six species of birds are recognised as being either endangered or vulnerable and therefore of high conservation status. (NPWS, 1997). The coastal wetlands, dunes and ocean foreshores are important feeding and roosting sites for a number of migratory and resident shorebirds. The Iluka Nature Reserve also protects a significant remnant area of sub-tropical littoral rainforest as part of a system of rainforest parks which are World Heritage listed (refer 2.2.1.3) (NPWS, 1997).

2.2.8.45 Yuraygir National Park - NSW

Yuraygir National Park on the north coast of NSW covers an area of 32,898 ha including over 80 kms of coastline. The park protects a wide range of vegetation communities and protects habitats which support a diverse range of wildlife communities including animals of ecological significance and species at the limit of their distribution (tropical and subtropical overlap). The park is also an important link in the north-south migration of certain animal species including the little tern, ruddy turnstone, Mongolian plover, pied oyster-catcher, sooty oyster-catcher, white-bellied sea eagle, eastern curlew, red-necked stint and the common sandpiper (NPWS, 2003).

2.2.8.46 Solitary Islands (State) Marine Park - NSW

Adjacent to the Yuraygir National Park and continuing south to Coffs Harbour is the Solitary Islands Marine Park which covers the area between the coast and the Commonwealth Solitary Islands Marine Park (refer Section 2.2.6.10). It has multiple zones including Sanctuary, Habitat Protection and General Use. It is approximately 710 km^2 from the mean high water mark to three nautical miles offshore, including estuaries to their tidal limit. The marine park is unique in that it contains diverse habitats (estuaries, sandy beaches, intertidal rocky shores, sub-tidal reefs, submerged solitary islands and open oceans) that support a diverse range of fish species including large pelagic fish. Turtles, shelled animals and many marine snails and slugs are also present, especially on the western side. In Anemone Bay in the north of the park the wildlife is particularly diverse and supports the dense coverage of anemone and anemone fish. The park is also the northern most breeding site recorded for the giant cuttlefish (DPI, 2019b).

2.2.8.47 Coffs Coast Regional Park and Moonee Beach Nature Reserve - NSW

Coffs Coast Regional Park covers a narrow, disjunct strip of coastal land stretching from near Corindi to the northern end of Park Beach, Coffs Harbour, covering an area of 562ha. The position of the park adjacent to a major regional city, a number of coastal villages and a wide range of tourism accommodation (including resorts and caravan parks) leads to pressure on the park from high visitation rates and varied land uses next to the park (NSW OEH, 2017c).

Moonee Beach Nature Reserve covers 336 ha and is located between areas covered by the Coffs Coast Regional Park. Many threatened species of fauna are found in the reserve, many of which are migratory bird species such as the wedge-tailed shearwater and the little tern. They too are threatened by increasing visitation rates (NSW OEH, 2012d).

2.2.8.48 Muttonbird Island Nature Reserve - NSW

Muttonbird Island Nature Reserve covers an area of around 9 hectares and is located adjacent to the coastline at Coffs Harbour on the mid north coast of NSW. It consists of two islands: Muttonbird Island and Little Muttonbird Island. As the name suggests, the reserve is a significant breeding site for the listed migratory wedge-tailed shearwaters (Puffinus pacificus) which migrate from Asia every year in August to breed on the island. As well as the migratory birds a number of threatened species have been recorded on the island including the vulnerable black-winged petrel (Pterodroma nigripennis), osprey (Pandion haliaetus) and sooty oystercatcher (Haematopus fuliginosus) (NPWS, 2009b)

2.2.8.49 Bongil Bongil National Park - NSW

Located 10km south of Coffs Harbour on the north coast of NSW is the 4,316 ha Bongil Bongil National Park. The park has over 10 km of coastline and is important as it protects coastal wetlands, creeks and estuaries that are crucial habitat for many native plant and animal species. The park contains diverse range of vegetation including threatened ecological communities such as Littoral Rainforest and Swamp Sclerophyll Forest on Coastal Floodplains. The park supports many species of shorebirds including the endangered Curlew sandpiper and Little Tern. With its close proximity to Coffs Harbour city and other smaller town, visitation to the park and enjoyment of the coastal areas is high (NSW OEH, 2017b)

2.2.8.50 Jagun Nature Reserve - NSW

Jagun reserve is located adjacent to the township of Valla Beach on the mid north coast of NSW. Although it is only 103 ha, the reserve is a critical part of a regional habitat corridor known as the

Oyster Creek Urunga Corridor linking large areas of coastal vegetation from Deep Creek in the south to the Bellinger River in the north, providing potential key linkages for threatened forest fauna. Jagun Nature Reserve has a number of small drainage lines which flow into Oyster Creek, which intermittently opens and closes to the ocean thereby having a short distance of transition between marine and freshwater vegetation, and variations in salinity dependent upon contact with the ocean. The entrance to Oyster Creek is highly significant to the Aboriginal Gumbaynggir people (NPWS, 2008).

2.2.8.51 Gaagal Wanggaan (South Beach) National Park- NSW

Gaagal Wanggaan (South Beach) National Park (637ha) is owned by the Aboriginal Gumbaynggir people and leased back to and jointly managed with the NSW Parks and Wildlife Service. Encompassing Warrell Creek, Gaagal Wanggaan (South Beach) National Park covers an undisturbed coastal dune system, littoral rainforest, shrubland, and estuarine mangroves which support a diverse range of coastal fauna and flora. The park contains significant Aboriginal cultural values including sites that show the continuous use of the area by Aboriginal people, as they have for thousands of years (NSW OEH, 2019b).

2.2.8.52 Hat Head National Park- NSW

Together with Limeburners Creek Nature Reserve, Sea Acres Nature Reserve and Crowdy Bay National Park, Hat Head National Park (7,220 ha) forms a system of protected areas between Harrington in the south and South West Rocks in the north which is broken only by the coastal towns and villages. Extensive wetlands of the Limeburners Creek Nature Reserve discussed below (refer Section 2.2.8.53) parallel the beaches of Hat Head National Park although these are being invaded by huge mobile dunes. Hat Head National Park contains the northern range limit of a number of temperate species of flora and fauna as well as the southern limit of many tropical and sub-tropical species as it is located at the Macleay-Mcpheerson Overlap; an ecological transition zone between the temperate southern areas of eastern Australia and the tropical north. The zone of overlap has significance for the number and diversity of both plant and animal species (NPWS, 1998a).

2.2.8.53 Limeburners Creek National Park - NSW

Limeburners Creek National Park covers 9,123 ha of coastal land north of Port Maquarie on the NSW mid-north coast. It incorporates large portion of Limeburners Creek Nature Reserve which is nationally significant freshwater and estuarine wetland. These provide habitat for many threatened and migratory bird species. Oher natural values include wet and dry heathland, littoral rainforest, eucalypt forest and woodland. The park contains a high concentration of indigenous relics including what may be fish trap, one of only three in the north coast of New South Wales (NPWS, 1998b).

2.2.8.54 Sea Acres National Park - NSW

Sea Acres National Park is located near Port Macquarie on the mid-north coast region of New South Wales. It is famous for its 1.3 km rainforest walk however has a coastal region also where evidence of its indigenous heritage and the way that the Birpai People likely used the area for fishing, hunting and gathering (NPWS, 2019c).

2.2.8.55 Crowdy Bay National Park and Watson Taylors Lake - NSW

Located on the mid-north coast of New South Wales, 25 km north-east of Taree is the 8,022 ha Crowdy Bay National Park which has within it the nationally significant, freshwater Watson Taylors Lake wetland. Part of the wetland is Blackfellows Bog, which is of high scientific value as it contains a wealth of palynological material which will allow scientists to reconstruct the many vegetative and climatic changes that have occurred over the last several thousand years in the Crowdy Bay area. Other significant natural values of the park include remnant stands of littoral rainforest at Crowdy Gap and Diamond Head and both wet and dry heath communities. The heath contributes to the park's attraction as a place for spring wildflower display, being renowned for many scenic features of the park together with beaches, headlands and sand plains. The park also contains undisturbed indigenous middens dating back approximately 6,000 years (NPWS, 1987).

2.2.8.56 Darawank, Khappinghat and Kattang Nature Reserves - NSW

Along the coast between Forster and Camden Haven are the Darawank (1191 ha), Khappinghat and Kattang (68 ha) Nature Reserves. Darawank Nature Reserve, occupies the largest area along the coast and supports a diversity of wetland and coastal vegetation communities providing habitat for threatened shorebird species including the Australian pied oystercatcher (Haematopus longirostris) and little tern (Sternula albifrons) and nesting site for the endangered black-necked stork (Ephippiorhynchus asiaticus). Consistent with the adjacent parks, these reserves have important ecological communities of littoral rainforest and subtropical rainforest (NSW OEH, 2014). Khappinghat is mainly inland but includes the approximately 3.45km of beach and Kattang is a dramatic cliffed headland which is a popular spot for fishing, viewing wildflowers and whale hatching (NPWS, 2019b).

2.2.8.57 Booti Booti National Park and Wallis Lake - NSW

Booti Booti National Park is 1566 ha park, approximately 10km long, 3.25 km wide at its widest point and 400m wide at its narrowest. It's a peninsula which runs between the Forster town in the North and Charlotte Head in the south and separates the ocean from Wallis Lake, which is a nationally important wetland. The park consists of what was 3 hill, island complexes that have been joined to the mainland through deposited sand. The dominant plant community is dry, subtropical rainforest and also includes Littoral rainforest as well as other plant communities (Griffith et al., 2014). Its estuarine waters provide habitat to over 200 bird species including the endangered little tern (NPWS, 2019d).

Wallis Lake is a nationally significant wetland and one of the lakes which form The Great Lakes of NSW (including Myall Lakes see Section 2.2.8.58 below). Wallis Lake supports the northern-most limit of the seagrass Posidonia australis and 20 per cent of the total seagrass communities in New South Wales (DoEE, 2006).

2.2.8.58 Myall Lakes National Park Little Broughton Island and Stormpetrel Nature Reserves-NSW

The extensive waterways including Bombah Broadwater, Boolambayte Lake and Myall Lake are the dominant feature of this park. The Myall Lakes Ramsar site also overlaps with the park (refer Section 2.2.3.10). Its proximity to Newcastle and Forster on the central coast of NSW and the dunes, waterways and 40kms of beach make Myall National Park the most frequently visited National Park in northern NSW.

The Myall Coast Reserves include Little Broughton Island (36 ha) and two islands known as Inner Rock and North Rock which together form Stormpetrel Nature Reserve (8 ha). They are located about 3 km offshore near Broughton Island. The three islands are important breeding sites for seabirds, of particular note are the White-bellied Sea Eagle and the Wedge-tailed Shearwater. Little Broughton Island is also recognised as the northern most breeding site for the short-tailed Shearwater (NPWS, 2002).

2.2.8.59 Tomaree National Park - NSW

Tomaree National Park is located in the Port Stephens area of NSW, approximately 45km north of Newcastle and covers an area of approximately 2,310 ha. The park is one of a group of conservation reserves in the Port Stephens area which protect a coastal landscape of regional and state importance. Nearby Nelson Bay is a popular holiday destination for people in Sydney and the park has over 100,000 visitors per year. The park's important values include evidence of important geological events, essential wintering habitat for a variety of birds, conservation of heath communities on volcanic rock (rhyodacite) which have restricted distribution in NSW (NPWS, 2006).

2.2.8.60 Worimi Conservation Lands - NSW

The Worimi Conservation Lands covers a total area of 4029 ha comprising the Worimi National Park (1812 ha), 881 ha of state conservation area and 1336 ha of regional park. It is located north of the Hunter River, Newcastle and covers approximately 25km of coastline including the intertidal zone down to the low water mark. Ownership of the land is by the Aboriginal Worimi people and it is leased back to the New South Wales government. It is managed under a jointly between the government and the Worimi people. It has significant indigenous heritage values with burial sites, ceremonial cites, middens extensive archaeological material. Worimi is an important habitat link within a broader wildlife corridor comprising the Wetlands National Park in the south-east and Tomaree National Park in the north-east (refer Section 2.2.8.59), linking Port Stephens to the Watagans, south-east of Newcastle. Many listed bird species are known to occur there including the endangered curlew sandpiper, little tern and pied oystercatcher (NSW, OEH, 2015).

2.2.8.61 Glenrock State Conservation Area and Awabakal Nature Reserve - NSW

Glenrock State Conservation Area of 534 ha is significant as it contains ten nationally significant vegetation communities, including lagoon (Glenrock Lagoon) and the threatened ecological community of littoral rainforest. The conservation area contains many cultural records, both Aboriginal and European, and is located within the Awabakal Local Aboriginal Land Council area (NPWS, 2010).

Awabakal Nature Reserve to the south of Glenrock State Conservation Area has similar values to Glenrock. The Redhead Lagoon provides one of the most important sources of information on the vegetation history of eastern Australia through the last full glacial–interglacial cycle.

Both areas are important habitat for the threatened terrestrial birds and mammal species. The proximity of these areas (8km and 15km to Newcastle city respectively) makes these highly used areas for educational and recreational purposes (NPWS, 2014c).

2.2.8.62 Munmorah State Conservation Area and Bird Island Nature Reserve and Wallarah National Park - NSW

Munmorah State Conservation Area is on the coast of NSW, approx. 40 km north of Gosford and has an area of 1,515 ha, including 12km of coastline. A range of vegetation communities including woodlands, open forests, wetlands, coastal tea tree shrubland and coastal heath support diverse fauna including the listed osprey (*Pandion haliaetus)* and sooty oystercatcher *(Haematopus fuliginosus).* The 7.3 ha Bird Island with its steep vertical cliffs is an important nesting and roosting area for seabirds including listed and migratory species including species of shearwater, godwit, curlew, terns and the arctic jaeger (also known as arctic skua) (*Stercorarius parasiticus)* (DoEE, 2019o) (NPWS, 2009a).

To the north of the park is the Wallarah National Park, primarily an inland park of 178 ha with approximately 2km of coastline. Seabirds and migratory birds found in the Munmorah State Conservation Area may also occur here (NPWS, 2014b)

2.2.8.63 Wyrrabalong National Park - NSW

Wyrrabalong National Park is located on the Central Coast of New South Wales approximately 105 km north of Sydney. The 620 ha park conserves the largest stands of littoral rainforest and Sydney red gums on the NSW Central Coast as well as significant freshwater wetlands. It also contains six endangered ecological communities (coastal saltmarsh, Littoral rainforest, swap oak and swap sclerophyll forest, freshwater wetlands and themeda grassland), significant habitat for a number of threatened animal species and a variety of Aboriginal sites, including an extensive midden at Pelican Point. The protected lake and foreshore and island provide important habitat for migratory birds and seabirds (NPWS, 2013).

2.2.8.64 Bouddi National Park, Brisbane Water National Park & Ku-ring-gai Chase National Park - NSW

Broken Bay, 46 km north of Sydney has three national parks at its entrance and is also the mouth of the Hawksbury River. Bouddi is at the north headland and comprises approximately 1,532 ha (NPWS, 2019a) and one of the first marine parks to extend down to the low water mark and therefore one of the first marine protected areas. Brisbane Waters National Park comprises approximately 11,506 ha. Both parks are significant is their representation of sandstone parks, coastal habitats and communities typical of the Sydney region. They are important in that together with the Ku-ring-gai Chase National Park on the south of the bay, also a National Heritage listed place (refer Section 2.2.2.2), they are a part of a system of reserves which protects the State and regionally significant waterways of the lower Hawkesbury River, Broken Bay, Pittwater and Brisbane Waters. The extensive areas covered by the three parks support a diverse range of communities which support native floral and faunal species. The parks also contain a large number of significant indigenous sites and representations of Sydney rock art (NPWS, 1992). With their proximity to suburban Sydney they are popular tourist and recreational locations.

2.2.8.65 Sydney Harbour National Park - NSW

Sydney Harbour National Park covers 393 ha of headlands, beaches and islands in and around Sydney Harbour. The park includes six headlands including North Head on the northern side and South Head on the south side. The five islands within the park are Shark Island, Clark Island, Fort Denison, Goat Island and Rodd Island, extending well into the harbour past the Sydney Harbour Bridge. All parts of the park are within suburban Sydney city. Its list of values include historic, conservation values for the protection of native flora and fauna, indigenous heritage, landscape and recreation and tourism (NPWS, 2012),

2.2.8.66 Malabar Headland National Park - NSW

The Malabar headland, located in Malabar, 12 km south of Sydney, is a 177 ha park which has dramatic sandstone cliffs and provides spectacular coastal views. The western and eastern sections of the headland contain rare examples of the once extensive Port Jackson mallee scrub (Eucalyptus obstans, formerly Obtusiflora). Malabar headland also contains one of the largest, continuous remnants of the endangered ecological community listed as Eastern Suburbs Banksia Scrub. The site is a renowned site for viewing seabirds and marine mammals, in particular the white bellied sea eagle and the humpback whale (NPWS, 2014a). The headland also has indigenous heritage significance and includes shell middens that can be seen today.

2.2.8.67 Towra Point Nature Reserve - NSW

Located at Kurnell, Botany Bay, in Southern Sydney, Towra Point Nature Reserve is a 603 ha reserve. The site is one of the first contacts between European and Aboriginal peoples, Towra Point is a hugely important place for Australia as we know it today. In April 1770, the Cook expedition explored the area and mapped Towra Lagoon as a source of fresh water. Its fresh drinking water and historical richness in seafood provided an abundant source of food to the indigenous people and the nature reserve is now a dedicated Aboriginal Place. Towra Point Nature reserve forms the largest and most diverse estuarine wetland complex in NSW. Representing around half of the remaining mangrove area near Sydney, and most of the saltmarshes remaining in the region. The abundance of mudflat, fresh water wetlands and sea grass beds, it provides breeding, feeding and roosting sites for many threatened and migratory bird species. Towra Point can only be accessed by boat or kayak (DECCW, 2010b).

2.2.8.68 Kamay Botany Bay National Park - NSW

Located within the Sydney metropolitan area, Kamay Botany Bay National Park (or Botany Bay National Park) covers approximately 456 ha of the northern and southern headlands of the entrance to Botany Bay and includes over 13 km of coastline. As discussed in the section on National Heritage (Section 2.2.2) the park includes the Kurnell Peninsula and Botany Bay botanical sites, listed National Heritage Places. It is also renowned for the place of arrival of the French expedition under the command of Jean-Francois de Galaup, Comte de Laperouse in 1788 before the departure of the first fleet. Laperouse stayed in Botany Bay for six weeks and built a stockade, observatory and a garden for fresh produce on the La Perouse peninsula before leaving and not seen again. The association of the park with the history of the European exploration and the botanical collection of native plants by Banks and Solander are the two most prominent values, however, together with those is the symbolism of the meeting of the Indigenous and European cultures and the historical social issues that have developed from that and the opportunity to further explore current social issues such as reconciliation (NPWS, 2016). The retention of the largest remnants of the original vegetation communities of the Kurnell Peninsula and Eastern Suburbs and prominent scenic coastal headlands at the entrance to Botany Bay are also defined as core values of the park. The park is also part of a broader network of conservation areas in the region that provide secure protection for native plants and animals, sites of Aboriginal and historic heritage value and recreational opportunities for a growing population. On the southern Headland, the park abuts the Caltex fuel import terminal on the inland side of the park (NPWS, 2018).

2.2.8.69 Royal National Park - NSW

Royal National Park is a 15,068 ha park situated on the coast of NSW, adjacent to the southern fringe of metropolitan Sydney and about 30 km north of Wollongong. Royal National Park adjoins Heathcote National Park (2,251 ha) to the west and Garawarra State Recreation Area (900ha) to the southwest. These adjoining parks do not include coastal areas. The parks are significant for many reasons and these can be partially attributed to their accessibility to suburban Sydney combined with the parks' diversity of natural and cultural heritage which makes for high public profile and visitation rates for recreation, scientific and educational purposes (NPWS, 2000)

The park is amongst the most floristically diverse areas of its size in the temperate parts of the world. Well over 1000 plant species have been recorded, including 26 species which are listed as nationally rare or threatened. The place is important for its richness in a wide array of species including heaths (Epacridaceae), peas and wattles (Mimosaceae and Fabaceae), orchids (Orchidaceae), grevilleas and banksias (Proteaceae) and members of the eucalypt family (Myrtaceae) (DoEE, 2019).

Royal National Park is also recognised for its rich invertebrate fauna. The place is also extremely important as a centre of temperate animal species richness for a range of groups including perching birds (Passeriformes) especially honeyeaters (Meliphagidae), tree-frogs (Hylidae), reptiles (Reptilia) and butterflies (Lepidoptera). The place can be regarded as exemplifying the biodiverse Hawkesbury Sandstone environment.

Royal NP is one of only four coastal national parks in NSW that protect land below high water mark and associated estuarine habitats. The submerged and intertidal lands of South West Arm and Cabbage Tree Basin, both in Port Hacking, are part of Royal NP. Both areas are sheltered bodies of water which support nursery grounds for juvenile fish and invertebrates, seagrass beds and a diverse benthic fauna. Cabbage Tree Basin also supports a mangrove community and is an area frequented by migratory birds (NPWS 2000).

The Royal National Park and Garawarra State Conservation Area are listed on the National Heritage list, recognised for its importance as Australia's first National Park and the diverse and fascinating nature environments protected in the area (refer Section 2.2.2).

Other values of the park include:

Indigenous Heritage

- Aboriginal sites in the parks are of importance to the present day Aboriginal community for cultural revival, educational and historical reasons.
- Provides protection for a large number of Aboriginal sites, particularly rock engravings stylistically distinct from those north of the Georges River.
- Royal National Park protects several cultural landscapes, including the Audley precinct and the Bulgo and South Era cabins.

Natural Heritage

- The three reserves comprise a moderately large area of land protecting important landforms and plant and animal communities which are typical of the coastal and sub-coastal parts of the Sydney Basin.
- The three reserves are an important link in a corridor of natural lands extending from southern and south-western Sydney southwards to the Illawarra escarpment, the water catchment areas and beyond.

Historic

- Royal National Park protects several cultural landscapes, including the Audley precinct and the Bulgo and South Era cabins.

2.2.8.70 Five Islands Nature Reserve - NSW

Five Islands Nature Reserve includes five small islands clustered off the coast of Port Kembla, immediately south of the city of Wollongong within the Wollongong Local Government Area. The islands are clustered between approximately 0.5 kilometres and 3.5 kilometres off the coast. The main values of the islands include (NPWS, 2005):

- Evidence of geological and geomorphologic processes related to the formation of the Sydney Basin and subsequent landscape evolution;
- Habitat and breeding sites for the sooty oystercatcher (Haematopus fuliginosus), classified as vulnerable
- Breeding sites for the wedge-tailed shearwater (Puffinus pacificus), the shorttailed shearwater (Puffinus tenuirostris) and habitat for the white-bellied sea-eagle (Haliaeetus leucogaster), all of which are listed migratory species
- Importance to the Aboriginal community due to continuing cultural associations and past occupation of the area.

2.2.8.71 Seven Mile Beach National Park and Comerong Island Nature Reserve - NSW

Seven Mile Beach National Park and Comerong Island Nature Reserve are located on the south coast of NSW, approximately 50 km south of Wollongong. The national park covers much of the sand dune barrier along Seven Mile Beach and part of adjacent Coomonderry Swamp (NPWS, 2019). It was reserved in 1971 and has a current area of 898 ha. The nature reserve comprises several islands in the Shoalhaven delta and the beds of Comerong Bay, Comerong Lagoon and the channels between the islands. It was reserved in 1986 and has an area of 660 ha. Seven Mile Beach National Park contains one of the largest areas of natural coastal dune vegetation on the central part of the NSW coastline and the uncommon orchid *Dipodium hamiltonianum* occurs there.

Coomonderry Swamp is the only large semi-permanent freshwater wetland on the south coast and protects approximately one third of this type of habitat within NSW. It is an important drought refuge when smaller coastal wetlands and inland wetlands are dry and supports a diverse range of bird species. The swamp has a large population of the threatened green and golden bell frog *Litoria aurea*. Other threatened fauna recorded at Coomonderry Swamp include the Australasian bittern *Botaurus poiciloptilus* and black-necked stork *Ephippiorhynchus asiaticus*. Threatened species recorded elsewhere in the national park include the tiger quoll *Dasyurus maculatus*, yellow-bellied sheathtail-bat

Saccolaimus flaviventris, greater broad-nosed bat *Scoteanax rueppellii*, swift parrot *Lathamus discolor*, olive whistler *Pachycephala olivacea*, regent honeyeater *Xanthomyza phrygia*, masked owl *Tyto novaehollandiae* and powerful owl *Ninox strenua*.

The Comerong Island nature reserve protects one of the few large naturally vegetated delta systems in NSW. It contains an important sample of three major habitat types - tidal shallows, mangrove swamp and has the largest remaining area of littoral forest on the south coast of NSW. It provides habitat for a large number of threatened waterbirds and shorebirds including two species of oystercatchers and sandpipers and is an important estuarine system for waders. The park and reserve are important recreational resources for sightseeing and fishing (NPWS 1998).

2.2.8.72 Jervis Bay Marine Park - NSW

Jervis Bay Marine Park on the NSW South coast covers approximately 215 km2 and spans over 100 km of coastline and adjacent oceanic and estuarine waters. It extends from Kinghorn Point south to Sussex Inlet. It includes most of the waters of Jervis Bay, with the remainder forming part of the Booderee National Park on Bherwerre Peninsula. It contains the tidal waters of Currambene Creek, Moona Creek, Carama Inlet, Wowly Gully, Callala Creek and Currarong Creek, and the mean high water mark along the shores. The marine park has six estuaries, excluding Jervis Bay, four small coastal creeks and two larger, wave-dominated estuaries. Four seagrass species are abundant making it an important nursery for fish and providing food and shelter for recreationally and commercially valuable species such as snapper, bream, luderick, whiting and flathead. The rocky shores are important roosting and feeding grounds for shorebirds including the threatened sooty oystercatcher. Shallow and intermediate reefs support a wide range of biodiversity, including habitat for commercially and recreationally valuable fish and for invertebrates such as cuttlefish, crabs and rock lobsters (NSW DPI, 2019).

The park was established in 1998. The park contains important habitat for the endangered grey nurse shark. Protected species known to occur in the park include the eastern blue devilfish, elegant wrasse, black rockcod, some hard and soft corals, sea anemones, zooanthids, and all pipefishes and seahorses. Pied and sooty oystercatchers, hooded plovers and ospreys are among the threatened bird species known to nest, roost and/or feed on the rocky shores. Humpback and southern right whales are often spotted during migration and are an important tourist attraction.

Indigenous people have strong ties to the land with midden sites located in areas around the marine park. Nine shipwrecks have been found in Jervis Bay, including the Hive which was the only convict transport ship to be wrecked on mainland Australia.

2.2.8.73 Booderee National Park - NSW

Booderee National Park stretches across 6,379 hectares at the southern section of Jervis Bay on the south coast of New South Wales and includes 875 hectares of marine environment with values similar to those in Jervis Bay Marine Park. Booderee National Park is owned by the Wreck Bay Aboriginal Community and is jointly managed with Parks Australia. The park includes Bowen Island which has a sanctuary zone on the west coast to protect nesting seabirds and their habitat from disturbance. The marine environment has a habitat protection zoning designed to safeguard sensitive, rare and endangered habitats, including littoral areas and seagrass beds (PA, 2019 b).

2.2.8.74 Conjola National Park - NSW

Located in the mid coast of NSW the Conjola National Park covers 11,060 ha including forests, woodlands, rainforest, coastal scrub and wetlands and four endangered ecological communities: Coastal Saltmarsh; Swamp Sclerophyll Forest (important feeding; Swamp Oak Floodplain Forest and Bangalay Sand Forest. 429 plant species are represented, five of which are threatened. Twenty five species of threatened fauna occur in the park. Of these the regent honeyeater (Xanthomyza phrygia), swift parrot (Lathamus discolor), little tern (Sterna albifrons), hooded plover (Thinornis rubricollis) and green and golden bell frog (Litoria aurea) are endangered. High diversity and occurrence of Aboriginal sites including middens, campsites, rock shelters and grinding grooves. A number of heritage features are located in the park including a burial and monument for the 1870 shipwreck of the Walter Hood (NPWS, 2009).

2.2.8.75 Narrawallee Creek Nature Reserve - NSW

Narrawallee Creek Nature Reserve is located on the mid south coast of New South Wales approximately 7km north of Ulladulla and covers an area of 878 ha. It includes five endangered ecological communities being Coastal Saltmarsh, Swamp Sclerophyll Forest (dominated by swamp mahogany, an important food source for several threatened fauna including the yellow-bellied glider and grey-headed flying fox), Swamp Oak Floodplain Forest, Littoral Rainforest and Bangalay Sand Forest). Eleven species of threatened fauna recorded, including breeding sites for the little tern, hooded plover and pied oystercatcher. Both indigenous and historical values are placed on the reserve (NPWS, 2006).

2.2.8.76 South Pacific Heathland Reserve - NSW

The South Pacific Heathland Reserve is a 14 hectare flora and fauna reserve on the cliffs above the rock platform between Rennies Beach and Racecourse Beach at the southern end of Ulladulla. Its value is based on its diversity of local flora, birdlife, and spectacular heathland and panoramic coastal views and is a popular nature walking track. Whales may be seen from the viewing platforms during their migration seasons (DNSW, 2019).

2.2.8.77 Parks & Reserves – Meroo National Park - NSW

Meroo National Park is 3,731 ha of coastline, coastal lakes and inland forested areas located 5 km south of Ulladulla on the NSW south coast. High conservation values are attributed to the coastal lakes included in the park (Termeil, Tabourie and Wairo Beach Lagoon) and the foreshores and fringing wetlands of the adjoining lakes s (Meroo, Burrill and Willinga Lakes). As per the Narrawallee Creek Nature Reserve it includes endangered ecological communities Swamp Oak Floodplain Forest (Casuarina glauca – Melaleuca ericifolia), Coastal Saltmarsh, Littoral Rainforest, Bangalay Sand Forest (E. botryoides – Banksia serrata) and Themeda Grassland on Seacliffs and Coastal Headlands. At least 12 threatened fauna species including significant populations of the nationally endangered green and golden bell frog (Litoria aurea) have been recorded here. The park also has indigenous and recreational values due to mythological sites and a range of bush camping locations (NPWS, 2010).

2.2.8.78 Murramurang National Park - NSW

Murramurang National Park spans 44 km of coastline on the NSW south coast and supports more than 90 species of bird including gannets, shearwaters, White-faced storm petrels, Sooty oystercatchers and Little penguins. The forest of spotted gums stretches right to the ocean (NPWS, 2018).

2.2.8.79 Batemans Marine Park - NSW

The Batemans Marine Park was established in 2006 and covers approximately 85,000 hectares, extending from the north end of Murramarang Beach near Bawley Point to Wallaga Lake in the south. It includes all of the seabed and waters from the mean high water mark on the coast to three nautical miles offshore. It includes all estuaries, creeks, rivers and lakes (except Nargal Lake) to the limit of tidal influence. Scuba diving, snorkelling, beach going, whale, seal and other wildlife watching, fishing, swimming, surfing and boating are all popular pastimes.

The park covers a range of habitats, including continental shelf sea floor along with sponge gardens, beaches, rocky shores, kelp beds, coralline algal banks, rocky reefs, islands, seagrass, mangroves and estuarine habitats.

The Montague Island Nature Reserve, within the Marine Park, is a breeding and nesting place for over 40,000 sea birds including Shearwaters, Little penguins, Crested terns and Silver gulls and is a haul out site for Australian and New Zealand fur seals. Both Montague Island and the Tollgate Islands (also within the park) are aggregation sites for Grey nurse sharks.

Local Aboriginal communities have strong links to the area within and adjoining the Marine Park. The local Aboriginal communities within the Yuin Nation are actively involved in consultation on park issues affecting traditional use (DPI, 2018).

2.2.8.80 Eurobodalla National Park - NSW

Eurobodalla National Park contains a range of aquatic environments including lagoons, lakes, estuaries, sheltered and wild beaches that protect a wide variety of plants and animals. The National

Park provides an important habitat for a wide variety of birds with 131 bird species having been recorded in the park. Estuaries and headlands are important over-wintering areas for migratory birds, including 17 species of waders, and the Hooded plover and Little tern nest on the sand islands, sand spits and dunes.

Water based activities such as boating, fishing and swimming are all popular in the park (NPWS, 2018).

2.2.8.81 Mimosa Rocks National Park - NSW

Mimosa Rocks National Park takes its name from the Paddle Steamer Mimosa that wrecked in 1863 after running aground on rocks at the northern end of the park. The rocks of the park have distinctive castle-like features that are the result of geological folds, faults and intrusions.

The park provides important habitat for many migratory birds, including Hooded plovers and Pied oystercatchers that nest along the coastline. The Bar tailed godwit rests briefly here in summer months during its migration from Alaska to New Zealand.

The park is popular for fishing, surfing, snorkelling and birdwatching. From May to November, the headlands are excellent whale watching vantage points (NPWS, 2018).

2.2.8.82 Bournda National Park - NSW

Bournda has been a special place for the Dhurga and Yuin people for thousands of years and its name means ‘place of tea tree and kangaroos’. The estuarine wetlands provide roosting and feeding areas for a large variety of waders and waterfowl including threatened species such as Little tern, Hooded plover and Pied oystercatcher (NPWS, 2018).

2.2.8.83 Ben Boyd National Park - NSW

The Ben Boyd National Park is comprised of three sections, extending approximately 45 km along the coast north and south of Twofold Bay near Eden. The park’s vegetation reflects its location in the driest, windiest part of the state’s coastline. Open forest and woodland cover most of the park. The park’s varied habitat supports a highly diverse bird population and about 50 species of mammal including a number of threatened species. Migrating whales can often be seen from the coast between late May and December and the former Davidson Whaling Station located on Twofold Bay is a tourist attraction (NPWS 2017b).

2.2.8.84 K’gari, Great Sandy National Park – QLD

Fraser Island, Cooloola, Hervey Bay and some adjacent areas in south-east Queensland form the K’gari, Great Sandy Region National Park of about 840,000ha and is listed on the World Heritage list (refer Section 2.2.1.4). The habitats of a number of internationally and nationally threatened terrestrial and marine animals and plants occur within the Region. The marine areas and associated tidal wetlands of Hervey Bay, and the Great Sandy Strait and adjacent beaches support and harbour a diversity of marine life. Species include seasonal populations of humpback whales, dugong, dolphins, turtles, and trans-equatorial migratory wading birds which depend upon the Region for roosting and staging during their annual migrations. The Great Sandy Strait is recognised as a Ramsar Wetland of International Importance (refer Section 2.2.3.16) (QEPA, 2005).

2.2.8.85 Noosa National Park – QLD

Noosa National Park (2,280 ha) is situated on the Sunshine Coast about 150 km north of Brisbane. The Sunshine Coast has strong links to the adjacent Great Sandy Region in terms of geology, landscape components, climate, soils and vegetation. More than 181 bird species have been recorded in the park and adjacent intertidal areas. The Noosa Heads area provides habitat for 28 birds of conservation significance, including 20 migratory birds covered under agreements between Australia and Japan (JAMBA) and Australia and China (CAMBA) (QPWS, 1999).

2.2.8.86 Bribie Island National Park – QLD

Bribie Island is part of a network of coastal sand landscapes stretching from Stradbroke Island to Woodgate. The island is low-lying, with a maximum elevation of less than 10 metres, and the coastal environments including the salt marsh, tidal flats, mangroves, sandy beaches, wetlands and freshwater lakes, provide habitat for diversity of native animals including internationally protected resident and migratory shorebirds. The critically endangered eastern curlew is known to roost there. Shorebirds are threatened by human disturbance and destruction of nest sites (QPWS, 2013a).

2.2.8.87 Moreton Island, Southern Moreton Bay Islands South Stradbroke Island National Park – QLD

Moreton Island National Park (16,900ha), Southern Moreton Bay Islands National Park (1,646 ha) and North and South Stradbroke Island Conservation Park (1,440 ha) are located on the eastern edge of Moreton Bay, Queensland. Like the surrounding sand islands, these are ecologically significant with forest woodland, heathland, mangrove and grassland communities. The Southern Moreton Bay Islands National Park contains the most southern distribution of black mangrove Lumnitzera racemosa in Queensland (QPWS, 2013b). Moreton Bay and the sand islands provide a vital feeding and resting point for over 50,000 migratory waders and parts of Moreton Bay are listed as a wetland of international importance (refer Section 2.2.3.15) (PQWS, 2007), each area representing different extents of the various wetland systems.

2.2.8.88 Naree Budjong Djara National Park – QLD

Naree Budjong Djara National Park (132 km^2, forming approximately 50% of North Stradbroke Island) features places of incredible conservation value and a variety of special habitats, including endangered heathlands, freshwater lakes and woodlands, similar to the other islands in Moreton Bay. Its cultural significance to the traditional owners, the Quandamooka people, dates back thousands of years and the park is jointly managed by the Quandamooka people and Queensland Parks and Wildlife Service (QPWS) (QPWS, 2020).

2.2.8.89 Special Management Areas

Skerries

The Skerries, offshore from Wingan Inlet, near Croajingolong National Park is home to a major seal breeding colony with an estimated population of 11,500 representing approximately 12% of the national population.

Montague Island

The Montague Island Nature Reserve, within the Batemans Marine Park (Refer Section 2.2.8.79), is a breeding and nesting place for over 40,000 sea birds including Shearwaters, Little penguins, Crested terns and Silver gulls and is a haul out site for Australian and New Zealand fur seals. Both Montague Island and the Tollgate Islands (also within the park) are aggregation sites for Grey nurse sharks.

2.3 Ecological Environment

2.3.1 Fauna

The EPBC Act Protected Matters search tool on the Department of Environment and Energy site was used to inform the listed marine, migratory and threatened faunal species (or species habitat) that occur, or may occur in the DA (DoEE 2019b, DoEE 2019l, DoEE 2019m, DoEE 2019r, DoEE 2019at, DoEE 2019au).

2.3.1.1 Fish

2.3.1.2 Fish (bony)

Bony fish are a diverse group of fish that have skeletons primarily composed of bone tissue, as opposed to cartilage; most living species of fish are bony fish. The vast majority of fish are members of Osteichthyes, which is an extremely diverse and abundant group consisting of 45 orders, and over 435 families and 28,000 species.

Syngnathidae is a group of bony fishes that includes seahorses, pipefishes, pipehorses and sea dragons; the closely related Solenostomidae family includes ghost pipefish. These species occupy a range of habitats, however generally display a preference for seagrass and macroalgal beds, coral reefs, mangroves or sponge gardens (i.e. a habitat offering a protective environment. Habitat that supports syngnathid populations is generally patchy, so populations of syngnathid species may be dispersed and fragmented (DSEWPaC, 2012f). Syngnathids are typically carnivorous, feeding in the water column on or near the sea floor; their diet including small crustaceans, invertebrates, and zooplankton. Generally, the pipefishes, seahorses and seadragons are associated with vegetation in sheltered to moderately exposed reef areas at a range of depths from 0 to 50 m, depending on the species (Edgar, 1997), but usually at depths of between 5 and 25 m. Given that these species normally inhabit shallow reefs and kelp beds (Kuiter 2000).

It is estimated that there are over 500 species of fish found in the Gippsland Basin, including a number of species of importance to commercial and recreational fisheries (LCC, 1993). Species of commercial importance are covered in Section 2.4.1.

Fish species listed under the EPBC Act that may occur in the DA are given in Table 2-32 (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). Two species listed as ‘critically endangered’, the Spotted handfish and the Red handfish, may occur within the DA. There are less than forty Red handfish known to exist with a second (secret) location only recently discovered along the east coast of Tasmania (ABC 2018). Ziebell’s Handfish, also may occur in the DA and is listed as vulnerable. Handfish have a depth distribution of 3-20 metres and use their hand-like fins to crawl across the sea floor. The species’ diet includes small crustaceans and polychaete worms and the species is endemic to Tasmania (DoEE, 2015).

Two other fish species potentially occurring within the DA were listed as ‘vulnerable’ under the EPBC Act; the Australian grayling (Prototroctes maraena) and the Black rockcod (Epinephelus daemelii) (DoEE 2017a). The Australian grayling is a small to medium-sized, slender, silvery fish with soft-rayed fins. It is endemic to south-eastern Australia, including Victoria, Tasmania and New South Wales, and is a migratory species that inhabits estuarine waters and coastal seas as larvae/juveniles, but spend most of their lives in freshwater, inhabiting rivers and streams as adults (DSE, 2008). The Black cod’s range includes warm temperate and subtropical waters of the southwestern Pacific, including south-eastern Australia and the North Island, Kermadec Islands and Poor Knights Islands of New Zealand. The last known significant population of Black cod is at Elizabeth and Middleton Reefs (refer 2.2.3.14). Black cod generally inhabit near-shore rocky and offshore coral reefs at depths down to 50 m. In coastal waters juveniles are often found in estuary systems with adults moving into rock caves, rock gutters and on rock reefs (DoEE, 2012a).

Pipefishes, seahorses and seadragons, as listed under the EPBC Act, require a permit to remove them from the area. Generally, the pipefishes, seahorses and seadragons are associated with vegetation in sheltered to moderately exposed reef areas at a range of depths from 0 to 50 m, depending on the species (Edgar, 1997), but usually at depths of between 5 and 25 m. These species normally inhabit shallow reefs and kelp beds, they are not commonly found within the operational area itself but occur around adjacent shorelines in the DA (Kuiter 2000). Four additional species of pipefish and seadragon are listed as may occur within the DA.

A review of data collected in 1998 and 1999 by Neira (2005) suggested that the presence of Bass Strait offshore production facilities (and subsea infrastructure) within and near the Gippsland Basin Exclusion Zone provides additional habitat for early life stages of a large suite of teleost fish families. However, it is likely that both species composition and abundance around the operational area are closely linked to the ichthyofauna inhabiting hard/soft megahabitats off the Gippsland coastline and, to a lesser extent, those at the south-east corner of mainland Australia (e.g. Howe/Gabo complex).

Table 2-32 EPBC Act listed fish species or species habitat that may occur within the DA (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m)

Scientific Name	Common Name	Threatened Species	Migratory Species	Listed Marine Species	Type of Presence

Table 2-33 Key threats and management actions for threatened fish species or species habitat that may occur within the DA

Common Name	Conservation Advice or Recovery Plan	Key Threats (relevant to petroleum activities)
Spotted Handfish	Approved Conservation Advice for *Brachionichthys hirsutus* (spotted handfish) (DoEE, 2012c). Australian national Recovery Plan for Three Handfish Species: spotted handfish (*Brachionichthys hirsutus*), red handfish (*Thymichthys politus*) and Ziebell's handfish (*Brachiopsilus ziebelli*) (DoEE, 2015e	None identified
Ziebell's Handfish	Australian national Recovery Plan for Three Handfish Species: spotted handfish (*Brachionichthys hirsutus*), red handfish (*Thymichthys politus*) and Ziebell's handfish (*Brachiopsilus ziebelli*) (DoEE, 2015)	None identified
Red Handfish	Australian national Recovery Plan for Three Handfish Species: spotted handfish (*Brachionichthys hirsutus*), red handfish (*Thymichthys politus*) and Ziebell's handfish (*Brachiopsilus ziebelli*) (DoEE, 2015)	None Identified
Black Rock cod	Approved Conservation Advice for *Epinephelus daemelii* (black cod) (DoEE, 2012a)	None Identified
Australian Grayling	National Recovery Plan for the Australian Grayling Prototroctes maraena, 2008 (VDSE, 2008)	Reduction in water quality

2.3.1.3 Fish (cartilaginous)

Cartilaginous fish are jawed vertebrates with skeletons made of cartilage rather than bone. This group includes two subclasses:

- Elasmobranchii (sharks, rays, skates and sawfish); and
- Holocephali (chimaeras or ghost sharks).

There are six shark and three ray species (or species habitat) that may occur within the DA; this includes species classified as threatened and migratory (Table 2-32) (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). Only one species (Great White Shark) has an important behaviour (breeding) identified for the DA.

A list of the conservation advice and/or recovery plans, with relevant management actions, is shown in Table 2-35.

Sharks and Rays

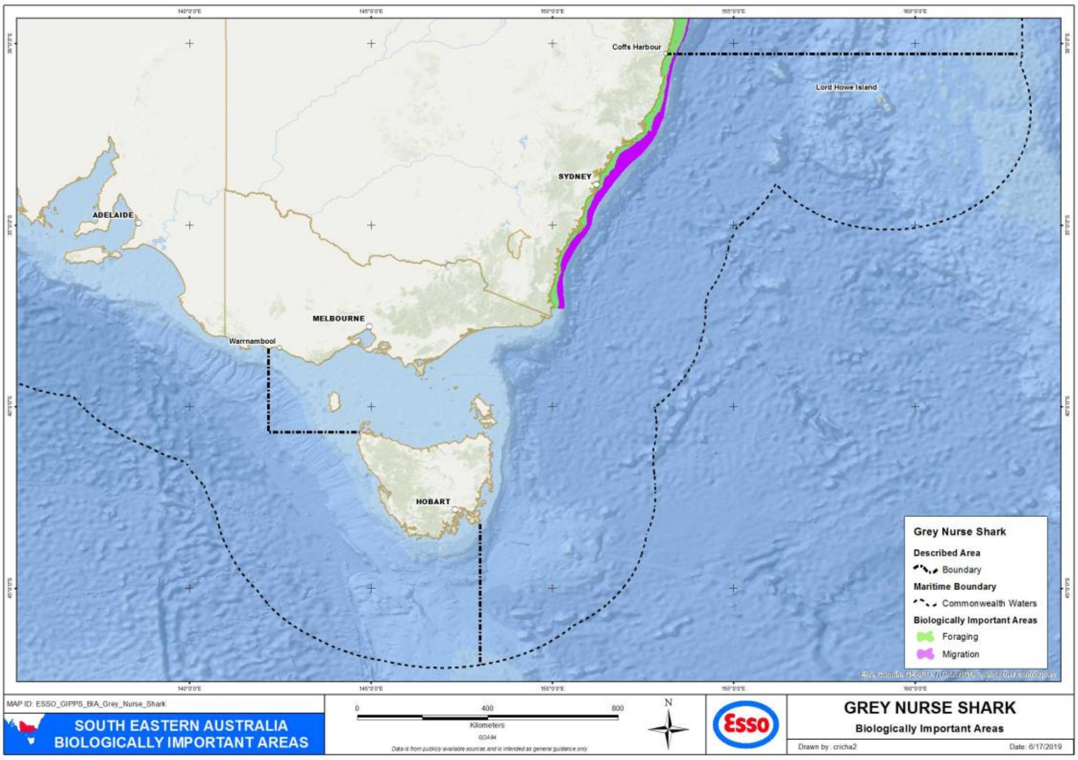
In Australia, the Grey Nurse Shark primarily has an inshore coastal distribution in sub-tropical to cool temperate waters on the continental shelf (DoE, 2014). The east coast population covers a range extending from the Capricornia coast (central Queensland) to Narooma in southern New South Wales (DoE, 2014), and is listed as critically endangered (TSSC, 2001). The species is rarely found travelling in the northern section of the Commonwealth south-east marine bioregion (DoEE 2015a and is uncommon in Victorian, South Australian and Tasmanian waters. The Grey Nurse Shark generally occurs as solitary individuals or in small schools; larger aggregations of individuals may occur for courtship and mating (DoE, 2014). A number of key aggregation sites[2] and habitat critical for the survival of the Grey Nurse Shark have been identified; the following two areas occur within the DA: Tollgate Islands (near Batemans Bay), and Montague Island (near Narooma). The Grey Nurse Shark migrates within its range, making seasonal north–south movements to form aggregations at critical habitat sites, thought to be related to breeding (DoEE, 2017f). The precise timing of mating and pupping in Australian waters is unknown; however, in South Africa mating occurs between late-October and late-November (DoEE, 2017f). A BIA for foraging and migration has been identified for the Grey Nurse Shark along the east coast of Australia (Figure 2-22).

The shortfin mako shark (*Isurus oxyrinchus*) has been recorded in offshore waters all around the Australian coastline except for the Arafura Sea, Gulf of Carpentaria and Torres Strait in the north (TSSC, 2014b). It is a pelagic species, primarily occurring in offshore, oceanic waters (Last and Stevens, 2009). The shortfin mako is highly migratory and can cover large distances, migrating from Australian waters to areas well beyond the Australian Exclusive Economic Zone (Rogers et al., 2009). The shortfin mako inhabits depths down to 600 m, with a slight trend indicating the species spend the majority of the night in shallow water, and the majority of daylight hours in deeper waters (Rogers et al., 2009). It is not normally found in waters below 16°C (RPS, 2015). Satellite tracking data for shortfin mako showed a potential for year round occupation of the Otway, Bass Strait and Gippsland Basins (Rogers and Bailleul, 2015). The longfin mako (*Isurus paucus)*, often mistaken for the shortfin mako, is an epipelagic species with a usual depth range between 120 and 240 metres. Its exact range is not known however it known to have a worldwide distribution in tropical and temperate seas. Within Australia it is known to occur in the north and to the south to at least Port Stephens in NSW. It is thought to feed on pelagic fish and cephalopods (DSEWPAC, 2012g).

The Great White Shark has a range extending from central Queensland, around the south coast, to north-west Western Australia (DSEWPaC, 2013a). The shark is primarily found on the continental shelf and coastal waters, including inshore waters around oceanic islands. The Great White Shark is not evenly distributed throughout its range, with observations more frequent in some areas, including those around fur-seal or sea-lion colonies (DSEWPaC, 2013a). Juveniles appear to aggregate seasonally in key areas, including Wilsons Promontory (Victoria), and the Skerries (DSEWPaC, 2013a). Recent studies have found that juvenile white sharks (<3m) occupy estuaries Corner Inlet, Victoria during October to January (Harasti *et al*., 2017). A BIA for breeding (nursery ground) has been established in

[2] 'Key Aggregation Sites' defined as being locations where five or more Grey Nurse Sharks were consistently found throughout the year (DoEE, 2014).

the coastal region extending east from Wilsons Promontory (Figure 2-22). The Great White Shark moves seasonally along the south and east Australian coasts, moving northerly along the coast during autumn and winter, and returning to southern Australian waters by early summer. The Great White Shark is not known to form and defend territories, however, its ability to return on a seasonal basis implies a degree of site fidelity (DSEWPaC, 2013a).



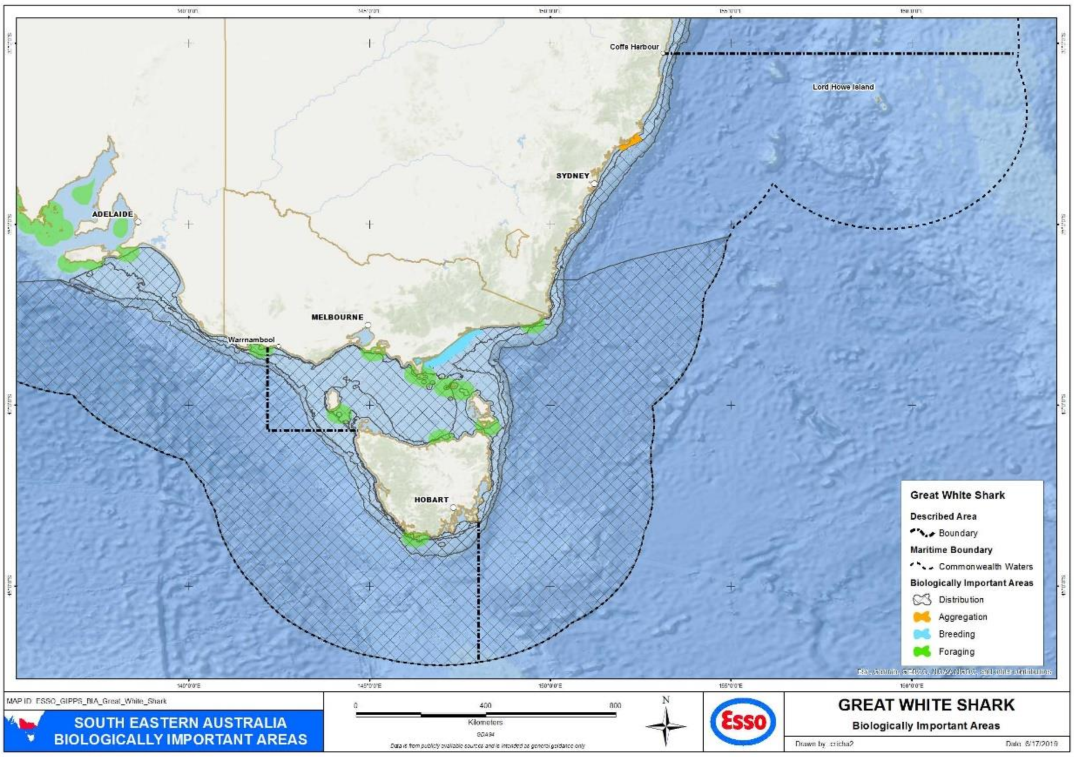


Figure 2-22 Biologically important areas for shark species

Whale sharks (*Rhincodon typus*) are generally found in warmer oceanic waters (where temperatures range from 21 to 25°C) and mainly occur in waters off the Northern Territory, Queensland and northern Western Australia. However, there have been a few isolated reports of immature male whale sharks in New South Wales and Victoria (Last & Stevens 1994). The Whale sharks are not likely to occur in the EGBPA.

The Porbeagle or Mackerel Shark (*Lamna nasus*) is listed as a migratory marine species under the EPBC Act, likely to occur in the DA. The timing and details of these migratory movements are not well-understood for the Porbeagle however it primarily inhabits oceanic waters and areas around the edge of the continental shelf. They occasionally move into coastal waters, but these movements are temporary. The Porbeagle utilises a broad vertical range of the water column and is known to dive to depths exceeding 1300 m. The Porbeagle is thought to be reasonably flexible in the types of habitat used for foraging. Whilst protected from targeted fishing, bycatch remains its greatest threat.

The Giant manta ray (*Manta birostris*) (Australian Museum, 2014) is the largest species of ray in the world. The Manta ray lives in tropical waters but is also found occasionally in temperate seas. In Australia it is recorded from south-western Western Australia, around the tropical north of the country and south to the southern coast of NSW, where it may overlap with the DA. The Manta ray feeds on plankton which are filtered from the water through the gills (DoEE, 2018c).

Another species of the Manta found in the DA is the Reef manta ray (*Manta alfredi*), distinguishable from the Giant manta ray as it has dark spots on the ventral surface between the gills (Australian Museum, 2019). It is a listed migratory species and has similar distribution and feeding habits as the Giant Manta ray. No specific conservation advice exits for either species of the ray (DoEE, 2019x).

The Green Sawfish, is a species of ray listed as vulnerable, with a body of a shark and a flattened head and an elongated snout with 24–28 pairs of unevenly-spaced rostral (saw-like) teeth. The species was last recorded in waters of NSW in 1926 but appears to have contracted its range and has not been detected in NSW or southern Queensland waters since then. It is currently distributed from the Whitsundays in Queensland across northern Australian waters to Shark Bay in Western Australia. The fins are highly sought after in the international market and anecdotal reports suggest sawfish populations have declined significantly as a result (DoEE, 2019ap).

Table 2-34 Fish species or species habitat that may occur within the DA (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m)

Whale Shark	Approved Conservation Advice for *Rhincodon typus* (Whale Shark)	Vessel strike Habitat disruption from mineral exploration, production and transportation Marine debris

2.3.1.4 Birds

Birds in the marine environment can include both seabirds and shorebirds:

- Seabirds refers to those species of bird whose normal habitat and food sources are derived from the ocean (both coastal and pelagic); seabirds include such species as pelicans, gannets, cormorants, albatrosses and petrels.
- Shorebirds (sometimes referred to as wading birds) refers to those species of bird commonly found along sandy or rocky shorelines, mudflats, and shallow waters; shorebirds include such species as plovers and sandpipers.

There are 121 seabird and shorebird species (or species habitat) that may occur within the DA; this includes species classified as threatened and migratory (Table 2-36) (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). The type of presence varies between species, and includes important behaviours (e.g. foraging, roosting, breeding) for some species.

The coast and neighbouring islands within the DA provide feeding and nesting habitats for many coastal and migratory bird species. Seabirds spend much of their lives at sea in search of prey only to return for a short time to breed and raise chicks. Most species tend to forage on their own, though large feeding flocks will gather at rich or passing food sources. Squid, fish and krill are common sources of food. Islands in the Gippsland Basin are nesting sites for many seabird species, many of which migrate to these islands each year. Colonies of seabirds occur in Corner Inlet and on the islands around Wilsons Promontory, to the east at The Skerries, Tullaberga Island and Gabo Island and to the south on Curtis Island and the Hogan Island Group (Harris & Norman 1981). Species that nest and breed on these islands include the listed marine species, Little penguin (*Eudyptula minor*), White-faced storm petrel (*Pelagodroma marina*), Short-tailed shearwater (*Puffinus tenuirostris*) and the Fairy prion (*Pachyptila turtur*).

A list of the conservation advice and/or recovery plans, with relevant management actions for petroleum activities, is shown in Table 2-37.

Albatross

There are 15 species of albatross that may occur within the DA, and all except two (Sooty Albatross and Grey-headed Albatross) has been identified as using the area for foraging (Table 2-36). Albatross species exhibit a broad range of diets and foraging behaviours; this combined with their ability to cover vast oceanic distances, means all waters within Australian jurisdiction can be considered foraging habitat for this species (DSEWPaC, 2011a). However, the most critical foraging habitat is considered to be in waters south of 25°S where most species spend the majority of their foraging time (DSEWPaC, 2011a).

Albatross' typically feed offshore, mainly along the edge of the continental shelf and over open waters, where they catch fish and cephalopods (e.g. squid, cuttlefish) by diving into the water (DSEWPaC, 2011a). A BIA for foraging, has been identified for the following albatross species: Antipodean, Buller's, Shy, Black-browed, Campbell, Wandering, Indian Yellow-nosed and White-capped (Figure 2-23) (DoEE, 2015h). There is only one species, the Shy Albatross, that is known to breed within the waters off mainland Australia, and this occurs outside of the DA.

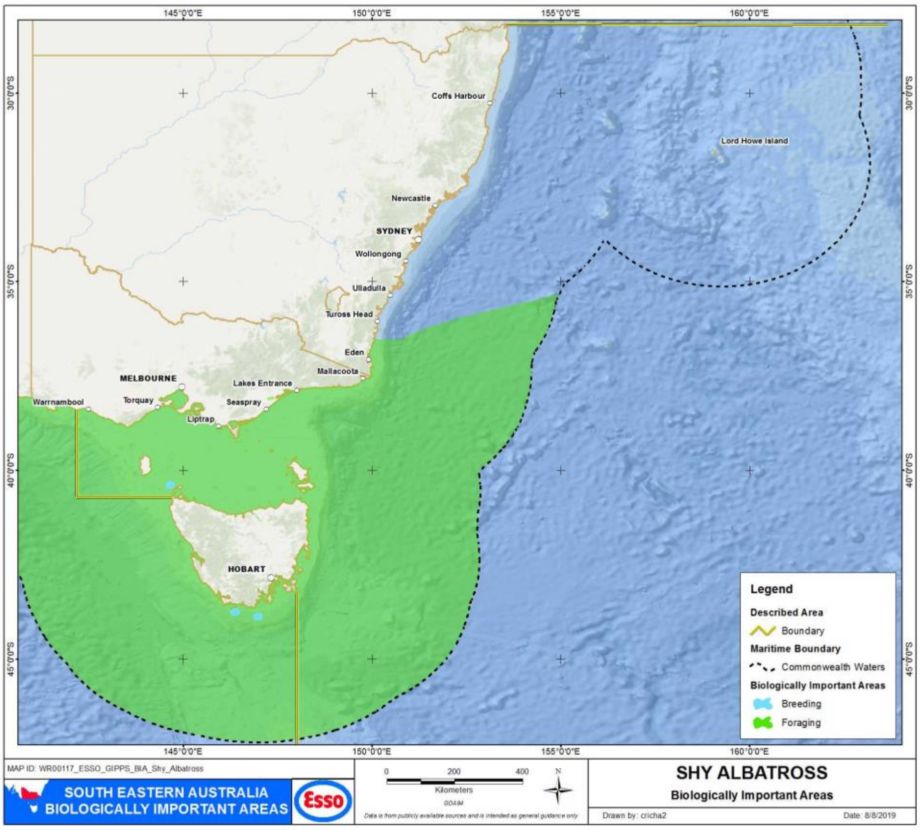

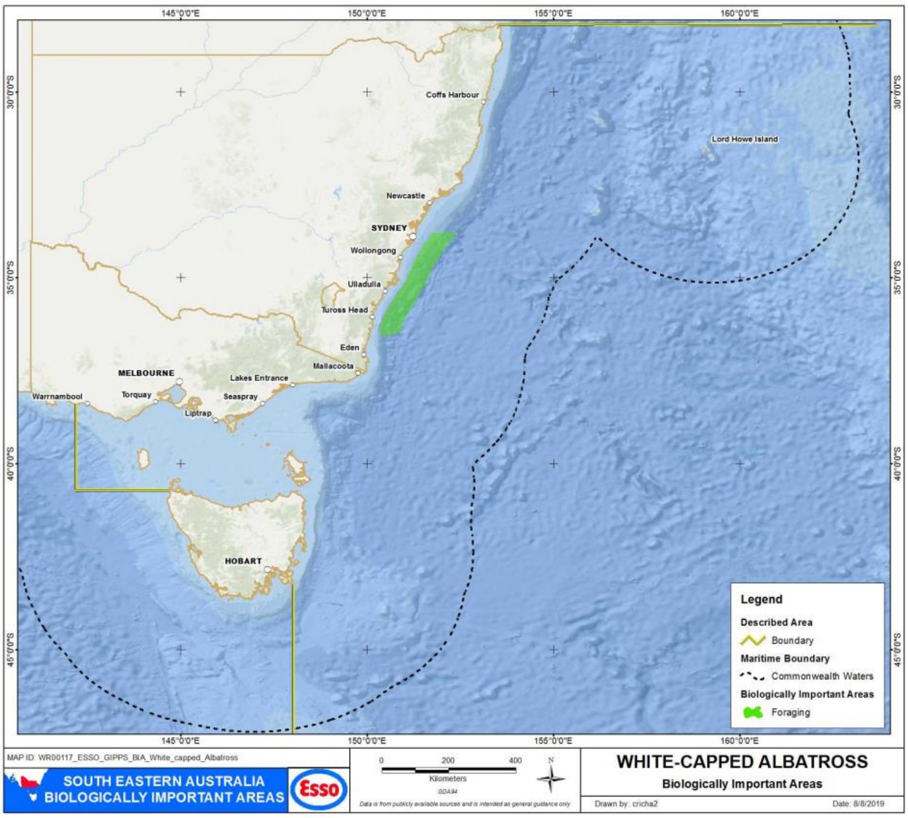

Figure 2-23 Biologically Important Areas for albatross species

Petrels

There are 13 species of petrel that may occur within the DA, with most either foraging and/or breeding within the area (Table 2-36). Similar to albatrosses, the petrels have a diverse foraging range, and all waters within Australian jurisdiction can be considered foraging habitat for this species. Typical diet for petrels includes cephalopods (e.g. squid) and fish, and prey is predominately caught by surface-seizing (DSEWPaC, 2011a).

BIAs, for foraging and breeding, have been identified for the White-faced Storm Petrel, Common Diving-Petrel, Black-winged Petrel and Providence Petrel. BIAs for foraging have also been defined for the Northern and Southern Giant Petrel and the Great-winged Petrel (Figure 2-24) (DoEE, 2015h).

Both the Common Diving-Petrel and the White-faced Storm Petrel are listed as marine species under the EPBC Act, and have large populations within Australia, accounting for 5% and 25% respectively of the global population (DoEE, 2015a). The Common Diving-Petrel breeds on islands off south-east Australia and Tasmania; there are 30 sites with significant breeding colonies (defined as more than 1,000 breeding pairs) known in Tasmania, and 12 sites in Victoria (including Seal Island, Wilson's Promontory and Lady Julia Percy Island) (DoEE, 2015a). There are 15 sites with significant breeding colonies in Tasmania, and three sites with Victoria, for the White-faced Storm Petrel (DoEE, 2015a). One critically endangered species, the Herald Petrel has been estimated to only have about 10-25 breeding birds in Australia. Although they are known to breed on Raine Island in North Queensland waters, they are highly oceanic birds that are listed as likely to occur in the DA (TSSC 2015).

The Black-winged Petrel (Pterodroma nigripennis) and Providence Petrel (Pterodroma solandri) are listed marine species whose only known breeding sites in Australia are on Lord Howe Island, and for the Providence Petrel, Philip Island (in NSW off Norfolk island). Both have been identified as a conservation value in the Temperate East Marine Region (DoEE, 2019af). The Black-winged Petrel forms a burrow of up to 1m long in sandy soil to nest and is prone to predation by the Masked Owl and introduced rodents. The Black-winged Petrel is also known to occur in other parts of the Pacific (NSW OEH, 2019c). The distribution of the Providence Petrel is far more restricted with breeding sites only known to occur in Lord Howe and Philip Island. Their main known threats are from predation and disturbance of nests by tourists on the island. They nest on the tops of Mount Gower and Mount Lidgbird and to a less extent, on the lower slopes of the mountains (NSW OEH, 2019d).

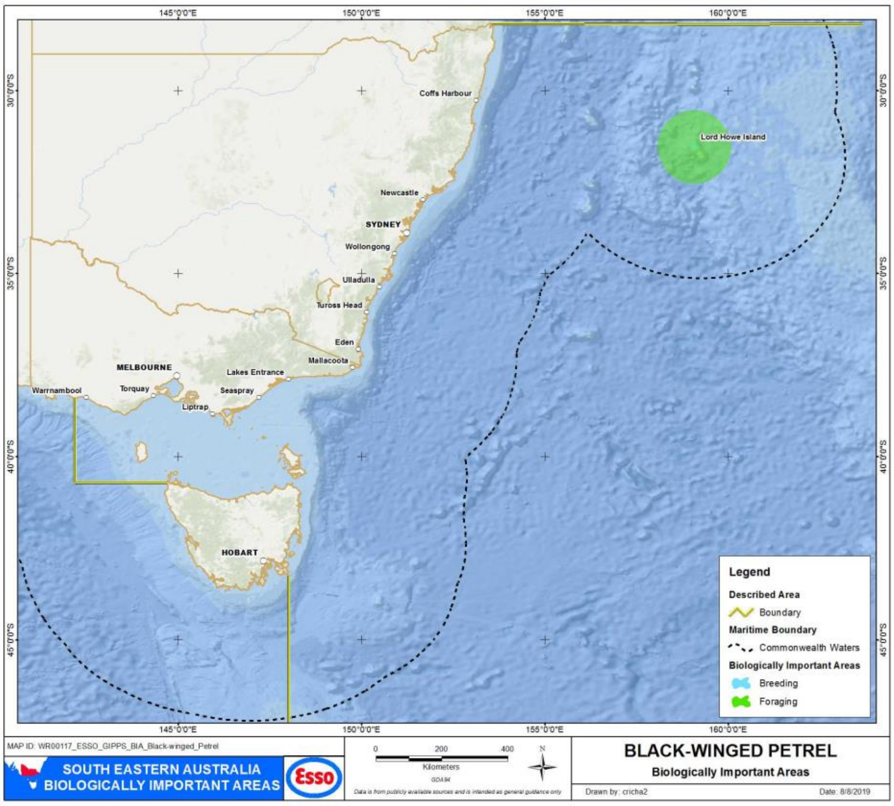

Figure 2-24 Biologically Important Areas for Petrel species.

Shearwaters

The shearwaters represent the most abundant seabird in Australia. There are five species of shearwater that may occur within the DA, and all have been identified as using the area for foraging and breeding (Table 2-36). BIAs, for foraging and breeding, have been identified for the following species: Sooty, Wedge-tailed, and Short-tailed shearwaters; and a BIA for foraging for the Flesh-footed Shearwater (Figure 2-25) (DoEE, 2015h).

Shearwaters are typically pelagic species, except during breeding seasons where they are found on remote islands or coastal headlands. Known breeding locations include New South Wales oceanic islands (e.g. Solitary Island, Cabbage Tree Island, Muttonbird Island, Bird Island) (Sooty Shearwater, Wedge-tailed Shearwater). Breeding season in south-eastern Australia for shearwaters is typically over summer; late-August/early-September to May (DoEE 2017a, 2017b, 2017d, 2017e). Shearwater nests are usually in burrows or rock crevices.

Shearwaters are known to forage for a variety of pelagic prey, including krill, cephalopods, fish and crustaceans. Food is usually taken by pursuit-plunging, surface plunging or surface-seizing; however other methods (e.g. hydroplaning, deep plunging) may be used.

The Short-tailed Shearwater is one of few native birds that is commercially harvested (Tasmania Parks & Wildlife Service, 2014).

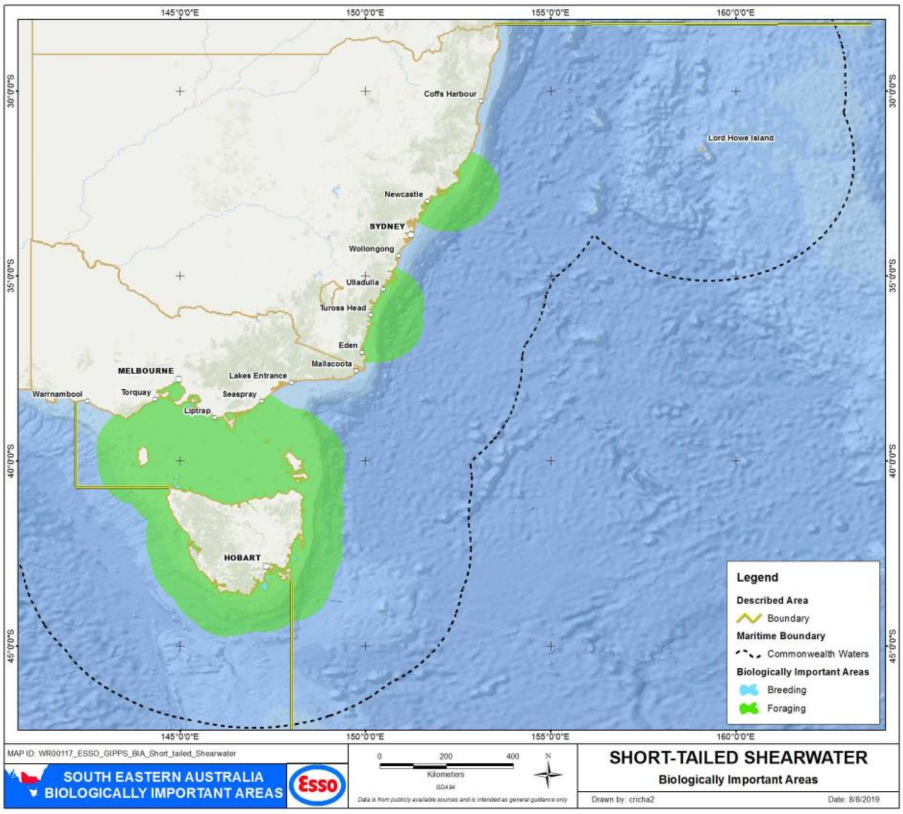

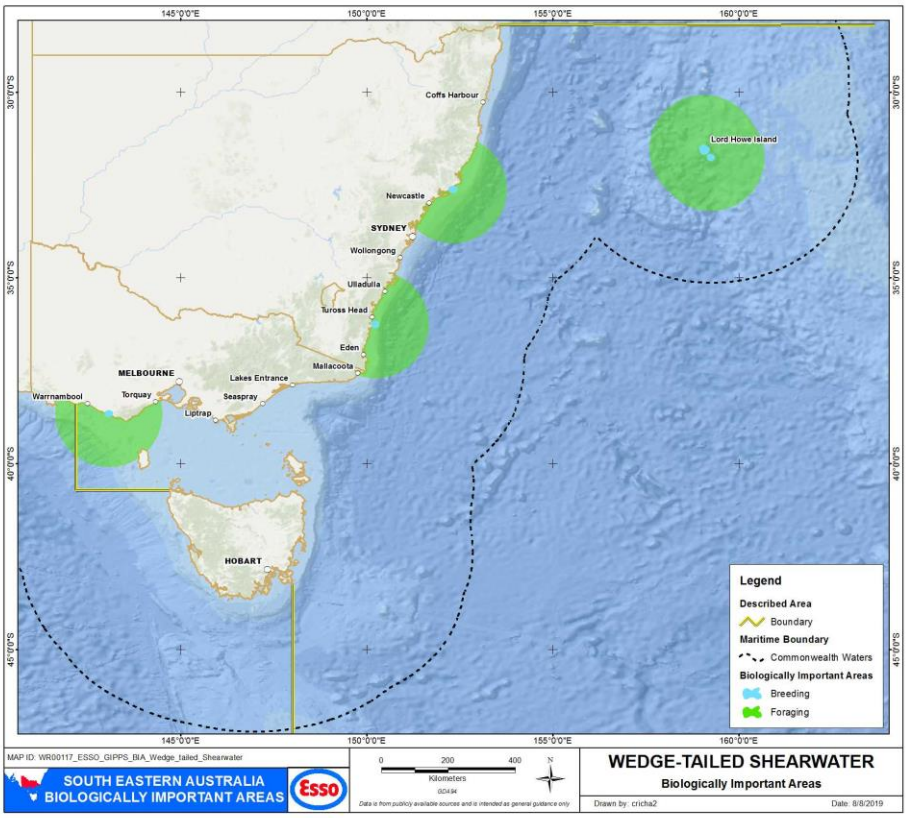

Figure 2-25 Biologically Important Areas for Shearwater species

Terns

There are eight species of tern that may occur within the DA, and all have been identified as using the area for breeding (Table 2-36). A BIA, for foraging and breeding, has been identified for the Crested Tern (Figure 2-26) (DoEE, 2015h).

Many of the tern species are widespread and occupy beach, wetland, grassland and beach habitats. Terns rarely swim; they hunt for prey in flight, dipping to the water surface or plunge-diving for prey (Flegg, 2002) usually within sight of land, for fish, squid, jellyfish and sometimes crustaceans (DEHWA, 2007).

Terns breed in colonies on small offshore islands, including those of the Furneaux Group in eastern Bass Strait. Nests are typically in sand or coral scrapes (Birdlife Australia, 2017a, 2017b; NSW OEH, 2017a).

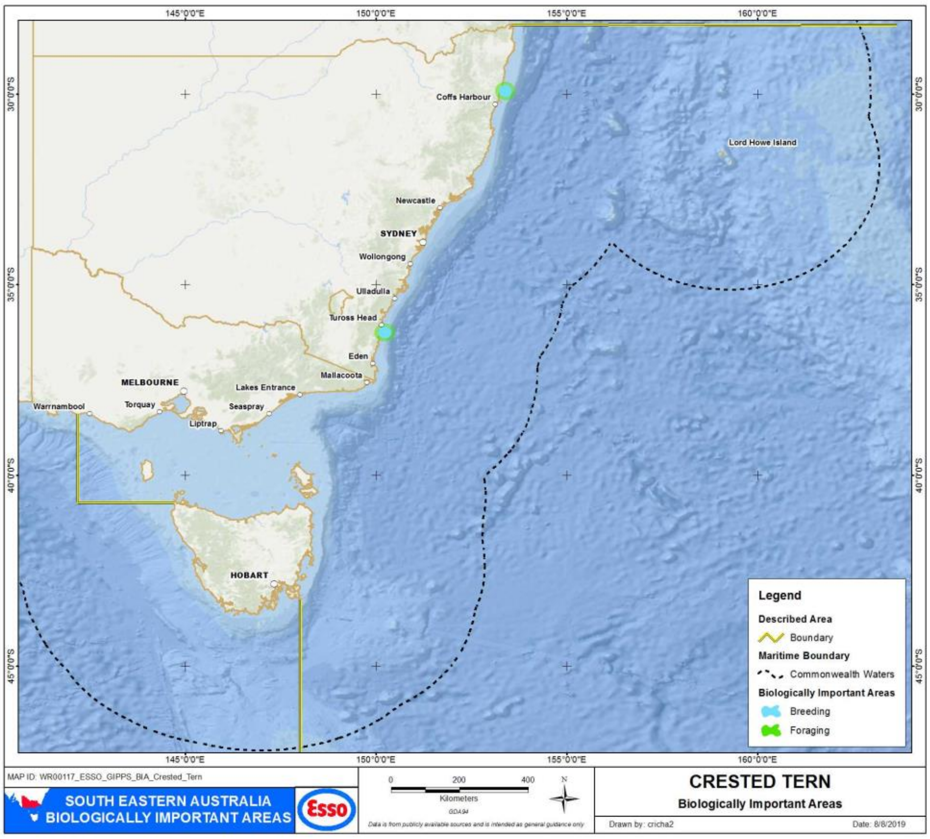

Figure 2-26 Biologically Important Areas for Crested Tern

Migratory Waterbirds

Migratory birds are species where a substantial proportion of the global or a regional population makes regular cyclical movements beyond the breeding range, with predictable timing and destinations. Many species of migratory waterbirds occur in the DA including eight species of sandpipers

Plovers

There are nine species of plover that are known to occur in the DA, six of which are wetland migratory species and most of which have a known to feed or form rookeries in the DA. Many plovers feed by running along wet sand, mud or beaches and shorelines, snapping up small, aquatic, molluscs and insects for food. The nest is in a slight hollow in the ground where two to five (usually four) spotted eggs are laid and both parents incubate and care for the young. Some of the species here including the vulnerable Greater Sand Plover and the endangered Lesser Sand Plover are strongly migratory, birds breeding in the northern hemisphere and wintering in sandy beaches of Asia and Australasia. These are part of the East Asian – Australasian Flyway (EAAF) (DoEE, 2019ah) which stretches from the Russian Far East and Alaska, southwards through East Asia and South-east Asia, to Australia and New

Zealand and encompasses 22 countries. During migration, waterbirds rely on a system of highly productive wetlands to rest and feed, building up sufficient energy to fuel the next phase of their journey. Whilst wintering in Australia, they occur in coastal areas of all states though the greatest numbers occur in northern Australia. Of the three non-migratory species, the eastern form of the Hooded Plover (*Thinornis cucullatus cucullatus)* is listed as vulnerable. It is a small bird that nests on the back of usually wide beaches above the high water mark. Its main threat is human disturbance from unleashed domestic dogs (DoEE, 2019ai).

Sandpipers

Eight sandpiper species are known to occur within the DA. Sandpiper refers to the small to middle sized shorebirds (15-30sm) in the family Scolopacidae which are seen at beaches and inland mudflats during migration and wintering. They are all migratory breeding in the northern hemisphere Arctic and sub-Arctic regions and travel in large flocks when migrating. The majority of these species eat small invertebrates probed out of the mud or soil or sand with their sensitive bills which distinguishes them from the plovers that are darting across the surface feeding by sight. The critically endangered Curlew Sandpiper's (*Calidris ferruginea*) sighted population in Australia has significantly declined. Breeding does not occur in Australia, it is part of the EAAF and breeding occurs in Siberia, however its wetland resting habitat on its winter migration, particularly in East Asia, is being threatened by degradation through habitat loss, pollution and other human disturbance resulting in an estimated reduction in population size in Australia by >80% (DoEE, 2015b). In Australia the main threat for all sandpipers is from disturbance from humans and their domestic animals.

Also in the Scolopacidae family are all of the other listed wetland migratory species found in the DA (other than the Osprey) including the snipes, knots, godwits, dowitchers, sanderlings, turnstones, shanks, curlews, phalarope, whimbrel and tatters. These have similar breeding habits as the Sandpipers. Their feeding habitat is generally coastal with large intertidal mudflats or sandflats and they roost on sandy beaches, sandbars, and spits. There are three critically endangered species, the Great Knot, the Northern Siberian Bar-tailed Godwit and the Eastern Curlew. The Red Knot is listed as endangered and the Bar-tailed Godwit (auera) is listed as vulnerable (note the Bar-tailed Godwit is a subspecies of the Siberian Bar-tailed Godwit (TSSC, 2016a)). These species are all migratory birds breeding in the northern hemisphere (e.g., Siberia/Alaska) and migrating south during their winter. Recorded numbers are in decline in Australia and, like the Sandpipers, this is largely attributed to the decline in wetlands in Asia used as staging areas for resting and feeding during migration. In Australia threats include human disturbance as well as habitat loss and degradation from pollution, changes to the water regime and invasive plants (DoEE, 2015c).

Other

Many other species also occur within areas of the DA (Table 2-36), those that are critically endangered, endangered or vulnerable are discussed below.

The Swift Parrot and Orange-bellied Parrot are both critically endangered, they both breed in Tasmania and migrate to the mainland for the non-breeding season. The Swift parrot's habitat is mainly forest and it's threatened mainly by native predators and also loss of forest habitat (TSSC, 2016b). The orange bellied parrot is ground feeding and inhabits salt marshes, coastal dunes, pastures, shrub lands, estuaries, islands, beaches and moorlands generally within 10 km of the coast. As with many of the migratory species, it is threatened by the loss of wetland habitat, in this case through changes to land use practices such as drainage of wetlands for grazing, alteration and destruction of saltmarsh for industrial and urban development, vegetation clearance for agricultural purposes (TSSC, 2006).

The Australian Painted snipe, a listed endangered species has been recorded at wetlands in all states of Australia and whilst called a snipe it is in the family Rostratulidae. It is known to nest in Australia and generally inhabits shallow terrestrial freshwater but also brackish wetland and also seen in saltmarshes. Its decline has been attributed to the loss of wetland habitat since European settlement in Australia (DoEE, 2019aj).

The endangered Australasian Bittern is mainly a freshwater wetland species and rarely occurs in estuaries or tidal wetlands, favouring tall dense vegetation where it forages on small aquatic animals including frogs, fish, freshwater crayfish, reptiles and insects. These birds are also culturally significant to Aboriginal people. This species is capable of moving between habitats from south-east Queensland to south-east South Australia as suitability changes. Wetland habitat loss and degradation is a threat to the Australasian Bittern (TSSC, 2019).

The endangered Eastern Bristlebird is a small, well-camouflaged, ground-dwelling bird spending most of its time in low, dense vegetation in coastal, subcoastal and coastal escarpment scrubland / grassland / sedgeland and in open grassy forest on inland ranges. The species has contracted to four genetically isolated populations in three disjunct areas of south-eastern Australia. Within the DA these are the Illawarra and Jervis Bay regions of eastern NSW (central populations) and the NSW/Victorian border coastal region (southern population) near Nadgee Mallacoota. They feed mainly on invertebrates but also on seeds and grasses. Habitat loss through clearing of coastal heath and escarpment forest is recognised as the main process that has reduced the distribution and abundance of the Eastern Bristlebird in the last 150 years. Another potential threat to the species is predation, particularly by feral predators and particularly after fire (NSW OEH, 2012c).

Within Australia, the vulnerable Fairy Prion (southern) breeds only on Maquarie Island (outside of the DA) and outside Australia is also known to breed in other subantarctic islands including New Zealand and Falklands. During the non-breeding season it frequents sub-tropical waters and it feeds by plucking food off the ocean surface. Its main threat in Australia was predation from introduced black rats which have now been eradicated on Macaquarie Island (TSSC, 2015e).

The Little Penguin is the smallest species of penguin in the world and are permanent residents on a number of inshore and offshore islands. The Australian population is large but not thought to exceed one million birds (DoEE, 2015a). Bass Strait has the largest proportion (approximately 60%) of the known breeding colonies in Australia; however, breeding populations are also found on the New South Wales coast. Individuals exhibit strong site fidelity, returning to the same breeding colony each year to breed in the winter and spring months (Gillanders *et al.*, 2013). The diet of a Little Penguin includes small school fish, squid and krill. Prey is typically caught with rapid jabs of the beak and swallowed whole. A BIA for breeding and foraging, has been identified for the Little Penguin (Figure 2-27) (DoEE, 2015h). Little penguins are also an important component of the Australian and New Zealand fur-seals' diet (PoSA, 2011).

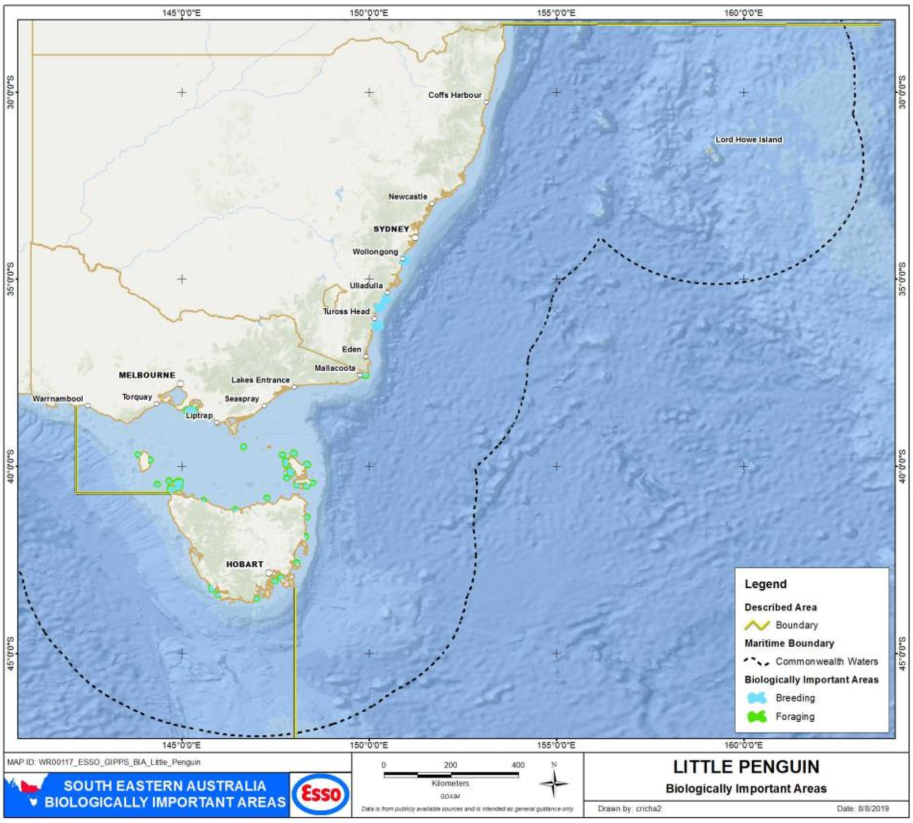

Figure 2-27 Biologically Important Area for Little Penguin

The Australasian Gannet generally feeds over the continental shelf or inshore waters. Their diet is comprised mainly of pelagic fish, but also squid and garfish. Prey is caught mainly by plunge-diving, but it is also seen regularly attending trawlers. Breeding is highly seasonal (October–May), nesting on the ground in small but dense colonies (DoEE, 2015a). While breeding behaviour has been identified (Table 1), known important breeding locations for the Australian Gannet occur outside the DA at Pedra Branca, Eddystone Rocks, Sidmouth Rocks, and Black Pyramid (Tasmania) and Lawrence Rocks (Victoria).

The Black-faced Cormorant is endemic to southern Australia (DoEE, 2015a); and favours rocky coasts. The species feeds in coastal waters on a variety of fish, typically catching prey by pursuit-diving. There are 40 significant breeding sites (defined as more than 10 breeding pairs) known for the species in southern Australia. Breeding usually occurs on rocky islands, but also on stacks, slopes and sea cliffs in colonies of up to 2500 individuals (DoEE, 2015a).

The Red-tailed Tropicbird is a medium sized (45-55cm) seabird and listed marine and migratory species that exists in tropical Pacific and Indian oceans (DoEE, 2019v). It nests on cliffs by the water's edge, and less so inland on smaller islands and has been identified as a conservation value in the Temperate East Marine Region. The red-tailed tropicbird is mostly a plunge-diver, diving anywhere from an above-water height 6 to 50 metres to a depth of about 4.5 metres (AOLA, 2019a). No specific conservation plans exist for this species.

The Masked Booby is a large listed marine and migratory species that has a breeding population on Lord Howe Island (Mutton Bird Point, King Point, Roach Island, South Island, Sugarloaf Island, Mutton Bird Island, Gower Island, Sail Rocks and Ball's Pyramid) that is the most southerly known breeding colony in the world (DoEE, 2019w). The masked Booby nests in small colonies, laying on sandy beaches and feeds by plunge diving on the ocean (AOLA, 2019b).

The Red-necked Phalarope (*Phalaropus lobatus*) is a listed migratory and marine wader and the smallest of the Phalarope species (18-19 cm). This is one of only two Phalaropes that occurs regularly at sea where feeding is expected to occur. In Australia it is recorded in both coastal and inland lakes/swamps including highly saline waters and saltfields. In Victoria it has been seen in near coastal lakes such as Lake Cooewarre and Lake Victoria near the entrance to Port Phillip Bay. Sightings occur from Mid October to early April. From a global perspective there are no important sites for this species in Australia (i.e. a site is considered important if it is occupied by more than 1% of the bird's total population). It breeds in the Arctic and sub-Arctic North America and spends its non-breeding winter season at sea (DoEE, 2019ag).

The Magpie Goose is widespread in northern Australia, where it may congregate in huge flocks, often comprising thousands of birds. They were also commonly found in the southern parts of Australia but are now not seen in Tasmania, endangered in Victoria and vulnerable in NSW. They are a listed marine species, a waterfowl which nests near wetlands on floating reeds or tree-tops. They feed on aquatic vegetation (Birdlife Australia, 2019).

Some listed bird species, whilst not seabirds or shorebirds, inhabit islands and nearshore habitats such as forests and freshwater wetlands and include the critically endangered Regent Honeyeater, endangered Wedge-tailed Eagle (Tasmanian), Forty-spotted Pardalote, and the vulnerable Masked Owl and Painted Honeyeater. These are terrestrial/freshwater species and though they occur in or near the DA they are not expected to be impacted by petroleum activities.

The Regent Honeyeater is most commonly associated with box-ironbark eucalypt woodland and dry sclerophyll forest. Its utilisation of lowland coastal forest occurs when its usual habitat is affected by drought and coastal regions become a refuge. Its diet primarily consists of nectar, but also includes invertebrates (mostly insects) and their exudates. Loss of habitat is its primary threat (TSSC, 2015d).

The Wedge-tailed Eagle (Tasmanian) is found only in Tasmania and nearby islands. The subspecies is widespread on mainland Tasmania, where it inhabits coastal, lowland and highland regions. It is carnivorous, and feeds on both live prey and carrion, capable of killing prey several times its own body weight with birds being approximately 10% of items consumed. The major threats to the Wedge-tailed Eagle (Tasmanian) are loss of nesting habitat (old growth Eucalyptus forest) and disturbance of nesting birds and, to a lesser degree, persecution by humans. The loss of suitable habitat has also increased conflict between the Wedge-tailed Eagle (Tasmanian) and the White-bellied Sea-Eagle Haliaeetus leucogaster for nest sites, and this is known to have caused breeding failures in both species (DoEE, 2019ak)

The Masked Owl (Tasmanian) is endemic to Tasmania, including several near-shore islands. It is the second largest nocturnal raptor in Australia with a wingspan up to 128cm. It feeds predominately on introduced rodents and Rabbits and other native fauna in less disturbed habitats. Its greatest threat is loss of habitat through clearing and fragmentation (DEWHA, 2010a).

The Forty-spotted Pardalote is confined to south-eastern Tasmania including the offshore islands. It inhabits sclerophyll forests and open woodlands where White Gum is present and feeds on invertebrates, manna from Eucalyptus trees (including E. dalrympleana and White Gum) and lerps (sugary secretions produced by psyllid insects) (TSSC, 2016c). Its primary threat is of habitat through clearing and fragmentation. Similar to the Pardalote, the Regent Honeyeater also occurs in woodland, mostly box ironbark, and feeds on nectars, insects and their lerps. Its distribution is patchy but extends from south east Queensland to through to Victoria (DoEE, 2015 f). The Painted Honeyeater is the most specialized of Australia's honeyeaters and inhabits eucalypt forests/woodlands but its diet consists mainly of mistletoe fruits and therefore its primary threat is loss of habitat through clearing (DoEE, 2015g).

The endangered Tasmanian Azure Kingfisher is endemic to Tasmania and occurs along several river systems on the south, west and north-west coast with outlying occurrences in the north-east, east, centre and Bass Strait islands. It utilizes a wide range of forest types but mainly wet sclerophyll eucalypt forests. It feeds on small fish, freshwater crayfish, aquatic insects and occasionally amphibians. Its primary threat is habitat clearing and acidic runoff from mining activities (DEWHA, 2010b).

2.3.1.5 Marine Mammals

2.3.1.6 Cetaceans

Cetaceans are a widely distributed and diverse group of carnivorous, finned, aquatic marine mammals. They comprise whales, dolphins and porpoises. Cetaceans are generally found in the ocean, but can also inhabit river systems.

There are 25 whale, and 18 dolphin species (or species habitat) that may occur within the DA; this includes species classified as threatened and migratory (Table 2-38) (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). A list of the conservation advice and/or recovery plans, with relevant key threats and management actions, is shown in Table 2-39. The type of presence varies between species, and includes important behaviours (e.g. foraging, breeding) for some species.

Whales

Southern Right Whales generally occur along the southern coast of Australia, they migrate annually along the eastern coastline from high latitude feeding grounds to lower latitudes for calving between mid-May and September (DoEE, 2017h). Known calving and aggregation grounds in the south-east region are Warrnambool, Port Fairy, Port Campbell and Portland in Victoria, and Encounter Bay in South Australia (DSEWPaC, 2012d; DoEE, 2015a). Nursery grounds are occupied from May to October, with female-calf pairs generally staying in the area for two to three months (Charlton, 2017). Calving itself usually occurs in very shallow (<10 m depth) waters. Other population classes stay in the nursery grounds for shorter and variable periods of time; there is typically a lot of movement along the coast, and thus habitat connectivity is important for this species. The summer offshore distribution and migration routes of Southern Right Whales largely is unknown, but is known to include directly southern and western migration pathways, but may include offshore habitat where mating (Burnell, 2001; Mackay et al., 2015). Figure 2-28 shows whale migration pathways and aggregation around the Bass Strait petroleum permit areas, including those for the Southern Right Whales. A BIA for the Southern Right Whale, for migration and distribution exists within the DA (Figure 2-31) (DoEE, 2015h).

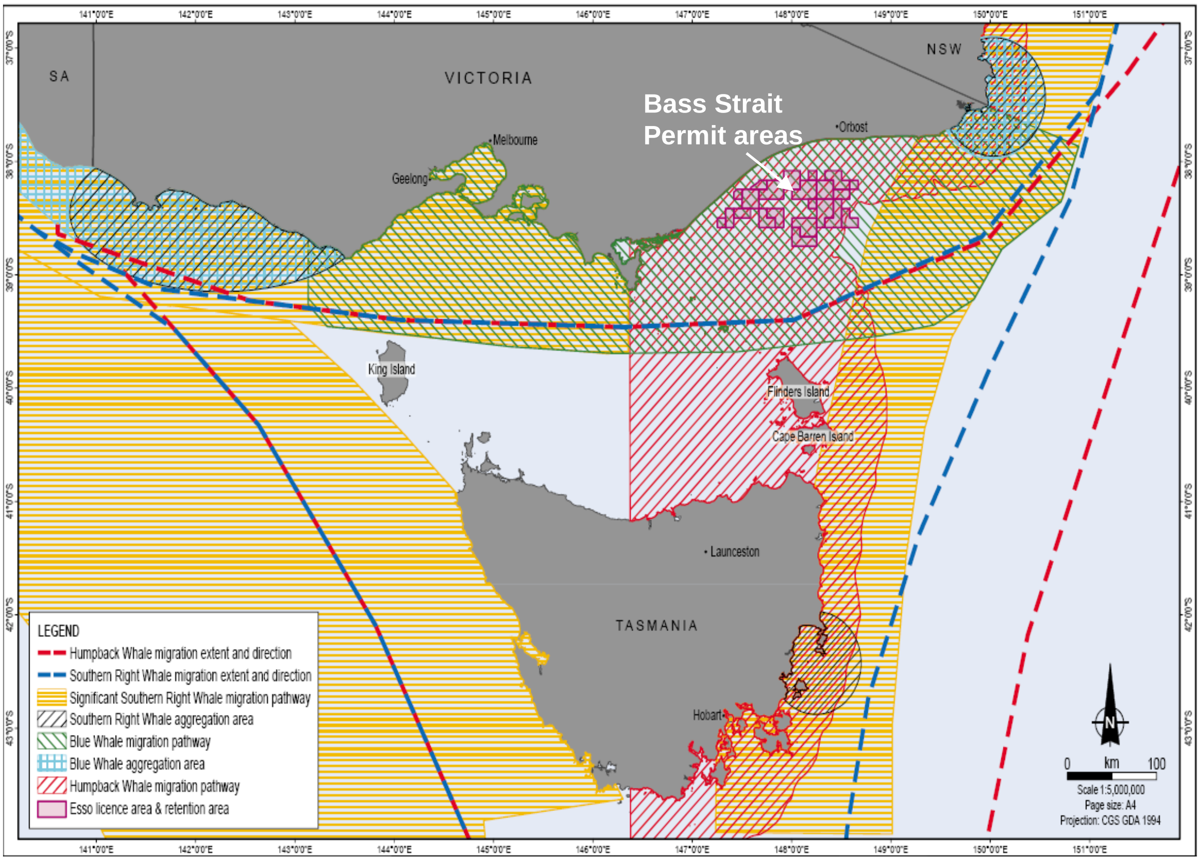

Figure 2-28 Whale migration pathways and aggregation around the Bass Strait petroleum permit areas

Humpback whales migrate annually along the eastern coast of Australia heading north to tropical calving grounds from June to August, and south to Southern Ocean feeding areas from September to November (Figure 2-29). While the main migration route of this species is along the east coast of Australia along the continental shelf to the east of Bass Strait, some animals migrate through Bass Strait. Humpback whales do not feed, breed or rest in Bass Strait and the Victorian coastal waters are not a key location for this whale species (Bannister et al., 1996). Most feeding grounds are south of Australian waters (TSSC, 2015c). A BIA for the Humpback Whale, for migration and breeding, has been identified along the east coast of Australia (Figure 2-31) (DoEE, 2015h). Humpback whales in the southern Hemisphere primarily feed on Antarctic krill (Euphausia superba). While most feeding grounds are south of Australian waters, there are some feeding grounds that are regularly used on the southern migration in Australian coastal waters: off the coast of Eden in New South Wales, and east coast of Tasmania (TSSC, 2015c).

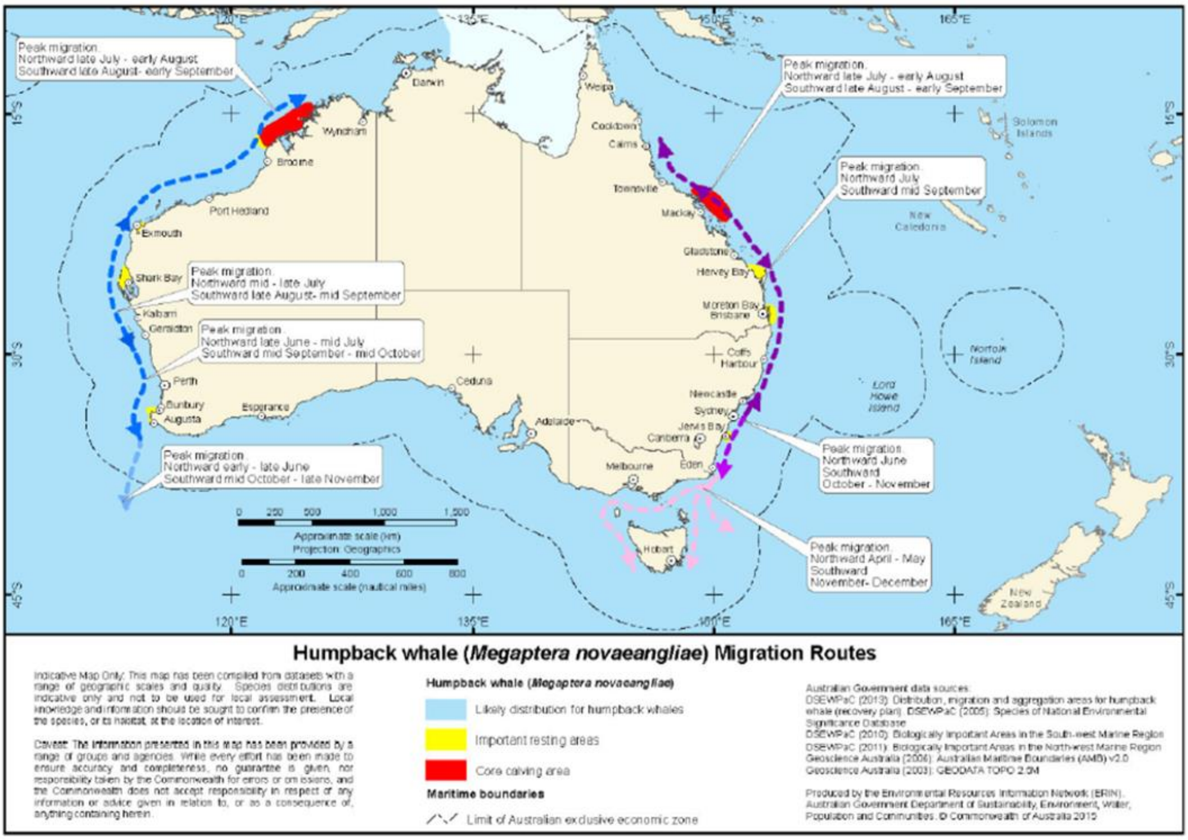

Figure 2-29 Migration routes for Humpback Whales around Australia (TSSC, 2015c)

There are two subspecies of Blue Whale that occur within Australian waters: Antarctic Blue Whale, and the Pygmy Blue Whale. Blue Whales have the highest known prey requirements, consuming up to two tonnes of krill per day (DoEE, 2015d). Blue whale sightings in Australia are widespread, and much of the shelf and coastal waters are unlikely to hold significance for this species with the exception of some foraging locations. Australia has two known seasonal feeding aggregations of Pygmy Blue Whales, one occurs adjacent to the Bonney Upwelling system off South Australia and Victoria (Figure 2-30) (Gill 2002; Gill & Morrice 2003). Pygmy Blue Whales are typically foraging in this area between January and April (DoEE, 2015d). The abundance of whales in the area varies within and between seasons (DoEE, 2015d). Outside these main feeding areas, foraging areas for the Pygmy Blue Whale also include in Bass Strait, and diving and presumably feeding at depth off the west coast of Tasmania (DoEE, 2015d). A BIA for the Pygmy Blue Whale for foraging and distribution has been identified in the DA (Figure 2-31) (DoEE, 2015h). Acoustic detections of blue whales indicates that New Zealand pygmy blue whales occur predominantly eastward of Bass Strait, Australian pygmy blue whales occur west of Bass Strait, and Antarctic blue whales occur along the entire southern coastline (McCauley et al., 2018). Sightings of Blue whales in the Gippsland Basin are reasonably rare (Bannister et al. 1996).

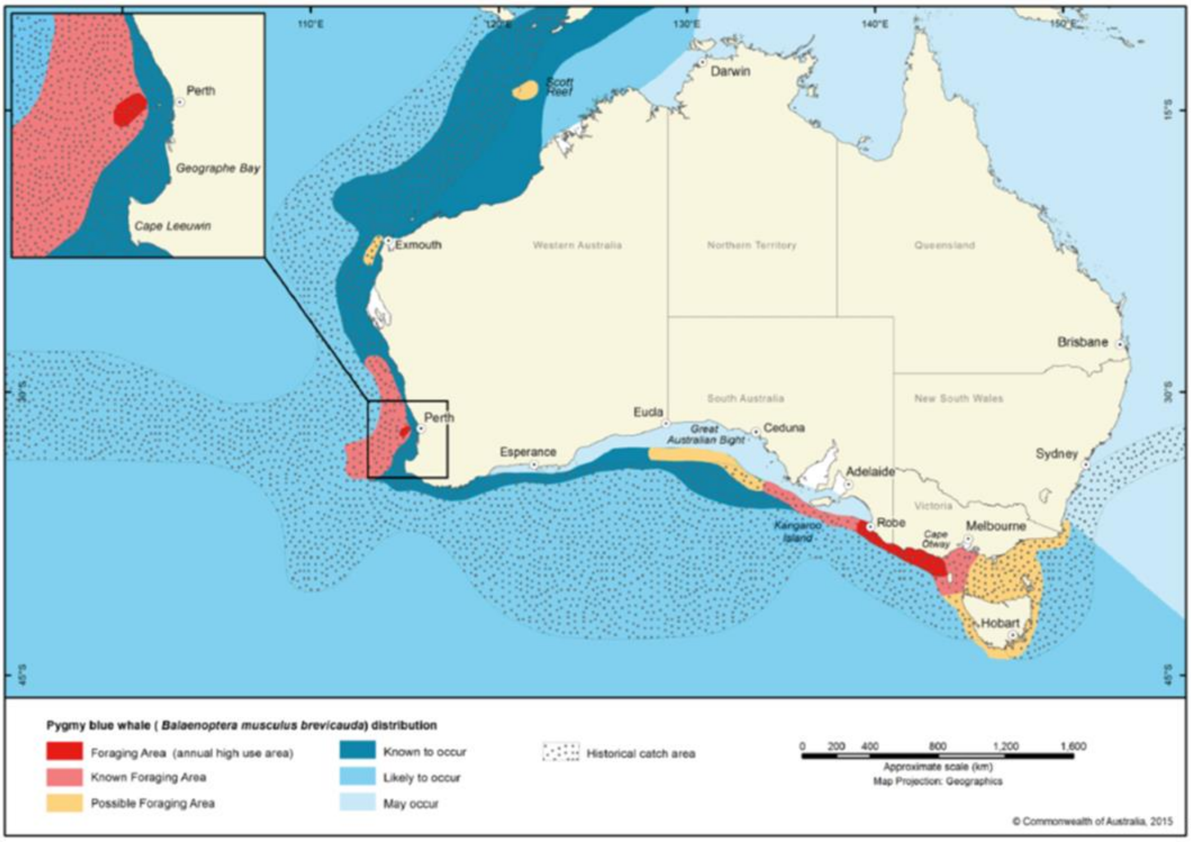

Figure 2-30 Distribution and foraging areas for the Pygmy Blue Whale (DoE, 2015d)

Sei Whales have been infrequently recorded in Australian waters; however occasional sightings have been recorded off Tasmania, New South Wales, Queensland and within the Great Australian Bight (DoEE, 2017p). Sei Whales typically feed between the Antarctic and Subtropical convergences, and their diet is planktonic crustacea, in particular copepods and amphipods. However, Sei Whales have also been observed feeding on the continental shelf in the Bonney Upwelling region during November and May, suggesting the area may be used for opportunistic feeding (DoEE, 2018a).

The distribution of Fin Whales in Australian waters is uncertain, but they have been recorded in Commonwealth waters off most States (the species is rarely found in inshore waters) (DoEE, 2017r). Fin Whales frequently lunge or skim feed, at or near the surface, feeding on planktonic crustacea, some fish and cephalopods (DoEE, 2017r). Fin Whales generally feed in high latitudes, however depending upon prey availability and locality, it may also feed in lower latitudes. Fin whales have been observed in waters off the Bonney Upwelling during November and May, suggesting the region may be used for opportunistic feeding (DoEE 2018b). Fin whales have also been detected acoustically south of Portland, Victoria (Erbe et al., 2016).

Records of Pygmy Right Whales in Australian waters are distributed between 32°S and 47°S, but are not uniformly spread around the coast (DoEE, 2017t). Areas of coastal upwelling events appear to be an important component regulating Pygmy Right Whale distribution. Pygmy right whales (Caperea truncates) have primarily been recorded in areas associated with upwellings and with high zooplankton abundance, which constitute their main prey. There is some evidence to indicate that the area south of 41°S is important for weaned Pygmy Right Whales, possibly because of the higher prey abundance in these waters (DoEE, 2017t).

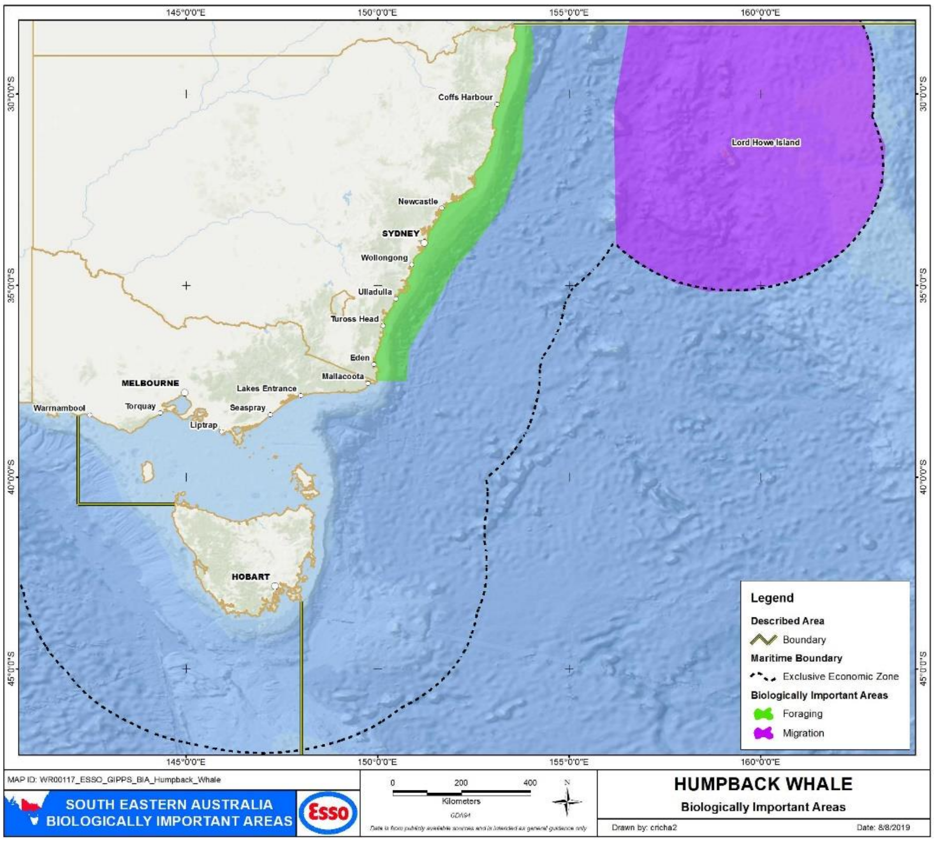

Figure 2-31 Biologically Important Areas for whale species

Dolphins

All dolphins are a protected species in Australian waters. None that are listed as occurring in the DA are listed as vulnerable, endangered or critically endangered. They are found in a variety of marine habitats, from the open ocean to coastal bays and inlets. Dolphins are migratory animals and their habits vary. Species that live in coastal areas are less likely to travel compared to species that live in open water.

The Indian Ocean Bottlenose Dolphin is distributed continuously around Australia (DoEE, 2017u). The Indian Ocean Bottlenose Dolphin occurs mainly in riverine and shallow coastal waters (on the shelf or around oceanic islands) (DSEWPaC, 2012e). Known populations include: Jervis Bay, Twofold Bay, and Phillip Bay (DSEWPaC, 2012e). Calving peaks occur in spring and summer or spring and autumn (DoEE, 2017u). Gestation lasts approximately 12 months, so peak mating period coincides with peak calving period in each location (DoEE, 2017u). A BIA for breeding for the Indian Ocean Bottlenose Dolphin has been identified within New South Wales coastal waters (Figure 2-32) (DoEE, 2015h).

The Indo-Pacific Humpback dolphin (*Sousa chenisis*) has similar habitat type as the Indian Ocean Bottlenose and occurs in tropical/subtropical waters from approximately the Queensland–New South Wales border to western Shark Bay, Western Australia. Humpback dolphins have been observed feeding mainly in near-shore habitats and in a wide range of inshore-estuarine coastal habitats including rivers and creeks, exposed banks, shallow flats, rock and coral reefs as well as over submerged reefs in waters at least up to 40 m deep. Although listed as a migratory species, they do not appear to undergo large scale seasonal migrations (DoEE, 2019y). BIA for this species occur in northern Queensland, outside of this DA (NCVA, 2019).

The Bottle-nosed dolphin (*Tursiops truncates*) and the Common dolphin (Delphinus delphis) are commonly sighted in near-shore Victorian waters.

Dusky dolphins are listed as a migratory marine species likely to be present in the vicinity of the EGBPA. Although they have been sighted off Tasmania, there is no known calving locality for this species in Australian waters (Gill et al. 2000). Of the same genus as the Dusky dolphins are the Hourglass dolphins which may occur in the area. These are circumpolar in pelagic waters of the Subantarctic and Antarctic zones. Little information is known about species feeding or breeding habitats (DoEE, 2019am).

There are a number of pelagic dolphins that may occur in the DA. The population size of these species is not known however none are considered to be rare. No specific conservation or listing advice exists and their distribution has not been specifically defined. All species feed on pelagic fish, squids, octopus, shrimps and other marine fauna taken at depths exceeding 250 m. The extent of occurrence is large in all cases, estimated to be greater than 20,000 km^2. All are tropical to subtropical species (occasionally temperate) with distribution varying depending on water temperature and flow of warm currents.

The Striped Dolphin (*Stenella coeruleoalba*) inhabits pelagic and oceanic waters. All sightings have been made in waters where the sea surface temperature exceeds 25 °C. Striped Dolphins may travel in large groups of several hundreds and even thousands, and are most frequently found in deep waters (deeper than 1000 m), preferring areas with large seasonal changes in surface temperature and thermocline depth and with seasonal upwelling (DoEE, 2019ac). Striped Dolphins do not co-occur with tuna as commonly as Spotted and Spinner Dolphins do, and so are less vulnerable to being entangled and caught in tuna purse seine nets.

The distribution of Spotted Dolphin (also called Pantropical Spotted Dolphins) (*Stenella attenuate)* has not been surveyed however there have been sightings recorded off the Northern Territory, Western Australia down south to Augusta, Queensland and NSW. This species inhabits both near-shore and oceanic habitats in tropical and warm temperate seas. They have also been found on the shelf and along the continental slope, indicating that they may use neritic (over the continental slope) habitat as well. The Spotted Dolphin diet overlaps greatly with that of Yellowfin Tuna and a close association has been noted between these species and sea birds in the eastern tropical Pacific (DoEE, 2019ad).

Long-snouted Spinner Dolphins (*Stenella longirostris*) are primarily pelagic (occurring in open ocean) but they can be neritic (occurring over the continental shelf) in some regions. They occur in tropical, subtropical and occasionally temperate waters around the world. Long-snouted Spinner Dolphins associate with tuna. The lack of abundance and distribution data prohibits definitive assessment of the Australian populations of Long-snouted Spinner Dolphins however they are not considered rare (DoEE, 2019ab).

Similar to the other pelagic dolphin species described above, the Rough-toothed Dolphin (*Steno bredanensis)* has been recorded from Western Australia (Barrow Island), the Northern Territory, Queensland and southern New South Wales. They are regularly seen with Pilot Whales and Bottlenose Dolphins, and occasionally with Spotted and Spinner Dolphins. Specific information on the Rough-toothed Dolphin is also lacking. Their notoriety for stealing bait and fish off fishing lines makes them unpopular with many recreational and commercial fishers and may lead to both incidental captures and mortalities from fisher targeting. Additionally, their regular association with schools of Yellowfin and Skipjack Tuna, plus Dorado (Dolphinfish/Mahi Mahi), may make them susceptible to entanglement in purse-seine nets set for these fish species (DoEEa, 2019ae).

Fraser's Dolphin is another pelagic or oceanic dolphin which in Australia is found north of 300 S and in waters deeper than 1000 m. Increasing ocean temperatures predicted by climate change scenarios could potentially increase the extent of occurrence of Fraser's Dolphin, with warmer water extending southwards along both coasts. Fraser's Dolphin feeds on mesopelagic fish, squid and crustaceans. It is a stocky dolphin with a short beak and thick tail stock. Distribution information on this species in Australia is derived from beach casts and is thought to be potentially abundant, however it is not well surveyed (DoEE, 2019as).

Australian Snubfin Dolphins are characterised by a broadly rounded head and no beak, with a straight mouth line. All available data on the distribution and habitat preferences of Australian Snubfin Dolphins indicate that they mainly occur in one location: shallow coastal and estuarine waters of Queensland, Northern Territory and north Western Australia. Feeding may occur in a variety of habitats, from mangroves to sandy bottom estuaries and embayments, to rock and/or coral reefs, primarily in waters less than 20m depth. A study of a population in Cleveland Bay, north Queensland showed that the species spends most of its time foraging and travelling and little time socialising. This population only spent approximately 30 days in the year in this one location, following a pattern of emigration and reimigration, suggesting that the territories or ranges for this species is large (DoEE, 2019aq).

2.3.1.7 Pinnipeds

Pinnipeds are a widely distributed and diverse group or carnivorous, fin-footed, semiaquatic marine mammals. They comprise the families Odobenidae (i.e. walrus), Otariidae (i.e. the eared seals, such as sea lions and fur seals), and Phocidae (i.e. the earless or true seals).

There are three pinniped species (or species habitat) that may occur within the DA; this includes species classified as threatened and migratory. The type of presence varies between species, and includes important behaviours (e.g. breeding) for some species (Table 2-40) (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m).

There are 10 established breeding colonies of the Australian fur seal, which are restricted to islands in the Bass Strait; six occurring off the coast of Victoria and four off the coast of Tasmania (Kirkwood et al., 2010; Pemberton & Kirkwood 1994; Warneke, 1995). Australian fur seals breed during the summer months, with pups born from late October to late December. The closest colonies of the Australian fur seal are located at Gabo Island, Kanowna Island (off Wilson's Promontory) and The Skerries, which is home to a major Australian fur seal breeding colony with an estimated population of 11,500, representing approximately 12% of the national population. Between feeding trips seals return to land to rest, for example at the resting site at Cape Conran.

Satellite tracking of seals from both Kanowna Island and The Skerries, and reports from offshore facilities within the Gippsland Basin Exclusion Zone near the shore show that Australian fur seals commonly occur in the vicinity of these facilities (Arnould & Kirkwood, 2008) and commonly rest on these structures.

The New Zealand Fur-seal (long-nosed Fur seal) and the Australian Fur-seal have the widest range of the pinnipeds, occurring in coastal regions from South Australia through to New South Wales. While breeding for the New Zealand Fur-seal does occur along the coasts of Victoria and southern Tasmania (Figure 2-34), the main breeding sites (accounting for over 80% of the national population) are located further east in Western and South Australia (TSSC, 2017; Kirkwood et al., 2009; DSEWPaC, 2012c). Conversely, the main breeding locations for the Australian Fur-seal are typically on islands within Bass Strait (Figure 2-33) (DoEE, 2017n; Kirkwood et al., 2010). New Zealand Fur-seal breeding colonies are typically found in rocky habitat with jumbled boulders; Australian Fur-seal prefer flatter rocky shelves (Shaughnessy, 1999). Colonies for both species are typically occupied year-round, with greater activity during breeding seasons (Shaughnessy, 1999; DoEE, 2017n). Numbers of Australian Fur-seals on Montague Island (New South Wales), fluctuate through the year, with peak numbers occurring in September and October; this reflects the northward migration over the winter, and the subsequent return to the breeding colonies of the Bass Strait in late spring (DoEE, 2017n). The Australian and New Zealand Fur-seals have been recorded using Beware Reef as a haul-out site (Parks Victoria, 2017b).

The Australian Sealion (*Neophoca cineria*) is a listed vulnerable species which is endemic to South Australia, and is found from Kangaroo Island, South Australia, to the Houtman Abrolhos Islands in Western Australia. Breeding colonies occur on islands or remote sections of coastline and biologically important areas occur outside the bounds of the DA (refer Figure 2-35). Lone or small numbers of animals will regularly visit known haul-out sites and occasionally visit other locations. The species has been sighted at over 200 locations and is known to occur within the DA (DoEE, 2019z). The Australian sea-lion uses a variety of habitats when onshore, including exposed islands and reefs, rocky terrain, sandy beaches and vegetated fore dunes and swales. They also use caves and deep cliff overhangs as haul-out sites or breeding habitat. Australian sea-lions are benthic foragers feeding on a wide variety of prey including fish, cephalopods and crustaceans (Gales, 2008). Females forage on the continental shelf, with the majority of diving occurring at 40–80 metres. Young sealions (as young as 7 months old) have been observed foraging at depths of 60m, up to 10km from birth colony (TSSC, 2010).

2.3.1.8 Sirenia

The dugong is the only species in the Family Dugongidae and one of four species in the Order Sirenia. It is most closely related to Steller's Sea Cow (Hydrodamalis gigas), which is extinct (Marsh et al. 2002).

The dugong or its habitat may occur in the north- eastern region of the DA (Table 2-42) (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). Biologically important areas for the dugong are in the north-west of Australia and do not occur in the DA. Dugongs occur in coastal and inland waters from Shark Bay in Western Australia (25° S) across the northern coastline to Moreton Bay in Queensland (27° S) (Marsh et al. 2002, 2011a). The winter range includes about 24 000 km of Australia's coast, which represents about 19% of the global extent of occurrence along coastline habitats (Marsh et al. 2011a). Stranded dugongs have been recorded as far south as ~36.5° S on the east coast, with occasional sightings south to 32–33.5° S (Newcastle region) in summer. In NSW the dugongs were sighted in coastal and estuarine waters around Wallis Lake, Port Stephens, Lake Macquarie and Brisbane Water in the summer of 2002/2003 (Allen et al., 2004). These areas are associated with some of the largest seagrass beds in New South Wales, some of which contain the Halophila seagrass species. The presence of dugongs in these areas at this time coincided with warm water temperatures (>18 °C).

2.3.1.9 Marine Reptiles - Turtles

Adult marine turtles spend the majority of their lives in the ocean, typically only coming onshore to nest. Females can lay (on average) between two and six clutches per season (DoEE, 2017g); with the period between clutches known as the internesting period. Female turtles typically remain close to the same nesting site during an internesting period. Egg incubation varies between species, but is typically approximately two months (DoEE, 2017g). Hatchlings disperse into oceanic currents, and the juveniles will stay in pelagic waters until large enough to settle into coastal feeding habitats. Leatherback Turtles are an exception to these general patterns, often exhibiting larger internesting zones, and travelling vast distances to forage rather than settling in a coastal habitat (DoEE, 2017g). Flatback Turtles also lack an oceanic phase and remain in the surface waters of the continental shelf.

There are six marine turtle species (or species habitat) that may occur within the DA; this includes species classified as threatened and migratory (Table 2-43) (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). A list of the conservation advice and/or recovery plans, with relevant management actions, is shown in Table 2-44. The type of presence varies between species, and includes important behaviours (e.g. foraging, breeding) for some species.

The Loggerhead Turtle has a global distribution throughout tropical, sub-tropical and temperate waters; and in Australia typically occurs in the waters of coral and rocky reefs, seagrass beds, or muddy bays throughout eastern, northern and western Australia (DoEE, 2017i). Loggerhead Turtles are carnivorous, feeding primarily on benthic invertebrates. While the species has a broad foraging range throughout Australian waters, nesting is known to occur (from two different genetic stocks) on sandy beaches on the central western and eastern coasts (Figure 2-36) (DoEE, 2017i). The eastern Australian population is smaller than the western Australian population; and has also undergone a decline from approximately 3,500 nesting females in 1977, to approximately 500 nesting females in 2000 (DoEE, 2017i). No nesting or internesting critical habitat, or BIAs, have been identified for the Loggerhead Turtle within the DA.

Green Turtles are found in tropical and subtropical waters throughout the world; usually occurring within the 20°C isotherms, although individuals can stray into temperate waters (DoEE, 2017j). Within Australia, Green Turtles typically nest, forage and migrate across tropical northern Australia (Figure 2-36) (DoEE, 2017j). No nesting or internesting critical habitat, or BIAs, have been identified for the Green Turtle within the EGBPA. The total Australian population of Green Turtles is approximately

70,000 individuals, with approximately 8,000 of these found in the Southern Great Barrier Reef area. Adult Green Turtles consume mainly seagrass and algae, although they will occasionally eat mangroves, fish-egg cases, jellyfish, and sponges; juvenile Green Turtles are typically more carnivorous, and will also consume plankton during their pelagic stage (DoEE, 2017j).

The Leatherback Turtle has the widest distribution of any marine turtle, occurring in tropical to sub-polar oceans (TSSC, 2008). In Australia, the Leatherback Turtle has been recorded foraging in all Australian states, but no large nesting populations have been recorded (Figure 2-36) (TSSC, 2008). The Leatherback Turtle is a highly pelagic species, venturing close to shore mainly during the nesting season (DoEE, 2017k). Adults feed mainly on pelagic soft-bodied creatures such as jellyfish, tunicates, salps, squid (DoEE, 2017k). No nesting or internesting critical habitat, or BIAs, have been identified for the Leatherback Turtle within the DA.

The Flatback Turtle is found in tropical waters of northern Australia, and is one of only two species of sea turtle without a global distribution (DoEE, 2017l). All known nesting locations for this species are within Australia (Figure 2-36) (DoEE, 2017l). No nesting or internesting critical habitat, or BIAs, have been identified for the Flatback Turtle within the DA. Flatback Turtles are primarily carnivorous, feeding on soft-bodied invertebrates; juveniles eat gastropod molluscs, squid, siphonophores. Limited data also indicate that cuttlefish, hydroids, soft corals, crinoids, molluscs and jellyfish may also form part of their diet (DoEE, 2017l).

The Hawksbill Turtle is found in tropical, subtropical and temperate waters all around the world (DoEE, 2017m). No nesting or internesting critical habitat, or BIAs, have been identified for the Hawksbill Turtle within the DA. Hawksbill Turtles are omnivorous, feeding on sponges, hydroids, cephalopods (octopus and squid), gastropods (marine snails), cnidarians (jellyfish), seagrass and algae (DoEE, 2017g, 2017m). During their pelagic phase (while drifting on ocean currents), young Hawksbill Turtles will feed on plankton. Hawksbill Turtles that forage on the Great Barrier Reef migrate to neighbouring countries including Papua New Guinea, Vanuatu, and the Solomon Islands; it is not known from which stock Hawksbill Turtles foraging in New South Wales originate (DoEE, 2017g).

The Olive Ridley Turtle is the smallest of Australian sea turtles. Low density nesting of the Olive Ridley turtle occurs in the northern parts of Australia including Arnhem Land coast and north-western Cape York Peninsula. Important foraging areas include the Great Barrier Reef but other shallow foraging habitats extend to south-east Queensland; most individuals have been captured by trawlers in the East Coast Otter Trawl fishery in Queensland. The EPBC database lists the species as likely to breed in the area of the DA, the Olive Ridley turtle has been identified as a conservation value in the North and North-west bioregional plans only and the literature suggests that only foraging may occur within the DA (DoEE, 2019ao).

2.3.1.10 Marine Reptiles –Other

The Elegant Seasnake is widespread in tropical Australia. This includes Queensland, Western Australia and the Northern Territory (Dell & Fry 2003) and it may occur in the DA (DoEE, 2019b, DoEE, 2019l, DoEE, 2019m). Its distribution extends from Shark Bay in Western Australia to Moreton Bay in Queensland. Sea snakes are air breathing reptiles and must come to the surface to breathe, however they can spend from 30 minutes to two hours diving between breaths. They also carry out cutaneous respiration whereby oxygen diffuses from sea water across the snake's skin into the blood. The waste product, carbon dioxide, is then diffused out of the snake's body, via the skin. The Elegant Seasnake uses a variety of marine and estuarine habitats, including sandy substrates in less than two metres of water to depths of approximately 80 m but is also sometimes found in freshwater habitats. They feed on benthic (bottom-dwelling) fish such as Catfish, burrowing eels, Whiting, Gobies and Squid. Their main threat is bycatch from trawling, no specific conservation or listing advice exists for the species (DoEE, 2019z).

The Yellow-bellied sea snake is the most widely distributed of all sea snake species in Australia, while there have not been any recent surveys, it is found in most waters except for the colder southern coastline. The population living near the central coast of New South Wales was thought to be permanent and breeding at the time of the survey in 1975. It is the most pelagic of all known sea snakes, occurring in the open waters well away from coasts and reefs. Fish are attracted to it as it rests motionless on the surface of the sea (like an inanimate object) and are subsequently caught with a sudden lunge. The main threat to the species is through bycatch from trawling. No specific conservation or listing advice exists for the species (DoEE, 2019aa). This snake species may occur in the DA.

The Stokes' Seasnake inhabits the tropical seas of northern Australia, including Western Australia, the Northern Territory and Queensland. It occurs in the Great Barrier Reef Marine Park and in the Commonwealth Reserve of Ashmore Reef in Western Australia. It is amongst the largest and bulkiest of seasnakes reaching 2 metres in length and 26cm in girth. The Stokes' Seasnake is a strong swimmer and forages for slow-moving fish in holes and crevices on the sea floor, muddy substrates and in reefs. In Australia, the Stokes' Seasnake moves southward into more temperate latitudes of Queensland and Western Australia during summer and therefore may approach the DA in this season (DoEE, 2019ar). Of the other five tropical seasnakes the Olive seasnake is also large reaching up to 2 metres.

Sea kraits are sea snakes that depend on the shore of coral islets for digestion, reproduction (mating and egg laying), skin sloughing and resting after foraging at sea. They are distinct by the black bands that go down their body. Two species of sea kraits are listed as may occurring in the DA. Although they are widely distributed from India, particularly the Andaman Islands to the islands of the west Pacific only extralimital specimens have been encountered on beaches in QLD, NSW and VIC. No breeding is known to occur in Australia (DAWE, 2020e).

The Salt-water Crocodile is the largest species of crocodile and the largest living reptile in the world and is found in Australian coastal waters, estuaries, lakes, inland swamps and marshes from Gladstone in Queensland (beyond the DA) through the Northern Territory and as far south as Carnarvon in the Western Australia (DAWE, 2020d).

2.3.2 Plankton Species

Plankton species, including both phytoplankton and zooplankton, are a key component in oceanic food chains.

Phytoplankton are autotrophic planktonic organisms living within the photic zone that spend either part or all of their lifecycle drifting with the ocean currents. They and are the start of the food chain in the ocean (McClatchie et al., 2006). Phytoplankton communities are largely comprised of protists, including green algae, diatoms, and dinoflagellates (McClatchie et al. 2006). There are three size classes of phytoplankton: microplankton (20-200 µm), nanoplankton (2-20 µm) and picoplankton (0.2-2 µm). Diatoms and dinoflagellates are the most abundant of the micro and nanoplankton size classes, and are generally responsible for the majority of oceanic primary production (McClatchie et al. 2006). Phytoplankton are dependent on oceanographic processes (e.g. currents and vertical mixing), that supply nutrients needed for photosynthesis. Thus, phytoplankton biomass is typically variable (spatially and temporally), but greatest in areas of upwelling, or in shallow waters where nutrient levels are high. Seasonal variation in phytoplankton (via chlorophyll-a concentrations) has been demonstrated in Australian waters from the analysis for MODIS-Aqua sensor imagery (Figure 2-37).

Phytoplankton biomass ranges across Bass Strait (integrated over 0-100m depth), from about 1.6 µg chlorophyll *a*/L from shallow to 0.1µg/L in deeper waters (Gibbs *et al*. 1991). Phytoplankton biomass rapidly drops off with water depth, to about 0.1 µg/L below 100m, due to diminishing light penetration.

Zooplankton is the faunal component of plankton, comprised of small protozoa, crustaceans (such as krill) and the eggs and larvae from larger animals. More than 170 species of zooplankton have been recorded in eastern and central Bass Strait, but it has been found that seven dominant species make up 80% of individuals (Esso, 2009). Zooplankton biomass is higher in shallow waters of Bass Strait (16.1 mg/m^3 dry weight off Mallacoota and 15.5 mg/m^3 off Seaspray), dropping to between 1.2 – -2.1 mg/m^3 further offshore (integrated over the top 50 m of the water column), near the deepest regions of the EGBPA (Gibbs *et al*. 1991). As with phytoplankton, zooplankton biomass appears to be higher in the shallow waters of the shelf. Copepods dominate the species encountered (Watson & Chaloupka, 1982).

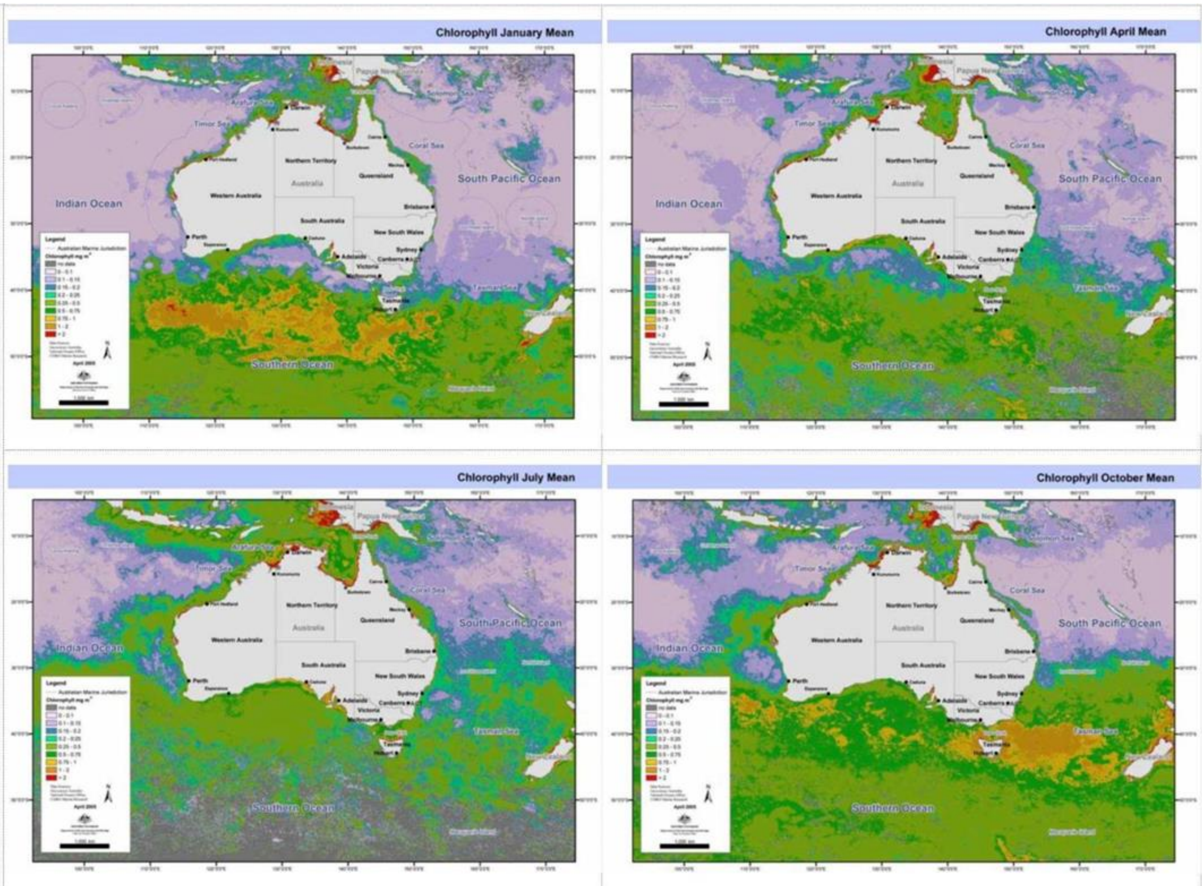

Figure 2-37 Seasonal phytoplankton growth from MODIS ocean colour composites (McClatchie et al. 2006)

2.3.3 Benthic Habitat

2.3.3.1 Bare Substrate

Unvegetated bare substrate is a widespread habitat in both intertidal and subtidal areas, particularly in areas beyond the photic zone. The biodiversity and productivity can vary depending upon depth, light, temperature and the type of sediment present.

In the Gippsland Basin, seabed material is predominantly calcium carbonate comprised of calcarenite marls and marine shales (Esso, 2009). Folk sediment classification of the samples taken at the West Kingfish and Tuna platforms describe the sediments as ranging between slightly muddy, gravelly ((m)/g/S) and muddy, gravelly sand (m/g/S) with two locations at Tuna being classed as gravelly sand (g/S) (Cardno, 2019). Similarly, the West Barracouta geophysical survey classified the seabed as featureless with consistently medium to high variable reflectivity, with backscatter characteristics indicative of fine to coarse calcerous sand with shells (DWSS, 2018). The 2009 Snapper study found that the seabed surrounding the platform is entirely comprised of soft sediments with no areas of hard substrate of rocky reef (Coffey, 2009). Generalised cross section taken from the Blackback Site survey report and accompanying representative sediment photographs indicate that the seabed sediments at the Blackback region are dense fine to medium grained siliceous carbonate sand (carbonate content ~80%) with some silt and shell debris. The samples from the canyon areas had a higher proportion of gravel and shell fragments relative to the slope and ridge samples.

The Gippsland Basin is composed of a series of massive sediment flats, interspersed with small patches of reef, bedrock and consolidated sediment. The sandy plains are only occasionally broken by low ribbons of reef; however, these reefs do not support the large brown seaweeds characteristic of many Victorian reefs, but instead are inhabited by resilient red seaweeds and encrusting animals that can survive the sandy environment (Esso, 2009). A study of the seascape of the south-eastern Australian continental shelf conducted in 2001 found that 89% of the seabed was sediment flats/bare substrate with prominent hard-grounds making up the remaining 11% of the seabed (CSIRO, 2001).

The benthic fauna present on the soft sediment can be broadly divided into two groupings:

- The epibenthos which includes sessile species such as sponges and bryozoans, hydroids, ascidians, poriferans and mobile fauna including hermit crabs, sea stars and octopus;
- The infauna which includes a diverse range of species such as amphipods, shrimps, bivalves, tubeworms, small crustaceans, nematodes, nemerteans, seapens, polychaetes and molluscs (Parry et al. 1990).

Many of these species are burrowing organisms that cause moderate bioturbation (Edgar, 2001).

Scientific surveys have shown that some shallow Victorian sandy environments have the highest levels of animal diversity in the sea ever recorded (ParksVic, 2016). In the area around the Ninety Mile Beach Gippsland more than 600 different marine animal species, many of them very small, have been found within an area of 10 m2 (ParksVic, 2016). This high species richness was a major factor in the creation of a Marine National Park on the Ninety Mile Beach (ParksVic, 2017c). The subtidal sand invertebrate fauna are dominated by small animals, mostly crustaceans, molluscs, echinoderms and polychaetes (Plummer et al. 2003, Bax and Williams, 2001).

Parry et al. (1990) found high diversity and patchiness of benthos sampled off Lakes Entrance, where a total of 353 species of infauna was recorded. Crustaceans (53%), polychaetes (32%) and molluscs (9%) dominated sample results. A significant site for the listed opistobranch mollusc (seaslug) Platydoris galbana is located off Delray Beach, 2 km south-west of Golden Beach on the shoreline (O'Hara & Barmby, 2000). An ROV seabed survey was conducted following drilling at the Snapper operational area in 2009 (Coffey 2010) and a seabed monitoring program conducted near West Tuna in 1999 (URS, 2000) confirmed that polychaetes and crustaceans were the most abundant infaunal taxa present in the seabed sediments.

This results were further supported by two studies conducted in 2018 for Esso. The first, an in-situ sediment quality and infauna sampling program conducted at West Kingfish and Tuna (including reference locations), confirmed that polychaetes, crustaceans and molluscs were the most abundant groups of taxa at all the sampled locations. The dominance (in terms of abundance) of particular taxa varied among zones and reference locations at each platform and between platforms. The benthic infauna assemblages were diverse with a range of taxa having a substantial contribution to the overall assemblage structure. The study investigated the drivers for potential influence on the entire assemblage of benthic infauna and found that it was the proportion of gravel (> 2.00 mm) particles in the sediment that was the most significant influencing factor. Figure 2-38 shows the proportion of the assemblage represented by the Crustacea, Polychaeta, Mollusca, Echinodermata and the Order groups for 'Other Worm Phlya' and 'Other Phyla' for the West Kingfish sampling and Figure 2-39 shows the proportion of the those assemblages for the sampling conducted at Tuna. The graphs show that the proportions of these assemblages were generally consistent between locations at the West Kingfish platform, however there were significant differences in the benthic infauna assemblages between locations at Tuna platform. Analysis indicated these differences were driven by changes in the physical characteristics of the environment, for example grain size and hydrodynamic differences between locations (Cardno, 2019).

The second 2018 Esso baseline study for the West Barracouta project found similarities in the dominant taxa throughout the survey locations which included annelids (polychaetes), crustaceans (amphipoda, isopoda and decapoda) and molluscs (gastropods and bivalves). This study also found that there was dissimilarity between infauna groups and these were variable throughout the survey area, likely reflecting the heterogeneous nature of the survey area (MST, 2018). Figure 2-40 shows the taxa-classed abundance of infauna at each of the monitoring sites at West Barracouta. The variation in abundance seen between the West Kingfish/Tuna studies and the West Barracouta study is due to the sample sizes taken. West Kingfish/Tuna sample size averaged 2.3L. West Barracouta sample size was 66L (0.66m^2).

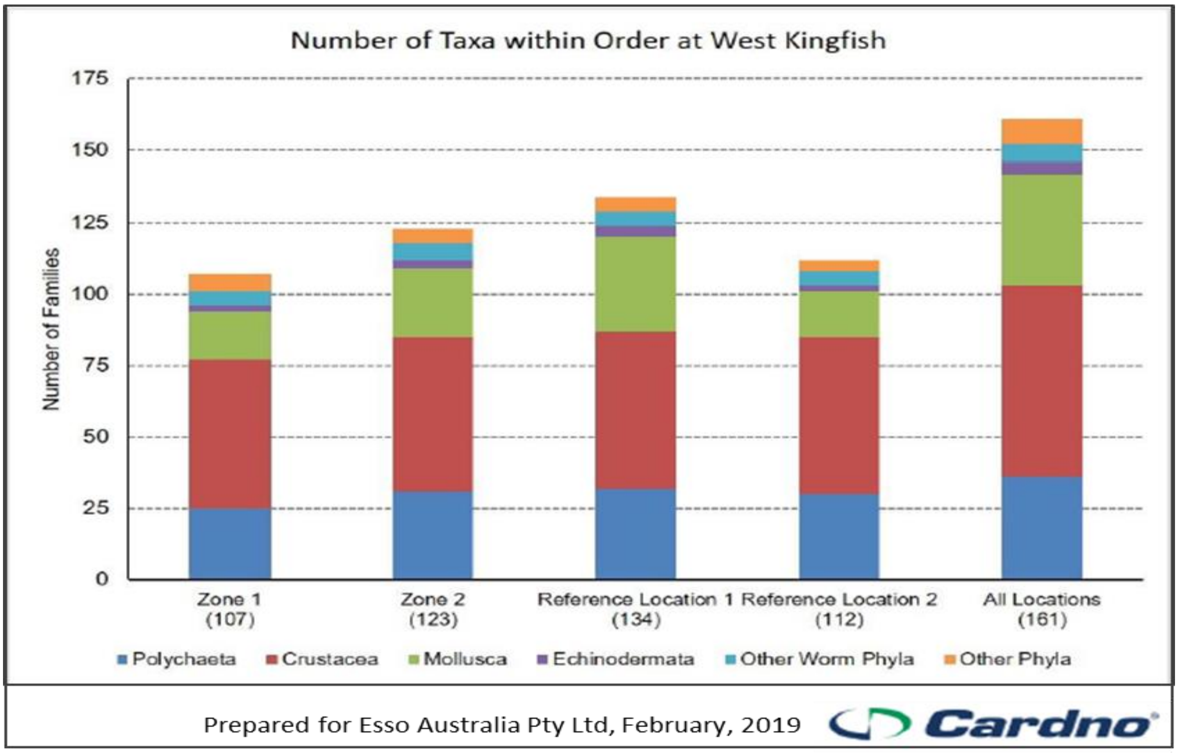

Figure 2-38 Number of taxa sampled at West Kingfish platform (Zones 1 and 2) and reference locations (Locations 1 and 2). Values in parentheses indicate the total number of taxa sampled.

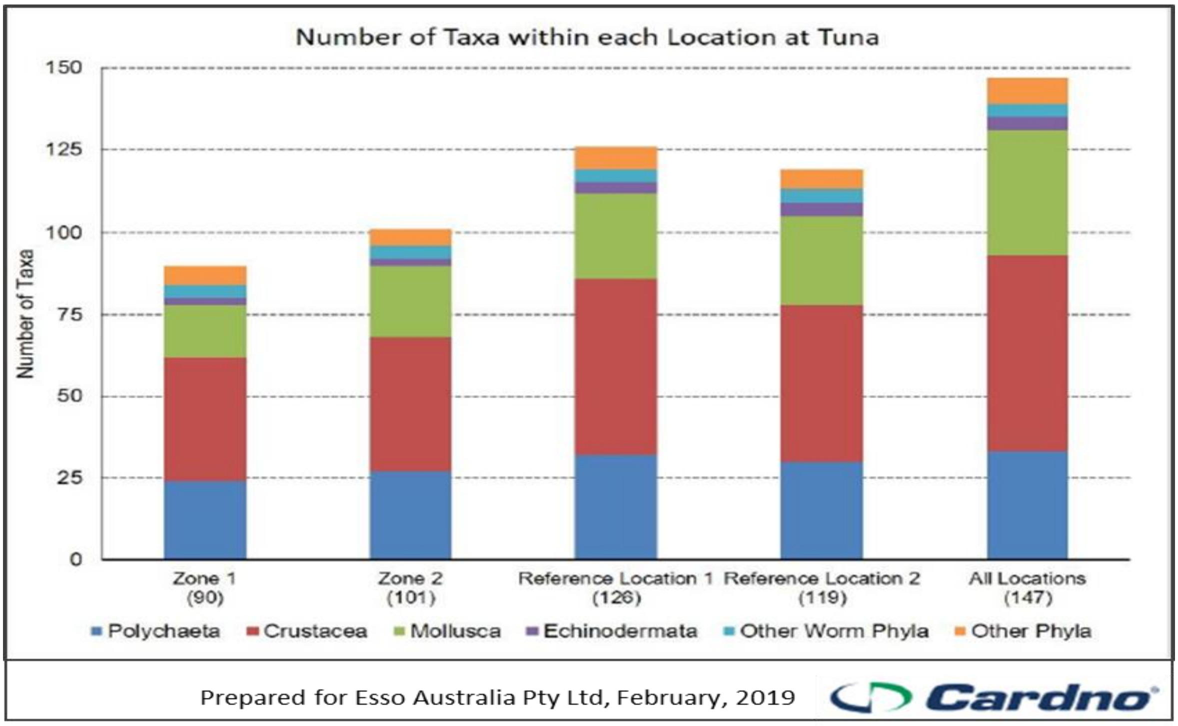

Figure 2-39 Number of taxa sampled at Tuna platform (Zones 1 and 2) and reference locations (Locations 1 and 2). Values in parentheses indicate the total number of taxa sampled.

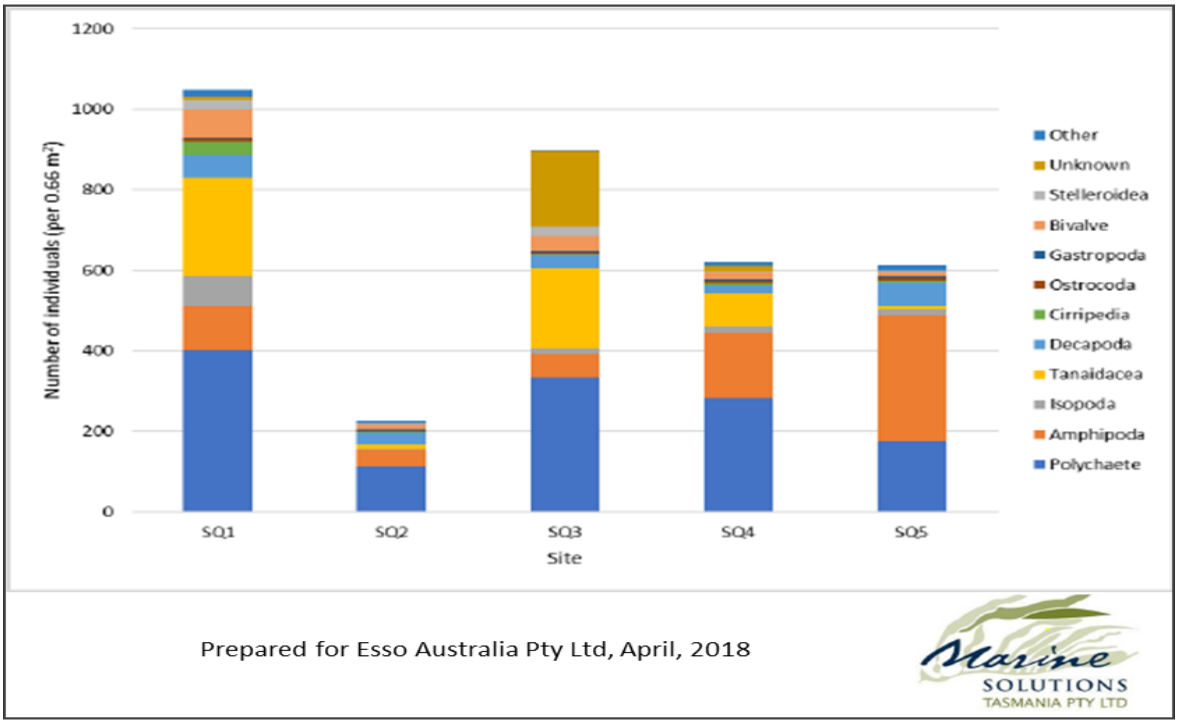

Figure 2-40 Taxa classed abundance of infauna at West Barracouta monitoring

The studies above suggest there is a consistent variation in the types and abundance of benthic infaunal species forming assemblages across the across Bass Strait. Though the benthic infauna taxa collected during this study are similar to those previously recorded, the contribution of each one to the overall assemblage was different in the majority of cases. The differences in the contribution of individual taxa to the overall assemblage between studies could have resulted from a number of natural factors including habitat heterogeneity (mirco and macro-scale), depth and sediment characteristics (URS 2000, Marine Solutions 2018) and temporal differences between sampling periods (Cardno, 2017). This is consistent with the 2004 study of Sediments and Benthic Biota of Bass Strait (GA, 2004), which concluded that it is not possible to classify the biological assemblages into a scheme that can be mapped across Bass Strait. The study emphasized that assemblages can have different distribution patterns to species and that environmental gradients rather than discrete bioregions or habitats better explain the biotic patterns observed in the sea bed of Bass Strait. Analysis of physical variables, derived from data collected on previous surveys by Geoscience Australia and supplemented by more recent data, show that longitude and depth are also important factors in explaining the biological diversity (GA, 2004).

The introduced New Zealand screw shell (Maoricolpus roseus) is present in eastern Bass Strait and is known to form extensive and dense beds on the sandy seafloor spreading to the 80 m isobath off eastern Victoria and NSW (Patil et al. 2004).

Larger animals found in these soft sediment environments in Victoria have included Smooth Stingray (Dasyatis brevicaudata), Pipi (Plebidonax deltoids), Dumpling Squid (Euprymna tasmanica), Common Stargazer (Kathetostoma leave) and Heart Urchin (Echinocardium cordatum) (Parks Victoria, 2016).

Soft sediment habitat is the dominant habitat within the EGBPA.

2.3.3.2 Seagrass

Seagrasses are marine flowering plants, with about 30 species found in Australian waters (Huisman 2000). There is a distinction between tropical and temperate seagrasses, and the approximate latitude for the change occurs at Moreton Bay (southern Queensland). The dominant temperate species in the DA are Amphibolis antarctica, Halophila australis, Heterozostera tasmanica, Posidonia australis, Posidonia angustifolia and Zostera muelleri (Kirkham 1997). Seagrasses generally grow in sediments in intertidal and shallow subtidal waters where there is sufficient light, and are common in sheltered coastal areas such as bays, lees of island and fringing coastal reefs (DEWR, 2006; McLeay et al., 2003; Rogers et al., 2013; McClatchie et al. 2006).

Seagrass meadows are important in trapping and stabilising sediments, as seagrass leaves baffle wave action and reduce water movement to the extent that fine suspended particles settle out and are trapped (Edyvane, 1999). Seagrass meadows also provide habitat and nursery grounds for juvenile fish and invertebrates, enhance biodiversity and promote primary production (Huisman 2000; Rogers et al. 2013; Kirkman 1997).

Known areas of seagrass within the DA include Corner Inlet and Lakes Entrance in Victoria, and numerous inlets and estuaries along the NSW coast (Figure 2-41) (Lucieer et al., 2017). While seagrass meadows are present throughout this region, the proportion of seagrass habitat is not high compared to the rest of Australia, in particular with parts of South Australia and Western Australia) (Kirkham, 1997).

Seagrasses are highly productive habitats that occur on intertidal flats and in shallow coastal waters worldwide from arctic to tropical climates. Water temperature, light penetration, sediment type, salinity, and wave or current energy control seagrass distribution. Seagrasses provide breeding and nursery grounds for fish and wildlife. Seagrasses are used by fish and shellfish as nursery areas.

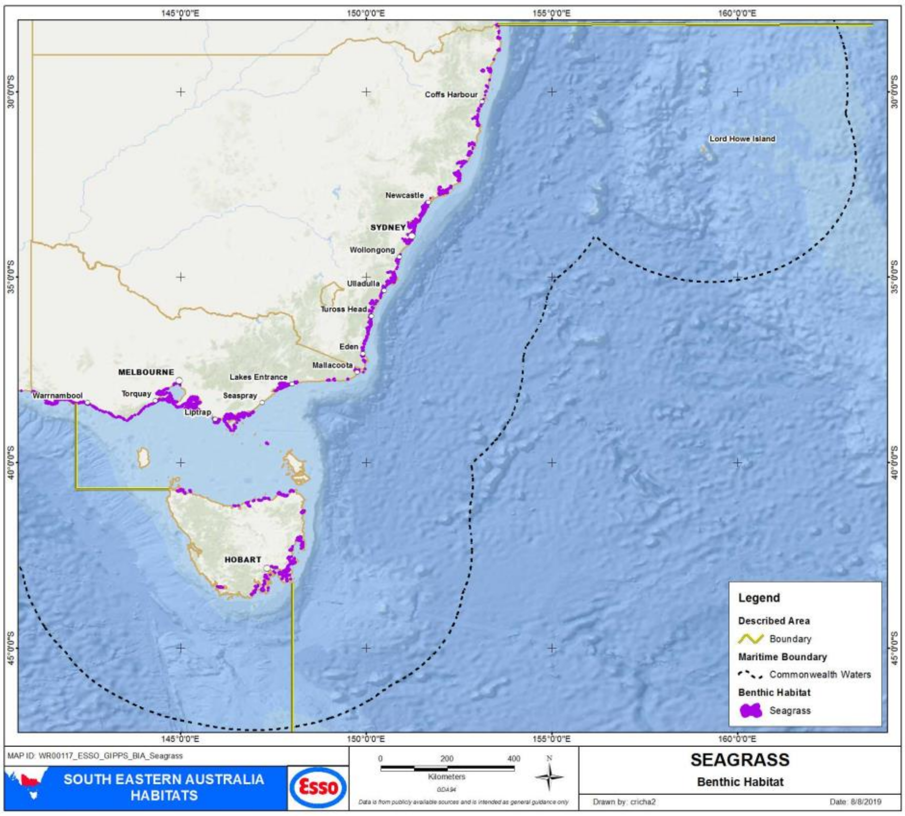

Figure 2-41 Seagrass dominated nearshore habitat within the DA

2.3.3.3 Subtidal Rocky Reefs

This habitat occurs either as extensions of intertidal rocky shores or as isolated offshore reefs and are always submerged. The rocky reefs of southern Australia support a highly endemic marine flora and fauna. Subtidal rocky reefs are scattered along the Gippsland shore and make up approximately 11% of the south-eastern Australian shelf (CSIRO, 2001).

This habitat consists of subtidal substrates composed primarily of limestone reefs and outcrops of sandstone and granite. The composition and characteristics of the substrate varies across the region based on its geologic origin and history. Fossiliferous limestone, as the name suggests, is composed of skeletons of dead animals, such as bivalve and bryozoan clasts. The skeletal elements are cemented together by a fine-grained calcareous matrix formed by a slow rate of sedimentation suggesting that the process is continuing to (slowly) occur on the Gippsland basin continental shelf (CSIRO, 2001). Known locations of this type of substrata are Howe Reef, Gabo Reef and Broken Reef.

Limestones usually form in large, tabular slabs of low relief (<2 m) as is the case in Broken Reef, however they can also form as low-lying hard grounds that are bored and encrusted by benthic organisms. These are likely to form ‘patches’ or mosaics of hard substratum that show little (<20 cm) or no vertical relief. An example of this is the low relief limestone South-east Reef which is mapped to occur in the VIC/L5 licence area and beneath the Cobia platform. Based on ROV video surveillance, the presence of South East Reef is not evident when comparing the abundance of biota around the Cobia platform versus other facilities (base on Esso ROV inspection data from 2010, 2013 and 2014). This may be due to the layer of sediment coverage over the hard substrate or the lack of extrusions/elevations.

Another form of the hard substrate is the coarse-grained, quartz rich sandstone. In Gippsland, sandstone, together with fossiliferous sandstone, occurs as elongate, low relief slabs which crop out from soft sediments along the Gippsland coastline. Whilst not confirmed this type of sandstone is also likely to be a common constituent of banks or reefs further offshore.

On the inner shelf of the Gippsland coastline are relatively localized, higher relief (>10m) outcrops formed of distinctive irregular, hexagonally jointed, coarsely crystalline granite, or hard reefs. Point Hicks and New Zealand Star Banks are areas of granite reef. Figure 2 43 shows high level substrata distribution in south-east Australia (CSIRO, 2001).

Rocky reef habitats can support rich, diverse communities of attached epifauna (e.g., stalked chrinoids, sponges, ascidians etc.) and associated algae and other fauna. Structures with a higher relief (reef or bank) several metres high can provide protection and food and attract a diversity of fish and invertebrate species (NOAA 2010).

The substrata is only one factor which influences the presence of biological communities. The distribution of fish and invertebrate communities is also correlated with latitude, depth, temperature and hydrology. Areas where the overlap of temperate and subtropical currents coincide will have a different distribution of communities to places like Horseshoe Canyon where upwelling occurs.

Other known areas of subtidal rocky reef include ; Bastion Point, Quarry Beach, Little Rame Head, Long Reef, Wingan Point, The Skerries Special Management Area, Rame Head, Petrel Point, Thurra River, Pearl Point, Yeerung River Estuary (Intermittently open), Cape Conran (East Cape, Cowrie Bay, Flat Rocks), Point Ricardo and Ricardo Beach.

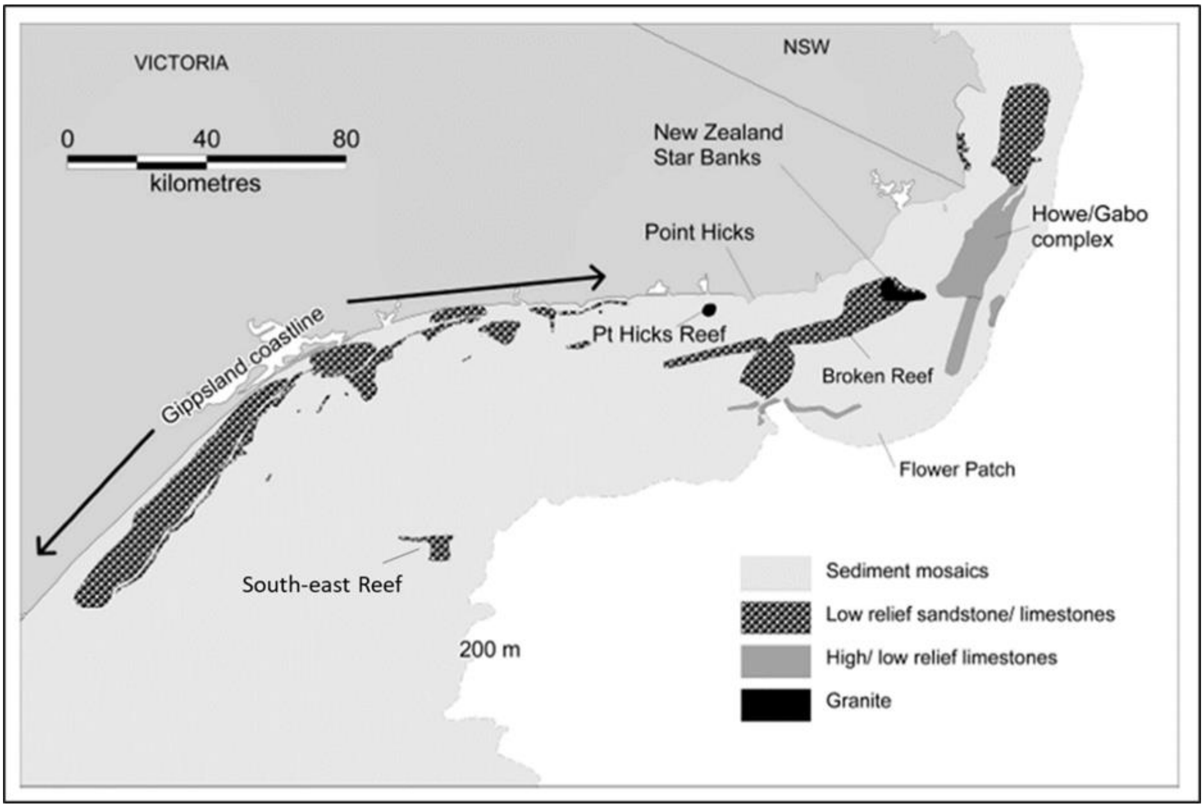

Figure 2-42 Substrata on the south-eastern Australian continental shelf

2.3.3.4 Macroalgae

Macroalgae are multicellular, marine algae, commonly known as seaweed. Macroalgae communities are generally found on intertidal and shallow subtidal rocky substrates as they require a surface to attach themselves to, and can occur throughout Australian nearshore waters. Macroalgae are divided into three groups: Phaeophyceae (brown algae), Rhodophyta (red algae), and Chlorophyta (green algae). Brown algae are typically the most visually dominant and form canopy layers (McClatchie et al. 2006). Macroalgae assemblages vary, but Ecklonia radiata and Sargassum sp. are typically common in deeper areas. The principal physical factors affecting the presence and growth of macroalgae include temperature, nutrients, water motion, light, salinity, substratum, sedimentation and pollution (Sanderson, 1997). Macroalgal systems are an important source of food and shelter for many ocean species; including in their unattached drift or wrack forms (McClatchie et al. 2006).

Kelps are very large brown algae that grow on hard sub tidal substrates in cold temperate regions. Kelps have a holdfast that attaches to the substrate, a stem-like or trunk-like stipe, and large, flattened, leaf-like blades called fronds. The Giant Kelp Marine Forests are classed as threatened ecological communities. Refer to section 2.2.4.1 for information on giant kelp marine forests.

Macroalgae is not a common dominant habitat within the EGBPA, however known areas include around Gabo Island and within the Bemm River estuary (Figure 2-43) (Lucieer et al., 2017).

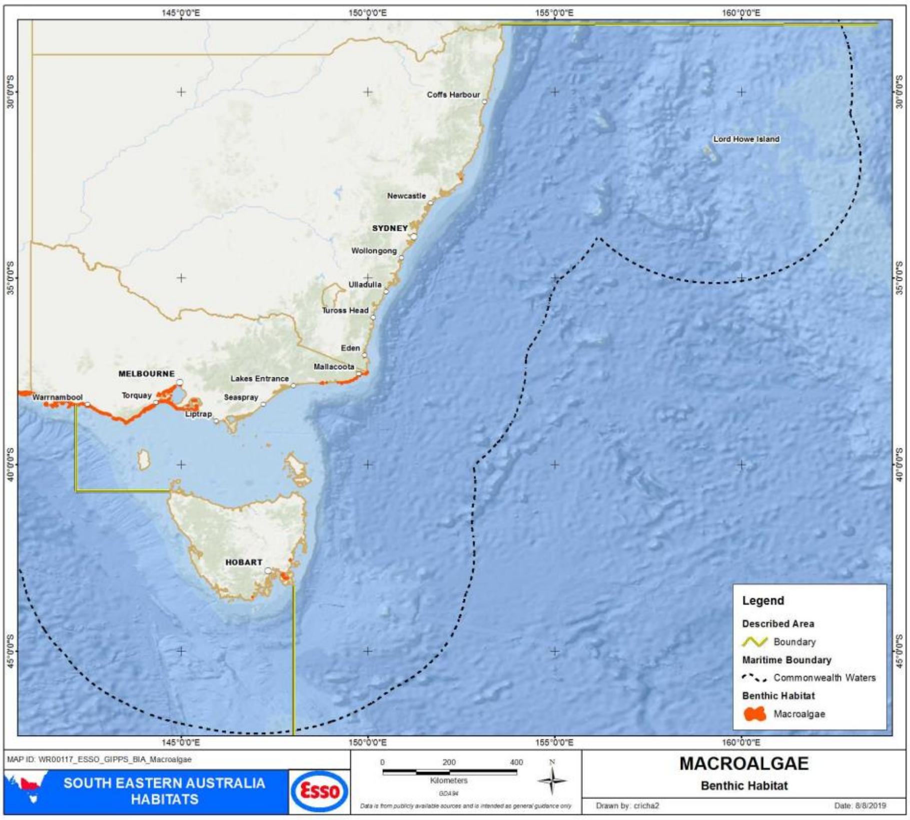

Figure 2-43 Macroalgae dominated nearshore habitat within the DA

2.3.3.5 Coral

Corals are generally divided into two broad groups: the zooxanthellate ('reef-building', 'hermatypic' or 'hard') corals, which contain symbiotic microalgae (zooxanthellae) that enhance growth and allow the coral to secrete large amounts of calcium carbonate; and the azooxanthellate ('ahermatypic' or 'soft') corals, which are generally smaller and often solitary (Tzioumis and Keable, 2007). Hard corals are generally found in shallower (<50 m) waters, while soft corals are found at most depths, including in deeper waters throughout the continental shelf, slope and offslope regions, to well below the limit of light penetration.

There are three factors that appear to drive the spawning of warm water corals – a gradual rise in sea temperature (this triggers the gametes to mature), the lunar cycle, and the diurnal light cycle. As such, the timing of coral spawning events varies around Australia. Large spawning events for Great Barrier Reef corals typically occur four to five days after the full moon in October or November (and occasionally into December). Reproduction methods for cold water corals are not as well understood, but it is likely that some are still broadcast spawners (like their tropical counterparts), while others brood and release formed larvae (Roberts et al., 2009).

While corals may not occur as a dominant habitat type within the Gippsland sector, their presence has been recorded within the region (e.g. Kent Group Marine Reserve, Freycinet Marine Park, and around Wilsons Promontory). Soft corals are typically present in deeper waters throughout the continental shelf, slope and offslope regions, to well below the limit of light penetration.

Subtidal rocky reefs located along the Gippsland shore include; Bastion Point, Quarry Beach, Little Rame Head, Long Reef, Wingan Point, The Skerries, Rame Head, Petrel Point, Thurra River, Point Hicks Marine National Park, Pearl Point, Yeerung River Estuary (Intermittently open), Cape Conran (East Cape, Cowrie Bay, Flat Rocks), Beware Reef, Point Ricardo and Ricardo Beach.

2.3.3.6 Submarine Canyons

Submarine canyons are abundant features along continental and oceanic island margins that connect continental shelves to deep ocean basins. Because of the physical complexity of canyon habitats, predictions concerning the effects of canyons on diversity are not straightforward since a variety environmental and physical characteristics interact in canyon habitats. The most important driver affecting biodiversity and biomass/abundance patterns in canyons is organic matter input and is mostly related to coastal detrital inputs or pelagic productivity regimes (De Leo et al., 2010).

Seafloor terrain and substrate heterogeneity account for the second most important driver of benthic biodiversity in submarine canyons. One of these factors, sediment grain size, can be considered as a 'super-parameter' (Etter and Grassle 1992) since it directly or indirectly reflects local physical energy and sedimentation patterns. At moderate rates of flow and sediment deposition, suspension- and deposit feeding, macrobenthos can be enhanced in abundance and/or diversity in canyons (Vetter and Dayton, 1998), whereas at high rates of flow and sediment accumulation, canyon fauna can become impoverished, yielding low species richness and high dominance by a few tolerant species (Rowe et al. 1982, Gage et al., 1995, Vetter and Dayton, 1998).

While some studies have reported levels of megafaunal biodiversity in canyons rivalling seamounts (Schlacher et al., 2007), in other cases high disturbance rates (Rowe et al., 1982) and absence of stable habitat heterogeneity lead to faunal impoverishment compared to adjacent slope environments (Vetter et al., 2010).

Bass Canyon System

The Bass Canyon is an 80 km long, narrow (10 km wide) and linear, southeast trending flat bottomed canyon located at 3,000–4,000 m depth in the Gippsland Basin (Figure 2-44) (Mitchell et al., 2007). Entering the head of the Bass Canyon at 3,000 m depth are five shelf-breaching tributary canyons and three slope-confined tributary canyons (Mitchell et al., 2007). The Bass Strait canyons are characterised by dense shelf water cascades (Godfrey et al. 1980).

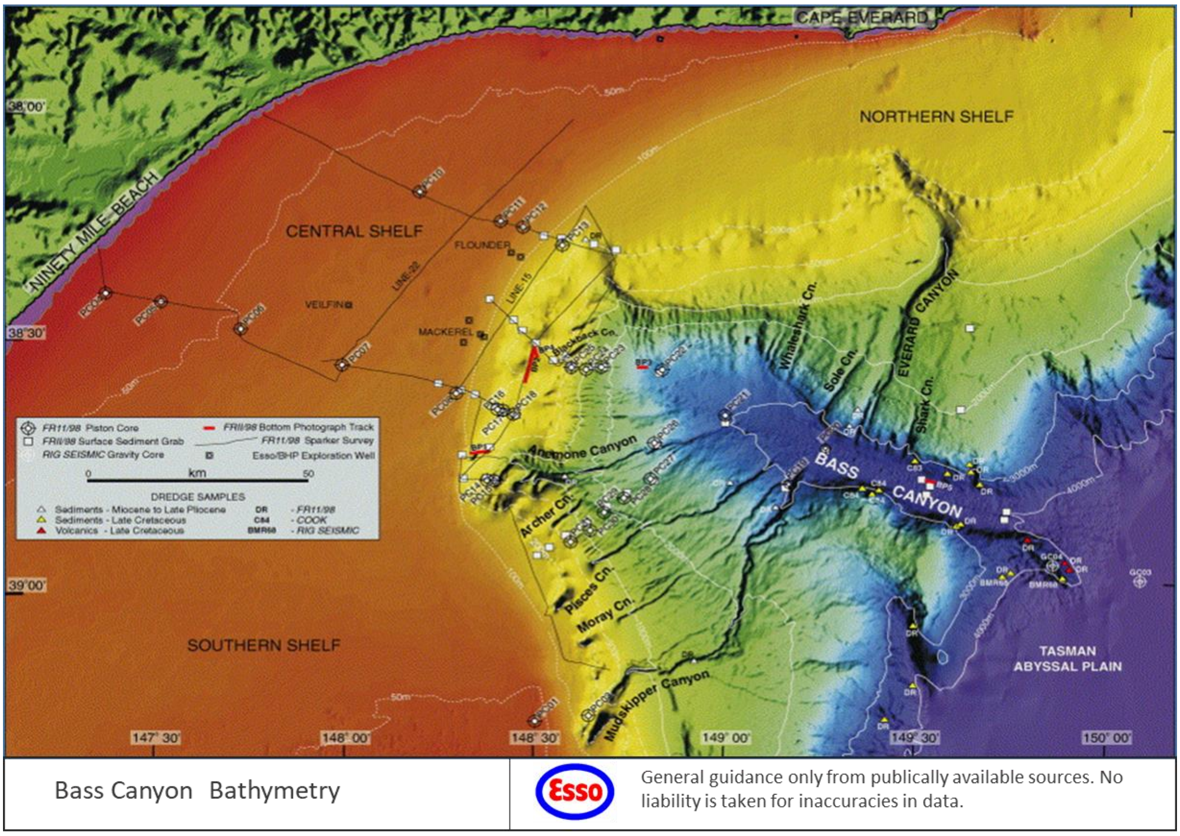

Figure 2-44 Bathymetry of the Bass Canyon

2.3.3.7 Seamounts

Seamounts are also classed as key ecological features. The Seamounts of South and East Tasmania occur in the DA, refer to section 2.2.7.5 for information on seamounts.

2.3.4 Coastal Habitat

A range of shoreline types are represented along the coastal areas within the DA. Figure 2-45 (Griffin et al., 2012) depicts the shorelines in the region and the characteristics of each habitat is described in the sections below.

The coastline, from Wilson’s Promontory in the west to Cape Howe in the east near the NSW border consists mainly of steep sandy beaches and rocky outcrops. The shoreline of the inland waters adjacent to the EGBPA which includes Corner Inlet, the Gippsland Lakes and Mallacoota Inlet consist of sandy beach, salt marsh, mangrove or mudflats (Boon et al., 2010).

The NSW coast consists primarily rocky outcrops with sections of sandy beaches and rocky cliffs. The offshore islands in Bass Strait are characterised by their steep cliffs and rocky shores. These shoreline types are also dominant along the north and east coast of Tasmania.

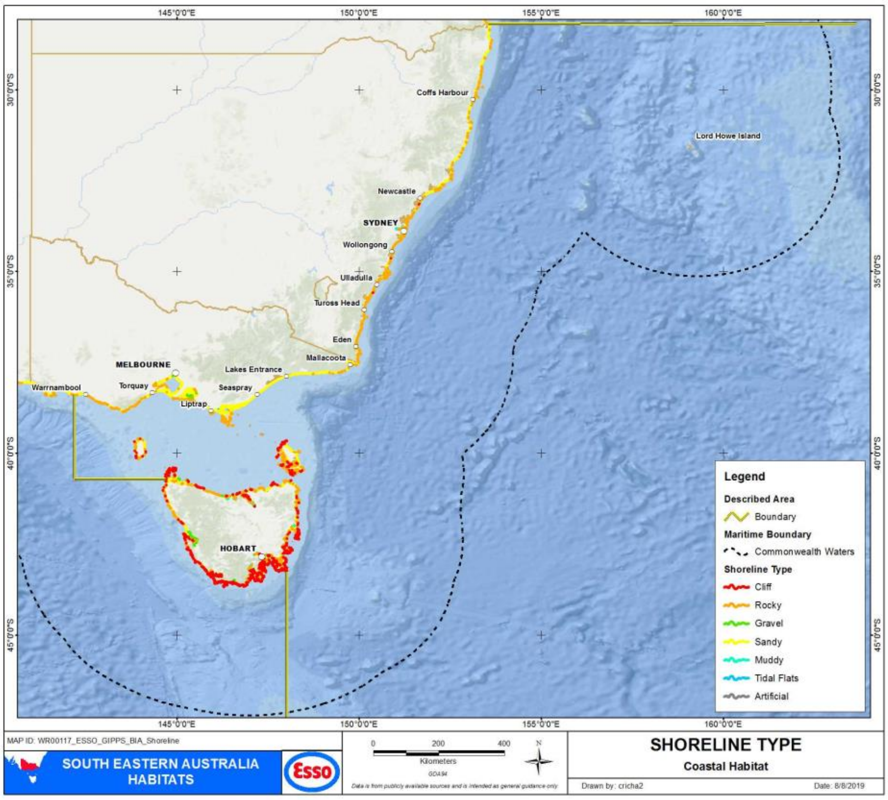

Figure 2-45 Shoreline types within the DA

2.3.4.1 Shoreline (Sandy)

This shoreline type has been defined as beaches dominated by sand-sized (0.063–2 mm) particles, and also includes mixed sandy beaches (i.e. sediments may include muds or gravel, but sand is the dominant particle size).

Sandy beaches are dynamic environments, naturally fluctuating in response to external forcing factors (e.g. waves, currents etc.). Sandy beaches can support a variety of infauna, and provide nesting and/or foraging habitat to shorebirds and seabirds and pinnipeds. Sand particles vary in size, structure and mineral content; this in turn affects the shape, colour and inhabitants, of the beach.

This shoreline type is the most common along the entire Victorian coast, including popular locations such as Ninety Mile Beach (East Gippsland, Victoria) and Squeaky Beach (Wilsons Promontory, Victoria).

2.3.4.2 Shoreline (Rocky)

Sheltered rocky shores are characterized by a rocky substrate that can vary widely in permeability. This shoreline type has been defined as hard and soft rocky shores, including bedrock outcrops, platforms, low cliffs (less than five metres in height), and scarps. Depending on exposure, rocky shores can be host to a diverse range of flora and fauna, including barnacles, mussels, tube building worms, sea squirts (cunjevoi), sea anemones, sponges, sea snails, starfish and algae. Australian fur-seals are also known to use rocky shores for haul-out and/or breeding. Most animals on the intertidal rocky shores are herbivorous molluscs, grazing algae off rock surfaces.

This is a common shoreline type along the southern NSW coast, the islands of Bass Strait, and for smaller areas of Victoria's coast (e.g. Wilsons Promontory). Intertidal rocky shores occur at Bastion Point, Quarry Beach, Shipwreck Creek, Seal Cove, Little Rame Head, Sandpatch Point, Petrel Point, Thurra River, Clinton Rocks, Cloke Rock, Tamboon Inlet and Shelley Beach.

2.3.4.3 Shoreline (Cliff)

The intertidal zone is steep (>30° slope) and narrow with very little width.

Sediment accumulations are uncommon because waves remove debris that has slumped from the eroding cliffs. There is strong vertical zonation of intertidal biological communities. Species density and diversity vary greatly, but barnacles, snails, mussels, polychaetes, and macroalgae can be abundant (NOAA, 2010).

This environment occurs behind Betka Beach and Secret Beach through to Little Rame Head, Sandpatch Point, Wingan Point, The Skerries, Rame Head, Petrel Point, Point Hicks, Clinton Rocks, Tamboon Inlet, Pearl Point, Cape Conran (Needle Rocks, Irvine Rocks, Quincy Rocks Salmon Rocks), and at Ricardo Point.

This is a common shoreline type for the Furneaux Island group in Bass Strait (e.g. Flinders Island, Clarke Island) (Figure 2-45).

2.3.4.4 Muddy- Sheltered Intertidal Flats and Bare Sediment

This shoreline type has been defined as areas with predominantly mud-sized (<0.063 mm) particles, and also includes mixed sediments (e.g. sands, shell or gravel), where the mud fraction is dominant. These areas are also exposed to high tidal variation, including tidal flats, and are often associated with mangrove or saltmarsh environments.

Sheltered intertidal flats are composed primarily of mud with minor amounts of sand and shell. They are usually present in calm-water habitats, sheltered from major wave activity, and frequently backed by marshes like estuaries or bays. The sediments are very soft and cannot support even light foot traffic in many areas. There can be large concentrations of bivalves, worms, and other invertebrates in the sediments. They are heavily used by birds for feeding (NOAA 2010).

Sheltered intertidal flats occur at Corner Inlet and Nooramunga Marine and Coastal Parks. Bare sediment occurs at Mallacoota Inlet, Wingan Inlet, Sydenham Inlet - Bemm River and Mud Lake.

Mangroves

Along the Gippsland coast, mangroves can be found in Corner Inlet and Nooramunga Marine and Coastal Park and more recently have also been found in Cunningham Arm at Lakes Entrance (Figure 2-46) (Lucieer et al., 2017).

The roots and trunks are intertidal, with only the lowest leaves inundated by high tide. The width of the forest can range from one tree, to many kilometres. The substrate can be sand, mud, leaf litter, or peat, often as a veneer over bedrock. They are highly productive, serve as nursery habitat, and support a great diversity and abundance of animal and plant species (NOAA, 2010).

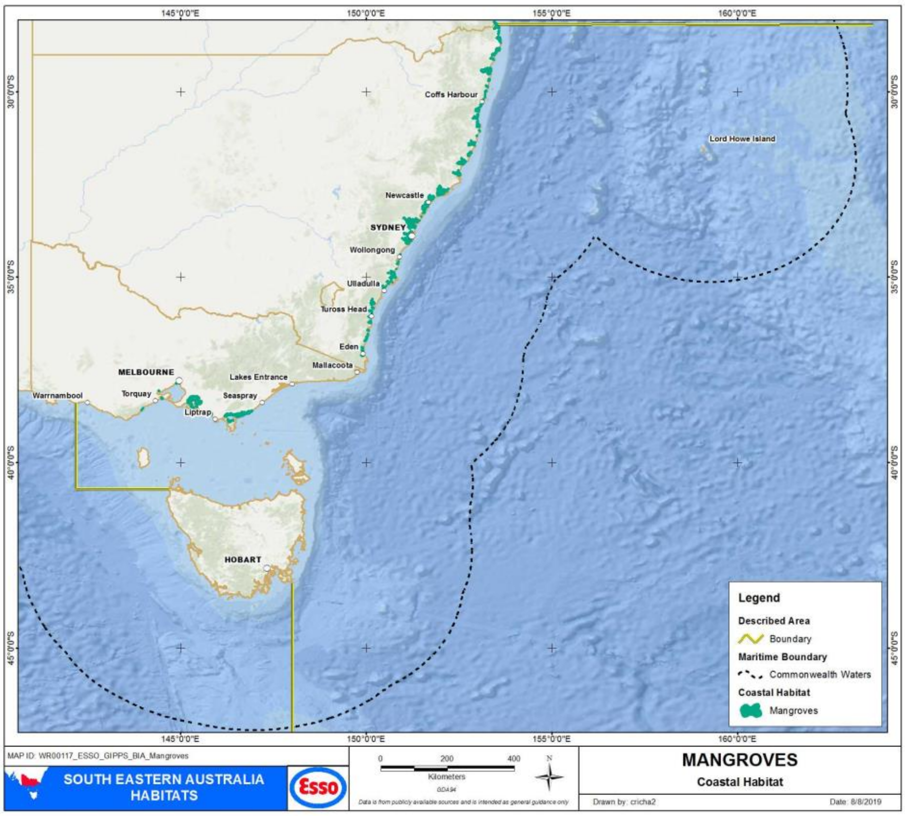

Figure 2-46 Distribution of Mangroves within DA

2.3.4.5 Saltmarsh

Saltmarshes are terrestrial halophytic (salt-adapted) ecosystems that mostly occur in the upper-intertidal zone, and are widespread along the coast. They are typically dominated by dense stands of halophytic plants such as herbs, grasses and low shrubs. Depending on location and inter-annual variations in rainfall and runoff, associated vegetation may include species tolerant or adapted to salt, brackish, or even tidal freshwater conditions. The diversity of saltmarsh plant species increases with increasing latitude (in contrast to mangroves). The vegetation in these environments is essential to the stability of the saltmarsh, as they trap and bind sediments. The sediments are generally sandy silts and clays, and can often have high organic material content. Saltmarshes provide a habitat for a wide range of both marine and terrestrial fauna, including infauna and epifaunal invertebrates, fish and birds (NOAA, 2010).

Saltmarsh is found along the coast throughout the DA (Figure 2-47), although is most extensive behind the sand dunes of Ninety Mile Beach in Gippsland (Boon et al., 2011).

Salt marshes can be found behind Mallacoota Entrance to Lake Barracouta, Wingan Inlet, inside Cann River Estuary, Tamboon Inlet, Sydenham Inlet (Bemm River Estuary and Mud Lake), Dock Inlet, inside Snowy River Estuary, Lake Tyers Estuary, and inside Lakes Entrance - Gippsland Lakes Ramsar Site. In southern NSW between Towradgi Creek about 40km north of the limits of the DA to the Victorian border there are approximately 12km2 of saltmarsh spread over 62 estuaries (NSW DPI, 2013). These include the areas of Shoalhaven River, Carama Creek, Clyde River, Tomaga River and Moruya River, Tuross Lake, Wapengo Lake, Bega River, Merimbula Lake and Wonboyn River (Creese et at., 2009).

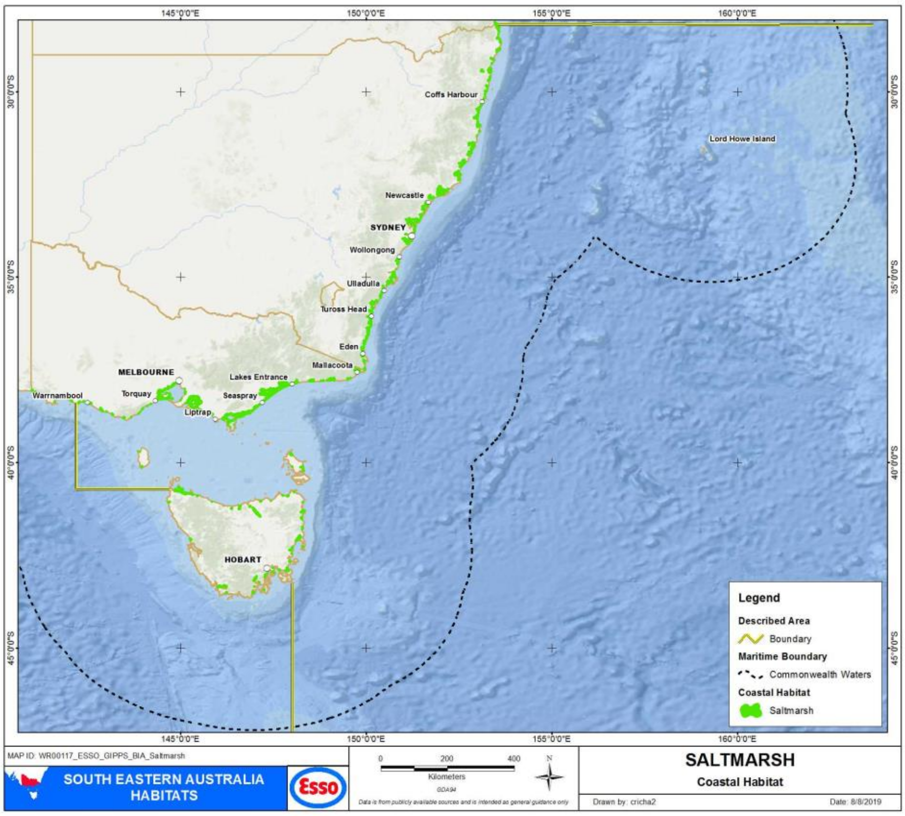

Figure 2-47 Saltmarsh dominated nearshore habitat within the DA

2.3.4.6 Coastal Vine Thicket

Coastal vine thickets are also classed as threatened ecological communities. These occur in the DA, refer to section 2.2.4.2 for information on coastal vine thickets.

2.4 Economic Environment

2.4.1 Fishing

2.4.1.1 Commercial Fishing

Commercial fishing in south-eastern Australia includes inshore coastal waters, mainly state administered fisheries, and areas along the continental slope, mainly Commonwealth fisheries. The majority of the commercial fishing (volume basis) occurs in Commonwealth waters along the continental shelf and the upper continental slope (see Figure 2-48).

The main commercial Commonwealth fisheries in the vicinity of the EGBPA are the Southern and Eastern Scalefish and Shark Fishery (SESSF) which includes ((AFMA, 2014a, 2016, ABARES, 2016 and 2017) :

- Commonwealth Trawl Sector (CTS); and
- Gillnet, Hook and Trap Sectors (GHTS)

Of these, Danish seiners and otter-board trawlers of the Commonwealth Trawl Sector are most likely to be encountered near the EGBPA.

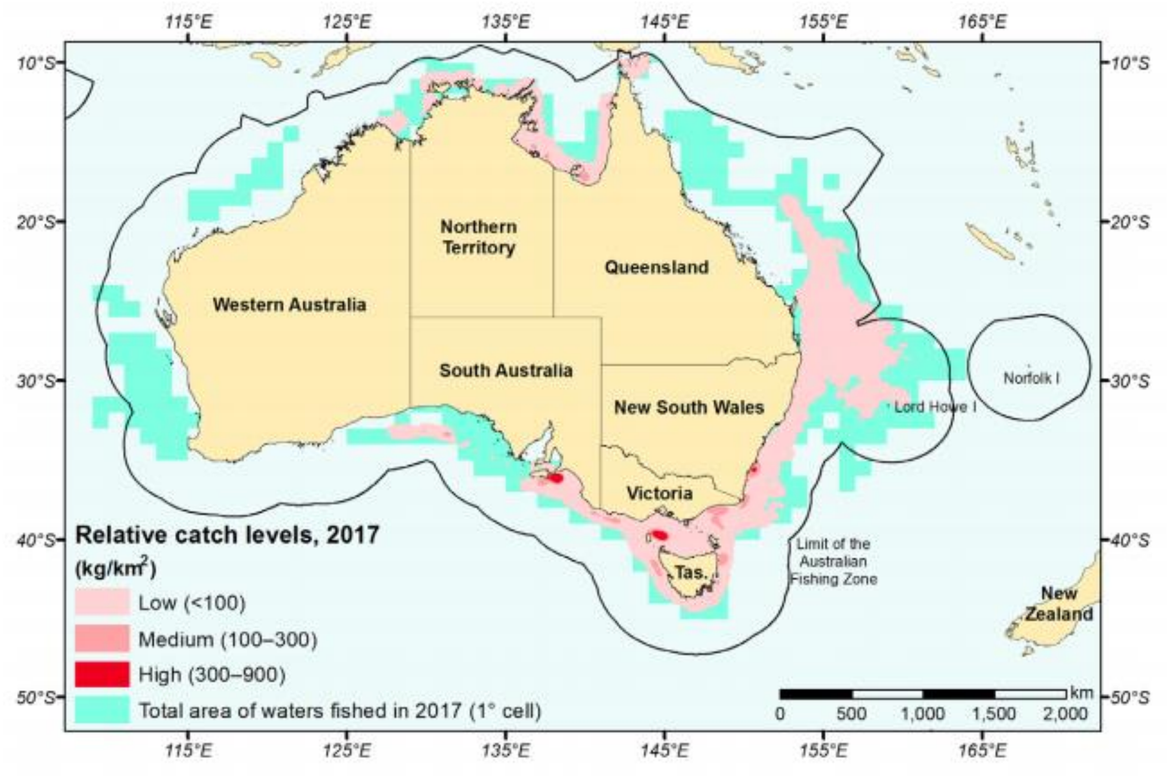

Figure 2-48 Relative catch levels of Commonwealth-managed fisheries, 2017 (ABARES, 2018)

2.4.1.2 Commercial Fishing – Commonwealth

Commonwealth fisheries are managed by the Australian Fisheries Management Authority (AFMA), with the fisheries typically operating within 3 nm to 200 nm offshore (i.e. to the extent of the Australian Fishing Zone). In 2016-2017 the Gross Value of Production (GVP) from Commonwealth fisheries was estimated at $403 million; contribution 23% of Australia's wild catch fisheries GVP (Figure 2-49) (Patterson et al., 2018).

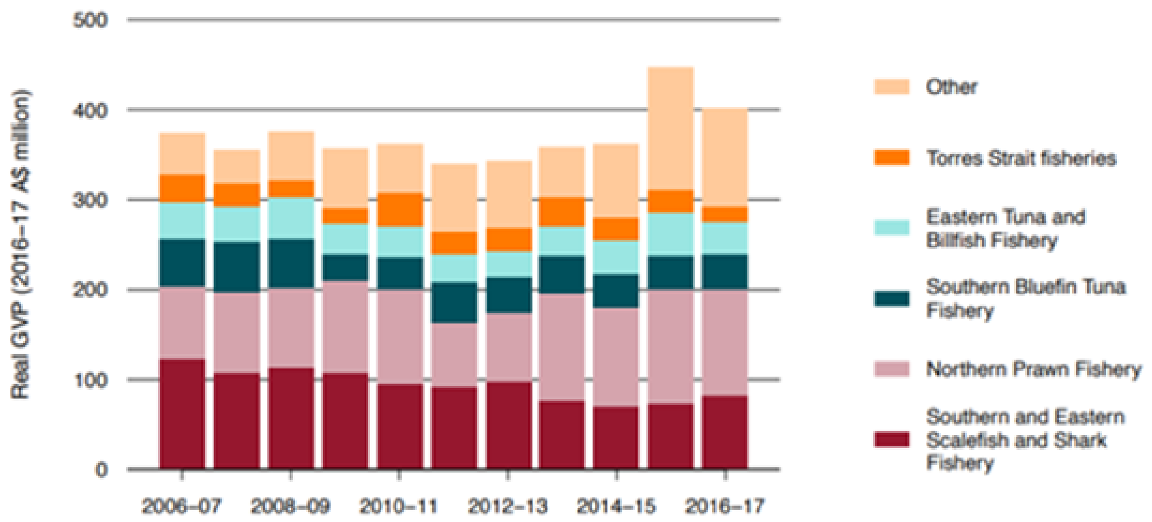

Figure 2-49 Gross Value of Production of Commonwealth Fisheries for 2016-2017 (Patterson et al., 2018).

There are seven commonwealth-managed commercial fisheries with management areas that intersect with the DA:

- Bass Strait Central Zone Scallop;
- Eastern Tuna and Billfish Fishery;
- Small Pelagic Fishery;
- Southern and Eastern Scalefish and Shark Fishery;
- Southern Bluefin Tuna Fishery;
- Southern Squid Jig Fishery; and
- Norfolk Island Fishery.

2.4.1.3 Bass Strait Central Zone Scallop Fishery

There are three zones of scallop fishing in Bass Strait and these are divided into state/commonwealth jurisdictions with the states zones extending out to 20nm from the high tide water mark. The current boundaries were settled in 1986 with an Offshore Constitutional Settlement agreed between the three jurisdictions. Figure 2-50 shows the jurisdictional allocation of the Bass Strait scallop fisheries. Refer to Section 2.4.1.10, Table 2-46 for information on the Victorian and Tasmanian scallop fisheries.

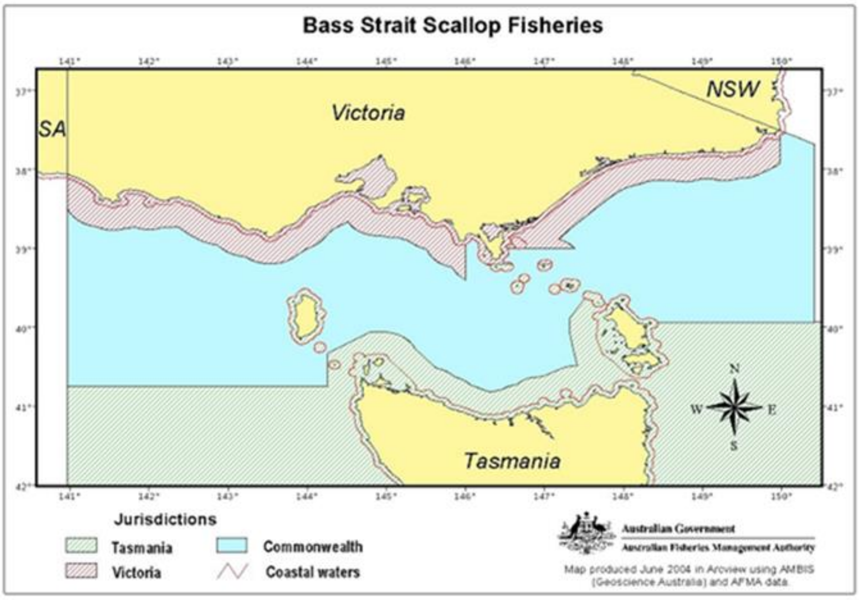

Figure 2-50 Bass Strait Scallop Fisheries (VFA, 2019)

The Bass Strait Central Zone Scallop Fishery operates in Commonwealth waters between Victoria and Tasmania (Figure 2-51). The default fishing season is 1 April to 31 December each year (note, the exact dates can vary each year) (DSEWPaC, 2013c); and the target species is Commercial Scallop (Pecten fumatus). The commercial scallop usually matures at about 12 to 18 months of age. Once maturity has been reached (fecundity increases with age), scallop spawning occurs from winter to spring (June to November); however, the timing is dependent on environmental conditions such as wind and water temperature (Sause et al., 1987). Scallop populations throughout the world fluctuate quite dramatically in response to variable environmental conditions. Relatively high populations occur in some years. These can be followed by relative scarcity, but populations can quickly rebound to large numbers provided enough adults remain for successful breeding and recruitment (VFA 2017b). Scallops are seldom found in commercial quantities in depths greater than 60-70 m.

Fishing method is via scallop dredge. Primary landing ports are Queenscliff and Apollo Bay (Victoria), and Stanley (Tasmania). The primary market for commercial scallops is domestic (Marton et al., 2012).

During 2017, fishing was concentrated on beds east of King Island (a similar area to that of 2014, 2015 and 2016) (Figure 2-51). The fishery experienced a peak in 2017, despite a reduction in dredge-hours

(Patterson et al., 2018).The value of the fishery can vary markedly, with estimates for the 2014-2015 financial year of $2.8 million (Patterson et al., 2016) and 2016-2017 financial year of $6 million (30% increase) (Patterson et al., 2018).

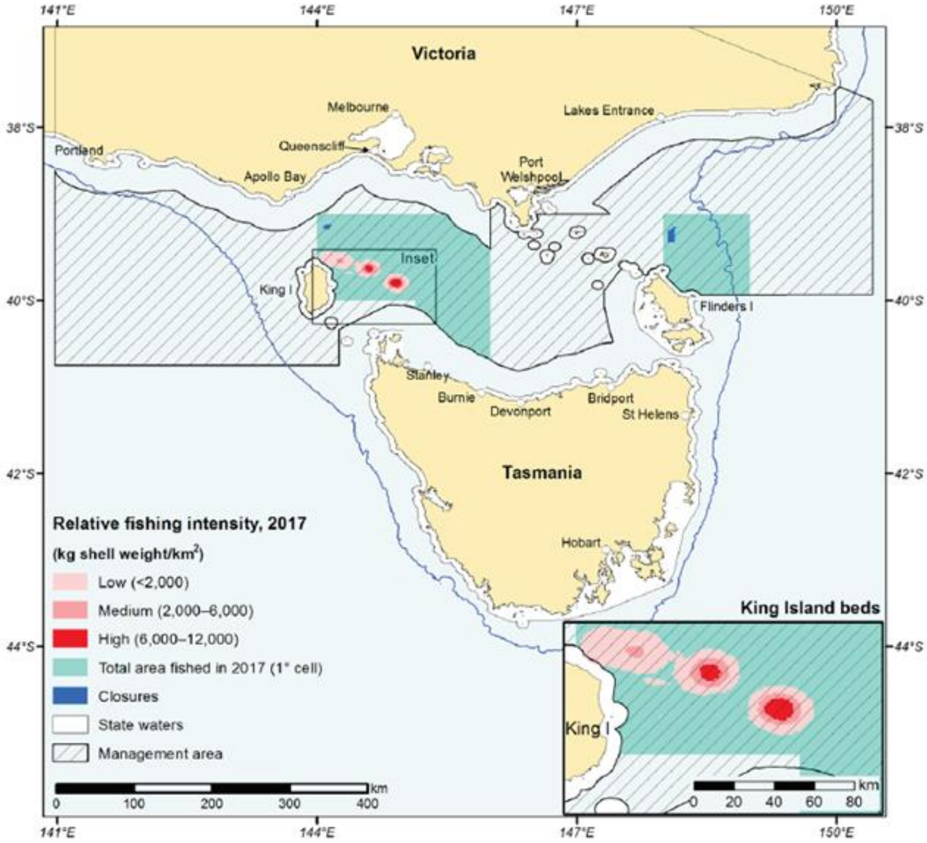

Figure 2-51 Bass Strait Central Zone Scallop Fishery Management Area and 2017 Relative Fishing Intensity (Patterson et al., 2018).

2.4.1.4 Eastern Tuna and Billfish Fishery

The Eastern Tuna and Billfish Fishery operates in Commonwealth waters from Cape York (Queensland) to the Victoria – South Australia border (Figure 2-52).

It is a 12-month fishing season, commencing 1 March each year. Primary target species are:

- Albacore Tuna (Thunnus alulunga);
- Bigeye Tuna (Thunnus obesus);
- Yellowfin Tuna (Thunnus albacares);
- Broadbill Swordfish (Xiphias gladius);
- Striped Marlin (Tetrapturus audux).

Primary landing ports for the Eastern Tuna and Billfish Fishery are Bermagui, Coffs Harbour, Ulladulla (New South Wales), and Cairns, Mooloolaba, Southport (Queensland). Fishing methods include pelagic longline, and minor line (trolling, rod and reel, handline).

During 2017, fishing was concentrated offshore of New South Wales and southern/central Queensland coasts (Figure 2-52). The number of active vessels in the fishery have decreased over the last decade from approximately 150 in 2002 to 39 in 2017 (Patterson et al., 2018). The value of the fishery during 2016-2017 financial year was $35.67 million (Patterson et al., 2018).

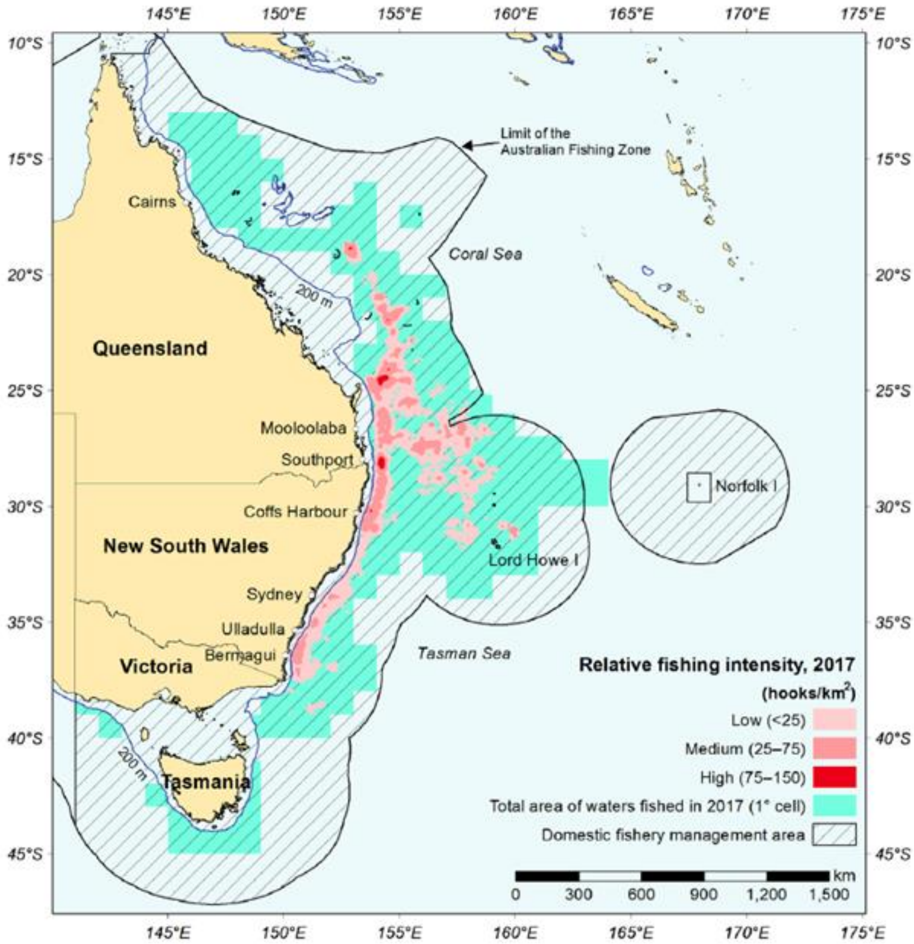

Figure 2-52 Eastern Tuna and Billfish Fishery Management Area and 2017 Relative Fishing Intensity (Patterson et al., 2018).

.

2.4.1.5 Small Pelagic Fishery

The Small Pelagic Fishery operates in Commonwealth waters from southern Queensland to southern Western Australia (Figure 2-53). Most historical fishing efforts has occurred of the east and west coasts of Tasmania. It is a 12-month fishing season, commencing 1 May each year. Primary target species are:

- Australian sardine (Sardinops sagax);
- Blue mackerel (Scomber australasicus);
- Jack mackerel (Trachurus declivis, T. murphyi);
- Redbait (Emmelichthys nitidus).

Primary landing ports within the DA are Eden and Iluka (New South Wales). Fishing methods include purse seine and midwater trawl; midwater trawl has been the main method since 2002. Commercial value of the fishery is confidential (Patterson et al., 2018).

Small pelagic fish are generally caught during targeted fishing for a single species. They are also caught in small quantities in other Commonwealth- and state-managed fisheries, including the Southern and Eastern Scalefish and Shark Fishery, the Eastern Tuna and Billfish Fishery, the Western Tuna and Billfish Fishery, and the New South Wales Ocean Hauling Fishery. There are no active small pelagic fisheries near the EGBPA.

Jack mackerel are found in continental shelf waters between 27 to 460 m, although generally in waters less than 300m deep. They live for 16 years, maturing at 3 to 4 years. Spawning occurs between December and March (ABARES, 2018).

Blue mackerel are found in continental shelf waters between 87 to 265 m. They live for about 7 years, maturing at 2 years. Spawning occurs between September and May (ABARES, 2018).

Redbait are found in continental shelf waters between 86 to 500 m. They live for about 21 years, maturing at 2 to 4 years. Spawning occurs between September and November (ABARES 2018).

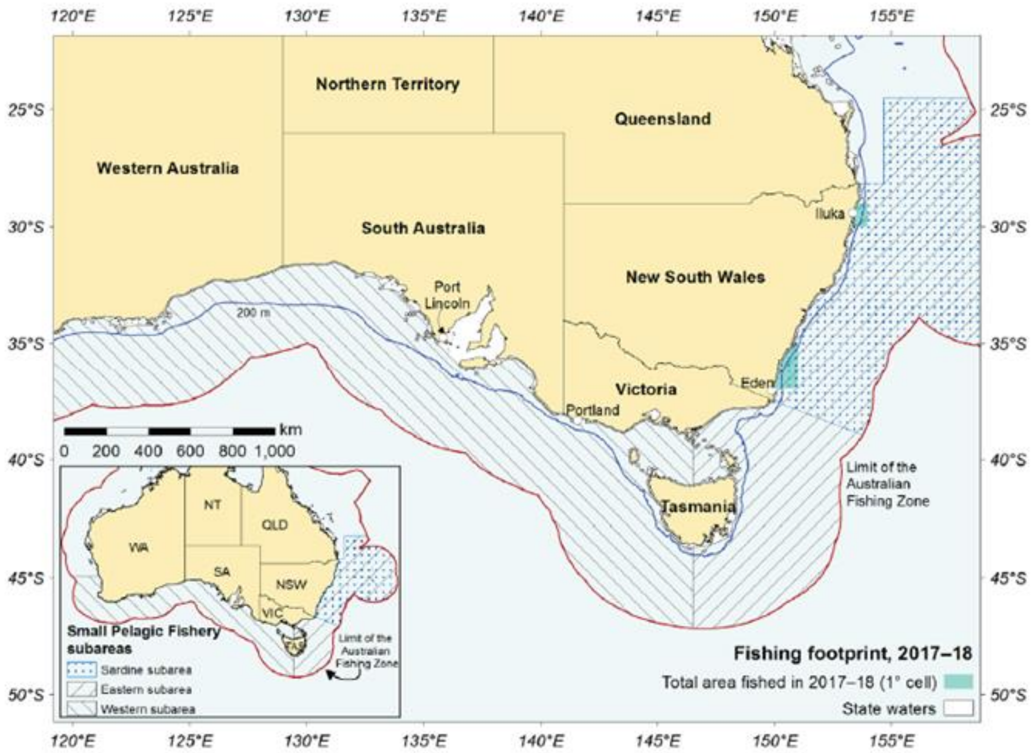

Figure 2-53 Small Pelagic Fishery Management Area and 2017-18 Fishing Footprint

(NB: Some effort data are not shown on this map for confidentiality reasons) (Patterson et al., 2018).

2.4.1.6 Southern and Eastern Scalefish and Shark Fishery

The Southern and Eastern Scalefish and Shark Fishery (SESFF) is a multisector, multigear and multispecies fishery, targeting a variety of fish, squid and shark stock (Figure 2-54). Primary target species include:

- Blue grenadier (Macruronus novaezelandiae);
- Tiger flathead (Neoplatycephalus richardsoni);
- Silver warehou (Seriolella punctata);
- Gummy shark (Mustelus antarcticus);
- Pink ling (Genypterus blacodes).

It is a 12-month fishing season, commencing 1 May each year. Primary ports include Eden (New South Wales), Lakes Entrance, Portland, Port Welshpool (Victoria), and Devonport and Hobart (Tasmania).

The SESSF incorporates the Commonwealth Trawl Sector (formerly the Southeast Trawl Sector), the Great Australian Bight Trawl Sector (GABTS), East Coast Deepwater Trawl Sector (ECDTS) and Gillnet, Hook and Trap Sector (GHTS; formerly the Southern Shark and Southeast Non-trawl Sectors) under a common set of management objectives. The SESSF extends from waters off southern Queensland, south around Tasmania and then west to Cape Leeuwin in Western Australia. Fishing intensity varied in location for each fishery, with no catch effort within the East Coast Deep Water Trawl Sector for 2016-2017 (Figure 2-55). The value of the fishery in 2016-2017 was approximately $72.3 million ($47.01 million from the Commonwealth Trawland Scalefish Hook Sectors; $25.29 million from the Shark Gillnet and Shark Hook Sector) (Patterson et al., 2018).

Sharks are fished using predominantly demersal gillnets (Walker et al., 2001), with a small percentage caught by demersal longlines. The deepwater demersal sharks occur between 50 and 1,800m depth offshore and live up to 50 years, maturing between 25 and 30 years (ABARES, 2016c).

The trawl and scalefish-hook sectors of the fishery include over 100 species that are captured, but 16 species provide the bulk of trawl landings and are subject to quota management. Fishing is year round, varying according to availability, market price and progress with quotas.

The trawl sector includes otter trawl and Danish seine methods. Otter trawlers use larger boats, generally greater than 20 m long, while Danish seiners use smaller boats and operate in nearshore shelf areas often in more restricted areas unavailable to otter trawlers (Larcombe & Begg 2008). Board boats can stay out at sea for 5 -7 days, whilst Danish seiners usually fish for a maximum of three days. The range of Danish seiners, which target predominantly flathead, is limited to a 100 km radius from Lakes Entrance.

Otter board trawlers, operating out of Lakes Entrance, concentrate their fishing operations in deeper waters and consequently catch more morwong, ling, blue grenadier and other deep sea species. The net is towed by two wire ropes and fixed, between these ropes and the net, are paravanes (commonly known as boards or doors). Unlike the Danish seine net which closes and stops fishing after about two minutes of towing, the board trawl net remains open and may be towed for any length of time, although it is rare for tows to exceed four hours (Leftrade 2013). Distribution of the fishing effort shows a predominance of effort concentrated along the 100-250 m contour; ABARES 2017).

The SESSF includes several stocks that are classified as overfished. These overfished stocks are blue warehou (Seriolella brama), eastern gemfish (Rexea solandri), gulper sharks (Centrophorus harrissoni, C. moluccensis, C. zeehaani), school shark (Galeorhinus galeus), redfish (Centroberyx affinis) and orange roughy (Hoplostethus atlanticus) in two zones (southern and western) (ABARES, 2017).

2.4.1.7 Southern Bluefin Tuna Fishery

The Southern Bluefin Tuna Fishery operates within the Australian Fishing Zone. It is a 12-month fishing season, commencing 1 December each year. Primary target species is the Southern Bluefin Tuna (Thunnus maccoyii).

The majority of the catch is taken in the Great Australian Bight (i.e. outside of the Environment Sectors) by purse-seine vessels. Longline fishing is used off the east coast, and the number of vessels and fishing intensity is variable (Figure 2-56). The value of the fishery during 2016-2017 financial year was $38.54 million (Patterson et al., 2018).

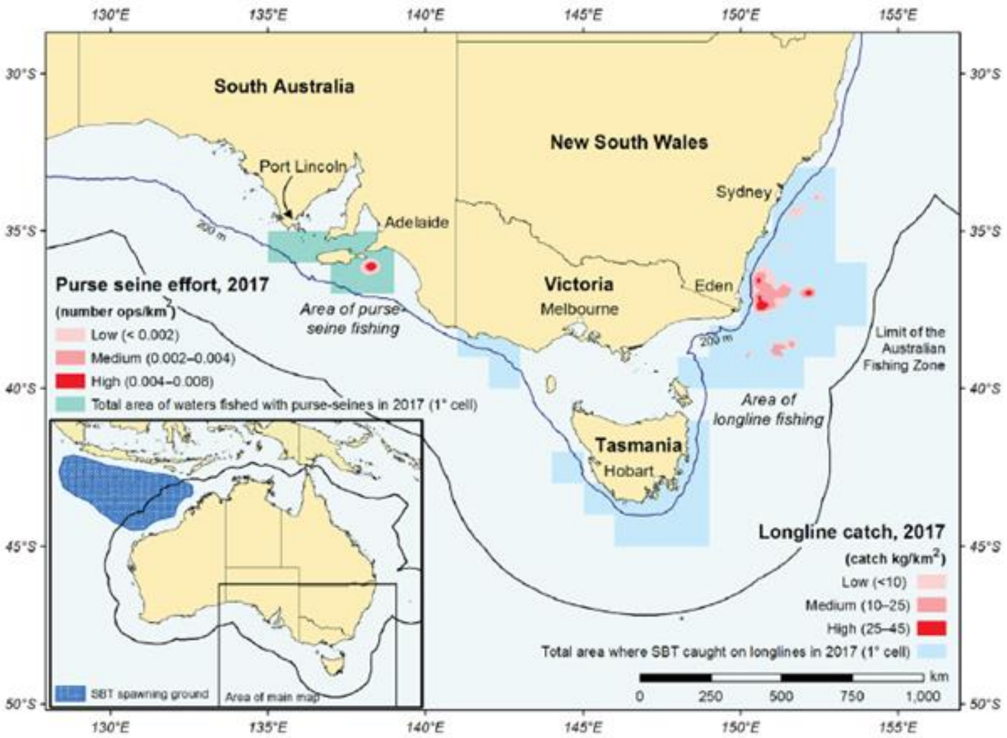

Figure 2-56 Southern Bluefin Tuna Management Area and 2017 Fishing Intensity (Patterson et al., 2018)

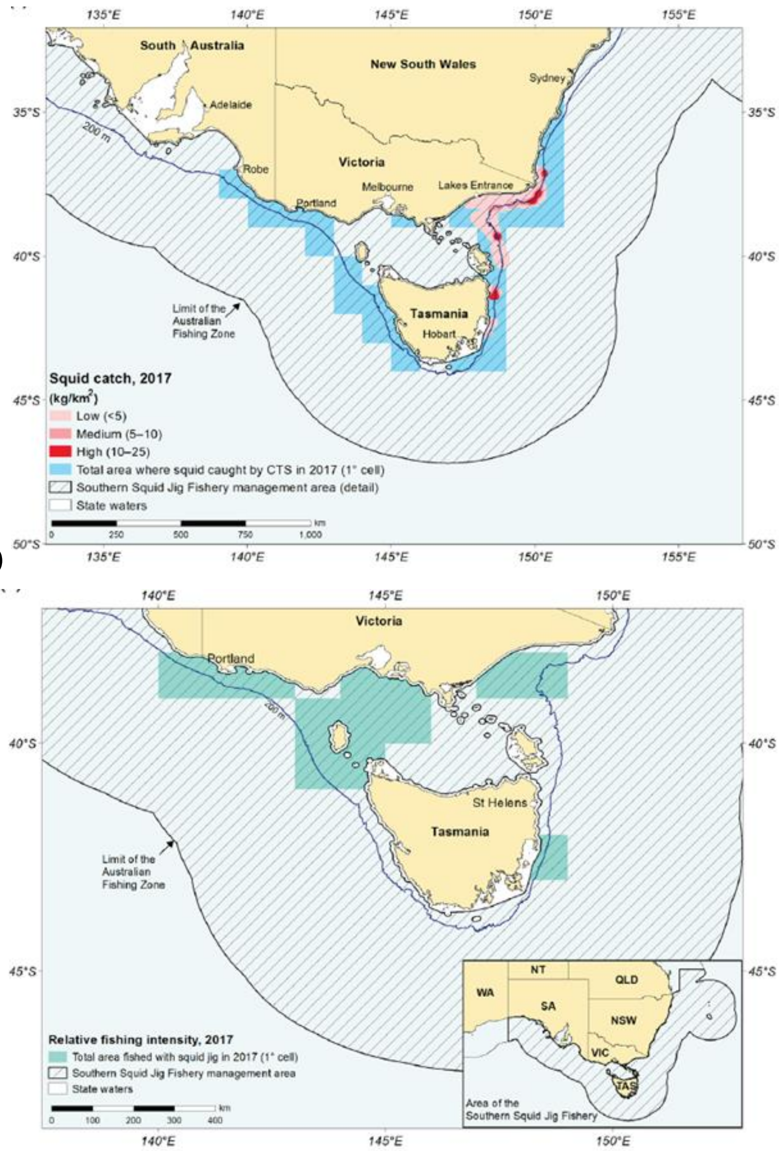
2.4.1.8 Southern Squid Jig Fishery

The Southern Squid Jig Fishery is located in waters off New South Wales, Victoria, Tasmania and South Australia, and in a small area off southern Queensland. The Southern Squid Jig Fishery is a single-method (jigging) fishery, primarily targeting the Gould's squid (Nototodarus gould). Vessels typically operate at night in continental shelf waters between 60–120 m water depths. Squid are also caught in the Commonwealth Trawl Sector and GAB Trawl Sector of the Southern and Eastern Scalefish and Shark Fishery.

It has a 12-month fishing season, commencing 1 January each year. Most direct fishing effort occurs off Lakes Entrance (Victoria) (Figure 2-57) (a)), however in recent years a greater catch has come from the Trawl Sectors (Figure 2-57(b)). The value of the Southern Squid Jig Fishery during the 2016-2017 financial year is $2.24 million (Patterson et al., 2018).



(a)

(b)

Figure 2-57 (a) Squid Catch from the Commonwealth Trawl Sector 2017, and (b) 2017 Fishing Intensity in the Southern Squid Jig Fishery (Patterson et al., 2018)

2.4.1.9 Norfolk Island Fishery

The Norfolk Island Fishery is currently an inshore recreational and charter-based line fishery (Figure 2-58).

An offshore exploratory commercial trawl-and-line fishery operated between 2000 and 2003. Limited effort in the fishery during this period meant that the permit holders failed to meet the required 50 days of fishing over three years.

No harvest strategy has been developed for the fishery because of the absence of commercial fishing. A harvest strategy and management plan will need to be developed before establishment of a commercial fishery (Patterson et al., 2019).

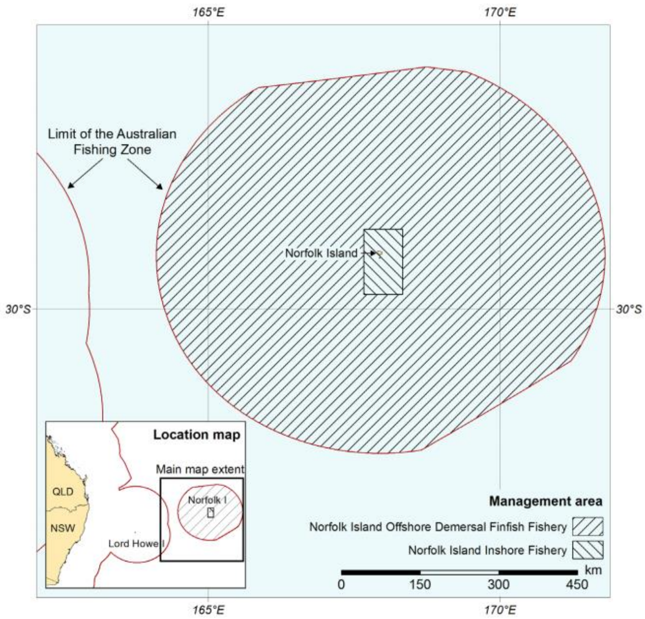


Figure 2-58 Managed area of the Norfolk Island Fishery

2.4.1.10 Commercial Fishing - State

Each state operations under their own constitutional arrangement:

- Tasmanian fisheries are managed under the Living Marine Resources Management Act 1995;
- South Australian fisheries are managed under the Fisheries Management Act 2007;
- Victorian fisheries are managed under the Fisheries Act 1995;
- New South Wales fisheries are managed under the Fisheries Management Act 1994; and
- Queensland fisheries are managed under the Fisheries Act 1994.

The Offshore Constitutional Settlement (OCS) allows for individual fisheries to be managed under relevant State government, with fishing areas extending into both Commonwealth and State waters.

There are seven Victorian and eight New South Wales state-managed commercial fisheries with management areas that intersect with the DA (Table 2-46).

Table 2-46 State-managed commercial fisheries with management areas that intersect the DA.

Fishery	Description	Extends into Cth Waters	Target Species
Victoria			
Abalone Fishery	Abalone are caught along the majority of the Victorian coastline. Abalone diving activity typically occurs close to the shoreline (generally up to water depths of 30 m). The fishery is quota managed, with a total allowable commercial catch set annually based on the outcomes of a stock assessment process. There are three (Western, Central and Eastern) management zones. The blacklip abalone (Haliotis rubra) forms the basis of the abalone fisheries in NSW, Victoria and Tasmania, however greenlip abalone (Haliotis laevegata) are also targeted. Blacklip abalone are commonly found, mainly on rocky substrates, and are widely distributed along the southern half of Australia as far as Rottnest Island in the West to Coffs Harbour in the East. Abalone are sourced from the wild and from coastal farms. There are about 40 reefs from Iron Prince to Marlo Reef in Victoria. In NSW, most commercial abalone fishing takes place on the south coast, primarily from Jervis Bay to the Victorian border (DPI 2007). Victoria's abalone farms are situated primarily in Port Phillip Bay and southwest Victoria, however farms are also located off Tullaberga Island and Gabo Island.	Yes	Greenlip Abalone (*Haliotis laevigate*) Blacklip Abalone (*Haliotis rubra*)
Eel Fishery	Eel are harvested in Victorian coastal river basins south of the Great Dividing Range. Short-finned eels are found across the State, while long-finned eels are only found in eastern Victoria.	No	Short-finned eel (*Anguilla australis*) Long-finned eel (*Anguilla reinhardtii*)
Giant Crab Fishery	The commercial fishery has two management zones, the Western Zone and Eastern Zone, a division which reflects the zonal boundaries of the rock lobster fishery. The fishery is based in the Western Zone; at the time of writing there was no giant crab fishing in the Eastern Zone. Giant crabs inhabit the continental slope at approximately 200 m depth and are most abundant along the narrow band of the shelf edge.	Yes	Giant crab (*Pseudocarcinus gigas*)
Pipi Fishery	Pipi is the common name given to the small bivalve which is found on high-energy sandy beaches in the intertidal zone. The fishery covers the entire Victorian coastline, with the exception of Port Phillip Bay and Marine National Parks where shellfish cannot be harvested in the intertidal region. However, the fishery is only currently open at Discovery Bay (targeted primarily by commercial fishers) and Venus Bay (primarily a recreational fishery).	No	Pipi (*Donax deltoids*)

Fishery	Description	Extends into Cth Waters	Target Species
Rock Lobster Fishery	The fishery is divided into two separately managed zones: Eastern and Western. The Eastern Zone extends west from the New South Wales border to Apollo Bay; the Western Zone extends from Apollo Bay west to the border with South Australia. The main ports in the Eastern Zone are Queenscliff, San Remo and Lakes Entrance. The Victorian, the southern rock lobster (Jasus edwardsii). Rock lobster is Victoria's second most profitable fishery after abalone. Southern Rock Lobsters are found to depths of 150 m, with most of the catch coming from inshore waters less than 100 m deep. Eastern rock lobster (Jasus verreauxi) is the main species harvested by the NSW Lobster Fishery, but occasionally southern rock lobster, and tropical rock lobster are also caught. Rock lobster fishing grounds exist around Ulladulla and Bateman's Bay, the southern tip of Wilsons Promontory and around Bass Strait islands, such as the Hogan Group, Curtis Group, Kent Group islands and Flinders Island. Most fishing occurs between mid-November and March, outside the June to mid-November spawning season.	Yes	Southern rock lobster (*Jasus edwardsii*) Eastern rock lobster (Jasus verreauxi)
Scallop Fishery	The Victorian Scallop Fishery is one of three scallop zones in the Bass Strait, and extends out from the coastline to 20 nm excluding the bays and inlets along the coast where commercial fishing for scallops is prohibited. The same arrangement is in place for Tasmania. Historically, the majority of the fishing activity in the Victorian zone has occurred in the eastern waters of the State, with most vessels launching from the ports of Lakes Entrance and Welshpool. The Victorian Scallop Fishery is based on the species, Pecten Fumatus. Occasionally, incidental catches of doughboy scallops (Chlamys asperrimus) are taken as by-product, but are generally not in commercial quantities. Scallop abundance is naturally highly variable causing catches to fluctuate widely from season to season. When open, the fishery is managed using a quota management system of individual transferable quota. Annual consultation is undertaken to determine the total allowable catch (TAC) and is based on a combination of stock survey analysis and scientific and industry expertise. Fisheries Victoria, on behalf of the Minister for Agriculture and Food Security, sets the TAC via a Quota Notice which is distributed equally amongst the 91 maximum allowable licences.	No	Primary: Commercial scallop (*Pecten fumatus*) Other: Doughboy scallop (*Chlamys asperrimus*)
Wrasse Fishery	The commercial fishery extends along the entire length of the Victorian coastline and out to 20 nm offshore, except for marine reserves. Most wrasse is harvested by hook and line although commercial rock lobster fishers who also hold a commercial wrasse licences can keep those fish that they catch in their rock lobster pots.	No	Primary: Bluethroat Wrasse (*Notolabrus tetricus*) Purple Wrasse (*N. fucicola*) Other:

Fishery	Description	Extends into Cth Waters	Target Species
			Rosy Wrasse (*Pseudolabrus psittaculus*) Senator Wrasse (*Pictilabrus laticlavius*) Southern Maori Wrasse (*Ophthalmolepis lineolatus*)
Sea Urchin Fishery	The sea urchin fishery comprises four individual management zones. The central and eastern zones intersect the DA. The central zone covers Victorian waters from Hopkins River to Lakes Entrance. The eastern zone extends from Lakes Entrance to the NSW border. The target species are the White sea urchin (*Heliocidaris erythrogramma*) and the Black, long-spined sea urchin (*Centrostephanus rodgersii*). The sea urchin is usually collected by hand by divers. Currently, sea urchin will only be harvested in eastern Victoria, primarily out of Mallacoota, and in Port Phillip Bay (VFA 2017b).		White sea urchin (*Heliocidaris erythrogramma*) Black, long-spined sea urchin (*Centrostephanus rodgersii*)
Commercial Bay and Inlet Fisheries	The commercial bay and inlet fisheries of Victoria are a collection of complex multi-species, multi-gear fisheries which operate in environments that are ecologically distinct to those existing in waters of both their catchment tributaries and the nearby ocean. Although between 60 to 80 fish species have been recorded from commercial bay and inlet catches, only about a dozen or so key species, including King George whiting, black bream, snapper, flathead, mullet, garfish, flounder, anchovies and pilchards, are usually targeted by commercial fishers. Commercial fishing for fin fish occurs in Port Phillip Bay, Corner Inlet/Nooramunga and the Gippsland Lakes. All other Victorian bays, inlets and estuaries are closed to commercial fishing (other than for eels and bait). The main bay and inlet commercial fishing methods are seine nets and gillnets.	no	King George Whiting Black Bream Snapper Flathead Mullet Garfish Flounder Anchovies Pilchards
New South Wales			
Abalone Fishery	The blacklip abalone forms the basis of the abalone fishery in NSW. Abalone are commercially harvested from rocky reefs by divers typically using surface-supplied air or scuba. In practice, most commercial abalone fishing	No	Blacklip abalone (*Haliotis rubra*)

Fishery	Description	Extends into Cth Waters	Target Species
	takes place on the south coast of NSW, primarily from Jervis Bay to the Victorian border, with most abalone found close to the shore.		
Estuary General Fishery	The Estuary General Fishery is a diverse multi-species multi-method fishery that may operate in 76 of the NSW's estuarine systems. This fishery is a significant contributor to regional and state economies providing high quality seafood and bait to the community. The fishery includes all forms of commercial estuarine fishing (other than estuary prawn trawling) in addition to the gathering of pipis and beachworms from ocean beaches. The most frequently used fishing methods are mesh and haul netting. Other methods used include trapping, hand-lining and hand-gathering. Sea mullet, luderick, yellowfin bream, school prawn, blue swimmer crab, dusky flathead, sand whiting, pipi, mud crab and silver biddy make up over 80% of the catch (DPI 2014).	No	Sea Mullet (*Mugil cephalus*) Luderick (*Girella tricuspidata*) Yellowfin bream (*Acanthopagrus australis*) School Prawn (*Metapenaeus macleayi*) Blue Swimmer Crab (*Portunus pelagicus*) Dusky Flathead (*Platycephalus fuscus*) Sand Whiting (*Sillago ciliata*) Pipi (*Donax deltoides*) Mud Crab (*Scylla serrata*) Silver Biddy (*Gerres subfasciatus*)
Estuary Prawn Trawl Fishery	The fishery uses otter trawl nets in three estuaries in NSW, (the Clarence, Hawkesbury and Hunter Rivers). With the exception of the Hawkesbury River, the fishery operates for defined seasons (generally October to May) and within each estuary is confined to specific times and areas. The majority of prawn catches are landed during the 'dark' of the moon (between the last and first quarter), on either run out or 'slack' tides.	No	School Prawns Eastern King Prawns
Lobster Fishery	The Fishery extends from the Queensland border to the Victorian border and includes all waters under jurisdiction of NSW to around 80 miles from the coast.	Yes	Primary:

Fishery	Description	Extends into Cth Waters	Target Species
	It is characterised by inshore and offshore sectors. Inshore fishers use small beehive or square traps in waters up to 10 metres in depth, whilst offshore fishers use large rectangular traps.		Eastern rock lobster (*Sagmaraisus verreauxi*) Other: Southern Rock Lobster (*Jasus edwardsii*) Tropical Rock Lobster (*Panulirus longipes* and *P. ornatus*).
Ocean Hauling Fishery	The Ocean Hauling Fishery is broken up into seven regions along the NSW coast and targets approximately 20 finfish species using commercial hauling and purse seine nets from sea beaches and in ocean waters within 3 nautical miles of the coast.	No	Pilchards (*Sardinops sagax*) Sea Mullet (*Mugil cephalus*) Australian Salmon (*Arripis trutta*) Blue Mackerel (*Scomber australasicus*) Yellowtail Scad (*Trachurus novaezelandiae*) Yellowfin Bream (*Acanthopagrus australis*)
Ocean Trap and Line Fishery	The Ocean Trap and Line fishery is a multi-method, multi species fishery targeting demersal and pelagic fish along the entire NSW coast, in continental shelf and slope waters. The Ocean Trap and Line Fishery is a share management fishery. This means that commercial fishers must hold sufficient shares to be eligible for an endorsement to operate in the fishery. An endorsement authorises the use of specific gear to take fish for sale from certain waters.	Yes	Primary: Snapper Yellowtail kingfish Leatherjackets Bonito Silver trevally

Fishery	Description	Extends into Cth Waters	Target Species
			Other: Rubberlip (grey) Morwong Blue-eye Trevalla Sharks Bar Cod Yellowfin Bream Spanner Crabs
Ocean Trawl Fishery	There are two sectors to the Ocean Trawl Fishery: the prawn trawl sector and the fish trawl sector. Both sectors use otter trawl nets. The fishery is a share management fishery; meaning commercial fishers must hold sufficient shares to be eligible for an endorsement to operate in the fishery. An endorsement authorises the use of specific gear to take fish for sale from certain waters. Many of the fishers endorsed for fish trawling are also endorsed for prawn trawling.	Yes	School whiting (comprising of stout whiting and red spot whiting) Eastern King, School and Royal Red prawns Tiger Flathead Silver Trevally Various species of sharks and rays, squid, octopus and bugs
Sea Urchin and Turban Shell Restricted Fishery	The NSW Sea Urchin and Turban Shell restricted fishery is relatively small with few divers participating. The main constraint on development is high processing costs and limited domestic markets. Fishing for sea urchins is generally constrained to that part of the year when the roe is well developed. A number of the fishing sub-regions have been closed to commercial fishing since 1994.	No	Sea Urchin Turban Shell
Tasmania			
Shellfish Fishery	The commercial shellfish fishery includes clams (*Veneruptis largillierti*) for which there are three licences restricted to Georges Bay, native oyster (*Ostrea angasi*) for which there are two licences restricted to Georges Bay and cockles (*Katelysia scalarina*) for which there are four licences restricted to Ansons Bay and wild Pacific oyster (*Crassostrea gigas*) (DPIPWE 2017d).	no	clams (Veneruptis largillierti) native oyster (*Ostrea angasi*)

Fishery	Description	Extends into Cth Waters	Target Species
	Temperate climate bivalves generally have two spawning periods within a year following spring and autumnal peaks in phytoplankton production.		cockles (*Katelysia scalarina*) wild Pacific oyster (*Crassostrea gigas*)
Abalone Fishery	The Tasmanian abalone fishery is the largest wild abalone fishery in the world and the fishery area surrounds the entire island of Tasmania extending northwards into Bass Strait to include Bass Strait islands such as the Furneaux Group. The Tasmanian wild harvest abalone fishery for Blacklip *(H. rubra*) and Greenlip *(H. laevigata*) produces 25% of the total annual global production of wild caught abalone and is harvested by divers. Annual catch limits are set by the government and the limits are spread across the fishing zones to manage resource sustainability. This system includes closures of some parts of the fishery as published by the Tasmanian regulator Department of Primary Industries, Parks, Water & Environment (DPIPWE, 2019a).	no	Blacklip (H. rubra) Greenlip (H. laevigata)
Rock Lobster Fishery	The rock lobster fishery is a major Tasmanian industry providing significant benefits from exports from the commercial fishery. The Southern rock lobster (*Jasus edwardsii*) commonly known as crayfish, lives in a variety of habitats ranging from shallow rocky inshore pools out to the continental shelf. Pots are used as the catch method and over 300 licences issued each year. The fishery is managed by quota management, supplemented by size limits, gear restrictions and seasonal closures (DPIPWE, 2019b).	no	Southern rock lobster (Jasus edwardsii)
Giant Crab	The Giant Crab (*Pseudocarcinus gigas*) fishery is a comparatively small fishery with annual harvest set at 46.6 tonnes, but is of relatively high value, with the landed valued estimated to be around $2 million. The Tasmanian Giant Crab fishery is managed by limited entry, setting a total annual commercial catch and by an individual transferable quota management system. This regime is supplemented by size limits, gear restrictions and seasonal closures. The permitted gear types are pot (or trap) for the commercial fishery. (Ogier et al., 2018)	no	Giant Crab (*Pseudocarcinus gigas*)
Scalefish Fishery	The Tasmanian Scalefish Fishery is a multi-species and multi-gear fishery that is predominantly made up of small owner operated commercial businesses and a large and diverse recreational fishery. Some of the species commercially targeted include: banded morwong, southern calamari, octopus, tiger flathead, school whiting, southern garfish, wrasse, Gould's squid, bastard trumpeter, blue warehou, silver warehou, flounder, silver trevally and striped trumpeter. The main gear types include gillnet, hooks and seine nets, other fishing gears in use include traps, Danish seine, dip nets and spears. For many commercial operators, scalefish represent an adjunct to other activities, for instance rock lobster fishing (DPIPWE, 2019c)	yes	Wrasse Banded morwong (*Cheilodactylus spectabilis)* Southern calamari *(Sepioteuthis australis)*

Fishery	Description	Extends into Cth Waters	Target Species
Commercial Dive Fishery	The fishery primarily targets Purple Sea Urchin (*Heliocidaris erythrogramma*), Longspine Sea Urchin (*Centrostephanus rodgersii*), and Periwinkle (*Lunella undulata*). It operates entirely in state waters in five separate management zones (central eastern, south eastern, north eastern, northern and eastern) (DoEE, 2016).	no	Purple Sea Urchin (*Heliocidaris erythrogramma*) Longspine Sea Urchin (*Centrostephanus rodgersii*) Periwinkle (*Lunella undulata*)
Scallop	This fishery targets Commercial Scallop (*Pecten fumatus*) using a scallop harvester (dredge). Although commercial fishers can legally take the doughboy scallop and the queen scallop, these species have only minor commercial significance in Tasmania. Pre-season surveys are carried out to determine which areas meet predetermined criteria and can be opened for scallop fishing. The market for commercial harvested scallops is largely domestic. Scallops beds occur on the shelf in water deeper than 20 metres (Ogier et al., 2018).	no	Commercial Scallop (*Pecten fumatus*)
Queensland			
Type	**Category**	**Name**	**Target species**
Crab	Crab Method: Pots Fishing Area: throughout the state's coastal waters, including the Gulf of Carpentaria, except for areas that are closed to fishing in general or to crabbing in particular.	Blue Swimmer Crab Fishery Mud Crab Fishery Spanner Crab Fishery	• mud crab fishery • blue swimmer crab fishery • spanner crab fishery.
Eel	Eel Method: eel trap Fishing Area: All of the east coast drainage division catchments except offshore islands but mainly in privately owned farm dams	Eel Fishery	• longfin eel (*Anguilla reinhardtii*) • southern shortfin eel (*A. australis*)

Fishery	Description		Extends into Cth Waters	Target Species
	East coast fin fishery has 2 major commercial net fisheries:: - the Gulf of Carpentaria inshore fin fish fishery (not in DA) - the east coast inshore fin fish fishery.			• king and blue threadfins - 7% of total net catch • barramundi - 6% of total net catch • shark - 9% of total net catch • grey mackerel - 3% of total net catch. The southern areas of the east coast inshore fin fish fishery harvests mainly subtropical fin fish species, such as: • mullet • tailor • whiting • flathead • bream • mulloway • school mackerel
Development	Developmental fishing determines whether a potential new fishery is commercially viable, socially acceptable and ecologically sustainable. Developmental fishing is generally regarded as: • fishing for a species of fish that has been previously unexploited or significantly underutilised • fishing for an existing commercial species using apparatus currently not permitted by legislation • fishing for an existing commercial species or use of prescribed apparatus (or both) in locations where such activities have not previously occurred • combinations of the above.	Developmental Jellyfish Fishery		

2.4.1.11 Commercial Aquaculture – State

The Sydney rock oyster (Saccostrea glomerata) is the main species grown in NSW. Commercial production in the State occurs in 41 estuaries between Eden in the south to the Tweed River in the north. Wallis Lake and the Hawkesbury River are the main producing areas.

The Sydney rock oyster industry in NSW is largely dependent on natural spawning. The first spawning of a Sydney rock oyster is usually as a male and subsequent spawnings as a female. During spawning, adult females disperse up to 20 million eggs and males hundreds of millions of sperms into the water when the tide and current are optimal for the widest distribution. Fertilisation takes place in the water column and development continues for up to 3 to 4 weeks as the larval stages of the oyster grow, with the 'spat' ultimately being caught on 'sticks'. Oysters are knocked off these sticks at 0.5 to 3 years of age for growing intertidally on trays until maturity in 3 to 4 years. Alternative growing systems such as baskets and tumblers are also being used, and some oysters are grown subtidally on rafts or on floating culture.

2.4.2 Oil and Gas

Statistics from 2014–2015 showed that oil (38%) and gas (24%) remained Australia's largest energy sources (APPEA, 2017). The industry also contributed approximately $34 billion to the Australian economy during the 2014–2015 financial year (APPEA, 2016).

Victoria's petroleum (oil and gas) exploration and production is concentrated in the offshore Commonwealth waters of the Otway and Gippsland basins; there are a number of current exploration and offshore production permit areas within both basins (Figure 2-59). Information on the Production licences, Exploration Permits and Retention Leases within Gippsland Basin at the time of writing are presented in Table 2-47.

From 1967–2015, the Gippsland Basin Joint Venture alone produced 54% of Australia's crude oil and gas (DIIS, 2017). Petroleum infrastructure in Gippsland Basin is well developed, with a network of pipelines transporting hydrocarbons produced offshore to onshore petroleum processing facilities at Longford and Orbost (Figure 2-60). Overall production of crude oil and condensate from the Gippsland Basin had been declining for over three decades, while gas production remained steady. However, in recent years, hydrocarbon production has remained relatively strong due to infill drilling in the developed fields and work-overs undertaken to renew down-hole equipment and to open new zones (DIIS, 2017). Total petroleum production from the Gippsland Basin was 74.8 MMboe (11.9 GL) in 2016, up from 61.4 MMboe (9.76 GL) in 2015 (DIIS, 2017).

2.4.3 Shipping

The south-east and eastern coasts are some of Australia's busiest in terms of shipping activity and volumes. This traffic includes international and coastal cargo trade, and passenger and ferry services. Major ports include Melbourne, Geelong, Western Port, Sydney and Brisbane; with other minor ports important to commercial and recreational fishing, yachts and other pleasure craft. Bass Strait is one of Australia's busiest shipping areas, with more than 3,000 vessels passing through Bass Strait each year (NOO 2002).

A shipping exclusion zone ('area to be avoided') exists around the operating oil and gas platforms in the Gippsland Basin, whereby unauthorised vessels larger than 200 gross tonnes are excluded from entry (Figure 2-61). Two traffic separation schemes have been implemented to enhance safety of navigation around the 'Area to be Avoided' by separating shipping into one-direction lanes for vessels heading north eastwards and those heading south westwards. One separation area is located south of Wilson's Promontory, and the other south of the Kingfish B platform.

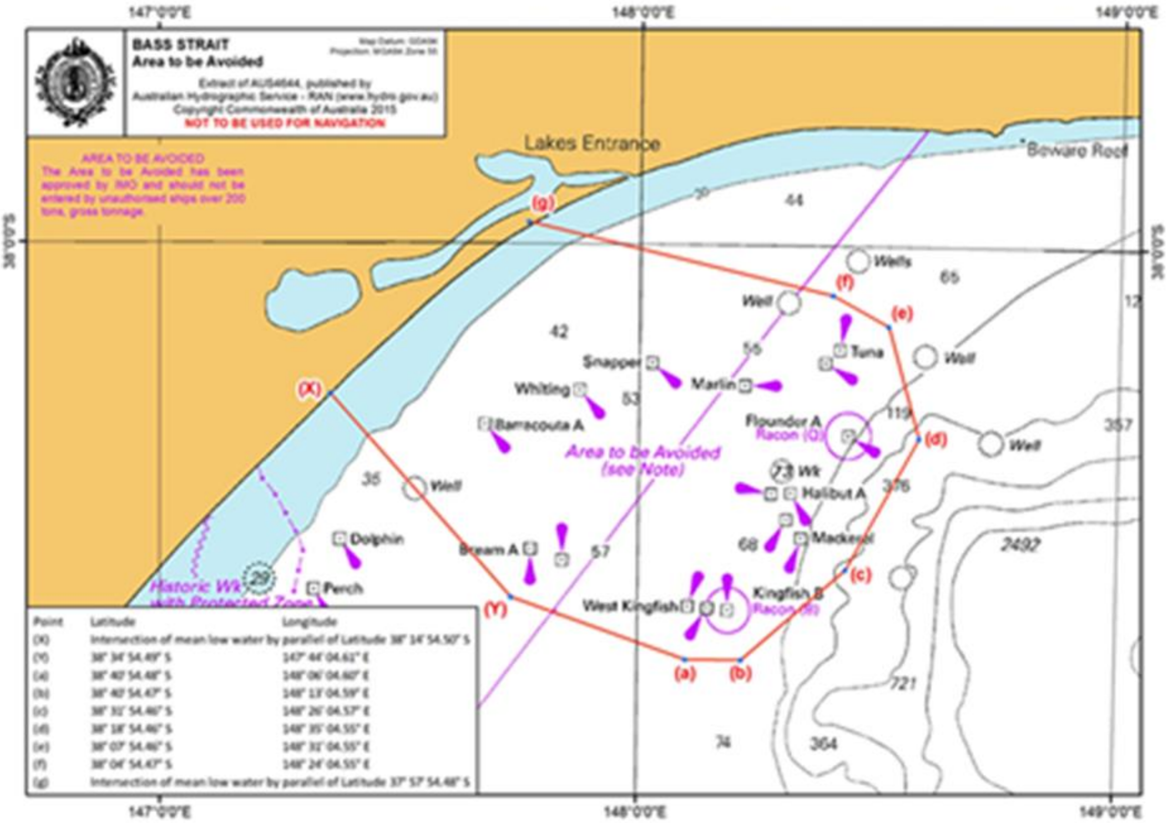

Figure 2-61 Shipping exclusion zones (Area to be Avoided) (ABF, 2017)

Figure 2-62 show real time vessel density maps around the area to be avoided as derived from the position of individual vessels, as broadcast by AIS (Automatic Identification System). Figure 2-63 shows similar time vessel density map for the DA.

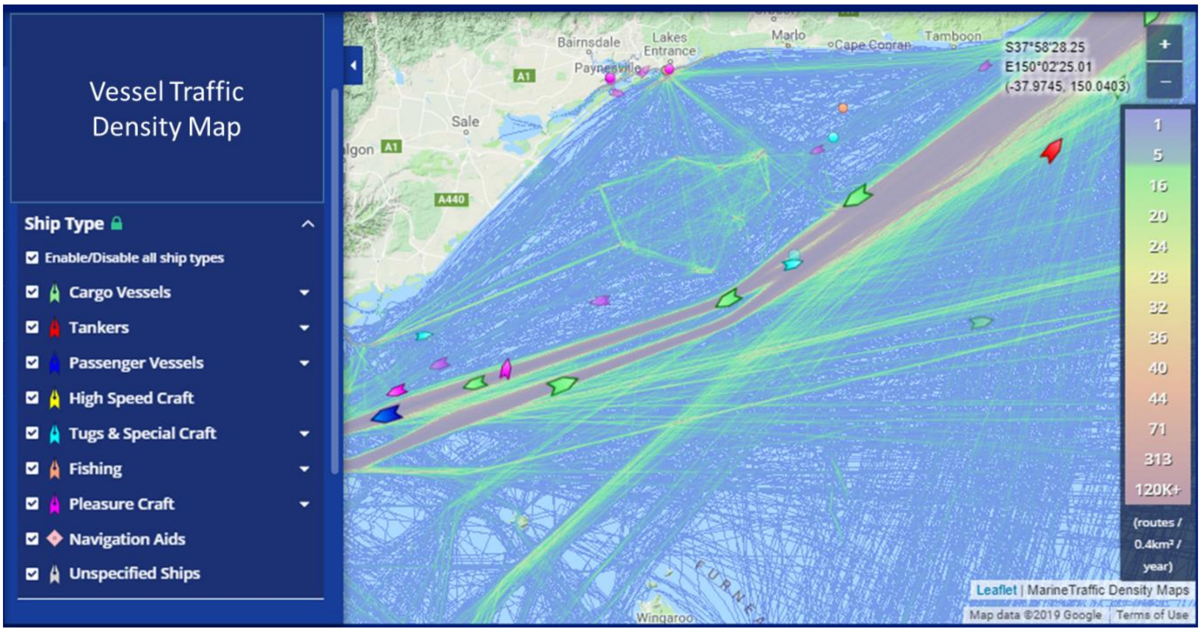

Figure 2-62 Shipping density around the Area to be Avoided real time data April, 2019 (VT, 2019)

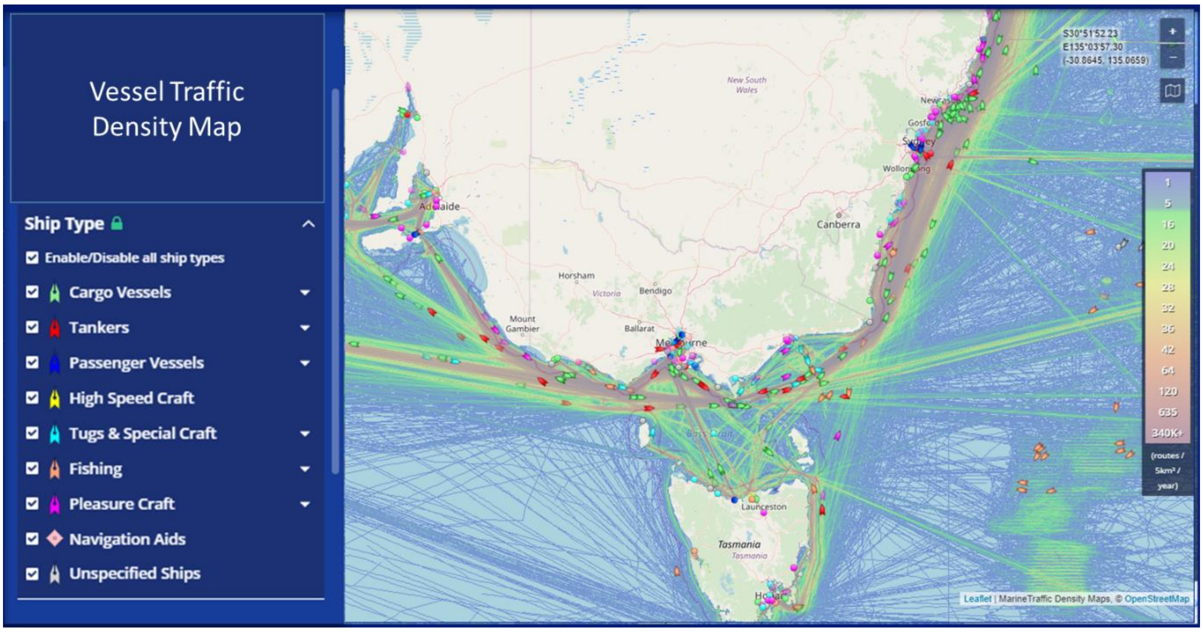

Figure 2-63 Shipping density in the DA real time data May, 2019 (VT, 2019)

2.4.4 Defence

The Australian Defence Force conducts a range of training, research activities, and preparatory operations in Australian waters (Figure 2-64). These activities may include transit of naval vessels, training exercises, shipbuilding and repairs, hydrographic survey, surveillance and enforcement, demolition, use of explosives, use of radar, sonar, sonobuoys, flares, sensors and other equipment, and search and rescue.

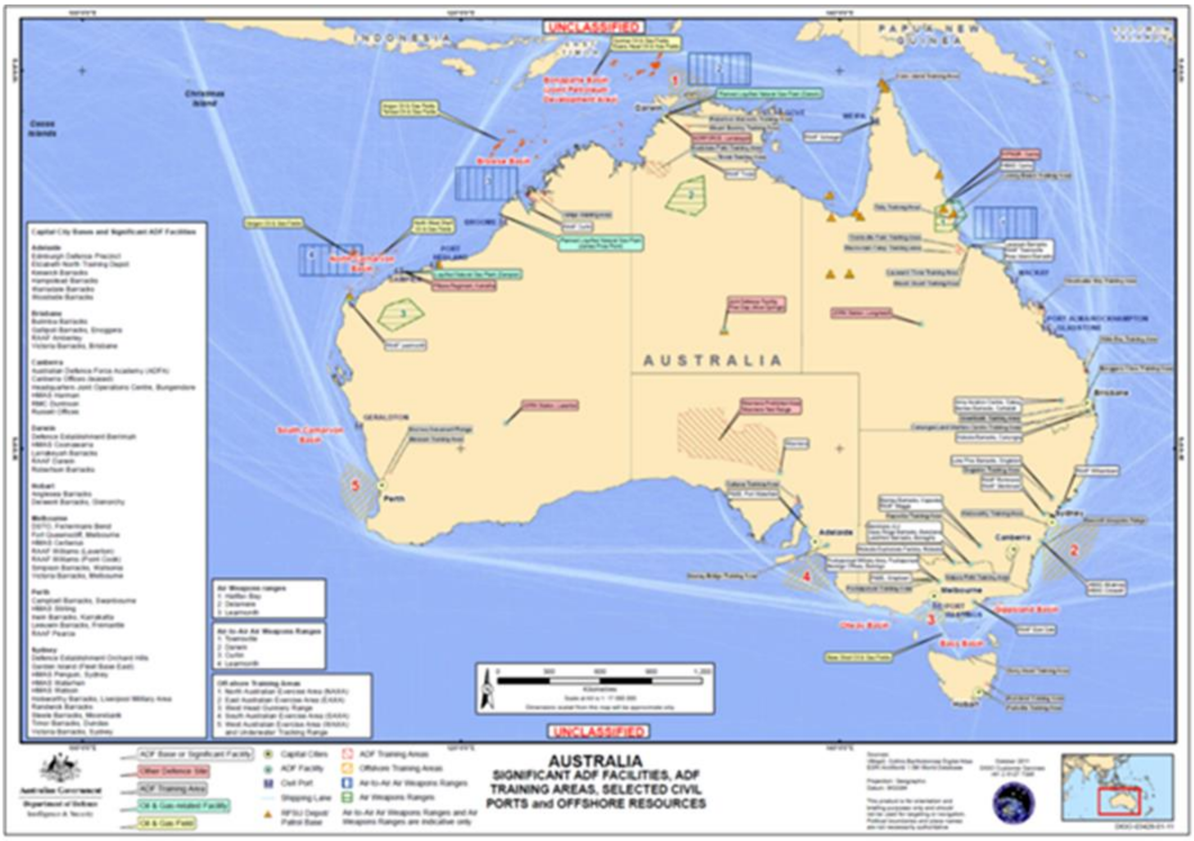

Figure 2-64 Significant Defence bases and facilities (Department of Defence, 2014)

Major defence bases within the DA include the multi-purpose wharf (naval operations) at Twofold Bay, Eden (New South Wales).

Primary training locations within the DA include the East Australia Exercise Area off the south coast of New South Wales.

Mine fields were laid in Australian waters during World War II. Post-war minefields were swept to remove mines and to make marine waters safe for maritime activities. There are three areas identified as dangerous due to unexploded ordnances, located south and east of Wilson's Promontory.

2.4.5 Tourism

The Australian coast and marine waters provide a diverse range of recreation and tourism opportunities, including scuba diving, charter boat cruises, cruise shipping, whale and wildlife watching, sailing, snorkelling, surfing, and kayaking.

In 2013-2014 the tourism industry contributed approximately $1.2 billion to the Gippsland economy; and employed approximately 12,400 (12.2%) (Tourism Victoria, 2014a, 2014b). Overnight visitors to the Gippsland area were predominantly Australian (86% intrastate, 11% interstate), with low (3%) international visitors (Tourism Victoria, 2014a). In East Gippsland, primary tourist locations are the Gippsland Lakes (the largest inland waterway in Australia), Lakes Entrance, Marlo, Cape Conran and Mallacoota. The area is renowned for its nature-based tourism (e.g. Croajingolong National Park), recreational fishing and water sports (lake and beaches) (Travel Victoria, 2017).

NSW has the highest expenditure and most domestic and international visitors in all of Australia, even excluding Sydney, regional NSW leads regional Australia in its share of visitors (Destination NSW, 2019). In 2017-2018 the South Coast NSW tourism industry contributed $2.6 billion to the economy. National and international visitor surveys identified ‘going to the beach’ as the second most popular activity (Destination NSW, 2018). The South Coast Region includes all the towns from Wollongong south to the Victorian border. The northern NSW regions, including Central, Hunter and North coast, collectively contributed approximately $9.3 billion to the economy (Destination NSW, 2019).

Tourism in Tasmania directly contributed $1.44 billion or about 4.9% to Tasmania's Gross Product in the 2016-2017 period (TT, 2019). It directly supports around 18 900 jobs in Tasmania or about 7.9 per cent of total Tasmanian employment.

Tourism directly and indirectly supports around 38,000 jobs in Tasmania or about 15.8% of total Tasmanian employment - higher than the national average and the highest in the country.

The East Coast has been identified as one of the most tourism-dependent regions in Australia. Port Arthur and the Freycinet National Park are rated in the top ten destinations in Tasmania (DT, 2019).

Visitors to the three, southern most tourist regions of QLD (Gold Coast, Brisbane and Sunshine Coast) spent over $15 billion in the year ending September 2019 (TEQ, 2020a), representing three of the top four tourist regions in Qld (Tropical North Queensland is the 3rd highest performing region). Tourism is QLD's third largest export industry and supports over 200,000 jobs directly and indirectly (TEQ, 2020b).

2.5 Cultural

The Commonwealth Heritage List is a list of Indigenous, historic and natural heritage places owned or controlled by the Australian Government which have a significant heritage value to the nation. These and other places within the DA with cultural values are described in this section.

2.5.1 Indigenous

No indigenous places are listed on the Commonwealth Heritage List within the DA. Other indigenous protected and recognised places are described below. In addition, places with indigenous cultural values are described within the National Parks and Reserves where they exist (Refer Section 2.2.8).

Indigenous Protected Areas

Indigenous Protected Areas are an essential component of Australia's National Reserve System, which is the network of formally recognised parks, reserves and protected areas across Australia, designed to protect the nation's biodiversity. Indigenous Protected Areas protect cultural heritage into the future, and provide employment, education and training opportunities for Indigenous people in remote areas. At the time of writing there were 75 Indigenous Protected Areas in Australia of which five occur in the DA. They are all areas on and around Flinders Island in Tasmania as shown in Figure 2-65 and are all important rookeries for mutton birds and important cultural resource for Tasmanian Aboriginal people.

Figure 2-65 Indigenous Protected Areas in the DA (DMPC, 2019 a)

Native Title

Non-exclusive native title rights and interests that exist over land and water in the determination area include:

- Rights of access.
- Rights to use and enjoy the land.
- Rights to take resources from the land for non-commercial purposes.
- Rights to protect and maintain sites of importance within the determination area.
- Rights to engage in certain activities on the land (including camping, cultural activities, rituals, ceremonies, meetings, gatherings, and teaching about the sites of significance within the determination area).

These rights do not confer exclusive rights of possession, use and enjoyment of the land or waters. Native title does not exist in minerals, petroleum or groundwater.

The Gunai-Kurnai people hold native title over much of Gippsland. The native title determination area (Tribunal file no. VCD2010/001) covers approximately 45,000 hectares and extends from west Gippsland near Warragul, east to the Snowy River, and north to the Great Dividing Range, (Figure 2-66). It also includes 200 metres of offshore sea territory between Lakes Entrance and Marlo. The area includes 10 parks and reserves that are jointly managed by the Victorian government and the Gunai-Kurnai people (NNTT, 2010).

Aboriginal occupancy by the Gunai-Kurnai people pre-dates the time at which the sea reached its present level by many thousands of years; thus, many early hunting grounds are now under the sea.

In the past, coastal wetlands were highly productive areas for hunter-gatherer people, having a variety of habitats and species, so the majority of archaeological sites in Victoria are found within 1 km of the coast (LCC 1993). Along the Gippsland coast, stone artefacts that have been found were mostly made from silcrete and quartz from the hinterland. Middens on offshore islands indicate that in the past, Aboriginal people from the area now known as Wilsons Promontory were likely to have visited (Jones & Allen 1979).

At the time of writing a Native Title Claimant Application was registered by the Gunai-Kurnai People (VID734/2014) for an area covering the Wilsons Promontory area (NNTT, 2019).

There are no native title determinations in NSW within the limits of the DA however a Native Title Claimant Application was registered by the South Coast People (NSD1331/2017) for an area covering the NSW south coast from the south of Sydney to Eden, including the coastal waters (NNTT, 2018). Indigenous places along the southern NSW coast include Barlings Beach, Ten Pelican Lake BrouBarunguba Aboriginal Place, Mystery Bay Fish Trap, Merriman Island and Bermagui Waterhole (NSW OEH, 2019a).

There are no native title determinations in Tasmania, although there are areas of indigenous cultural significance and indigenous protected areas including Mt Chappell Island, Badger Island, Babel Island, Great Dog Island in the Fernaux Group (DPMC, 2019).

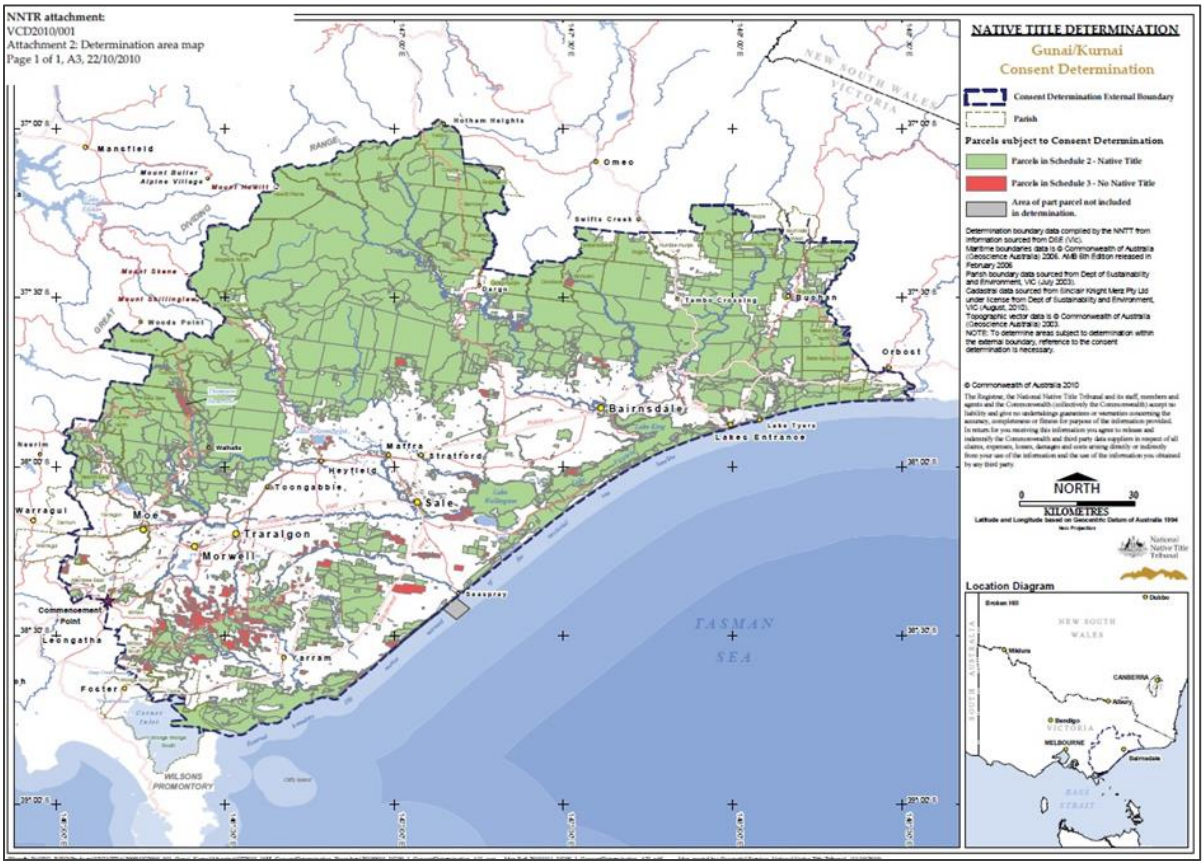

Figure 2-66 Gunai-Kurnai Native Title Determination Area (VCD2010/01)

2.5.2 Natural

The Commonwealth Heritage List is a list of Indigenous, historic and natural heritage places owned or controlled by the Australian Government. There are four listings on the Commonwealth Heritage list under the natural classification which occur in the DA.

- Point Wilson is an important part of the Western Port Phillip Bay Ramsar Area in Victoria, an internationally significant wetland that provides habitat for many migratory and resident wading birds and waterfowl. The Point Wilson Defence Area is a productive and diverse wetland and saltmarsh habitat supporting many shorebirds.
- The Beecroft Peninsula is the best example of a Permian cliffed coast in New South Wales. It is about 4040ha south of the town of Currarong. The area supports a high diversity of vegetation types within a small area including mangroves, saltmarsh, freshwater swamps, heathland, eucalypt forest and subtropical and littoral rainforest. Beecroft Peninsula retains the largest area of heath remaining on the south coast of New South Wales. This floristically rich vegetation provides important habitat for a variety of bird species, including the vulnerable ground parrot

(PEZOPORUS WALLICUS). The place supports 35 bird species listed on international migratory bird treaties (JAMBA, CAMBA, and the Bonn Convention). The ground parrot (PEZOPORUS WALLICUS), which is listed as vulnerable in New South Wales, occurs in heath, swamp and sedgeland habitats and has an estimated maximum population size of 450 individuals on the peninsula.

- The Malabar Headland just north of Botany Bay, NSW contains two significant bushland remnants – referred to as the coastal section and the western section. Together, these contain what is probably the largest area of essentially unmodified bushland in Sydney's Eastern Suburbs. The bushland is a significant part of one of two semi-natural corridors between Botany Bay and Port Jackson. The two sections support at least seven distinct plant communities. This diversity of habitats is only matched in the Eastern Suburbs in Botany Bay National Park (DoEE, 2019al).
- Tasmanian Seamounts Area – also a key ecological feature, refer to Section 2.2.7.5 for information on the Seamounts South and East of Tasmania.

2.5.3 Historic – Commonwealth Heritage

The majority of listings on the Commonwealth Heritage list under the historic classification which occur in the DA are lighthouses; these and the other listings are not considered relevant.

No Historic Indigenous Commonwealth listed places were found within the DA (DoEE, 2019am).

2.5.3.1 Historic – Maritime

A search of the National Shipwrecks Database which includes all known shipwrecks in Australian waters, identified 1160 historic shipwrecks within the DA at the time of writing. The Historic Shipwrecks Act, 1976, protects historic wrecks that are more than 75 years old and in Commonwealth waters (DoEE, 2019g). Table 2-48 below summarises both the historic and other shipwrecks within the DA, by state. Figure 2-67 maps the location of the shipwrecks.

Table 2-48 Shipwreck numbers within the DA by state

	Historic Shipwrecks	Other Shipwrecks
Victoria	417	126
Tasmania	415	167
New South Wales	328	76
Queensland	172	54

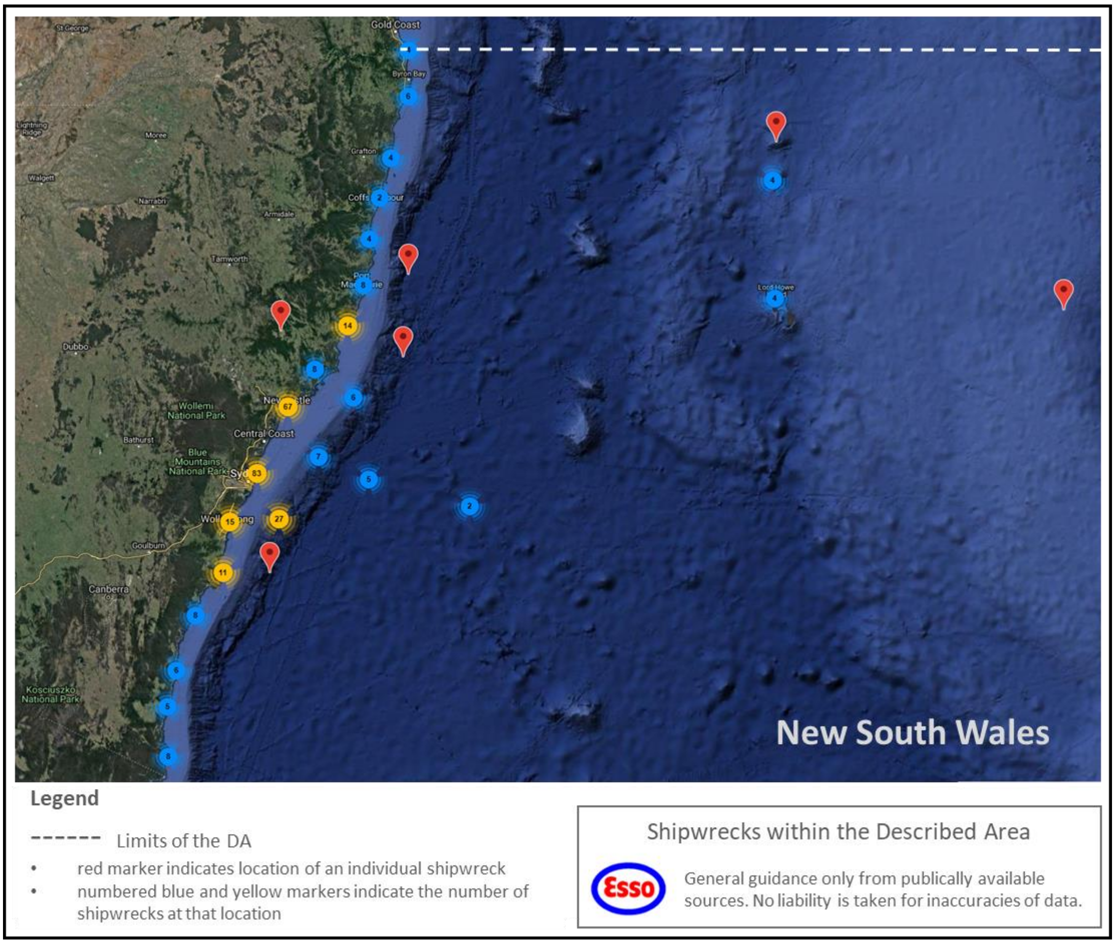

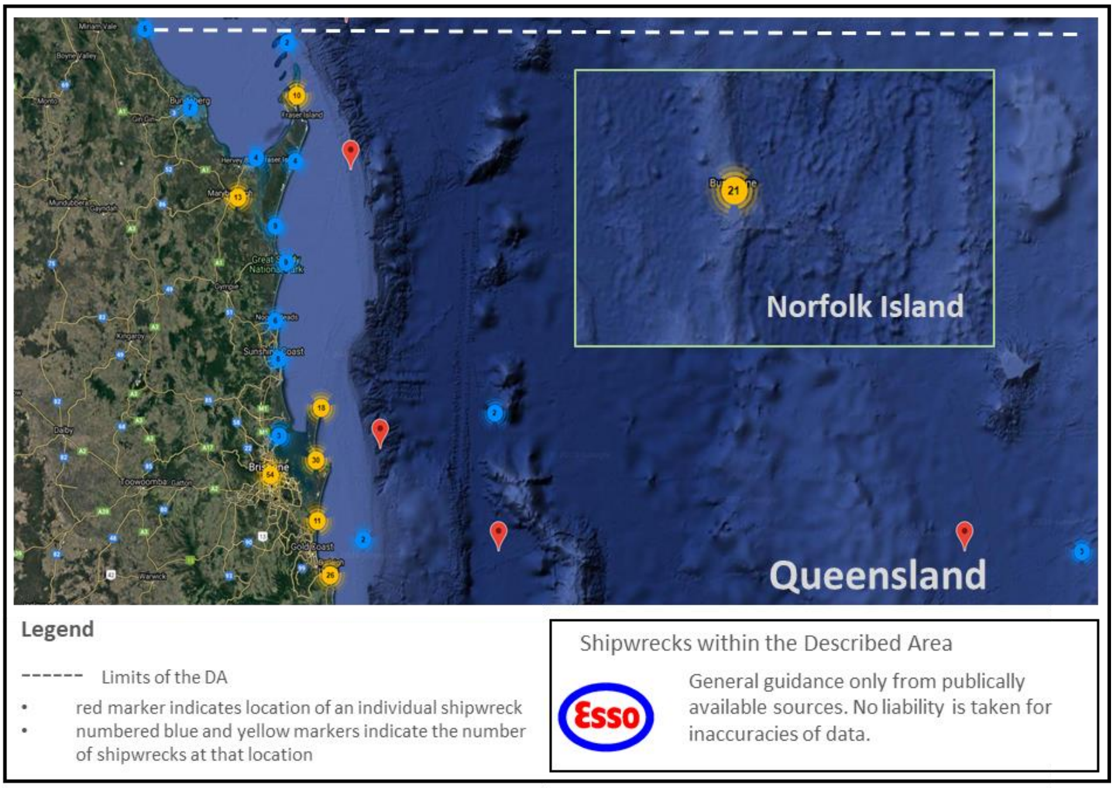

Figure 2-67 Shipwreck sites in the DA as listed in the National Shipwrecks Database (DoEE, 2019)

Table 2-49 lists the shipwrecks within the ATBA; five of these are along the coastline and none occur within the exclusion zones of the production facilities.

Table 2-49 Shipwrecks within the Area to Be Avoided.

Vessel Name	Year wrecked	Location Latitude	Location Longitude
Struan Sailing vessel	1856	-38.5	147.75
Rembrandt Sailing vessel	1861	-38.67	148.2
Talark	unknown	-38.37	148.3
Favourite Sailing Vessel	1852	-38.215	147.95
Unidentified (ID 6719)*	unknown	-37.98	147.79
Latrobe Sailing Vessel*	1978	-37.97	147.79
Pretty Jane*	1882	-38.045	147.64
Norfolk Screw Steamer*	1914	-38.055	147.61
Julius*	1892	-38.09	147.565
Leven Lass	1854	-38.165	148.46
Colleen Bawn	1913	-38.265	147.425

* *Coastal shipwrecks*

Some historic shipwrecks lie within protected or no-entry zones. These zones cover an area around a wreck site, and ensure that a fragile or sensitive historic shipwreck is actively managed.

Five of the historic shipwreck protected zones occur within nearshore coastal waters of the DA (Figure 2-68):

- SS Alert (1893)
- Clonmel (1841)
- SS Glenelg (1900),
- SS Federal (1901) and
- M24 (Japanese Midget Submarine) (1942)
- AHS Centaur (1943)
- Aarhus (1894)

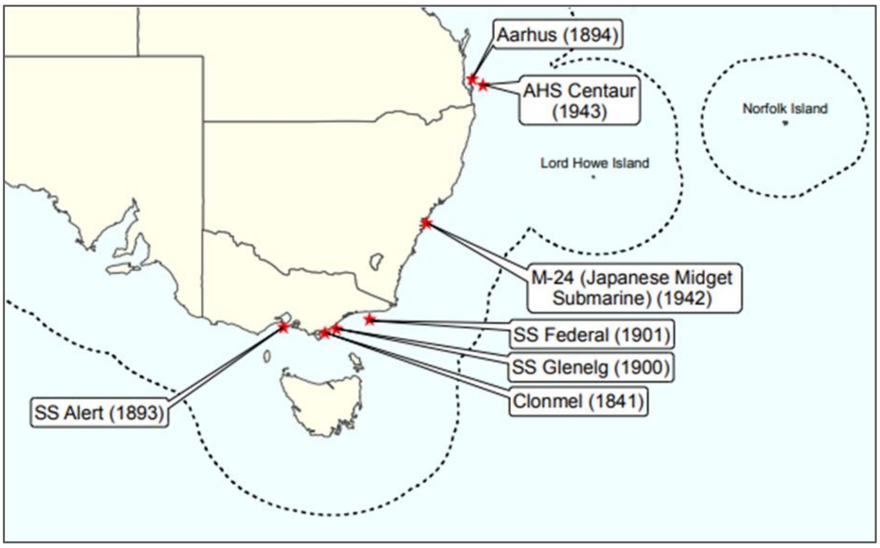

Figure 2-68 Historic Shipwreck Protected Zones within DA (ERIN, 2017)

The SS Glenelg, located approximately 10km from the EGBPA at the entrance to Gippsland Lakes, was a twin screw steamer owned by J.B.Ellerker. It was put on the coastal run during 1893 in opposition to Huddart Parker's S.S. Despatch. The vessel foundered suddenly on 25 March 1900, shortly after leaving Lakes Entrance. Only three people got ashore in a lifeboat. At the Marine Court of Inquiry, a number of possible reasons for the disaster were suggested. However, no evidence was found to explain the sinking, which took 38 lives.

The Clonmel is a famous Australian historic shipwreck located at the entrance to Corner Inlet approximately 60km west of the EGBPA. The luxury paddle steamer Clonmel was one of the first steamships to operate in Australian waters and was built especially for the Australian intercolonial passenger trade, intending to ply the sea-route between Sydney, Melbourne and Launceston in the early 1840s. It was also one of the last wooden steamships to be built before iron became the more popular construction material.

On just its second inter-colonial voyage, en route from Sydney to Port Phillip (Melbourne) with 80 passengers and crew, the Clonmel stuck a sandbar on the east coast of Victoria. All passengers were transferred to the shore, where a makeshift survivors' camp was established. The passengers stayed for nine days after the wrecking, before being finally transferred to their destination.

Favourable descriptions of the arable land and 'welcoming bay' near the wrecksite were seized upon with great enthusiasm by the press and shortly thereafter the Gipps Land Company was formed. The wreck of the Clonmel was consequently instrumental in opening up East Gippsland for trade and pastoral settlement, and throughout the 1850s and 1860s was the centre of trade for south eastern Victoria (DOEE, 2019). Little is known about the SS Federal other than it was last seen in Cape Everand off Bass Strait. It was discovered during mine sweeping operations in World War I.

Both the M24 submarine and the AHS Centaur were wrecks resulting from World War II. No one knew of the fate of the M24 until it was discovered in 2006. It was last seen leaving Sydney in May 1942. The AHS Centaur was a merchant ship converted to an Australian Hospital Ship (AHS) but was torpedoed on its first medical voyage by the Japanese resulting in 268 casualties (DAWE, 2020f). The Aarhus, wrecked in 1894 was an Iron sailing Barque which sailed from New York and wrecked on Smith Rock off cape Morton whilst waiting for a pilot vessel. It is now a popular dive site as the wreck is in 21m of water (DEHP, 2020).

2.6 Social Environment

The Social values of the environment can be defined in many ways and the relative importance of the values will vary depending on the perspective and interests of the people, groups or organisations affected (or otherwise). Social values, therefore can be described in terms of conservation and biodiversity values (Section 2.2), economic drivers (Section 2.4) or cultural significance (Section 2.5). These values have been described in the sections noted. This section describes the values of the recreational activities in the DA.

2.6.1 Recreational Fishing

Recreational fishing in Australia is a multi-billion dollar industry. Most recreational fishing typically occurs in nearshore coastal waters (shore or inshore vessels), and within bays and estuaries. Offshore fishing (>5 km from the coast) only accounts for approximately 4% of recreational fishing activity in Australia; charter fishing vessels are likely to account for the majority of this offshore fishing activity.

The variation in recreational fishing intensity along the coast is illustrated in Figure 2-69; there is moderate to high recreational use along the majority of the coast in the DA. Common recreational fish species include Tiger Flathead, bream, snapper, Australian Salmon, and lobster. Offshore catches can include mackerel, tuna, groper and shark.

Recreational fishing amongst the Nooramunga islands, on the Gippsland Lakes, along Ninety Mile Beach, at Cape Conran Coastal Park and Croajingolong National Park and off the coast of Mallacoota, comprising both boat based fishing and beach based surf fishing. Boat based fishing includes charter operations and private craft launched from boat ramps in the region. Boatyards and slipways are located at Bullock Island (Lakes Entrance), Port Welshpool and Mallacoota.

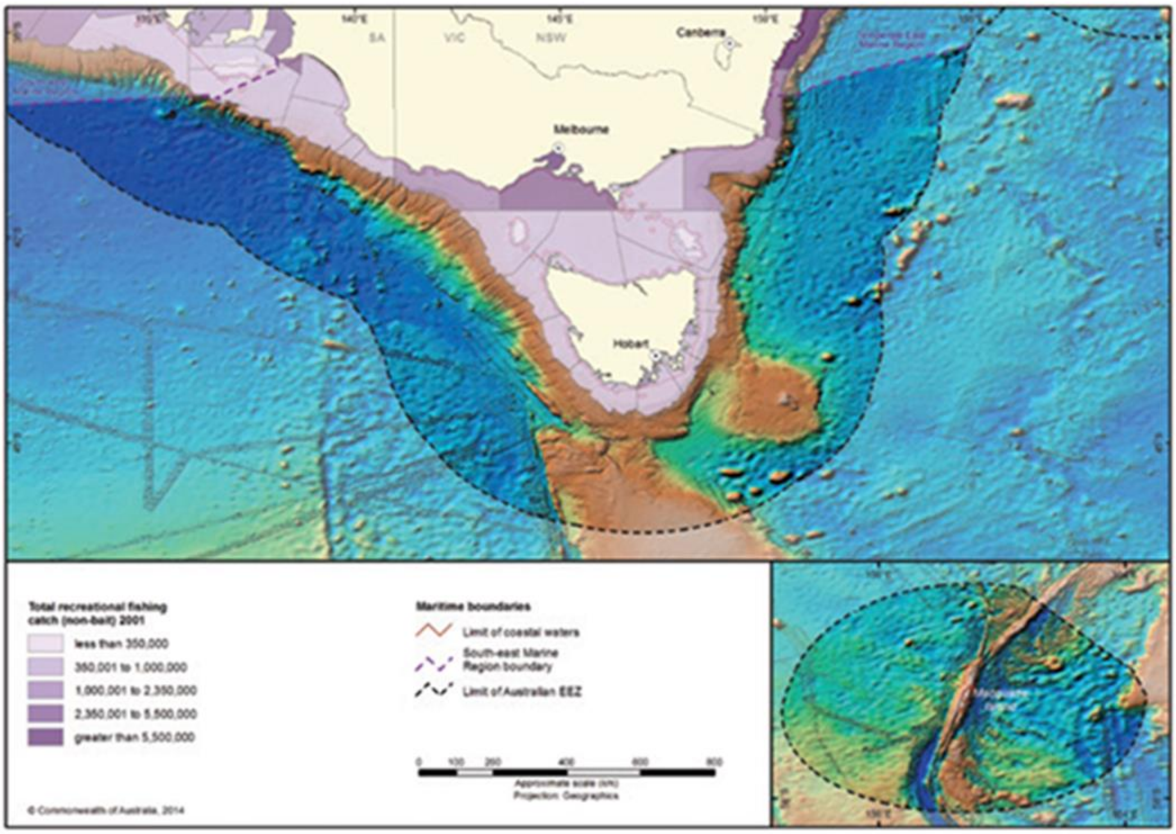

Figure 2-69 Recreational Fishing Catch in Temperate East (top) and South-eastern (bottom) Marine Region (DoEE, 2015a)

2.6.2 Recreational Boating and Leisure Activities

Australia and its people are renowned for their love of the outdoors – the outback and the beaches are often celebrated as part of its (our) cultural identity. With the majority of the population residing in coastal areas, recreational boating, coastal camping, hiking, touring and visits to the beach are leisure activities accessible to all most people and are integral to life in Australia for all ages. Popular coastal destinations are located across the coastline of the DA. Further description of declared parks and reserves are provided in Section 2.2.8.

3 Legislative and other requirements

3.1 Legislative Framework

The principal offshore legislation for production activities beyond three nautical miles to the outer extent of the Australian Exclusive Economic Zone at 200 nautical miles is the Commonwealth Offshore Petroleum and Greenhouse Gas Storage (OPGGS) Act 2006. The OPGGS Act is administered by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

3.2 Relevant Legislation

In accordance with Regulation 13(4), relevant Commonwealth, Victorian, New South Wales and Tasmanian Legislation as it applies to the operation of facilities and petroleum pipelines and projects is provided in Table 3-1, Table 3-2, Table 3-3 and Table 3-4 respectively.

The Australian Petroleum Production and Exploration Association (APPEA) Code of Environmental Practice 2008 provides guidance on a set of recommended minimum standards for petroleum industry activities offshore. These standards are aimed at minimising adverse impact on the environment, and ensuring public health and safety by using the best practical technologies available.

The Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC 2000) are also relevant to the activity and provide water quality guidelines proposed to protect and manage the environmental values supported by the water resources.

Table 3-1 Key Commonwealth legislation

Legislation	Coverage and Applicability to Activity		International Convention Enacted	Administering Authority
Offshore Petroleum & Greenhouse Gas Storage Act 2006 & associated regulations (associated regulations include: OPGGS (Environment) Regulations 2009, Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011 [RMAR], Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009)	The *OPGGS Act* addresses all **licensing, health, safety, environmental** and royalty **issues for offshore petroleum exploration and recovery operations** extending beyond the 3 nautical mile limit. The *OPGGS (Environment) Regulations* ensures that petroleum activities are carried out in a manner; consistent with the principles of ecologically sustainable development set out in section 3A of the EPBC Act; and by which the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable and will be of an acceptable level.	All Gippsland facilities operate under an accepted Environment Plan in accordance with the *OPGGS (Environment) Regulations, 2009.* All Gippsland facilities operate under an approved Safety Case per the *OPGGS (Safety) Regulations, 2009*. All wells in Gippsland are operated under an approved Well Operations Management Plan per the *OPGGS (Resource Management and Administration) Regulations 2011* which includes measures for well control as described in Vol 2		National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA)
Environment Protection & Biodiversity Conservation Act 1999	This Act focuses on environmental matters of National Significance, streamlines the Commonwealth environmental assessment and approval process and provides an integrated system for biodiversity conservation and management of protected areas. **Matters of national environmental significance** are world heritage properties; Ramsar wetlands; listed threatened species and communities; migratory species under international agreements; nuclear actions and the	Relevant Matters of National environmental significance covered in Volume 1 – Description of the Environment EPBC Protected matters search tool utilised to identify relevant data Approved conservation advice and management plans relating to listed species or threatened ecological communities have been identified and considered where appropriate	1992 Convention on Biological Diversity & Agenda 21. Convention on International Trade in Endangered Species of Wildlife and Flora 1973 (CITES). Japan/Australia Migratory Birds Agreement 1974 (JAMBA). Legislation	Coverage and Applicability to Activity		International Convention Enacted	Administering Authority
	commonwealth marine environment. On 28 February 2014, NOPSEMA became the sole designated assessor of petroleum and greenhouse gas activities in Commonwealth waters in accordance with the Ministers for the Environment's endorsement of NOPSEMA' s environmental authorisation process under Part 10, Section 146 of the EPBC Act.		Republic of Korea Migratory Birds Agreement 2006 (ROKAMBA). USSR-Australia Migratory Bird Agreement. Convention on Wetlands of International Importance especially waterfowl habitat 1971 (Ramsar). International Convention on Whaling 1946. Convention on the Migratory Species of Wild Animals (Bonn Convention) 1979. Convention concerning the Protection of the World Cultural and Natural Heritage 1972.	
Environment Protection (Sea Dumping) Act 1981	Act prevents the deliberate **disposal of wastes** (loading, dumping, and incineration) **at sea** from vessels, aircraft, and operational areas.	Activities described in this plan are controlled to prevent actions that would contravene this Act. Relevant control measures are described in Vol 2 and the implementation strategy is described in Vol 4.	Convention on the Prevention of Marine Pollution by dumping of waste & other materials 1972 (London Convention) MARPOL	Department of Agriculture, Water and the Environment (DAWE)
Australian Maritime Safety Authority Act 1990	Facilitates international cooperation and mutual assistance in **preparing and responding to a major oil spill incident** and encourages countries to develop and maintain an adequate capability to deal with oil pollution	Oil spill preparedness and response plans for dealing with a potential worst case scenario spill is described in Vol 3 including consultation and coordination of activities with AMSA	International Convention on Oil Pollution (Preparedness, Response and Cooperation) 1990 (OPRC)	Australian Maritime Safety Authority (AMSA)

Legislation	Coverage and Applicability to Activity		International Convention Enacted	Administering Authority
	emergencies. Requirements are given effect through AMSA.			
Historic Shipwrecks Act 1976	Protects the heritage values of shipwrecks and relics.	Heritage listed shipwrecks within the DA are identified in Vol 1.	Convention on Conservation of Nature in the South Pacific (APIA Convention) 1976. Aust-Netherlands Agreement concerning old Dutch Shipwrecks 1972. Convention on Protection of Underwater Cultural Heritage 2001.	Department of Agriculture, Water and the Environment (DAWE)
National Environment Protection Council Act 1994 Associated act: National Environment Protection Measures (Implementation) Act 1998	Council develops (in conjunction with other state authorities) through the Intergovernmental Agreement on the Environment on consistent environmental standards to be adopted between states. These requirements take the form of National Environment Pollution Measures (NEPMs) such as **National Pollutant Inventory.**	Standards required under the NEPM are used to define operating limits and reporting of emissions required by the National Pollutant Inventory is conducted annually for all Esso operated activities covered by this plan.		Natural Resources Management Ministerial Council / Environment Protection & Heritage Council
National Greenhouse and Energy Reporting Act 2007	Provides for the reporting and dissemination of information related to greenhouse gas emissions, greenhouse gas projects, energy production and energy consumption.	Annual submission covering Gippsland activities provided to Clean Energy Regulator	United Nations Framework Convention on Climate Change,1992, and the Kyoto Protocol	Clean Energy Regulator
Protection of the Sea (Prevention of Pollution from Ships) Act 1983	Regulates ship-related operational activities and invokes certain requirements of the MARPOL convention relating to discharge of noxious liquid substances, sewage, garbage, air pollution etc.	Activities described in this plan are controlled to prevent actions that would contravene this Act. Relevant control measures are described in Vol 2 and the implementation strategy is described in Vol 3	International Convention for the Prevention of Pollution from Ships [MARPOL 73/78] provisions and unified interpretations of the articles, protocols and Annexes of MARPOL 73/78, including the	Australian Maritime Safety Authority (AMSA)

Legislation	Coverage and Applicability to Activity		International Convention Enacted	Administering Authority
			incorporation of all of the amendments that have been adopted by the MEPC and have entered into force, up to and including the 2000 amendments (as adopted by resolution MEPC 89(45)).	
Biosecurity Act 2015	The Act is about managing diseases and pests that may cause harm to human, animal or plant health or the environment. It empowers authorities to monitor, authorise, respond to and control biosecurity risks for the movement of goods, vessels and people to **prevent the introduction, establishment or spread of diseases or pests** affecting human beings, animals, or plants.	The risk of introduction of Invasive Marine Species is considered and managed for all vessels covered under this activity as described in Vol 2.	International Convention for the Control and Management of Ships Ballast Water & Sediments 2004 United Nations Convention on the Law of the Sea 1982 Convention on Biological Diversity 1992	Department of Agriculture, Water and the Environment (DAWE)
Navigation Act 2012	Regulates ship-related activities and invokes certain requirements of the MARPOL convention relating to **equipment and construction of ships**.	Vessels operating within the permit areas comply with the requirements of the Navigation Act. Specifically in relation to environment protection, activities relating to control of discharges are discussed in Vol 2.	International Convention for the Prevention of Pollution from Ships [MARPOL 73/78] (certain sections) Convention on the International Regulations for Preventing Collisions at Sea 1972	Department of Infrastructure, Regional Development and Cities(DoIRDC) /AMSA (formerly Department of Infrastructure & Regional Development)
Coastal Waters (State Powers) Act 1980	This Act transferred **constitutional power over coastal waters**, and title to seabed minerals within territorial	Consultation, reporting and other matters impacting coastal waters are addressed with State authorities as described in Vol 4		Geoscience Australia (Maritime Boundaries Advice Unit)

Legislation	Coverage and Applicability to Activity		International Convention Enacted	Administering Authority
	limits, from the Commonwealth to the States.			
Protection of the Sea (Harmful Anti-fouling Systems) Act 2006	Regulates the use of harmful **anti-fouling systems employed on vessels** and their effects on the marine environment.	The risk of introduction of Invasive Marine Species is considered and managed for all vessels covered under this activity as described in Vol 2. This includes consideration of appropriate antifouling systems.	International Convention on the Control of Harmful Anti-fouling Systems on Ships 2001	AMSA
Native Title Act 1993	Allows for **recognition of native title** through a claims and mediation process and also sets up regimes for obtaining interests **in lands or waters** where native title may exist.	Native Title within the DA is identified and recognised in Vol 1.		Attorney-General's Department
Civil Aviation Act 1988 and associated regulations (including Civil Aviation Safety Regulations 1998)	The Act sets up a Civil Aviation Safety Authority with functions to regulate the safety of civil aviation, including the carrying of dangerous goods, airworthiness standards for aviation, maintenance; general operational and flight rules; and aerial application operations.	Rotary wing aircraft servicing the Gippsland facilities operate under the requirements of CASA. This contributes to safe operation and transport of goods thereby reducing risk of incidents which could have environmental impacts as described in Vol 2.	Chicago Convention 1944.	Civil Aviation Safety Authority (CASA)
Radiocommunications Act 1992	The Act provides for the **management of the radiofrequency spectrum** in order to make adequate provision of the spectrum for use by agencies involved in the defence or national security of Australia, law enforcement or the provision of emergency services; and for use by the public or community services.	Radiocommunications systems on platforms, vessels and aircraft operate within frequency ranges permitted under the Act. Clear communication channels are required to enable effective controls preventing or limiting potential impacts from incidents (e.g., collision, emergency response) as defined in Vol 2 and Vol 3		Australian Communications and Media Authority (ACMA)

Legislation	Coverage and Applicability to Activity		International Convention Enacted	Administering Authority
		Prevention of collision		

Table 3-2 Key Victorian legislation

Legislation	Coverage
Environment Protection Act 1970	This Act is the key Victorian Legislation regulating emissions to the environment within Victoria (relevant for waste transfer and disposal, National Pollutant Inventory reporting). Administered by the Victorian Environment Protection Authority.
Pollution of Waters by Oil and Noxious Substances Act 1986	This Act is the Victorian state legislation giving effect to the requirements of MARPOL 73/78 within state waters. Administered by the Victorian Environment Protection Authority
Emergency Management Act 1986	This Act ensures that the components of emergency management (prevention, response and recovery) are organised to facilitate planning, preparedness, operational coordination and community participation. Administered by Department of Justice's Police and Emergency Management Division.
Port Management Act 1995	Under this Act all managers of local and commercial ports must prepare a Safety Management Plan and Environmental Management Plan (together known as SEMPs).
Marine Safety Act 2010	This Act provides for safe marine operations in Victoria.
Heritage Act 1995	This Act is the Victorian state legislation which protects the heritage values of shipwrecks and relics within state waters. Administered by the Heritage Council of Victoria.
National Parks Act 1975	This Act provides for the protection, use and management of Victoria's national and other parks. Administered by the Department of Environment and Primary Industries.
Radiation Act 2005	This Act provides for licencing for use and management of radioactive sources, and conducting radiation practice (including radiation testing).
Catchment and Land Protection Act 1994	This Act sets up a framework for the integrated management and protection of catchments. Administered by the Catchment Management Authorities.
Coastal Management Act 1995	This Act provides for co-ordinated strategic planning and management for Victorian coast, the preparation and implementation of management plans for coastal Crown land and a co-ordinated approach to approvals for use and development of coastal Crown land.
Land Titles Validation Act 1994	This Act validates past acts, provides for compensation rights for the holders of native title which has been affected by past acts, and confirms certain existing rights. The Act also confirms ownership by the Crown of natural resources, the right to regulate water flows and

Legislation	Coverage
	existing fishing rights under State law; and public access to waterways, beds and banks of waterways, coastal waters, beaches and public areas.
Dangerous Goods Act 1985	This Act, the associated Dangerous Goods (Storage and Handling) Regulations 2012 and the Code of Practice for the Storage and Handling of Dangerous Goods 2013 (WorkSafe) promotes the safety of persons and property in relation to the manufacture, storage, transfer, transport, sale, purchase and use of dangerous goods and the import of explosives and other dangerous goods.
OPGGS Act 2010 and OPGGS Regulations 2011	This Act and Regulations apply to petroleum operations effectively within three nautical miles of the Victorian coast and address licensing, health, safety, environmental and royalty issues for offshore petroleum exploration and development operations. Waters greater than 3 nautical miles offshore from the coast are Commonwealth waters and are covered by Commonwealth legislation (*OPGGS Act 2006*). The Commonwealth and Victorian legislation are, by agreement, very similar with regard to petroleum.

Table 3-3 Key New South Wales legislation

Legislation	Coverage
Protection of the Environment Operations Act 1997	This is the main piece of NSW environmental legislation covering water, land, air and noise pollution and waste management. Administered by the NSW Environment Protection Authority
Marine Pollution Act 2012	This Act is the NSW state legislation giving effect to the requirements of MARPOL 73/78 within state waters. Administered by Transport for NSW.
Ports and Maritime Administration Act 1995	This Act provides for the provision of marine safety services and emergency environment protection services for dealing with pollution incidents in NSW waters.
Heritage Act 1977	This Act provides for the identification, registration and interim protection of items of State heritage significance (including shipwrecks within state waters) in NSW. Administered by Heritage Council of NSW.
National Parks and Wildlife Act 1974	This Act provides for the care, control and management of all national parks, historic sites, nature reserves, conservation reserves, Aboriginal areas and game reserves, and the protection and care of native flora and fauna, and Aboriginal places and objects. Administered by the NSW National Parks and Wildlife Service.
Wilderness Act 1987	This Act affords declared wilderness the most secure level of protection, requiring it to be managed in a way that will maintain its wilderness values and pristine condition by limiting activities likely to damage flora, fauna and cultural heritage. Administered by the NSW National Parks and Wildlife Service.
Marine Parks Act 1997	This Act provides for the protection and management of marine areas. Administered by the NSW Marine Parks Authority.

Table 3-4 Key Tasmanian legislation

Legislation	Coverage
Environmental Management and Pollution Control Act 1994	This is the primary environment protection and pollution control legislation in Tasmania. Administered by the Environment Protection Authority Tasmania
Pollution of Waters by Oil and Noxious Substances Act 1987	This Act is the Tasmanian state legislation giving effect to the requirements of MARPOL 73/78 within state waters. Administered by Environment Protection Authority Tasmania.
Emergency Management Act 2006	This Act establishes the Tasmanian emergency management framework which operates at state, regional and municipal levels.
Marine and Safety Authority Act 1997	This Act establishes Marine and Safety Tasmania as the authority responsible for the safe No probs. operation of vessels in Tasmanian waters and managing its marine facilities.
Historic Cultural Heritage Act 1995	This Act provides for the identification, assessment, protection and conservation of places having historic cultural heritage significance (including shipwrecks within state waters) in Tasmania. Administered by Tasmanian Heritage Council and Historic Heritage Section of Parks and Wildlife Service Tasmania (shipwrecks).
National Parks and Reserves Management Act 2002	This Act provides for the management of national parks and other reserved land. Administered by the Parks and Wildlife Service Tasmania.

APPENDIX A – Esso's Environmental Policy

INTRODUCTION

The high quality of the directors, officers, and employees of Exxon Mobil Corporation is the Corporation's greatest strength. The resourcefulness, professionalism, and dedication of those directors, officers, and employees make the Corporation competitive in the short term and well positioned for ongoing success in the long term.

The Corporation's directors, officers, and employees are responsible for developing, approving, and implementing plans and actions designed to achieve corporate objectives. The methods we employ to attain results are as important as the results themselves. The Corporation's directors, officers, and employees are expected to observe the highest standards of integrity in the conduct of the Corporation's business.

The Board of Directors of the Corporation has adopted and oversees the administration of the Corporation's *Standards of Business Conduct*. The policies in the *Standards of Business Conduct* are the foundation policies of the Corporation. Wholly-owned and majority-owned subsidiaries of Exxon Mobil Corporation generally adopt policies similar to the Corporation's foundation policies. Thus, the Corporation's foundation policies collectively express the Corporation's expectations and define the basis for the worldwide conduct of the businesses of the Corporation and its majority-owned subsidiaries.

The directors, officers, and employees of Exxon Mobil Corporation are expected to review these foundation policies periodically and apply them to all of their work. The Corporation publishes from time to time guidelines with respect to selected policies. Those guidelines are interpretive and administrative and are not part of the *Standards of Business Conduct*. Any employee who has questions concerning any aspect of these policies should not hesitate to seek answers from management or the other sources indicated in the section below called "Procedures and Open Door Communication."

No one in the ExxonMobil organization has the authority to make exceptions or grant waivers with respect to the foundation policies. Regardless of how much difficulty we encounter or pressure we face in performing our jobs, no situation can justify the willful violation of these policies. Our reputation as a corporate citizen depends on our understanding of and compliance with these policies.

Darren W. Woods
Chairman
January 2017

ENVIRONMENT POLICY

It is Exxon Mobil Corporation's policy to conduct its business in a manner that is compatible with the balanced environmental and economic needs of the communities in which it operates. The Corporation is committed to continuous efforts to improve environmental performance throughout its operations.

Accordingly, the Corporation's policy is to:

- comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist;
- encourage concern and respect for the environment, emphasize every employee's responsibility in environmental performance, and foster appropriate operating practices and training;
- work with government and industry groups to foster timely development of effective environmental laws and regulations based on sound science and considering risks, costs, and benefits, including effects on energy and product supply;
- manage its business with the goal of preventing incidents and of controlling emissions and wastes to below harmful levels; design, operate, and maintain facilities to this end;
- respond quickly and effectively to incidents resulting from its operations, in cooperation with industry organizations and authorized government agencies;
- conduct and support research to improve understanding of the impact of its business on the environment, to improve methods of environmental protection, and to enhance its capability to make operations and products compatible with the environment;
- communicate with the public on environmental matters and share its experience with others to facilitate improvements in industry performance;
- undertake appropriate reviews and evaluations of its operations to measure progress and to foster compliance with this policy.

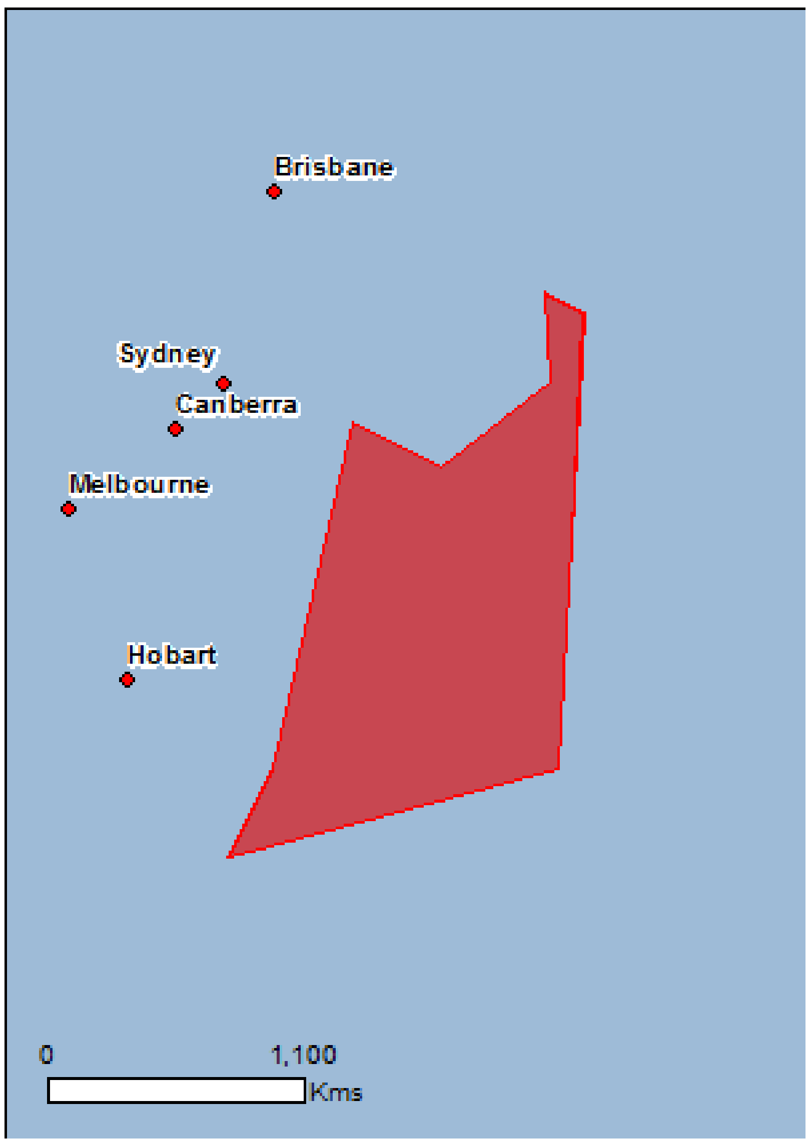
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

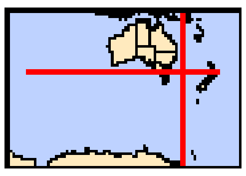
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 29/07/19 20:30:28



Coordinates

Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	36
Listed Migratory Species:	41

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	34
Whales and Other Cetaceans:	40
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
Extended Continental Shelf

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat likely to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within

Name	Status	Type of Presence
		area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pterodroma heraldica Herald Petrel [66973]	Critically Endangered	Species or species habitat may occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Pterodroma neglecta neglecta Kermadec Petrel (western) [64450]	Vulnerable	Foraging, feeding or related behaviour may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Species or species habitat likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Foraging, feeding or related behaviour likely

Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Species or species habitat likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Species or species habitat likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Species or species habitat likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Species or species habitat likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat may occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Species or species habitat likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Species or species habitat likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Species or species habitat likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Species or species habitat likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Species or species habitat may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat likely to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Phocoena dioptrica Spectacled Porpoise [66728]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tasmacetus shepherdi Shepherd's Beaked Whale, Tasman Beaked Whale [55]		Species or species habitat may occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Extra Information

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

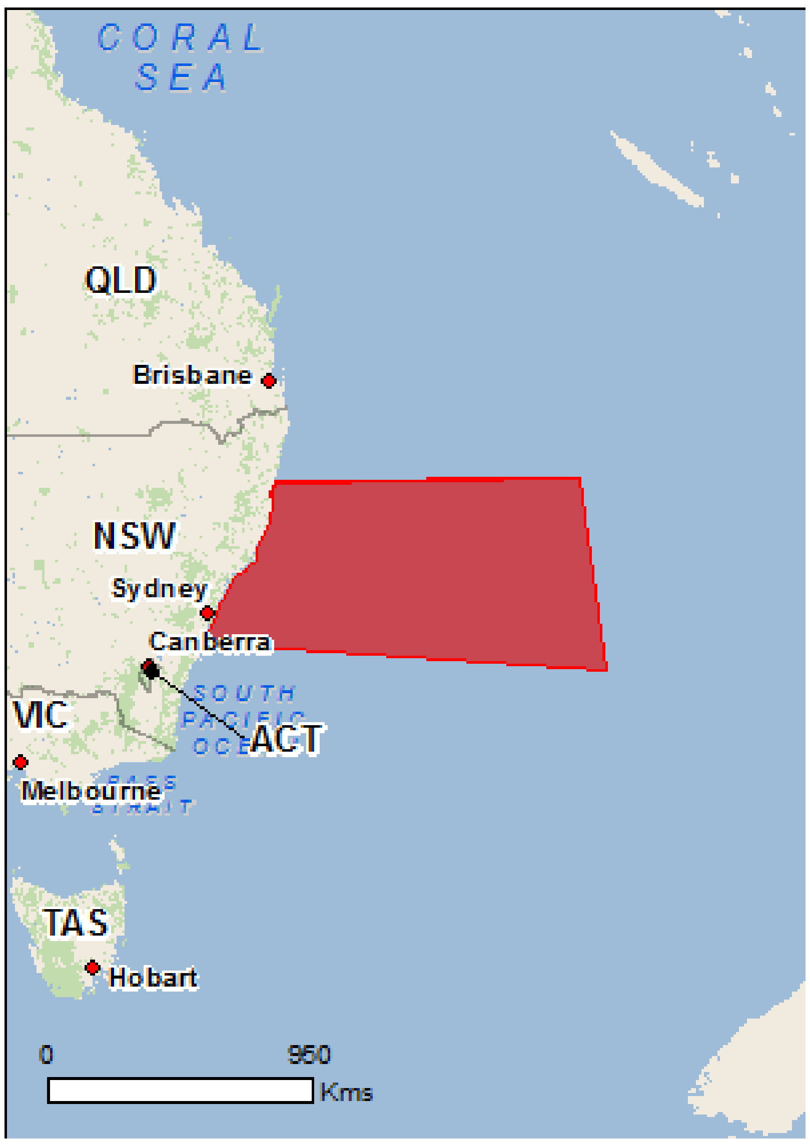
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

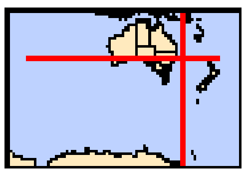
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 27/05/19 20:16:47



Coordinates

Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	1
National Heritage Places:	8
Wetlands of International Importance:	3
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	10
Listed Threatened Species:	152
Listed Migratory Species:	91

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	21
Commonwealth Heritage Places:	19
Listed Marine Species:	138
Whales and Other Cetaceans:	40
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	11

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	42
Regional Forest Agreements:	1
Invasive Species:	58
Nationally Important Wetlands:	7
Key Ecological Features (Marine)	5

Details

Matters of National Environmental Significance

World Heritage Properties [Resource Information]

Name	State	Status
Lord Howe Island Group	NSW	Declared property

National Heritage Properties [Resource Information]

Name	State	Status
Natural		
Ku-ring-gai Chase National Park, Lion, Long and Spectacle Island Nature Reserves	NSW	Listed place
Lord Howe Island Group	NSW	Listed place
Royal National Park and Garawarra State Conservation Area	NSW	Listed place
Historic		
Bondi Beach	NSW	Listed place
Kamay Botany Bay: botanical collection sites	NSW	Listed place
Kurnell Peninsula Headland	NSW	Listed place
North Head - Sydney	NSW	Listed place
Bondi Surf Pavilion	NSW	Within listed place

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Hunter estuary wetlands	Within 10km of Ramsar
Myall lakes	Within Ramsar site
Towra point nature reserve	Within 10km of Ramsar

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea
Extended Continental Shelf

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
Temperate East

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Central Hunter Valley eucalypt forest and woodland	Critically Endangered	Community may occur within area
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	Endangered	Community likely to occur within area
Coastal Upland Swamps in the Sydney Basin Bioregion	Endangered	Community likely to occur within area
Eastern Suburbs Banksia Scrub of the Sydney Region	Endangered	Community known to occur within area
Illawarra and south coast lowland forest and woodland ecological community	Critically Endangered	Community likely to occur within area
Littoral Rainforest and Coastal Vine Thickets of Eastern Australia	Critically Endangered	Community likely to occur within area

Name	Status	Type of Presence
Lowland Rainforest of Subtropical Australia	Critically Endangered	Community likely to occur within area
Posidonia australis seagrass meadows of the Manning-Hawkesbury ecoregion	Endangered	Community likely to occur within area
Subtropical and Temperate Coastal Saltmarsh	Vulnerable	Community likely to occur within area
Upland Basalt Eucalypt Forests of the Sydney Basin Bioregion	Endangered	Community may occur within area

Listed Threatened Species

[Resource Information]

Name	Status	Type of Presence
Birds		
Anthochaera phrygia		
Regent Honeyeater [82338]	Critically Endangered	Species or species habitat known to occur within area
Botaurus poiciloptilus		
Australasian Bittern [1001]	Endangered	Species or species habitat known to occur within area
Calidris canutus		
Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris		
Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius leschenaultii		
Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus		
Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Dasyornis brachypterus		
Eastern Bristlebird [533]	Endangered	Species or species habitat likely to occur within area
Diomedea antipodensis		
Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni		
Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora		
Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans		
Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi		
Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Erythrotriorchis radiatus		
Red Goshawk [942]	Vulnerable	Species or species habitat likely to occur within area
Fregetta grallaria grallaria		
White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Breeding known to occur within area
Grantiella picta		
Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area

Name	Status	Type of Presence
Hypotaenidia sylvestris Lord Howe Woodhen [87732]	Endangered	Breeding likely to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pterodroma heraldica Herald Petrel [66973]	Critically Endangered	Species or species habitat likely to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Breeding known to occur within area
Pterodroma neglecta neglecta Kermadec Petrel (western) [64450]	Vulnerable	Breeding known to occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding likely to occur within area
Strepera graculina crissalis Lord Howe Island Currawong, Pied Currawong (Lord Howe Island) [25994]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Name	Status	Type of Presence
Thalassarche cauta steadi		
White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita		
Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini		
Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Fish		
Epinephelus daemelii		
Black Rockcod, Black Cod, Saddled Rockcod [68449]	Vulnerable	Species or species habitat likely to occur within area
Maccullochella peelii		
Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Macquaria australasica		
Macquarie Perch [66632]	Endangered	Species or species habitat may occur within area
Prototroctes maraena		
Australian Grayling [26179]	Vulnerable	Species or species habitat likely to occur within area
Frogs		
Heleioporus australiacus		
Giant Burrowing Frog [1973]	Vulnerable	Species or species habitat known to occur within area
Litoria aurea		
Green and Golden Bell Frog [1870]	Vulnerable	Species or species habitat known to occur within area
Litoria littlejohni		
Littlejohn's Tree Frog, Heath Frog [64733]	Vulnerable	Species or species habitat likely to occur within area
Mixophyes balbus		
Stuttering Frog, Southern Barred Frog (in Victoria) [1942]	Vulnerable	Species or species habitat likely to occur within area
Mixophyes iteratus		
Giant Barred Frog, Southern Barred Frog [1944]	Endangered	Species or species habitat may occur within area
Insects		
Argynnis hyperbius inconstans		
Australian Fritillary [88056]	Critically Endangered	Species or species habitat likely to occur within area
Dryococelus australis		
Lord Howe Island Phasmid, Land Lobster [66752]	Critically Endangered	Species or species habitat known to occur within area
Phyllodes imperialis smithersi		
Pink Underwing Moth [86084]	Endangered	Species or species habitat may occur within area
Mammals		

Name	Status	Type of Presence
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Species or species habitat may occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Chalinolobus dwyeri		
Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat known to occur within area
Dasyurus maculatus maculatus (SE mainland population)		
Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (southeastern mainland population) [75184]	Endangered	Species or species habitat known to occur within area
Eubalaena australis		
Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Isoodon obesulus obesulus		
Southern Brown Bandicoot (eastern), Southern Brown Bandicoot (south-eastern) [68050]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae		
Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Petauroides volans		
Greater Glider [254]	Vulnerable	Species or species habitat known to occur within area
Petrogale penicillata		
Brush-tailed Rock-wallaby [225]	Vulnerable	Species or species habitat likely to occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT)		
Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Potorous tridactylus tridactylus		
Long-nosed Potoroo (SE mainland) [66645]	Vulnerable	Species or species habitat known to occur within area
Pseudomys novaehollandiae		
New Holland Mouse, Pookila [96]	Vulnerable	Species or species habitat known to occur within area
Pteropus poliocephalus		
Grey-headed Flying-fox [186]	Vulnerable	Roosting known to occur within area
Other		
Gudeoconcha sophiae magnifica		
Magnificent Helicarionid Land Snail [82864]	Critically Endangered	Species or species habitat likely to occur within area
Mystivagor mastersi		
Masters' Charopid Land Snail [81247]	Critically Endangered	Species or species habitat known to occur within area
Placostylus bivaricosus		
Lord Howe Flax Snail, Lord Howe Placostylus [66769]	Endangered	Species or species habitat known to occur within area
Pseudocharopa ledgbirdi		
Mount Lidgbird Charopid Land Snail [85279]	Critically Endangered	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Pseudocharopa whiteleggei Whitelegge's Land Snail [81249]	Critically Endangered	Species or species habitat likely to occur within area
Plants		
Acacia bynoeana Bynoe's Wattle, Tiny Wattle [8575]	Vulnerable	Species or species habitat may occur within area
Acacia courtii Northern Brother Wattle [56299]	Vulnerable	Species or species habitat likely to occur within area
Acacia terminalis subsp. terminalis MS Sunshine Wattle (Sydney region) [88882]	Endangered	Species or species habitat known to occur within area
Acronychia littoralis Scented Acronychia [8582]	Endangered	Species or species habitat likely to occur within area
Allocasuarina defungens Dwarf Heath Casuarina [21924]	Endangered	Species or species habitat known to occur within area
Allocasuarina glareicola [21932]	Endangered	Species or species habitat may occur within area
Allocasuarina portuensis Nielsen Park She-oak [21937]	Endangered	Species or species habitat known to occur within area
Allocasuarina simulans Nabiac Casuarina [21935]	Vulnerable	Species or species habitat likely to occur within area
Allocasuarina thalassoscopica [21927]	Endangered	Species or species habitat known to occur within area
Angophora inopina Charmhaven Apple [64832]	Vulnerable	Species or species habitat may occur within area
Arthraxon hispidus Hairy-joint Grass [9338]	Vulnerable	Species or species habitat known to occur within area
Asperula asthenes Trailing Woodruff [14004]	Vulnerable	Species or species habitat likely to occur within area
Asterolasia elegans [56780]	Endangered	Species or species habitat known to occur within area
Caladenia tessellata Thick-lipped Spider-orchid, Daddy Long-legs [2119]	Vulnerable	Species or species habitat known to occur within area
Calystegia affinis [48909]	Critically Endangered	Species or species habitat known to occur within area
Commersonia prostrata Dwarf Kerrawang [87152]	Endangered	Species or species habitat may occur within area
Corunastylis insignis Wyong Midge Orchid 1, Variable Midge Orchid 1 [84692]	Critically Endangered	Species or species habitat known to occur within area

Name	Status	Type of Presence
Corunastylis littoralis Tuncurry Midge Orchid [82945]	Critically Endangered	Species or species habitat likely to occur within area
Cryptocarya foetida Stinking Cryptocarya, Stinking Laurel [11976]	Vulnerable	Species or species habitat may occur within area
Cryptostylis hunteriana Leafless Tongue-orchid [19533]	Vulnerable	Species or species habitat known to occur within area
Cynanchum elegans White-flowered Wax Plant [12533]	Endangered	Species or species habitat known to occur within area
Diploglottis campbellii Small-leaved Tamarind [21484]	Endangered	Species or species habitat may occur within area
Diuris praecox Newcastle Doubletail [55086]	Vulnerable	Species or species habitat likely to occur within area
Elymus multiflorus subsp. kingianus Phillip Island Wheat Grass [82413]	Critically Endangered	Species or species habitat known to occur within area
Endiandra hayesii Rusty Rose Walnut, Velvet Laurel [13866]	Vulnerable	Species or species habitat may occur within area
Eucalyptus camfieldii Camfield's Stringybark [15460]	Vulnerable	Species or species habitat likely to occur within area
Eucalyptus parramattensis subsp. decadens Earp's Gum, Earp's Dirty Gum [56148]	Vulnerable	Species or species habitat known to occur within area
Euphrasia arguta [4325]	Critically Endangered	Species or species habitat may occur within area
Geniostoma huttonii [56368]	Endangered	Species or species habitat known to occur within area
Genoplesium baueri Yellow Gnat-orchid [7528]	Endangered	Species or species habitat likely to occur within area
Grevillea caleyi Caley's Grevillea [9683]	Critically Endangered	Species or species habitat likely to occur within area
Grevillea parviflora subsp. parviflora Small-flower Grevillea [64910]	Vulnerable	Species or species habitat may occur within area
Grevillea shiressii [19186]	Vulnerable	Species or species habitat may occur within area
Haloragis exalata subsp. exalata Wingless Raspwort, Square Raspwort [24636]	Vulnerable	Species or species habitat likely to occur within area
Haloragodendron lucasii Hal [6480]	Endangered	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Hicksbeachia pinnatifolia Monkey Nut, Bopple Nut, Red Bopple, Red Bopple Nut, Red Nut, Beef Nut, Red Apple Nut, Red Boppel Nut, Ivory Silky Oak [21189]	Vulnerable	Species or species habitat may occur within area
Kunzea rupestris [8798]	Vulnerable	Species or species habitat likely to occur within area
Lepidorrhachis mooreana Little Mountain Palm, Moorei Palm [6388]	Critically Endangered	Species or species habitat known to occur within area
Macadamia integrifolia Macadamia Nut, Queensland Nut Tree, Smooth-shelled Macadamia, Bush Nut, Nut Oak [7326]	Vulnerable	Species or species habitat may occur within area
Macadamia tetraphylla Rough-shelled Bush Nut, Macadamia Nut, Rough-shelled Macadamia, Rough-leaved Queensland Nut [6581]	Vulnerable	Species or species habitat known to occur within area
Marsdenia longiloba Clear Milkvine [2794]	Vulnerable	Species or species habitat likely to occur within area
Melaleuca biconvexa Biconvex Paperbark [5583]	Vulnerable	Species or species habitat known to occur within area
Melaleuca deanei Deane's Melaleuca [5818]	Vulnerable	Species or species habitat may occur within area
Parsonsia dorrigoensis Milky Silkpod [64684]	Endangered	Species or species habitat likely to occur within area
Persicaria elatior Knotweed, Tall Knotweed [5831]	Vulnerable	Species or species habitat likely to occur within area
Persoonia hirsuta Hairy Geebung, Hairy Persoonia [19006]	Endangered	Species or species habitat known to occur within area
Phaius australis Lesser Swamp-orchid [5872]	Endangered	Species or species habitat known to occur within area
Pimelea curviflora var. curviflora [4182]	Vulnerable	Species or species habitat known to occur within area
Pimelea spicata Spiked Rice-flower [20834]	Endangered	Species or species habitat likely to occur within area
Polystichum moorei Rock Shield Fern [40755]	Endangered	Species or species habitat likely to occur within area
Prasophyllum sp. Wybong (C.Phelps ORG 5269) a leek-orchid [81964]	Critically Endangered	Species or species habitat may occur within area
Prostanthera askania Tranquillity Mintbush, Tranquility Mintbush [64958]	Endangered	Species or species habitat known to occur within area
Prostanthera densa Villous Mintbush [12233]	Vulnerable	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Prostanthera junonis Somersby Mintbush [64960]	Endangered	Species or species habitat may occur within area
Pterostylis gibbosa Illawarra Greenhood, Rufa Greenhood, Pouched Greenhood [4562]	Endangered	Species or species habitat likely to occur within area
Pterostylis saxicola Sydney Plains Greenhood [64537]	Endangered	Species or species habitat may occur within area
Pterostylis sp. Botany Bay (A.Bishop J221/1-13) Botany Bay Bearded Greenhood, Botany Bay Bearded Orchid [64965]	Endangered	Species or species habitat likely to occur within area
Pultenaea aristata [18062]	Vulnerable	Species or species habitat likely to occur within area
Pultenaea glabra Smooth Bush-pea, Swamp Bush-pea [11887]	Vulnerable	Species or species habitat likely to occur within area
Rutidosis heterogama Heath Wrinklewort [13132]	Vulnerable	Species or species habitat known to occur within area
Samadera sp. Moonee Creek (J.King s.n. Nov. 1949) [86885]	Endangered	Species or species habitat likely to occur within area
Syzygium paniculatum Magenta Lilly Pilly, Magenta Cherry, Daguba, Scrub Cherry, Creek Lilly Pilly, Brush Cherry [20307]	Vulnerable	Species or species habitat known to occur within area
Tetratheca juncea Black-eyed Susan [21407]	Vulnerable	Species or species habitat known to occur within area
Thelymitra kangaloonica Kangaloon Sun Orchid [81861]	Critically Endangered	Species or species habitat may occur within area
Thesium australe Austral Toadflax, Toadflax [15202]	Vulnerable	Species or species habitat known to occur within area
Tylophora woollsii [20503]	Endangered	Species or species habitat likely to occur within area
Xylosma parvifolia [48040]	Endangered	Species or species habitat known to occur within area
Zieria granulata Hill Zieria, Hilly Zieria, Illawarra Zieria [17147]	Endangered	Species or species habitat likely to occur within area
Zieria prostrata Headland Zieria [56782]	Endangered	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Name	Status	Type of Presence
Christinus guentheri		
Lord Howe Island Gecko, Lord Howe Island Southern Gecko [59250]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hoplocephalus bungaroides		
Broad-headed Snake [1182]	Vulnerable	Species or species habitat likely to occur within area
Natator depressus		
Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Oligosoma lichenigera		
Lord Howe Island Skink [82034]	Vulnerable	Species or species habitat known to occur within area
Saiphos reticulatus		
Three-toed Snake-tooth Skink [88328]	Vulnerable	Species or species habitat may occur within area
Sharks		
Carcharias taurus (east coast population)		
Grey Nurse Shark (east coast population) [68751]	Critically Endangered	Species or species habitat known to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Rhincodon typus		
Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus		
Common Noddy [825]		Breeding known to occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes		
Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Breeding known to occur within area
Ardenna grisea		
Sooty Shearwater [82651]		Breeding known to occur within area
Ardenna pacifica		
Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Ardenna tenuirostris		
Short-tailed Shearwater [82652]		Breeding known to occur within area
Calonectris leucomelas		
Streaked Shearwater [1077]		Species or species habitat known to occur within area
Diomedea antipodensis		
Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Breeding known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Sternula albifrons Little Tern [82849]		Breeding known to occur within area
Sula dactylatra Masked Booby [1021]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur

Name	Threatened	Type of Presence
		within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat may occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Dugong dugon Dugong [28]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat known to occur within area
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat known to occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat known to occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species

Name	Threatened	Type of Presence
		habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris subminuta Long-toed Stint [861]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Foraging, feeding or related behaviour known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Species or species habitat known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Thalasseus bergii Crested Tern [83000]		Breeding known to occur

Name	Threatened	Type of Presence
		within area
[Tringa brevipes] Grey-tailed Tattler [851]		Roosting known to occur within area
[Tringa incana] Wandering Tattler [831]		Roosting known to occur within area
[Tringa nebularia] Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
[Tringa stagnatilis] Marsh Sandpiper, Little Greenshank [833]		Foraging, feeding or related behaviour known to occur within area
[Xenus cinereus] Terek Sandpiper [59300]		Roosting known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Nobbys Lighthouse	NSW	Listed place
North Head Artillery Barracks	NSW	Listed place
Shark Point Battery	NSW	Listed place
Smoky Cape Lighthouse	NSW	Listed place
Sugarloaf Point Lighthouse	NSW	Listed place
Ten Terminal Regiment Headquarters and AusAid Training Centre	NSW	Listed place

Listed Marine Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus Common Noddy [825]		Breeding known to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Breeding known to occur within area
Ardea ibis Cattle Egret [59542]		Breeding likely to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris subminuta Long-toed Stint [861]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur

Name	Threatened	Type of Presence
		within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius ruficapillus Red-capped Plover [881]		Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eudyptula minor Little Penguin [1085]		Breeding known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Foraging, feeding or related behaviour known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Heteroscelus brevipes Grey-tailed Tattler [59311]		Roosting known to occur within area
Heteroscelus incanus Wandering Tattler [59547]		Roosting known to occur within area
Himantopus himantopus Pied Stilt, Black-winged Stilt [870]		Roosting known to occur within area
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat known to occur within area
Larus dominicanus Kelp Gull [809]		Breeding known to occur within area

Name	Threatened	Type of Presence
Larus novaehollandiae Silver Gull [810]		Breeding known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat known to occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat known to occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Pelagodroma marina White-faced Storm-Petrel [1016]		Breeding known to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Breeding known to occur within area

Name	Threatened	Type of Presence
Philomachus pugnax Ruff (Reeve) [850]		Species or species habitat known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Procelsterna cerulea Grey Noddy, Grey Ternlet [64378]		Breeding known to occur within area
Pterodroma nigripennis Black-winged Petrel [1038]		Breeding known to occur within area
Pterodroma solandri Providence Petrel [1040]		Breeding known to occur within area
Puffinus assimilis Little Shearwater [59363]		Breeding known to occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Breeding known to occur within area
Puffinus griseus Sooty Shearwater [1024]		Breeding known to occur within area
Puffinus pacificus Wedge-tailed Shearwater [1027]		Breeding known to occur within area
Puffinus tenuirostris Short-tailed Shearwater [1029]		Breeding known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Roosting known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Sterna albifrons Little Tern [813]		Breeding known to occur within area
Sterna bergii Crested Tern [816]		Breeding known to occur within area
Sula dactylatra Masked Booby [1021]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed	Vulnerable	Species or species

Name	Threatened	Type of Presence
Albatross [64459]		habitat may occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Foraging, feeding or related behaviour known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area
Fish		
Acentronura tentaculata Shortpouch Pygmy Pipehorse [66187]		Species or species habitat may occur within area
Campichthys tryoni Tryon's Pipefish [66193]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys ocellatus Orange-spotted Pipefish, Ocellated Pipefish [66203]		Species or species habitat may occur within area
Cosmocampus howensis Lord Howe Pipefish [66208]		Species or species habitat may occur within area
Festucalex cinctus Girdled Pipefish [66214]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus boothae Booth's Pipefish [66218]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippichthys cyanospilos Blue-speckled Pipefish, Blue-spotted Pipefish [66228]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Hippichthys heptagonus Madura Pipefish, Reticulated Freshwater Pipefish [66229]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus kelloggi Kellogg's Seahorse, Great Seahorse [66723]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Hippocampus whitei White's Seahorse, Crowned Seahorse, Sydney Seahorse [66240]		Species or species habitat known to occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Micrognathus andersonii Anderson's Pipefish, Shortnose Pipefish [66253]		Species or species habitat may occur within area
Micrognathus brevirostris thorntail Pipefish, Thorn-tailed Pipefish [66254]		Species or species habitat may occur within area
Microphis manadensis Manado Pipefish, Manado River Pipefish [66258]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Solegnathus dunckeri Duncker's Pipehorse [66271]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Solenostomus paradoxus Ornate Ghostpipefish, Harlequin Ghost Pipefish, Ornate Ghost Pipefish [66184]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area
Dugong dugon Dugong [28]		Species or species habitat may occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known

Name	Threatened	Type of Presence
		to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat may occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Berardius arnuxii Arnoux's Beaked Whale [70]		Species or species habitat may occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Globicephala melas Long-finned Pilot Whale [59282]		Species or species habitat may occur within area

Name	Status	Type of Presence
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Hyperoodon planifrons Southern Bottlenose Whale [71]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lissodelphis peronii Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Mesoplodon grayi Gray's Beaked Whale, Scamperdown Whale [75]		Species or species habitat may occur within area
Mesoplodon hectori Hector's Beaked Whale [76]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
Mesoplodon mirus True's Beaked Whale [54]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat likely to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tasmacetus shepherdi Shepherd's Beaked Whale, Tasman Beaked Whale [55]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Australian Marine Parks [Resource Information]

Name	Label
Central Eastern	Habitat Protection Zone (IUCN IV)

Name	State
North East NSW RFA	New South Wales

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Acridotheres tristis Common Myna, Indian Myna [387]		Species or species habitat likely to occur within area
Alauda arvensis Skylark [656]		Species or species habitat likely to occur within area
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Carduelis carduelis European Goldfinch [403]		Species or species habitat likely to occur within area
Carduelis chloris European Greenfinch [404]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Lonchura punctulata Nutmeg Mannikin [399]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Passer montanus Eurasian Tree Sparrow [406]		Species or species habitat likely to occur within area
Pycnonotus jocosus Red-whiskered Bulbul [631]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Turdus merula Common Blackbird, Eurasian Blackbird [596]		Species or species habitat likely to occur within area
Turdus philomelos Song Thrush [597]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Capra hircus Goat [2]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Feral deer Feral deer species in Australia [85733]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus norvegicus Brown Rat, Norway Rat [83]		Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Rattus rattus		
Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa		
Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes		
Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Alternanthera philoxeroides		
Alligator Weed [11620]		Species or species habitat likely to occur within area
Anredera cordifolia		
Madeira Vine, Jalap, Lamb's-tail, Mignonette Vine, Anredera, Gulf Madeiravine, Heartleaf Madeiravine, Potato Vine [2643]		Species or species habitat likely to occur within area
Asparagus aethiopicus		
Asparagus Fern, Ground Asparagus, Basket Fern, Sprengi's Fern, Bushy Asparagus, Emerald Asparagus [62425]		Species or species habitat likely to occur within area
Asparagus asparagoides		
Bridal Creeper, Bridal Veil Creeper, Smilax, Florist's Smilax, Smilax Asparagus [22473]		Species or species habitat likely to occur within area
Asparagus plumosus		
Climbing Asparagus-fern [48993]		Species or species habitat likely to occur within area
Asparagus scandens		
Asparagus Fern, Climbing Asparagus Fern [23255]		Species or species habitat likely to occur within area
Cabomba caroliniana		
Cabomba, Fanwort, Carolina Watershield, Fish Grass, Washington Grass, Watershield, Carolina Fanwort, Common Cabomba [5171]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera		
Bitou Bush, Boneseed [18983]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera subsp. monilifera		
Boneseed [16905]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera subsp. rotundata		
Bitou Bush [16332]		Species or species habitat likely to occur within area
Cytisus scoparius		
Broom, English Broom, Scotch Broom, Common Broom, Scottish Broom, Spanish Broom [5934]		Species or species habitat likely to occur within area
Dolichandra unguis-cati		
Cat's Claw Vine, Yellow Trumpet Vine, Cat's Claw Creeper, Funnel Creeper [85119]		Species or species habitat likely to occur within area
Eichhornia crassipes		
Water Hyacinth, Water Orchid, Nile Lily [13466]		Species or species habitat likely to occur within area
Genista linifolia		
Flax-leaved Broom, Mediterranean Broom, Flax Broom [2800]		Species or species habitat likely to occur within area
Genista monspessulana		
Montpellier Broom, Cape Broom, Canary Broom, Common Broom, French Broom, Soft Broom		Species or species habitat likely to occur

Name	Status	Type of Presence
[20126]		within area
Genista sp. X Genista monspessulana		
Broom [67538]		Species or species habitat may occur within area
Lantana camara		
Lantana, Common Lantana, Kamara Lantana, Large-leaf Lantana, Pink Flowered Lantana, Red Flowered Lantana, Red-Flowered Sage, White Sage, Wild Sage [10892]		Species or species habitat likely to occur within area
Lycium ferocissimum		
African Boxthorn, Boxthorn [19235]		Species or species habitat likely to occur within area
Nassella neesiana		
Chilean Needle grass [67699]		Species or species habitat likely to occur within area
Nassella trichotoma		
Serrated Tussock, Yass River Tussock, Yass Tussock, Nassella Tussock (NZ) [18884]		Species or species habitat likely to occur within area
Opuntia spp.		
Prickly Pears [82753]		Species or species habitat likely to occur within area
Pinus radiata		
Radiata Pine Monterey Pine, Insignis Pine, Wilding Pine [20780]		Species or species habitat may occur within area
Rubus fruticosus aggregate		
Blackberry, European Blackberry [68406]		Species or species habitat likely to occur within area
Sagittaria platyphylla		
Delta Arrowhead, Arrowhead, Slender Arrowhead [68483]		Species or species habitat likely to occur within area
Salix spp. except S.babylonica, S.x calodendron & S.x reichardtii		
Willows except Weeping Willow, Pussy Willow and Sterile Pussy Willow [68497]		Species or species habitat likely to occur within area
Salvinia molesta		
Salvinia, Giant Salvinia, Aquarium Watermoss, Kariba Weed [13665]		Species or species habitat likely to occur within area
Senecio madagascariensis		
Fireweed, Madagascar Ragwort, Madagascar Groundsel [2624]		Species or species habitat likely to occur within area
Solanum elaeagnifolium		
Silver Nightshade, Silver-leaved Nightshade, White Horse Nettle, Silver-leaf Nightshade, Tomato Weed, White Nightshade, Bull-nettle, Prairie-berry, Satansbos, Silver-leaf Bitter-apple, Silverleaf-nettle, Trompillo [12323]		Species or species habitat likely to occur within area
Ulex europaeus		
Gorse, Furze [7693]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus		
Asian House Gecko [1708]		Species or species habitat likely to occur within area

Nationally Important Wetlands

[Resource Information]

Name	State
Avoca Lagoon	NSW
Clybucca Creek Estuary	NSW
Cockrone Lagoon	NSW
Crowdy Bay National Park	NSW

Name	State
Five Islands Nature Reserve	NSW
Limeburners Creek Nature Reserve	NSW
Port Stephens Estuary	NSW

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Canyons on the eastern continental slope	Temperate east
Lord Howe seamount chain	Temperate east
Shelf rocky reefs	Temperate east
Tasman Front and eddy field	Temperate east
Tasmantid seamount chain	Temperate east

Caveat
The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

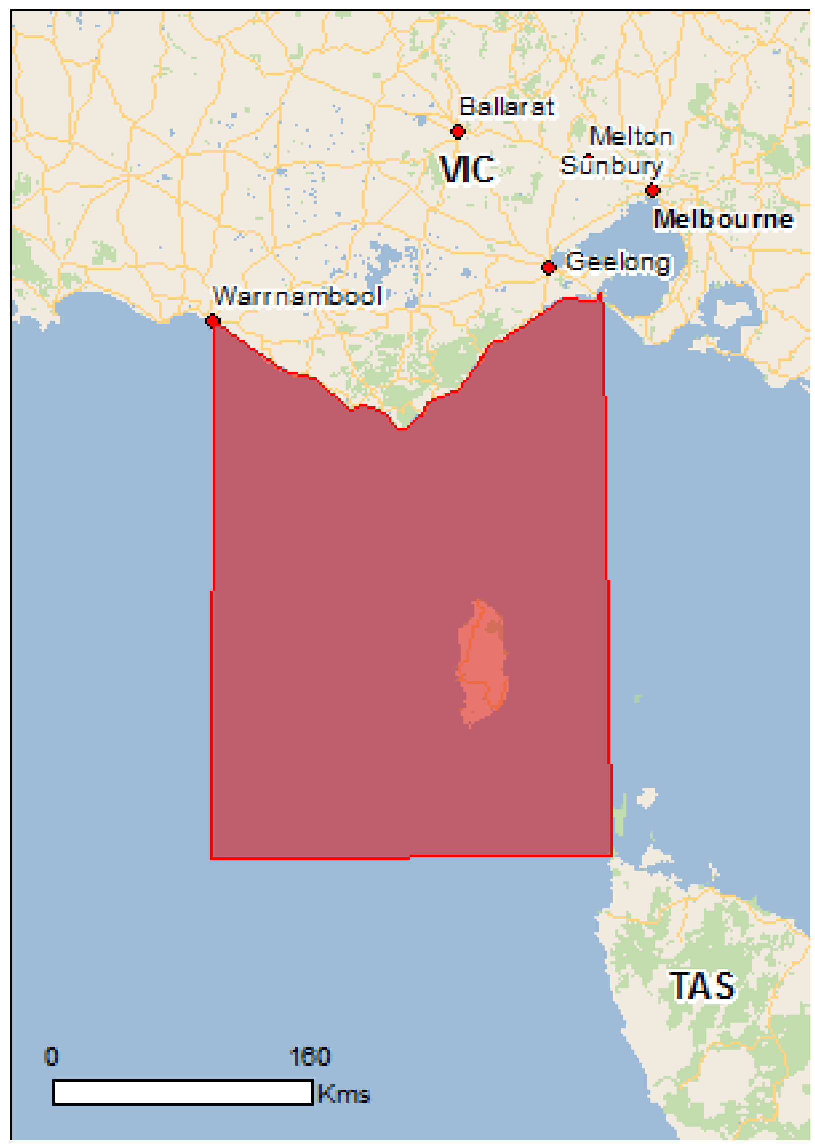
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

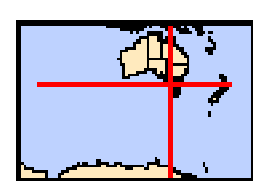
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 27/05/19 20:05:01



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	2
Wetlands of International Importance:	2
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	8
Listed Threatened Species:	98
Listed Migratory Species:	69

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	1
Commonwealth Heritage Places:	1
Listed Marine Species:	113
Whales and Other Cetaceans:	29
Critical Habitats:	1
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	4

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	63
Regional Forest Agreements:	2
Invasive Species:	52
Nationally Important Wetlands:	11
Key Ecological Features (Marine)	1

Details

Matters of National Environmental Significance

National Heritage Properties [Resource Information]

Name	State	Status
Historic		
Great Ocean Road and Scenic Environs	VIC	Listed place
Point Nepean Defence Sites and Quarantine Station Area	VIC	Listed place

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Lavinia	Within Ramsar site
Port phillip bay (western shoreline) and bellarine peninsula	Within Ramsar site

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community	Endangered	Community likely to occur within area
Giant Kelp Marine Forests of South East Australia	Endangered	Community may occur within area
Grassy Eucalypt Woodland of the Victorian Volcanic Plain	Critically Endangered	Community likely to occur within area
Natural Damp Grassland of the Victorian Coastal Plains	Critically Endangered	Community likely to occur within area
Natural Temperate Grassland of the Victorian Volcanic Plain	Critically Endangered	Community likely to occur within area
Seasonal Herbaceous Wetlands (Freshwater) of the Temperate Lowland Plains	Critically Endangered	Community likely to occur within area
Subtropical and Temperate Coastal Saltmarsh	Vulnerable	Community likely to occur within area
White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland	Critically Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Acanthiza pusilla archibaldi		
King Island Brown Thornbill, Brown Thornbill (King Island) [59430]	Endangered	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Acanthornis magna greeniana King Island Scrubtit, Scrubtit (King Island) [82329]	Critically Endangered	Species or species habitat known to occur within area
Anthochaera phrygia Regent Honeyeater [82338]	Critically Endangered	Foraging, feeding or related behaviour likely to occur within area
Aquila audax fleayi Tasmanian Wedge-tailed Eagle, Wedge-tailed Eagle (Tasmanian) [64435]	Endangered	Breeding likely to occur within area
Botaurus poiciloptilus Australasian Bittern [1001]	Endangered	Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Ceyx azureus diemenensis Tasmanian Azure Kingfisher [25977]	Endangered	Species or species habitat known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur within area
Pedionomus torquatus Plains-wanderer [906]	Critically Endangered	Species or species habitat likely to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Platycercus caledonicus brownii Green Rosella (King Island) [67041]	Vulnerable	Species or species habitat known to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding likely to occur within area
Strepera fuliginosa colei Black Currawong (King Island) [67113]	Vulnerable	Breeding likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Breeding known to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area

Name	Status	Type of Presence
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini		
Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis rubricollis		
Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tyto novaehollandiae castanops (Tasmanian population)		
Masked Owl (Tasmanian) [67051]	Vulnerable	Species or species habitat known to occur within area
Crustaceans		
Astacopsis gouldi		
Giant Freshwater Crayfish, Tasmanian Giant Freshwater Lobster [64415]	Vulnerable	Species or species habitat may occur within area
Fish		
Galaxiella pusilla		
Eastern Dwarf Galaxias, Dwarf Galaxias [56790]	Vulnerable	Species or species habitat likely to occur within area
Maccullochella peelii		
Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Nannoperca obscura		
Yarra Pygmy Perch [26177]	Vulnerable	Species or species habitat likely to occur within area
Prototroctes maraena		
Australian Grayling [26179]	Vulnerable	Species or species habitat known to occur within area
Frogs		
Litoria raniformis		
Growling Grass Frog, Southern Bell Frog, Green and Golden Frog, Warty Swamp Frog [1828]	Vulnerable	Species or species habitat known to occur within area
Insects		
Synemon plana		
Golden Sun Moth [25234]	Critically Endangered	Species or species habitat may occur within area
Mammals		
Antechinus minimus maritimus		
Swamp Antechinus (mainland) [83086]	Vulnerable	Species or species habitat known to occur within area
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Dasyurus maculatus maculatus (SE mainland population)		
Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (southeastern mainland population) [75184]	Endangered	Species or species habitat known to occur within area

Name	Status	Type of Presence
Dasyurus maculatus maculatus (Tasmanian population) Spotted-tail Quoll, Spot-tailed Quoll, Tiger Quoll (Tasmanian population) [75183]	Vulnerable	Species or species habitat known to occur within area
Dasyurus viverrinus Eastern Quoll, Luaner [333]	Endangered	Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Breeding known to occur within area
Isoodon obesulus obesulus Southern Brown Bandicoot (eastern), Southern Brown Bandicoot (south-eastern) [68050]	Endangered	Species or species habitat known to occur within area
Mastacomys fuscus mordicus Broad-toothed Rat (mainland), Tooarrana [87617]	Vulnerable	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Miniopterus orianae bassanii Southern Bent-wing Bat [87645]	Critically Endangered	Breeding known to occur within area
Neophoca cinerea Australian Sea-lion, Australian Sea Lion [22]	Vulnerable	Species or species habitat known to occur within area
Perameles gunnii gunnii Eastern Barred Bandicoot (Tasmania) [66651]	Vulnerable	Species or species habitat likely to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat may occur within area
Potorous tridactylus tridactylus Long-nosed Potoroo (SE mainland) [66645]	Vulnerable	Species or species habitat known to occur within area
Pseudomys fumeus Smoky Mouse, Konoom [88]	Endangered	Species or species habitat likely to occur within area
Pseudomys novaehollandiae New Holland Mouse, Pookila [96]	Vulnerable	Species or species habitat likely to occur within area
Pteropus poliocephalus Grey-headed Flying-fox [186]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Sarcophilus harrisii Tasmanian Devil [299]	Endangered	Species or species habitat likely to occur within area
Plants		
Amphibromus fluitans River Swamp Wallaby-grass, Floating Swamp Wallaby-grass [19215]	Vulnerable	Species or species habitat likely to occur within area
Caladenia caudata Tailed Spider-orchid [17067]	Vulnerable	Species or species habitat likely to occur within area
Diuris lanceolata Snake Orchid [10231]	Endangered	Species or species habitat known to occur within area
Glycine latrobeana Clover Glycine, Purple Clover [13910]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Haloragis exalata subsp. exalata Wingless Raspwort, Square Raspwort [24636]	Vulnerable	Species or species habitat known to occur within area
Hypolepis distans Scrambling Ground-fern [2148]	Endangered	Species or species habitat likely to occur within area
Ixodia achillaeoides subsp. arenicola Sand Ixodia, Ixodia [21474]	Vulnerable	Species or species habitat may occur within area
Lachnagrostis adamsonii Adamson's Blown-grass, Adamson's Blowngrass [76211]	Endangered	Species or species habitat may occur within area
Leiocarpa gatesii Wrinkled Buttons [76212]	Vulnerable	Species or species habitat likely to occur within area
Lepidium aschersonii Spiny Pepper-cress [10976]	Vulnerable	Species or species habitat likely to occur within area
Pimelea spinescens subsp. spinescens Plains Rice-flower, Spiny Rice-flower, Prickly Pimelea [21980]	Critically Endangered	Species or species habitat likely to occur within area
Prasophyllum frenchii Maroon Leek-orchid, Slaty Leek-orchid, Stout Leek-orchid, French's Leek-orchid, Swamp Leek-orchid [9704]	Endangered	Species or species habitat likely to occur within area
Prasophyllum secutum Northern Leek-orchid [64954]	Endangered	Species or species habitat likely to occur within area
Prasophyllum spicatum Dense Leek-orchid [55146]	Vulnerable	Species or species habitat known to occur within area
Pterostylis chlorogramma Green-striped Greenhood [56510]	Vulnerable	Species or species habitat likely to occur within area
Pterostylis cucullata Leafy Greenhood [15459]	Vulnerable	Species or species habitat known to occur within area
Pterostylis tenuissima Swamp Greenhood, Dainty Swamp Orchid [13139]	Vulnerable	Species or species habitat known to occur within area
Pterostylis ziegeleri Grassland Greenhood, Cape Portland Greenhood [64971]	Vulnerable	Species or species habitat may occur within area
Senecio psilocarpus Swamp Fireweed, Smooth-fruited Groundsel [64976]	Vulnerable	Species or species habitat likely to occur within area
Taraxacum cygnorum Coast Dandelion [2508]	Vulnerable	Species or species habitat likely to occur within area
Thelymitra epipactoides Metallic Sun-orchid [11896]	Endangered	Species or species habitat known to occur within area
Thelymitra matthewsii Spiral Sun-orchid [4168]	Vulnerable	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Xerochrysum palustre Swamp Everlasting, Swamp Paper Daisy [76215]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area
Ardenna tenuirostris Short-tailed Shearwater [82652]		Breeding known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Sternula albifrons Little Tern [82849]		Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Breeding known to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Breeding known to occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species

Name	Threatened	Type of Presence
		habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Migratory Terrestrial Species		
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat known to occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat likely to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur

Name	Threatened	Type of Presence
		within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Phalaropus lobatus Red-necked Phalarope [838]		Roosting known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat likely to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Pelagodroma marina White-faced Storm-Petrel [1016]		Breeding known to occur within area
Pelecanoides urinatrix Common Diving-Petrel [1018]		Breeding known to occur within area
Phalacrocorax fuscescens Black-faced Cormorant [59660]		Breeding known to occur within area
Phalaropus lobatus Red-necked Phalarope [838]		Roosting known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Foraging, feeding or related behaviour likely to occur within area
Puffinus tenuirostris Short-tailed Shearwater [1029]		Breeding known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Roosting known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Sterna albifrons Little Tern [813]		Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Breeding known to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis Hooded Plover [59510]		Species or species habitat known to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species

Name	Threatened	Type of Presence
		habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus minotaur Bullneck Seahorse [66705]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area
Lissocampus caudalis Australian Smooth Pipefish, Smooth Pipefish [66249]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys mollisoni Mollison's Pipefish [66260]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phycodurus eques Leafy Seadragon [66267]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Pugnaso curtirostris Pugnose Pipefish, Pug-nosed Pipefish [66269]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Breeding likely to occur within area
Neophoca cinerea Australian Sea-lion, Australian Sea Lion [22]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Name	Threatened	Type of Presence
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area

Whales and other Cetaceans

[Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata		
Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis		
Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Berardius arnuxii		
Arnoux's Beaked Whale [70]		Species or species habitat may occur within area
Caperea marginata		
Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis		
Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis		
Southern Right Whale [40]	Endangered	Breeding known to occur within area
Globicephala macrorhynchus		
Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Globicephala melas		
Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
Grampus griseus		
Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Kogia breviceps		
Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus		
Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenorhynchus obscurus		
Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lissodelphis peronii		
Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae		
Humpback Whale [38]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon grayi Gray's Beaked Whale, Scamperdown Whale [75]		Species or species habitat may occur within area
Mesoplodon hectori Hector's Beaked Whale [76]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
Mesoplodon mirus True's Beaked Whale [54]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Acridotheres tristis Common Myna, Indian Myna [387]		Species or species habitat likely to occur within area
Alauda arvensis Skylark [656]		Species or species habitat likely to occur within area
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Callipepla californica California Quail [59451]		Species or species habitat likely to occur within area
Carduelis carduelis European Goldfinch [403]		Species or species habitat likely to occur within area
Carduelis chloris European Greenfinch [404]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Meleagris gallopavo Wild Turkey [64380]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Passer montanus Eurasian Tree Sparrow [406]		Species or species habitat likely to occur within area
Pavo cristatus Indian Peafowl, Peacock [919]		Species or species habitat likely to occur within area
Phasianus colchicus Common Pheasant [920]		Species or species habitat likely to occur within area
Pycnonotus jocosus Red-whiskered Bulbul [631]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Turdus merula Common Blackbird, Eurasian Blackbird [596]		Species or species habitat likely to occur within area
Turdus philomelos Song Thrush [597]		Species or species habitat likely to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Capra hircus Goat [2]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Feral deer Feral deer species in Australia [85733]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus norvegicus Brown Rat, Norway Rat [83]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Alternanthera philoxeroides Alligator Weed [11620]		Species or species habitat likely to occur within area
Anredera cordifolia Madeira Vine, Jalap, Lamb's-tail, Mignonette Vine, Anredera, Gulf Madeiravine, Heartleaf Madeiravine, Potato Vine [2643]		Species or species habitat likely to occur within area
Asparagus asparagoides Bridal Creeper, Bridal Veil Creeper, Smilax, Florist's Smilax, Smilax Asparagus [22473]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Asparagus scandens Asparagus Fern, Climbing Asparagus Fern [23255]		Species or species habitat likely to occur within area
Austrocylindropuntia spp. Prickly Pears [85132]		Species or species habitat likely to occur within area
Carrichtera annua Ward's Weed [9511]		Species or species habitat may occur within area
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat may occur within area
Chrysanthemoides monilifera Bitou Bush, Boneseed [18983]		Species or species habitat may occur within area
Chrysanthemoides monilifera subsp. monilifera Boneseed [16905]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera subsp. rotundata Bitou Bush [16332]		Species or species habitat likely to occur within area
Cytisus scoparius Broom, English Broom, Scotch Broom, Common Broom, Scottish Broom, Spanish Broom [5934]		Species or species habitat likely to occur within area
Eichhornia crassipes Water Hyacinth, Water Orchid, Nile Lily [13466]		Species or species habitat likely to occur within area
Genista linifolia Flax-leaved Broom, Mediterranean Broom, Flax Broom [2800]		Species or species habitat likely to occur within area
Genista monspessulana Montpellier Broom, Cape Broom, Canary Broom, Common Broom, French Broom, Soft Broom [20126]		Species or species habitat likely to occur within area
Genista sp. X Genista monspessulana Broom [67538]		Species or species habitat may occur within area
Lycium ferocissimum African Boxthorn, Boxthorn [19235]		Species or species habitat likely to occur within area
Nassella neesiana Chilean Needle grass [67699]		Species or species habitat likely to occur within area
Nassella trichotoma Serrated Tussock, Yass River Tussock, Yass Tussock, Nassella Tussock (NZ) [18884]		Species or species habitat likely to occur within area
Olea europaea Olive, Common Olive [9160]		Species or species habitat may occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Rubus fruticosus aggregate Blackberry, European Blackberry [68406]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Salix spp. except S.babylonica, S.x calodendron & S.x reichardtii Willows except Weeping Willow, Pussy Willow and Sterile Pussy Willow [68497]		Species or species habitat likely to occur within area
Ulex europaeus Gorse, Furze [7693]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

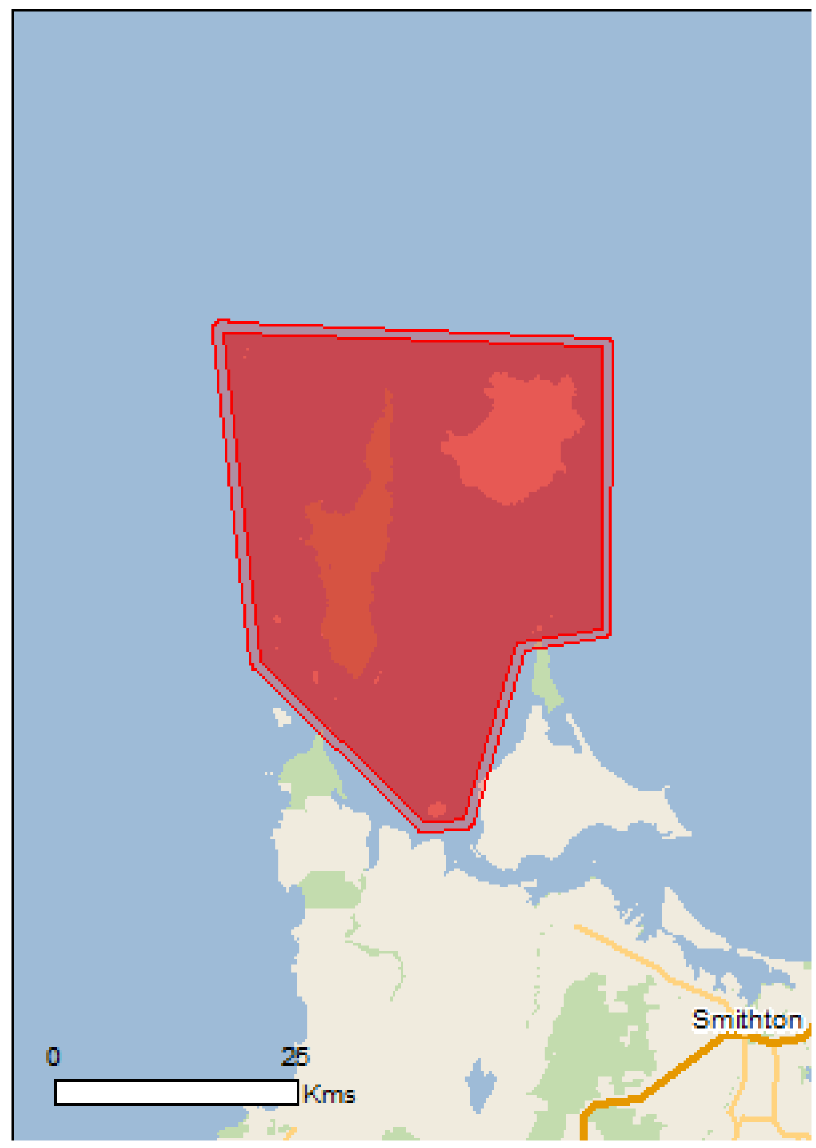
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

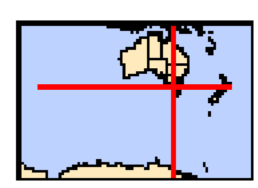
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 15/05/19 16:27:26



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	1
Listed Threatened Species:	58
Listed Migratory Species:	60

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	99
Whales and Other Cetaceans:	13
Critical Habitats:	1
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	10
Regional Forest Agreements:	1
Invasive Species:	21
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Giant Kelp Marine Forests of South East Australia	Endangered	Community may occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Aquila audax fleayi		
Tasmanian Wedge-tailed Eagle, Wedge-tailed Eagle (Tasmanian) [64435]	Endangered	Breeding likely to occur within area
Botaurus poiciloptilus		
Australasian Bittern [1001]	Endangered	Species or species habitat likely to occur within area
Calidris canutus		
Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris		
Great Knot [862]	Critically Endangered	Roosting known to occur within area
Ceyx azureus diemenensis		
Tasmanian Azure Kingfisher [25977]	Endangered	Species or species habitat likely to occur within area
Charadrius leschenaultii		
Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus		
Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur

Name	Status	Type of Presence
		within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat likely to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Breeding known to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tyto novaehollandiae castanops (Tasmanian population) Masked Owl (Tasmanian) [67051]	Vulnerable	Species or species habitat known to occur within area
Crustaceans		
Astacopsis gouldi Giant Freshwater Crayfish, Tasmanian Giant Freshwater Lobster [64415]	Vulnerable	Species or species habitat may occur within area
Fish		
Galaxiella pusilla Eastern Dwarf Galaxias, Dwarf Galaxias [56790]	Vulnerable	Species or species habitat may occur within area
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat likely to occur within area
Frogs		
Litoria raniformis Growling Grass Frog, Southern Bell Frog, Green and Golden Frog, Warty Swamp Frog [1828]	Vulnerable	Species or species habitat likely to occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Dasyurus maculatus maculatus (Tasmanian population) Spotted-tail Quoll, Spot-tailed Quoll, Tiger Quoll (Tasmanian population) [75183]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Dasyurus viverrinus Eastern Quoll, Luaner [333]	Endangered	Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Sarcophilus harrisii Tasmanian Devil [299]	Endangered	Species or species habitat likely to occur within area
Plants		
Caladenia caudata Tailed Spider-orchid [17067]	Vulnerable	Species or species habitat likely to occur within area
Caladenia dienema Windswept Spider-orchid [64858]	Endangered	Species or species habitat may occur within area
Diuris lanceolata Snake Orchid [10231]	Endangered	Species or species habitat likely to occur within area
Prasophyllum atratum Three Hummock Leek-orchid [82677]	Critically Endangered	Species or species habitat known to occur within area
Prasophyllum secutum Northern Leek-orchid [64954]	Endangered	Species or species habitat likely to occur within area
Pterostylis cucullata Leafy Greenhood [15459]	Vulnerable	Species or species habitat known to occur within area
Pterostylis ziegeleri Grassland Greenhood, Cape Portland Greenhood [64971]	Vulnerable	Species or species habitat may occur within area
Reptiles		
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Ardenna tenuirostris Short-tailed Shearwater [82652]		Breeding known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Sternula albifrons Little Tern [82849]		Species or species habitat may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Breeding known to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely

Name	Threatened	Type of Presence
		to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat likely to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area

Name	Threatened	Type of Presence
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area

Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pelagodroma marina White-faced Storm-Petrel [1016]		Breeding known to occur within area
Pelecanoides urinatrix Common Diving-Petrel [1018]		Breeding known to occur within area
Phalacrocorax fuscescens Black-faced Cormorant [59660]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Foraging, feeding or related behaviour likely to occur within area
Puffinus tenuirostris Short-tailed Shearwater [1029]		Breeding known to occur within area
Sterna albifrons Little Tern [813]		Species or species habitat may occur within area
Sterna caspia Caspian Tern [59467]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Breeding known to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis Hooded Plover [59510]		Species or species habitat known to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Lissocampus caudalis Australian Smooth Pipefish, Smooth Pipefish [66249]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phycodurus eques Leafy Seadragon [66267]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Pugnaso curtirostris Pugnose Pipefish, Pug-nosed Pipefish [66269]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		

Name	Threatened	Type of Presence
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area
Reptiles		
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Critical Habitats [Resource Information]

Name	Type of Presence
Thalassarche cauta (Shy Albatross) - Albatross Island, The Mewstone, Pedra Branca	Listed Critical Habitat

Extra Information

State and Territory Reserves [Resource Information]

Name	State
Albatross Island	TAS
Bird Island	TAS
Harbour Islets	TAS
Hunter Island	TAS
Kangaroo Island	TAS
Penguin Islet	TAS
Petrel Islands	TAS
Seacrow Islet	TAS
Stack Island	TAS
Three Hummock Island	TAS

Regional Forest Agreements [Resource Information]

Note that all areas with completed RFAs have been included.

Name	State
Tasmania RFA	Tasmania

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Alauda arvensis Skylark [656]		Species or species habitat likely to occur within area
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Carduelis carduelis European Goldfinch [403]		Species or species habitat likely to occur within area
Carduelis chloris European Greenfinch [404]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Pavo cristatus Indian Peafowl, Peacock [919]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Turdus merula Common Blackbird, Eurasian Blackbird [596]		Species or species habitat likely to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Capra hircus Goat [2]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Plants		
Chrysanthemoides monilifera Bitou Bush, Boneseed [18983]		Species or species habitat may occur within area
Lycium ferocissimum African Boxthorn, Boxthorn [19235]		Species or species habitat likely to occur within area
Rubus fruticosus aggregate Blackberry, European Blackberry [68406]		Species or species habitat likely to occur within area
Salix spp. except S.babylonica, S.x calodendron & S.x reichardtii Willows except Weeping Willow, Pussy Willow and Sterile Pussy Willow [68497]		Species or species habitat likely to occur within area
Ulex europaeus Gorse, Furze [7693]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

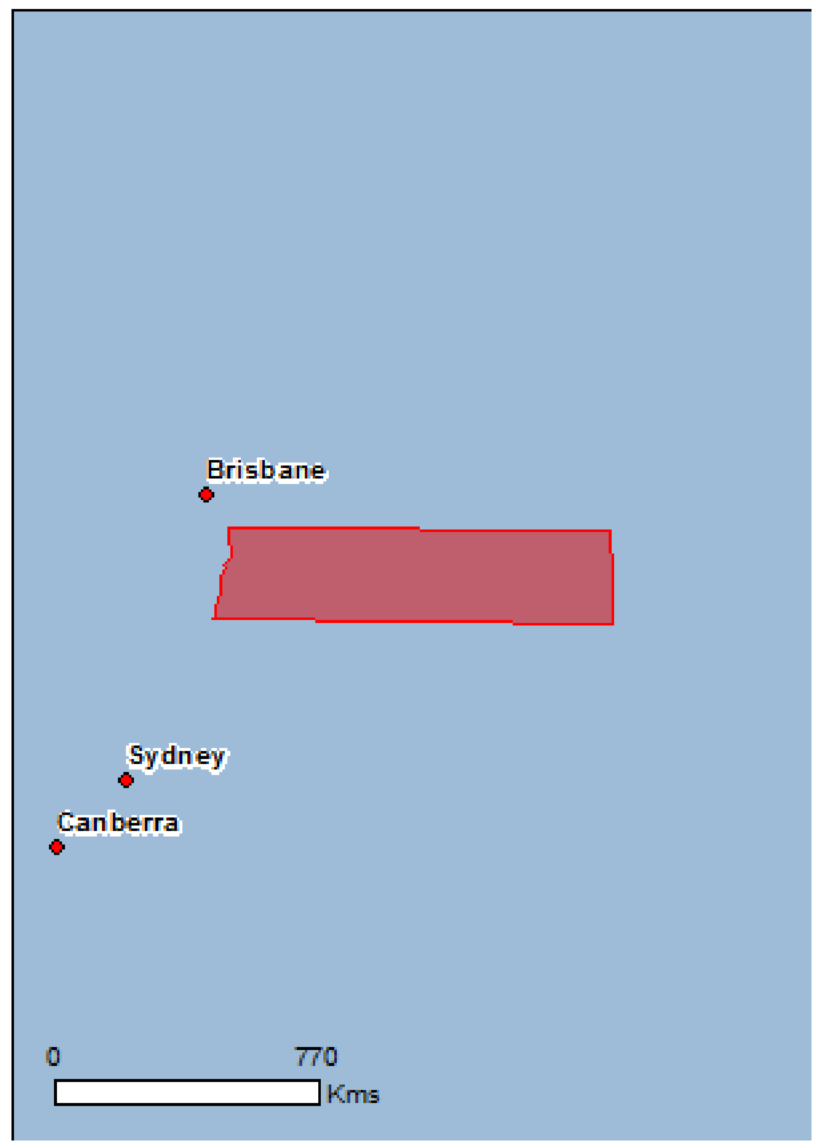
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

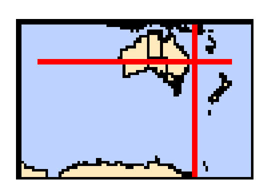
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 02/08/19 16:45:18



Coordinates
Buffer: 2.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	1
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	3
Listed Threatened Species:	107
Listed Migratory Species:	89

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	1
Listed Marine Species:	118
Whales and Other Cetaceans:	36
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	9

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	15
Regional Forest Agreements:	1
Invasive Species:	43
Nationally Important Wetlands:	3
Key Ecological Features (Marine)	6

Details

Matters of National Environmental Significance

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Elizabeth and middleton reefs marine national nature reserve	Within Ramsar site

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea
Extended Continental Shelf

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
Temperate East

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	Endangered	Community likely to occur within area
Littoral Rainforest and Coastal Vine Thickets of Eastern Australia	Critically Endangered	Community likely to occur within area
Subtropical and Temperate Coastal Saltmarsh	Vulnerable	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Anthochaera phrygia		
Regent Honeyeater [82338]	Critically Endangered	Species or species habitat known to occur within area
Botaurus poiciloptilus		
Australasian Bittern [1001]	Endangered	Species or species habitat known to occur within area
Calidris canutus		
Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris		
Great Knot [862]	Critically Endangered	Roosting known to occur within area

Name	Status	Type of Presence
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Cyclopsitta diophthalma coxeni Coxen's Fig-Parrot [59714]	Endangered	Species or species habitat known to occur within area
Dasyornis brachypterus Eastern Bristlebird [533]	Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur

Name	Status	Type of Presence
		within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Poephila cincta cincta Southern Black-throated Finch [64447]	Endangered	Species or species habitat may occur within area
Pterodroma heraldica Herald Petrel [66973]	Critically Endangered	Species or species habitat likely to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma neglecta neglecta Kermadec Petrel (western) [64450]	Vulnerable	Foraging, feeding or related behaviour may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species habitat likely to occur within area
Fish		
Epinephelus daemelii Black Rockcod, Black Cod, Saddled Rockcod [68449]	Vulnerable	Species or species habitat likely to occur within area
Nannoperca oxleyana Oxleyan Pygmy Perch [64468]	Endangered	Species or species habitat known to occur within area
Frogs		
Litoria aurea Green and Golden Bell Frog [1870]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Litoria olongburensis Wallum Sedge Frog [1821]	Vulnerable	Species or species habitat known to occur within area
Mixophyes fleayi Fleay's Frog [25960]	Endangered	Species or species habitat likely to occur within area
Mixophyes iteratus Giant Barred Frog, Southern Barred Frog [1944]	Endangered	Species or species habitat may occur within area
Insects		
Argynnis hyperbius inconstans Australian Fritillary [88056]	Critically Endangered	Species or species habitat likely to occur within area
Phyllodes imperialis smithersi Pink Underwing Moth [86084]	Endangered	Breeding may occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat may occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Chalinolobus dwyeri Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat likely to occur within area
Dasyurus maculatus maculatus (SE mainland population) Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (southeastern mainland population) [75184]	Endangered	Species or species habitat known to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Congregation or aggregation known to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat likely to occur within area
Petrogale penicillata Brush-tailed Rock-wallaby [225]	Vulnerable	Species or species habitat may occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT) Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Potorous tridactylus tridactylus Long-nosed Potoroo (SE Mainland) [66645]	Vulnerable	Species or species habitat likely to occur within area
Pseudomys novaehollandiae New Holland Mouse, Pookila [96]	Vulnerable	Species or species habitat known to occur within area
Pteropus poliocephalus Grey-headed Flying-fox [186]	Vulnerable	Roosting known to occur

Name	Status	Type of Presence
		within area
Xeromys myoides Water Mouse, False Water Rat, Yirrkoo [66]	Vulnerable	Species or species habitat likely to occur within area
Other		
Thersites mitchellae Mitchell's Rainforest Snail [66774]	Critically Endangered	Species or species habitat known to occur within area
Plants		
Acronychia littoralis Scented Acronychia [8582]	Endangered	Species or species habitat likely to occur within area
Allocasuarina thalassoscopica [21927]	Endangered	Species or species habitat known to occur within area
Arthraxon hispidus Hairy-joint Grass [9338]	Vulnerable	Species or species habitat known to occur within area
Corokia whiteana [17820]	Vulnerable	Species or species habitat likely to occur within area
Cryptocarya foetida Stinking Cryptocarya, Stinking Laurel [11976]	Vulnerable	Species or species habitat known to occur within area
Cryptostylis hunteriana Leafless Tongue-orchid [19533]	Vulnerable	Species or species habitat likely to occur within area
Cynanchum elegans White-flowered Wax Plant [12533]	Endangered	Species or species habitat likely to occur within area
Davidsonia jerseyana Davidson's Plum [67219]	Endangered	Species or species habitat known to occur within area
Davidsonia johnsonii Smooth Davidsonia, Smooth Davidson's Plum, Small-leaved Davidson's Plum [67178]	Endangered	Species or species habitat likely to occur within area
Diploglottis campbellii Small-leaved Tamarind [21484]	Endangered	Species or species habitat may occur within area
Elaeocarpus williamsianus Hairy Quandong [8956]	Endangered	Species or species habitat likely to occur within area
Endiandra floydii Floyd's Walnut [52955]	Endangered	Species or species habitat known to occur within area
Endiandra hayesii Rusty Rose Walnut, Velvet Laurel [13866]	Vulnerable	Species or species habitat likely to occur within area
Eucalyptus tetrapleura Square-fruited Ironbark [7490]	Vulnerable	Species or species habitat may occur within area
Floydia praealta Ball Nut, Possum Nut, Big Nut, Beefwood [15762]	Vulnerable	Species or species habitat likely to occur within area
Fontainea australis Southern Fontainea [24037]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat may occur within area
Hicksbeachia pinnatifolia Monkey Nut, Bopple Nut, Red Bopple, Red Bopple Nut, Red Nut, Beef Nut, Red Apple Nut, Red Boppel Nut, Ivory Silky Oak [21189]	Vulnerable	Species or species habitat likely to occur within area
Leucopogon confertus Torrington Beard-heath [14417]	Endangered	Species or species habitat likely to occur within area
Macadamia integrifolia Macadamia Nut, Queensland Nut Tree, Smooth-shelled Macadamia, Bush Nut, Nut Oak [7326]	Vulnerable	Species or species habitat may occur within area
Macadamia tetraphylla Rough-shelled Bush Nut, Macadamia Nut, Rough-shelled Macadamia, Rough-leaved Queensland Nut [6581]	Vulnerable	Species or species habitat known to occur within area
Marsdenia longiloba Clear Milkvine [2794]	Vulnerable	Species or species habitat likely to occur within area
Ochrosia moorei Southern Ochrosia [11350]	Endangered	Species or species habitat likely to occur within area
Olax angulata Minnie Waters Olax [10666]	Vulnerable	Species or species habitat likely to occur within area
Persicaria elatior Knotweed, Tall Knotweed [5831]	Vulnerable	Species or species habitat likely to occur within area
Phaius australis Lesser Swamp-orchid [5872]	Endangered	Species or species habitat known to occur within area
Prostanthera palustris Swamp Mint-bush [66703]	Vulnerable	Species or species habitat likely to occur within area
Randia moorei Spiny Gardenia [10577]	Endangered	Species or species habitat known to occur within area
Rutidosis heterogama Heath Wrinklewort [13132]	Vulnerable	Species or species habitat likely to occur within area
Samadera sp. Moonee Creek (J.King s.n. Nov. 1949) [86885]	Endangered	Species or species habitat likely to occur within area
Syzygium hodgkinsoniae Smooth-bark Rose Apple, Red Lilly Pilly [3539]	Vulnerable	Species or species habitat likely to occur within area
Syzygium moorei Rose Apple, Coolamon, Robby, Durobby, Watermelon Tree, Coolamon Rose Apple [12284]	Vulnerable	Species or species habitat known to occur within area
Thesium australe Austral Toadflax, Toadflax [15202]	Vulnerable	Species or species habitat known to occur within area
Zieria prostrata Headland Zieria [56782]	Endangered	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur

Name	Status	Type of Presence
		within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Furina dunmalli Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Breeding likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sharks		
Carcharias taurus (east coast population) Grey Nurse Shark (east coast population) [68751]	Critically Endangered	Species or species habitat known to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Breeding may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat known to occur within area
Ardenna pacifica Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Sternula albifrons Little Tern [82849]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat likely to occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat may occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding known to occur within area
Dugong dugon Dugong [28]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Breeding likely to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Congregation or aggregation known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Breeding may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat likely to occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris subminuta Long-toed Stint [861]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Thalasseus bergii Crested Tern [83000]		Breeding known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area

Name	Threatened	Type of Presence
Tringa incana Wandering Tattler [831]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area

Cape Byron Lighthouse	NSW	Listed place

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Anseranas semipalmata Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Breeding known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species

Name	Threatened	Type of Presence
		habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat likely to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris subminuta Long-toed Stint [861]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius ruficapillus Red-capped Plover [881]		Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eudyptula minor Little Penguin [1085]		Breeding known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area

Name	Threatened	Type of Presence
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Heteroscelus brevipes Grey-tailed Tattler [59311]		Roosting known to occur within area
Heteroscelus incanus Wandering Tattler [59547]		Roosting known to occur within area
Himantopus himantopus Pied Stilt, Black-winged Stilt [870]		Roosting known to occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Larus novaehollandiae Silver Gull [810]		Breeding known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat likely to occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area

Name	Threatened	Type of Presence
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat may occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Species or species habitat known to occur within area
Puffinus pacificus Wedge-tailed Shearwater [1027]		Breeding known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Species or species habitat known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Sterna albifrons Little Tern [813]		Breeding known to occur within area
Sterna bergii Crested Tern [816]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Species or species habitat may occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area
Fish		
Acentronura tentaculata Shortpouch Pygmy Pipehorse [66187]		Species or species habitat may occur within area
Campichthys tryoni Tryon's Pipefish [66193]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys ocellatus Orange-spotted Pipefish, Ocellated Pipefish [66203]		Species or species habitat may occur within area
Festucalex cinctus Girdled Pipefish [66214]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Hippichthys cyanospilos Blue-speckled Pipefish, Blue-spotted Pipefish [66228]		Species or species habitat may occur within area
Hippichthys heptagonus Madura Pipefish, Reticulated Freshwater Pipefish [66229]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus kelloggi Kellogg's Seahorse, Great Seahorse [66723]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Hippocampus whitei White's Seahorse, Crowned Seahorse, Sydney Seahorse [66240]		Species or species habitat known to occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Micrognathus andersonii Anderson's Pipefish, Shortnose Pipefish [66253]		Species or species habitat may occur within area
Micrognathus brevirostris thorntail Pipefish, Thorn-tailed Pipefish [66254]		Species or species habitat may occur within area
Microphis manadensis Manado Pipefish, Manado River Pipefish [66258]		Species or species habitat may occur within area
Solegnathus dunckeri Duncker's Pipehorse [66271]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Solenostomus paradoxus Ornate Ghostpipefish, Harlequin Ghost Pipefish, Ornate Ghost Pipefish [66184]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Mammals		
Dugong dugon Dugong [28]		Species or species habitat may occur within area
Reptiles		
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Breeding likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat may occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area

Name	Status	Type of Presence
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Globicephala melas Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Hyperoodon planifrons Southern Bottlenose Whale [71]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Lissodelphis peronii Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Congregation or aggregation known to occur within area
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Mesoplodon grayi Gray's Beaked Whale, Scamperdown Whale [75]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
Orcaella brevirostris Irrawaddy Dolphin [45]		Species or species habitat likely to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area

Name	Status	Type of Presence
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

North East NSW RFA	New South Wales

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Acridotheres tristis Common Myna, Indian Myna [387]		Species or species habitat likely to occur within area
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Carduelis carduelis European Goldfinch [403]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Lonchura punctulata Nutmeg Mannikin [399]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Pycnonotus jocosus Red-whiskered Bulbul [631]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Turdus merula Common Blackbird, Eurasian Blackbird [596]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Feral deer Feral deer species in Australia [85733]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus norvegicus Brown Rat, Norway Rat [83]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Alternanthera philoxeroides Alligator Weed [11620]		Species or species habitat likely to occur within area
Anredera cordifolia Madeira Vine, Jalap, Lamb's-tail, Mignonette Vine, Anredera, Gulf Madeiravine, Heartleaf Madeiravine, Potato Vine [2643]		Species or species habitat likely to occur within area
Asparagus aethiopicus Asparagus Fern, Ground Asparagus, Basket Fern, Sprengi's Fern, Bushy Asparagus, Emerald Asparagus [62425]		Species or species habitat likely to occur within area
Asparagus africanus Climbing Asparagus, Climbing Asparagus Fern [66907]		Species or species habitat likely to occur within area
Asparagus plumosus Climbing Asparagus-fern [48993]		Species or species habitat likely to occur within area
Cabomba caroliniana Cabomba, Fanwort, Carolina Watershield, Fish Grass, Washington Grass, Watershield, Carolina Fanwort, Common Cabomba [5171]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera Bitou Bush, Boneseed [18983]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Chrysanthemoides monilifera subsp. rotundata Bitou Bush [16332]		Species or species habitat likely to occur within area
Dolichandra unguis-cati Cat's Claw Vine, Yellow Trumpet Vine, Cat's Claw Creeper, Funnel Creeper [85119]		Species or species habitat likely to occur within area
Eichhornia crassipes Water Hyacinth, Water Orchid, Nile Lily [13466]		Species or species habitat likely to occur within area
Genista sp. X Genista monspessulana Broom [67538]		Species or species habitat may occur within area
Lantana camara Lantana, Common Lantana, Kamara Lantana, Large-leaf Lantana, Pink Flowered Lantana, Red Flowered Lantana, Red-Flowered Sage, White Sage, Wild Sage [10892]		Species or species habitat likely to occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Pinus radiata Radiata Pine Monterey Pine, Insignis Pine, Wilding Pine [20780]		Species or species habitat may occur within area
Rubus fruticosus aggregate Blackberry, European Blackberry [68406]		Species or species habitat likely to occur within area
Sagittaria platyphylla Delta Arrowhead, Arrowhead, Slender Arrowhead [68483]		Species or species habitat likely to occur within area
Salix spp. except S.babylonica, S.x calodendron & S.x reichardtii Willows except Weeping Willow, Pussy Willow and Sterile Pussy Willow [68497]		Species or species habitat likely to occur within area
Salvinia molesta Salvinia, Giant Salvinia, Aquarium Watermoss, Kariba Weed [13665]		Species or species habitat likely to occur within area
Senecio madagascariensis Fireweed, Madagascar Ragwort, Madagascar Groundsel [2624]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus Asian House Gecko [1708]		Species or species habitat likely to occur within area

Nationally Important Wetlands [Resource Information]

Name	State
Bundjalung National Park	NSW
Elizabeth and Middleton Reefs	EXT
Solitary Islands Marine Park	NSW

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Canyons on the eastern continental slope	Temperate east
Elizabeth and Middleton reefs	Temperate east
Lord Howe seamount chain	Temperate east
Shelf rocky reefs	Temperate east

Name	Region
Tasman Front and eddy field	Temperate east
Tasmantid seamount chain	Temperate east

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

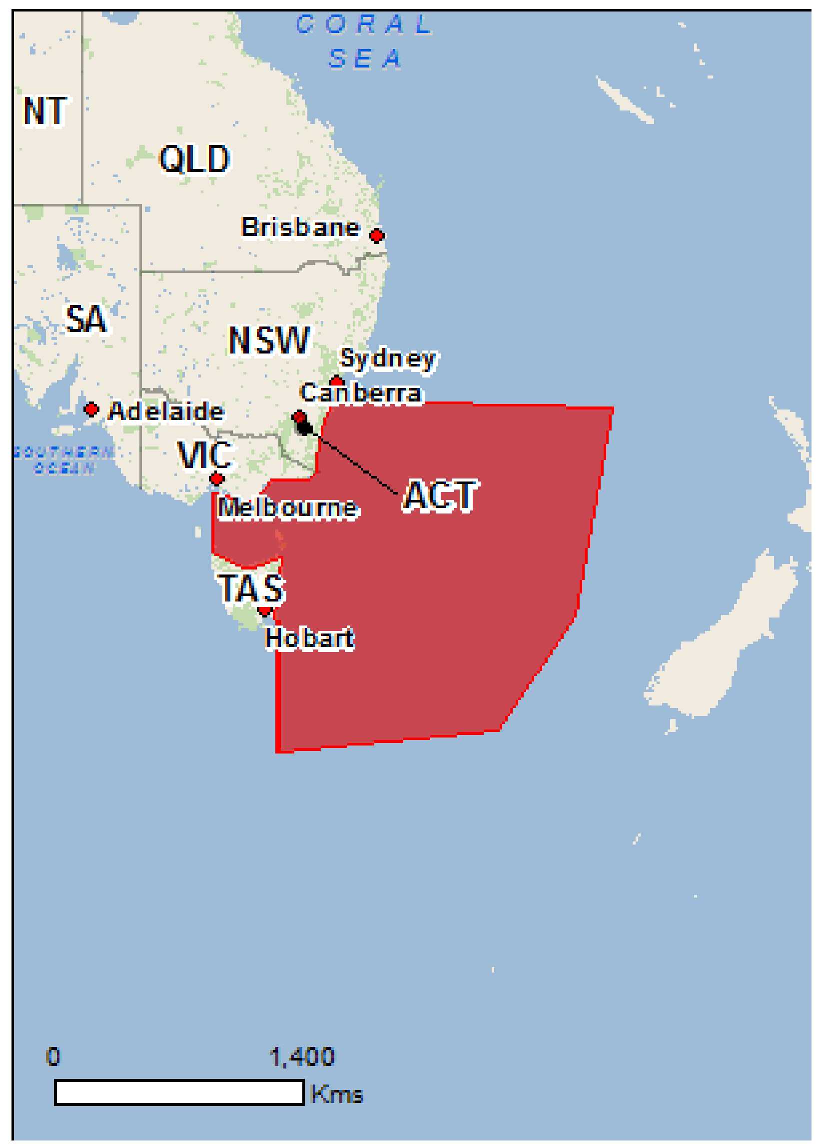
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

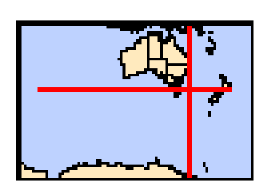
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 01/03/19 12:21:17



Coordinates

Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	2
National Heritage Places:	4
Wetlands of International Importance:	11
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	17
Listed Threatened Species:	213
Listed Migratory Species:	91

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	29
Commonwealth Heritage Places:	20
Listed Marine Species:	143
Whales and Other Cetaceans:	38
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	13

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	615
Regional Forest Agreements:	5
Invasive Species:	64
Nationally Important Wetlands:	93
Key Ecological Features (Marine)	5

Details

Matters of National Environmental Significance

World Heritage Properties [Resource Information]

Name	State	Status
Australian Convict Sites (Darlington Probation Station Buffer Zone)	TAS	Buffer zone
Australian Convict Sites (Darlington Probation Station)	TAS	Declared property

National Heritage Properties [Resource Information]

Name	State	Status
Historic		
Darlington Probation Station	TAS	Listed place
Point Nepean Defence Sites and Quarantine Station Area	VIC	Listed place
Port Arthur Historic Site	TAS	Listed place
Quarantine Station and Surrounds	VIC	Within listed place

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Apsley marshes	Within Ramsar site
Corner inlet	Within Ramsar site
East coast cape barren island lagoons	Within Ramsar site
Flood plain lower ringarooma river	Within Ramsar site
Gippsland lakes	Within Ramsar site
Jocks lagoon	Within Ramsar site
Little waterhouse lake	Within Ramsar site
Logan lagoon	Within Ramsar site
Moulting lagoon	Within Ramsar site
Port phillip bay (western shoreline) and bellarine peninsula	Within 10km of Ramsar
Western port	Within Ramsar site

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea
Extended Continental Shelf

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
South-east
Temperate East

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Alpine Sphagnum Bogs and Associated Fens	Endangered	Community likely to occur within area
Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community	Endangered	Community likely to occur within area
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	Endangered	Community likely to occur within area

Name	Status	Type of Presence
Eucalyptus ovata - Callitris oblonga Forest	Vulnerable	Community likely to occur within area
Giant Kelp Marine Forests of South East Australia	Endangered	Community likely to occur within area
Gippsland Red Gum (Eucalyptus tereticornis subsp. mediana) Grassy Woodland and Associated Native Grassland	Critically Endangered	Community likely to occur within area
Illawarra and south coast lowland forest and woodland ecological community	Critically Endangered	Community likely to occur within area
Littoral Rainforest and Coastal Vine Thickets of Eastern Australia	Critically Endangered	Community likely to occur within area
Lowland Grassy Woodland in the South East Corner Bioregion	Critically Endangered	Community likely to occur within area
Lowland Native Grasslands of Tasmania	Critically Endangered	Community likely to occur within area
Natural Damp Grassland of the Victorian Coastal Plains	Critically Endangered	Community likely to occur within area
Natural Temperate Grassland of the South Eastern Highlands	Critically Endangered	Community may occur within area
Seasonal Herbaceous Wetlands (Freshwater) of the Temperate Lowland Plains	Critically Endangered	Community likely to occur within area
Southern Highlands Shale Forest and Woodland in the Sydney Basin Bioregion	Critically Endangered	Community likely to occur within area
Subtropical and Temperate Coastal Saltmarsh	Vulnerable	Community likely to occur within area
Upland Basalt Eucalypt Forests of the Sydney Basin Bioregion	Endangered	Community may occur within area
White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland	Critically Endangered	Community may occur within area

Listed Threatened Species

[Resource Information]

Name	Status	Type of Presence
Birds		
Anthochaera phrygia Regent Honeyeater [82338]	Critically Endangered	Species or species habitat known to occur within area
Aquila audax fleayi Tasmanian Wedge-tailed Eagle, Wedge-tailed Eagle (Tasmanian) [64435]	Endangered	Breeding likely to occur within area
Botaurus poiciloptilus Australasian Bittern [1001]	Endangered	Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Ceyx azureus diemenensis Tasmanian Azure Kingfisher [25977]	Endangered	Breeding known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Dasyornis brachypterus Eastern Bristlebird [533]	Endangered	Species or species habitat known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Name	Status	Type of Presence
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Breeding known to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Breeding known to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur within area
Pardalotus quadragintus Forty-spotted Pardalote [418]	Endangered	Species or species habitat known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pterodroma heraldica Herald Petrel [66973]	Critically Endangered	Species or species habitat likely to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Breeding known to occur within area

Name	Status	Type of Presence
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Pterodroma neglecta neglecta Kermadec Petrel (western) [64450]	Vulnerable	Foraging, feeding or related behaviour may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta cauta Shy Albatross, Tasmanian Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tyto novaehollandiae castanops (Tasmanian population) Masked Owl (Tasmanian) [67051]	Vulnerable	Breeding known to occur within area
Crustaceans		
Astacopsis gouldi Giant Freshwater Crayfish, Tasmanian Giant Freshwater Lobster [64415]	Vulnerable	Species or species habitat known to occur within area
Engaeus granulatus Central North Burrowing Crayfish [78959]	Endangered	Species or species habitat known to occur within area
Engaeus martigener Furneaux Burrowing Crayfish [67220]	Endangered	Species or species habitat known to occur within area
Engaeus yabbimunna Burnie Burrowing Crayfish [66781]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Fish		
Brachionichthys hirsutus Spotted Handfish [64418]	Critically Endangered	Species or species habitat may occur within area
Brachiopsilus ziebelli Ziebell's Handfish, Waterfall Bay Handfish [83757]	Vulnerable	Species or species habitat likely to occur within area
Epinephelus daemelii Black Rockcod, Black Cod, Saddled Rockcod [68449]	Vulnerable	Species or species habitat likely to occur within area
Galaxias fontanus Swan Galaxias [26167]	Endangered	Species or species habitat likely to occur within area
Galaxiella pusilla Eastern Dwarf Galaxias, Dwarf Galaxias [56790]	Vulnerable	Species or species habitat known to occur within area
Maccullochella peelii Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area
Macquaria australasica Macquarie Perch [66632]	Endangered	Species or species habitat may occur within area
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat known to occur within area
Thymichthys politus Red Handfish [83756]	Critically Endangered	Species or species habitat likely to occur within area
Frogs		
Heleioporus australiacus Giant Burrowing Frog [1973]	Vulnerable	Species or species habitat known to occur within area
Litoria aurea Green and Golden Bell Frog [1870]	Vulnerable	Species or species habitat known to occur within area
Litoria littlejohni Littlejohn's Tree Frog, Heath Frog [64733]	Vulnerable	Species or species habitat known to occur within area
Litoria raniformis Growling Grass Frog, Southern Bell Frog, Green and Golden Frog, Warty Swamp Frog [1828]	Vulnerable	Species or species habitat known to occur within area
Mixophyes balbus Stuttering Frog, Southern Barred Frog (in Victoria) [1942]	Vulnerable	Species or species habitat likely to occur within area
Insects		
Antipodia chaostola leucophaea Tasmanian Chaostola Skipper, Heath-sand Skipper [77672]	Endangered	Species or species habitat known to occur within area
Hoplogonus bornemisszai Bornemissza's Stag Beetle [66754]	Critically Endangered	Species or species habitat known to occur within area
Hoplogonus simsoni Simson's Stag Beetle [66796]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Lissotes latidens Broad-toothed Stag Beetle, Wielangta Stag Beetle [66760]	Endangered	Species or species habitat known to occur within area
Oreixenica ptunarra Ptunarra Brown, Ptunarra Brown Butterfly, Ptunarra Xenica [26327]	Endangered	Species or species habitat may occur within area
Synemon plana Golden Sun Moth [25234]	Critically Endangered	Species or species habitat may occur within area
Mammals		
Antechinus minimus maritimus Swamp Antechinus (mainland) [83086]	Vulnerable	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Chalinolobus dwyeri Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat known to occur within area
Dasyurus maculatus maculatus (SE mainland population) Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (southeastern mainland population) [75184]	Endangered	Species or species habitat known to occur within area
Dasyurus maculatus maculatus (Tasmanian population) Spotted-tail Quoll, Spot-tailed Quoll, Tiger Quoll (Tasmanian population) [75183]	Vulnerable	Species or species habitat known to occur within area
Dasyurus viverrinus Eastern Quoll, Luaner [333]	Endangered	Species or species habitat known to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Isoodon obesulus obesulus Southern Brown Bandicoot (eastern), Southern Brown Bandicoot (south-eastern) [68050]	Endangered	Species or species habitat known to occur within area
Mastacomys fuscus mordicus Broad-toothed Rat (mainland), Tooarrana [87617]	Vulnerable	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Perameles gunnii gunnii Eastern Barred Bandicoot (Tasmania) [66651]	Vulnerable	Species or species habitat known to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat known to occur within area
Petrogale penicillata Brush-tailed Rock-wallaby [225]	Vulnerable	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT)		
Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Potorous longipes		
Long-footed Potoroo [217]	Endangered	Species or species habitat known to occur within area
Potorous tridactylus tridactylus		
Long-nosed Potoroo (SE mainland) [66645]	Vulnerable	Species or species habitat known to occur within area
Pseudomys fumeus		
Smoky Mouse, Konoom [88]	Endangered	Species or species habitat likely to occur within area
Pseudomys novaehollandiae		
New Holland Mouse, Pookila [96]	Vulnerable	Species or species habitat known to occur within area
Pteropus poliocephalus		
Grey-headed Flying-fox [186]	Vulnerable	Roosting known to occur within area
Sarcophilus harrisii		
Tasmanian Devil [299]	Endangered	Translocated population known to occur within area
Other		
Megascolides australis		
Giant Gippsland Earthworm [64420]	Vulnerable	Species or species habitat likely to occur within area
Parvulastra vivipara		
Tasmanian Live-bearing Seastar [85451]	Vulnerable	Species or species habitat likely to occur within area
Tasmanipatus anophthalmus		
Blind Velvet Worm [66773]	Endangered	Species or species habitat known to occur within area
Plants		
Acacia axillaris		
Midlands Mimosa, Midlands Wattle [13563]	Vulnerable	Species or species habitat known to occur within area
Acacia bynoeana		
Bynoe's Wattle, Tiny Wattle [8575]	Vulnerable	Species or species habitat may occur within area
Acacia caerulescens		
Limestone Blue Wattle, Buchan Blue, Buchan Blue Wattle [21883]	Vulnerable	Species or species habitat known to occur within area
Acacia constablei		
Narrabarba Wattle [10798]	Vulnerable	Species or species habitat known to occur within area
Acacia georgensis		
Bega Wattle [9848]	Vulnerable	Species or species habitat known to occur within area
Amphibromus fluitans		
River Swamp Wallaby-grass, Floating Swamp Wallaby-grass [19215]	Vulnerable	Species or species habitat known to occur within area
Astrotricha crassifolia		
Thick-leaf Star-hair [10352]	Vulnerable	Species or species habitat may occur within area
Banksia vincentia		
[88276]	Critically Endangered	Species or species habitat known to occur within area

Name	Status	Type of Presence
Barbarea australis Native Wintercress, Riverbed Wintercress [12540]	Endangered	Species or species habitat likely to occur within area
Bertya tasmanica subsp. tasmanica Tasmanian Bertya [78359]	Endangered	Species or species habitat known to occur within area
Boronia deanei Deane's Boronia [8397]	Vulnerable	Species or species habitat known to occur within area
Boronia gunnii Gunn's Boronia, Cataract Gorge Boronia [29394]	Vulnerable	Species or species habitat known to occur within area
Boronia hippopala Velvet Boronia [78925]	Vulnerable	Species or species habitat known to occur within area
Budawangia gnidioides Budawangs Cliff-heath [55850]	Vulnerable	Species or species habitat may occur within area
Caladenia campbellii Thick-stem Caladenia [64857]	Critically Endangered	Species or species habitat known to occur within area
Caladenia caudata Tailed Spider-orchid [17067]	Vulnerable	Species or species habitat known to occur within area
Caladenia dienema Windswept Spider-orchid [64858]	Endangered	Species or species habitat may occur within area
Caladenia lindleyana Lindley's Spider-orchid [9305]	Critically Endangered	Species or species habitat may occur within area
Caladenia orientalis Eastern Spider Orchid [83410]	Endangered	Species or species habitat known to occur within area
Caladenia robinsonii Frankston Spider-orchid [24375]	Endangered	Species or species habitat likely to occur within area
Caladenia tessellata Thick-lipped Spider-orchid, Daddy Long-legs [2119]	Vulnerable	Species or species habitat known to occur within area
Caladenia tonellii Robust Fingers [64861]	Critically Endangered	Species or species habitat known to occur within area
Callitris oblonga Pygmy Cypress-pine, Pigmy Cypress-pine, Dwarf Cypress-pine [66687]	Vulnerable	Species or species habitat likely to occur within area
Callitris oblonga subsp. oblonga South Esk Pine [64864]	Endangered	Species or species habitat known to occur within area
Cassinia rugata Wrinkled Cassinia, Wrinkled Dollybush [21885]	Vulnerable	Species or species habitat may occur within area
Colobanthus curtisiae Curtis' Colobanth [23961]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Commersonia prostrata Dwarf Kerrawang [87152]	Endangered	Species or species habitat known to occur within area
Conospermum hookeri Variable Smoke-bush [68161]	Vulnerable	Species or species habitat likely to occur within area
Correa baeuerlenii Chef's Cap [17007]	Vulnerable	Species or species habitat likely to occur within area
Corunastylis brachystachya Short-spiked Midge-orchid [76410]	Endangered	Species or species habitat known to occur within area
Corunastylis firthii Firth's Midge-orchid [76411]	Critically Endangered	Species or species habitat known to occur within area
Cryptostylis hunteriana Leafless Tongue-orchid [19533]	Vulnerable	Species or species habitat known to occur within area
Cynanchum elegans White-flowered Wax Plant [12533]	Endangered	Species or species habitat known to occur within area
Daphnandra johnsonii Illawarra Socketwood [67186]	Endangered	Species or species habitat likely to occur within area
Dianella amoena Matted Flax-lily [64886]	Endangered	Species or species habitat known to occur within area
Diuris lanceolata Snake Orchid [10231]	Endangered	Species or species habitat known to occur within area
Dodonaea procumbens Trailing Hop-bush [12149]	Vulnerable	Species or species habitat known to occur within area
Epacris apsleyensis Apsley Heath [15428]	Endangered	Species or species habitat likely to occur within area
Epacris barbata Bearded Heath, Freycinet Heath [17625]	Endangered	Species or species habitat likely to occur within area
Epacris exserta South Esk Heath [19879]	Endangered	Species or species habitat known to occur within area
Epacris grandis Grand Heath, Tall Heath [18719]	Endangered	Species or species habitat known to occur within area
Epacris limbata Border Heath, Bordered Heath [24011]	Critically Endangered	Species or species habitat known to occur within area
Epacris virgata Pretty Heath, Dan Hill Heath [20375]	Endangered	Species or species habitat known to occur within area
Eucalyptus langleyi Albatross Mallee [56224]	Vulnerable	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Eucalyptus strzeleckii Strzelecki Gum [55400]	Vulnerable	Species or species habitat likely to occur within area
Euphrasia amphisysepala Shiny Cliff Eyebright [4534]	Vulnerable	Species or species habitat likely to occur within area
Euphrasia collina subsp. muelleri Purple Eyebright, Mueller's Eyebright [16151]	Endangered	Species or species habitat known to occur within area
Euphrasia phragmostoma Buftons Eyebright, Hairy Cliff Eyebright [7720]	Vulnerable	Species or species habitat likely to occur within area
Euphrasia semipicta Peninsula Eyebright [9986]	Endangered	Species or species habitat likely to occur within area
Euphrasia sp. Bivouac Bay (W.R.Barker 7626 et al.) Masked Eyebright, Masked Cliff Eyebright [82044]	Endangered	Species or species habitat known to occur within area
Genoplesium baueri Yellow Gnat-orchid [7528]	Endangered	Species or species habitat known to occur within area
Genoplesium vernale East Lynne Midge-orchid [68379]	Vulnerable	Species or species habitat known to occur within area
Glycine latrobeana Clover Glycine, Purple Clover [13910]	Vulnerable	Species or species habitat known to occur within area
Grevillea celata Colquhoun Grevillea, Nowa Nowa Grevillea [64907]	Vulnerable	Species or species habitat likely to occur within area
Grevillea parviflora subsp. parviflora Small-flower Grevillea [64910]	Vulnerable	Species or species habitat known to occur within area
Haloragis exalata subsp. exalata Wingless Raspwort, Square Raspwort [24636]	Vulnerable	Species or species habitat known to occur within area
Irenepharsus trypherus Delicate Cress, Illawarra Irene [14664]	Endangered	Species or species habitat known to occur within area
Leionema ralstonii [64926]	Vulnerable	Species or species habitat likely to occur within area
Lepidium hyssopifolium Basalt Pepper-cress, Peppercress, Rubble Pepper-cress, Pepperweed [16542]	Endangered	Species or species habitat known to occur within area
Leucochrysum albicans var. tricolor Hoary Sunray, Grassland Paper-daisy [56204]	Endangered	Species or species habitat known to occur within area
Limonium australe var. baudinii Baudin's Sea-lavender [86369]	Vulnerable	Species or species habitat likely to occur within area
Melaleuca biconvexa Biconvex Paperbark [5583]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Persicaria elatior Knotweed, Tall Knotweed [5831]	Vulnerable	Species or species habitat likely to occur within area
Persoonia hirsuta Hairy Geebung, Hairy Persoonia [19006]	Endangered	Species or species habitat may occur within area
Phebalium daviesii Davies' Waxflower, St Helens Waxflower [16959]	Critically Endangered	Species or species habitat known to occur within area
Philotheca freyciana Freycinet Waxflower [68227]	Endangered	Species or species habitat known to occur within area
Pimelea spicata Spiked Rice-flower [20834]	Endangered	Species or species habitat known to occur within area
Pomaderris brunnea Rufous Pomaderris [16845]	Vulnerable	Species or species habitat likely to occur within area
Pomaderris parrisiae Parris' Pomaderris [22119]	Vulnerable	Species or species habitat likely to occur within area
Prasophyllum affine Jervis Bay Leek Orchid, Culburra Leek-orchid, Kinghorn Point Leek-orchid [2210]	Endangered	Species or species habitat likely to occur within area
Prasophyllum apoxychilum Tapered Leek-orchid [64947]	Endangered	Species or species habitat known to occur within area
Prasophyllum atratum Three Hummock Leek-orchid [82677]	Critically Endangered	Species or species habitat known to occur within area
Prasophyllum castaneum Chestnut Leek-orchid [64948]	Critically Endangered	Species or species habitat likely to occur within area
Prasophyllum correctum Gaping Leek-orchid [64533]	Endangered	Species or species habitat likely to occur within area
Prasophyllum frenchii Maroon Leek-orchid, Slaty Leek-orchid, Stout Leek-orchid, French's Leek-orchid, Swamp Leek-orchid [9704]	Endangered	Species or species habitat likely to occur within area
Prasophyllum incorrectum Golfers Leek-orchid [78898]	Critically Endangered	Species or species habitat may occur within area
Prasophyllum limnetes Marsh Leek-orchid [82678]	Critically Endangered	Species or species habitat may occur within area
Prasophyllum pulchellum Pretty Leek-orchid [64953]	Critically Endangered	Species or species habitat known to occur within area
Prasophyllum secutum Northern Leek-orchid [64954]	Endangered	Species or species habitat likely to occur within area
Prasophyllum spicatum Dense Leek-orchid [55146]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Prostanthera densa Villous Mintbush [12233]	Vulnerable	Species or species habitat likely to occur within area
Prostanthera galbraithiae Wellington Mintbush [64959]	Vulnerable	Species or species habitat known to occur within area
Pterostylis chlorogramma Green-striped Greenhood [56510]	Vulnerable	Species or species habitat known to occur within area
Pterostylis commutata Midland Greenhood [64535]	Critically Endangered	Species or species habitat may occur within area
Pterostylis cucullata Leafy Greenhood [15459]	Vulnerable	Species or species habitat known to occur within area
Pterostylis gibbosa Illawarra Greenhood, Rufa Greenhood, Pouched Greenhood [4562]	Endangered	Species or species habitat known to occur within area
Pterostylis pulchella Pretty Greenhood [6448]	Vulnerable	Species or species habitat known to occur within area
Pterostylis tenuissima Swamp Greenhood, Dainty Swamp Orchid [13139]	Vulnerable	Species or species habitat known to occur within area
Pterostylis vernalis Halbury Rustyhood [84711]	Critically Endangered	Species or species habitat known to occur within area
Pterostylis ziegeleri Grassland Greenhood, Cape Portland Greenhood [64971]	Vulnerable	Species or species habitat likely to occur within area
Pultenaea aristata [18062]	Vulnerable	Species or species habitat may occur within area
Rhizanthella slateri Eastern Underground Orchid [11768]	Endangered	Species or species habitat known to occur within area
Senecio psilocarpus Swamp Fireweed, Smooth-fruited Groundsel [64976]	Vulnerable	Species or species habitat may occur within area
Spyridium lawrencei Small-leaf Spyridium [27036]	Endangered	Species or species habitat likely to occur within area
Spyridium obcordatum Creeping Dusty Miller [17447]	Vulnerable	Species or species habitat likely to occur within area
Stenanthemum pimeleoides Spreading Stenanthemum, Propellor Plant [15450]	Vulnerable	Species or species habitat may occur within area
Stonesiella selaginoides Clubmoss Bush-pea [68100]	Endangered	Species or species habitat likely to occur within area
Syzygium paniculatum Magenta Lilly Pilly, Magenta Cherry, Daguba, Scrub Cherry, Creek Lilly Pilly, Brush Cherry [20307]	Vulnerable	Species or species habitat known to occur within area

Name	Status	Type of Presence
Thelymitra epipactoides Metallic Sun-orchid [11896]	Endangered	Species or species habitat known to occur within area
Thelymitra jonesii Sky-blue Sun-orchid [76352]	Endangered	Species or species habitat known to occur within area
Thelymitra kangaloonica Kangaloon Sun Orchid [81861]	Critically Endangered	Species or species habitat likely to occur within area
Thelymitra matthewsii Spiral Sun-orchid [4168]	Vulnerable	Species or species habitat may occur within area
Thesium australe Austral Toadflax, Toadflax [15202]	Vulnerable	Species or species habitat known to occur within area
Triplarina nowraensis Nowra Heath-myrtle [64544]	Endangered	Species or species habitat known to occur within area
Xanthorrhoea arenaria Sand Grasstree [21603]	Vulnerable	Species or species habitat likely to occur within area
Xanthorrhoea bracteata Shiny Grasstree [7950]	Endangered	Species or species habitat known to occur within area
Xerochrysum palustre Swamp Everlasting, Swamp Paper Daisy [76215]	Vulnerable	Species or species habitat known to occur within area
Zieria baeuerlenii Bomaderry Zieria, Bomaderry Creek Zieria [56781]	Endangered	Species or species habitat known to occur within area
Zieria granulata Hill Zieria, Hilly Zieria, Illawarra Zieria [17147]	Endangered	Species or species habitat likely to occur within area
Zieria tuberculata Warty Zieria [56736]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hoplocephalus bungaroides Broad-headed Snake [1182]	Vulnerable	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Name	Status	Type of Presence
Sharks		
Carcharias taurus (east coast population)		
Grey Nurse Shark (east coast population) [68751]	Critically Endangered	Species or species habitat known to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Rhincodon typus		
Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus		
Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes		
Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area
Ardenna grisea		
Sooty Shearwater [82651]		Breeding known to occur within area
Ardenna pacifica		
Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Ardenna tenuirostris		
Short-tailed Shearwater [82652]		Breeding known to occur within area
Calonectris leucomelas		
Streaked Shearwater [1077]		Species or species habitat known to occur within area
Diomedea antipodensis		
Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora		
Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans		
Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi		
Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregata ariel		
Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat likely to occur within area
Fregata minor		
Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Hydroprogne caspia		
Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus		
Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely

Name	Threatened	Type of Presence
		to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Sternula albifrons Little Tern [82849]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Breeding known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Dugong dugon Dugong [28]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Phocoena dioptrica Spectacled Porpoise [66728]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Migratory Terrestrial Species		
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat known to occur within area

Name	Threatened	Type of Presence
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat known to occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Foraging, feeding or related behaviour known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area

Name	Threatened	Type of Presence
Gallinago megala Swinhoe's Snipe [864]		Species or species habitat known to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Thalasseus bergii Crested Tern [83000]		Breeding known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa incana Wandering Tattler [831]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Name
Commonwealth Land -
Commonwealth Land - Australian Academy of Science
Commonwealth Land - Australian National University

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Breeding known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius ruficapillus Red-capped Plover [881]		Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Foraging, feeding or related behaviour known to occur within area

Name	Threatened	Type of Presence
Chrysococcyx osculans Black-eared Cuckoo [705]		Species or species habitat known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eudyptula minor Little Penguin [1085]		Breeding known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat likely to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Species or species habitat known to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting known to occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Breeding known to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Heteroscelus brevipes Grey-tailed Tattler [59311]		Roosting known to occur within area
Heteroscelus incanus Wandering Tattler [59547]		Roosting known to occur within area
Himantopus himantopus Pied Stilt, Black-winged Stilt [870]		Roosting known to occur within area
Hirundapus caudacutus White-throated Needletail [682]		Species or species habitat known to occur within area
Larus dominicanus Kelp Gull [809]		Breeding known to occur within area
Larus novaehollandiae Silver Gull [810]		Breeding known to occur within area

Name	Threatened	Type of Presence
Larus pacificus Pacific Gull [811]		Breeding known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Breeding known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Morus serrator Australasian Gannet [1020]		Breeding known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Pelagodroma marina White-faced Storm-Petrel [1016]		Breeding known to occur within area

Name	Threatened	Type of Presence
Pelecanoides urinatrix Common Diving-Petrel [1018]		Breeding known to occur within area
Phalacrocorax fuscescens Black-faced Cormorant [59660]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Foraging, feeding or related behaviour likely to occur within area
Puffinus griseus Sooty Shearwater [1024]		Breeding known to occur within area
Puffinus pacificus Wedge-tailed Shearwater [1027]		Breeding known to occur within area
Puffinus tenuirostris Short-tailed Shearwater [1029]		Breeding known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Roosting known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Sterna albifrons Little Tern [813]		Breeding known to occur within area
Sterna bergii Crested Tern [816]		Breeding known to occur within area
Sterna caspia Caspian Tern [59467]		Breeding known to occur within area
Sterna fuscata Sooty Tern [794]		Breeding known to occur within area
Sterna nereis Fairy Tern [796]		Breeding known to occur within area
Sterna striata White-fronted Tern [799]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta Tasmanian Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely

Name	Threatened	Type of Presence
		to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis Hooded Plover [59510]		Species or species habitat known to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area
Fish		
Acentronura tentaculata Shortpouch Pygmy Pipehorse [66187]		Species or species habitat may occur within area
Cosmocampus howensis Lord Howe Pipefish [66208]		Species or species habitat may occur within area
Festucalex cinctus Girdled Pipefish [66214]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species

Name	Threatened	Type of Presence
		habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus minotaur Bullneck Seahorse [66705]		Species or species habitat may occur within area
Hippocampus whitei White's Seahorse, Crowned Seahorse, Sydney Seahorse [66240]		Species or species habitat known to occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area
Lissocampus caudalis Australian Smooth Pipefish, Smooth Pipefish [66249]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys mollisoni Mollison's Pipefish [66260]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phycodurus eques Leafy Seadragon [66267]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Pugnaso curtirostris Pugnose Pipefish, Pug-nosed Pipefish [66269]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Solenostomus paradoxus Ornate Ghostpipefish, Harlequin Ghost Pipefish, Ornate Ghost Pipefish [66184]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Breeding known to occur within area
Dugong dugon Dugong [28]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Berardius arnuxii Arnoux's Beaked Whale [70]		Species or species habitat may occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area

Name	Status	Type of Presence
Globicephala melas Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Hyperoodon planifrons Southern Bottlenose Whale [71]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenorhynchus cruciger Hourglass Dolphin [42]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lissodelphis peronii Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Mesoplodon grayi Gray's Beaked Whale, Scamperdown Whale [75]		Species or species habitat may occur within area
Mesoplodon hectori Hector's Beaked Whale [76]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
Mesoplodon mirus True's Beaked Whale [54]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area

Name	Status	Type of Presence
Phocoena dioptrica Spectacled Porpoise [66728]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tasmacetus shepherdi Shepherd's Beaked Whale, Tasman Beaked Whale [55]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Acridotheres tristis Common Myna, Indian Myna [387]		Species or species habitat likely to occur within area
Alauda arvensis Skylark [656]		Species or species habitat likely to occur within area
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Callipepla californica California Quail [59451]		Species or species habitat likely to occur within area
Carduelis carduelis European Goldfinch [403]		Species or species habitat likely to occur within area
Carduelis chloris European Greenfinch [404]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Gallus gallus Red Junglefowl, Domestic Fowl [917]		Species or species habitat likely to occur within area
Lonchura punctulata Nutmeg Mannikin [399]		Species or species habitat likely to occur within area
Meleagris gallopavo Wild Turkey [64380]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Passer montanus Eurasian Tree Sparrow [406]		Species or species habitat likely to occur within area
Pavo cristatus Indian Peafowl, Peacock [919]		Species or species habitat likely to occur within area
Phasianus colchicus Common Pheasant [920]		Species or species habitat likely to occur within area
Pycnonotus jocosus Red-whiskered Bulbul [631]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Turdus merula Common Blackbird, Eurasian Blackbird [596]		Species or species habitat likely to occur within area
Turdus philomelos Song Thrush [597]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat may occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Capra hircus Goat [2]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Feral deer Feral deer species in Australia [85733]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Rattus norvegicus Brown Rat, Norway Rat [83]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Alternanthera philoxeroides Alligator Weed [11620]		Species or species habitat likely to occur within area
Anredera cordifolia Madeira Vine, Jalap, Lamb's-tail, Mignonette Vine, Anredera, Gulf Madeiravine, Heartleaf Madeiravine, Potato Vine [2643]		Species or species habitat likely to occur within area
Asparagus aethiopicus Asparagus Fern, Ground Asparagus, Basket Fern, Sprengi's Fern, Bushy Asparagus, Emerald Asparagus [62425]		Species or species habitat likely to occur within area
Asparagus asparagoides Bridal Creeper, Bridal Veil Creeper, Smilax, Florist's Smilax, Smilax Asparagus [22473]		Species or species habitat likely to occur within area
Asparagus plumosus Climbing Asparagus-fern [48993]		Species or species habitat likely to occur within area
Asparagus scandens Asparagus Fern, Climbing Asparagus Fern [23255]		Species or species habitat likely to occur within area
Austrocylindropuntia spp. Prickly Pears [85132]		Species or species habitat likely to occur within area
Cabomba caroliniana Cabomba, Fanwort, Carolina Watershield, Fish Grass, Washington Grass, Watershield, Carolina Fanwort, Common Cabomba [5171]		Species or species habitat likely to occur within area
Carrichtera annua Ward's Weed [9511]		Species or species habitat may occur within area
Chrysanthemoides monilifera Bitou Bush, Boneseed [18983]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera subsp. monilifera Boneseed [16905]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera subsp. rotundata Bitou Bush [16332]		Species or species habitat likely to occur within area
Cytisus scoparius Broom, English Broom, Scotch Broom, Common Broom, Scottish Broom, Spanish Broom [5934]		Species or species habitat likely to occur within area
Eichhornia crassipes Water Hyacinth, Water Orchid, Nile Lily [13466]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Genista linifolia Flax-leaved Broom, Mediterranean Broom, Flax Broom [2800]		Species or species habitat likely to occur within area
Genista monspessulana Montpellier Broom, Cape Broom, Canary Broom, Common Broom, French Broom, Soft Broom [20126]		Species or species habitat likely to occur within area
Genista sp. X Genista monspessulana Broom [67538]		Species or species habitat may occur within area
Lantana camara Lantana, Common Lantana, Kamara Lantana, Large-leaf Lantana, Pink Flowered Lantana, Red Flowered Lantana, Red-Flowered Sage, White Sage, Wild Sage [10892]		Species or species habitat likely to occur within area
Lycium ferocissimum African Boxthorn, Boxthorn [19235]		Species or species habitat likely to occur within area
Nassella neesiana Chilean Needle grass [67699]		Species or species habitat likely to occur within area
Nassella trichotoma Serrated Tussock, Yass River Tussock, Yass Tussock, Nassella Tussock (NZ) [18884]		Species or species habitat likely to occur within area
Olea europaea Olive, Common Olive [9160]		Species or species habitat may occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area
Pinus radiata Radiata Pine Monterey Pine, Insignis Pine, Wilding Pine [20780]		Species or species habitat may occur within area
Rubus fruticosus aggregate Blackberry, European Blackberry [68406]		Species or species habitat likely to occur within area
Sagittaria platyphylla Delta Arrowhead, Arrowhead, Slender Arrowhead [68483]		Species or species habitat likely to occur within area
Salix spp. except S.babylonica, S.x calodendron & S.x reichardtii Willows except Weeping Willow, Pussy Willow and Sterile Pussy Willow [68497]		Species or species habitat likely to occur within area
Salvinia molesta Salvinia, Giant Salvinia, Aquarium Watermoss, Kariba Weed [13665]		Species or species habitat likely to occur within area
Senecio madagascariensis Fireweed, Madagascar Ragwort, Madagascar Groundsel [2624]		Species or species habitat likely to occur within area
Ulex europaeus Gorse, Furze [7693]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus Asian House Gecko [1708]		Species or species habitat likely to occur within area

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Big Horseshoe Canyon	South-east
Seamounts South and east of Tasmania	South-east
Upwelling East of Eden	South-east
Canyons on the eastern continental slope	Temperate east
Shelf rocky reefs	Temperate east

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

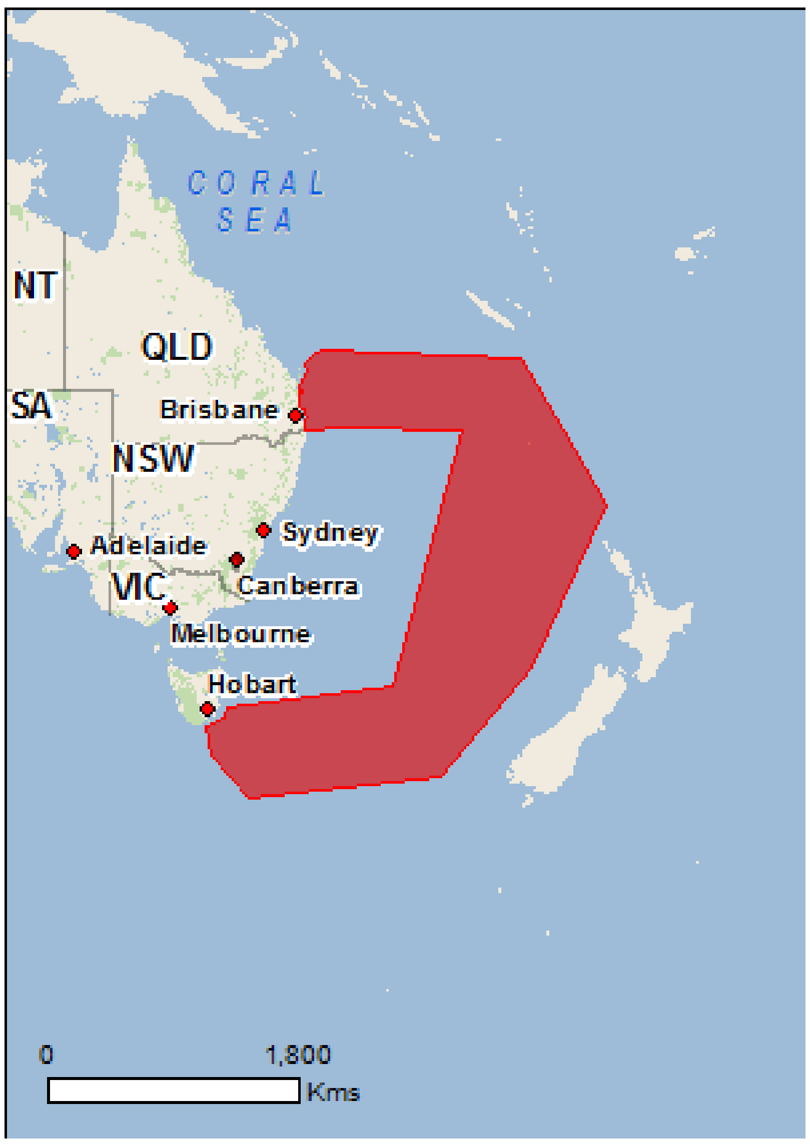
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

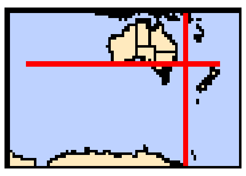
Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 11/05/20 11:18:52



Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	3
National Heritage Places:	4
Wetlands of International Importance:	2
Great Barrier Reef Marine Park:	2
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	4
Listed Threatened Species:	168
Listed Migratory Species:	96

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	2
Commonwealth Heritage Places:	7
Listed Marine Species:	150
Whales and Other Cetaceans:	44
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	3
Australian Marine Parks:	12

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	12
Regional Forest Agreements:	2
Invasive Species:	54
Nationally Important Wetlands:	8
Key Ecological Features (Marine)	9

Details

Matters of National Environmental Significance

World Heritage Properties [Resource Information]

Name	State	Status
Australian Convict Sites (Kingston and Arthurs Vale Historic Area)	EXT	Declared property
Fraser Island	QLD	Declared property
Great Barrier Reef	QLD	Declared property

National Heritage Properties [Resource Information]

Name	State	Status
Natural		
Fraser Island	QLD	Listed place
Great Barrier Reef	QLD	Listed place
Historic		
HMS Sirius Shipwreck	EXT	Listed place
Kingston and Arthurs Vale Historic Area	EXT	Listed place

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Great sandy strait (including great sandy strait, tin can bay and tin can	Within Ramsar site
Moreton bay	Within Ramsar site

Great Barrier Reef Marine Park [Resource Information]

Type	Zone	IUCN
Buffer	B-22-3012	IV
Marine National Park	MNP-22-1154	II

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea
Extended Continental Shelf

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
Coral Sea
South-east
Temperate East

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	Endangered	Community likely to occur within area
Giant Kelp Marine Forests of South East Australia	Endangered	Community may occur within area
Subtropical and Temperate Coastal Saltmarsh	Vulnerable	Community likely to occur within area
Tasmanian Forests and Woodlands dominated by black gum or Brookers gum (Eucalyptus ovata / E. brookeriana)	Critically Endangered	Community may occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Anthochaera phrygia Regent Honeyeater [82338]	Critically Endangered	Foraging, feeding or related behaviour likely to occur within area
Botaurus poiciloptilus Australasian Bittern [1001]	Endangered	Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Cyanoramphus cookii Norfolk Island Green Parrot, Tasman Parakeet, Norfolk Island Parakeet [67046]	Endangered	Breeding known to occur within area
Cyclopsitta diophthalma coxeni Coxen's Fig-Parrot [59714]	Endangered	Species or species habitat may occur within area
Dasyornis brachypterus Eastern Bristlebird [533]	Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Vulnerable	Species or species habitat known to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat likely to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Ninox novaeseelandiae undulata Norfolk Island Boobook, Southern Boobook (Norfolk Island) [26188]	Endangered	Breeding known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachycephala pectoralis xanthoprocta Golden Whistler (Norfolk Island) [64444]	Vulnerable	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur within area
Petroica multicolor Norfolk Island Robin, Pacific Robin [604]	Vulnerable	Breeding likely to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pterodroma heraldica Herald Petrel [66973]	Critically Endangered	Species or species habitat likely to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Pterodroma neglecta neglecta Kermadec Petrel (western) [64450]	Vulnerable	Breeding known to occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat known to occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Species or species habitat known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross	Vulnerable	Foraging, feeding or

Name	Status	Type of Presence
[82273]		related behaviour likely to occur within area
Thalassarche cauta cauta Shy Albatross [82345]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta steadi White-capped Albatross [82344]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Turnix melanogaster Black-breasted Button-quail [923]	Vulnerable	Species or species habitat known to occur within area
Tyto novaehollandiae castanops (Tasmanian population) Masked Owl (Tasmanian) [67051]	Vulnerable	Species or species habitat likely to occur within area
Fish		
Brachionichthys hirsutus Spotted Handfish [64418]	Critically Endangered	Species or species habitat may occur within area
Epinephelus daemelii Black Rockcod, Black Cod, Saddled Rockcod [68449]	Vulnerable	Species or species habitat likely to occur within area
Nannoperca oxleyana Oxleyan Pygmy Perch [64468]	Endangered	Species or species habitat likely to occur within area
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat likely to occur within area
Thymichthys politus Red Handfish [83756]	Critically Endangered	Species or species habitat may occur within area
Frogs		
Litoria olongburensis Wallum Sedge Frog [1821]	Vulnerable	Species or species habitat known to occur within area
Mixophyes fleayi Fleay's Frog [25960]	Endangered	Species or species habitat may occur within area
Insects		

Name	Status	Type of Presence
Argynnis hyperbius inconstans Australian Fritillary [88056]	Critically Endangered	Species or species habitat may occur within area
Phyllodes imperialis smithersi Pink Underwing Moth [86084]	Endangered	Species or species habitat may occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Chalinolobus dwyeri Large-eared Pied Bat, Large Pied Bat [183]	Vulnerable	Species or species habitat likely to occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Dasyurus maculatus maculatus (SE mainland population) Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (southeastern mainland population) [75184]	Endangered	Species or species habitat likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Petauroides volans Greater Glider [254]	Vulnerable	Species or species habitat may occur within area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT) Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Vulnerable	Species or species habitat known to occur within area
Potorous tridactylus tridactylus Long-nosed Potoroo (SE Mainland) [66645]	Vulnerable	Species or species habitat likely to occur within area
Pseudomys novaehollandiae New Holland Mouse, Pookila [96]	Vulnerable	Species or species habitat likely to occur within area
Pteropus poliocephalus Grey-headed Flying-fox [186]	Vulnerable	Roosting known to occur within area
Xeromys myoides Water Mouse, False Water Rat, Yirrkoo [66]	Vulnerable	Species or species habitat known to occur within area
Other		
Advena campbellii Campbell's Helicarionid Land Snail [81250]	Critically Endangered	Species or species habitat known to occur within area
Mathewsoconcha grayi ms Gray's Helicarionid Land Snail [81852]	Critically Endangered	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Mathewsoconcha phillipii Phillip Island Helicarionid Land Snail [81252]	Critically Endangered	Species or species habitat likely to occur within area
Mathewsoconcha suteri a helicarionid land snail [81851]	Critically Endangered	Species or species habitat likely to occur within area
Quintalia stoddartii Stoddart's Helicarionid Land Snail [81253]	Critically Endangered	Species or species habitat likely to occur within area
Thersites mitchellae Mitchell's Rainforest Snail [66774]	Critically Endangered	Species or species habitat may occur within area
Plants		
Abutilon julianae Norfolk Island Abutilon [27797]	Critically Endangered	Species or species habitat known to occur within area
Acacia attenuata [10690]	Vulnerable	Species or species habitat likely to occur within area
Achyranthes arborescens Chaff Tree, Soft-wood [65879]	Critically Endangered	Species or species habitat known to occur within area
Achyranthes margaretarum Phillip Island Chaffy Tree [68426]	Critically Endangered	Species or species habitat known to occur within area
Acronychia littoralis Scented Acronychia [8582]	Endangered	Species or species habitat known to occur within area
Allocasuarina thalassoscopica [21927]	Endangered	Species or species habitat may occur within area
Archidendron lovelliae Bacon Wood, Tulip Siris [13451]	Vulnerable	Species or species habitat likely to occur within area
Arthraxon hispidus Hairy-joint Grass [9338]	Vulnerable	Species or species habitat likely to occur within area
Baloghia marmorata Marbled Balogia, Jointed Baloghia [8463]	Vulnerable	Species or species habitat may occur within area
Blechnum norfolkianum Norfolk Island Water-fern [65885]	Endangered	Species or species habitat known to occur within area
Boehmeria australis subsp. australis Tree Nettle, Nettletree [83309]	Critically Endangered	Species or species habitat known to occur within area
Bosistoa transversa Three-leaved Bosistoa, Yellow Satinheart [16091]	Vulnerable	Species or species habitat likely to occur within area
Calystegia affinis [48909]	Critically Endangered	Species or species habitat known to occur within area
Clematis dubia a creeper, Clematis [22035]	Critically Endangered	Species or species habitat known to occur within area

Name	Status	Type of Presence
Coprosma baueri Coastal Coprosma [37851]	Endangered	Species or species habitat known to occur within area
Coprosma pilosa Mountain Coprosma [37884]	Endangered	Species or species habitat known to occur within area
Cordyline obtecta Ti [65878]	Vulnerable	Species or species habitat known to occur within area
Cryptocarya foetida Stinking Cryptocarya, Stinking Laurel [11976]	Vulnerable	Species or species habitat known to occur within area
Cryptostylis hunteriana Leafless Tongue-orchid [19533]	Vulnerable	Species or species habitat known to occur within area
Cynanchum elegans White-flowered Wax Plant [12533]	Endangered	Species or species habitat may occur within area
Dendrobium brachypus Norfolk Island Orchid [2592]	Endangered	Species or species habitat known to occur within area
Diploglottis campbellii Small-leaved Tamarind [21484]	Endangered	Species or species habitat may occur within area
Dysoxylum bijugum Sharkwood, a tree [65892]	Vulnerable	Species or species habitat known to occur within area
Elatostema montanum Mountain Procris [33862]	Critically Endangered	Species or species habitat known to occur within area
Elymus multiflorus subsp. kingianus Phillip Island Wheat Grass [82413]	Critically Endangered	Species or species habitat known to occur within area
Endiandra floydii Floyd's Walnut [52955]	Endangered	Species or species habitat likely to occur within area
Eucalyptus conglomerata Swamp Stringybark [3160]	Endangered	Species or species habitat may occur within area
Euphorbia norfolkiana Norfolk Island Euphorbia [65887]	Critically Endangered	Species or species habitat known to occur within area
Euphorbia obliqua a herb [44385]	Vulnerable	Species or species habitat likely to occur within area
Fontainea australis Southern Fontainea [24037]	Vulnerable	Species or species habitat may occur within area
Gossia fragrantissima Sweet Myrtle, Small-leaved Myrtle [78867]	Endangered	Species or species habitat may occur within area
Hibiscus insularis Phillip Island Hibiscus [30614]	Critically Endangered	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Hypolepis dicksonioides Downy Ground-fern, Brake Fern, Ground Fern [10243]	Vulnerable	Species or species habitat likely to occur within area
Ileostylus micranthus Mistletoe [65891]	Vulnerable	Species or species habitat known to occur within area
Lastreopsis calantha Shield-fern, Shieldfern [65884]	Endangered	Species or species habitat known to occur within area
Macadamia integrifolia Macadamia Nut, Queensland Nut Tree, Smooth-shelled Macadamia, Bush Nut, Nut Oak [7326]	Vulnerable	Species or species habitat known to occur within area
Macadamia ternifolia Small-fruited Queensland Nut, Gympie Nut [7214]	Vulnerable	Species or species habitat likely to occur within area
Macadamia tetraphylla Rough-shelled Bush Nut, Macadamia Nut, Rough-shelled Macadamia, Rough-leaved Queensland Nut [6581]	Vulnerable	Species or species habitat likely to occur within area
Macrozamia pauli-guilielmi Pineapple Zamia [5712]	Endangered	Species or species habitat likely to occur within area
Marattia salicina King Fern, Para, Potato Fern [16197]	Endangered	Species or species habitat likely to occur within area
Melicope littoralis Shade Tree [22042]	Vulnerable	Species or species habitat known to occur within area
Melicytus latifolius Norfolk Island Mahoe [56677]	Critically Endangered	Species or species habitat known to occur within area
Melicytus ramiflorus subsp. oblongifolius Whiteywood, a tree [56680]	Vulnerable	Species or species habitat likely to occur within area
Meryta angustifolia a tree [65881]	Vulnerable	Species or species habitat known to occur within area
Meryta latifolia Shade Tree, Broad-leaved Meryta [65882]	Critically Endangered	Species or species habitat likely to occur within area
Muehlenbeckia australis Shrubby Creeper, Pohuehue [68510]	Endangered	Species or species habitat known to occur within area
Myoporum obscurum Popwood, Sandalwood, Bastard Ironwood [50255]	Critically Endangered	Species or species habitat known to occur within area
Myrsine ralstoniae Beech [83889]	Vulnerable	Species or species habitat known to occur within area
Pennantia endlicheri Pennantia [65890]	Endangered	Species or species habitat known to occur within area
Persicaria elatior Knotweed, Tall Knotweed [5831]	Vulnerable	Species or species habitat may occur within area

Name	Status	Type of Presence
Phaius australis Lesser Swamp-orchid [5872]	Endangered	Species or species habitat known to occur within area
Phaius bernaysii Yellow Swamp-orchid [4918]	Endangered	Species or species habitat likely to occur within area
Phreatia limenophylax Norfolk Island Phreatia [9239]	Critically Endangered	Species or species habitat known to occur within area
Phreatia paleata an orchid [20193]	Endangered	Species or species habitat known to occur within area
Pittosporum bracteolatum Oleander [47181]	Vulnerable	Species or species habitat known to occur within area
Planchonella costata [30944]	Endangered	Species or species habitat known to occur within area
Polyphlebium endlicherianum Middle Filmy Fern [87494]	Endangered	Species or species habitat known to occur within area
Pteris kingiana King's Brakefern [35183]	Endangered	Species or species habitat likely to occur within area
Pteris zahlbruckneriana Netted Brakefern [65893]	Endangered	Species or species habitat likely to occur within area
Randia moorei Spiny Gardenia [10577]	Endangered	Species or species habitat known to occur within area
Samadera bidwillii Quassia [29708]	Vulnerable	Species or species habitat likely to occur within area
Senecio australis a daisy [40250]	Vulnerable	Species or species habitat likely to occur within area
Senecio evansianus a daisy [55340]	Endangered	Species or species habitat known to occur within area
Senecio hooglandii a daisy [55346]	Vulnerable	Species or species habitat known to occur within area
Sophora fraseri [8836]	Vulnerable	Species or species habitat may occur within area
Streblus pendulinus Siah's Backbone, Sia's Backbone, Isaac Wood [21618]	Endangered	Species or species habitat known to occur within area
Syzygium hodgkinsoniae Smooth-bark Rose Apple, Red Lilly Pilly [3539]	Vulnerable	Species or species habitat likely to occur within area
Syzygium moorei Rose Apple, Coolamon, Robby, Durobby, Watermelon Tree, Coolamon Rose Apple [12284]	Vulnerable	Species or species habitat may occur within area

Name	Status	Type of Presence
Taeniophyllum norfolkianum Minute Orchid, Ribbon-root Orchid [82347]	Vulnerable	Species or species habitat likely to occur within area
Thelymitra jonesii Sky-blue Sun-orchid [76352]	Endangered	Species or species habitat may occur within area
Thesium australe Austral Toadflax, Toadflax [15202]	Vulnerable	Species or species habitat may occur within area
Tmesipteris norfolkensis Hanging Fork-fern [65895]	Vulnerable	Species or species habitat known to occur within area
Triunia robusta Glossy Spice Bush [14747]	Endangered	Species or species habitat likely to occur within area
Ungeria floribunda Bastard Oak [41714]	Vulnerable	Species or species habitat known to occur within area
Wikstroemia australis Kurrajong [42074]	Critically Endangered	Species or species habitat known to occur within area
Zehneria baueriana Native Cucumber, Giant Cucumber [39253]	Endangered	Species or species habitat known to occur within area
Reptiles		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Christinus guentheri Lord Howe Island Gecko, Lord Howe Island Southern Gecko [59250]	Vulnerable	Species or species habitat likely to occur within area
Delma torquata Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Furina dunmalli Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Oligosoma lichenigera Lord Howe Island Skink [82034]	Vulnerable	Species or species habitat likely to occur within area
Saiphos reticulatus Three-toed Snake-tooth Skink [88328]	Vulnerable	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Sharks		
Carcharias taurus (east coast population) Grey Nurse Shark (east coast population) [68751]	Critically Endangered	Species or species habitat known to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Breeding may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Breeding known to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat known to occur within area
Ardenna grisea Sooty Shearwater [82651]		Species or species habitat likely to occur within area
Ardenna pacifica Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Breeding known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Sternula albifrons Little Tern [82849]		Breeding known to occur within area
Sula dactylatra Masked Booby [1021]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Migratory Marine Species		
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat known to occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely

Name	Threatened	Type of Presence
		to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Dugong dugon Dugong [28]		Species or species habitat known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour known to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]		Species or species habitat likely to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur

Name	Threatened	Type of Presence
		within area
Phocoena dioptrica Spectacled Porpoise [66728]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Breeding may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Breeding known to occur within area
Migratory Terrestrial Species		
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur

Name	Threatened	Type of Presence
		within area
Calidris subminuta Long-toed Stint [861]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa incana Wandering Tattler [831]		Roosting known to occur within area

Name	Threatened	Type of Presence
Tringa nebularia		
Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis		
Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus		
Terek Sandpiper [59300]		Roosting known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Name

Kingston and Arthurs Vale Commonwealth Tenure Area	EXT	Listed place

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus		
Common Noddy [825]		Breeding known to occur within area
Anseranas semipalmata		
Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba		
Great Egret, White Egret [59541]		Breeding known to occur within area
Ardea ibis		
Cattle Egret [59542]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris subminuta Long-toed Stint [861]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Catharacta skua Great Skua [59472]		Species or species habitat may occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius ruficapillus Red-capped Plover [881]		Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea gibsoni Gibson's Albatross [64466]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Heteroscelus brevipes Grey-tailed Tattler [59311]		Roosting known to occur within area
Heteroscelus incanus Wandering Tattler [59547]		Roosting known to occur within area
Himantopus himantopus Pied Stilt, Black-winged Stilt [870]		Roosting known to occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat likely to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area

Name	Threatened	Type of Presence
Monarcha trivirgatus Spectacled Monarch [610]		Species or species habitat known to occur within area
Morus serrator Australasian Gannet [1020]		Breeding known to occur within area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Breeding known to occur within area
Philomachus pugnax Ruff (Reeve) [850]		Roosting known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Procelsterna cerulea Grey Noddy, Grey Ternlet [64378]		Breeding known to occur within area
Pterodroma cervicalis White-necked Petrel [59642]		Breeding known to occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Pterodroma nigripennis Black-winged Petrel [1038]		Breeding known to occur within area
Pterodroma solandri Providence Petrel [1040]		Breeding known to occur within area
Puffinus assimilis Little Shearwater [59363]		Breeding known to occur within area
Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [1043]		Species or species habitat known to occur within area
Puffinus griseus Sooty Shearwater [1024]		Species or species habitat likely to occur within area

Name	Threatened	Type of Presence
Puffinus pacificus Wedge-tailed Shearwater [1027]		Breeding known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Roosting known to occur within area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat known to occur within area
Sterna albifrons Little Tern [813]		Breeding known to occur within area
Sula dactylatra Masked Booby [1021]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche eremita Chatham Albatross [64457]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche sp. nov. Pacific Albatross [66511]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable*	Foraging, feeding or related behaviour likely to occur within area
Thinornis rubricollis rubricollis Hooded Plover (eastern) [66726]	Vulnerable	Species or species habitat known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area

Name	Threatened	Type of Presence
Fish		
Acentronura tentaculata Shortpouch Pygmy Pipehorse [66187]		Species or species habitat may occur within area
Campichthys tryoni Tryon's Pipefish [66193]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys ocellatus Orange-spotted Pipefish, Ocellated Pipefish [66203]		Species or species habitat may occur within area
Festucalex cinctus Girdled Pipefish [66214]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus boothae Booth's Pipefish [66218]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippichthys cyanospilos Blue-speckled Pipefish, Blue-spotted Pipefish [66228]		Species or species habitat may occur within area
Hippichthys heptagonus Madura Pipefish, Reticulated Freshwater Pipefish [66229]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus kelloggi Kellogg's Seahorse, Great Seahorse [66723]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Hippocampus whitei White's Seahorse, Crowned Seahorse, Sydney Seahorse [66240]		Species or species habitat known to occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Micrognathus andersonii Anderson's Pipefish, Shortnose Pipefish [66253]		Species or species habitat may occur within area
Micrognathus brevirostris thorntail Pipefish, Thorn-tailed Pipefish [66254]		Species or species habitat may occur within area
Microphis manadensis Manado Pipefish, Manado River Pipefish [66258]		Species or species habitat may occur within area
Mitotichthys mollisoni Mollison's Pipefish [66260]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Solegnathus dunckeri Duncker's Pipehorse [66271]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Solenostomus paradoxus Ornate Ghostpipefish, Harlequin Ghost Pipefish, Ornate Ghost Pipefish [66184]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Mammals		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area
Dugong dugon Dugong [28]		Species or species habitat known to occur within area
Reptiles		
Acalyptophis peronii Horned Seasnake [1114]		Species or species habitat may occur within area
Aipysurus duboisii Dubois' Seasnake [1116]		Species or species habitat may occur within area
Aipysurus laevis Olive Seasnake [1120]		Species or species habitat may occur within area
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Disteira kingii Spectacled Seasnake [1123]		Species or species habitat may occur within area
Disteira major Olive-headed Seasnake [1124]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Emydocephalus annulatus Turtle-headed Seasnake [1125]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Laticauda colubrina a sea krait [1092]		Species or species habitat may occur within area
Laticauda laticaudata a sea krait [1093]		Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Berardius arnuxii Arnoux's Beaked Whale [70]		Species or species habitat may occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species

Name	Status	Type of Presence
		habitat known to occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Globicephala melas Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Hyperoodon planifrons Southern Bottlenose Whale [71]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Lagenorhynchus cruciger Hourglass Dolphin [42]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lissodelphis peronii Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Mesoplodon grayi Gray's Beaked Whale, Scamperdown Whale [75]		Species or species habitat may occur within area
Mesoplodon hectori Hector's Beaked Whale [76]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within

Name	Status	Type of Presence
		area
Mesoplodon mirus True's Beaked Whale [54]		Species or species habitat may occur within area
Orcaella brevirostris Irrawaddy Dolphin [45]		Species or species habitat likely to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area
Phocoena dioptrica Spectacled Porpoise [66728]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Breeding known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tasmacetus shepherdi Shepherd's Beaked Whale, Tasman Beaked Whale [55]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Acridotheres tristis Common Myna, Indian Myna [387]		Species or species habitat likely to occur within area
Anas platyrhynchos Mallard [974]		Species or species habitat likely to occur within area
Callipepla californica California Quail [59451]		Species or species habitat likely to occur within area
Carduelis carduelis European Goldfinch [403]		Species or species habitat likely to occur within area
Carduelis chloris European Greenfinch [404]		Species or species habitat likely to occur within area
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area
Gallus gallus Red Junglefowl, Feral Chicken, Domestic Fowl [917]		Species or species habitat likely to occur within area
Lonchura punctulata Nutmeg Mannikin [399]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area
Pycnonotus jocosus Red-whiskered Bulbul [631]		Species or species habitat likely to occur within area
Streptopelia chinensis Spotted Turtle-Dove [780]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Turdus merula Common Blackbird, Eurasian Blackbird [596]		Species or species habitat likely to occur within area
Turdus philomelos Song Thrush [597]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat known to occur within area
Mammals		
Bos taurus Domestic Cattle [16]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Feral deer Feral deer species in Australia [85733]		Species or species habitat likely to occur within area
Lepus capensis Brown Hare [127]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Rattus exulans Pacific Rat, Polynesian Rat [79]		Species or species habitat likely to occur within area
Rattus norvegicus Brown Rat, Norway Rat [83]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Sus scrofa Pig [6]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Alternanthera philoxeroides Alligator Weed [11620]		Species or species habitat likely to occur within area
Anredera cordifolia Madeira Vine, Jalap, Lamb's-tail, Mignonette Vine, Anredera, Gulf Madeiravine, Heartleaf Madeiravine, Potato Vine [2643]		Species or species habitat likely to occur within area
Asparagus aethiopicus Asparagus Fern, Ground Asparagus, Basket Fern, Sprengi's Fern, Bushy Asparagus, Emerald Asparagus [62425]		Species or species habitat likely to occur within area
Asparagus africanus Climbing Asparagus, Climbing Asparagus Fern [66907]		Species or species habitat likely to occur within area
Asparagus plumosus Climbing Asparagus-fern [48993]		Species or species habitat likely to occur within area
Asparagus scandens Asparagus Fern, Climbing Asparagus Fern [23255]		Species or species habitat likely to occur within area
Cabomba caroliniana Cabomba, Fanwort, Carolina Watershield, Fish Grass, Washington Grass, Watershield, Carolina Fanwort, Common Cabomba [5171]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera Bitou Bush, Boneseed [18983]		Species or species habitat likely to occur within area
Chrysanthemoides monilifera subsp. rotundata Bitou Bush [16332]		Species or species habitat likely to occur within area
Cryptostegia grandiflora Rubber Vine, Rubbervine, India Rubber Vine, India Rubbervine, Palay Rubbervine, Purple Allamanda [18913]		Species or species habitat likely to occur within area
Dolichandra unguis-cati Cat's Claw Vine, Yellow Trumpet Vine, Cat's Claw Creeper, Funnel Creeper [85119]		Species or species habitat likely to occur within area
Eichhornia crassipes Water Hyacinth, Water Orchid, Nile Lily [13466]		Species or species habitat likely to occur within area
Genista sp. X Genista monspessulana Broom [67538]		Species or species habitat may occur within area

Name	Status	Type of Presence
Hymenachne amplexicaulis		
Hymenachne, Olive Hymenachne, Water Stargrass, West Indian Grass, West Indian Marsh Grass [31754]		Species or species habitat likely to occur within area
Lantana camara		
Lantana, Common Lantana, Kamara Lantana, Large-leaf Lantana, Pink Flowered Lantana, Red Flowered Lantana, Red-Flowered Sage, White Sage, Wild Sage [10892]		Species or species habitat likely to occur within area
Lycium ferocissimum		
African Boxthorn, Boxthorn [19235]		Species or species habitat likely to occur within area
Opuntia spp.		
Prickly Pears [82753]		Species or species habitat likely to occur within area
Parthenium hysterophorus		
Parthenium Weed, Bitter Weed, Carrot Grass, False Ragweed [19566]		Species or species habitat likely to occur within area
Pinus radiata		
Radiata Pine Monterey Pine, Insignis Pine, Wilding Pine [20780]		Species or species habitat may occur within area
Rubus fruticosus aggregate		
Blackberry, European Blackberry [68406]		Species or species habitat likely to occur within area
Sagittaria platyphylla		
Delta Arrowhead, Arrowhead, Slender Arrowhead [68483]		Species or species habitat likely to occur within area
Salix spp. except S.babylonica, S.x calodendron & S.x reichardtii		
Willows except Weeping Willow, Pussy Willow and Sterile Pussy Willow [68497]		Species or species habitat likely to occur within area
Salvinia molesta		
Salvinia, Giant Salvinia, Aquarium Watermoss, Kariba Weed [13665]		Species or species habitat likely to occur within area
Senecio madagascariensis		
Fireweed, Madagascar Ragwort, Madagascar Groundsel [2624]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus		
Asian House Gecko [1708]		Species or species habitat likely to occur within area
Ramphotyphlops braminus		
Flowerpot Blind Snake, Brahminy Blind Snake, Cacing Besi [1258]		Species or species habitat likely to occur within area

Nationally Important Wetlands [Resource Information]

Name	State
Bribie Island	QLD
Fraser Island	QLD
Great Barrier Reef Marine Park	QLD
Great Sandy Strait	QLD
Moreton Bay	QLD
Noosa River Wetlands	QLD
North Stradbroke Island	QLD
Pumicestone Passage	QLD

Key Ecological Features (Marine) [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Tasmantid seamount chain	Coral Sea
Seamounts South and east of Tasmania	South-east
Canyons on the eastern continental slope	Temperate east
Lord Howe seamount chain	Temperate east
Norfolk Ridge	Temperate east
Shelf rocky reefs	Temperate east
Tasman Front and eddy field	Temperate east
Tasmantid seamount chain	Temperate east
Upwelling off Fraser Island	Temperate east

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

DOCUMENT REVIEW AND UPDATE:

The Document Owner is responsible for maintaining and controlling changes to this document in accordance with the Document Management Manual (AUGO-PO-DMM-001). In the course of using this document, users may identify opportunities to improve its content. They are requested to provide suggestions to the Document Owner.

This document should be reviewed for accuracy and currency on a 5 yearly basis commencing from the original formal issue date. Major revisions to this manual are to comply with the OIMS System Manual/Process Management of Change procedures.

DISTRIBUTION:

An electronic copy of this document is lodged on U-Docs. Any updates to this document will be communicated to the relevant personnel in accordance with the Document Management Manual (AUGO-PO-DMM-001).

TITLEHOLDER DETAILS

Esso Australia Resources Pty Ltd (Esso), a wholly owned subsidiary of ExxonMobil Australia Pty Ltd, is the operator for the Gippsland Basin Joint Venture (GBJV) (Esso and BHP Billiton Petroleum (Bass Strait) Pty Ltd (BHP)) and the Kipper Unit Joint Venture (KUJV) (Esso, BHP, and MEPAU A Pty Ltd). Esso receives services, including personnel, from its wholly owned subsidiary, Esso Australia Pty Ltd, which is also a wholly owned subsidiary of ExxonMobil Australia Pty Ltd.

Petroleum Production Licences and pipeline licences applicable to this Environment Plan are listed in Appendix A.

Petroleum Production Licenses fall under the GBJV with the exception of VIC/L25 which falls under KUJV.

The nominated registered office for the proponent is as follows:

Esso Australia Resources Pty Ltd (ACN 091 829 819)

Level 9, 664 Collins Street
Docklands VIC 3008

The environmental contact for this activity is:

Hena Kalam
Offshore Risk, Environment and Regulatory Supervisor
Esso Australia Pty Ltd for and on behalf of Esso Australia Resources Pty Ltd
Telephone: (03) 9261 0000
Email: hena.kalam1@exxonmobil.com

The Regulator will be notified of a change in titleholder, a change in the environmental contact or a change in the contact details for either the titleholder or the environmental contact in accordance with Regulation 15(3) of the Offshore Petroleum and Greenhouse Gas (Environment) Regulations 2009 (OPGGS(E)R).

1 Introduction

1.1 Overview

Esso Australia Resources Pty Ltd (Esso) is the operator of joint ventures for the exploration, development and production of oil and gas from Bass Strait, Victoria. Bass Strait operations consist of 19 platforms and five subsea facilities (four existing and one proposed) located within Commonwealth waters, and ~600 km of subsea pipeline.

Esso has developed this Environment Plan (EP) to identify, evaluate and manage the environmental impacts and risks associated with operation and maintenance of its oil and gas production facilities in Bass Strait.

This EP is submitted as a revision to the following EPs, and will cover a period of 5 years from the date of acceptance:

- Barracouta Whiting Environment Plan (AUGO-PO-EMP-033) NOPSEMA Reference: A384170 ID2787
- Bream Environment Plan (AUGO-PO-EMP-036) NOPSEMA Reference: A398118 ID2956
- Central Fields Environment Plan (AUGO-PO-EMP-034) NOPSEMA Reference: A398121 ID2957
- Flounder Environment Plan (AUGO-PO-EMP-035) NOPSEMA Reference: A387094 ID2893
- Kingfish Environment Plan (AUGO-PO-EMP-037) NOPSEMA Reference: A402033 ID2996
- Marlin Complex Environment Plan (AUGO-PO-EMP-031) NOPSEMA Reference: A401973 ID2999
- Perch Dolphin Environment Plan (AUGO-PO-EMP-032) NOPSEMA Reference: A384504 IDRMS2791
- Snapper Environment Plan (AUGO-PO-EMP-038) NOPSEMA Reference: A401990 ID2997
- Tuna Environment Plan (AUGO-PO-EMP-039) NOPSEMA Reference: A387092 ID2894
- West Tuna Environment Plan (AUGO-PO-EMP-030) NOPSEMA Reference: A384187 ID2357

This EP also includes the start-up, operations and maintenance of the West Barracouta subsea facility, which will be installed in 2020. Installation of the facility will be covered under a separate EP.

1.2 Scope

1.2.1 Operational Area

The Operational Area applicable to the scope of this EP includes the area within a 500 m Petroleum Safety Zone (PSZ) around the platforms and subsea facilities listed in , and a 200 m operational zone around the petroleum pipelines and secondary lines within Commonwealth waters (>3 NM from shore), as defined in the "Bass Strait Pipeline Network Safety Case" (BSPNSC).

1.2.2 Activities

Activities included in the scope of this EP are described in Section 2, and include Platform Operations, Support Operations, Inspection Maintenance and Repair (IMR), and Wellwork.

Activities excluded from the scope of this EP include:

- Activities in State waters, such as operation of export pipelines. These are managed under the Bass Strait State Waters Environment Plan (AUGO-PO-EMP-059) under the Victorian Offshore Petroleum and Greenhouse Gas Storage Act 2010 and associated regulations.
- Management of onshore activities.

- Vessels transiting to or from the Operational Area. These vessels are deemed to be operating under the Commonwealth Navigation Act 2012 and not performing a petroleum activity.
- Decommissioning activities. These will be covered in future permissioning documents.
- Activities using mobile offshore drilling units or platform-based drilling rigs.

1.2.3 Infrastructure

The infrastructure applicable to this Environment Plan is listed in Volume 2, Appendix A.

1.2.4 Stages of activity

A titleholder may choose what is involved in a particular stage of a petroleum activity and provide adequately for those activities in an EP. As defined in the NOPSEMA Guideline A515816, a New Stage of activity is defined as “A change to the spatial or temporal limits of the petroleum activity described in the accepted EP”. Esso has defined the stages of petroleum activity for pipelines and facilities in Figure 1-1 and Table 1-1.

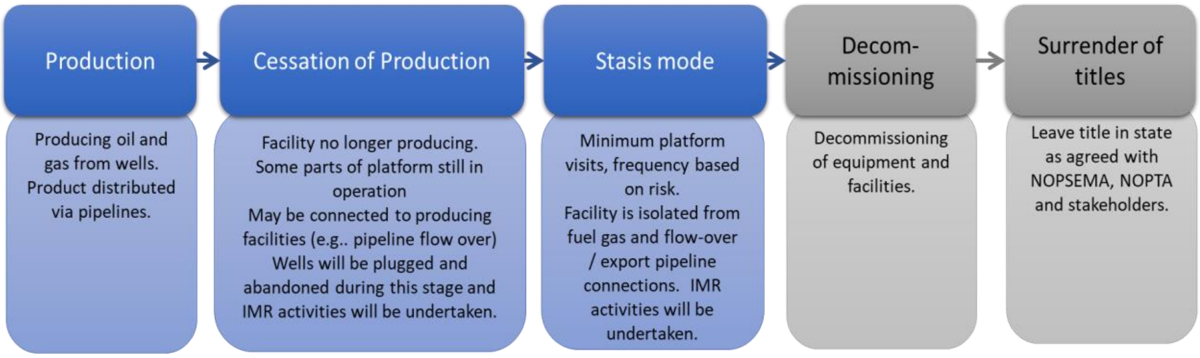

Figure 1-1 Lifecycle of a Facility

Stages of activity within the scope of this Environment Plan include:

- Production
- Cessation of Production
- Platform ‘Stasis Mode’.

The decommissioning and surrender of titles/licences stage of pipelines and facilities is not within the scope of this EP.

Once a platform ceases production of oil and gas it may be a number of years before all of the activities under the Cessation of Production stage are completed. Early in the Cessation of Production stage, wells may be required to be temporarily brought online to support key activities of the stage (e.g. pipeline pigging using gas driven pig). Given the complexity and interconnectedness of the Esso Bass Strait network, a platform may continue to be maintained to facilitate operations on other producing platforms (e.g. via pipeline ‘flow over’) and platform systems may also be used to prepare facilities for decommissioning (such as enabling the flushing of pipelines or umbilicals and subsequent liquids disposal) and support IMR activities. Hence, a platform may continue to be ‘in use’ for many years following the commencement of Cessation of Production stage. During this period, activities will continue in order to maintain the platform to an appropriate standard, to ensure safety and environmental risks are reduced to ALARP and acceptable levels, and to preserve all decommissioning outcomes up to and including full removal (as required under the OPGGS Act 2006 unless deviations are justified and accepted by NOPSEMA). These activities include well integrity testing, structural and corrosion control maintenance/repair (as required) and checks on operating systems such as fuel gas, air compressors, crane and lifting equipment, open and closed piles and safety systems.

During the Cessation of Production stage, normally once wells are plugged and abandoned, a variety of activities will take place on the platform to make it safe and prepare for decommissioning (e.g. isolate and shutdown systems; prepare the topsides and jackets for lifting activities; remove hydrocarbons; cleaning of import and export pipelines; air-gapping of risers on platforms and in some cases underwater cutting of pipelines and risers). Pipeline fluids may continue to 'flow over' platforms during the Cessation of Production stage whilst upstream facilities continue to produce or whilst they are prepared for decommissioning. It is expected to be a number of years before this work is completed and a facility or pipeline is ready for decommissioning.

Decommissioning of facilities is expected to be carried out via the use of a Heavy Lift Vessel (HLV) during one or more decommissioning campaigns as discussed further in Section 3.2 (although removal of smaller items of property will be ongoing consistent with the philosophy described in Section 3.1.3) – this stage of the activity is not within the scope of this EP. Therefore, following the completion of preparation for decommissioning, some facilities may remain in Stasis Mode with appropriate visits for IMR activities until such time as a decommissioning campaign commences. This stage is within the scope of this EP.

Following the completion of decommissioning and the undertaking of post decommissioning monitoring as appropriate and agreed with NOPSEMA, Esso will apply to NOPTA to surrender the relevant petroleum titles.

Notwithstanding that the decommissioning and surrender of titles stages are not activities covered by this EP, an overview of the planning underway for the decommissioning of facilities, equipment and pipelines is provided in Sections 3.1 – 3.3. The indicative decommissioning plans and schedules provided in these sections are preliminary and subject to change as technical, environmental and execution studies progress as well as key contracting activities are completed.

Table 1-1 Stages of activity

Item	Definition		Within the scope of this EP	Relevant Activities
	Facilities (including platforms and subsea)	Pipelines		
Production	Facility is producing oil and gas which is distributed via pipelines. In some instances during this stage, production may temporarily be ceased while future development plans are being evaluated. A facility will move to the CoP stage when production has ceased and there is no intention of returning to production in the future.	Pipeline used to transport oil and/or gas to shore or; used to supply other facilities with required resources (e.g. fuel gas, gas-lift gas, hydraulic fluid, hydrate inhibitor). For clarity, production stage includes pipelines which are used to transport oil and/or gas to shore from an upstream facility which is still in Production stage. Transport of oil and/or gas in a pipeline in production stage may 'flow over' or supply resources to a platform which is in CoP stage. A pipeline may remain in service while the associated platform has ceased production to allow flow over of product from other platforms.	Yes	• Operations (Section 2.4.1) • Wellwork (Section 2.4.2) • IMR (Section 2.4.3) • Support Operations (Section 2.4.3)
Cessation of production (CoP)	<u>Key change from prior stage:</u> Cessation of Production (CoP) stage commences when a facility is no longer producing oil and gas (wells are shut-in). There are a number of activities within the CoP stage: Care and Preservation (C&P) pre well plug and abandonment (P&A): • Wells are shut–in except in certain circumstances such as for supply of fuel gas for power generation. • Systems are being maintained and/or preserved where they are required for future P&A and decommissioning activities and/or to facilitate upstream asset ongoing production. • Wells continue to be monitored as per the WIMS and risk assessments undertaken as required prior to P&A. Wells may be plugged and secured (P&S) using a wireline rig to preserve wellbore integrity for the period prior to P&A.	In Cessation of Production stage, pipelines are no longer used to transport oil and gas to shore or to supply other facilities with resources. Some pipelines, while in CoP stage, may still be used to support activities in the lead up to decommissioning (e.g. for wellwork and/or platform flushing and draining and ultimately for pipeline flushing). Normal maintenance and inspection operations, excluding regular pigging activities, will continue for pipelines which remain in service while they are in CoP stage. During the CoP stage: • Risk based inspection and/or maintenance activities will be undertaken to prepare pipelines for decommissioning. • Pipelines will be filled with water treated with chemicals suitable for the period until decommissioning.	Yes	• Operations (Section 2.4.1) • Wellwork (Section 2.4.2) • IMR (Section 2.4.3) • Support Operations (Section 2.4.3)

<table>
<tr><th rowspan="2">Item</th><th colspan="2">Definition</th><th rowspan="2">Within the scope of this EP</th><th rowspan="2">Relevant Activities</th></tr>
<tr><th>Facilities (including platforms and subsea)</th><th>Pipelines</th></tr>
<tr><td></td><td>Once platforms are de-staffed, periodic platform visits are conducted as required to complete operations and maintenance tasks (e.g. WIMS testing, well operations, restart equipment that has shut down, top up lube oils, launch / receive pigs, re-establish communications) to facilitate upstream platform operations and/or maintain equipment for future decommissioning preparation activities. Platform visits may be conducted as day trips, or by temporarily re-staffing the facility for several weeks.

Well Plug and Abandonment (P&A) and Well Conductor Pull:
• Wells will be plugged and abandoned (P&A) during the CoP stage. Timing of P&A is dependent on the risk profile of the well.
• Well conductors will be removed either post P&A or as part of the Decommissioning stage.
• Some systems on the platform are still in operation with temporary or permanent connections (e.g. power, air, safety systems, fuel systems, pig launcher/receivers, cathodic protection, etc.)
Care and Preservation (C&P) post well P&A (as applicable):
• Platforms are normally de-staffed, with platform visits conducted as required to complete operations and maintenance tasks (e.g. restart equipment that has shut down, top up lube oils, launch/receive pigs, re-establish communications) to facilitate upstream platform operations and/or maintain equipment for future decommissioning preparation activities. Platform visits may be conducted as day trips, or by temporarily re-staffing the facility for several weeks.
Preparation for Decommissioning:
• Activities are being undertaken to prepare the platform for decommissioning in parallel with IMR to preserve the facility for a period of Stasis Mode.</td><td>• Sections of risers and pipelines including below FVOs/LVOs and/or underwater may be removed in preparation for platform or pipeline decommissioning.</td><td></td><td></td></tr>
</table>

Item	Definition		Within the scope of this EP	Relevant Activities
	Facilities (including platforms and subsea)	Pipelines		
	• Facilities will be progressively isolated from fuel gas and flow-over / export pipeline connections. The overall duration of CoP is dependent on current and potential future use requirements of the facility. Due to the high level of interconnectedness of the Bass Strait facilities, some platforms are used to allow pipeline 'flow over' to or from producing facilities. Some platform systems will also be used to facilitate the preparation of other facilities for decommissioning such as the flushing of pipelines and umbilicals, and removal of topsides hydrocarbons.			
Stasis Mode (minimal visits)	<u>Key change from prior stage</u> Activities to prepare facility for a period of minimal activity and decommissioning are complete. • Facilities are isolated from fuel gas and flow-over / export pipeline connections. • Facilities are considered to be 'not in use, nor to be used' in connection with the operations (as per Section 572 of the OPGGS Act 2006) when Stasis Mode is reached. Facility is ready for Decommissioning. The duration for which a platform will remain in 'Stasis Mode' is dependent on the current and future use requirements (i.e. to facilitate preparation for removal of other facilities) of the facility and the timing of decommissioning campaigns. Platform visits may be undertaken to complete IMR activities to maintain platform prior to future decommissioning.	Pipeline is ready for Decommissioning. Pipelines are considered to be 'not in use, nor to be used' in connection with the operations (as per Section 572 of the OPGGS Act 2006) when Stasis Mode is reached. Pipeline filled with seawater or water treated with chemicals suitable for the period until decommissioning.	Yes	• IMR (Section 2.4.3) • Support Operations (Section 2.4.3)
Decommissioning	This stage is not part of this EP. Dependent on technical, environmental and execution studies, regulatory approvals and feedback from stakeholders, decommissioning may include:	This stage is not part of this EP. Dependent on technical, environmental and execution studies, regulatory approvals and	No	• Not applicable to this plan.

Decommissioning activities will be addressed in a separate permissioning document(s).

2 Description of the Activity

2.1 Operations history

In 1965 the Esso/BHP Billiton joint venture under the GBJV operating agreement drilled Australia's first offshore well and discovered the Barracouta gas field in Bass Strait. Two years later Kingfish was discovered, the first offshore oil field, which to this day remains the largest oil field ever discovered in Australia.

The GBJV invested in the continued exploration, development and production of oil and gas in the Bass Strait which has been used to power industry, fuel vehicles, heat homes and manufacture products in Australia and overseas for the last 50 years.

The offshore activities in Bass Strait are supported by up to 350 people who live and work offshore at any one time. They are supported by many more onshore, who process the oil and gas at our plants at Longford and Long Island Point before sending to customers.

Platform operations are also supported by helicopters and supply vessels. The helicopter fleet operates regular flights to transfer personnel to and from platforms, and supply vessels operate out of Barry Beach Marine Terminal, moving between platforms to load and unload cargo.

Since establishment, the Bass Strait operations have produced over 50% of Australia's crude oil and liquids production and supplied over 40% of all Eastern Australia's natural gas consumption.

2.2 Location of the Activity

The Gippsland Basin is located in the Bass Strait, offshore Victoria's southern coast. Facilities and permit areas are shown in Figure 2-1.

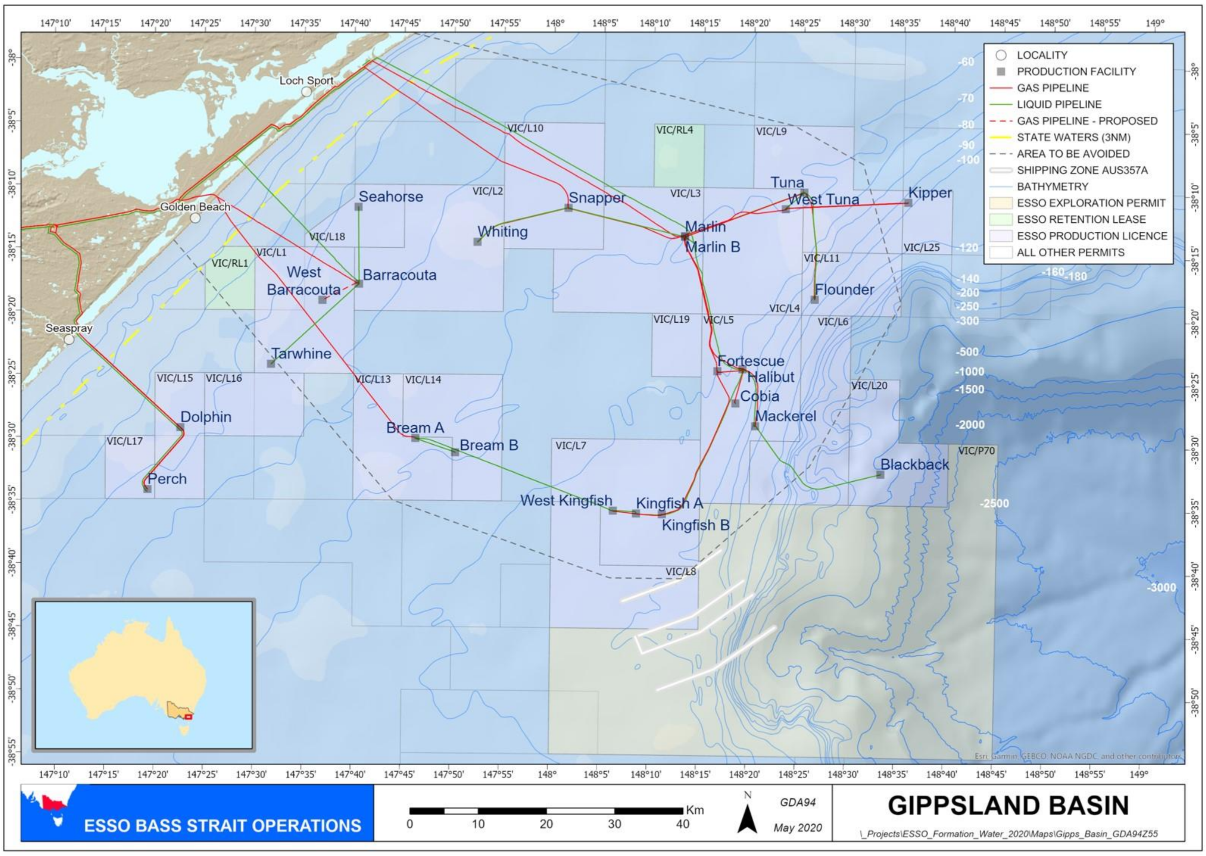

Figure 2-1 Esso Production Facilities in Bass Strait

The infrastructure includes 19 platforms, 5 subsea facilities (including the planned BTW Subsea Facility), and a network of subsea pipelines. Water depths at each facility range from 38 m (DPA) to 95 m (KPA).

An Area to Be Avoided (ATBA) excludes unauthorised vessels greater than 200 tonnes or 24 m length from entering the area around the Bass Strait platforms. The ATBA is defined in Schedule 2 of the Offshore Petroleum and Greenhouse Gas Storage Act 2006 (OPGGS Act) and administered by NOPSEMA. A traffic separation scheme operates to the south of the ATBA to control coastal shipping.

All the Esso operated Bass Strait Platforms (with the exception of PCA and DPA) are located within the ATBA. The BTW, SHA and TWA subsea facilities are located within the ATBA, whilst KPA and BKA are located outside. All pipelines (with the exception of part of the WTN350 (North & South), MKA-BKA65 and BKA – MKA200, and the PCA – Shore300 and Shore – PCA100) are located within the ATBA.

2.3 Gippsland Basin Facilities Description

The Bass Strait Oil and Gas Production Systems consist of staffed and unstaffed facilities and subsea systems as described in Appendix A, with interconnecting pipelines and umbilicals.

2.3.1 Platforms

Esso operates 19 platforms in the Bass Strait as listed in Table 2-1. The location and status of all facilities is summarised in Appendix A.

Note that the Marlin A and Marlin B platforms are connected via a walkway.

Table 2-1 Platforms

#	Title	Name	Abbreviation
1	VIC/L02	Barracouta	BTA
2	VIC/L02	Whiting	WTA
3	VIC/L03	Marlin A	MLA
4	VIC/L03	Marlin B	MLB
5	VIC/L04	West Tuna	WTN
6	VIC/L05	Halibut	HLA
7	VIC/L05	Fortescue	FTA
8	VIC/L05	Cobia	CBA
9	VIC/L05	Mackerel	MKA
10	VIC/L07	Kingfish B	KFB
11	VIC/L07	West Kingfish	WKF
12	VIC/L07	Kingfish A	KFA
13	VIC/L09	Tuna	TNA
14	VIC/L10	Snapper	SNA
15	VIC/L11	Flounder	FLA
16	VIC/L13	Bream A	BMA
17	VIC/L14	Bream B	BMB
18	VIC/L15	Dolphin	DPA
19	VIC/L17	Perch	PCA

Most of Esso's platforms have a tubular steel base structure (or jacket) which is fastened to the sea floor by piles. The jackets support the 'topsides' which include the production facilities, living quarters for the personnel working on the platform and a helicopter landing pad. Each platform typically consists of the following elements:

- Conductors, connecting the wellheads to the seabed.
- Pipeline risers connecting the platform to pipelines.
- Processing Equipment / Production facilities which typically include –
- Gas separators/scrubbers, oil separators, test separators, slug catcher/receivers
- Open and closed drain systems, including skimmer vessels and open and closed drain piles
- Potable water systems
- Produced water processing facilities, including hydrocyclones and/or dissolved gas flotation units
- Diesel/methanol/glycol storage & injection systems
- LPG/condensate reinjection facilities
- Instrument air systems
- Workover/wireline rig
- Living quarters, including
- Control room, radio room, offices
- Ablutions, laundry and galley
- Macerators for disposal of food scraps and sewage treatment
- Helideck
- Safety features including evacuation capsules
- Variable number of decks, including sea deck and cellar deck
- Laydown area and one or more cranes
- Pumps, compressors and electricity generators
- Maintenance workshop
- Flare/vent boom & scrubbers

Figure 2-2 shows a schematic of a typical Bass Strait oil and gas platform.

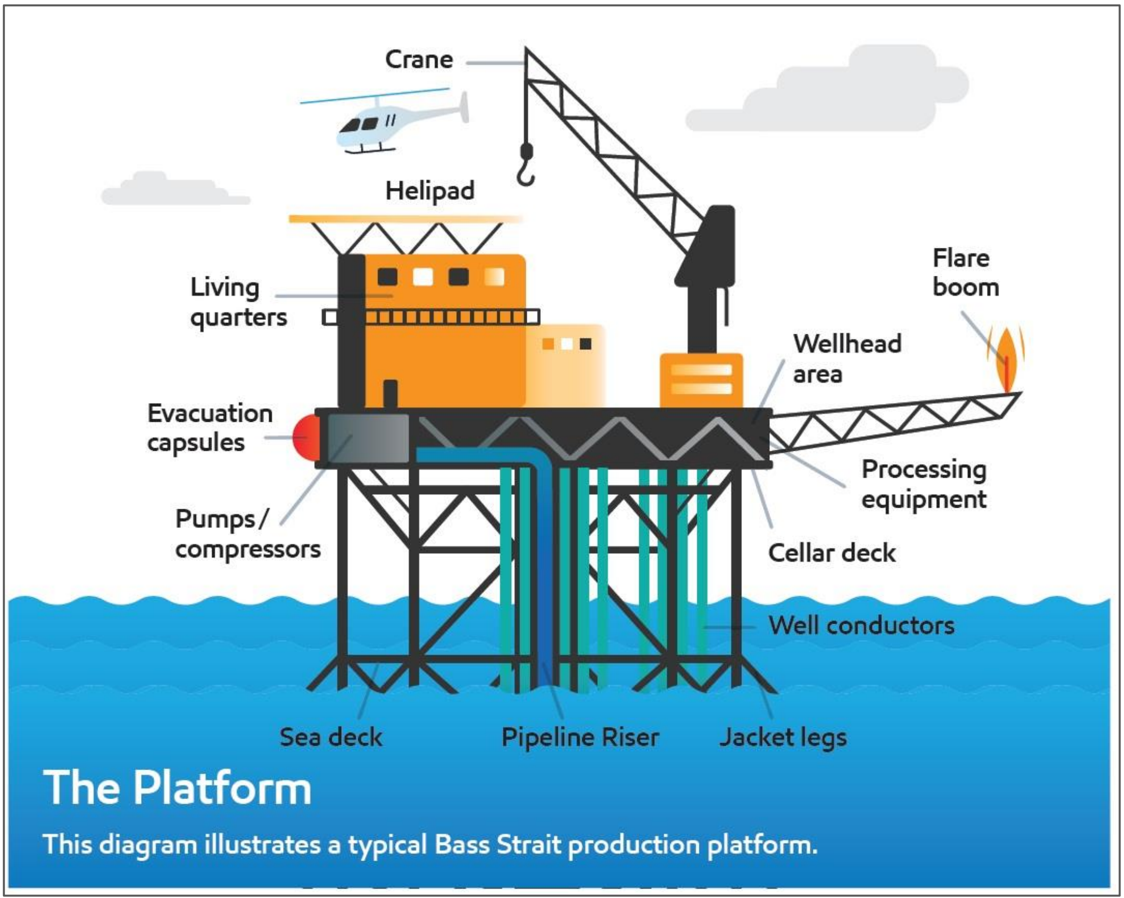

Figure 2-2 Schematic - Bass Strait Oil and Gas Platform

2.3.2 Subsea Facilities

Esso operates 5 subsea in the Bass Strait as listed in Table 2-2. The location and status of all facilities is summarised in Appendix A.

Table 2-2 Subsea Facilities

#	Title	Name	Abbreviation
1	VIC/L01	Tarwhine	TWA
2	VIC/L02	West Barracouta	BTW
3	VIC/L18	Seahorse	SHA
4	VIC/L20	Blackback	BKA
5	VIC/L25	Kipper	KPA

2.3.2.1 Kipper Subsea Facility

The Kipper Subsea Facility (KPA) consists of four subsea trees with trawl protection frames and four subsea coolers, designed to reduce the temperature of the produced hydrocarbons, connected via flowlines/jumpers and flying leads to a production manifold. KPA is connected to the WTN platform via two 350 mm pipelines, designed to allow round trip pigging, and an electrical and chemical (MEG, methanol and hydraulic fluid) umbilical.

2.3.2.2 West Barracouta Subsea Facility

The West Barracouta Subsea Facility (BTW) was installed in early 2021 with operations commencing in April 2021. BTW will consist of two subsea trees with trawl-protection frames connected via jumpers and flying leads to a Flowline End Manifold (FLEM) and umbilical termination assembly (UTA). BTW will be connected via an electrical and chemical umbilical to BTA platform, and via the BTW300 pipeline and subsea hot tap into the existing BTA-Shore 450 mm pipeline.

2.3.2.3 Blackback Subsea Facility

The Blackback Subsea Facility (BKA) was permanently plugged and abandoned in 2019 and the subsea trees were removed. The disconnected flowlines and electrical and chemical connections remain on the seabed. The UTA, umbilical, pipeline termination assembly (PTA) and 200 mm production pipeline and associated gas lift line connected to MKA platform also remain on the seabed. This equipment will be assessed for removal in the future, as described in Section 2.4.4.3.

2.3.2.4 Seahorse and Tarwhine Subsea Facilities

The Seahorse (SHA) and Tarwhine (TWA) Subsea Facilities was permanently plugged and abandoned in October 2020. Subsea trees were removed during the plug and abandonment activities. Minor infrastructure remained in place at these facilities for removal in the future, as described in Section 2.4.4.3.

2.3.3 Pipelines

Crude oil and gas produced offshore are transported to Longford Plants for processing, via a network of pipelines. Crude oil is collected offshore at three points (Halibut, Barracouta and Perch-Dolphin) and then piped to Longford Plants via dedicated pipelines. Gas is transported from the four major gas-producing offshore platforms (Marlin, Barracouta, Bream A and Snapper) to Longford Plants through dedicated gas pipelines. There are 31 licensed pipelines and eight secondary (gaslift and fuel gas) lines, as listed in Appendix A. For pipelines to shore, this EP covers the portion of these pipelines in Commonwealth Waters up to the 3 NM Victorian waters boundary only.

2.3.4 Products

A variety of products are produced from operations around the Strait, ranging from gas, condensate to oil. Different reservoirs produce hydrocarbon products with different properties. Pipelines contain a combination of different reservoir fluids.

The range of condensates and crude oils produced by the Bass Strait operations have been presented in Appendix A. Bass Strait Crudes can be classified into three groups based on ITOPF Oil Type classifications (ITOPF, 2015) as outlined in Table 2-3.

The main physical properties that affect the behaviour of spilt oil are specific gravity, distillation characteristics, viscosity and pour points.

Table 2-3 Physical Properties of condensate and crude oils produced in Bass Strait Operations

Group (ITOPF, 2015)	Oil Type	Description
Group 1	Condensate	Condensate is a Group 1 liquid hydrocarbon resulting from a change in pressure and or temperature of gas — 'liquid gas'. Condensates comprise a very high content of volatile (or non-persistent) constituents (~97–99%). Therefore, it is expected that any hydrocarbons reaching the sea-surface would quickly be lost to the atmosphere via evaporation. Any persistent (heavy) hydrocarbons may persist longer in the form of small solid relatively non-toxic waxy flakes on the sea-surface or entrained in the water column

Group (ITOPF, 2015)	Oil Type	Description
		Group I oils (non-persistent) tend to dissipate completely through evaporation within a few hours and do not normally form emulsions.
Group 2	Light Crude	Light crudes contain volatiles and semi to low volatile compounds constituting approximately 85% of the crude. The remaining proportion is heavier hydrocarbons. In the marine environment, light ends will evaporate leaving the heavier hydrocarbons. Group II and III oils can lose up to 40% volume through evaporation but because of their tendency to form viscous emulsions, there is an initial volume increase as well as a curtailment of natural dispersion.
Group 4	Waxy Crude	These crudes contain a high proportion of wax–with a corresponding high pour point. Group IV oils are very persistent in the marine environment due to their lack of volatile material and high viscosity, which precludes evaporation and dispersion.

2.4 Description of Activities resulting in Environmental Aspects

The primary purpose of offshore facilities is to extract, process and store oil and gas in order to transport products onshore for further processing and distribution to customers. In order to do this, a wide variety of activities are undertaken to directly and indirectly support oil and gas production. In order to decommission facilities, many of these activities continue, even once production of oil and gas has ceased.

This section describes the activities within the scope of this EP that have the potential to result in environmental aspects leading to impacts on, or risks to the environment. The activities included are:

- Operations (including platform, subsea facility and pipelines)
- Wellwork
- Inspection, maintenance and repair (including activities to prepare for decommissioning)
- Support operations (including vessels, ROV and Helicopters)

2.4.1 Operations

2.4.1.1 Platform Operations

All Esso platforms (with the exception of PCA and DPA) are located within the Area to Be Avoided (ATBA). Petroleum Safety Zones (PSZ) extending 500 m from each of the platforms and subsea facilities have also been established under the OPGGS Act. Vessels are prohibited from unauthorised entry into, or presence in, a PSZ.

All platforms are equipped with navigation lighting but also have a variety of other light sources including crane clearance lights, helipad lights and radio tower lights. Where facilities are staffed there is also lighting for accommodation and related infrastructure.

Gas compression turbines and the turbine power generators on platforms produce continuous noise. Fuel combustion equipment on platforms burn fuel gas and diesel. Equipment includes standby generators and compressors, and normally-operating turbines, compressors, generators and pumps, as well as other smaller equipment. Once facilities cease producing oil and gas, power generation systems remain in service, supplied by fuel gas or diesel.

Platforms usually generate potable water by reverse osmosis (RO) desalination of sea water. However, supply vessels may supply additional potable water, if required.

Platforms that have overnight accommodation discharge food and sewage / greywater. Platforms without overnight accommodation discharge sewage / greywater only when staffed. Domestic wastes generated on platforms are primarily sewage and liquid wastes from the kitchens, bathrooms and laundries. The grey water is comprised of potable water, soap and detergents. Persons on Board (POB) and staffing status at each platform is provided in Appendix A.

Platform operation generates both general wastes (solid inert materials including plastics, paper, glass and metal) and hazardous wastes (such as waste oil and chemicals, laboratory wastes, separator sludge and sand, oily filters, oily rags and empty drums containing oil or chemical residues). Solid and hazardous wastes are temporarily stored on the platform, then transported onshore and appropriately disposed.

Oils and Chemicals Storage and Handling

Oils and chemicals are used as part of the daily operation of the platform (e.g. cleaning decks, fuelling crane, striping and painting handrails etc.) and in the platform process (e.g. corrosion inhibitors, water handling chemicals, well workover base fluid and chemical additives), and are bulk stored on the platform. Use of chemicals is part of the daily operation and production process and these production chemicals may be discharged to the environment, provided they meet environmental discharge criteria.

Oils and chemicals are transferred via crane and stored as either packaged goods, in drums or in intermediate bulk containers (IBCs). If larger volumes are required (such as for diesel, glycol or methanol) they can be transferred to the platform via hose into a tank.

Bulk stored volumes vary between platforms, with the greatest volumes stored on WTN (582,000 L of glycol stored), SNA (diesel tank has a maximum capacity of 80,000 L) and TNA (220,000 L of methanol stored in TNA jacket leg). There is no storage of large volumes of glycol, methanol or diesel on FLA, HLA, KFA, KFB, WKF, MKA, MLA, MLB, PCA or DPA. Volumes of glycol at WTN will increase during the 5 year period for which this EP is in place, however volumes are not expected to be larger than those stored at other platforms.

Drain and pile system

There are three distinct drain systems on the platform:

Deluge drains that:

- Dispose of excess deluge water directly overboard.

Open drain (low pressure) systems that handle:

- Chemicals, oils and waste from bunded areas or designated containment areas.
- Residual chemicals and hydrocarbons from process equipment draining
- Rainwater or sea spray runoff on decks

Closed drain (high pressure) systems that:

- Drain process equipment at higher than atmospheric pressure such as wellheads, separators and flowlines, process equipment and instrument bridles.
- Handle oils, chemicals and water in process streams, such as drainage from pressured equipment such as pig launchers/receivers and separators.

Skimmer piles are used to separate hydrocarbons from water in liquids directed to the open and closed drain. The open and closed drain systems each have their own skimmer pile caisson that interfaces with the sea via the pile window. Hydrocarbon vapours and liquids migrate to the top of each pile and settle out on top of the water (Figure 2-3). The piles run at atmospheric pressure.

Hydrocarbon liquids from the open drain system are pumped to the closed drain skimmer pile. Hydrocarbon liquids from the closed drain skimmer pile are recycled to the process.

Note Figure 2-3 shows a schematic of the open drain and pile system with feeds from deck drains. Feeds from the closed pile system come from pressurised equipment. Details of feeds to the pile systems are described in Table 2-5.

As feeds to the pile are either the same density or less dense than water, as they enter the pile they displace existing water in the pile downwards, resulting in the displaced water being discharged from the subsea window. As hydrocarbons are pumped out of the pile, the volume is replaced with fresh seawater from the subsea window.

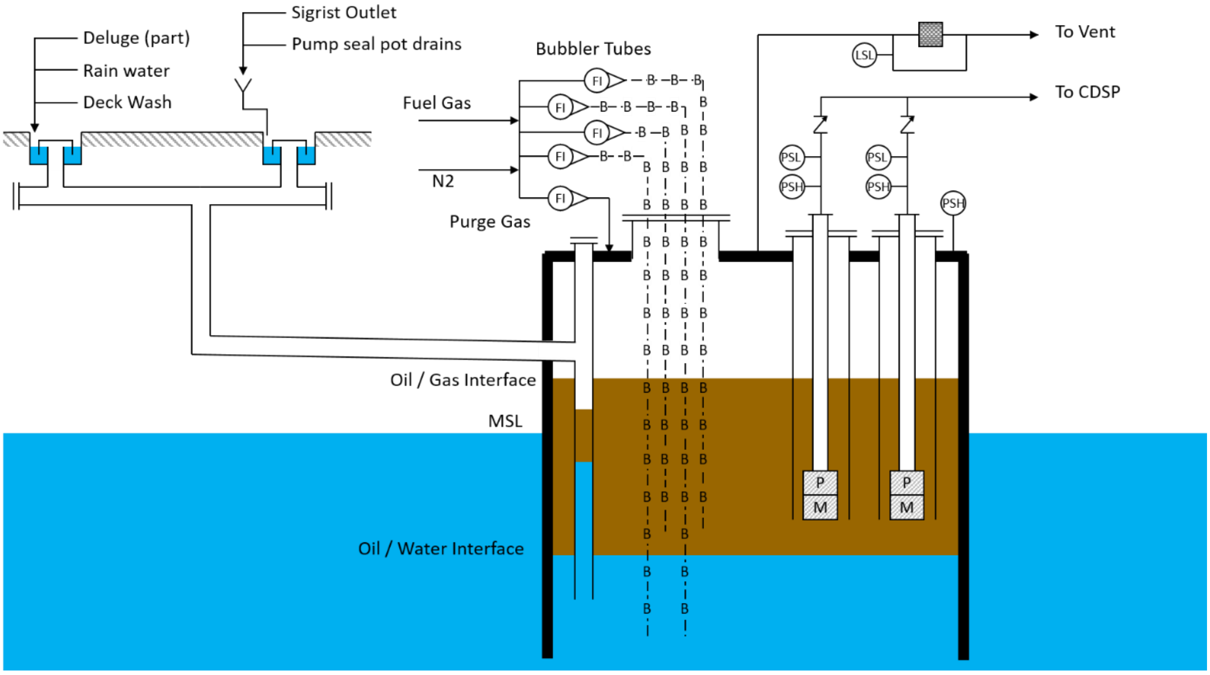

Figure 2-3 Schematic of open drains and pile system

Open Drain Skimmer Pile (ODSP)

The open drain skimmer pile is used to collect all liquids from the atmospheric drains and to separate the hydrocarbons from the water by allowing water to flow out to sea via the sub-sea window, more than 30 metres below sea level. Hydrocarbons are then pumped to the closed drain skimmer pile by the open drain skimmer pile pump(s) and then to the skimmer vessel by the closed drain skimmer pile pump.

All open drains connected to the open drain skimmer pile have an atmospheric break between the equipment and the open drain header to avoid the possibility of pressuring up the open drains or open drain skimmer pile system. The only connection to the closed drain skimmer pile is via the open pile pump discharge line, which is protected against backflow by check valves and a shutdown valve.

Closed Drain Skimmer Pile (CDSP)

The closed drain skimmer pile is used to collect all liquids from the closed drain system, and to separate the hydrocarbons from water by allowing the water to flow out to sea via the subsea window, again more than 30 metres below sea level. Hydrocarbons are then pumped to the skimmer vessel by the closed drain skimmer pile pumps.

Details of the open and closed drain skimmer piles for all platforms are included in Table 2-4.

The volume of oil in each skimmer pile is determined from the position of the oil/water interface. This is detected by measuring the differential pressure across two bubbler tubes positioned at different depths in the pile. For example, the WTN CDSP has these at 4m below MSL and 35m below MSL. The position of this interface can be measured directly as long as the interface sits between these levels. Levels are kept within these limits by high and low level trips that activate the pumps. Purge gas is used to operate the bubbler tubes (nitrogen gas may be used if purge gas is not available).

Signals from level interface transmitters are used to:

- Start and stop the submersible skimmer pump(s) automatically, although a manual mode is available to suit operational requirement to ensure hydrocarbon does not escape out of the subsea window;

- Shutdown the pump(s) on low oil volume level to protect the pump(s) from damage
- Trigger low / high oil volume alarm(s), and / or;
- Trigger a surface shutdown on high oil volume (typically CDSP only).

Table 2-4 Open and Closed Drain Skimmer Piles

Platform	Closed Drain Skimmer Pile (CDSP)	Open Drain Skimmer Pile (ODSP)
BMA	• CDSP volume – 200 kL (at 23 m) • Subsea window depth (MSL) – 50.9m • The CDSP is dosed with biocides (BMB only). • Liquid originates from the production system and the ODSP.	• ODSP volume – 23 kL (at 23 m) • ODSP subsea window – 34.2 m • Liquid originates from BMA open drain systems
BMB	• BMB has the HP Drain Vessel that is used to drain process fluids when preparing equipment for maintenance. • HP Drain Vessel volume – 0.9 kL • The vessel is connected to the BMB-BMA pipeline. There are no planned discharges from this vessel.	• BMB has an Open Drain (OD) Sump Tank • Sump Tank Volume – 2 kL • This tank is fitted with two coalescer plate packs and a hydrocarbon skimmer box. • Liquid originates from BMB open drain system.
BTA	• CDSP volume – 12.5 kL • Subsea window depth (MSL) – 43 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquid originates from the production system and the ODSP	• ODSP volume – 12.5 kL • ODSP subsea window – 43 m • Liquid originates from open drain system, hydrocarbon liquids from fuel gas system
CBA	• CDSP volume – 240 kL (at 35 m) • Subsea window depth (MSL) – 55.7 – 57.7 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquid originates from the production system and the ODSP	• ODSP volume – 38 kL (38 m) • ODSP subsea window – 55.7 – 57.7 m • Liquid originates from open drain system
FLA	• CDSP volume – 200 kL (at 25 m) • Subsea window depth (MSL) – 49.6 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquid originates from the production system and the ODSP	• ODSP volume – 35 kL (at 32 m) • ODSP subsea window – 40 m • Liquid originates from open drain system
FTA	• CDSP volume – 164 kL (at 18 m) • Subsea window depth (MSL) – 60 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquid originates from the production system and the ODSP	• ODSP volume – 38 kL (at 35 m) • ODSP subsea window – 40 m • Liquid originates from open drain system
HLA	• CDSP volume – 17.9 kL • Subsea window depth (MSL) – 50 m • The CDSP is dosed with biocides and demulsifier. • Liquid originates from the production system, the flare scrubber and the ODSP	• ODSP volume – 5.5 kL • ODSP subsea window – 46.5 m • Liquid originates from open drain system
KFA	• CDSP volume – 35.5 kL (at 35 m) • Subsea window depth (MSL) – 50 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquids originate from the production system, flare scrubber and ODSP.	• ODSP volume – 35.5 kL (at 35 m) • ODSP subsea window – 46 m • Liquid originates from open drain system
KFB	• KFB - 35.5 kL (at 35 m) • Subsea window depth (MSL) - 50 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquids originate from the production system, flare scrubber and ODSP.	• ODSP volume – 35.5 kL (at 35 m) • ODSP subsea window – 46 m • Liquid originates from open drain system

Platform	Closed Drain Skimmer Pile (CDSP)	Open Drain Skimmer Pile (ODSP)
MKA	• CDSP volume – 235 kL (at 30 m) • Subsea window depth (MSL) – 84m, 85m, 86m, 87m (4 windows) • The CDSP is dosed with biocides and demulsifier. • Liquid originates from the production system and the ODSP	• ODSP volume – 38 kL (at 35 m) • ODSP subsea window – 56.5 m • Liquid originates from open drain system
MLA	• CDSP volume – 14.5 kL • Subsea window depth (MSL) – 47 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals • Liquid originates from the MLA production system, ODSP, fuel gas scrubber	• ODSP volume – 14.5 kL • ODSP subsea window – 47 m • Liquid originates from open drain system
MLB	• CDSP volume – 57.5 kL • Subsea window depth (MSL) – 16.9 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals • Liquid originates from MLB production system, flare scrubber and the ODSP (via the skimmer vessel)	• ODSP volume – 57.5 kL • ODSP subsea window – 16.9 m • Liquid originates from open drain system
PCA /DPA	• PCA and DPA have a drain sump that is used to drain process fluids when preparing equipment for maintenance. • Drain sump is connected to the pipeline. There are no planned discharges from this sump. • The drain sump is dosed with biocides, emulsion breakers, and other process chemicals	
SNA	• CDSP volume – 240 kL • Subsea window depth (MSL) – 49 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals • Liquid originates from the Low pressure drain systems, and the ODSP	• ODSP volume – 38 kL • ODSP subsea window – 35.8 m • Liquid originates from open drain system, fuel gas system
TNA	• CDSP volume – 215 kL (at 21.4 m) • Subsea window depth (MSL) – 52.1 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals • Liquid originates from the production system and the ODSP	• ODSP volume – 38 kL (35 m) • ODSP subsea window – 38.5 m • Liquid originates from open drain system, fuel gas system
WKF	• CDSP volume – 240 kL (at 35 m) • Subsea window depth (MSL) – 69.5 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquids originate from the production system, flare scrubber and ODSP.	• ODSP volume – 55 kL (35 m) • ODSP subsea window – 67 m • Liquid originates from open drain system
WTA	• CDSP volume – 113 kL • Subsea window depth (MSL) – 50 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals • Liquid originates from the ODSP	• ODSP volume – 55 kL • ODSP subsea window – 50 m • Liquid originates from open drain system
WTN	• CDSP volume – 150 kL • Subsea window depth (MSL) – 44 m • The CDSP is dosed with biocides, emulsion breakers, and other process chemicals. • Liquids originate from the skimmer vessel, HP closed drain system flare scrubber, ODSP.	• ODSP volume – 130 kL • ODSP subsea window – 44 m • Liquid originates from the open drain system, hydrocarbon liquids from fuel gas system

Pile Feeds

Feeds to pile systems vary between platforms. In general, platforms which have a low pressure oil production system process liquids which may be directed to the pile system. Platforms which produce primarily gas and condensate have minimal feeds to the pile system as they produce less liquids. Platforms that have ceased production have minimal feeds to the pile system.

PLATFORMS WITH OIL PRODUCTION SYSTEMS – CBA, HLA, MLB, SNA, TNA, WKF, WTN

On platforms with oil production systems, trends show that, during normal operations, hydrocarbons from the closed pile system are pumped out approximately once per month removing approximately 15-20% of the pile volume each time. This accounts for the volume of feeds to the pile during normal operations from activities.

Pile feeds could include continuous feeds from platform equipment, produced water clean-up, discharges due to equipment or platform trips, pigging etc. Ongoing production fluids are generally directed to the closed pile system. Minimal residual production fluids may be directed to the open pile system however, the open pile system primarily processes water runoff from platform decks. A detailed list of pile feeds is provided in Table 2-5.

During periods of planned maintenance or during annual shut downs, discharges will increase and piles are required to be pumped out more frequently. Annual shutdowns can result in up to ~400 kL of discharges to the pile over the duration of the shutdown (generally 2 – 4 weeks). Planned shutdowns occur once per year although unplanned shutdowns (due to unplanned maintenance requirements) could occur 2 – 3 times per year.

Rate and / or duration of discharges to the pile are managed dependent on pile volume to ensure levels are maintained below high level alarms and risk of release of hydrocarbons through the subsea pile window is minimised.

Discharge from the closed pile has been modelled assuming 3 m^3 and 8 m^3 per hour to conservatively take into account water components in the discharge which cannot be measured by bubbler tubes. Pile pump out rates indicate that feeds to the pile and hence, discharges to ocean due to displacement, are expected to be significantly less than this.

PRODUCING GAS PLATFORM – BTA, MLA

Platforms which produce primarily gas and condensate have significantly less discharges to the pile system. During planned and unplanned shutdowns, the production system is depressured by flaring gas with minimal volumes of condensate being fed to the pile.

On these platforms, piles are pumped out less frequently, approximately once per three months removing approximately 15-20% of the pile volume each time. This accounts for the volume of feeds to the pile during normal operations from activities and hence, the volume of water displaced and discharged to ocean. Pile feeds on gas platforms are primarily from fuel gas condensate. A detailed list of pile feeds is provided in Table 2-5.

Modelling of pile discharges assumes discharges from producing platform with oil systems with ongoing production discharges. Platforms which produce primarily gas and condensate have significantly less discharges to the pile system and therefore, modelling is assumed to be worst case and highly conservative for gas and non-producing platforms.

NON PRODUCING PLATFORMS – BMA, FLA, FTA, KFA, KFB, MKA, WTA

Non producing platforms will be drained and de-pressured once production is complete and prior to restaffing. This period of draining and de-pressuring is equivalent to a full platform shutdown. This activity has already been completed on the platforms listed but may occur on platforms transitioning to CoP (per Figure 3-1).

- BMA
- FLA
- FTA
- KFA
- KFB
- MKA
- WTA

Once drained and de-pressured, platforms which are no longer producing have minimal feeds to the pile system. Feeds could include liquids from the fuel gas system. A detailed list of pile feeds is provided in Table 2-5.

On these platforms, piles are pumped out intermittently or upon campaign visits to the platforms when pump levels require. Observations from de-staffed platforms indicate a minimal rate of condensate accumulation in the pile requiring pump out once per year.

Modelling of pile discharges assumes discharges from producing platform with ongoing production discharges. Non-producing platforms have minimal discharges and therefore, modelling is assumed to be worst case and highly conservative for gas and non-producing platforms.

Table 2-5 Pile Feeds

Feed	Description	Producing	COP	Stasis mode
Primary pile feeds				
Draining of process fluids during equipment isolation / depressuring or wellwork	Majority of draining from pressured vessels or wellwork operations is directed to the closed pile. Residual process fluids are directed to open drains to confirm vessel or equipment is depressured and hydrocarbon free (draining to closed pile can only be completed until pressure in vessel equalizes with closed drain system). Prior to vessel entry or PVI any residual solids, sand or sludge is collected and disposed of onshore. Prior to wellwork activities, wells will be depressured to the flare (for gas wells) or to the closed pile system (for oil wells)	✓	Applicable during final draining prior to CoP. No continuous draining of process fluids occurs post CoP. Feeds to the pile will occur during wellwork activities to P&S/P&A wells.	Not applicable. All drainage activities complete.
Waste oils from continuous operations (filter coalescers, pump seals, gas lift condensate)	On some platforms, equipment generates low volumes of waste oil from continuous operations. This is directed to the closed pile system where it is recycled into the process via the close pile pump.	✓	Not applicable once production has ceased.	Not applicable once production has ceased.
Liquids from the fuel gas system	In order to supply ongoing power to staffed and destaffed facilities, gas is used as fuel to power generators. Minor amounts of condensate may drop out from the gas lift system. These are directed to the closed pile system.	✓	✓	Not applicable. Power generation ceased during stasis mode.
Low volume feeds				
Waste oils (lube oil, hydraulic fluid, ATF) from machinery servicing	Bulk volumes of waste oils from scheduled machinery servicing are collected in stainless steel waste oil bulkies for onshore disposal. Minor machinery servicing may generate small volumes of waste oils which is directed to the closed pile system and recycled into the process via the closed pile pump.	✓	Significant reduction in discharges as majority of machinery is out of service.	Not applicable. All maintenance and drainage activities complete.
Fluid samples taken from well testing / pipeline sampling	Sampling is undertaken intermittently to test composition of wells or water in pipelines. Involves taking a small sample into an open container (e.g. measuring flask approx.1 L). Once sampling is complete, excess sample is discharged to the open drain system where it can be recycled to the process (via closed pile). The frequency of sampling is dependent on the platform and the number of wells but could be up to several times a month per well.	✓	✓	Not applicable. No ongoing sampling required.
Pigging Wax	On some platforms, pigs received are covered in wax/waxy residue. Wax consistency varies between platforms dependent on crude type. Wax is collected for onshore disposal. Residual amounts of wax may be directed to the open pile system to avoid personnel exposure to unprocessed crude.	✓	✓	Not applicable once pipelines suspended.

Feed	Description	Producing	COP	Stasis mode
Diesel from Pump Seal Draining	On some platforms, flushing of MOL pump seals is required to monitor the integrity of the pump seal system. Seal failure has been identified as a key hazard in offshore safety cases. Flushing of 4-8 L of diesel occurs periodically (daily on some platforms).	✓	Not applicable once production has ceased.	Not applicable once production has ceased.
Water feeds with residual hydrocarbon	For example, water with condensate from flare loop seals, excess water from formation water sampling.	✓	✓	Not applicable once flare is out of service.
Water Feeds				
Water with residuals from deck cleaning	Cleaning chemicals and water are used to clean residue from platform decks. Water from deck cleaning is directed to the open pile system. Water soluble chemicals will leave the pile through the subsea window with the water phase. Any chemicals discharged via subsea window are subject to chemical assessment to ensure they are approved for discharge Residual amounts of sediment from deck cleaning may make their way into the drain system.	✓	✓	Not applicable.
Rain water	Rain water is directed to open drain systems as runoff.	✓	✓	✓
Water from deluge tests	Sea water used during deluge testing is directed to the open drain system as runoff. Pile systems are pumped out prior to testing and the majority of water is directed overboard. An estimated 10-15% of water is directed to the open drains. Tests run for 3-5 minutes.	✓	✓	Not applicable.
Produced water clean up	During start-up of the produced water handling system, water generally has a high oil in water content until the system is running at optimal process conditions. To ensure off spec water is not discharged overboard, oily water is directed to the 'clean up line' until it is below regulatory limits and acceptable limits for discharge. This is to allow excess oil in the water to separate and be recycled to the process. For more detail on the PFW system, refer to Table 2-7.	Applicable for platforms with water handling systems	Not applicable	Not applicable
Other Feeds				
Closed pile biocide	Small volumes of biocide are injected to the closed pile to mitigate the growth of SRB which can cause corrosion leading to loss of integrity.	✓	✓	Not applicable

Cranes and lifting

Each platform is equipped with cranes which undertake lifts for operation and maintenance activities.

Safety Systems

All platforms are equipped with a firefighting system in case of an emergency. Firewater pumps supply water to deluge and sprinkler systems upon detection of a fire.

Fire-fighting foam can be applied via the deluge system or hose reels. It is also used as a pile blanket when removing and replacing the skimmer pile pump(s).

All platforms (excluding PCA and DPA) have a foam deluge system. Operation of the foam deluge system could occur either as part of testing the system or as demanded during an actual fire event.

Flaring and Venting

A flare is present on all platforms apart from PCA, DPA and BMB. Non-routine and safety flaring is conducted for the safe disposal of hydrocarbons during process upset, maintenance, commissioning / start-up or emergency conditions. Flare systems are designed for a maximum flow rate capacity such that the entire platform is able to be blown down rapidly. No routine flaring is undertaken.

Use of flares to combust gas significantly reduces greenhouse gas emissions (CO_2-e levels) when compared to venting because gas (mainly methane, CH_4) is converted to CO_2 and H_2O. Methane has a global warming potential (GWP, or CO_2-e value) of 28 to 36 (i.e. releasing 1 kg of CH_4 into the atmosphere is equivalent to releasing 28 to 36 kg of CO_2). Flares can achieve 95% efficiency, so that flaring of excess gases – instead of cold venting - results in a significant reduction in GWP (over 95% reduction if gas stream is assumed to be 100% methane).

Flares are used to safely combust gases collected from process and emergency streams, ensuring that they are disposed of in a safe manner, minimising the risk to personnel or adverse environmental impact. The safe disposal of hydrocarbon that is unable to be processed is integral to the safe operation of an offshore processing facility. Despite this, the aim is to minimise flaring, both because it results in unnecessary GHG emissions, and it represents an economic loss.

During standard operation, the flare tip remains lit with a pilot light. The pilot light is maintained with a small amount of gas such that the flare normally stays alight. If the pilot light is blown out (e.g. due to high winds) the flare is relit as soon as practicable. Once facilities cease production, the flare remains in service for safety reasons and to allow for depressuring in preparation for decommissioning activities.

Each flare has a flare scrubber located at the base of the flare boom. The flare scrubber removes bulk liquid from the gas stream to minimise burning of liquids at the flare tip. Liquids removed from the flare scrubber are directed to the closed skimmer pile. Typical sources of flared gas are shown in Figure 2-4.

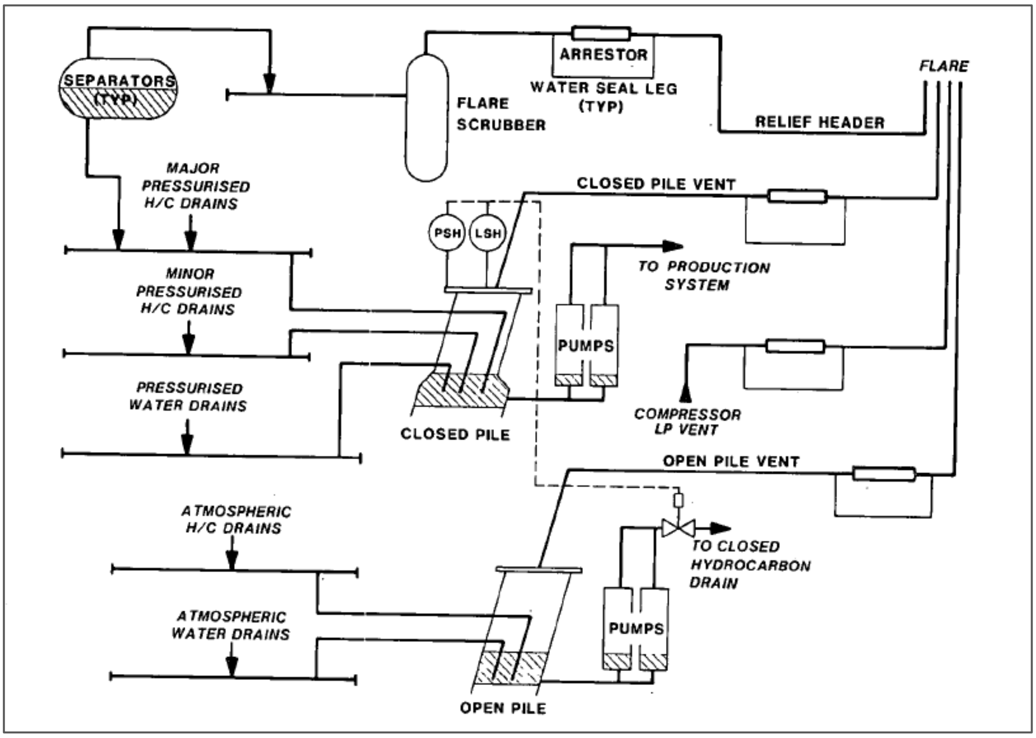

Figure 2-4 Generic Flare Vent & Drain Model

Flaring targets are set annually for all offshore facilities. The combined daily average target is typically 25-30 ksm^3/d. Elevated flaring rates are generally due to process upsets, during maintenance activities, or during start-ups. Annual flaring targets from 2020 until 2025 for each of Esso's platforms in Bass Strait are provided in Table 2-6. These flaring volumes are based on long term averages and account for maintenance and process upsets. Flaring volumes involved in commissioning and start-up are incorporated into the flaring forecasts provided in Table 2-6. Flaring is reviewed daily by OIMs and monitored on a monthly basis by engineers. There is a strong focus on reducing flaring where possible.

Flaring guidelines detail the approval process required where flaring is anticipated to be sustained above normal levels for >12 hours. In maintenance planned activities, the preference will be to send gas to flare rather than vent.

For low pressure systems, such as open and closed drains, there are small volumes of gas that are vented via dedicated lines up the flare boom. These vent sources include low pressure compressor vents, seal gas vents and flexible pipeline gas vents. An annual review is undertaken of all identified venting events via these sources across the offshore platforms. The quantity of venting is typically ~350 tonnes per year.

No additional flaring is expected during start up of West Barracouta operations as BTW feeds directly to the BTA450 pipeline.

Table 2-6 Bass Strait Operations - Flaring Forecast (km^3/day)

Facility	2020	2021	2022	2023	2024	2025	Average

Produced Formation Water

Produced Formation Water (PFW) is generated throughout the Bass Strait Operations on platforms SNA, TNA, WTN, HLA, WKF and CBA. PFW is either treated offshore before discharge or transported back to shore. Platforms which are shut in and do not, and will not for the life of the EP discharge PFW include: MKA, KFA, WTA, KFB, FLA, BMA, BMB, PCA, DPA and FTA. Water produced on the MLA, WTN and BTA platforms is transported to shore for treatment. There is currently no PFW discharge at MLB, however water treatment facilities is planned to be commissioned in the future.

Crude and produced water are separated in production separators. Chemical additives are injected at various points to assist oil/water separation. Oily water from separators is drawn off and directed to a secondary separation stage. Secondary separation consists of treatment through dissolved gas flotation units, hydrocyclones, degasser vessels or a combination. Details of PFW treatment systems on each platform are described in Table 2-7.

Reject oil from the secondary separation stage is returned to the process. 'De-oiled' water is discharged. Oil content in PFW being discharged overboard is monitored. In the event that oil in water content of PFW being discharged exceeds accepted limits, the water handling system has an alarm with associated procedures for corrective actions, and an automated water discharge shutdown is triggered if the level is too high. There are also low interface level alarms on the production separators.

Water handling system monitoring and control

A water overboard oil-in-water monitor ("Sigrist") is located upstream of the water overboard line shutdown valve and acts to continuously monitor the oil in water using ultraviolet fluorescence. Alarm and shutdown functions are embedded within the monitor's functionality. The water handling system is bypassed when testing or calibrating the oil-in-water monitor.

A 'clean-up' line allows any oily water in the water handling facilities to be flushed out into the closed drain skimmer pile. The clean-up line is utilised on platform start-up whilst processes are settling or during other process upsets. The line has a restriction orifice plate installed to limit the clean-up flow to the pile, to avert oil present in the water exiting via the closed pile window. The clean-up line is used until typical oil in water quality is obtained at the sample point provided in the clean-up line. There are limitations to the use of the clean-up line however, as whilst the clean-up line is in use, the hydrocyclones cannot operate efficiently because of inadequate differential pressures, and hence they must be started or restarted with the water overboard valve open to gain normal oil-water primary separation following the use of the clean-up line.

Both oil-in-water monitors require to be bypassed whilst flow is diverted to the clean-up line to avoid system shutdown. Manual samples are taken to ensure the system is functioning as intended. Online monitoring is established once the system stabilises and within maximum time limits allowed as stated in procedures.

Dye may be injected into the PFW stream if the need arises to monitor the discharge plume in the environment.

Depth of produced water discharge piping

Due to the difference in temperature and salinity of the produced water discharge, the plume is strongly buoyant, and dilutes rapidly as it rises with the surrounding ambient water owing to the combined effects of the momentum and buoyancy-induced mixing of the fluid discharged from the orifice (Walker *et. al*., 2019). The rate of dilution caused by these forces is quite rapid in the first few seconds to minutes after exiting the orifice and then decreases markedly after the momentum and buoyancy are dissipated. Details of the produced water discharge pipe depth for each platform is shown in Table 2-8.

Table 2-7 Bass Strait Operations – reservoir liquids processing description

Platform	Primary Separation	Secondary Separation	PFW Reject Stream
HLA	Primary separation of bulk fluids is achieved by the production separators with chemicals being injected at varying rates at the inlet of each separator to assist with oil/water separation.	Post primary separation, the water stream is passed through Dissolved Gas Flotation (DGF) vessels and/or a hydrocyclone unit. Treated water from the DGFs and hydrocyclone is discharged to sea.	Reject streams generated from the DGFs and the hydrocyclone will be further processed in the degasser vessel or the skimmer vessel before being reinjected into the oil pipeline.
CBA	Primary separation of bulk fluids is achieved by the production separators.	The water stream generated from the separator is directed to hydrocyclone skids. Treated water generated from the hydrocyclones is discharged overboard through the water overboard line. Chemicals are injected at the inlets of the production separators to aid oil/water separation.	The reject oily water generated from the hydrocyclones flows to degasser vessels and is subsequently pumped back into the main oil line or is automatically directed to the closed skimmer pile.
WKF	Primary separation of bulk fluids is achieved by the production separators	Treated water generated from the hydrocyclones is discharged overboard through the water overboard line.	Reject streams generated from the hydrocyclones are fed to the degasser vessel for further treatment. The gas from the degasser vessel feeds into the relief header, which the liquids are pumped back into the production separators.
TNA	Primary separation of bulk fluids is achieved by the production separators.	The water stream generated from the separator is directed to hydrocyclones. Treated water generated from the hydrocyclones is either passed through a degasser vessel or discharged overboard through the water overboard line.	Reject oily water from the deoiler hydrocyclones is sent to the skimmer vessel for further separation.
SNA	Primary separation of bulk fluids is achieved by the production separators.	The water stream generated from the separator is directed to deoiler hydrocyclones. Chemicals are then injected into the water stream to aid with oil/water separation.	Reject streams generated from the hydrocyclones and the DGF vessel combine and pass through a subsequent DGF vessel. Gas evolved from this is directed to the relief headers whilst oil generated is

Platform	Primary Separation	Secondary Separation	PFW Reject Stream
		Treated water generated from the hydrocyclones is then passed through a DGF vessel and discharged overboard through the water overboard line.	returned to the suction end of the MOL pump through oily water pumps.
MLB	Primary separation of bulk fluids is achieved by the production separators.	The water stream generated from the separator is directed to hydrocyclones. Treated water generated from the hydrocyclones is either passed through a degasser vessel or discharged overboard through the water overboard line.	Reject oily water from the deoiler hydrocyclones is sent to the skimmer vessel for further separation before being reinjected into the oil pipeline.

CBA	27.7
WKF	16.0
TNA	28.8
SNA	8.2
MLB	11.0

2.4.1.2 Subsea Facility Operation

The West Barracouta (BTW), Seahorse and Tarwhine (SHA and TWA) subsea facilities are located within the ATBA, whilst Kipper (KPA) and Blackback (BKA) are located outside. In lieu of AMSA approval to extend the ATBA, subsea coolers are positioned at KPA to assist in protecting the manifold and flowbases from fishing snag loads. Locations and details of subsea facilities are described in Appendix A and are shown in the schematic in Figure 2-2.

Subsea facilities are complex systems designed to transfer hydrocarbons from subsea wells to the platform or pipeline. The subsea facilities are typically made up of a combination of the following infrastructure:

- **Subsea Trees**: used to control well conditions temperature/ pressure and supply chemicals if required
- **Subsea Control Modules (SCMs)**: electrical and hydraulic systems that control the flow of hydrocarbons and chemicals through the subsea facility
- **Electric and hydraulic jumpers**: connect the subsea infrastructure and used to communicate hydraulic and electric communications
- **Flowlines/ spools**: Transport hydrocarbons from wells to the pipelines or platform risers
- **Flowline End Manifolds (FLEM)** that connect flowlines to jumpers
- **Pipeline Terminal Assemblies (PTA)** – again for connecting flowlines or pipelines to jumper
- **Flowbases:** where well heads and trees are located
- **Subsea coolers:** Cooling systems on the subsea floor to cool down process fluids
- **Umbilicals:** Transport electric and hydraulic signals between the platform and the SCM/subsea trees. May also have chemical lines to supply chemicals to the wells and pipelines.

- **Risers:** Transport hydrocarbons for the seabed to the platforms

The subsea facilities are 'hosted' from a platform and controlled via hydraulic and electrical umbilicals. Hydraulically actuated subsea tree, wellhead and subsurface safety valves are remotely operated from the host platform. A small volume of production chemicals such as hydraulic fluid (approx. 1000 L per week), are released to the marine environment at each subsea tree valve operation.

Chemicals for corrosion inhibition and hydrate inhibition (e.g. Monoethylene Glycol (MEG) and methanol) are injected into the subsea wells via a chemical umbilical from the host platform.

2.4.1.3 Pipeline Operation

All pipelines (with the exception of part of the WTN350 (North & South), MKA-BKA65 and BKA – MKA200, and the PCA – Shore300 and Shore – PCA100) are located within the ATBA.

Locations and details of pipelines are described in Appendix A. Offshore pipelines are laid on the seabed between platforms, between platforms and subsea facilities and between platforms and shore, as shown in the schematic in Figure 2-2. Many pipelines are either fully or partially self-buried. In addition to having concrete weight coating some are stabilised with concrete or grout mattresses to provide resistance to pipeline movement.

External pipeline surfaces are coated to prevent corrosion and external corrosion protection is further augmented via cathodic protection (impressed current local to the host platform and sacrificial anodes along the pipe). Both oil and gas pipelines are pigged to remove potential obstructions and pooled water and injected with corrosion inhibitor. MEG and/or methanol is injected into the gas streams at each platform to inhibit the formation of hydrates.

The only routine planned discharge from pipelines is from valve actuation and involves small (<10 L) intermittent discharges of hydraulic fluid.

2.4.2 Wellwork

2.4.2.1 Wireline / Workover Activities (general)

Wellwork activities include any work performed on or in the subsurface part of an existing wellbore.

Wellwork activities can include completions, productivity improvement workovers, well servicing workovers and plug and abandon workovers. Wellwork can be completed via conventional workovers, concentric workovers, wireline workovers or rigless workovers.

- **Conventional workovers**: When the production Christmas tree is removed and BOP equipment is installed on top of the tubing head or wellhead flange.
- **Concentric workovers**: When small diameter pipe is used, with or without removing the Christmas tree. BOP equipment is installed above the Christmas tree. This also applies to wellwork involving coiled tubing equipment.
- **Wireline workovers**: When slick, braided, or conductor line is used through the tubing string, with or without removing the Christmas tree. Wireline BOP equipment is installed above the existing Christmas tree.
- **Rigless workovers**: When WellWork Execution operations are being conducted without the use of any type of rig. These could involve high pressure pumping operations (acidizing), well circulations, and so forth.

Conventional and concentric workovers require a workover rig to be assembled on the platform. Workover rigs used on Bass Strait platforms sit on the platform main deck. All rigs have a power generation source and pumps with the ability to pump fluids into the well. Wireline workovers use a workover spread which consists of an A-frame, BOP/pressure-control equipment, line units, and pump.

Prior to completing wellwork activities, the well and topsides must be depressured. Returns during depressuring are directed to the platform's production system as far as practicable (until at equal pressure with the system). Final depressuring to atmospheric pressure requires residual gas to be vented and liquids directed to the drain system.

All workovers use workover fluids as part of the workover operations. This includes brines, barite, and additives such as baracarb and other salts, corrosion inhibitor, biocide, oxygen scavenger, friction reducers, viscosifying agents, solvent and/or surfactant spacers, gels, polymer and cement. Fluid returns are directed to tanks or shakers prior to discharge to allow for settling of solids and/or monitoring of hydrocarbons. If hydrocarbon liquids are detected, returns are diverted to the platform's pipeline without discharge to the environment.

In some cases, milling is required to cut and remove material from equipment or tools located in the wellbore. Following milling, circulated fluids may bring up milled material from the wellbore, which is captured and disposed on shore.

In some cases, wellwork can include the removal and replacement of the production tubing string after the well has been killed and a workover rig has been placed on location.

Well logging is undertaken to determine rock and fluid properties of the targets. The well may be evaluated using Logging While Drilling (LWD) techniques and mud logging. Nuclear, Electric or Acoustic measurement tools can be used to identify different rock types down the well.

As part of Wellwork operations, formation samples can be collected to determine the presence of oil or gas. At the same time, reservoir pressure can be measured, using a down-hole pressure gauge to determine aquifer and hydrocarbon pressures.

Restrictions to wellwork operations on the Moonfish reservoir are in place to manage the risk of loss of well control during wellwork operations due to the unique properties of Moonfish Crude. Refer to Section 7.7.2 for further details.

2.4.2.2 Well Decommissioning

Esso has an ongoing well abandonment programme. The Esso Bass Strait Well Operations Management Plan (WOMP) includes a current list of wells within the Gippsland Basin and their status. Where a suspended well is P&A'd and/or fully abandoned, the WOMP is updated to reflect the revised well status. A list of all wells relevant to this EP and their status at time of writing is provided in Appendix A.

2.4.2.3 Cementing

Remedial cementing consists of operations performed to repair a well or to alter its configuration. This usually involves the placement of small volumes of cement to seal perforations or defects in the primary cement sheath or to set cement plugs to isolate all or part of the wellbore.

The type of cement, cement additives and volume required for cementing operations is dependent on a number of factors such as the type of completion, the age of the well, the type of fluid in the wellbore, and the depth of the workover operation. Additives may be added to cement to alter the characteristics to meet technical requirements. Key considerations for cement type are the weighting and the time to set.

2.4.2.4 Conductor cutting and pulling

Conductor cutting and pulling will occur when well casing is removed. Wells are plugged and abandoned prior to cutting and pulling conductors. Flowback between the flowline and casing annulus will occur, with limited discharge of interface fluids to the marine environment during the final cut.

2.4.2.5 Conductor clean out

Conductor clean-out operations involve cleaning the conductor of seabed sediment before a hole is cased. A pump transports mobilised sand and brine inside the conductor up-hole and overflows the conductor directly to sea.

2.4.2.6 Sandwash

Sandwash operations involve cleaning of the casing inside the cased hole to gain access to reservoir zones deeper than the well hang-up depth. The well will be killed, or appropriate pressure control equipment used, prior to sandwash operations, meaning that there will be no hydrocarbons in the well. A pump transports mobilised sand and brine inside the casing up-hole to a hose that discharges into a drum that collects the sand deposits and allows the fluid to overflow the drum and overboard. The sand is captured and sent onshore for disposal. In some cases, a gel pill will be used to provide additional mobilisation / flow of sand.

2.4.3 Support Operations

2.4.3.1 Vessel Operations

Vessels are used to support offshore activities. Types of vessels include: platform supply vessels; support vessels; installation support vessels, dive support vessels and multipurpose support vessels.

Platform supply vessels are used for loading and unloading of a variety of materials to and from the platform. This includes moving materials via the platform crane, bulk transfer of fluids, such as glycol, methanol, drilling fluids, brine, and some solid powders (such as cement, barite), and waste transfer.

Other vessels are used for underwater inspections, drilling, and specialised services. These vessels operate on an as-needs basis from onshore terminals. Typical subsea support vessels use DP to manoeuvre and to avoid anchoring when undertaking works near subsea infrastructure. Various support vessels are used (depending on type of work, schedules and availability) for activities.

The specifications for the Skandi Feistein are listed in Table 2-9 as a typical subsea support vessel.

Table 2-9 Indicative vessel specifications (Skandi Feistein)

Specification	Details
Length overall	87.9 m
Breadth	419 m
Draft	6.6 m
Deadweight tonnage	4,700 tonnes
DP System	DP-2
Fuel capacity	1070 m^3

Vessels are operated in accordance with International and Australian regulatory requirements and are subject to a marine assurance program.

All vessels supporting the offshore activities will be specified and operated in accordance with International and Australian regulatory requirements. All vessels will be subject to ExxonMobil's Marine Quality Assurance Best Practice and will be certified as being in compliance with international maritime legislative requirements by a Classification Society registered with International Association of Classification Societies (IACS) or by the Australian Maritime Safety Authority (AMSA).

DNV Clean class vessels (DNVGL-RU-SHIP) are used preferentially. These are constructed to provide environmental protection and pollution control.

2.4.3.2 Helicopter Operations

A fleet of aircraft operate out of the Longford heliport on a scheduled basis to support operations. In addition to transporting personnel, the helicopters carry urgent freight and critical spares for the operation of the facilities in Bass Strait. The number, type, and frequency of helicopters available depends upon the planned operations.

Helicopter operations are performed in accordance with Civil Aviation Safety Authority (CASA) regulations. Helicopter type, suitability, and performance criteria are contractually controlled, as are minimum flight and engineering crew qualifications and experience levels. Non-emergency helicopter flights are limited to daylight hours.

2.4.3.3 ROV Operations

Subsea inspection, maintenance and repair may be undertaken by ROV or divers (either platform or vessel-based deployment).

ROVs and divers are linked to the vessel typically by umbilical cable and a tether management system (TMS). Most ROVs and divers are equipped with at least a video camera and lights. Additional equipment may include sonars, magnetometers, a still camera, a manipulator or cutting arm, water samplers, and instruments that measure water clarity, water temperature, water density, sound velocity, light penetration and temperature.

2.4.4 Inspection, Maintenance and Repair (IMR)

Inspection, maintenance and repair is undertaken regularly on all platforms (Facility IMR – 2.4.3.1) and on pipelines and subsea structures (Pipeline and Subsea IMR – Section 2.4.4.2). Subsea is the term used for all infrastructure found below the waterline, e.g. riser, platform legs, pipelines and subsea components.

2.4.4.1 Facility IMR

Facility IMR activities are required to ensure platform wells and topside equipment are maintained in good repair to perform their intended function and in order to prepare facilities for decommissioning. An inspection regime as defined by the relevant Facility Integrity Management System (FIMS) program is in place to identify faults before they become health, safety or environmental issues. Facility IMR consists of a wide variety of mechanical, electrical and structural activities which fall into two categories:

- Preventative maintenance, which is planned, and;
- Repairs as a result of an unplanned failure of equipment or identification through inspection.

A number of activities may be undertaken to prepare equipment for IMR, including:

- Air freeing;
- Hydrocarbon freeing (potential small volumes of venting);
- Breaking containment;
- Pigging;
- Piping modifications;
- Isolation and depressuring; and
- Cleaning / flushing and the removal of hydrocarbons.
- Handling of fluids via reinjection to existing wells or discharge overboard in accordance with discharge limits

Full platform facility shutdowns may be required during IMR activities. Once maintenance and repair activities are completed the platform is re-started.

Inspection Methods

The primary inspection methods during Facility IMR are listed in Table 2-10. An estimation of the durations and frequency of the inspection activities have been included, however these may vary when faults or maintenance is required, additional maintenance beyond the defined FIMS program elements is required, or equipment is taken out of service (e.g. for non-producing facilities).

Table 2-10 Inspection methods during Facility IMR

Activity	Purpose	Frequency	Duration
Non-destructive testing	Non-destructive testing (NDT) is a non-invasive technique for evaluating the properties of a material. Various FIMS programs complete extensive NDT across platforms to evaluate fitness for service.	NDT completed continuously, crews rotate between platforms	~1-3 month campaigns per platform per year

Activity	Purpose	Frequency	Duration
Leak and pressure testing	Leak and pressure testing can be completed prior to or following maintenance work to test the integrity of equipment and identify required maintenance.	Majority of leak testing is completed following annual shutdown, however ad-hoc testing is completed to support maintenance jobs throughout the year as required	Majority of shutdown pressure testing is for 1-4 days following annual shutdown
Deluge testing	The deluge system is designed to supply firewater simultaneously to one deluge area and two hose reels, using one firewater pump.	Deluge testing is conducted twice annually.	Testing of pumps typically lasts 30 mins.

Note: This table is not an exhaustive list of inspection activities. Activities may be adapted or added to accommodate specific scope requirements.

Maintenance and Repair Activities

Periodic preventative maintenance activities are undertaken regularly on all platforms. Maintenance intervals are defined by the Facility Integrity Management System (FIMS), and are based on a predetermined schedule which is updated based on the outcome of inspections.

Abrasive blasting involves the use of sand, grit or hydro gritting/ultra-high pressure water for surface preparation including rust and paint removal, and can be undertaken on surface pipework and production vessels (internal and external). Blasting is also undertaken during recoating programs during which the original coating/paint is removed to ensure a clean surface remains for the new protective coating, such as passive fire protection (PFP). The majority of blasting is completed during shutdowns, some external painting campaigns take place on platforms as required.

Hot work may be required to complete maintenance activities. Hot Work includes; welding, cutting, burning, use of open flame, grinding, and any work activity generating sparks or slag. The majority of hot work is completed during annual platform shutdowns but some ad-hoc work outside of shutdowns for maintenance work may be completed as required.

Maintenance may involve regular activities such as:

- Maintenance and calibration of instrumentation;
- Function testing;
- De-sanding;
- Pump, compressor and generator servicing;
- Greasing of equipment; and
- Structural maintenance.
- Flushing pipework or vessels with water treated with chemicals to aid cleaning of the system

The majority of general maintenance activities occur either in platform campaigns throughout the year or during platform shutdowns.

For larger turbine equipment, maintenance could involve:

- Filter changes (oil filters, fuel gas filters) which involves draining oil/diesel from turbine generators;
- Oil changes which involves draining of old oil and replacement with new oil; and
- Washing of engines which involves pumping water (sometimes with a cleaning agent) into engines to assist in cleaning.

The frequency of these activities range from every 12 months (filter changes) to 4 – 6 years for oil changes.

Platform well maintenance activities may include:

- Valve maintenance: Consists of greasing and functioning the valves to ensure integrity and working correctly; Valves on gas platforms are greased every 12 months and on oil platforms every 18 months. Valves are functioned every 6 months for active wells and every 12 months for plug and secured wells
- Well interventions, which are undertaken if a well is not functioning correctly and may include the following activities: change out of valves, trees and chokes; chemical squeezes, as well as slickline interventions, installation of valves, perforating wells. Well interventions are undertaken when a failure of a barrier occurs in a well in order to make the well safe and reinstate two barriers wherever possible. Barriers are independently tested every 6 months for active wells and every 12 months for plug and secured wells. Typical operations to reinstate a second barrier in a well are;
    - changing out a failed gas lift valve,
    - isolating a tubing leak by plugging and securing the well,
    - isolating a production casing leak by plugging and securing the well,
    - changing out of failed tree valves,
    - remediating wellhead leaks via chemical squeezes,
    - replacing failed WR-SSSV's,
    - locking out failed TR-SSSV's and installing WR-SSSV's,
    - installing casing plugs to isolate packer failures.
- Well unloading and clean up. Well clean-up and unloading may be required for either maintenance of wells to handle oil in water or to clean the remaining fluid from a newly drilled or perforated well. Well unloading occurs; after a well has been unplugged and secured to unload inhibited seawater from the well, unloading completion brine from a well after drilling a well or performing a tubing pull workover. Well clean-up occurs when plugging and securing a well to clean up hydrocarbon from the well and replace with inhibited seawater, completing a P&A of a well to clean up annuli prior to conducting a cement job.

Repairs may be identified through an inspection or surveillance program. Repair activities may include:

- Spooling wraps, clamps or replacements;
- Repair or replacement of valves;
- Pump repair and replacement;
- Electrical repairs; and
- Repairs to turbine equipment such as generators, MOL pumps, gas compressors.
- Repair or replace tertiary structural equipment such as grating and handrails.

Repairs are undertaken as required and identified during inspections, majority of repair work is timed to coincide with annual platform shutdowns (2-4 weeks/year), however some ad-hoc work is completed outside of shutdowns. Temporary equipment and/or temporary re-configuration / alteration of a system flow path may be utilised to enable the repair activity to be undertaken.

2.4.4.2 Pipeline and Subsea Facility IMR

Inspection, Maintenance and Repair is completed on subsea assets including pipelines, piled steel jackets, concrete gravity base structures and subsea facilities. Subsea and pipeline IMR activities require a subsea support vessel and the specifications for a typical vessel are provide in Table 2-9.

Inspection methods

Inspection is the process of physical verification to detect differences from previous or baseline inspections. Inspections are undertaken throughout the life of the field and can be used to determine changes in subsea infrastructure or existing environment. Results of inspections are used to inform FIMS assessments and prioritise subsea and pipeline maintenance and repair activities.

The primary inspection methods during pipeline and subsea facility IMR are listed in Table 2-11. The duration and frequency of activities have been estimated for the next 5 years, the activities associated with preparing facilities for decommissioning have also been included as required

Subsea inspections generally do not cause seabed disturbance with the exception of environmental surveys (e.g. seabed sampling, seabed survey, geophysical scopes). Environmental surveys may require sediment samples and extend further than the PSZ, to gather data for the reference or background case.

Table 2-11 Inspection Methods during Pipeline and Subsea IMR

Activity	Purpose	Typical Frequency	Typical Duration
Visual Inspections	Inspect infrastructure for integrity and for corrosion.	Pipelines and subsea inspections are typically undertaken 3 or 6 years.	Approximately 1 month for pipelines Approximately 1 month for subsea
		Riser inspections below water are undertaken every 5 years	Approximately 1 day
		As required for pipeline and subsea infrastructure, 2 per 5 years.	Approximately 12 days
Side Scan Sonar (SSS) / Multibeam Sonar (MBES)	Used to identify pipeline alignment and location (free spans, pipeline crossings, supports exposure/burial) and subsea features (debris etc.)	Undertaken 3 or 6 years for pipelines and subsea	This is typically undertaken in conjunction with Visual surveys
		As required, 2 per 5 years.	This is typically undertaken in conjunction with Visual surveys
		As required per facility	Approximately 3 days
Sub bottom profiling	Generates shallow depth profile of the seabed	Included as part of visual inspections and MBES/SSS	Included as part of visual inspections and MBES/SSS
Non-destructive Testing	Use of technologies (e.g. ultra-sonic, eddy current, time of flight detection (TOFD), x-ray, radioactive) to evaluate material properties and test for defects	As required subsea, riser and pipeline	Up to 5 days
Flooded member Detection	Used to inspect subsea platform structural members for through wall defects	As required	5 days per platform
Environmental Surveys	Sediment, water and environmental sampling and characterisation of the marine biota.	Environmental surveys may be undertaken as required	Approximately 5 days
		Environmental baseline surveys	Approximately 14 days per campaign.
Pigging / intelligent pigging	Internal integrity inspection and / or cleaning of pipelines	Pipelines typically batch pigged monthly.	Batch pigging: 1-3 days per pig.
		Intelligent pigging completed 4, 8 or 10 yearly.	Intelligent pigging 1-3 days per pig; same time as batch pigging. 2-3 batch pigs required prior for oil pipelines

Activity	Purpose	Typical Frequency	Typical Duration
		As required pigging campaigns	Pigging operations may range in durations from 5-20 days.
Cathodic Protection Potentials Measurement	Verification of cathodic protection effectiveness of structures and pipelines using a CP probe	Included as part of visual inspections.	Included as part of visual inspections.

Note: This table is not an exhaustive list of inspection activities. Activities may be adapted or added to accommodate specific scope requirements. Frequency subject to change based on inspection findings

Maintenance Activities

Maintenance activities (Table 2-12) are undertaken at regular scheduled intervals to prevent deterioration and maintain performance of subsea equipment. The duration and frequency of activities have been estimated for the next 5 years, the activities associated with preparation of facilities for decommissioning have also been included as required.

Subsea maintenance activities generally occur within close proximity to existing infrastructure. ROVs may require tool basket to be positioned on the seabed, these typically have a seabed footprint of approximately 15 m^2.

Table 2-12 Typical Maintenance Activities

Activity	Purpose	Methods	Typical Frequency	Typical Duration
Debris clearance	Access subsea infrastructure	ROV / divers	As required following visual inspection / MBES.	Approximately 2 days.
Marine growth removal	To remove excess marine growth to allow access to subsea infrastructure	ROV water jetting, brush systems or acid to dissolve calcium deposits.	As required following visual inspection / MBES.	Approximately 2-5 days for external depending on amount.
Sediment relocation	Access subsea infrastructure	Suction pump / dredging unit typically mounted on an ROV.	As required following visual inspection / MBES.	Approximately 1-2 days.
Flushing	To remove internal obstructions/ hydrocarbons and minimise long term internal corrosion	Internal pigging of pipelines or pumping of fluids Drive fluids down pipelines at pressure	As required per platform/pipeline	Approximately 1-2 days
Hydrate inhibition	To prevent formation of hydrates in gas pipelines.	Glycol or methanol injected into gas pipelines to inhibit formation of hydrates in pipework, pipelines and associated fittings. Pipelines may require depressurisation.	Continuous with gas production.	N/A.
Leak detection	To identify location of the leak.	Flush infrastructure with dye to detect leak.	As required following visual inspection / MBES or other identification of leaks (process monitoring / aerial surveillance)	Approximately 1 day.

Activity	Purpose	Methods	Typical Frequency	Typical Duration
Installation of sleeves / clamps	Protect pipeline, prevent corrosion, prevent leaks	Installation of sleeves/clamps on subsea infrastructure by ROVs	As required following leak detection	Approximately 1-2 days.
Grinding	To remove rusted bolts/materials/ equipment from subsea infrastructure	Grinder tool typically mounted on ROV	As required per platform.	Can range between 1-10 days per platform activity.
Installation of grout bags	Span rectification, protection and stabilisation	Bags are placed on the seabed and filled with grout or rocks installed on the seabed through a downline from a vessel.	As required following visual inspection / MBES.	Approximately 1 day per span.
Installation of concrete mattresses	Scour control, span rectification, protection and stabilisation	Installed on the seabed from a vessel.	As required following visual inspection / MBES.	Approximately 1-2 days per mattress.
Rock placement	Span rectification, protection and stabilisation	Placement of rock on the seabed from a vessel.	As required following visual inspection / MBES.	Approximately 1-2 days
Underwater cutting/drilling of equipment	To cut pipelines, spools, flexibles, umbilicals in preparation for platform decommissioning. Drill holes in risers to secure risers.	Cutting and drilling tools typically installed by and operated via ROV. HP water blaster may be required for removing coatings. Hydraulically operated shears may be used for underwater cuts (ROV assisted).	As required per platform.	Can range between 1-10 days per platform activity.
Plugging or capping of pipelines	Install plugs or blinded end connectors or caps on pipelines	Installed with an ROV	As required per pipeline.	Approximately 3 days
Temporary storage	Store subsea infrastructure and/equipment on the seabed until final decommissioning.	Placement of equipment /infrastructure on the seabed using ROV /divers	Project based.	
Corrosion protection	Protect subsea infrastructure from corrosion	Installation of anodes or corrosion resistant material. Injection of corrosion inhibitor.	As required following visual inspection / CP stabs.	Approximately 1 day per anode.
Installation of subsea rigging	Temporary dropped object mitigations	Manipulation and installation of subsea rigging using ROV friendly slings/tools	As required per platform.	Approximately 1-3 days. Undertaken as part of grinding activity or cutting activity.

Activity	Purpose	Methods	Typical Frequency	Typical Duration
Pipeline depressurisation	Suspend or preserve for safety reasons as part of maintenance	Pipeline and wells may be depressured to the flare system.	As required per platform.	Approximately 1-2 days. Dependent on length of pipeline.
Redundant equipment and facilities removal	To remove spare and redundant equipment and facilities from facility topsides	Typical construction and maintenance methods e.g. cutting, grinding, unbolting, lifting and transportation	As required per platform	1-10 days per activity

Note:

This table is not an exhaustive list of maintenance activities. Activities may be adapted or added to accommodate specific scope requirements. Frequency subject to change based on inspection findings.

Note: A number of these maintenance activities may occur together as part of a repair / replacement / suspension scope

Repair / Replacement Activities

Repair or replacement activities are required when infrastructure is damaged or deteriorating to a level outside acceptance limits and poses an elevated risk to safety, health, production reliability or ability to remove. These activities require the use of specialist vessels, equipment (ROVs) and potentially divers. The following subsea infrastructure may require repairs and/or replacements: Subsea valves, spools, subsea control modules, caisson, electric / chemical / hydraulic distribution, umbilicals, subsea trees, trawl-protection frames, concrete mattresses and/or grout bags, pipeline crossings, pipelines, risers and riser clamps.

The IMR activities required to replace subsea infrastructure typically follow the same general sequence:

- As found inspection: Using ROVs to take video footage of the infrastructure and surrounding area.
- Cleaning and removing any marine growth: Generally undertaken using ROV with specialist equipment such as brushes or jetting equipment. Chemicals (e.g. acids) may be used to aid the cleaning process
- Sediment relocation: Generally undertaken with ROV with specialist equipment to allow access to subsea infrastructure (pipelines)
- Flushing: Typically flushing cleans the infrastructure using chemicals (such as corrosion inhibitors and oxygen scavengers) at high pressures to clear the lines of more toxic chemicals or hydrocarbons.
- Isolation: To ensure equipment is safely isolated from the remaining subsea infrastructure and can be done through mechanically (ROV) or hydraulically.
- Repair or replacement/ installation: using a specialist vessel with ROVs with specialist tools, such as cutting tools to either repair or perform lifts and installation.
- Leak/ Pressure Tests: Are performed to ensure equipment is correctly installed and hold pressure prior to commissioning. Dye may be used.

A repair activity varies in length and is dependent on the equipment to be repaired. Generally the preparation of a repair activity will consist of a number of activities detailed in Table 2-11 and Table 2-12, the recovery and replacement of infrastructure will depend on the size of equipment. Subsea repair activities occur in close proximity to existing infrastructure. ROVs may require tool basket to be positioned on the seabed, these typically have a seabed footprint of approximately 15 m^2.

2.4.4.3 Overview of Compliance with Section 572

In accordance with Section 572 (3) of the OPGGS Act 2006 a titleholder must remove from the title area all structures that are, and all equipment and other property that is neither used nor to be used in connection with the operations. Removal of all property is the "base case" for all offshore activities.

However, Section 572 (7) of the OPGGS Act 2006 outlines that the obligation to fully remove all property is subject to other provisions of the OPGGS Act, the regulations, directions and other applicable laws. Hence there is a mechanism for titleholders to demonstrate that deviations from the complete removal of property are acceptable. These proposed deviations are presented to NOPSEMA for assessment in an EP, along with appropriate justification. An indicative timeline for key regulatory submissions for Gippsland Basin decommissioning activities is provided in Section 3.3.

Section 572 (2) of the OPGGS Act 2006 requires that a titleholder must maintain property in good condition and repair from the point the property is brought onto the title area until the property is removed. This requirement relates to maintenance that ensures property is fit for purpose and is able to be removed when neither used, nor to be used, in connection with the operations.

The following sections provide an overview of how Esso maintains compliance with Section 572 requirements while planning for decommissioning is ongoing.

Deviation from immediate removal of property

In accordance with the definitions provided in Table 1-1, facilities and pipelines are considered to be not in use, nor to be used, when 'Stasis Mode' has been reached. The property status provided in the inventory in Volume 2, Appendix A can be summarised as show in Table 2-13:

Table 2-13 Summary of Property Status

	Status as at Dec 2020		Status as at Dec 2025	
	In use	Not in use	In use	Not in use
Facilities (platforms)	19	0	12	7
Facilities (subsea)	1[2]	3[1]	2	3[1]
Pipelines (primary)	33	6	21	18
Pipelines (secondary)	8	0	4	4
Umbilicals	8[2]	4	8	5
Debris	Detailed in Subsea Material Register (refer to Section 'Ongoing Property Removal' below)			

Note 1: Subsea trees at SHA, TWA and BKA have been removed.

Note 2: BTW and the BTA to BTW umbilical is scheduled to be operational in 2021 hence is not included in this count.

Additional facilities and pipelines are likely to also transition to a status of 'not in use' during the 5 year timeframe of this EP. It should be noted that property within Esso title areas that is listed in Volume 2, Appendix A with a status of 'CoP' is still categorised as 'in use' because it is either being prepared for decommissioning, supporting decommissioning activities, or supporting facilities that are still producing.

The current status of all of the Gippsland Basin wells is included in Appendix A, Section 4.3. The plug and abandonment of wells will continue to be managed as per the WOMP.

The marine vessels that are already servicing Esso's Bass Strait operations may be capable of retrieving smaller items of equipment (for example items of debris) but are not capable of recovering larger items for which the current planning basis is removal as part of a Heavy Lift Vessel (HLV) campaign. A process is being implemented to assess the removal of smaller items using existing Esso support vessels on an ongoing basis, which will commence in 2021.

The environmental impacts and risks of the temporary storage of not in use equipment continue to be reviewed. The mobilization of dedicated vessels solely to accelerate the removal of property and the associated resources required to manage risks of this work in accordance with Esso's Operations Integrity Management System (OIMS) is currently considered by Esso to be disproportionate to any potential reduction in environmental risks and impacts that may be achieved by their earlier removal.

This EP therefore requests a temporary deviation from immediate removal for the subset of property listed in Volume 2, Appendix A that is currently *not in use, nor to be used* until such time as permissioning documents detailing the proposed end states for this property are submitted in accordance with the indicative timelines provided in Section 3.2.

This temporary deviation is requested to allow for:

- detailed planning, studies and preparatory work in order to manage the operations integrity risks associated with a large project interfacing with ongoing operations to be carried out prior to the complete removal of property;
- property to be removed in a carefully planned, cost effective and efficient manner via a 'decommissioning campaign' (refer to Section 3.1.1);
- investigations to be undertaken with third parties as to the potential re-use of some offshore property (pipelines and facilities); and
- the preparation, submission and assessment of proposed deviations from complete removal where the provisional end state for property in Volume 2, Appendix A is partial or full decommissioning in place.

Section 3 of this EP provides further detail on the proposed approach to decommissioning, including provisional end states and justified timeframes.

As detailed planning for the complete removal of property and approvals for any deviations are being undertaken, Esso will:

- ensure property is maintained so as not to preclude its future removal (see Section *Maintenance of property* and Volume 2, Appendix B for further detail);
- ensure property that does not require the use of a HLV or specialist equipment to be removed continues to be assessed for removal on an ongoing basis (See Section *Ongoing property removal*);
- ensure that environmental risks and impacts related to the property not in use are assessed and continue to be reduced to ALARP and acceptable levels (See Section *Assessment of ALARP and acceptability*);
- ensure planning reflects that, until any deviation to the complete removal of property is accepted by NOPSEMA in a future EP, complete removal of all property that is neither used, nor to be used in connection with the operations is the expectation (Section *Planning for full removal*).

Maintenance of property

The Esso Facility Integrity Management System (FIMS) continues to be used to manage the maintenance of equipment (excluding wells, which is managed by WIMS) on a risk basis (regardless of producing or non-producing status). Further detail on FIMS is provided in Volume 4, Section 2.3 of this EP. Changes in the status of a platform from producing to non-producing does not alter the fundamental approach to the maintenance of equipment within FIMS. However, as facilities progress through the stages of decommissioning and the underlying risk profile changes, it is expected that many pieces of equipment will represent a reduced SSHE risk, and subsequently their maintenance requirements will change and may be reduced.

A Section 572(2) Maintenance Review mechanism is being planned and developed as part of the initial activities undertaken as a facility begins to approach CoP. This process is intended to review, on a facility basis, the critical inspection and maintenance controls which are needed to ensure that decommissioning outcomes, up to and including full removal, are preserved. The critical maintenance and inspection controls will continue to be managed via the electronic maintenance management system, IPES (International Production Enterprise System).

Volume 2, Appendix B includes an overview of maintenance philosophies for property throughout the CoP and Stasis Mode stages for the purposes of Section 572(2). The Section 572(2) Maintenance

Review will be undertaken to ensure critical inspection and maintenance controls are appropriate for the facility/facilities in question and that they are implemented.

This process will be triggered as part of the MOC process of transitioning a producing facility into CoP.

The Section 572(2) Maintenance Review process has been developed and will be adopted for all facilities moving into CoP from 1Q 2021. A review of critical inspection and maintenance controls for facilities already in CoP has commenced and is anticipated to be completed for all facilities currently in CoP by 1Q, 2022. Facilities that have been in the CoP stage for the longest period of time (i.e. WTA and PCA/DPA) have been prioritised for the completion of this review.

Until such time that a Section 572 (2) Maintenance Review is undertaken, equipment will continue to be managed in accordance with existing FIMS processes, regardless of operating status.

Ongoing property removal

While decommissioning campaigns are planned to remove property which requires the use of specialist equipment (including a HLV), Esso has and is continuing to assess and remove other items of property. These ongoing removal activities include the plug and abandonment of wells (in accordance with the indicative schedules provided in Table 3-2 and Figure 3-1), the subsequent removal of wellheads and the removal of smaller items of subsea property as suitable vessels are available.

To facilitate planning for the ongoing removal of smaller items of subsea property, Esso has undertaken an analysis of existing electronic GIS data and historical hard copy records to consolidate relevant details on all subsea property (including known debris) into a Subsea Material Register (SMR). The SMR is intended to be utilised as the principal register for all subsea property, including its associated status.

The SMR will act as the basis for planning removal operations for property which does not require the use of a HLV or specialist removal equipment.

The SMR includes details on the estimated weight, depth and location of the subsea property. Using this information, Esso will assess the potential for the recovery of the item against current and future scheduled vessel activities. When vessels are contracted, a review of the SMR will be completed to identify whether an opportunity exists for the removal of subsea property within the operational capability of the vessel.

Considerations for recovering items during a vessel campaign will include vessel availability (weather etc.), vessel capability (lifting equipment type/capacity etc.), material location (depth, proximity to other infrastructure etc.) and recovery methodology. This information will assist in determining the practicability of recovery and assessment of any potential additional risks in accordance with the Esso Work Management System (WMS) and associated interface documentation. The SMR will be evergreen and updated as property is recovered and in the event other items such as debris are identified.

Assessment of ALARP and acceptability

The existing Environmental Management of Change process as detailed in Volume 4, Section 2.7.1 is the mechanism used to manage permanent or temporary changes during operations and ensure that additional environmental impacts and risks are not introduced by these changes.

The Environmental Management of Change process includes a ‘Temporary Storage Assessment’ which is completed when the requirement to store property on the seabed temporarily as planning for its removal is being undertaken, or a proposed deviation to complete removal is being prepared or assessed.

This assessment includes consideration of environmental aspects and impacts related to the temporary storage of property and will be adopted for all facilities moving into CoP from 1Q 2021. The process of undertaking Temporary Storage Assessments for facilities and property already in CoP is underway. This process will be closely integrated with the Section 572(2) Maintenance Review as IMR activities are fundamental in ensuring environmental risks and impacts continue to be reduced to ALARP and acceptable levels.

Until such time as Temporary Storage Assessments are finalised for all property currently in CoP, Esso has assessed that the environmental impacts and risks associated with the temporary storage of this property continues to be reduced to ALARP and acceptable levels for the following reasons:

- IMR activities for all facilities currently in CoP continue in accordance with the processes detailed in Volume 4 of this EP, until such time as the Section 572 (2) Maintenance Review is completed to define critical inspection and maintenance controls for the CoP and Stasis stages;
- A number of facilities (5 of 10) listed as being in the CoP stage in Volume 2, Appendix A have recently transitioned to CoP (in the past 18 months). Given that these facilities continue to be managed in accordance with the processes and controls detailed in this EP for facilities still in the production stage (where relevant), the environmental impacts and risks are anticipated to be unchanged i.e. it is not considered there is an increase in risk caused by the transition from a producing facility to a non-producing facility;
- Facilities that have been in CoP for the longest duration (i.e. WTA and PCA/DPA) have been prioritised for both the Section 572 (2) Maintenance Review and the Temporary Storage Assessment.

If the outcome of a Temporary Storage Assessment concludes that an activity or environmental impact or risk is not provided for in the current EP, a revision to this EP will be submitted to NOPSEMA for assessment in accordance with the Management of Change process.

Figure 2-5 provides a summary and indicative schedule of the activities Esso is undertaking to maintain compliance with Section 572 (2) requirements while planning for decommissioning is ongoing.

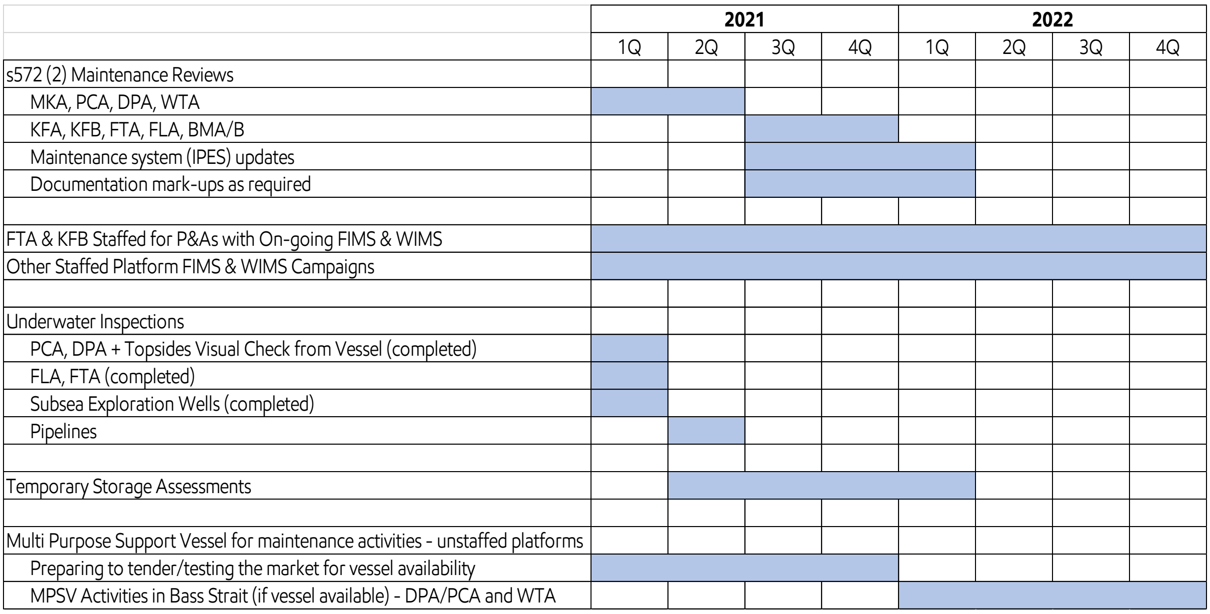

Figure 2-5 Summary of Maintenance Activities

Planning for full removal

As stated in Section 2.4.4.3 above, removal of all property is the “base case” required for all offshore activities. Esso is continuing to plan for the full removal of all property in parallel with planning for the provisional end states presented in Table 3-3, in the event the justifications for the provisional end states (where these differ from full removal) are not accepted by NOPSEMA. This planning includes:

- incorporating considerations such as the timing of third party contracting in relation to EP(s) seeking deviations from the full removal of property;
- the development of a shortlist of capable contractors that can execute the broadest range of possible removal scope and methods;

- ensuring HLV scope definition, early engagement with contractors and concept development reflects consideration of both the provisional end state and full removal; and
- undertaking technical feasibility/concept studies to inform the removal of concrete gravity structures and pipelines.

3 Future Planning

3.1 Decommissioning – Approach and Timing

3.1.1 Decommissioning of Property via Heavy Lift Vessel (HLV) Campaigns

Decommissioning of facilities is planned to be carried out via decommissioning 'campaigns' utilising heavy lift vessel (HLV) capability. For a decommissioning scope the size of the Gippsland Basin facilities, the aggregation of facilities into campaigns for decommissioning is the chosen approach as:

- One or two carefully planned campaigns are expected to deliver better safety outcomes. Planning per OIMS process for project activity (OIMS 3-1) ensures that all aspects of risk are managed when embarking on a major activity requiring specialist skillsets (OIMS 2-1, OIMS 6-1), training of personnel (OIMS 5-1), specialist equipment and competent contractors (OIMS 8-1), integrated plans with operating facilities (OIMS 6-4) and key input from stakeholders (OIMS 4-2, OIMS 10-1);
- The interconnectedness of facilities and varying CoP timing throughout the Gippsland Basin makes it important to ensure that the disconnection of non- producing facilities for decommissioning is carefully planned with limited impact to operating facilities, hence ensuring energy reliability;
- The approach seeks to capitalise on the expertise and competence of specialists with the most appropriate technology and equipment for large scale facility decommissioning;
- A campaign ensures there is sufficient workscope to attract international and competitive tenders from contractors with the appropriate experience and competencies for decommissioning activities of this scale and complexity.
- The remote geographical location and sea conditions of the Gippsland Basin also limits the availability of vessels with suitable size and capability to undertake a work program of this scale.
- A well planned campaign allows time for consideration of all options for onshore reception and demolition centres, noting that the establishment of an Australian centre would require extensive planning to become operational with the appropriate infrastructure and labour and available for Esso's use.
- Execution benefits are achieved by allowing the most efficient use of the significant HLV spread mobilisation and demobilisation costs to Bass Strait (which are currently estimated to be in excess of tens of millions of dollars).
- Campaigns are also expected to result in better environmental outcomes by aggregating work and minimising prolonged and repeated environmental disturbances.

3.1.2 HLV Campaign Timing Justification

The current planning basis is for the first HLV campaign to commence from approximately 2027. This start timing is subject to change based on a number of factors including, but not limited to, suitable specialist contractor and HLV availability. This section and Section 2.4.4.3 provide justification as to why this timeframe is the planning basis for commencement of the first HLV campaign. The length of the HLV campaign is not known at this stage as it is dependent on the type of specialist equipment to be used and detailed execution planning outcomes. This will be defined during engagement with potential HLV contractors.

Planning activities are currently focused on what is required to execute HLV Campaign #1 and this forms the basis of the information presented in this Section.

The Decommissioning Project Management System (DMPS), environmental and technical studies undertaken as part of this planning and lessons learned will be applicable to the planning of future decommissioning campaigns. While timings for the P&A campaigns for facilities not included in the first HLV campaign are still to be finalised (and will be driven by CoP of the facilities), the Bass Strait P&A program will be ongoing and lessons learnt from current P&A activities are being incorporated into planning for these future campaigns. Planning for future campaigns will flow on from planning from the first decommissioning campaign and in some instances (such as planning for P&A campaigns), planning will occur in parallel.

The preliminary timing of, and selection of infrastructure for inclusion into, the first HLV campaign has been based on detailed analysis and planning which has taken into account:

- The actual and predicted CoP timing for facilities, which varies across the Gippsland Basin;
- The completion of well P&A and preparation of facilities for decommissioning;
- Aggregating a sufficient number of facilities for decommissioning prior to arrival of a HLV and its fleet of support vessels, most likely from an overseas location;
- The degree of interconnectedness of the Gippsland Basin facilities and pipelines, hence planning for decommissioning whilst minimising the impact on producing facilities;
- The range of technical feasibility and safety studies and detailed execution planning required to successfully and safely execute a decommissioning program of this nature and scale with a high degree of complexity, due to the interconnectedness of facilities and also facilities that are all unique due to their construction, age and the modifications that have been made over their producing life;
- Information (i.e. vessel specifications, mob/demob details, execution opportunities and vulnerabilities) gathered from potential HLV contractors via an early Expression of Interest (EOI) process that has been completed;
- The environmental studies, research, approvals and stakeholder engagement required to facilitate the proposed decommissioning activities to ensure that all relevant aspects and potential impacts are appropriately understood;
- Retaining an option to establish an onshore demolition, disposal and recycling centre that is sufficiently equipped with necessary infrastructure to safely receive and process facilities brought in from offshore. Sites and requirements for this centre are still being evaluated for both Australian and overseas locations. Depending on the location, site specific regulatory approvals/licensing may need to be completed.

The indicative and preliminary timeframes referenced in this EP will be revisited throughout the planning process.

It should be noted that no comparable decommissioning program to the Esso Bass Strait facilities has been undertaken in Australia to date. Esso has compared the proposed timeframe of the HLV campaign to two examples of recent decommissioning projects that ExxonMobil have recently been involved in as shown in Table 3-1.

Table 3-1 Summary Comparison of Decommissioning Programs

Decommissioning Scope	Operator	Overview of infrastructure	Timeframe from planning to completion (approximate)
Esso Bass Strait (Campaign #1 only)	Esso	14 facilities, 3 subsea facilities, 31 pipelines, approx. 260 wells	8-10 years (well P&A execution 7 years)
Sable Offshore Energy Project, Canada1	ExxonMobil Canada	7 facilities, 5 pipelines, 22 wells.	> 8 years (still ongoing) Well P&A activities 2 years
Brent Field, UK2	Shell UK (50% ExxonMobil)	4 facilities, 3 substructures, 28 pipelines, 146 wells	20 years (10 years of studies, well P&A activities 12 years)

[1] https://soep.com/about-the-project/timeline/index.html .
[2] Brent Field Decommissioning Programmes as submitted to UK Department for Business, Energy and Industrial Strategy by Shell UK, February 2017

A summary of decommissioning activities planned during each year from 2020 until the approximate commencement of HLV campaign #1 has been provided in Table 3-2 below.

Table 3-2 Decommissioning Activity Breakdown – Preliminary Planning Basis for HLV Campaign #1

Approx. wells plugged, cumulative 1,2	15	45	85	130	170	215	260	-	
ONGOING REMOVAL OF PROPERTY	Development of Subsea Material Register (SMR)	Removal of property that does not require a HLV using existing Esso marine vessels.							
ONSHORE DISMANTLEMENT AND DISPOSAL SITE	Early planning and options assessment			Possible sites – options assessment to match contracted HLV methodology	Selected site preparation – regulatory approvals, site design and modifications, etc. (as required)				
HLV CONTRACTING	End of Field Life Strategy	Contracting strategy Early contractor engagement	Develop contracting scope	Assess contractor vessel availability and proposals	Award contract(s) Removal methodology optimisation	Removal methodology optimisation	Final execution planning	Removal execution – HLV Campaign #1	

- The number of wells plugged in each year is a preliminary estimate subject to further refinement: the actual numbers in any particular year will depend on the order of wells to be plugged, the time taken to plug each particular well and other real-time logistical drivers.
- The number of wells does not include the plugging and abandonment of exploration wells (Gudgeon, Terakihi, East Pilchard, Mulloway, Whiptail, and HLA-1).

3.1.3 Decommissioning – Preparation of Facilities

An indicative decommissioning sequence for platforms, pipelines and subsea equipment has been provided in Figure 3-1 to illustrate the physical preparation work that must be completed prior to execution of the HLV campaign.

The basis for the timing and duration of the stages included in Figure 3-1 is explained in the following sections.

Well Plug and Abandonment program

Campaigns to plug and abandon wells on non-producing facilities are underway. Learnings from previous abandonment operations (Mackerel, Whiting, Seahorse, Tarwhine and Blackback) have been applied when developing the Bass Strait abandonment activity schedule presented in Figure 3-1. A risk based approach drives the well abandonment priority, hence why some facilities that are currently in CoP are not scheduled for immediate P&A. For example, based on this risk based approach, P&A has been completed for BKA & WTA.

The plug and abandonment schedule in Figure 3-1 has been based on two parallel platform based Hydraulic Workover Rigs and ongoing wireline activities operating on normally staffed facilities. Jackup/MODU rig campaigns and operations supported by a 'walk to work' multi-purpose support vessel (MPSV) are planned to be used for normally unstaffed or subsea facilities and exploration wells. This activity level, in addition to Esso's existing wireline operations, will be planned, managed and supervised by Esso and supported by Esso's logistics infrastructure (marine, helicopters) along with third party service companies. The pace of these activities represents a challenge to ensuring safe operations and the provision of appropriately trained personnel is a key focus area. The schedule aims to minimise the time that plugged and secured wells are awaiting final abandonment within the bounds of the multi activity schedule and high-graded by well risk. Depending on the condition of the wells, following inspection and plug and secure operations at PCA and BMB (scheduled to be carried out in 2022), BMB well cementing operations are planned to be undertaken to further reduce any risks from these wells prior to final abandonment. PCA and DPA wells will also be evaluated for well cementing operations prior to final abandonment.This program of work will provide more information on the well status thereby supporting further planning for abandonment of these wells in accordance with the indicative P&A sequence in Figure 3-1.

In accordance with this proposed schedule, Esso is already ramping up from one platform based P&A rig to two. This has required the addition of the following:

- Competent and appropriately experienced Wellwork supervisors
- Competent and appropriately experienced Wells engineers
- Rig refurbishment, substructure manufacture, pipe deck manufacture , stair tower manufacture
- Rig support equipment – seawater lift pump
- Suitable third party equipment and competent personnel – cementing, wireline, fishing (back to back plus coverage for leave)
- Competent and experienced platform Care & Preservation crew and camp staff to support operations (back to back plus coverage for leave)
- Boat time and BBMT logistics to support operations
- Helicopters to support operations

As shown in Table 3-2, the proposed two platform rig schedule (in combination with the other well decommissioning activities) is forecast to plug and abandon approximately 260 wells by the end of 2026, which is approximately 65% of the approximately 400 wells currently operated by Esso in Bass Strait. The remaining approximately 140 wells will still be operational at this time.

Esso has investigated three additional options for undertaking the platform based P&A program.

The first alternative option considered was introducing a third platform based P&A rig. In terms of planning time, it would take approximately eighteen months to be ready for a third rig. Esso would need to source, contract and mobilise a hydraulic workover rig or alternatively manufacture significant equipment to allow operations of a platform rig that is currently only partially complete, as well as plan for operations to be safely executed in accordance with Safety Cases and OIMS processes. Esso would also need to build up well engineering and wellwork supervisor teams and expedite planning the abandonments of each well which requires detailed analysis of the well's current state, history and the local geology.

Additional rig lines take a significant number of additional personnel to support. Esso has seen historically that the introduction of a large number of new personnel in a short space of time can challenge an organisation's ability to provide sufficient, experienced supervision so as to ensure workplace competencies are satisfied. Steady continuous operations with a stable, experienced workforce has been demonstrated to be a better way of ensuring the ability to safely supervise new personnel, and ensure workplace competencies are satisfied.

Adding a third platform rig to the proposed two rig P&A program will not expedite the planned commencement of the Heavy Lift Vessel (HLV) campaign, hence this alternative was not considered further.

The second alternative option considered was replacing the proposed two platform based P&A rigs with a larger package rig. Esso's platform based well abandonment campaign is focused on normally staffed oil block platforms which have ceased production, namely MKA, KFB, FTA, FLA, KFA, BMA. Rig availability and a smaller rig footprint are two leading factors which have driven the selection of the Superior Energy Hydraulic Workover Units for this work scope. A rig tender conducted in 2019 failed to identify any other suitable rigs which would fit on the smaller first generation platforms. Locally sourced rigs also provide flexibility for batch operations which allow for increased operational efficiency and the monitoring of reservoir plugs between batch operations - practices recommended by the NOPSEMA Well Integrity team. Further, replacing the two smaller platform based rigs with a larger package rig will not expedite the planned commencement of the Heavy Lift Vessel (HLV) campaign, hence this alternative was not considered further.

The third alternative option considered was using a jack-up rig to complete P&A of the platform based wells. Whilst some Bass Strait normally staffed platforms could be accessed with a jack-up rig for the purposes of abandonment, others are unsuitable due to soil subsidence concerns and well accessibility. Further, rig rates for Hydraulic Workover rig packages are in the order of 1/6th of the cost of a jack-up rig, leading to a cost effective abandonment solution. In terms of planning time, it is expected that it would take approximately two years to source, contract and gain the necessary approvals for a jack-up rig to undertake platform based P&A activities. Additionally, jack-up rigs are predominately staffed by international crews which creates operational challenges and the potential for downtime in the current operating environment impacted by COVID-19 . For these reasons this alternative was not considered further.

Whilst awaiting abandonment, well monitoring and barrier verification will continue to be conducted as per Esso's Well Integrity Management System (WIMS) and any changes in well status will be addressed under existing processes as outlined in the Well Operations Management Plan.

Facility Preparation

Following P&A, the facility is prepared for decommissioning, which includes further topside draining and flushing, relocation of equipment, isolation of piping and pipelines, installation of module lifting apparatus, removal of loose objects, structural works and shutdown of remaining systems and living quarters. The planning assumption is for preparation activities to be undertaken by two teams working in parallel on offshore platforms, with current timing estimates at up to 18 months per facility depending on the complexity of the facility and the chosen topsides removal methodology. Esso is still in the process of determining the topsides removal methodology which will guide the level of activity required to facilitate HLV activities.

Once activities to prepare the facility or pipeline for decommissioning are complete, a facility may enter a period of stasis mode until a decommissioning HLV campaign commences. The majority of steel pile jacket (SPJ) platforms utilise an impressed current cathodic protection (ICCP) system to manage corrosion to the facility sub-structure. Others have sacrificial anode systems.

Figure 3-1 provides an indicative potential sequence which is subject to change as Esso continues to plan for and optimise the decommissioning program. In particular, the CoP timings outlined for facilities such as CBA, HLA, WKF and BTA are dependent on considerations such as reservoir performance and depletion, oil and gas pricing and ongoing production costs, hence these timings are estimates based on a series of different scenarios. Further, production from the BTW subsea wells is dependent on the BTA platform.

Figure 3-1 shows facilities proposed for decommissioning prior to or as part of HLV Campaign #1. Facilities not listed in Figure 3-1 (MLA/MLB, SNA, TNA, WTN, KPA, BTW) are still producing. Over the remaining production life of these platforms, topside equipment may need to be modified, upgraded or replaced in order to optimise hydrocarbon production as production and reservoir parameters change. The timing for decommissioning of these facilities is dependant on their CoP.

While Volume 2, Appendix A states that the SNA and MLA wells are anticipated to be at CoP by 2025, these two facilities are not able to be removed in the first HLV campaign as MLA is required to provide staffing for ongoing production at MLB which has no accommodation facilities and SNA is required to support ongoing production at KPA via the gas pathway from KPA to shore (through the MLB450 pipeline).

The wells associated with MLA/MLB, SNA, TNA, WTN, KPA, BTW will be plugged and abandoned as part of future P&A programs following CoP. The timing of the P&A of these wells is not anticipated to have a bearing on the timing of the first HLV campaign.

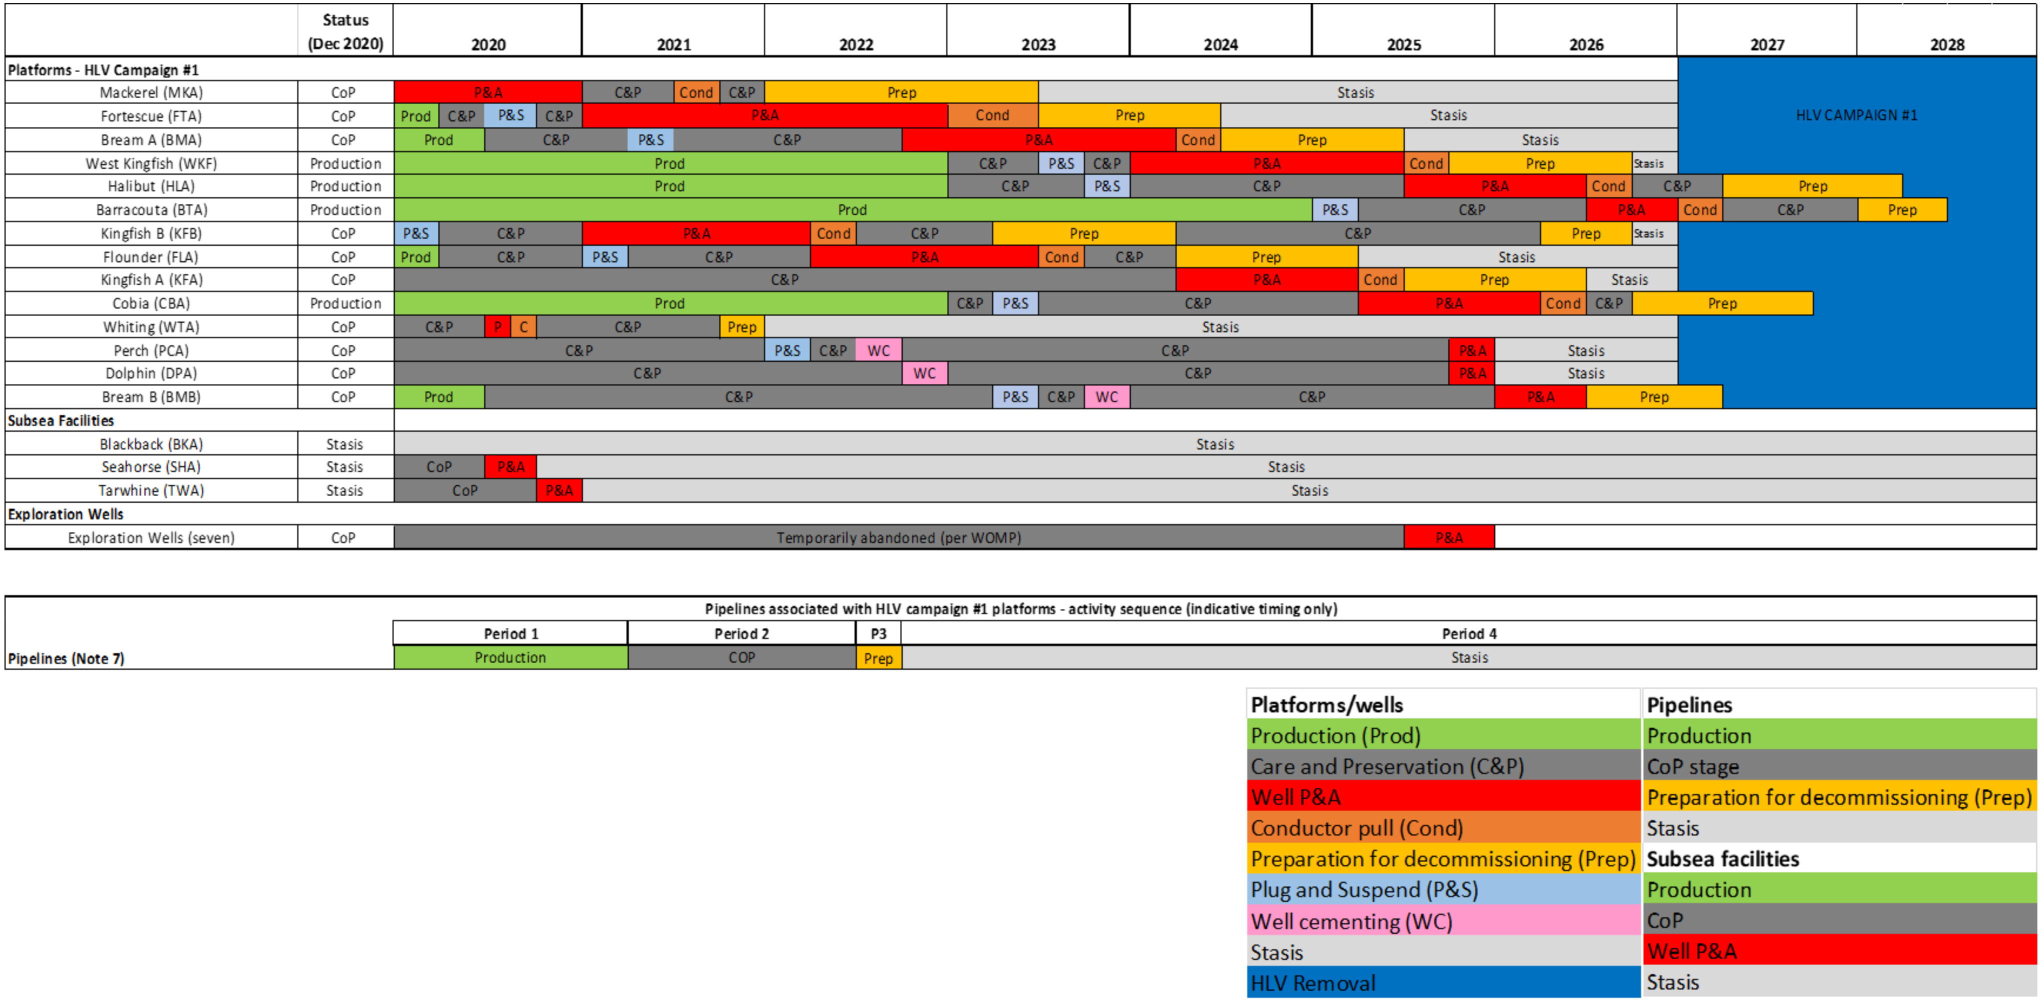

Figure 3-1 Indicative Decommissioning Sequence

3.1.4 Decommissioning – Planning for Execution

The following sections provide an overview of the activities underway and planned in order to ensure decommissioning of the Gippsland Basin facilities is executed successfully, in accordance with OIMS and results in environmental and safety impacts and risks that are reduced to ALARP and acceptable levels.

3.1.5 Overview of decommissioning project management

The ExxonMobil Capital Project Management System (EMCAPS) is applied to large capital projects to ensure a disciplined and consistent approach to project planning and execution throughout the Company. The decommissioning project will follow a specialised Decommissioning Project Management System (DPMS) based on EMCAPS principles. The DPMS has been enhanced to address specific objectives associated with a decommissioning project while many investment, technical quality and operability requirements in EMCAPS have been streamlined, as these are not applicable to decommissioning.

The DPMS includes 5 stages of project evolution covering End of Field Life (EoFL) to Surrender of Petroleum License or Titles. It is designed such that the project scope definition and execution plans mature in alignment with Company's objectives through each stage. Figure 3-2 below provides an overview of the DPMS stages and objectives associated with each stage.

Stage 1 End of Field Life	Stage 2 Select	Stage 3 Define	Stage 4 Execute		Stage 5 Closeout
End of Field Life Strategy, Cessation of Production and External Alignment	Concept Definition, Early Execution and Contracting Plans, Studies, Stakeholder Engagement and Regulatory alignment.	FEED/FEEP, Execution Planning, Contract bids assessed and removal methodology optimized, regulatory submissions (for deviations from full removal)	Design, Procurement and Preparation of facilities and pipelines for removal. award contracts, regulatory submissions (for execution), establish disposal yard	Facilities Removal, Transportation and Disposal	Surrender of Petroleum License/Title
	Gate 1 (2021)	Gate 2 (2023)	Gate 3 (2024)		Check Point

The gate timings shown in Figure 3-2 are indicative timings and subject to change.

Figure 3-2 Overview of the Decommissioning Project Management System (DPMS)

A 'gate' system is used by the Company to ensure that the project has achieved the objectives of the preceding stage and the deliverables of each stage are assessed and planned to move to the next 'gate'. Senior management reviews are typically associated with the passage of each gate. The DPMS is independent of the scope of the project. It describes the Gates and deliverables for each stage of the project. If the project scope is changed (for example in the event that proposed deviations are not accepted by NOPSEMA) the same process is applied to the changed scope. This process will also leverage project progress to date.

It should be noted that Esso will continue well Plug and Abandonment (P&A) activities and facilities Care and Preservation (C&P) activities independent of, but in close coordination of the DPMS. This allows P&A and C&P activities to progress as stand-alone decisions based on their readiness to proceed and not be dependent on total decommissioning project readiness.

3.1.6 DPMS – Planning for Execution

The extent of detailed planning and technical, execution and environmental studies required to safely execute a decommissioning campaign of this nature and scale is significant. Given the complexity and extent of the activities outlined below and in Figure 3-2, it is currently estimated that the early planning stages will take approximately 6-7 years to complete. During this time decommissioning activities such as the P&A of wells and removal of smaller items of property (as discussed in Section 2.4.4.3) will be ongoing.

During the early planning phases, contracting strategies are being developed, the market is being explored as to the availability, suitability and cost of potential HLV's, removal concepts are being developed and refined and, given other facilities in the Gippsland Basin must continue to supply reliable energy, interfaces with operations and logistics teams and simultaneous operations must be carefully planned for and managed.

Decommissioning concept definition and engagement with potential HLV and other contractors to define and optimise removal methodologies is critical during these stages to ensure facility and pipeline decommissioning preparation activities are undertaken as required per the chosen methodology, so that removal operations can be executed successfully. A wide range of technical studies are being (and will be) conducted to properly evaluate and determine the most feasible, safe, and efficient removal methodology(ies) for each platform. Specific removal methodology definition will subsequently drive the nature and magnitude of preparatory works required to be completed prior to the arrival of a HLV. Once execution plans are refined for preparatory works (including careful consideration of any impacts to ongoing production), a formal commercial tendering process will be completed with the HLV market to secure the specialist equipment and to confirm the HLV campaign window.

Esso is undertaking/planning to undertake a range of technical, environmental, socioeconomic, safety and cost studies during these stages. A number of these are research based and scientific in nature and will involve partnerships with tertiary academic institutions, specialist technical companies, other industry members and independent and internal subject matter experts. Extensive community and stakeholder engagement is also required to be undertaken.

The key environmental studies being undertaken to ensure a robust understanding of the potential environmental impacts from decommissioning in the Gippsland Basin are:

- Ecological analysis of historical ROV inspection footage
  - The objective of this study is to identify the marine organisms associated with the platforms, pipelines and subsea facilities using footage obtained from past ROV inspections. Taxonomic identification of marine species is the fundamental building block to characterise the ecological conditions at facilities in the operation area. Deakin University and the Australian Institute of Marine Science (AIMS) are currently reviewing over 1000 hours of ROV footage in order to identify footage suitable for taxonomic identification. Qualitative to quantitative assessment of common ecological indices will then be performed where feasible and the study will be used to inform the scope of the environment survey discussed below and future regulatory submissions.
- Gippsland Basin Environmental Survey
  - Esso is planning an offshore environmental survey to assess the potential impacts on marine ecology and sediments as a result of decommissioning activities. The three main components of the offshore environmental survey are:
  - An assessment of marine biota – this component builds upon the ecological analysis of historical ROV inspection footage discussed above. Data will be collected pertaining to marine biota associated with the Gippsland Basin facilities in order to clarify the ecological role provided by the facilities to general biodiversity and key commercial fisheries species; and to evaluate the condition of the marine organisms associated with the facilities (and at control locations).
  - Contaminants – sediments will be sampled from within the operations area and compared to control locations.
  - The marine biota and contaminant data will inform modelling and further assessment to evaluate the potential short and long term impacts from a range of potential decommissioning options.

The offshore environment survey is anticipated to be undertaken as multiple offshore deployments spanning approximately two years to ensure robust, seasonal and comprehensive data. Data and interpretation from this study will inform future regulatory submissions as well as provide information to assist with meeting the requirements of Section 270 (3) of the OPGGS Act regarding title surrender.

3.2 Decommissioning – Provisional Property End States

In order to guide planning for decommissioning, Esso has identified 'provisional end states' for the Gippsland Basin infrastructure groups (platforms, subsea facilities, pipelines and wells), which are provided in Table 3-3 and Appendix B.

Esso is not seeking acceptance for any deviations from complete removal of property in this EP, apart from temporary deviations for the subset of property currently not in use, as outlined in Section 2.4.4.3. NOPSEMA acceptance of any proposed deviation from the complete removal of property will be sought via future EPs, with the first of these expected to be submitted in approximately 2023. Section 3.3 provides further information on the basis for the timing of regulatory submissions.

As Esso is currently in the early stages of planning for decommissioning in the Gippsland Basin, the provisional property end states presented in Table 3-3 have not yet been subject to detailed environmental, safety and socioeconomic studies and assessment against EP acceptance criteria, such as demonstration that the environmental impacts and risks as a result of these provisional end states are ALARP and acceptable. Engagement with relevant stakeholders including commercial fishers and other users of the sea in accordance with the processes outlined in Volume 4, Section 10 of this EP and a decommissioning specific Stakeholder Engagement Plan is also yet to be undertaken and input from these stakeholders may result in a different approach.

As such, the provisional end states outlined in Appendix B and Table 3-3 are provisional only, subject to change and have been provided in this EP for the purpose of demonstrating Esso's planning basis for compliance with the expectations of Section 572 (3) and (7) of the OPGGS Act 2006.

Where deviation from complete removal has been provisionally outlined in Table 3-3, Esso is required to demonstrate in a future EP that the proposed deviations deliver equal or better environmental outcomes as compared to the complete removal of property. The EP must also meet the criteria for acceptance as outlined in Regulation 10A of the OPGGS (Environment) Regulations 2009.

Hence these end states remain 'provisional' until such time as the necessary studies and assessments, coupled with appropriate stakeholder engagement and consideration of issues raised, has been undertaken and this demonstration has been included within an EP (or EPs) for NOPSEMA's formal assessment.

If future EP/s are accepted by NOPSEMA, 'provisional end states' will become 'approved end states'.

Where deviation from complete removal has been outlined, this has been based on consideration of global practice, international guidelines and standards[1], the technical feasibility of removal works and available literature and studies on the anticipated environmental outcomes of decommissioning options.

An overview of the infrastructure groups and the provisional end states is provided in Table 3-3 below. Further detail is provided in Appendix B.

[1] International Maritime Organisation, Guidelines and Standards for the Removal of Offshore Installations and Structures.

Table 3-3 Overview of Provisional End States

Infrastructure Group	Provisional End State	Base Case End State expected under Section 572(3) of the OPGGS Act 2006
Platforms - Steel Pile Jackets shallow water – 9 of 16.	Topsides fully removed. Substructures fully removed to seabed.	Topsides fully removed. Substructures fully removed to seabed.
Platforms - Steel Pile Jackets deeper water – 7 of 16.	Topsides fully removed Substructures cut at approx. 55m below mean sea level and top section removed. Lower section of jacket left in place.	Topsides fully removed Substructures fully removed to seabed.
Platforms - Concrete Gravity Structures	Topsides fully removed. Substructure left in place.	Topsides fully removed Substructure fully removed
Platforms - monopods	Fully removed	Fully removed
Subsea production systems (excluding pipelines and umbilicals which are covered below)	Fully removed	Fully removed
Offshore pipelines, umbilicals and associated infrastructure	Left in place (some ancillary items, as detailed in Volume 2, Appendix B, removed)	Fully removed
Other property (i.e. debris)	Fully removed	Fully removed
Production wells	Wells plugged and abandoned. Conductors/subsea wellheads removed	Wells plugged and abandoned. Conductors/subsea wellheads removed
Exploration and appraisal wells	Wells plugged and abandoned. Subsea wellheads removed	Wells plugged and abandoned. Subsea wellheads removed.

3.3 Decommissioning – Regulatory Submissions and Approvals

Permissioning documents for decommissioning will be submitted once the detailed research and studies have been undertaken to allow assessment of the decommissioning execution works and the provisional end states outlined in Table 3-3 and Volume 2, Appendix B. A timeline outlining the key regulatory submissions and anticipated timelines for submission has been provided in Figure 3-3.

The timeline provided is indicative, based on early knowledge to date and subject to change as planning for decommissioning progresses. A detailed Permits, Consents, Notifications and Approvals matrix for decommissioning is in development to ensure all regulatory requirements are documented and understood.

The indicative timeline indicates submission of EP/s to seek deviation from complete removal will be submitted in approximately 2023. This is based on the inclusion of data from environmental surveys and studies as outlined in Section 3.1.6. Further discussion on the scope and basis of these EP/s will be held with NOPSEMA to determine if submission of these deviation EP/s could be achieved earlier (i.e. by basing EP’s on data obtained from publically available literature).

EP/s for HLV campaign #1 execution activities are targeted for submission in approximately 2025.

Approximate timing for EP submissions required for well P&A activities that will utilise a JUR/MODU campaign (PCA, DPA, BMB and exploration wells) and decommissioning activities utilising an MPSV are included in Figure 3-3.

Platform based well P&A and activities to be undertaken utilising a vessel are covered in this Bass Strait Operations EP (which will be reviewed and revised as required to ensure all activities are addressed).

Decommissioning activities using a MPSV (preparation at WTA/PCA/DPA/BMB) will be reviewed against this Bass Strait Operations EP as the scope of these activities is defined further (expected in early 2021). This review will determine if a new EP is required for these activities or these can be covered by a revision to this Bass Strait Operations EP. Hence this potential EP has been depicted in Figure 3-3 with a dashed box.

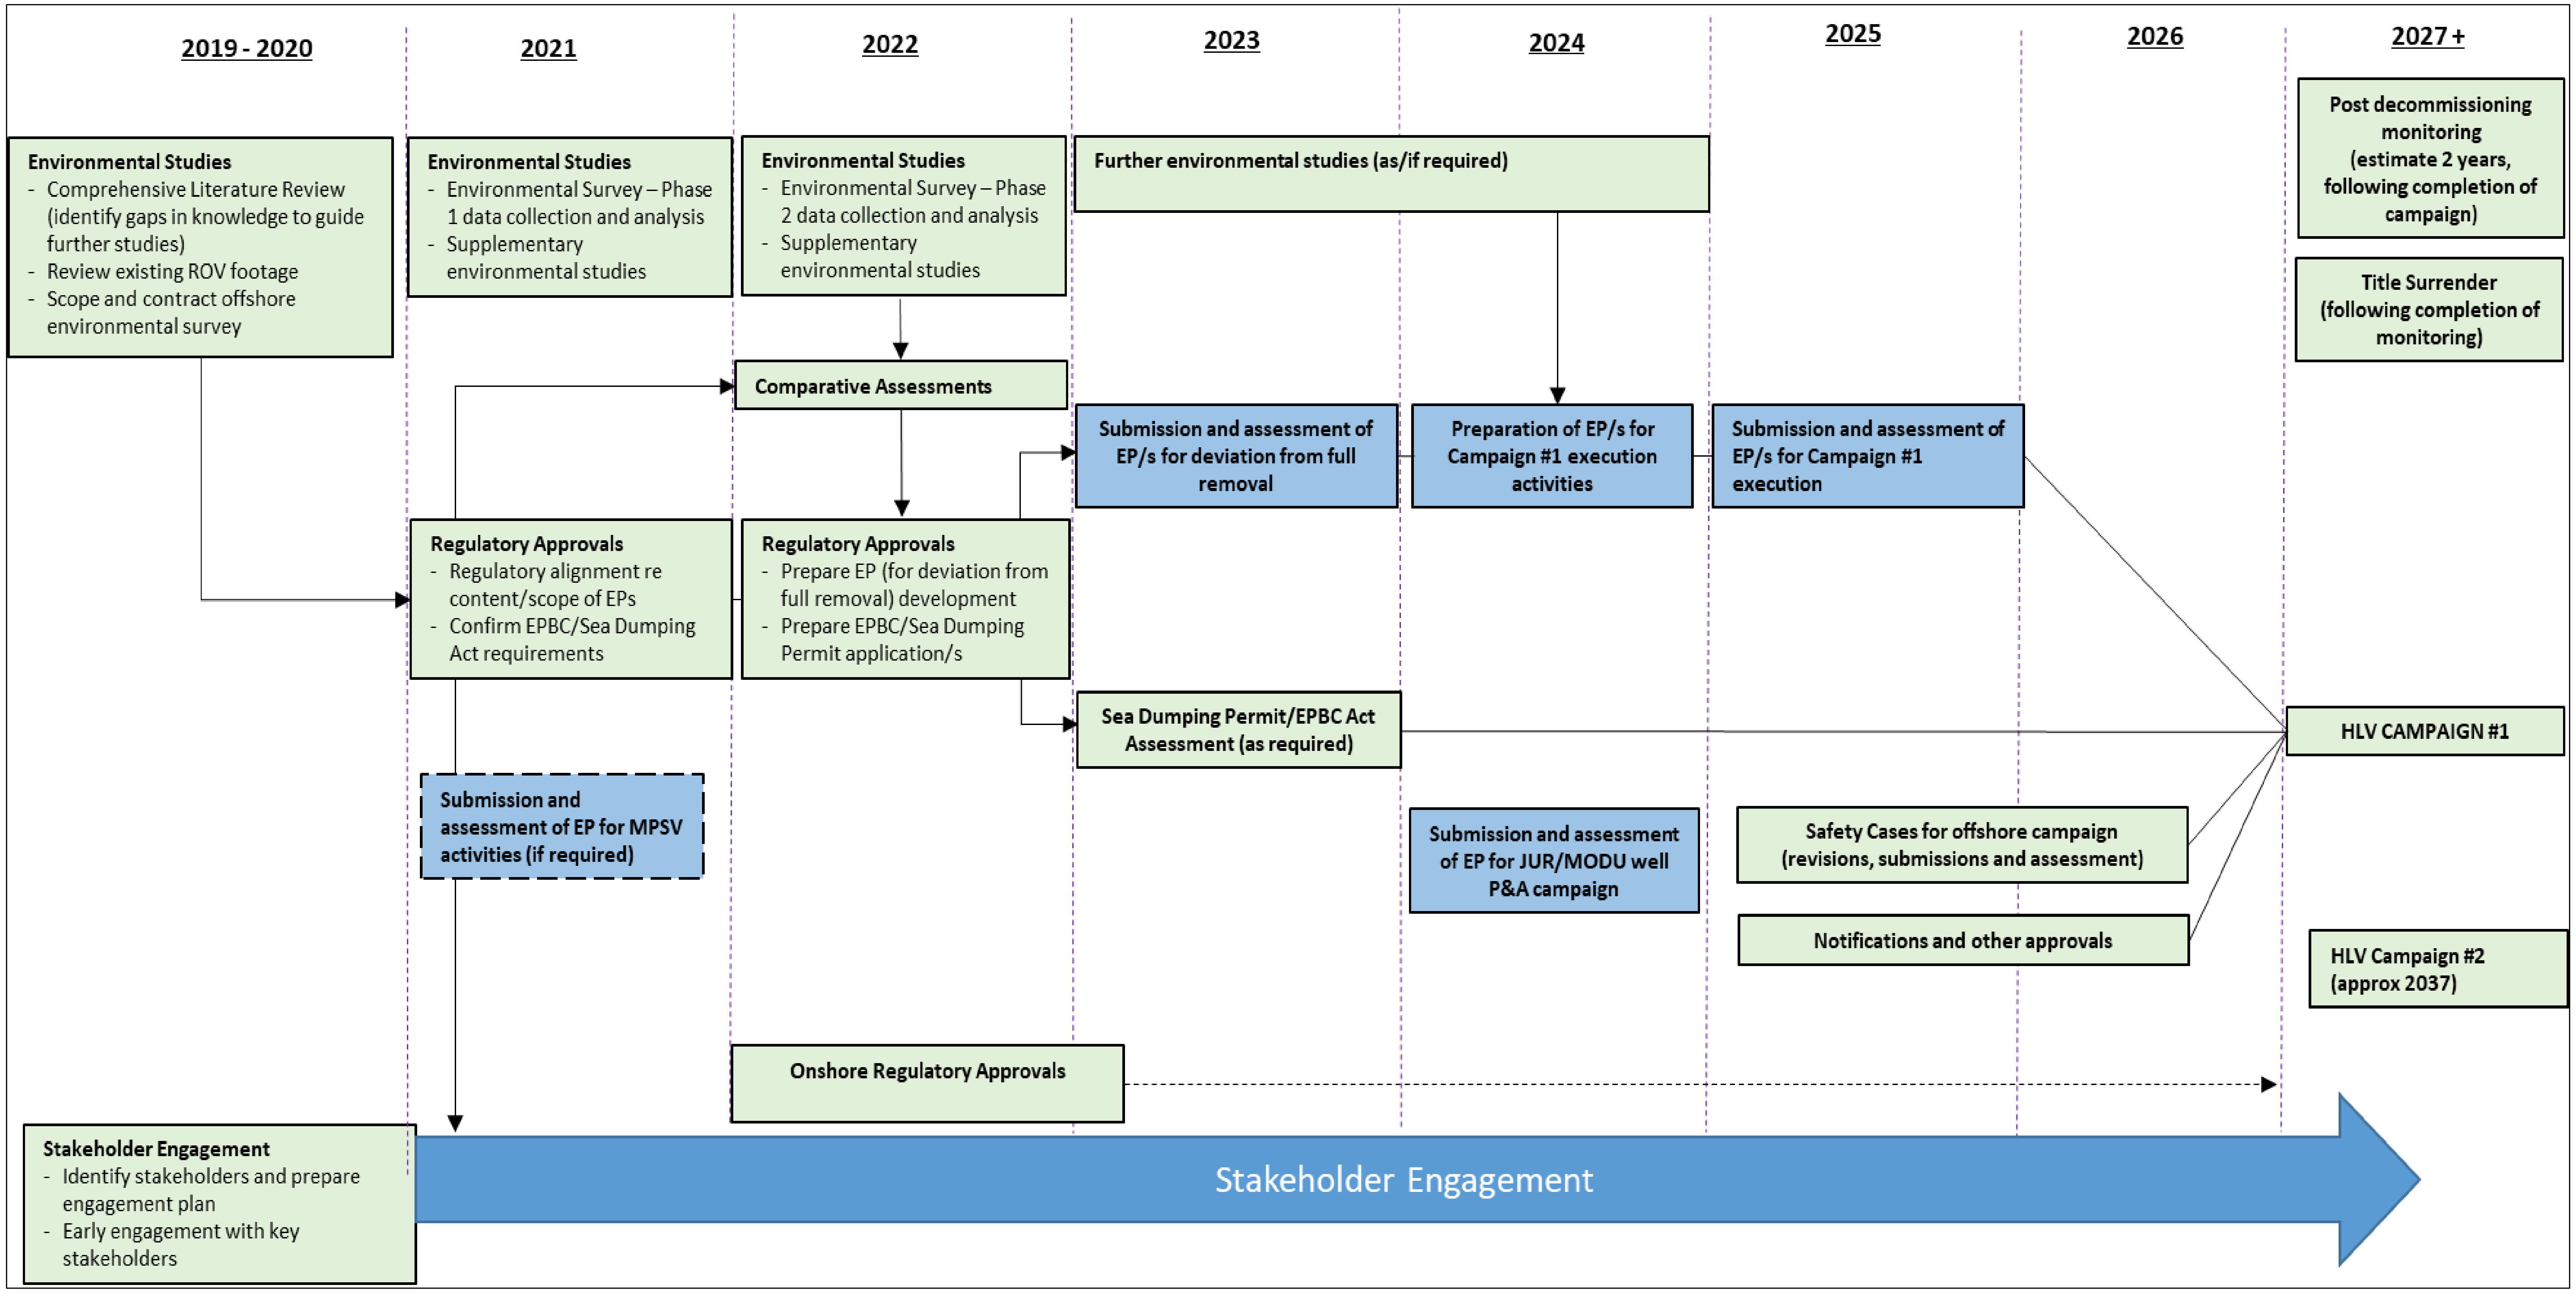

Figure 3-3 Indicative Gippsland Basin Decommissioning Regulatory Roadmap

4 Environmental Impact and Risk Assessment Methodology

4.1 Overview

Environmental Impact Assessment is concerned with assessing the impacts resulting from activities that are reasonably certain to occur (such as planned discharges to the air or water), while Environmental Risk Assessment is concerned with assessing the risks resulting from unplanned events that may possibly occur (such as hydrocarbon spills, introductions of marine pests, loss of waste overboard).

Environmental Impacts result from activities that are an inherent part of the petroleum activity and will result in a change to the environment or a component of the environment, whether adverse or beneficial. For example, discharge of produced formation water to the marine environment is an impact on the environment that cannot be avoided for the activity to achieve its aims.

Environmental Risks result from unplanned activities where a change to the environment or component of the environment may occur (i.e. there may be impacts if the event actually occurs). Risk is a combination of the impact or consequence of an event and the associated likelihood of the event occurring. For example, a hydrocarbon spill may occur if a support vessel's fuel tank is punctured by a collision during the activity. The risk of this event is determined by assessing the consequence or environmental impact (using factors such as the type and volume of fuel and the nature of the receiving environment) and the likelihood of this event happening (which may be determined qualitatively or quantitatively).

Impacts and risks associated with the petroleum activity have been identified in accordance with ExxonMobil's Environmental Aspects Guide (2012). This ExxonMobil Guide is designed to support the implementation of environmental management expectations of OIMS with special emphasis on, and linkage with ISO 14001 Environmental Management System specification.

4.2 Definitions

Table 4-1 Definitions

Term	Definition
Activity	An activity refers to a component or task within a project which results in one or more environmental aspects.
Aspect	An environmental aspect is an element or characteristic of an activity, product, or service that interacts or can interact with the environment. Environmental aspects can cause environmental impacts.
Impact (HB203:2012)	Any change to the environment or a component of the environment, whether adverse or beneficial, wholly or partly resulting from an organisation's environmental aspects.
Risk (HB203:2012)	The effect of uncertainty on objectives. The level of risk can be expressed in terms of a combination of the consequences and the likelihoods of those consequences occurring.
Direct impact	A direct impact occurs through direct interaction of an activity with the existing environment.
Indirect impact	An indirect impact is those which are not a direct impact but are the result of a complex impact pathway. These are often referred to as secondary impacts or risks.
Cumulative impact	Cumulative impacts occur when the incremental impact of the activity is combined with the cumulative effects of other past, present and reasonably foreseeable future projects.
Receptor	The term receptor refers to a feature of the natural and human surroundings that can potentially be impacted. This includes air, water, land, flora, and fauna including people.
Consequence	The consequence of an impact is the outcome of the event on affected receptors. Consequence can be positive or negative.
Likelihood	The likelihood of an impact is the chance (probability) of the impact occurring.

4.3 Identification and Characterisation of Environmental Aspects

In order to undertake meaningful impact and risk assessment, a clear understanding of the context of the assessment is required, through defining the activity and the receiving environment, and understanding any requirements (legislative or other) which are relevant to either the activity or the environment.

All components of the petroleum activity have been identified and described in Section 2 of this EP. The existing environment in the region is described in Volume 1, and a summary of environmental receptors in the receiving environment within the Operational Area and Potentially Exposed Area (PEA) is provided in Section 5 of this Volume (Volume 2).

In order to assess cumulative impacts, the spatial and temporal boundaries of the assessment must be set. For this EP, the following have been considered:

- Spatial – this is designed to capture all possible aspect interactions. The spatial boundaries for the assessment are described in Section 5.1.
- Temporal – this considered past, present and future activities and environments. The temporal boundary for this assessment is the duration of this EP validity i.e. 5 years.

4.4 Impact and Risk Identification

Once the context was established, an assessment was carried out to identify potential interactions between the petroleum activity and the receiving environment by considering impact pathways, known as environmental aspects. The relationships between activities and aspects is shown in Table 4-2.

Based upon an understanding of the environmental aspects, impacts or risks were defined and ecological and social receptors identified enabling a systematic evaluation to be undertaken.

Esso held a series of risk workshops (11 – 17 December 2018, 6 and 11 – 12 February 2019) focussed on validating the petroleum activity-specific impacts and risks and associated control measures.

Table 4-2 Activity – Aspect Relationships

4.5 Environmental Impact Assessment

The severity of an impact from a planned event, referred to as environmental consequence, can be evaluated in terms of the degree of the effects and the sensitivity of the environment. Esso evaluates three effect dimensions (scale, duration, and intensity) (Table 4-3) and three environmental sensitivity dimensions (irreplaceability, vulnerability, and influence) (Table 4-4).

The determination of impact severity involves evaluating each dimension as lower, moderate, or higher based on qualitative descriptions. Once each dimension is evaluated, results for effect and sensitivity are compared against interpretive criteria to define the overall environmental and public impact consequence level (Table 4-5).

Table 4-3 Evaluation of environmental effect dimensions

Effect Dimension	Value	Description
Duration	Short-term (Lower)	Hours to days; effects highly transitory
	Medium-term (Moderate)	Weeks to months. Trigger/cause is temporary; effects decline over time. For chemicals, consider persistence, breakdown product, and bioaccumulation potential in determining effects duration.
	Long-term (Higher)	Years; effects are ongoing. For chemicals, consider persistence or bioaccumulation potential in determining effects duration.
Size/Scale	Localised (Lower)	Within or near an operational site, facility, etc.; affecting an area similar to or smaller than a typical operational site (for small and/or mobile sources); effects are physically contained/controlled; not a significant portion of any sensitive area.
	Moderate	Affecting an area significantly larger than a typical operational site, facility, etc.; a significant portion of a *habitat*, watershed or single ecological area; a significant portion of the range or occurrence of a population of a species.
	Widespread (Higher)	Encompassing entire *ecosystems*, watersheds, or bioregions (landscape-scale); affecting most of the global range or occurrence of a species; having a noticeable impact on corporate-level *environmental performance* reporting.
Intensity	Minor (Lower)	Minor changes to wildlife, *habitat*, water occurrence/drainage, or vegetation; low density. For chemical effects: low concentration or hazard* potential.
	Moderate	Moderate or partial changes to *habitat*, water occurrence/flow, ground cover, ground stability, vegetation or wildlife. For chemicals, moderate concentrations, bioaccumulation or hazard* potential; sub-lethal, non-reproductive direct or indirect effects on organisms.
	Significant (Higher)	Notable changes to, fragmentation of, or elimination of *habitat*, water drainage/features, ground cover, ground stability, vegetation, and/or wildlife; for chemicals, high concentrations, bioaccumulation, or hazard* potential. Significant direct or indirect survival and/or reproductive effects on organisms.

* *Chemical hazard generically includes radioactivity, reactivity, toxicity, carcinogenicity, mutagenicity, pathogenicity, reproductive effects potential, etc.*

Table 4-4 Evaluation of sensitivity dimensions

Sensitivity Dimension	Value	Description (applies to species, *ecosystem*, and/or *ecosystem* features/ functions/ services, all at same scale as Consequence)
Irreplaceability	Lower	Common, plentiful
	Moderate	Less common or plentiful, but not rare or unique
	Higher	Unique or rare
Vulnerability	Lower	Healthy, resilient, unthreatened, undamaged, or no remaining natural elements (such as some industrial settings)

Sensitivity Dimension	Value	Description (applies to species, *ecosystem*, and/or *ecosystem* features/ functions/ services, all at same scale as Consequence)
	Moderate	Moderately resilient, existing stress or damage not significantly impairing function. Sustainable demand on resources/services
	Higher	Not resilient or capable of recovery, highly stressed, threatened and/or endangered, functions/ services failing (such as collapsing fishery)
Influence	Lower	Providing few or no services (supporting, regulating, provisioning, cultural)
	Moderate	Considered moderately important, providing a range of ecological, cultural, social, or commercial services for humans and biodiversity
	Higher	Highly productive and/or bio diverse, critical for human well-being (such as subsistence), functions/services provide critical support for key human/biological communities (such as clean water), considered highly important by public

Table 4-5 Determination of environmental and public impact consequence

Consequence Level	Environmental Impact	Public Impact	Interpretative Examples of Environmental Consequence Dimension Considerations
I	Potential Widespread, Long Term, Significant Adverse Effects	Extended (> 3 Months) National or International Media Coverage; Large Community Disruption or Evacuation (> 1,000 people); Closure of Major Transportation Route > 24 hrs	Sensitivity of receptors are higher; Effects are longer term and widespread and / or of a higher intensity.
II	Potential Localised, Medium Term, Significant Adverse Effects	National Media Coverage; Medium Community Disruption or Evacuation (100–1,000 people); Closure of Major Transportation < 24 hrs.	Sensitivity of receptors are moderate or higher; Effects are medium to long term and / or have a moderate to higher intensity.
III	Potential Short Term, Minor Adverse Effects	Public Complaints; Small Community Impact (< 100 people); Closure of Secondary Transportation Route < 24 Hours; Tier 1 Process Safety Event (PSE)	Sensitivity of receptors are lower to moderate; Effects are medium term and/or moderate intensity. OR Sensitivity of receptors is lower, but Effects are longer term / higher intensity. OR Effects are localised, short-term and / or low intensity, regardless of receptor sensitivity.
IV	Inconsequential or No Adverse Effects	Public Complaint; Temporary Closure of Minor Transportation Route; Minor Inconvenience	Sensitivity of receptors are lower; Effects are generally short term, localised and of low to moderate intensity.

4.6 Environmental Risk Assessment

4.6.1 Determination of Consequence

When assessing the consequence of an unplanned event, the same methodology is used as for determining the consequence of a planned event (as described in Section 4.5 Environmental Impact Assessment).

4.6.2 Determination of Probability

Once the most severe environmental consequence of an unplanned event is assessed, the probability of the unplanned event occurring is assessed. This is done by assessing the probability for each failure, event, or condition necessary to produce the impact.

In order to ensure that the highest possible risk is identified, scenarios with a lower severity consequence but higher probability and potentially a higher overall risk are also considered.

The five categories of probability are as shown in Table 4-6.

Table 4-6 Probability categories

Probability Range	Qualitative Interpretation Guidance	Quantitative Interpretation Guidance (probability of occurring per year of exposure)
A	**Very Likely** • Similar event has occurred once or more at Site in the last 10 yrs. • Has happened several times at Site or many times in Company	**0.1 to 1**
B	**Somewhat Likely** • Has happened once before at Site or several times in Company	**0.01 to 0.1**
C	**Unlikely** • Has not happened before at Site or has happened a few times in Company	**0.001 to 0.01**
D	**Very Unlikely** • Have been isolated occurrences in Company or has happened several times in industry	**0.0001 to 0.001**
E	**Very Highly Unlikely** • Has happened once or not at all in Company • Has happened a few times or not at all in industry	**<0.0001**

4.6.3 Determining Significance of Risk

The combination of consequence severity and probability of occurrence determines the level of risk. ExxonMobil's risk framework considers existing controls when determining risk. The overall risk category is given on the basis of the likelihood of the consequence occurring after application of the control measures. The effectiveness of control measures was considered when determining the likelihood of events with control measures in place, i.e. factors such as functionality, availability, reliability, survivability, independence and compatibility of control measures, were considered.

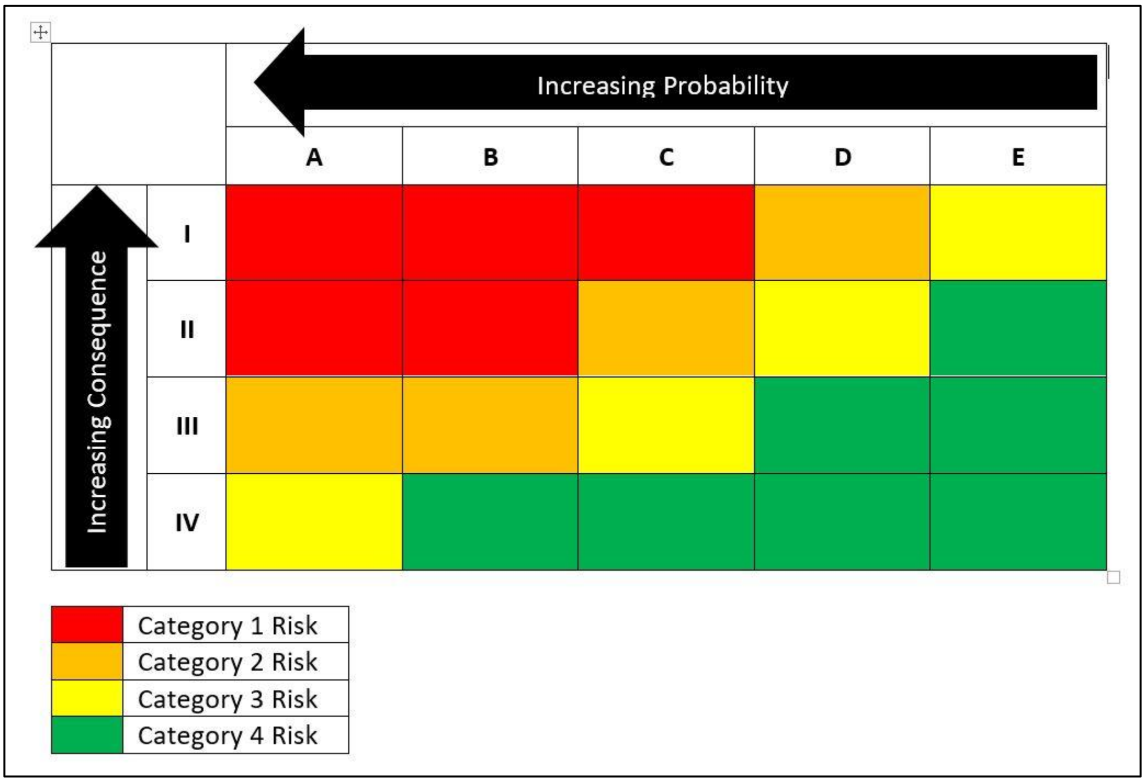

Figure 4-1 Risk Matrix

ExxonMobil classifies risk into four categories as follows:

Category 1: A higher risk that should have specific controls established in the short term and be reduced as soon as possible.

Category 2: A medium risk that should be reduced unless it is not "reasonably practicable" to do so. Reasonably practicable is:

- The level of resource expenditure is not significantly disproportionate in relation to the resulting decrease of risk.

Category 3: A medium risk that should be reduced if "lower cost" options exist to do so. Lower cost denotes follow-up work that can be completed without:

- Allocating extensive engineering, technical, and operations manpower, or;
- The need for unit shutdowns or activities which may introduce other risks or use resources that may be more appropriately used to address higher risk category items.

Category 4: A lower risk that is expected to be effectively managed in base OIMS practices

- Typically requires "No Further Action."
- Risk mitigation measures that are in place to manage the risk to Category 4 should be continued.

4.7 Demonstration of ALARP

Control measures are selected to reduce either the consequence of an impact or risk, or the likelihood of an unplanned event occurring. Control measures that are required by legislation are considered ‘Good Practice’ within the oil and gas or offshore industry and are therefore adopted regardless of the evaluated impact or risk level. In some cases, the risk or impact level will be so low that no control measures will be identified which can reduce the consequence or likelihood.

The OPGGS(E)R 13(5)(c) requires that the EP detail how the control measures will be used to reduce the impacts and risks of the activity to as low as reasonably practicable (ALARP) and to an acceptable level.

ALARP is achieved if the cost involved in reducing the risk further would be grossly disproportionate to the benefit gained. The ALARP principle arises from the fact that infinite time, effort and money could be spent attempting to reduce a risk or impact to zero. Where good practice controls measures do not sufficiently reduce the risk or impact level, consideration of additional control measures may be required, including undertaking a comparative assessment of impacts or risks, costs and environmental benefits for identified control measures.

NOPSEMA's Environment Plan Decision Making Guideline (GL1721, Rev 5, and June 2018) states that in order to demonstrate ALARP, a titleholder must be able to implement all available control measures where the cost is not grossly disproportionate to the environmental benefit gained from implementing the control measure.

There is no universally accepted guidance to applying the ALARP principle to environmental assessments. In alignment with NOPSEMA's ALARP Guidance Note (N-04300-GN0166, Rev 6, June 2015), Esso has adapted the approach developed by Oil and Gas UK (OGUK) (OGUK, 2014) for use in an environmental context to determine the assessment technique required to demonstrate that potential impacts and risks are ALARP (Figure 4-2).

Specifically, the framework considers impact severity and several guiding factors:

- Activity type
- Risk and uncertainty
- Stakeholder influence.

Good practice is considered sufficient demonstration of ALARP in cases where the risk is relatively well understood, the potential impacts are low, activities are well practised, and there are no conflicts with company values nor significant media interest. This is referred to as a Type A Decision.

An engineering risk assessment is required to demonstrate ALARP in cases where there is greater uncertainty or complexity around the activity and/or risk, the potential impact is moderate, it may attract local media attention and some persons may object. This is referred to as a Type B Decision.

A Type C decision typically involves sufficient complexity, high potential impact, uncertainty, or stakeholder influence to require a precautionary approach. In this case, relevant good practice still must be met, engineering risk assessment is required, and the precautionary approach applied for those controls that only have a marginal cost benefit.

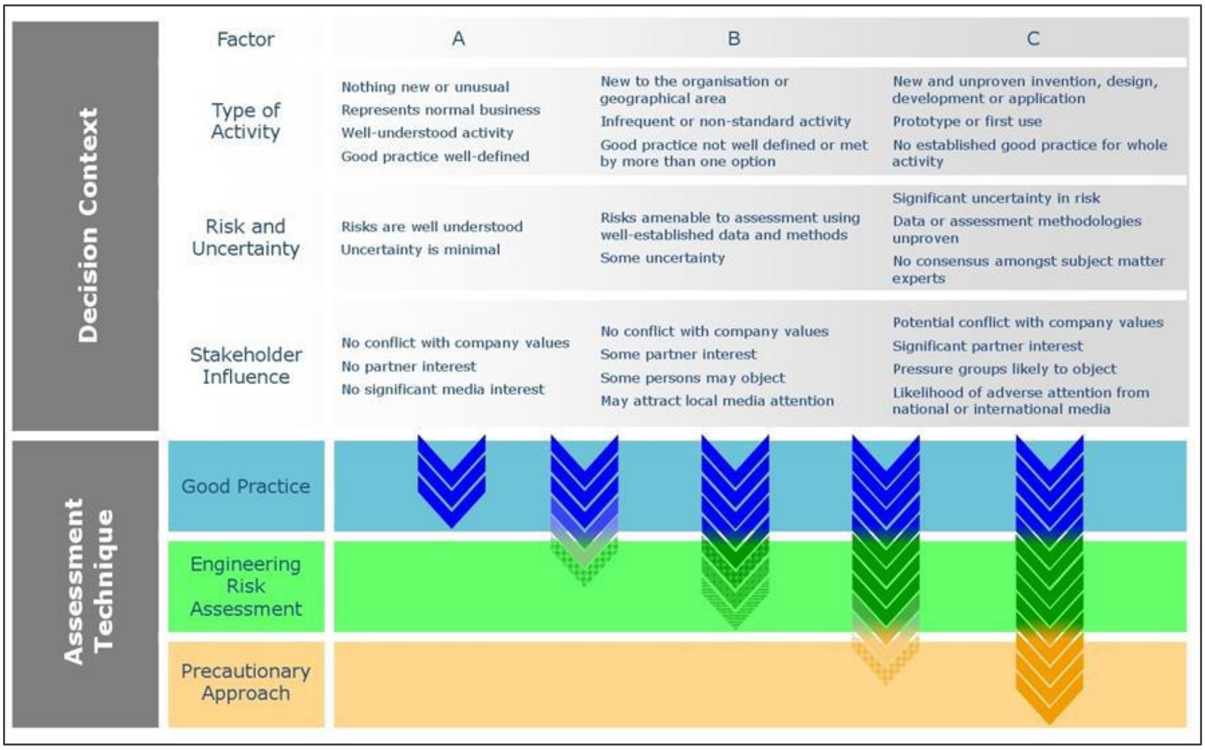

Figure 4-2 ALARP Decision Support Framework

This decision-making context has been applied to each aspect in Section 4.

The assessment techniques considered include:

- Good practice
- Engineering risk assessment
- Precautionary approach.

4.7.1 Good Practice

OGUK (2014) defines 'Good Practice' as:

"*The recognised risk management practices and measures that are used by competent organisations to manage well-understood hazards arising from their activities*".

'Good Practice' can also be used as the generic term for those measures that are recognised as satisfying the law. For this EP, sources of good practice include:

- Requirements from Australian legislation and regulations
- Relevant Australian policies
- Relevant Australian Government guidance
- Relevant industry standards
- Relevant international conventions.

If the ALARP technique is determined to be 'Good Practice', further assessment ('Engineering Risk Assessment') is not required to identify additional controls. However, additional controls that provide a suitable environmental benefit for an insignificant cost are also identified at this point.

4.7.2 Engineering Risk Assessment

All impacts and risks that require further assessment are subject to an 'Engineering Risk Assessment' in which a comparative assessment of risks, costs, and environmental benefit is conducted (OGUK, 2014). The cost–benefit analysis shows the balance between the environmental benefit and the cost of implementing the identified measure.

4.7.3 Precautionary Approach

OGUK (2014) states that if the assessment, considering all available engineering and scientific evidence, is insufficient, inconclusive, or uncertain, then a precautionary approach to hazard management is needed.

A precautionary approach will mean that environmental considerations are expected to take precedence over economic considerations, and a control measure that may reduce environmental impact is more likely to be implemented.

4.8 Demonstration of Acceptable Level

One of the objects of the *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009* (regulations) is to ensure that any petroleum activity carried out in an offshore area is carried out in a manner by which the environmental impacts and risks of the activity will be of an acceptable level. This is also one of the key criteria for acceptance of an environment plan.

The acceptable level of environmental impact and risk for each receptor needs to be defined before the environmental performance outcomes (EPOs) can be decided and the evaluation of those impacts and risks can take place.

An 'Acceptable level' is the specified amount of environmental impact and risk that the activity may have which would not be inconsistent with relevant principles, and not compromise management / conservation / protection objectives or the attainment of stakeholder / wider-community views in defining acceptable levels.

Esso considers a range of factors when evaluating the acceptability of environmental impacts or risks associated with its activities. This evaluation is based on several factors, as outlined in Table 4-7 and is based on NOPSEMA's Guidance Notes for Environment Plan Content Requirements (N04750-GN1344, Rev 3, April 2016) and guidance issued in Decision-making – Criterion 10A(c) Acceptable Level (N-04750-GL1637, Rev B, Nov 2016). The acceptability evaluation for each aspect associated with this activity is undertaken in accordance with Table 4-7. These factors are used to demonstrate acceptability in Sections 6 and 7.

Table 4-7 Demonstration of acceptability test

Factor	Demonstration of acceptability	
Risk Assessment Process for Unplanned Event	The level of environmental risk is either Category 2, 3 or 4.	
Consequence Assessment for Planned Event	The level of environmental consequence is 3 or below.	
Principles of Ecologically Sustainable Development (ESD)	*Principles of Ecologically Sustainable Development as per EPBC Act Section 3A*	*Applicability to this EP*
	Decision making processes should effectively integrate both long term and short term economic, environmental, social and equitable considerations	This principle is inherently met through the EP assessment process. This principle is not considered separately for each acceptability evaluation.
	If there are threats of serious or irreversible environmental damage, lack of full scientific certainty should	An evaluation is completed to determine if the activity will result in serious or irreversible environmental

Factor	Demonstration of acceptability	
	not be used as a reason for postponing measures to prevent environmental degradation.	damage. Where the activity has the potential to result in serious or irreversible environmental damage, further assessment is undertaken to determine if there is significant uncertainty in the evaluation.
	The principle of inter-generational equity—that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	Where the potential impacts and risk are determined to be serious or irreversible the precautionary principle is implemented to ensure the environment is maintained for the benefit of future generations
	The conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	Impact assessment determines there are no significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved.
	Improved valuation, pricing and incentive mechanisms should be promoted	Not relevant to this EP.
Legislative and Other Requirements	All good practice control measures have been identified for the aspect. Acceptable levels identified in relevant EPBC listed species recovery plans or approved conservation advices as described in Table 4-8 below have been considered.	
Internal Context	All Esso management system standards and impact or risk control processes have been identified for the aspect.	
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	

Table 4-8 Acceptable levels listed in relevant EPBC listed species recovery plans or approved conservation advices

Receptor / Value and Sensitivity	Acceptable Level	Source
Commonwealth marine area	Undertake the activity in a manner that will not result in a known or potential pest species becoming established.	MNES Significant guidelines for Commonwealth Marine Waters
Physical Conditions		
Ambient water quality	<u>Normal discharges:</u> Undertake the activity in a manner that will not result in a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health. <u>Persistent or harmful chemicals:</u> Undertake the activity in a manner that will not result in persistent organic chemicals, heavy metals, or other potentially harmful chemicals accumulating in the marine environment such that biodiversity, ecological integrity, social amenity or human health may be adversely affected.	MNES Significant guidelines for Commonwealth Marine Waters
Ambient sediment quality	Undertake the activity in a manner that will not result in a substantial change in sediment quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health.	MNES Significant guidelines for Commonwealth Marine Waters

Receptor / Value and Sensitivity	Acceptable Level	Source
Air quality	Undertake the activity in a manner that will not result in a substantial change in air quality which may adversely impact on biodiversity, ecological integrity; social amenity or human health.	MNES Significant guidelines for Commonwealth Marine Waters
Climate	Undertake the activity in a manner that will not result in a substantial change in climate which may adversely impact on biodiversity, ecological integrity; social amenity or human health.	MNES Significant guidelines for Commonwealth Marine Waters
Ambient noise	Undertake the activity in a manner that will not result in a substantial change in ambient noise which may modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity results.	MNES Significant guidelines for Commonwealth Marine Waters
Ambient light	Undertake the activity in a manner that will not result in a substantial change in ambient light which may modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity results.	MNES Significant guidelines for Commonwealth Marine Waters
Ecological Receptors		
Listed threatened and migratory Species	Undertake the activity in a manner that will not lead to a long-term decrease in the size of a threatened or migratory listed species population.	For listed threatened and migratory species, EPBC Significant Impact Guideline 1.1 has been used to identify the relevant significant impact criteria.
Threatened albatross and giant petrel species	Undertake the activity in a manner that will not impact the long term survival and recovery of albatross and giant petrel populations breeding and foraging in Australian jurisdiction.	National Recovery Plan for threatened albatrosses and giant petrels 2011 – 2016
White Shark	Undertake the activity in a manner that will not hinder the recovery of white shark in the near future, or impact on the conservation status of the species in the future.	Recovery Plan for the White Shark (*Carcharodon carcharias*) (2013)
Benthic habitats and communities	Undertake the activity in a manner that will not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity in a Commonwealth marine area results.	MNES Significant guidelines for Commonwealth Marine Waters
Coastal habitats and communities		
Marine species that are not protected (i.e. not listed threatened or migratory species	Undertake the activity in a manner that will not have a substantial adverse effect on a population of a marine species including its life cycle (for example, breeding, feeding, migration behaviour, life expectancy) and spatial distribution.	MNES Significant guidelines for Commonwealth Marine Waters
Wetlands	Undertake the activity in a manner that will not result in a substantial and measurable change in the water quality of the wetland which may adversely impact on biodiversity, ecological integrity, social amenity or human health.	Significant impact criteria for Wetlands of International Importance relevant to water quality.
Key Ecological Feature	Undertake the activity in a manner that will not result in modification, destruction, fragmentation, isolation or disturbance of an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity in a Commonwealth marine area.	MNES Significant guidelines for Commonwealth Marine Waters

Receptor / Value and Sensitivity	Acceptable Level	Source
Economic, Cultural and Social Receptors		
Commercial fisheries Recreational users Commercial users Shipping Oil and Gas Activities	Undertake the activity in a manner that will not interfere with other marine users to a greater extent than is necessary for the reasonable exercise of right conferred by the titles granted.	The OPGGS Act Section 280

5 Description of the Environment

5.1 Project Areas

Project Areas relevant to this EP include:

Operational Area – the area where petroleum activities will take place. The Operational Area for this EP is defined as the area within a 500 m PSZ around the facilities listed in Appendix A, and a 200m operational zone along the secondary lines connecting the facilities and the petroleum pipelines in Commonwealth waters (>3 NM from shore), as defined in the "Bass Strait Pipeline Network Safety Case" (BSPNSC).

Potentially Exposed Area (PEA) - the outer edge of all simulations in stochastic modelling, using all worst case discharge scenarios (WCDSs) and the lowest relevant thresholds per Table 7-2, for the furthest reaching fate of hydrocarbons. While modelling carries some inherent uncertainty, the PEA as defined:

- Represents the area that could be affected by any oil spill; and
- Is conservative, as the lowest threshold relevant to any receptor is used.

Figure 5-1 shows the PEA for Bass Strait Operations, stochastic modelling of instantaneous contact at lowest hydrocarbon thresholds (10 ppb instantaneous entrained).

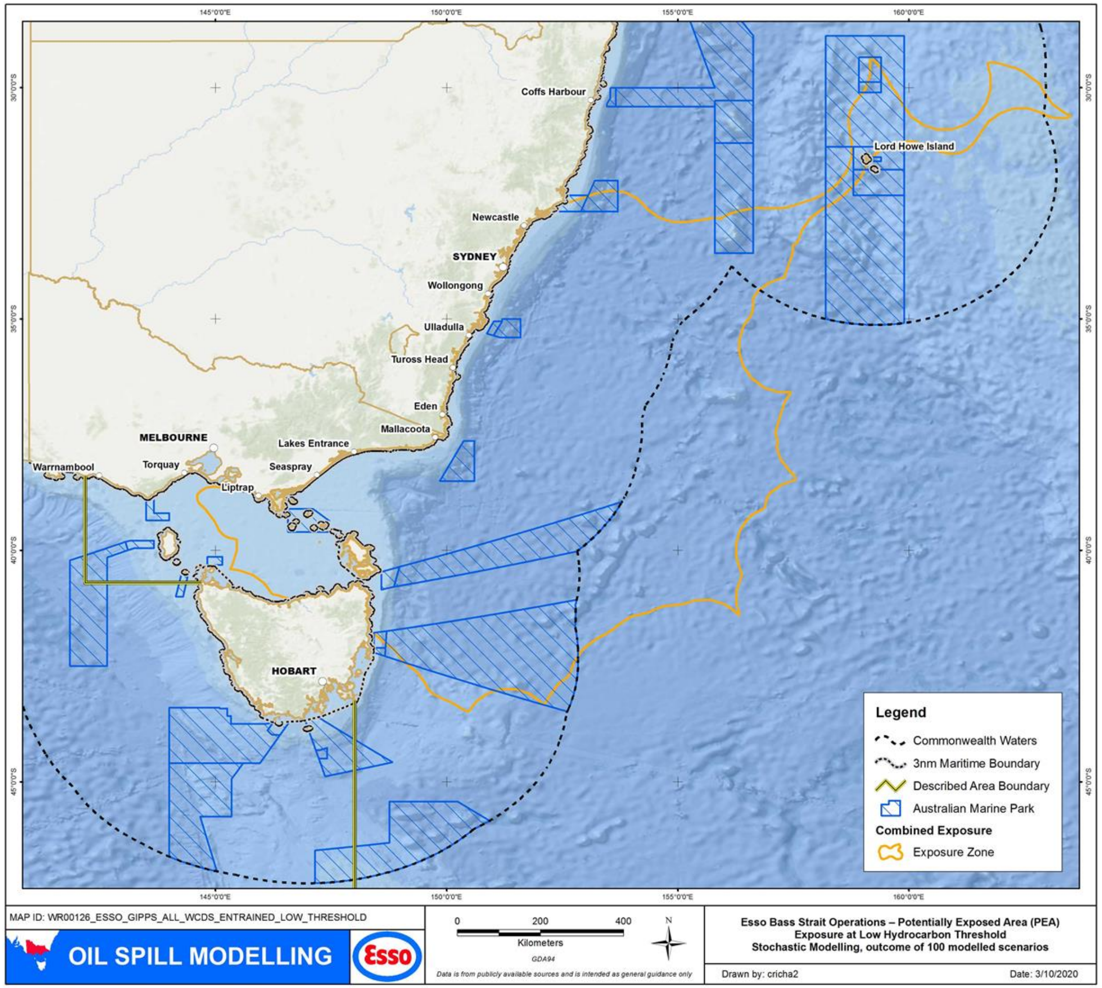

Figure 5-1 **Potentially Exposed Area – Worst Case Discharge Modelling. Stochastic modelling (combined outcome of 100 modelled scenarios) showing instantaneous contact at lowest hydrocarbon thresholds (10ppb instantaneous entrained).**

5.2 Receptors within the Operational and Potentially Exposed Areas

In order to set the environmental context required to assess impacts and risks associated with the Esso Bass Strait Operations, receptors found within both the Operational Area and PEA need to be described. Volume 1 of this Environment Plan includes a detailed description of the existing environment within the Described Area, which encompasses the Operational Area and the PEA. Presence / absence of receptors within the Operational Area and PEA are summarised in Table 5-1, with detailed descriptions of receptors found in Volume 1 of the EP. Figure 5-2 shows the facilities in Bass Strait with their proximity to marine protected areas.

Values and sensitivities associated with each of the receptors have been included in the tables. These values and sensitivities have been identified based on:

- Presence of listed threatened or migratory species or threatened ecological communities identified in the EPBC Protected Matter searches.
- Presence of BIAs and habitats critical to the survival of the species.
- Presence of important behaviours (e.g. foraging, roosting or breeding) by fauna, including those identified in the EPBC Protected Matter searches.
- The link they provide to other receptors (e.g. nursery habitat, food source, commercial species).
- The human benefit they provide (e.g. recreation and tourism, aesthetics, economic benefit).

The EPBC Protected Matters Search Tool results are presented in Appendix C.

Additional description of the environment in the Operational Area is provided in Section 5.2.1.1 below.

Table 5-1 Summary of the Values and Sensitivities in the existing environment within the Operational Area and PEA related to the EP

Receptor Group	Receptor	Receptor Description	Values and Sensitivities		Operational Area		Potentially Exposed Area (PEA)
Regional							
Regional Context	Commonwealth Marine Region	Seawaters of the Marine bioregion	• South-west Marine Region • Temperate East Marine Region	✓	**Present** The Operational Area lies entirely within the South-west Marine Region.	✓	**Present** The PEA lies within the South-west Marine Region and the Temperate East Marine Region.
Ecological Environment							
Marine Fauna	Fish	Fish (bony)	• Commercial and recreational species	✓	**Present** Commercial and recreational fish species occur within the Operational Area. Commercial fishing effort occurs in Commonwealth waters along the continental shelf and the upper continental slope. Most recreational fishing occurs in nearshore coastal waters & within bay and estuaries.	✓	**Present** The main commercial Commonwealth fisheries in the PEA are the Southern and Eastern Scalefish and Shark Fishery. Primary target species include Blue grenadier, Tiger flathead, Silver warehou, Gummy shark, Pink ling. Moderate to high recreational use along the majority of the coast. Common recreational fish species include Tiger flathead, bream, snapper, Australian Salmon, and lobster. Offshore catches can include mackerel, tuna, groper and shark.
			• Listed Marine Species • BIA	✓	**Present** 26 listed marine species (or species habitat) of fish may be found in the Operational Area. No important behaviours or BIAs have been identified.	✓	**Present** Pipefishes, seahorses and seadragons are associated with vegetation in sheltered to moderately exposed reef areas at a range of depths from 0 to 50m, depending on the species, but usually at depths of between 5 and 25 m 55 syngnathid species (or species habitat) may occur within the PEA. No

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
							important behaviours or BIAs have been identified.
			• Threatened Species	-	**Not Present** One listed threatened species (or species habitat), the Australian Grayling, may occur within the Operational Area. The Australian Grayling typically inhibits estuarine waters and coastal seas and is therefore not expected to be present within the Operational Area.	✓	**Present** Two species listed as 'critically endangered', the Spotted handfish and the Red handfish, may occur within the PEA. Two other fish species potentially occurring within the PEA are listed as 'vulnerable' under the EPBC Act; the Australian grayling and the Black rock cod.
		Fish (cartilaginous)	• Threatened Species • Migratory Species • BIA	✓	**Present** Two listed threatened shark species (or species habitat) may occur within the Operational Area: • White shark (breeding known to occur within the area) • Whale shark Two additional listed migratory species (mako shark and porbeagle shark) may occur within the Operational Area. The Operational Area is within a distribution BIA for the great white shark.	✓	**Present** There are five shark and two ray species (or species habitat) that may occur within the PEA; this includes species classified as threatened and migratory. • Grey nurse shark • White shark • Mako shark • Porbeagle shark • Whale shark • Giant manta ray • Reef manta ray Only one species (great white shark) has an important behaviour (breeding) identified in the PEA. Habitat critical for the survival of the grey nurse shark have been identified within the PEA.

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
	Birds	Seabirds and Shorebirds - live or frequent the coast or ocean	• Listed Marine Species • Threatened Species • Migratory Species • BIA	✓	**Present** 31 seabird and shorebird species (or species habitat), including 24 listed threatened species, may occur within the Operational Area. The Operational Area intersects foraging BIAs for: Antipodean albatross, black-browed albatross, Buller's albatross, Campbell albatross, Indian yellow-nosed albatross, shy albatross, wandering albatross, white-capped albatross, common diving-petrel, white-faced storm-petrel, flesh-footed shearwater and short-tailed shearwaters. Anecdotally, short-tailed shearwaters are commonly seen on and around platforms. Other listed sea birds are not commonly observed.	✓	**Present** There are 114 seabird and shorebird species (or species habitat) that may occur within the PEA; this includes species classified as threatened and migratory. The type of presence varies between species, and includes important behaviours (e.g. foraging, roosting, breeding) for some species.
	Marine Mammals	Cetaceans	• Listed Marine Species • Threatened Species • Migratory species • BIA	✓	**Present** 27 cetacean species or species habitats, including 5 listed threatened (Sei, Blue, Fin, Southern Right and Humpback whales), may occur within the Operational Area. Sei whale and fin whale are listed within the EPBC PMST as having foraging, feeding or related behaviours likely to occur within the Operational Area. The Operational Area intersects a distribution and a migration BIA for the southern right whale, a foraging and distribution BIA for the pygmy blue whale and a migration BIA for the humpback whale. Esso's seaward platforms regularly observe migrating humpback whales with peak numbers seen in March and October. On	✓	**Present** 25 whale and 12 dolphin species (or species habitat) that may occur within the PEA; this includes species classified as threatened and migratory. The type of presence varies between species, and includes important behaviours (e.g. foraging, breeding) for some species.

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
					occasion they have delivered playful displays close to the platforms and have even been observed rubbing / scratching themselves on the platform legs. Southern right whales and blue pygmy whales are rarely observed. Dolphins have also been observed from Esso platforms.		
		Pinnipeds	• Listed Marine Species • Threatened Species	✓	**Present** 2 pinniped species or species habitats may occur within the Operational Area: New Zealand fur-seal, Australian fur-seal. Seals are plentiful around Esso platforms and are often observed resting on platform structures and swimming in the surrounding sea. Anecdotal observation indicates that Australian fur seals appear to be the most common.	✓	**Present** 3 pinniped species (or species habitat) may occur within the PEA: New Zealand fur-seal, Australian fur-seal, Australian sealion (threatened). The type of presence varies between species and includes important behaviours (e.g. breeding) for some species. Breeding is restricted to islands in the Bass Strait – six in Victorian waters and four in Tasmanian waters.
			• BIA	-	**Not present**	-	**Not present**
		Sirenia	• Listed Marine Species • Migratory Species • BIA	-	**Not present** Dugongs primarily occur in coastal and inland waters and are not likely to occur in the Operational Area. No BIAs occur in the Operational Area.	✓	**Present** Dugongs (or species habitat) may occur in the north-eastern region of the PEA. No BIAs occur in the PEA.
	Marine Reptiles	Turtles	• Listed Marine Species • Threatened Species • Migratory Species	✓	**Present** 3 listed threatened marine reptiles have species (or species habitat) which may occur within the Operational Area: • Loggerhead turtle • Green turtle	✓	**Present** 5 marine turtle species (or species habitat) may occur within the PEA: • Loggerhead turtle • Green turtle

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
			• BIA or critical habitat		• Leatherback turtle. No BIAs or habitat critical to the survival of these species occur within the Operational Area. There have been no reports of turtle sightings near Esso's platforms throughout the history of operation.		• Leatherback turtle • Hawksbill turtle • Flatback turtle No BIAs or habitat critical to the survival of these species occur within the PEA.
		Snakes	• Listed Marine Species	-	**Not Present** Seasnakes are not expected to be found within the Operational Area and have not been listed within the EPBC PMST search results.	✓	**Present** 2 species of seasnakes (or species habitat) may occur within the PEA: Elegant Seasnake Yellow-bellied sea snake No BIAs occur within the PEA.
Plankton	Phytoplankton and zooplankton		• Food Source (e.g. fish, whales, turtles)	✓	**Present** Phytoplankton and zooplankton are widespread throughout oceanic environments and are expected to occur in the Operational Area.	✓	**Present** Phytoplankton and zooplankton are widespread throughout oceanic environments; however increased abundance and productivity can occur in areas of upwelling e.g. Upwelling East of Eden KEF (refer to KEFs below).
Benthic Habitat	Bare Substrate	Predominantly unvegetated soft sediment substrates	• Key habitat (e.g. benthic invertebrates)	✓	**Present** The Operational Area is located on the flat outer shelf plain of the Twofold Shelf and overlaps an area of inshore soft sediment habitat. The benthic habitat within the Operational Area is expected to include predominantly lightly muddy, gravelly sand substrate. Benthic infauna such as crustaceans and polychaete worms also occur.	✓	**Present** Unvegetated soft sediments are a widespread habitat in both intertidal and subtidal areas, particularly in areas beyond the photic zone. The Gippsland Basin is composed of a series of large sediment flats, interspersed with small patches of reef, bedrock and consolidated sediment.

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
					Where hard substrate or points of attachment (facilities) are present, colonisation by epifauna occurs mostly in the form of sessile, invertebrate, filter feeders. The degree of colonisation varies between platforms however sponge beds have only been detected at BMB.		
	Seagrass	Seagrass meadows in intertidal and shallow subtidal waters	• Nursery habitat (e.g. crustaceans, fish) • Food source (e.g. fish, turtles) • Trap and stabilise sediments	-	**Not present** The Operational Area does not include intertidal and shallow subtidal waters	✓	**Present** Areas of seagrass can be found within the PEA include Corner Inlet and Lakes Entrance in Victoria, and numerous inlets and estuaries along the NSW coast.
	Subtidal Rocky Reefs	Extensions of intertidal rocky shores or isolated offshore rocky reefs – substrate composed of rock, boulders, cobbles and patches of sand veneer	• Provides habitat for a wide range of flora and fauna	✓	**Present** South-east Reef, an isolated offshore rocky reef, is mapped to exist in the VIC/L5 area, including beneath the CBA platform, however the reef has not been detected in any of the survey work conducted for the Gippsland activities. The Operational Area does not include intertidal waters.	✓	**Present** Subtidal rocky reefs occur either as extensions of intertidal rocky shores or as isolated offshore reefs and are always submerged. Scattered along the Gippsland shore, including; Bastion Point, Quarry Beach, Little Rame Head, Long Reef, Wingan Point, The Skerries Special Management Area, Rame Head, Petrel Point, Thurra River, Point Hicks Marine National Park, Pearl Point, Yeerung River Estuary (Intermittently open), Cape Conran (East Cape, Cowrie Bay, Flat Rocks), Beware Reef, Point Ricardo, Ricardo Beach, New Zealand Star Bank.

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
							An example of an isolated offshore reef is the South-east Reef, thought to be located in the vicinity of VIC/L5.
	Macroalgae	Rocky substrates within nearshore intertidal and shallow subtidal zones	• Nursery habitat (e.g. crustaceans, fish) • Food source (e.g. birds, fish)	-	**Not present** The Operational Area does not include nearshore intertidal and tidal zones where macroalgal communities may be present.	✓	**May Occur** Macroalgae are not a common dominant habitat within the PEA, however known areas include around Gabo Island and within the Bemm River estuary. The 'Giant Kelp Marine Forests of South East Australia' is listed as an endangered TEC under the EPBC Act and may occur within the PEA. The ecological community is characterised by a closed to semi-closed surface or subsurface canopy of *Macrocystis pyrifera*. This ecological community occurs on rocky substrate; some patches may occur in Victoria or northern Tasmania
	Coral	Hard coral communities generally <50m of water and soft coral at most depths (throughout the continental shelf, slope and offslope regions)	• Nursery habitat (e.g. crustaceans, fish) • Breeding habitat (e.g. fish)	✓	**May Occur** The Operational Area includes deeper waters throughout the continental shelf, slope and off-slope regions where soft corals may occur. Soft corals (e.g. sea fans, sea whips) typically occur as part of mixed reef environments in waters along the coast and are only expected to be near platforms closest to the shoreline.	✓	**Present** Soft corals can be found at most depths throughout the continental shelf, slope and off the slope regions, to well below the limit of light penetration. Soft corals (e.g. sea fans, sea whips) occur as part of mixed reef environments in waters along the coast.
	Submarine Canyons	Abundant features along continental and oceanic island margins connecting continental shelves to deep ocean basins – variety of environmental	• High productivity • Aggregations of marine life	-	**Not present** The Operational Area does not include water depths associated with submarine canyons. Closest is Bass Canyon System closest to BKA facility, within approximately 50 km.	✓	**Present** Submarine canyons are abundant features along continental and oceanic island margins that connect continental shelves to deep ocean basins.

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
		and physical characteristics					The Bass Canyon System is located within the PEA. Refer to Bass Canyon System KEF below
	Seamounts	Key ecological feature – comprised hard and/or soft substrate	• Area of high productivity and aggregations of marine life	-	**Not present** Seamounts do not occur within the Operational Area. Closest are the Seamounts off the South and East of Tasmania over 400kms away	✓	**Present** Seamounts of South and East Tasmania occur in the PEA.
Coastal Habitat	Shoreline (Sandy)	Beaches dominated by sand-sized (0.063–2 mm) particles	• Foraging habitat (e.g. birds) • Nesting or Breeding habitat (e.g. birds, pinnipeds, turtles) • Haul-out sites (e.g. pinnipeds)	-	**Not present** The Operational Area does not include coastal or nearshore environments.	✓	**Present** Sandy shorelines are the most common shoreline type along the entire Victorian coast, including popular locations such as Ninety Mile Beach (East Gippsland, Victoria) and Squeaky Beach (Wilsons Promontory, Victoria).
	Shoreline (Rocky)	Hard and soft rocky shores, including bedrock outcrops, platforms, low cliffs (less than five metres in height), and scarps	• Foraging habitat (e.g. birds) • Nesting or Breeding habitat (e.g. birds, pinnipeds, turtles) • Haul-out sites (e.g. pinnipeds)	-	**Not present** The Operational Area does not include coastal or nearshore environments.	✓	**Present** Sheltered intertidal flats occur at Corner Inlet and Nooramunga Marine and Coastal Parks. Bare sediment occurs at Mallacoota Inlet, Wingan Inlet, Sydenham Inlet - Bemm River and Mud Lake
	Shoreline (Cliff)	Steep (>300) slope, and narrow width within the intertidal zone	• Habitat for sessile invertebrates	-	**Not present** The Operational Area does not include the coastal or nearshore environment	✓	**Present** Occurs behind Betka Beach and Secret Beach through to Little Rame Head, Sandpatch Point, Wingan Point, The Skerries, Rame Head, Petrel Point, Point

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
			• Foraging habitat (e.g. birds)				Hicks, Clinton Rocks, Tamboon Inlet, Pearl Point, Cape Conran (Needle Rocks, Irvine Rocks, Quincy Rocks Salmon Rocks), and at Ricardo Point
	Muddy – Sheltered Intertidal Flats and Bare Sediment	Predominantly mud-sized (<0.063 mm) particles with mixed sediments (e.g. sands, shell or gravel) – associated with mangrove & saltmarsh environments	• Habitat for sessile invertebrates • Foraging habitat (e.g. birds) • Nursery habitat (e.g. crustaceans, fish) • Highly productive	-	**Not present** The Operational Area does not include the coastal or nearshore environment	✓	**Present** Occur at Corner Inlet and Nooramunga Marine and Coastal Parks. Bare sediment occurs at Mallacoota Inlet, Wingan Inlet, Sydenham Inlet - Bemm River and Mud Lake
	Saltmarsh	Upper-intertidal zone comprised of dense stands of halophytic plants such as herbs, grasses and low shrubs	• Nursery habitat (e.g. crustaceans, fish) • Breeding habitat (e.g. fish)	-	**Not present** The Operational Area does not include coastal or nearshore environments. Closest point where Giant Kelps (may occur Volume 1, Section 2.2.4.1) are at Cape Conran, ~40 kms from KPA. Subtropical and Temperate Coastal Saltmarsh (Volume 1, Section 2.2.4.3) occur along the coastline, closest facilities are SHA at ~15kms to shoreline and SNA at ~34kms to Lakes Entrance.	✓	**Present** Saltmarshes occur along the coast throughout the Planning Area although is most extensive behind the sand dunes of Ninety Mile Beach in Gippsland. 'Subtropical and Temperate Coastal Saltmarsh' is listed as a vulnerable Threatened Ecological Community (TEC) and its known distribution includes the southern and eastern coasts of Australia
	Coastal Vine Thicket	Littoral Rainforest and coastal vine thickets	• Provides habitat for flora and fauna • Coastal buffer against erosion	-	**Not present** The Operational Area does not include coastal or nearshore environments.	✓	**Present** 'Littoral Rainforest and Coastal Vine Thickets of Eastern Australia' is listed as a critically endangered TEC.

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
					Littoral Rainforest (Volume 1, Section 2.2.4.2) occur along the coastline, closest facilities are SHA at ~15kms to shoreline and SNA at ~34kms to Lakes Entrance.		
	Wetlands	Wetlands of International Importance	• Wetlands of international importance	-	**Not present** The Operational Area does not include coastal or nearshore environments. Closest is Gippsland Lakes RAMSAR site (Volume 1 Section 2.2.3.1), approximately 34 kms to the SNA facility.	✓	**Present** Two RAMSAR wetlands are located in the nearshore area directly adjacent to the Operational Area, and several others are located within the PEA. These include: • Gippsland Lakes Ramsar Site • Corner Inlet Ramsar Site • Logan Lagoon Ramsar Site • East Coast Cape Barren Island Lagoons Ramsar Site • Floor Plain Lower Ringarooma • Moulting Lagoon Ramsar Site • Apsley Marshes Ramsar Site • Western Port Ramsar Site • Little Waterhouse Lake Ramsar Site • Lavinia Ramsar Site • Myall Lakes Ramsar Site • Hunter Estuary Wetlands Ramsar Site • Towra Point Nature Reserve Ramsar Site
Economic Environment							
Fishing		Commonwealth-managed	Economic benefit	✓	**Present**	✓	**Present**

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
	Commercial Fisheries				Six Commonwealth-managed fisheries have management areas that intersect the Operational Area of the pipelines (commercial fishing is not permitted within the platform petroleum safety zone which is equivalent to the area of the OA): • Bass Strait Central Zone Scallop • Eastern Tuna and Billfish Fishery • Small Pelagic Fishery • Southern and Easter Scalefish and Shark Fishery • Southern Bluefin Tuna Fishery, and • Southern Squid Jig Fishery		Six Commonwealth-managed fisheries have management areas that intersect with the PEA: • Bass Strait Central Zone Scallop • Eastern Tuna and Billfish Fishery • Small Pelagic Fishery • Southern and Easter Scalefish and Shark Fishery • Southern Bluefin Tuna Fishery, and • Southern Squid Jig Fishery
		State-managed	Economic benefit	✓	**Present** There are three Victorian state-managed fisheries with management areas which extend into Commonwealth waters. Given the water depth in the Operational Area, the only commercial fisheries which may be present within the Operational Area of the pipelines (commercial fishing is not permitted within the platform petroleum safety zone which is equivalent to the area of the OA) are: • Giant crab fishery • Rock lobster fishery • Octopus Fishery	✓	**Present** There are seven Victorian and eight New South Wales state-managed commercial fisheries with management areas that intersect with the PEA.
	Commercial Aquaculture	State-managed	Economic benefit	-	**Not present** There are no state-managed aquaculture sites within the Operational Area.	✓	**Present** The Sydney rock oyster commercial aquaculture occurs in 41 estuaries

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
							between Eden in the south to the Tweed River in the north.
Industry	Oil & Gas	Offshore oil and gas exploration and production activities	Economic benefit	-	**Not present** Esso facilities and activities are the only oil & gas activities undertaken within the Operational Area.	✓	**Present** Exploration and production activities are undertaken in the Otway and Gippsland Basins.
	Shipping	Commercial shipping	Economic benefit	✓	**Present** A shipping exclusion zone ('area to be avoided') exists around the operating oil and gas platforms in the Gippsland Basin, whereby unauthorised vessels larger than 200 gross tonnes are excluded from entry.	✓	**Present** The south-eastern coast is one of Australia's busiest in terms of shipping activity and volumes. Bass Strait is one of Australia's busiest shipping areas, with more than 3,000 vessels passing through Bass Strait each year. A shipping exclusion zone ('area to be avoided') exists around the operating oil and gas platforms in the Gippsland Basin, whereby unauthorised vessels larger than 200 gross tonnes are excluded from entry. Two traffic separation schemes have been implemented to enhance safety of navigation around the 'Area to be Avoided' by separating shipping into one-direction lanes for vessels heading north eastwards and those heading south westwards. One separation area is located south of Wilson's Promontory, and the other south of the Kingfish B platform.
	Defence	Offshore defence activities	Training and research activities	-	**Not present** No defence activities occur within the Operational Area.	✓	**Present** The Australian Defence Force conducts a range of training, research activities, and

Receptor Group	Receptor	Receptor Description	Values and Sensitivities		Operational Area		Potentially Exposed Area (PEA)
							preparatory operations in Australian waters. Defence activities within the PEA include a defence base at Twofold Bay, and training within the East Australia Exercise Area. Mine fields are located south and east of Wilson's Promontory.
	Tourism	Offshore and nearshore tourism	Economic benefit	-	**Not present** No tourism activities are expected within the Operational Area.	✓	**Present** The Australian coast and marine waters provide a diverse range of recreation and tourism opportunities, including scuba diving, charter boat cruises, cruise shipping, whale and wildlife watching, sailing, snorkelling, surfing, and kayaking.
Cultural Environment							
Commonwealth Heritage	World Heritage	World Heritage listings	Cultural heritage	-	**Not Present** There are no World Heritage sites within the Operational Area. Closest is Darlington Probation Station, in Tasmania (Volume 1 Section 2.2.1.1), over 400km from the Operational Area.	✓	**Present** Three World Heritage listings are located within the PEA: • Darlington Probation Station • Port Arthur Historic Site • Lord Howe Island Group
	National and Commonwealth Heritage	Natural Heritage	Natural heritage	-	**Not Present** There are no natural listed places or sites within the Operational Area.	✓	**Present** The following natural heritage sites are within the PEA: • Ku-ring-gai Chase National Park, Lion, Long and Spectacle Island Nature Reserves

Receptor Group	Receptor	Receptor Description	Values and Sensitivities		Operational Area		Potentially Exposed Area (PEA)
					Closest is Port Arthur Historic Site, Tasmania (Volume 1 Section 2.2.1.2) over 500 km from the Operational Area.		• Royal National Park and Garawarra State Conservation Area Four sites are listed for natural heritage on the Commonwealth Heritage List within the PEA: • Point Wilson • Beecrofy Peninsula • Malabar Headland • Tasmania Seamounts Area
		Indigenous Heritage	Cultural heritage	-	**Not present** There are no indigenous listed places or sites within the Operational Area. Closest are located at Flinders Island (Volume 1, Section 2.5.1), ~120kms south west of WKF	✓	**Present** No indigenous places are listed on the National Heritage List or Commonwealth Heritage List within the PEA. Indigenous Protected Areas occur on and around Flinders Island in Tasmania. At the time of writing a Native Title Claimant Application was registered by the Gunai-Kurnai People for an area covering the Wilsons Promontory area.
		Historic Heritage	Historic heritage Shipwrecks	–	**Not present** There are no historic listed places or sites within the Operational Area. Historic shipwrecks between ~5-10kms of facilities (Volume 1, Section 2.2.4.1): Struan Sailing Vessel (BMA), Favourite Sailing Vessel (WTA), Talark (HLA) and Leven Lass (TNA)	✓	**Present** The following sites listed on the National Heritage List are within the PEA: • The Great Ocean Road and Scenic Environs • North Head • Bondi Beach • Kurnell Peninsula Headland

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
							• Kamay Botany Bay: botanical collection sites No historic places are listed on the Commonwealth Heritage List within the PEA. The National Shipwrecks Database records 969 shipwrecks within the PEA. The three World Heritage listings above are also listed on Australia's National Heritage List under the historic classification.
Conservation	Australian Marine Parks (AMPs)	Established in Commonwealth Waters	Australian Marine Parks	-	**Not present** There are no AMPs within the Operational Area. Closest is Beagle Marine Park (Volume 1 Section 2.2.6.2) to PCA facility, ~62kms. To the southeast, East Gippsland Marine Park is ~120km from nearest facility (BKA)	✓	**Present** The following AMPs are located within the PEA: • East Gippsland Marine Park • Beagle Marine Park • Flinders Marine Park • Freycinet Marine Park • Boags Marine Park • Apollo Marine Park • Zeehan Marine Park • Franklin Marine Park • Huon Marine Park • Lord Howe Marine Park • Central Eastern Marine Park • Hunter Marine Park • Jervis Marine Park

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
							• South Tasman Rise Marine Park
	Key Ecological Features (KEFs)	Elements of Commonwealth Marine environment of regional importance	KEFs	-	**Not Present** The Upwelling East of Eden overlaps the OA of the MLA/WTN/TNA/KPA and FLA facilities. The non-spatially defined KEF the Bass Cascade (Volume 1 Section 2.2.7.4) is likely to be strongest at the area close to the head of the Bass Canyon, i.e. near BKA, but could have lesser effect at the other facilities. The non-spatially defined KEF Shelf rocky reefs and hard substrates (South-East Marine Region) (Volume 1 Section 2.2.7.6) is known to exist within 50 m to 150–220 m water depth on the continental shelf, including Bass Strait hence may underlay or exist near facilities. The South East Reef, an isolated offshore rocky reef, is mapped to exist in the VIC/L5 area, including beneath CBA facility, however the reef has not been detected in any of the survey work conducted for the Gippsland activities. The non-spatially defined KEF the East Tasmania subtropical convergence zone (Volume 1 Section 2.2.7.3) is not likely to occur at any facilities within the OA.	✓	**Present** The following spatially defined KEFs are found in the PEA: • Big Horseshoe Canyon • Upwelling East of Eden • Seamounts south and east of Tasmania • West Tasmania Canyons • Tasmantid Seamount Chain • Lord Howe Seamount Chain • Tasman Front and eddy field • Shelf rocky reefs and hard substrates (Temperate East Marine Region) • Canyons on the eastern continental slope The following non-spatially defined KEFs are found in the PEA: • Bass Cascade • Shelf rocky reefs and hard substrates (South East Marine Region) • The following non-spatially defined KEF may be found in the PEA: • East Tasmania subtropical convergence zone
	National Parks and Reserves	Protected under state legislation	National Parks and Reserves	-	**Not present**	✓	**Present**

Receptor Group	Receptor	Receptor Description	Values and Sensitivities	Operational Area		Potentially Exposed Area (PEA)	
					There are no National Parks and Reserves within the Operational Area. Closest is Ninety Mile Beach MNP (Volume 1 Section 2.2.8.10) to DPA facility ~ 15kms. To the east, the closest is Point Hicks MNP (Volume 1 Section 2.2.8.6) to KPA facility ~67Km and ~42 km to Beware Reef Marine Sanctuary (Volume 1 Section 2.2.8.7)		National Parks and Reserves within the PEA are located in Victoria, Tasmania and NSW jurisdiction.
Social Environment							
Recreational Activities	Recreational Fisheries	State-managed	• Community • Recreation	✓	**Present** Recreational fishing may occur within the Operational Area. Most recreational fishing typically occurs in nearshore coastal waters (shore or inshore vessels) and within bays and estuaries. Recreational fishing activity is expected to be minimal in the Operational Area.	✓	**Present** Most recreational fishing typically occurs in nearshore coastal waters, and within bays and estuaries; offshore (>5 km) fishing only accounts for approximately 4% of recreational fishing activity in Australia. There is moderate to high recreational use along the whole coastline adjacent to the PEA.
	Recreational Boating and Leisure Activities	Various human activities and interaction	• Community • Recreation • Economic benefit	✓	**Present** Marine-based recreation and tourism is unlikely to occur within the Operational Area due to the distance from shore and lack of seabed features; however, presence is possible.	✓	**Present** Popular coastal destinations are located across the coastline of the DA

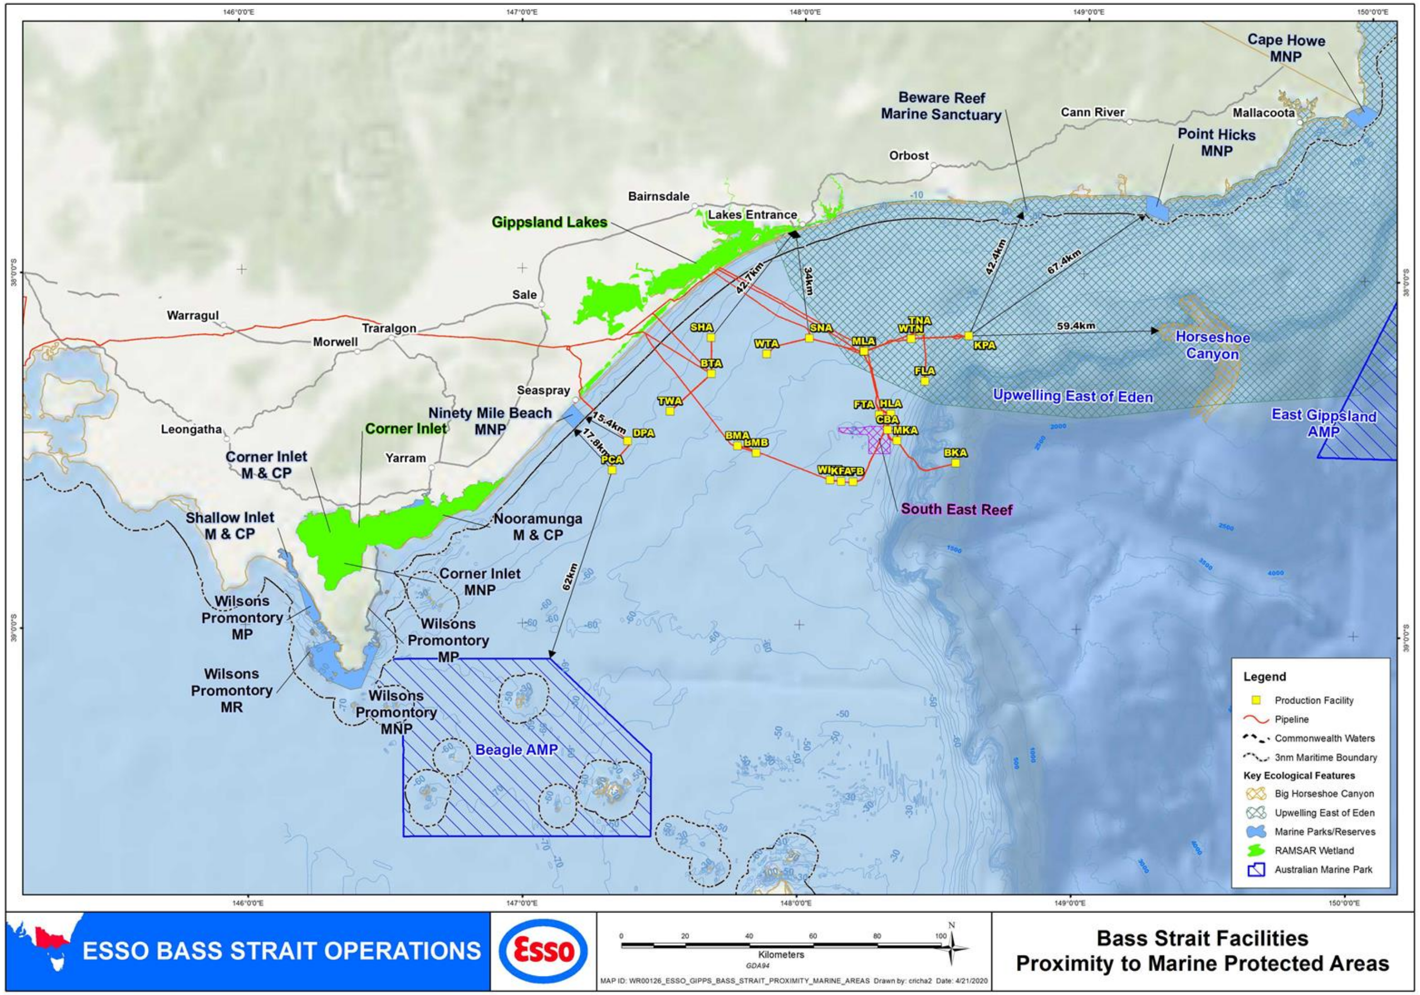

Figure 5-2 Bass Strait Facilities, proximity to Marine Protected Areas

5.2.1.1 Operational Area

EPBC Act Listed Species

As described in Section 2.3.1 the activity includes operation of 19 separate facilities. This section provides additional information of the environment around each facility. 13 EPBC searches were conducted to represent the OAs of the 19 facilities. These were chosen based on water depth and distance to one another. The results of the searches and corresponding EPBC search reports are provided in Appendix D. The results show that where variation in the protected species between facilities exists, it is primarily based on water depth.

For bony fish, all species identified occur consistently across all OAs except for the vulnerable Australian Grayling which only occur in the shallower waters <50 m depth. Of the cartilaginous fish, the vulnerable Great White shark has known breeding areas in shallower waters around the PCA/DPA/SHA/TWA/BTA and BTW areas and is known to occur out to the facilities in deeper waters >50 m depth.

8 species of vulnerable albatross and 2 endangered albatross species forage or feed up to water depths of approximately 60 m, and therefore are likely to be within the OAs of the facilities closer to shore mentioned above, as well as WTA/SNA/BMA/BMB/TNA/WTA and KPA. Following similar patterns as the albatross, the vulnerable Australian Fairy Tern is known to forage or feed up to water depths of approximately 60m. The vulnerable Hooded Plover is only found near coastal waters and thus may occur in the OA of SHA.

Six whale species occur uniformly across all the OAs including the Endangered Blue Whale and Southern Right Whale. Three other species including the vulnerable Sei Whale and Fin Whale are not known to occur in shallower waters and are only expected to occur at facilities in waters beyond approximately 50 m depth. In the Blackback OA (now plugged and abandoned) which is in approximately 400 m water depth (all other facilities are in waters of <100 m) , the likelihood of occurrence of whale species increases significantly with an additional 12 species of cetaceans listed as may occur in the OA.

The endangered Loggerhead Turtle and Leatherback Turtle are likely to occur uniformly across all facilities and the vulnerable Green Turtle is known to occur across all facility OAs.

Additional information on receptors within the OA is provided in Table 5-2.

Table 5-2 Receptors within the Operational Area by facility

Facility	Perch	Dolphin	West Barracouta	Barracouta	Tarwhine	Seahorse	Bream A	Bream B	West Kingfish	Kingfish A	Kingfish B	Halibut	Fortescue	Cobia	Mackerel	Blackback	Marlin Complex	West Tuna	Tuna	Kipper	Flounder	Snapper	Whiting	Moonfish
Receptor																								
Physical Environment																								
Climate & Meteorology	On an average scale no variation between facilities. Variation will always occur between facilities during any one time due to the large area spanned by the operations																							
Oceanography – Currents and tides	Generally - Shelf break – Bass Strait Water Cascade. Warmer, nutrient rich surface waters Offshore – cooler waters The factors influencing the currents and tides of the region are the same across all facilities (Volume 1 Section 2.1.2.1). Variation will always occur between facilities during any one time due to the large area spanned by the operations. Platform specific data, generated using sophisticated models that use hindcast current data and satellite measured tidal data, is used to predict oil spill modelling (Refer Volume 1, Appendix D). Similarly, PFW modelling has been conducted using platform specific conditions (Refer Volume 2, Section 5.3)																							
Oceanography – water temperature and density stratification	The factors influencing the water temperature and density stratification of the region are the same across all facilities (Volume 1 Section 2.1.2.2). Variation will always occur between facilities during any one time due to the large area spanned by the operations.																							
Oceanography – waves	The factors influencing the waves of the region are the same across all facilities (Volume 1 Section 2.1.2.3). Variation will always occur between facilities during any one time due to the large area spanned by the operations.																							
Bathymetry																								
Distance from coastline (km)	24	21	22	23	22	12	46	51	72	77	77	62-68	62-68	62-68	68	87	43	45	43	41	58	32	34

Values and Sensitivities																								
World Heritage	Outside of Operational Areas - closest Darlington Probation Station, Tasmania (Volume 1 Section 2.2.1.1)																							
National Heritage	Outside of Operational Areas - closest Port Arthur Historic Site, Tasmania (Volume 1 Section 2.2.1.2)																							
Wetlands	Outside of Operational Areas – closest Gippsland Lakes RAMSAR site (Volume 1 Section 2.2.3.1) to SNA facility																							
TECs	Outside of Operational Area – closest point where Giant Kelps (Volume 1, Section 2.2.4.1) may occur are at Cape Conran, ~40 kms from KPA. Littoral Rainforest (Volume 1, Section 2.2.4.2) and Subtropical and Temperate Coastal Saltmarsh (Volume 1, Section 2.2.4.3) occur along the coastline, closest facilities are SHA at ~15kms to shoreline and SNA at ~34kms to Lakes Entrance.																							
Commonwealth Marine Areas	All facilities within South-east Marine Region																							
Australian Marine Parks (AMPs)	None within Operational Areas – closest is Beagle Marine Park (Volume 1 Section 2.2.6.2) to PCA facility, ~50kms. To the east, East Gippsland Marine Park is ~120km from nearest facility (BKA)																							
KEFs																Bass Cascade	Upwelling East of Eden	Upwelling East of Eden	Upwelling East of Eden	Upwelling East of Eden	Upwelling East of Eden			
	Non spatially defined KEFs such as the East Tasmania Subtropical Convergence Zone (Volume 1 Section 2.2.7.3) not expected to overlap the facilities in the OA. The Bass Cascade (Volume 1 Section 2.2.7.4) may overlap these facilities, particularly BKA. Shelf Rocky Reef occurs across continental shelf in Bass Strait, South East Reef mapped existence in VIC/L5 area, including under CBA platform, however has not been observed through Gippsland activities. Closest facility to Horseshoe Canyon (Volume 1 Section 2.2.7.1) is KPA ~60kms																							
Marine National Parks	None within Operational Areas – Closest is Ninety Mile Beach MNP (Volume 1 Section 2.2.8.10) to DPA facility ~ 15kms. To the east the closest is Point Hicks MNP (Volume 1 Section 2.2.8.6) to KPA facility ~67Km and ~42 km to Beware Reef Marine Sanctuary (Volume 1 Section 2.2.8.7)																							
Ecological Environment																								
	Refer EPBC searches (Volume 2, Appendix D) 13 EPBC searches conducted representative of the locations of the facilities. Tables identify the similarities in listed species which may occur in the area. The differences identified to threatened species are highlighted below and can be attributed to proximity to shore and water depth.																							
Fauna – Fish (bony)	One threatened species only: V – Australian grayling., shown as 'may occur' in near shore facilities (PCA/BTA/SHA) however these are generally found in estuarine and fresh water environments and therefore not expected in OA when minimum distance to closest facility (SHA) is 12 kms																							
Fauna – Fish (cartilaginous)	V -Great White Shark – known to occur in continental shelf and coastal waters spanning all facilities. BIA (breeding) along coastline and overlaps facilities in shallower waters: PCA/DPA/BTA/SHA/TWA, distribution BIA at other facilities V – Whale shark – may occur in areas spanning all facilities																							
Fauna – Birds	Many of the Albatross are known to forage in shallower waters PCA/DPA/BTA/SHA/TWA/BMA/WTA/SNA/TNA. All Albatross are threatened species. The Northern Royal Albatross is endangered and the only one that has known foraging BIA around the facilities indicated here. The Chatham Albatross is also endangered and its BIA for foraging spans the SNA/WTA/TNA and KPA facilities The Australian Fairy Tern (V) is also known to forage in shallower waters with its BIA spanning the PCA/DPA/BTA/SHA/TWA/BMA/WTA/SNA/TNA/MLA and FLA facilities.																							
Fauna – MM (cetaceans)	5 species of whales occur across all the facilities and the Sei and Fin Whales in the deeper Waters only (i.e. not at PCA/DPA/BTA/SHA/TWA facilities), not listed for the PCA/DPA/BTA/SHA/TWA facilities. Foraging BIA for endangered Blue Whale, distribution BIA for endangered Southern Right Whale may span all facilities as identified in the SE Marine Region Bioregional plan.																							
Fauna – MM (pinnipeds)	The New Zealand Fur Seal and the Australian Fur Seal may occur in the OA of all facilities.																							
Fauna – MM (sirenians)	None listed as occurring in OAs																							
Fauna – MR (turtles)	Of the 3 turtles known to occur in the OAs, the Green Turtle (V) is known to occur in all OAs and the Loggerhead and Leatherback turtles(both E) are likely to occur in the OAs																							
Fauna – MM (snakes)	None listed as occurring in OAs

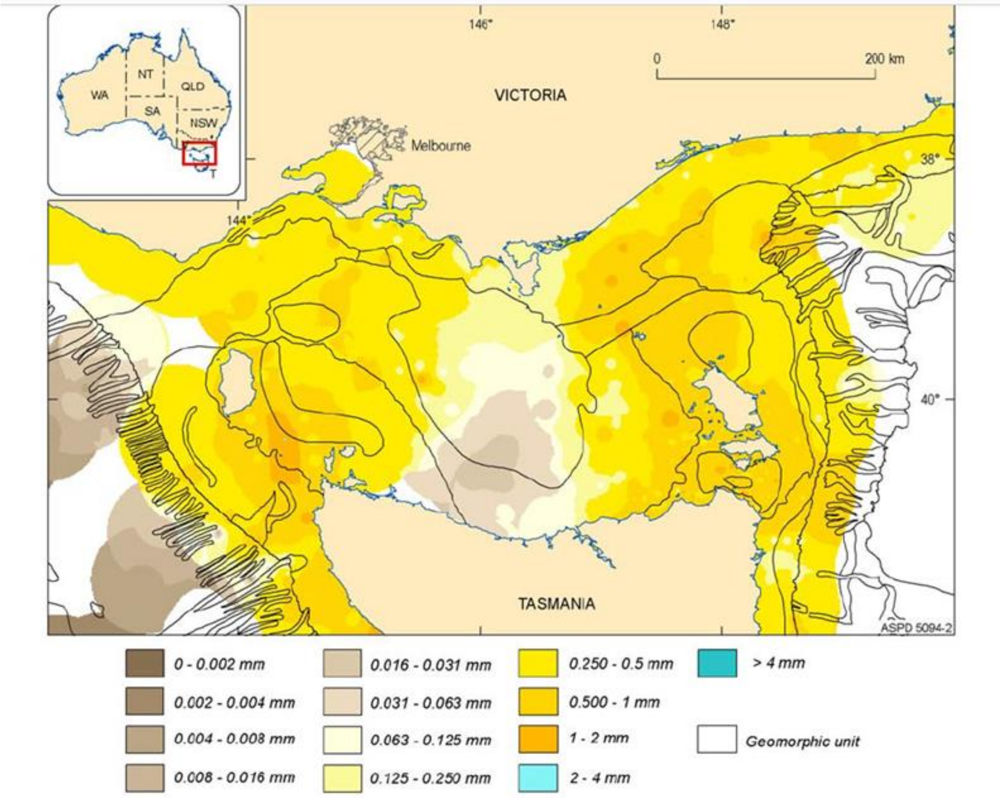
Table 5-3 Esso benthic survey data summary

Benthic survey data summary	**West Barracouta** (Marine Solutions, 2018)	**West Kingfish** (Cardno, 2018)	**Marlin Complex** ROV survey (Marine Solutions, 2015)	**Tuna** (Cardno, 2018**)**	**Snapper** (Coffey, 2010)
Infauna	Dominant taxa throughout the survey area included annelids (polychaetes), crustaceans (amphipoda, isopoda and decapoda) and molluscs (gastropods and bivalves;	Polychaetes, crustaceans and molluscs	No data	Polychaetes, crustaceans and molluscs	Small burrows and bioturbation mounds within the soft sediment, which have been created by benthic infauna such as crustaceans and polychaete worms.
Sediment size	Sediment at all sites were dominated by coarse size fractions, with all sites (with the exception of one site – SQ1) containing more than 50% of sediments over 1 mm.	Sand was the dominant sediment class at each platform slightly muddy, gravelly sand (WKF generally had higher proportion of sand than gravel)	Hard compact sand with shell grit, overlaid with fine sand ripples	Sand was the dominant sediment class at each platform lightly muddy (<0.06mm~2%), gravelly (>2mm~23%) sand (0.6mm – 2mm - ~75%)	The natural substrate was observed as unconsolidated, dark, fine to medium grained silt/sediment.
Features	A mosaic of bioturbated coarse sand, overlaid with patchy unconsolidated bivalve beds containing erect sponges, dead scallops with calcification, fragmented dead shells and a mixture of live and dead bivalves		Low-relief compacted soft sediments Hard natural substrate was absent from the surveyed area. Sponge growth was prolific on a number of pipelines laying on the seabed.		Given the lack of hard substrate, there was little to no colonisation of the seabed by benthic marine invertebrates such as bryzoans, ascidians and poriferans. Instead, there were a large number of small burrows and bioturbation mounds within the soft sediment, which have been created by benthic infauna such as crustaceans and polychaete worms.

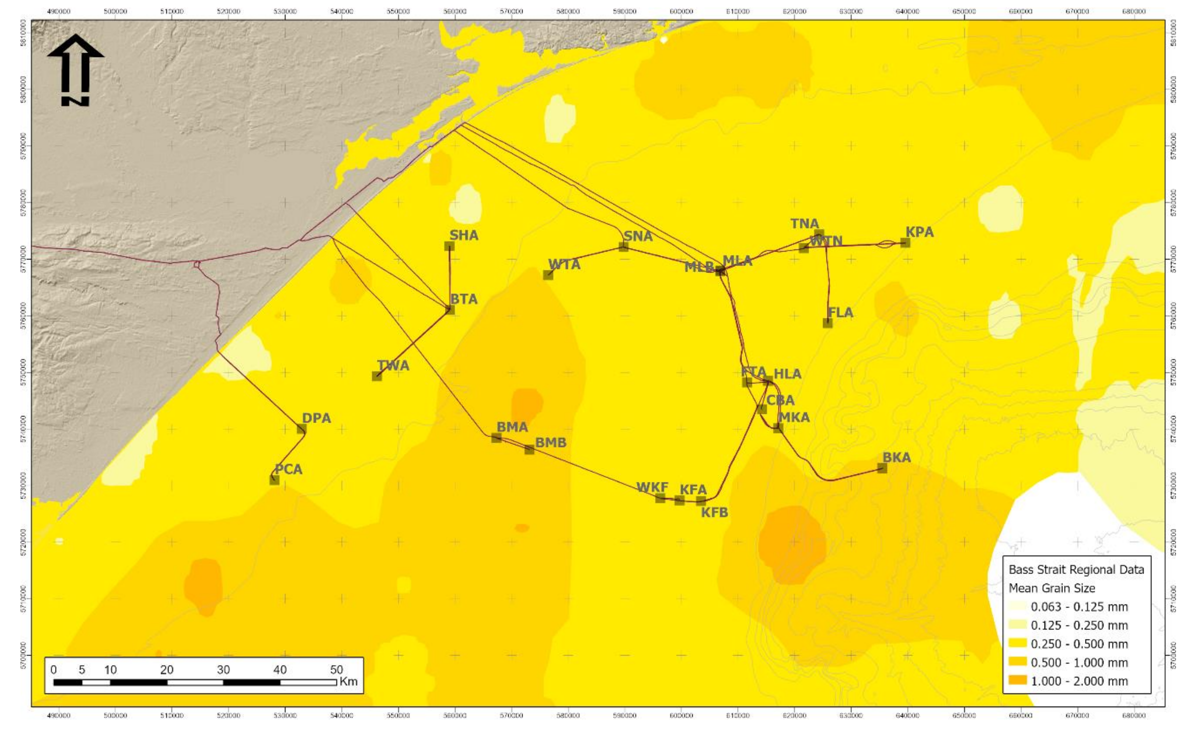
Benthic Habitat

Volume 1 provides a description of the benthic habitat of Bass Strait based on research that has been conducted and is supported by Esso specific surveys. The Esso surveys provide information on the environment around five facilities (BTW, WKF, MLA, TNA and SNA) and describe the type of sediment, infauna composition (not provided in MLA ROV survey where samples were not collected for analysis) and features. Figure 5-3 summarises the findings of the surveys.

Past studies that have mapped grain size provide a Bass Strait wide view (refer Figure 5-2) and show the area around the facilities to have a mean grain size of between 0.25 – 0.5 mm with the exception of the BMA and BMB facilities which have a mean grain size of 0.5-1 mm. These align with Esso survey findings which tell us that sand is the dominant sediment class at the platforms which were surveyed with low proportions of light mud (<0.06 mm, generally <5%), and generally about 25% of gravel (>2 mm~23%).



(a)



(b)

Figure 5-3 (a) Mean sediment grain size in Bass Strait; (b) Closer view showing regional sediment grain size overlaid with Esso Bass Strait platforms.

Grain size is one of the factors which is considered to contribute to presence/abundance of benthic fauna. Similarly, the presence of hard substrate can provide anchor points for benthic marine invertebrates such as bryozoans, ascidians and poriferans. The Shelf Rocky Reef, non-spatially defined KEF is known to occur in South East Marine Bioregion (Volume 1, Section 2.2.7.6) and known areas of reef in eastern Bass Strait are shown in Volume 1, Section 2.3, Figure 2-42. The South East Reef, mapped through the research conducted on habitat and fisheries productivity in the South East Fishery ecosystem (Bax & Williams, 2000) is shown in Figure 5-2 (based on the Bax & Williams mapping), placing it beneath CBA platform and extending to the south and west. The reef is described as a mostly flat bottomed, low relief reef, likely to have a sandstone/limestone composition which is predominantly sediment-covered (1-5 cm of sediment coverage) with occasional signs of exposed hard substrate (~40 cm in height). The exposed substrate provides attachment for intermittent patches of intermediate to dense covers of finger and cup sponges.

Changes to currents locally due to the presence of fixed structures may affect sediment grain size locally around the platform, for which certain benthic organisms prefer to habituate, and hence the proportion of different benthic organisms may differ near the platform.

The occurrence of sponges in Bass Strait is known, however the distribution of sessile faunal assemblages, including whether or not they occur in dense aggregations that would merit the term “sponge beds” are unknown. Between 1979 and 1983 Museum Victoria conducted surveys to assess the marine biodiversity of Bass Strait and reported large collections of sponges in southern central Bass Strait and other areas leading to sponge beds being identified as one of the unique marine areas for conservation (Butler et. al., 2002). Whereas some survey work occurred, further significant surveys for sponges have not occurred since the Museum Victoria work and further assessment was requested by the Commonwealth government in 2001 to determine the biodiversity values of sponge beds in Bass Strait. Desktop analysis conducted by CSIRO (Butler et. al., 2002) of available survey data determined that

- Collected sponges were unsorted and unidentified

- The survey was conducted over a number of widely separated sampling points.
- No surveys since the Museum Victoria surveys have ascertained the condition of these beds or whether these exist.
- In order to establish distribution of sponge beds across Bass Strait purpose designed surveys to establish spatial distribution would be required.
- The knowledge base around sponge bed species in South East Australia (octocorals, bryozoans and ascidians) is poor
- Bass Strait is the meeting of two provinces: Flindersian and Peronian, and therefore likely to result in high diversity of species
- There is no suggestion that the area is unique as there are areas like it throughout southern Australia.
- The complex structure of taxa forming the sponge beds result in an important habitat which influences the presence and or distribution of other seafloor fauna, including commercial fishing species.

The various studies conducted to understand the Bass Strait environment (benthic fauna and grain size discussed above (and summarised for Bass Strait in Volume 1, Section 2.3.3), bathymetry, oceanography, climate and meteorology (refer platform specific data used for PFW consequence evaluation, Oil Spill Modelling Sections 7.2.1.1 and summarised for Bass Strait in Volume 1, Section 2.1) provide specific data of the study areas. In some cases the characteristics can be described and applied broadly (e.g., climate and meteorology) however even then local factors can have a significant influence and thereby differ from broader description. This is demonstrated through a comparison of the theoretical stochastic spill modelling outputs of the WTA and BTW wells where similar oil types and volumes predicted significantly different size contours even though the facilities were in similar water depths and within 20km of one another (refer Esso, 2020). The differences were a result of the local variations in wind and current direction and speeds which predicted a significant variance in the distribution of the theoretically modelled spills.

Given the vast area covered by Bass Strait and in an effort to get a better understanding of the drivers influencing marine benthic fauna in Bass Strait, researchers have analysed the existing research data to see if any correlations can be drawn from the results which could provide an effective means of assessing biodiversity which can be extrapolated to other areas. The analyses looked at sediments and seafloor characterisation, fauna collected and the sampling/collection/identification techniques (Passlow *et.al*., 2006).

The analyses showed that Bass Strait supports particularly diverse benthic fauna and that overall, the similarity between samples is very low and a large degree of small scale variations exists. This is seen in the Esso survey results of WTN and TNA where there is variation in the rank order of major taxa on adjacent platforms (approximately 4 kms apart). This is seen more broadly across the Esso surveys where the overall groupings of phyla are similar but the class and order vary.

The analyses further suggest that the numerous environmental variables influence the composition of benthic assemblages and no one factor dominated the analysis. There was sufficient similarity between some samples to form recognisable clusters. But overall the primary clusters did not have a recognisable regional, water depth or sediment profile. The biotic pattern for Bass Strait is not strongly related to sediment composition as has been suggested. For benthic assemblages, the most significant correlation was seen with longitude. Overall it is not possible to classify the biological assemblages into a scheme that can be mapped across the area that was analysed (Passlow *et.al.,* 2006).

This data supports the need for specific, uniform and targeted analysis across all OAs to further describe the environment in the OAs. Previous studies such as the New Zealand Star Bank (GA Survey 233 in Passlow *et.al.,* 2006) have identified the importance of video camera visualisation in providing a coarse scale assessment of the environment and some quantification of abundance and diversity. Footage from Esso's log of inspections has been used to expand the knowledge of the environment in the OAs. Images have been tabularised and are shown in Appendix E.

The presence and abundance of biota appears to be linked to the presence of infrastructure. Sessile filter feeders largely require hard substrate as anchor/attachment points. Esso's facilities are providing this and biota can be seen growing on infrastructure across the facilities. The degree to which this is occurring varies. The abundance of biota appear to be greatest around platforms and decreasing with distance away from the platform or away from fixed structures such as pipelines or debris. DPA, TWA, SHA, SNA , FTA and HLA (Appendix E, Fig A, Fig B and Fig E) clearly show presence of sessile invertebrates on platforms structures and subsea infrastructure like risers, wellheads with comparatively low numbers of stands on the adjacent seabed.

- Other clear examples which link abundance of biota to the presence of infrastructure are the pipelines where the presence of sessile benthic invertebrates are seen attached to pipelines on what appear to be an otherwise bare seabed. Example of this are seen at MLA (MLA 150 pipeline to WKF, Appendix E Fig E &G), CBA (CBA 300 oil pipeline, Appendix e, Fig E) and the BKA 200 Oil pipeline (Appendix E, Fig D). This does not exclude the presence of benthic infauna which cannot be seen on video images. In some images bioturbation is more evident supporting the presence of infauna (FTA, Appendix E Fig E). This is supported by the Esso surveys which identify the presence of infauna in all places where samples were taken (Refer Table 5-3).

These images are recognised as being indicative of the environment that is directly in view and it is known that other areas which are not depicted may vary. The images also are only representative of the area at the time they were taken, therefore, potential changes due to seasonality, natural variation or other factors will not be represented. Even so, this consistent trend is seen across the facilities in Bass Strait where the presence of biota is around infrastructure and whilst communities are being formed, they would not typically be described as occurring in significant numbers nor be described as sponge beds.

An exception to this trend is evident at BMB platform (Appendix E, Fig I) and to a far lesser extent at BMA platform (Appendix E, Fig H). Platform inspections of BMA and BMB conducted in 2017-18 included seabed ROV survey transects beginning from each side of the platform and radiating out to 50 m (Diveworks, 2017-42). The trend of decreasing abundance from the platform to the 50 m radius is clearly evident at BMB and transects in all directions (north, south east and west). The difference from the other Esso Bass Strait facilities is in the abundance of the marine biota in this area. Significant assemblages forming what would be likely considered as sponge beds are seen up to 9 and 15 metres from the platform. There are also various species of large and small fish present in the images. From 20 m out to 40 m the abundance visibly decreases to patchy areas and individual stands. BMB is an example of complex sponge beds which, through their provision of shelter and/or food, have influenced the distribution of other mobile fauna and are likely hosting associated species such as small crustaceans, molluscs and worms as was found by O'Hara (2002). The only known variation in this area versus the other facilities is that the mean sediment grain size is larger than in other areas and may be contributing to the differences. The neighbouring BMA platform shows similarities but to a far lesser extent. This may lend support to the theory that grain size may be correlated to abundance. If we consider the finding by Passlow et al., (2006) that the most significant correlation with assemblages was seen with longitude and compare the images at WTA platform to the north of BMB (Appendix E, Fig B), we see a similarities in seabed type to BMA, with uniform spread of marine invertebrates on the seabed, however the abundance is not evident given the limited footage available from WTA.

The images around CBA are consistent with the trends seen at other platforms. The mapped presence of South East Reef in the area including beneath the platform does not appear to coincide with increased abundance of biota in the area. This may be due to the layer of sediment coverage over the hard substrate or the lack of extrusions/elevations, either naturally or due to seafloor disturbance such as through overfishing. Observations are consistent with fishing data of the area which note that large catches were taken from South East Reef in the 1970's through to the 1990's however no commercial catches were taken in late 1990's despite continued efforts (Bax & Williams, 2000). Bax & Williams speculate through discussion with the fisheries that the plausible reasons for the change include habitat modification due to stock overfishing and seismic testing.

The area to the south west of BTA, surveyed in 2018, was primarily a mosaic of bioturbated coarse sand, overlaid with patchy unconsolidated bivalve beds containing erect sponge stands, dead scallops with calcification, fragmented dead shells and a mixture of live and dead bivalves (Marine Solutions, 2018) (Appendix E, Fig A). This extent of calcified beds was only seen at this location however similar habitat, in much lesser abundance may also occur at WTA, MLA, WTN and TNA (Appendix E, Figs B and C).

5.3 Recovery Plans, Threat Abatement Plans and Species Conservation Advice Relevant to the Operational Area

The Description of the Environment (Volume 1) describes the key threats and management actions relevant to species which may occur within the Described Area. Based on the EPBC PMST searches and the summary provided in Section 5.2, the conservation advice and recovery plans relevant to species or species habitats which may occur within the Operational Area include:

Fish:

- Recovery Plan for the White Shark (Carcharodon carcharias)

Birds:

- National Recovery Plan for Threatened Albatrosses and Giant Petrels, 2011-2016
- Approved Conservation Advice for Thalassarche chrysostoma (Grey-headed Albatross)
- Approved Conservation Advice for Halobaena caerulea (Blue Petrel)
- Gould’s Petrel (Pterodroma leucoptera leucoptera) Recovery Plan
- Approved Conservation Advice for Calidris canutus (Red Knot)
- Wildlife conservation plan for migratory shorebirds
- Approved Conservation Advice for Numenius madagascariensis (Eastern Curlew)
- Approved Conservation Advice for Pachyptila turtur subantartica (Fairy Prion Southern)

Marine mammals:

- Approved Conservation Advice for Balaenoptera borealis (Sei Whale)
- Conservation Management Plan for the Blue Whale, 2015-2025
- Approved Conservation Advice for Balaenoptera physalus (Fin Whale)
- Conservation Management Plan for the Southern Right Whale, 2011-2021
- Approved Conservation Advice for Megaptera novaeangliae (Humpback Whale)

Marine reptiles:

- Recovery Plan for Marine Turtles in Australia, 2017-2027
- Approved Conservation Advice for Dermochelys coriacea (Leatherback Turtle)
- In addition, the following Threat Abatement Plans have been considered:
- Threat abatement plan for the impacts of marine debris on the vertebrate wildlife of Australia’s coasts and oceans (2018).
- These plans and management actions have been considered in the definition of acceptable levels of impacts described in Section 4.8.

6 Environmental Impact Assessment

6.1 Overview

The purpose of the environmental impact assessment is to ensure that all impacts associated with the petroleum activity are identified and evaluated, and the resulting impacts are demonstrated to be ALARP and Acceptable according to the Esso impact and risk assessment methodology (Section 0).

The assessment of impacts has been undertaken in two stages:

- Impact Scoping (Section 6.2)
- Detailed Evaluation (Section 6.3)

6.2 Impact Scoping

Scoping of the impacts relevant to the activity ensures that a systematic assessment can be undertaken. The context of the impact assessment has been set through the description of the activity (Section 2.4) and identification of potential environmental receptors within the Operational Area and the PEA (Section 2.4.4.3). By considering the relationship between environmental aspects and the activity (Table 4-2), Esso has identified all impacts to receptors which could potentially occur as a result of the petroleum activity.

The assessment of planned impacts has considered direct, indirect and cumulative impacts, as defined in Section 4.2.

A series of workshops were held to identify environmental impacts and risks associated with the petroleum activity and assess controls to ensure impacts and risks are managed to ALARP and an acceptable level. The workshops were attended by environment and asset personnel. Impacts and risks were evaluated using the impact assessment methodology (Section 0) to determine consequence to receptors and ALARP decision context, and for risks to determine likelihood and residual level of risk. Control measures were identified, and an assessment of acceptability was undertaken against the Esso Acceptability Criteria and the defined acceptable levels of environmental performance (Table 4-2).

For most impacts identified, the workshop was able to determine that the adopted controls lowered impacts to ALARP and to an acceptable level. These impacts, and the outcomes of the assessment, are described in Table 6-1, Table 6-2, Table 6-3 and Table 6-4

In some cases, it was not possible to finalise the impact evaluation during the workshops. This was typically due to the need for either modelling outcomes or an in-depth literature review to support the evaluation and assessment of potential impacts to receptors. In these cases, a detailed evaluation has been provided as follows:

- Produced Formation Water (Section 6.3)
- Operational Fluids (Section 5.4)

For all impacts, control measures have been considered as described in Section 4.7. Controls are applied where a reduction in the consequence of the impact will occur as a result of their adoption. They may also be required by legislation, or by internal Esso requirements. Where the assessment of the impact identified that there were no suitable Good Practice control measures, and additional controls considered would not lower the impact assessment outcomes, no controls have been adopted. This is identified in the table and assessed as part of the demonstration of acceptability.

Environmental Performance Outcomes and Standards relevant to impacts associated with the petroleum activity are provided in Volume 4.

6.2.1 Operations Activities

Table 6-1 Operations Activities – Impact Scoping

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Platform Operations Pipeline Operations Subsea facility operations	Physical Presence - Interference with Other Marine Users Presence of platform and pipeline operations can lead to interference with other marine users.	Change to the function, interests or activities of other users Change to the function, interests or activities of other users could occur through disruption of commercial and recreational activities. Disruption to activities includes: • exclusion of vessels to areas around the activity; • damage to fishing equipment; and • loss of commercial fish catch.	Commercial Fisheries	There are six Commonwealth-managed fisheries and three Victorian State-managed fisheries which may undertake fishing activities within the Operational Area. Presence of fisheries varies between platforms, typically due to water depth determining the location of prey species. Fisheries effort data, however, shows that relatively small numbers of vessels are likely to be encountered within the Operational Area. The physical presence of the platform operations, specifically the 500m Petroleum Safety Zone (PSZ) around each facility, results in the exclusion of commercial fishing vessels from parts of the fisheries management area and may result in vessels making minor deviations around the PSZ while transiting through the area. Impacts are limited to the Operational Area and will have little to no adverse effects. Impacts are limited to the Operational Area and, given the extensive operating area utilised by Commonwealth and State fisheries, will have inconsequential or no adverse effects.	IV	A	**CM6:** Temporary Storage Assessment **CM70:** The Subsea Material Register (SMR) will be reviewed by the Marine Group against the scope, location and operational capability of each vessel as they become available. **CM1:** Maintenance activities for facilities already at CoP are implemented in accordance with s572 (2) requirements. **CM1a:** Post CoP maintenance activities are implemented for facilities as they are assessed prior to reaching CoP stage in accordance with s572 (2) requirements	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented. • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
			Shipping	With the exception of PCA and DPA, all platforms are located within the ATBA. Shipping activity is limited within the ATBA, as vessels in excess of 200 gross tonnage are prohibited from unauthorised entry. Given this, the presence of surface infrastructure within the established PSZs (500 m extending from each platform) will not result in further impacts to shipping. Physical presence of subsea facilities and pipelines will not impact shipping.	No impacts expected						
			Recreational Activities	Recreational activities may occur within the Operational Area such as recreational fishing, recreational boating and leisure activities. However, given the distance from shore and the existing PSZs, no interaction with recreational activities is expected.	No impacts expected						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Platform Operations	<u>Underwater Sound Emissions</u> Normal platform operations generate sound at 162 dB RMS (Hannay, et al. 2004).	<u>Change in ambient noise</u> Underwater sound emissions generated by normal platform operations will result in a change in ambient noise.	Ambient noise	Based on spherical spreading (Richardson et al., 1995), platform generated noise will reduce to background noise levels of 120 dB RMS within 130m of the platform, indicating that impacts will be highly localised. Platform generated noise will be continuous throughout the life of the platform. Impacts are highly localised and will not result in a permanent change to ambient noise levels following completion of operations, therefore impacts will have no adverse effects.	IV	A	None identified	None	ALARP	Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened marine mammals or marine reptiles and will be undertaken in accordance with all applicable management actions • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		<u>Change in fauna behaviour</u> Underwater sound emissions generated by routine platform operations may result in a change in fauna behaviour	Fish	Based on levels adopted by NOAA Fisheries, the US Fish and Wildlife Services, and Canadian Science Advisory Secretariat (DFO, 2004), a conservative threshold level of 130 dB RMS for behavioural changes in fish has been adopted. Based on spherical spreading (Richardson et al., 1995), platform generated sound levels will reduce to below this level within 50m of the platform. Any impacts will be limited to within this localised area. Limited research has been conducted on shark responses to noise, however studies indicate that sharks will move suddenly away from sounds of more than 20 dB re 1µPa above broadband ambient SPL when approaching within 10m of the source (Myrberg, 1978). The Operational Area is within a distribution BIA for great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Impacts to fish are expected to be highly localised (i.e. within 50m of the sound source), and short-term (behavioural changes will cease once the noise subsides). Any impacts will be inconsequential or have no adverse effect.	IV						
			Marine Reptile	Using the limited information available, it has been reported that behavioural changes and impairment of hearing sensitivity in marine turtles are likely to occur at levels above 120 dB re 1 µPa (SVT Engineering Consultants 2009). Based on spherical spreading (Richardson et al., 1985), sound levels will be reduced to below 120 dB RMS within 1300m of the source. Any impacts will be limited to within this localised area. Five listed / threatened species of marine turtle may occur within the Operational Area, although there are no BIAs or critical habitats located within the PEA and all marine turtles are known to have a more northerly distribution. The Recovery Plan for Marine Turtles in	III						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				Australia, 2017-2027, lists noise interference as a key threat. Impacts to marine turtles are expected to be localised (i.e. within 1300m of the sound source), and short-term (behavioural changes will cease once the noise subsides). Any behavioural impacts resulting from underwater sound emissions will not impact the long term survival and recovery of threatened marine turtles. Given the receptor sensitivity to environmental impacts, potential short-term, minor adverse effects are possible.							
			Marine Mammals	Cetaceans and pinnipeds are known to experience temporary threshold shift (TTS) and behavioural responses to underwater sound emissions. Behavioural responses range from subtle changes in surfacing and breathing patterns, to cessation of vocalizations, to active avoidance or escape from the area of insonification. Using the National Marine Fisheries Service (NMFS) guidance for non-pulsed sound a behavioural disturbance limit of 120 dB RMS is adopted (NMFS, 2016). Richardson et al. (1995) and Southall et al. (2007) indicate that behavioural avoidance by baleen whales may onset from 140 to 160 dB re1µPa or possibly higher. Based on spherical spreading (Richardson et al., 1985), sound levels will be reduced to below 120 dB RMS within 130m of the source. Any impacts will be limited to within this localised area. The Operational Area is within the following BIAs: southern right whale (distribution), pygmy blue whale (foraging, distribution), and several other threatened species of marine mammals may be present within the Operational Area. Anthropogenic noise is listed as a threat in the Conservation Management Plan for the Southern Right Whale, 2011-2021 and Conservation Management Plan for the Blue Whale, 2015-2025. Impacts to marine mammals are expected to be localised (i.e. within 1300m of the sound source), and short-term (behavioural changes will cease once the noise subsides). Any behavioural impacts resulting from underwater sound emissions will not impact the long term survival and recovery of threatened marine mammals. Given the presence of BIAs within the Operational Area, potential short-term, minor adverse effects are possible.							

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Platform Operations	Light Emissions Navigational and safety lights used during normal platform operations will result in light emissions. Light emissions will also be generated during flaring, with rates varying between platforms and activities.	Change in ambient light A change in ambient light levels could result in a localised light glow.	Ambient light	Modelling conducted by ERM (2010) on navigational and safety lighting from a MODU showed that light intensity reduced to 0.1 Lux (equivalent to ambient light at full moon to twilight) within 800 m of the source and to 0.01 Lux (equivalent to ambient light at quarter moon) within 1.2 km. Outside 1.2 km, light from the facility would only be detected during a new moon or if the moon is not visible. Although light from the facility may be visible within 1.2 km, the intensity of the light and any associated sky glow will decrease with distance from the source. The only platforms located within 1.2 km are MLA and MLB. MLA and MLB are bridge -linked, meaning that although MLB is normally unstaffed the lighting levels may not be reduced as a result. Given this, MLA and MLB are assessed as a complex, and light levels are expected to decrease within the same distance. The impacts on ambient light from cumulative effects from MLA and MLB are not expected to be greater than the impacts from a single platform source. The consequences of a change in ambient light will be localised and low intensity, and impacts are expected to be inconsequential or have no adverse effect on ambient light.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened marine reptiles and will be undertaken in accordance with all applicable management actions. • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		Change in fauna behaviour A change in ambient light levels could lead to changes in fauna behaviour, through: • Attraction of light-sensitive species such as seabirds, squid and zooplankton in turn affecting predator-prey dynamics; and • Alteration of behaviour that may affect species during breeding periods (e.g. shearwaters, turtle hatchlings).	Fish	Fish, squid and zooplankton may be directly or indirectly attracted to lights at distances of up to 5 km (Shell, 2010), leading to aggregation at the surface and increased predation. These organisms' distributions are driven by oceanographic conditions, with seasonal and diurnal movements. For fish and squid, it is expected that any potential impact of increased predation would be undetectable at a population level and only affect transient individual fish and squid. The proportion of zooplankton exposed and subjected to higher predation rates within the platform light fields is negligible. In the event that deck or navigational lighting results as an attractant to an occasional seabird, it is not expected that this will permanently impact on migration or other behaviours. Most platforms are located more than 5 km from another operating platform, however WTN	IV					•	•

				and TNA are located approximately 4 km apart. At this location the area of impact to fish may overlap, resulting in a larger impact area. As light intensity will be significantly decreased at the overlap, however, no cumulative impacts are expected. The Operational Area is within a distribution BIA for great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Impacts to fish are expected to be localised (i.e. within 5km of the light source), and short-term (behavioural changes will cease once the light ceases). Any impacts will be inconsequential or have no adverse effect.							
			Birds	High levels of offshore lighting can attract and disorient seabird species resulting in behavioural changes (e.g. circling light sources leading to exhaustion or disrupted foraging), injury or mortality near the light source. Artificial light can cause significant impacts on burrow-nesting petrels and shearwaters. Fledglings often become disoriented and grounded because of artificial light adjacent to rookeries as they attempt to make their first flight to sea, a phenomenon known as 'fallout'. Rodrigez at al. (2014) investigated the effects of artificial lighting from road lighting on short-tailed shearwater fledglings. The study established that, by removing the light source from nesting areas, there was a decrease in grounded fledglings and a corresponding reduction in bird fatalities. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian yellow nosed albatross and wandering albatross, antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Light emissions are not identified as a threat in conservation advice or recovery plans for any of these species. Any impacts to birds from light emissions will be localised and have little / no adverse effect.	IV					•	•
			Marine Reptiles	Light pollution can be an issue along, or adjacent to, turtle nesting beaches where emerging hatchlings orient to, and head towards, the low light of the horizon unless distracted by other lights which disorient and affect their passage from the beach to the sea (EA, 2003). Pendoley (2000) discovered that in the absence of illumination from the moon, glow	IV					•	•

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				from tower flares may influence the orientation of turtles at close range (30–100 m). Five listed / threatened species of marine turtle may occur within the Operational Area, although there are no BIAs or critical habitats located within the PEA and all marine turtles are known to have a more northerly distribution. The Recovery Plan for Marine Turtles in Australia, 2017-2027, lists light pollution as a key threat, however this relates specifically to turtle hatchlings and nesting sites. There are no nesting sites within 5 km of the Operational Area, therefore any impacts will be inconsequential or have no adverse effect.							
Platform Operations	<u>Emissions to Air</u> Combustion of gaseous and liquid fuels and fugitive emissions vented will occur during platform operations, leading to emissions to air.	<u>Change in air quality</u> The release of combusted and un-combusted hydrocarbons into the atmosphere can lead to a change in air quality, cause atmospheric pollution and contribute to greenhouse gases.	Air Quality	Atmospheric emissions will be generated from platform, sources include emissions from internal combustion engines (including all equipment and generators), flares, fugitives and process vents. Emissions generated during platform operations include NOx, CO, SO_2, VOC's (benzene, xylenes, toluene, ethylbenzene), non-VOC's, particulate matter, CO_2, N_2O, CH_4, SF_6, HFCs and PFCs. The presence of these emissions will lead to a localised decline in air quality. Impacts to air quality from emissions to air will be localised to the source and quickly dissipated in the offshore environment. Any impacts will be inconsequential or have no adverse effect.	IV	A	**CM2:** Flaring occurs in accordance with Flare system procedures and Critical Depressuring and Draining procedure.	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened bird species and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented. • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • Esso meets the regulatory requirement to report GHG emissions to the Clean Energy Regulator	Acceptable
			Climate	Global greenhouse gas (GHG) generated by Esso operations in the Bass Strait are reported under the NGER Scheme. Data publish by NGER (2019) demonstrates that oil & gas activities contribute significantly less to state and country-wide GHG emissions than electricity supply and mining industries. Esso is not listed as a top-contributor for Scope 1 or Scope 2 emissions, therefore contribution to GHG emissions (and subsequent change in climate) is considered to be low. Based on this, the primary action (i.e. Esso operations in the Bass Strait) does not represent a 'substantial case; of the circumstance (climate change). Therefore, climate change is not considered an indirect consequence of Esso operations in the Bass Strait for the purposes of Section 527E of the EPBC Act (DSEWPaC 2013a). Impacts to climate from production operations emissions will be localised and will quickly dissipate on completion of flaring or venting	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				event. Any impacts will be inconsequential / have no adverse effect.						• No stakeholder objections or claims have been raised	
		Injury / mortality to fauna Generation of atmospheric emissions has the potential to result in chronic effects to fauna from localised and temporary decrease in air quality.	Birds	Models of combustion emissions from MODU operations (e.g. BP, 2013) indicate that non-GHG emissions such as NO_2 will reduce to below polluting concentrations within 10 km of the source. It is expected that production operations will generate less emissions than MODU operations, therefore the impact area is expected to be reduced. Any venting required during Platform Operations will be small volumes and infrequent discharges. Emissions will quickly dissipate to below detectable levels, and any impacts will be minor and restricted to the immediate vicinity of the vent. In some cases, gas will be directed to the flare during Platform Operations. Flared gas will be burned as efficiently as possible to limit fall-out. Emissions from flaring contain greenhouse gases and could therefore contribute to greenhouse gas emissions. However, volumes of gases released will be low, and given the high energy offshore environment any changes in air quality are expected to be below detectable levels and restricted to the immediate vicinity of the flare. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian Yellow nosed albatross and Wandering albatross, Antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Atmospheric emissions or reduction in air quality are not identified as a threat the conservation advice or recovery plans for any of these species. There is a high density of platforms within the Operational Area, therefore it is possible that cumulative effects to birds could occur. Platforms within 10 km of another platform may lead to an accumulation of atmospheric emissions resulting, however these areas of higher impacts are isolated and will not result in population or ecosystem level effects. Birds are sighted at all platforms within the Operational Area, indicating that a change in air quality is not leading to injury or mortality in bird species observed. Considering this, and the potential for sensitive life stages to be present, impacts are expected to have potential short term, minor adverse consequences.	IV

						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Platform Operations	Planned Discharge – Brine Brine is created by the onboard desalination system, via Reverse Osmosis (RO). Discharges will be continuous.	Change in water quality Planned discharges of brine will lead to a change in water quality through: • Increased salinity • Chemical exposure	Ambient water quality	Reject water discharges from the RO system will have an elevated salinity. The discharges will be quickly dispersed by ocean currents and rapidly mixed with the surrounding marine waters, meaning that any potential impacts are limited to the source of the discharge where concentrations are highest (Azis et.al, 2003). Scale inhibitors and biocides are used in RO systems and will therefore be present in the discharged brine. However, chemicals are used at trace concentrations that would be suitable for human consumption, therefore no impacts to fauna from chemical exposure are expected.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		Injury / mortality to fauna	Plankton	Elevated salinity can affect plankton. Plankton are known to have high levels of natural mortality and a rapid replacement rate (UNEP 1985), therefore recovery from disturbance is typically quick. As such, the activity will not result in serious or irreversible damage to organisms at population level which would affect ecological diversity or productivity within Commonwealth marine areas. Any impacts will be highly localised and temporary, and the consequence will be inconsequential or have no adverse effect.	IV						
Platform Operations	Planned Discharge - Sewage and Grey water Staffing levels vary between platforms, however normally staffed platforms discharge approximately 60-150 m^3 of sewage and grey water per day, depending on staffing levels. Discharge point remains stationary.	Change in water quality Change in water quality can occur through: • Nutrient loading (e.g. ammonia, nitrite, nitrate and orthophosphate). • Chemical exposure (organics and inorganics) • Turbidity / sedimentation of particulate matter	Ambient water quality	Nutrient loading can lead to increased growth in primary producers (such as plankton), followed by oxygen depletion. For discharge volumes up to 150 m^3/day the discharges are expected to remain within the nominal mixing zone boundary of 500 m around fixed facilities. The composition of sewage and grey water may include chemicals including organics (e.g. volatile and semi-volatile organic compounds, oil and grease, phenols, endocrine disrupting compounds) and inorganics (e.g. hydrogen sulphide, metals and metalloids, surfactants, phthalates, residual chlorine). There is also the potential for biological pathogens, such as bacteria, viruses, protozoa, parasites, etc. Organic chemicals are expected to degrade; however, some persistence may occur within sediments. In open water environments such as the Bass Strait, discharges are rapidly dispersed, and any nutrient enrichment, chemical exposure or increase in turbidity will be short-term and localised with no accumulation of impacts expected. Impacts will be inconsequential or have no adverse effect.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives	Acceptable

						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
		Injury / mortality to fauna	Plankton	Plankton communities have a naturally patchy distribution in both space and time (ITOPF, 2011). They are known to have naturally high mortality rates (primarily through predation), however in favourable conditions (e.g. supply of nutrients), plankton populations can rapidly increase. Once the favourable conditions cease, plankton populations will collapse and/or return to previous conditions. Plankton populations have evolved to respond to these environmental perturbations by copious production within short generation times (ITOPF, 2011). However, any potential change in phytoplankton or zooplankton abundance and composition is expected to be localised, typically returning to background conditions within tens to a few hundred metres of the discharge location (e.g. Abdellatif, 1993; Axelrad et al., 1981; Parnell, 2003). Effects on environmental receptors along the food chain, namely, fish, reptiles, birds and cetaceans are therefore not expected beyond the immediate vicinity of the discharge in deep open waters. In open water environments such as the Bass Strait, discharges are rapidly dispersed, and any nutrient enrichment, chemical exposure or increase in turbidity will be short-term and localised with no accumulation of impacts expected. Impacts will be inconsequential or have no adverse effect.	IV					• No stakeholder objections or claims have been raised	
			Commercial Fisheries	There are six Commonwealth-managed fisheries and three Victorian State-managed fisheries which may undertake fishing activities within the Operational Area. Fisheries effort data shows that relatively small numbers of vessels are likely to be encountered within the Operational Area. It is possible that seafood fished within the immediate vicinity of the discharge may not be safe for human consumption or may be tainted due to the presence of chemicals that bioaccumulate. In open water environments such as the Bass Strait, discharges will be rapidly dispersed, and chemical toxicity will be localised with no lasting impacts expected. Any impacts are expected to be limited to the Operational Area and, given the extensive operating area utilised by Commonwealth and State fisheries and that vessels will be excluded from the Operational Area by the PSZ, will have inconsequential or no adverse effects.	IV

						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
		<u>Change in aesthetic value</u> Solids found in sewage can affect the aesthetic value of an area such as ambient water colour, the presence of surface slicks/sheens and odour.	Tourism	Changes in water quality can lead to a change in aesthetic value. As described above, the intermittent discharge and high-energy marine environment means that discharges are expected to be quickly dissipated, with impacts restricted to the localised area around the discharge. Given the distance of the Operational Area from the nearest tourist site, and the low likelihood of tourism or recreation vessels within the Operational Area due to the distance from shore, presence of PSZ and lack of tourist features, no impacts to tourism from changes in aesthetic value are expected.	No impacts expected						
Platform Operations	<u>Planned Discharge – Food waste</u> 1-2kg of food waste will be discharged per person per day. Discharge point remains stationary.	<u>Change in fauna behaviour</u> Increased scavenging behaviour.	Fish Birds	The long-term discharge of food waste from fixed platforms can result in increased scavenging behaviour around the discharge point. In the high energy marine environment of the Bass Strait any discharges will be rapidly dispersed, therefore impacts will be limited to the Operational Area. In addition, the rapid consumption of this food waste by scavenging fauna, and physical and microbial breakdown, ensures that the impacts of food waste discharges are limited to the discharge point. The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian yellow nosed albatross and wandering albatross, antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Changes to predator / prey dynamics are not identified as a threat in the conservation advice or recovery plans for any of these species. Impacts to fish and birds from the planned discharge of food waste are expected to be highly localised (due to the high energy marine environment, intermittent discharge and rapid consumption) and temporary (behavioural changes will cease once water quality returns to background levels). Any impacts will be inconsequential or have no adverse effect.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened birds or fish and will be undertaken in accordance with all applicable management actions. • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable

						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Conductor cutting and pulling	<u>Seabed Disturbance</u> Conductor cutting and pulling can lead to seabed disturbance in the immediate vicinity of the well.	<u>Change in water quality</u> Seabed disturbance can lead to increased turbidity, which affects water quality.	Ambient water quality	Water quality change occurs when seabed sediments enter the water column (turbidity). After a period, the suspended sediments settle and the turbidity in the water column returns to pre disturbance levels. Any impacts will be highly localised and temporary. Wellwork activities are intermittent, and ambient water quality will return to background levels following seabed disturbance. Impacts will have inconsequential or no adverse effects on ambient water quality, and no impacts to ecological, economic, cultural or social receptors are expected as a result of a change in water quality.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		<u>Change in habitat</u> Seabed disturbance could lead to a change in habitat for benthic organisms. Impacts are restricted to the Operational Area.	Benthic habitats and communities	Smothering and alteration to benthic habitats can occur as a result of seabed disturbance. The type of damage that could be sustained due to smothering may include destruction of habitat. Benthic habitats and communities within the Bass Strait show natural small scale variation, however the area is mostly considered homogenous. Studies conducted by Esso (Cardno, 2019) demonstrate similarities in taxa but variation in composition between different sites. High rates of disturbance to benthic communities, such as long term disturbance from dredging or trawl fishing, can lead to reduced habitat structure. This results in homogenous, low diversity communities and loss of large and long-lived sedentary species that create habitat structure and leads to reductions in primary production and ecosystem function (Handley et al., 2014). Disturbance from IMR activities is not expected to result in high rates of disturbance at this scale, however it is possible that small scale disturbance will lead to similar outcomes. Seabed disturbance from wellwork activities will be limited to close proximity to existing infrastructure, and typically in areas which have previously been disturbed during installation of infrastructure. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be inconsequential or have no adverse effects.	IV

Wireline / Workover Activities (general)	<u>Emissions to Air</u> Non-routine flaring and venting will occur during depressurisation prior to wellwork activities. Non-routine flaring will occur during production start-up.	<u>Change in air quality</u> The release of combusted and un-combusted hydrocarbons into the atmosphere can lead to a change in air quality, cause atmospheric pollution and contribute to greenhouse gases.	Air quality	Atmospheric emissions will be generated from venting and flaring during workover operations and will lead to a localised decline in air quality. Volumes of venting / flaring during workover operations will be small. Larger volumes could occur during production start-up, however this will be an isolated event. Impacts to air quality from emissions to air will be localised to the source and quickly dissipated in the offshore environment. Any impacts will be inconsequential or have no adverse effect.	IV	A	**CM4:** Wireline / Workover work scope or plan.	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened bird species and will be undertaken in accordance with all applicable management actions • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • Esso meets the regulatory requirement to report GHG emissions to the Clean Energy Regulator • No stakeholder objections or claims have been raised	Acceptable
			Climate	Global greenhouse gas (GHG) generated by Esso operations in the Bass Strait are reported under the NGER Scheme. Data publish by NGER (2019) demonstrates that oil & gas activities contribute significantly less to state and country-wide GHG emissions than electricity supply and mining industries. Esso is not listed as a top-contributor for Scope 1 or Scope 2 emissions, therefore contribution to GHG emissions (and subsequent change in climate) is considered to be low. Based on this, the primary action (i.e. Esso operations in the Bass Strait) does not represent a 'substantial case; of the circumstance (climate change). Therefore, climate change is not considered an indirect consequence of Esso operations in the Bass Strait for the purposes of Section 527E of the EPBC Act (DSEWPaC 2013a). Impacts to climate from wellwork operations emissions will be localised and will quickly dissipate on completion of activities. Any impacts will be inconsequential / have no adverse effect.	IV						
		<u>Injury / mortality to fauna</u> Generation of atmospheric emissions has the potential to result in chronic effects to fauna from localised and temporary decrease in air quality.	Birds	Any venting required during wireline / workover activities will be small volumes and infrequent discharges. Emissions will quickly dissipate to below detectable levels, and any impacts will be minor and restricted to the immediate vicinity of the vent. In some cases, gas will be directed to the flare during wireline / workover activities. Flared gas will be burned as efficiently as possible to limit fall-out. Emissions from flaring contain greenhouse gases and could therefore contribute to greenhouse gas emissions. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian Yellow nosed albatross and Wandering albatross, Antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Atmospheric emissions or reduction in air quality are not identified	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				as a threat the conservation advice or recovery plans for any of these species. Impacts will be highly localised and temporary, ceasing once the workover operations are complete. Any impacts will be inconsequential or have no adverse effect.							
Wireline /workover Activities (general) Conductor cutting and pulling Conductor Clean-out Sandwash	Planned Discharge – Operational Fluids Fluids contained within the well will be discharged during sandwash and clean-out. Residual fluids may be discharged in the final stages of conductor cutting. Residual production fluids as well as chemicals dosed into the production system will be discharged into the drains during wellwork operations.	• See Section 6.4 for more details									
Cementing	Planned Discharge – Cement Cementing during wellwork will result in a discharge of dry and mixed cement. After wellwork activities, dry cement may be discharged from the facility. Impacts are restricted to the Operational Area.	Change in water quality	Ambient water quality	Cement released from the surface (mixed and dry cement) and the seabed (mixed cement) will result in increased turbidity in close proximity to the release. Modelling of larger cement surface discharges (e.g. 18 m^3 of cement wash modelled by de Campos et al., 2017) shows an average deposition of 0.05 mg/m^2 of material on the seabed; with particulate matter deposited within the three-day simulation period. Any impacts from cementing during wellwork will be greatly reduced from these spatial estimates. Chemical toxicity results from chemical additives added to the dry cement when mixing, therefore changes in water quality through chemical exposure are expected to be restricted to discharges of mixed cement. Low toxicity additives will be selected, and discharges are expected to be highly localised. Once hardened, toxic effects will cease (Terrens et al., 1998; CIN, 2005). Impacts to ambient water quality from planned discharge of cement will be highly localised and temporary, with turbidity and chemical toxicity impacts quickly ceasing following discharge. Any impacts will be inconsequential or have no adverse effect, and impacts to pelagic organisms (such as plankton, fish, marine fauna) are not expected.	IV	A	**CM3:** Chemical Discharge Assessment Process	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		Change in sediment quality	Ambient sediment quality	Cement has the potential to smother or alter the benthic substrate, resulting in a permanent change in sediment quality. Chevron (2014) indicated that planned cement discharges from overflow during drilling operations, which would be higher in volume than cementing during wellwork, may affect the seabed around the well to a radius of ~10 m–50 m.	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				Once cement has hardened, the sediment quality will be permanently changed. Wellwork will be undertaken at existing wells where cement discharges have already occurred, therefore no further changes to sediment quality are expected as a result of cementing during wellwork. Any impacts to ambient sediment quality will be inconsequential or have no adverse effect and impacts to benthic habitats and communities are not expected.							
Conductor Clean-out Sandwash	Planned Discharge – Solids Clean-out and sandwash will result in solids from inside the well bore being discharged to the seabed.	Change in water quality Solids discharged to the marine environment have the potential to change water quality. Impacts are restricted to the Operational Area.	Ambient water quality	Solids from the reservoir (e.g. sand) may exit the well with the workover brine during wellwork operations. There solids are captured as waste where possible, however in some cases capture is not feasible and solids will be discharged, for example during conductor clean-out operations where the discharge of returns run over the conductor lip. A typical sand discharge during conductor clean-up operations is 100 bbls of entrained sand in brine. The discharge of brine containing solids can result in increased turbidity in the water column. Volumes will be small, and discharges will be infrequent due to the sporadic nature of wellwork activities. Any discharges will be quickly dissipated in the high energy marine environment, with impacts restricted to close proximity to the discharge location. Impacts will be inconsequential or have no adverse effect, and no impacts to fauna are expected.	IV	A	**CM5:** Collection and onshore disposal of solids.	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable

6.2.3 IMR Activities

Table 6-3 IMR Activities – Impact Scoping

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Pipeline and Subsea IMR	<u>Physical Presence - Interference with Other Marine Users</u> Equipment or infrastructure temporary stored on the seabed may lead to interference to other marine users.	<u>Change to the function, interests or activities of other users</u> Change to the function, interests or activities of other users could occur through disruption of commercial and recreational activities. Disruption to activities includes: exclusion of vessels to areas around the activity; damage to fishing equipment; and loss of commercial fish catch. Impacts are restricted to other marine users which interact with the seabed within the Operational Area. No impacts to shipping are expected.	Commercial Fisheries	There are six Commonwealth-managed fisheries and three Victorian State-managed fisheries which may undertake fishing activities within the Operational Area. Presence of fisheries varies between platforms, typically due to water depth determining the location of prey species. Fisheries effort data, however, shows that relatively small numbers of vessels are likely to be encountered within the Operational Area. Temporary storage would be short-term and would occur within the PSZ of a facility or subsea infrastructure or within the 200 m operational zone around a pipeline. Any impacts are expected to be limited to the Operational Area and, given the extensive operating area utilised by Commonwealth and State fisheries and the low number of vessels likely to be operating within the Operational Area, will have inconsequential or no adverse effects.	IV	A	**CM31:** Temporary storage will occur within an existing PSZ or 200m operational zone around pipelines **CM36:** Pre start notifications to JRCC to enable AMSA to distribute an AUSCOAST warning. Stakeholders notified of programme of works each quarter and one week prior to commencement.	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
			Recreational Activities	Recreational activities may occur within the Operational Area such as recreational fisheries and recreational boating and leisure activities. However, given the distance from shore and that impacts are limited to the seabed, no interaction with recreational activities is expected.	No impacts expected						
Pipeline and Subsea IMR	<u>Physical Presence – NORM</u> Naturally occurring radioactive material (NORM) can accumulate in the form of scale on the internal surfaces of equipment which is in contact with the production fluids. NORM could be released as a result of temporary storage.	<u>Change in habitat</u> Radioactivity derived from natural sources is normally present in the open ocean, particularly at the seabed. Dissolved radium isotopes could be present in NORM scale, potentially increasing the radioactivity levels in close proximity to the scale. If NORM scale is contained in the flowlines it can emit radiation in the form of higher energy α and γ rays	Plankton	The pathways for exposure of NORM to marine species are through external γ radiation from radium-226, absorption (e.g. by phytoplankton) or through intake from water or food of either radium-226 or radium-228. Once absorbed, radium follows potassium in organisms and is primarily deposited in shell and bone tissue. Secretion from these is very slow and in general the deposited radium will remain there throughout the organism's lifetime (Norse Decom, 2003). There is little knowledge about the effects of deposited NORM on marine organisms, however studies indicate that there is no increased accumulative of radium-226 or	IV	A	**CM6:** Temporary Storage Assessment	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage	Acceptable

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
		from radium-226 or low energy β rays from radium-228 (APPEA, 2002).		radium-228 in marine organisms due to exposure to NORM (Hylland & Eriksen, 2013), and there is little upward transport through bioaccumulation (Norse Decom, 2003). Early lifestages of fish (embryos, larvae) and other plankton would be most susceptible to NORM exposure, as they are less mobile and therefore can become exposed to the highest concentration of radiation. However, these are expected to rapidly recover, as they have high levels of natural mortality and a rapid replacement rate UNEP (1985). As studies indicate that there is limited upward transport of radiation through the food chain, fauna which rely on plankton as prey are not expected to be impacted. As such, exposure of planktonic communities is not considered to result in significant impacts on population level of organisms that would affect ecological diversity or productivity within Commonwealth marine areas and therefore is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action.						• Good practise control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Pipeline and Subsea IMR	Seabed Disturbance Physical disturbance to the seabed can occur during IMR activities such as dredging, cutting and temporary storage.	Change in water quality Seabed disturbance can lead to increased turbidity, which affects water quality.	Ambient water quality	Water quality change occurs when seabed sediments enter the water column (turbidity). After a period, the suspended sediments settle and the turbidity in the water column returns to pre disturbance levels. Any impacts will be highly localised and temporary. IMR activities are intermittent, and ambient water quality will return to background levels following seabed disturbance. Impacts will have inconsequential or no adverse effects on ambient water quality, and no impacts to ecological, economic, cultural or social receptors are expected as a result of a change in water quality.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		Change in habitat Seabed disturbance could lead to a change in habitat for benthic organisms. Impacts are restricted to the Operational Area.	Benthic habitats and communities	Smothering and alteration to benthic habitats can occur as a result of seabed disturbance. The type of damage that could be sustained due to smothering may include destruction of habitat. Benthic habitats and communities within the Bass Strait show natural small scale variation, however the area is mostly considered homogenous. Studies conducted by Esso (Cardno, 2019) demonstrate similarities in taxa but variation in composition between different sites. High rates of disturbance to benthic communities, such as long term disturbance from dredging or trawl fishing, can lead to reduced habitat structure. This results in	IV	A	**CMP37:** Post campaign ROV inspection to check that temporary equipment has been recovered and dropped objects recovered where practicable				

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP: ALARP Decision Context	Demonstration of ALARP: Good Practice Control Measures	Demonstration of ALARP: Additional Control Measures Considered	Demonstration of ALARP: ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Demonstration of Acceptability: Acceptability Outcome
				homogenous, low diversity communities and loss of large and long-lived sedentary species that create habitat structure and leads to reductions in primary production and ecosystem function (Handley et al., 2014). Disturbance from IMR activities is not expected to result in high rates of disturbance at this scale, however it is possible that small scale disturbance will lead to similar outcomes. Seabed disturbance from IMR activities will be limited to close proximity to existing infrastructure, and typically in areas which have previously been disturbed during installation of infrastructure. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be inconsequential or have no adverse effects.							
Facility IMR Pipeline and Subsea IMR	Emissions to Air Non-routine or safety flaring or venting will occur during facility IMR. Depressuring or pipelines and subsea facilities directs vapours to the flare.	Change in air quality The release of combusted and un-combusted hydrocarbons into the atmosphere can lead to a change in air quality, cause atmospheric pollution and contribute to greenhouse gases.	Air quality	Atmospheric emissions will be generated from venting and non-routine flaring during Facility, subsea and pipeline IMR operations. The presence of these emissions will lead to a localised decline in air quality. Volumes of venting / non-routine flaring during Facility IMR operations will be small. Impacts to air quality from emissions to air will be localised to the source and quickly dissipated in the offshore environment. Any impacts will be inconsequential or have no adverse effect.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened bird species and will be undertaken in accordance with all applicable management actions. • No control measures identified which can further lower the impact consequence	Acceptable
			Climate	Global greenhouse gas (GHG) generated by Esso operations in the Bass Strait are reported under the NGER Scheme. Data publish by NGER (2019) demonstrates that oil & gas activities contribute significantly less to state and country-wide GHG emissions than electricity supply and mining industries. Esso is not listed as a top-contributor for Scope 1 or Scope 2 emissions, therefore contribution to GHG emissions (and subsequent change in climate) is considered to be low. Based on this, the primary action (i.e. Esso operations in the Bass Strait) does not represent a 'substantial case; of the circumstance (climate change). Therefore, climate change is not considered an indirect consequence of Esso	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				operations in the Bass Strait for the purposes of Section 527E of the EPBC Act (DSEWPaC 2013a). Impacts to climate from IMR emissions will be localised and will quickly dissipate on completion of flaring or venting event. Any impacts will be inconsequential / have no adverse effect.						• The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • Esso meets the regulatory requirement to report GHG emissions to the Clean Energy Regulator • No stakeholder objections or claims have been raised	
		Injury / mortality to birds Generation of atmospheric emissions has the potential to result in chronic effects to fauna from localised and temporary decrease in air quality.	Birds	Any venting required during Facility IMR activities will be small volumes and infrequent. Emissions will quickly dissipate to below detectable levels, and any impacts will be minor and restricted to the immediate vicinity of the vent. In some cases, gas will be directed to the flare during Facility IMR activities. Flared gas will be burned as efficiently as possible to limit fall-out. Emissions from flaring contain greenhouse gases and could therefore contribute to greenhouse gas emissions. However, volumes of gases released will be low, and given the high energy offshore environment any changes in air quality are expected to be below detectable levels and restricted to the immediate vicinity of the flare. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian Yellow nosed albatross and Wandering albatross, Antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Atmospheric emissions or reduction in air quality are not identified as a threat the conservation advice or recovery plans for any of these species. Impacts will be highly localised and temporary, ceasing once the Facility IMR operations are complete. Any impacts will be inconsequential or have no adverse effect.	IV						
Facility IMR Pipeline and Subsea IMR	Planned Discharge - Operational Fluids Residual production fluids as well as chemicals dosed into the production system will be discharged during IMR activities. Volumes typically 80 L. Separator maintenance or pigging at Marlin Complex and WTN platforms may results in trace amounts of mercury in fluids.	See Section 6.4 for more details									

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
	No routine discharge of Mercury occurs.										
Pipeline and Subsea IMR	Planned Discharge – Gas (subsea) During IMR activities there may be planned gas releases associated with depressurisation, flushing, isolations or valve operational activities.	Change in water quality Methane-consuming microbes (methano-trophic bacteria) may exhaust oxygen supply in the water column, resulting in a change in water quality.	Ambient water quality	Release of gas into the marine environment can lead to a bloom in methano-trophic bacteria, which will increase the biological oxygen demand (BOD) in the surrounding waters and quickly reduce the oxygen available for marine organisms such as plankton. In deep water (i.e. greater than 1,000m) there is potential for ocean stratification to concentrate the effects of methano-trophic bacteria to pockets within the water column, leading to 'dead zones' of oxygen poor waters. Stratification and resulting 'dead zones' are not likely to occur in the Operational Area as the waters are too shallow and hydrodynamics ensure that waters are well mixed. In addition, gas released subsea would quickly reach the surface and dissipate in prevailing winds, reducing the volume of gas in the water column available to methano-trophic bacteria, with oxygen levels in the water column expected to return to normal rapidly through natural processes. Any changes in water quality from a subsea release of gas will be limited to the Operational Area. Water quality will quickly return to ambient levels, due to the shallow water depth and high energy marine environment. Any impacts will be inconsequential or have no adverse effects on ambient water quality, and no impacts to ecological, economic, cultural or social receptors are expected as a result of a change in water quality.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
Facility IMR Pipeline and Subsea IMR	Planned Discharge – Solids IMR methods such as cleaning, abrasive blasting, hot work, repairs and maintenance will result in discharges of solids and fines either from the drains or at the seabed	Change in water quality Incidental discharge of sand blasting, weld/paint residue, coatings, cement, grit or other small solid debris to the marine environment has the potential to change water quality.	Ambient water quality	Surface discharges of solids can lead to a change in water quality. Discharges will be small and infrequent and will be quickly dissipated in the high energy marine environment therefore impacts are restricted to the Operational Area. Solids and fines will be captured on the facility where possible, reducing the volume. Discharges made at the seabed could result in short-term increase in turbidity localised to the discharge location, however seabed currents and the high energy marine environment will result in any discharges being quickly dissipated, with background levels of water quality rapidly returning. It is not possible to capture solids during subsea IMR activities. Impacts will have inconsequential or no adverse effects on ambient water quality, and no impacts to ecological, economic, cultural or social	IV	A	Facility IMR **CM7:** Abrasive blasting SWP 50.101 Pipeline and Subsea IMR None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented. Vessel Operations Helicopter Operations	Physical Presence - Interference with Other Marine Users	<u>Change to the function, interests or activities of other users</u> Change to the function, interests or activities of other users could occur through disruption of commercial and recreational activities. Disruption to activities includes: • exclusion of vessels to areas around the activity; • damage to fishing equipment; and • loss of commercial fish catch.	Commercial Fisheries	There are six Commonwealth-managed fisheries and three Victorian State-managed fisheries which may undertake fishing activities within the Operational Area. Presence of fisheries varies between platforms, typically due to water depth determining the location of prey species. Fisheries effort data, however, shows that relatively small numbers of vessels are likely to be encountered within the Operational Area. Project vessels and helicopters operating within the Operational Area may disrupt activities being undertaken by commercial fishing vessels. However, most activities undertaken by project vessels will be within the 500m Petroleum Safety Zone (PSZ) around each platform and subsea facility, therefore impacts to fishing vessels will be greatly reduced. Impacts are limited to the Operational Area and, given the extensive operating area utilised by Commonwealth and State fisheries and the low number of vessels likely to be operating within the Operational Area, will have inconsequential or no adverse effects.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
			Shipping	With the exception of PCA and DPA, all platforms are located within the ATBA. Shipping activity is limited within the ATBA, as vessels in excess of 200 gross tonnage are prohibited from unauthorised entry. Given this, the presence of vessels within the established PSZs (500 m extending from each platform) will not result in further impacts to shipping.	No impacts expected						
			Recreational Activities	Recreational activities may occur within the Operational Area such as recreational fishing, recreational boating and leisure activities. However, given the distance from shore and the existing PSZs, no interaction with recreational activities is expected.	No impacts expected						
ROV Operations	<u>Seabed Disturbance</u> ROV operations typically take place above the seabed however, operations close to and on the seabed can	<u>Change in water quality</u> Seabed disturbance can lead to increased turbidity, which affects water quality.	Ambient water quality	Water quality change occurs when seabed sediments enter the water column (turbidity). After a period, the suspended sediments settle and the turbidity in the water column returns to pre disturbance levels. Any impacts will be highly localised and temporary. ROV Operations are intermittent, and ambient water quality will quickly return to background levels following seabed disturbance. Impacts will have inconsequential or no adverse effects on ambient water quality, and no impacts to ecological, economic, cultural or social receptors are expected as a result of a change in water quality. 	lead to seabed disturbance.									• Activity will not result in serious or irreversible damage • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Vessel Operations Helicopter Operations	<u>Underwater Sound Emissions</u>	<u>Change in ambient noise</u>	Ambient noise	Vessels holding position generate sound of up to 182 dB re 1 µPa, with levels of 120 dB re 1 µPa recorded at 3–4 km (McCauley, 1998). Sound emitted from helicopter operations is typically of a low frequency, below 500 Hz (Richardson et al., 1995). Ambient noise levels increase in close proximity to shipping traffic. Given the proximity of the Operational Area to busy shipping lanes, 120 dB re 1 µPa is considered a conservative estimate of ambient noise levels. Any impacts to ambient noise will therefore be highly localised (within 3-4km of the source) and temporary, with ambient levels returning once the source moves away from an area. Impacts will be inconsequential or have no adverse effects.	IV	A	**CM8:** Vessel Master **CMP4**: Helicopter Pilot	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened fish, marine mammals or marine reptiles and will be undertaken in accordance with all applicable management actions and be consistent with conservation management plans. • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards	Acceptable
		<u>Change in fauna behaviour</u> Underwater sound emissions generated by vessel and helicopter operations can result in a change in fauna behaviour.	Fish	Sound generated by vessel operations will be below the recoverable injury threshold for fish (~207 dB re1µPa; Popper et al. 2014), and below the levels that strong 'startle' response has been observed (185 - 190 dB RMS; Pearson et al. 1992; Wardle et al. 2001). Limited research has been conducted on shark responses to noise, however studies indicate that sharks will move suddenly away from sounds of more than 20 dB re 1µPa above broadband ambient SPL when approaching within 10m of the source (Myrberg, 1978). Based on levels adopted by NOAA Fisheries, the US Fish and Wildlife Services, and Canadian Science Advisory Secretariat (DFO, 2004), a conservative threshold level of 130 dB RMS for behavioural changes in fish has been adopted. Based on spherical spreading (Richardson et al., 1995), sound levels will reduce to below this level within approximately 400m of the vessel. Any impacts will be limited to within this localised area. The frequency of helicopter noise is at the lower end of typical fish hearing range, however sensitivity varies between different species due to, for example, the presence / absence of a swim bladder. Studies (e.g. Greene and Moore 1995) indicate that, although sound generated by helicopters can be detected underwater, it will likely be masked by other noise sources such as platform noise, and no direct impacts from helicopter noise are therefore expected. The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Impacts to fish are expected to be highly localised (i.e. within 400m of the sound source), and short-term (behavioural changes will cease once the noise subsides). There is likely to be multiple vessels operating at any one	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP: ALARP Decision Context	Demonstration of ALARP: Good Practice Control Measures	Demonstration of ALARP: Additional Control Measures Considered	Demonstration of ALARP: ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Demonstration of Acceptability: Acceptability Outcome
				time within the Operational Area, therefore it is possible that cumulative effects could occur (from multiple vessels and from combination of vessel and platform emissions). Areas of higher activity, such platform complexes, or periods of higher activity, such as IMR activities using vessels, will be isolated and will not result in population or ecosystem level effects. Any impacts will be inconsequential or have no adverse effect.						and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
			Marine Reptiles	Using the limited information available, it has been reported that behavioural changes and impairment of hearing sensitivity in marine turtles are likely to occur at levels above 120 dB re 1 µPa (SVT Engineering Consultants 2009). Based on spherical spreading (Richardson et al., 1995), sound levels will be reduced to below 120 dB RMS within 1300m of the source. Any impacts will be limited to within this localised area. Five listed / threatened species of marine turtle may occur within the Operational Area, although there are no BIAs or critical habitats located within the PEA and all marine turtles are known to have a more northerly distribution. The Recovery Plan for Marine Turtles in Australia, 2017-2027, lists noise interference as a key threat. Impacts to marine turtles are expected to be localised (i.e. within 1300m of the sound source), and short-term (behavioural changes will cease once the noise subsides). Any behavioural impacts resulting from underwater sound emissions will not impact the long term survival and recovery of threatened marine turtles. There is likely to be multiple vessels operating at any one time within the Operational Area, therefore it is possible that cumulative effects could occur (from multiple vessels and from combination of vessel and platform emissions). Areas of higher activity, such platform complexes, or periods of higher activity, such as IMR activities using vessels, will be isolated and will not result in population or ecosystem level effects. Given the receptor sensitivity to environmental impacts, potential short-term, minor adverse effects are possible.	III	A					
		Injury, harm or interference with marine mammals	Marine Mammals	Cetaceans and pinnipeds can experience permanent (PTS) and temporary threshold shift (TTS) and behavioural responses to underwater sound emissions. Behavioural responses range from subtle changes in surfacing and breathing patterns, to cessation of vocalisations, to active avoidance or escape from the area of insonification. Using the National Marine Fisheries Service (NMFS) guidance for non-pulsed sound, such as vessel noise, a behavioural disturbance limit of 120 dB RMS is adopted (NFMS, 2016). Richardson et al. (1995) and Southall et al. (2007) indicate that behavioural avoidance by baleen whales may onset from 140 to 160 dB re1µPa or possibly higher. Based on spherical spreading (Richardson et al., 1995), calculated that sound levels will be reduced to below 120 dB RMS within 1300m of the source in those conditions. Any impacts will be limited to within this localised area. The Operational Area is within the following BIAs: southern right whale (distribution), pygmy blue whale (foraging, distribution), and several other threatened species of marine mammals may be present within the Operational Area. Anthropogenic noise is listed as a threat in the Conservation Management Plan for the Southern Right Whale, 2011-2021 (CMPSRW) (DSEWPAC, 2012c) and Conservation Management Plan for the Blue Whale, 2015-2025. May to October is the peak season for Southern right whales (SRW) in Australia. The BIA for migration and resting on migration for SRW (coastal BIA) includes the coastline from NSW around to the SA coast, part of which is adjacent to the Bass Strait facilities with whales preferentially occupying water less than 10 metres deep (DSEWPAC, 2012a). While it is	III	B	**CM8**: Vessel Master **CMP4**: Helicopter Pilot **CMP33**: Noise Management **CMP26**: Fauna Observations				

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				not known which path SRWs take to travel to and from the coast, it is possible they may traverse the operational areas in Bass Strait, where if higher noise activity is occurring (e.g., combination of cutting, grinding, vessel on DP) which exceeds the thresholds for Low Frequency cetaceans [PTS (199 SELcum 24 hr^{-1}) or TTS (179 SELcum 24 hr^{-1}) or behavioural change (120 dB RMS)] then this may interfere with migrating SRWs. Noise modelling was conducted for the Esso SHA P&A campaign (Jasco 2020) which had a jack-up rig, a standby vessel (at 1km) and another vessel (on DP) next to the rig operating an ROV doing underwater cutting. The model showed that at no point did sound pressure levels reach the 179 or 199 dB re 1 µPa. When considering 24hr cumulative sound exposure, PTS thresholds were predicted within 30m of the source and TTS out to 1.4km from the source. Behavioural thresholds of 120 dB re 1 µPa were predicted to 4.5km from the source. PTS and TTS values do not incorporate animal movement and therefore it is highly unlikely an animal would be exposed within these ranges over a continuous 24hr period. It is also unlikely for the noise to be maintained constantly at the high rate as operations (and corresponding noise levels) vary over a 24 hr period (e.g., platform resupply generally takes ~3-4 hrs and cutting in the SHA P&A campaign took ~4-6 hrs). The closest operating facility in Bass Strait from the coastal BIA where SRWs are most likely to be resting (and remain stationary) if present, is over 15km away. A combination of 4 noise sources occurring simultaneously would also be unlikely during routine operations. Given these factors, the risk of PTS or TTS is not considered credible. Behavioural impacts to marine mammals are expected to be localised when high noise sources are occurring simultaneously (dependent on activity), and short-term, behavioural changes will cease once the noise subsides. Any behavioural impacts resulting from underwater sound emissions will not impact the long term survival and recovery of threatened marine mammals. There is likely to be multiple vessels operating at any one time within the Bass Strait Operational Area, therefore it is possible that cumulative effects could occur (from multiple vessels and from combination of vessel and platform emissions) depending on the location and types of activities. Areas of higher activity, such as platform complexes, or periods of higher activity, such as IMR activities using vessels, will be isolated and managed through noise control measures in peak SRW period between May and October inclusive and will not result in population or ecosystem level effects for SRW. This is consistent with the requirements of the recovery plan in the CMPSRW.							
Vessel Operations ROV Operations	<u>Light Emissions</u> Navigational and safety lights used during normal vessel operations will result in light emissions. Light from ROVs may attract fish and marine fauna.	<u>Change in ambient light</u>	Ambient Light	Light emissions from vessel operations and ROVs will result in a change in ambient light. Light glow from the vessel is likely to be limited to the operational area and temporary in nature as the vessel moves through the water. As vessels will operated predominantly within the PSZ of existing platforms, vessel light is unlikely to be detectable within the existing light glow. Where vessels are operating at subsea facilities or pipelines, impacts will be inconsequential or have no adverse effect.	IV	A	**CMP30**: Vessel Lighting will be limited to that needed for safe work and navigation	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and	Acceptable
		<u>Change in fauna behaviour</u> A change in ambient light levels could result in a localised light glow. This can lead to changes in fauna behaviour.	Fish	Fish, squid and zooplankton may be directly or indirectly attracted to lights at distances of up to 5 km (Shell, 2010), leading to aggregation at the surface and increased predation. These organisms' distributions are driven by oceanographic conditions, with seasonal and diurnal movements. For fish and squid, it is expected that any potential impact of increased predation would be undetectable at a population level and only affect transient individual fish and squid. The proportion of zooplankton exposed and subjected to higher predation rates within the vessel light fields is negligible. In the event that deck or navigational lighting results as an attractant to an occasional	IV

				seabird, it is not expected that this will permanently impact on migration or other behaviours. The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Impacts to fish are expected to be localised (i.e. within 5km of the light source), and short-term (behavioural changes will cease once the light ceases). Any impacts will be inconsequential or have no adverse effect.						threatened fish, birds or marine reptiles and will be undertaken in accordance with all applicable management actions. • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
			Birds	High levels of offshore lighting can attract and disorient seabird species resulting in behavioural changes (e.g. circling light sources leading to exhaustion or disrupted foraging), injury or mortality near the light source. Artificial light can cause significant impacts on burrow-nesting petrels and shearwaters. Fledglings often become disoriented and grounded because of artificial light adjacent to rookeries as they attempt to make their first flight to sea, a phenomenon known as 'fallout'. Rodrigez at al. (2014) investigated the effects of artificial lighting from road lighting on short-tailed shearwater fledglings. The study established that, by removing the light source from nesting areas, there was a decrease in grounded fledglings and a corresponding reduction in bird fatalities. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian yellow nosed albatross and wandering albatross, antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Light emissions are not identified as a threat in conservation advice or recovery plans for any of these species. Any impacts to birds from light emissions will be localised and have little / no adverse effect.	IV						
			Marine Reptiles	Light pollution can be an issue along, or adjacent to, turtle nesting beaches where emerging hatchlings orient to, and head towards, the low light of the horizon unless distracted by other lights which disorient and affect their passage from the beach to the sea (EA, 2003). Pendoley (2000) discovered that in the absence of illumination from the moon, glow from tower flares may influence the orientation of turtles at close range (30–100 m). Five listed / threatened species of marine turtle may occur within the Operational Area, although there are no BIAs or critical habitats located within the PEA and all marine turtles are known to have a more northerly distribution. The Recovery Plan for Marine Turtles in Australia, 2017-2027, lists light pollution as a key threat, however this relates specifically to turtle hatchlings and nesting sites. There are no nesting sites within 5 km of the Operational Area, therefore any impacts will be inconsequential or have no adverse effect.	IV						
Vessel Operations	<u>Emissions to Air</u> Vessels are powered via the use of on-board generators. The operation of these (fuelled by	<u>Change in air quality</u> The release of combusted and un-combusted hydrocarbons into the atmosphere can lead to a decline in air quality, cause atmospheric pollution	Air quality	Atmospheric emissions will be generated from combustion during vessel operations. The presence of these emissions in the air will lead to a localised decline in air quality. Impacts to air quality from emissions to air will be localised to the source and quickly dissipated in the offshore environment. Any impacts will be inconsequential or have no adverse effect.	IV	A	**CM9:** Class certification	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and	Acceptable
			Climate	Global greenhouse gas (GHG) generated by Esso operations in the Bass Strait are reported under the NGER Scheme. Data publish by NGER (2019) demonstrates that oil & gas activities contribute significantly less to state and	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
	MDO) will result in combustion emissions.	and contribute to greenhouse gases.		country-wide GHG emissions than electricity supply and mining industries. Esso is not listed as a top-contributor for Scope 1 or Scope 2 emissions, therefore contribution to GHG emissions (and subsequent change in climate) is considered to be low. Based on this, the primary action (i.e. Esso operations in the Bass Strait) does not represent a 'substantial case; of the circumstance (climate change). Therefore, climate change is not considered an indirect consequence of Esso operations in the Bass Strait for the purposes of Section 527E of the EPBC Act (DSEWPaC 2013a). Impacts to climate from vessel operations emissions will be localised and will quickly dissipate in the high energy marine environment. Any impacts will be inconsequential / have no adverse effect.						ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened bird species and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • Class certification ensures that vessels adhere to the rules of an IACS Member society, such as MARPOL requirements and Marine Orders. • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
		<u>Injury / mortality to fauna</u> Generation of atmospheric emissions has the potential to result in chronic effects to fauna from localised and temporary decrease in air quality.	Birds	Models of combustion emissions from MODU operations (e.g. BP, 2013) indicate that non-GHG emissions such as NO_2 will reduce to below polluting concentrations within 10 km of the source. It is expected that vessel operations will generate less emissions than MODU operations, therefore the impact area is expected to be reduced. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian Yellow nosed albatross and Wandering albatross, Antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Atmospheric emissions or reduction in air quality are not identified as a threat in the conservation advice or recovery plans for any of these species. There is likely to be multiple vessels operating at any one time within the Operational Area, therefore it is possible that cumulative effects to birds could occur (from multiple vessels and from combination of vessel and platform emissions). Areas of higher activity, such platform complexes, or periods of higher activity, such as IMR activities using vessels, will be isolated and will not result in population or ecosystem level effects. Birds are sighted at all platforms within the Operational Area, indicating that a change in air quality is not leading to injury or mortality in bird species observed. Considering this, and the potential for sensitive life stages to be present, impacts are expected to have potential short term, minor adverse consequences.	III						
Vessel Operations	<u>Planned Discharge – Brine</u> Brine is created by the onboard desalination system, via Reverse Osmosis (RO). It will be discharged intermittently, during vessel movement.	<u>Change in water quality</u> Planned discharges of brine will lead to a change in water quality through: • Increased salinity • Chemical exposure	Ambient Water quality	Modelling of brine discharges from a vessel (Frick et al., 2001) assuming no ocean current predict salinity levels would return to ambient levels within 4m of the discharge point. Scale inhibitors and biocides are used in RO systems and will therefore be present in the discharged brine. However, chemicals are used at trace concentrations that would be suitable for human consumption, therefore no impacts to plankton from chemical exposure are expected. Impacts to ambient water quality will be localised (within 4m of the discharge point) and temporary, with any discharges quickly dissipated in the high energy marine environment. Any impacts will be inconsequential or have no adverse effect. Given the small impact area and short-term nature of the impact, no impacts to ecological, economic, cultural or social receptors will occur.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • No control measures identified which can	Acceptable

										further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Vessel Operations	Planned Discharge - Cooling Water	Change in water quality Discharges of cooling water can lead to changes in water quality through: • Increased temperature • Chemical exposure	Ambient Water quality	Discharges of cooling water from vessels will lead to a change in water quality. Volumes will vary with vessel size, however the maximum expected discharge is approximately 50 m³/d. Vessels requiring cooling water may discharge water continuously, however vessel presence within the Operational Area varies and continuous discharge of cooling water in a single location is not expected. Once a vessel moves away from an area, the high energy marine environment is expected to result in the change in water quality quickly dissipating, and ambient water quality will be quickly restored. Impacts will be localised and short-term. Cumulative impacts are not expected. Any impacts will be inconsequential or have no adverse effects on ambient water quality.	IV	A	None identified	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened fish, marine mammals or marine reptiles and will be undertaken in accordance with all applicable management actions. • No control measures identified which can further lower the impact consequence • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
		Injury / mortality to fauna	Plankton	Early lifestages of fish (embryos, larvae) and other plankton would be most susceptible to the toxic exposure from chemicals in the vessel cooling water discharges, as they are less mobile and therefore can become exposed to the plume at the outfall. However, these are expected to rapidly recover once the activity ceases, as they are known to have high levels of natural mortality and a rapid replacement rate (UNEP, 1985). As such, exposure of planktonic communities to cooling water discharge is not considered to result in significant impacts on population level of organisms that would affect ecological diversity or productivity within Commonwealth marine areas. Rather it is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action. Any impacts will be inconsequential or have no adverse effects.	IV						
			Fish	Modelling of continuous wastewater discharges (including cooling water) found that the temperature of the discharge decreases quickly as the discharge stream mixes with the receiving waters, with the temperature being <1 °C above ambient within 100 m (horizontally) of the discharge point, and 10 m vertically (WEL, 2014). Note that this study was undertaken at a facility and not from a vessel, therefore is considered conservative. Fish passing through the area will be able to actively avoid entrainment in any heated plume (Langford, 1990). Acclimation of test organisms at 15, 20 and 25°C allowed them to tolerate temperature increments of 8-9°C without damage (UNEP, 1985). The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Impacts to fish are expected to be highly localised (i.e. 100m of the discharge stream), and short-term (high-energy marine environment will dissipate the	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP				Demonstration of Acceptability	
						ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				discharge stream quickly, no long-term continuous discharges expected). Any impacts will be inconsequential or have no adverse effect.							
			Marine Mammals	Similar to fish, marine mammals passing through the area will be able to actively avoid any heated plume (Langford, 1990). Acclimation of test organisms at 15, 20 and 25°C allowed them to tolerate temperature increments of 8-9°C without damage (UNEP, 1985). The Operational Area is within the following BIAs: southern right whale (distribution), pygmy blue whale (foraging, distribution), and several other threatened species of marine mammals may be present within the Operational Area. A change or reduction in water quality has not been identified as a threat in any of the relevant conservation advice or management / recovery plans for these species. Impacts to marine mammals are expected to be highly localised (i.e. 100m of the discharge stream), and short-term (high-energy marine environment will dissipate the discharge stream quickly, no long-term continuous discharges expected). Any impacts will be inconsequential or have no adverse effect.	IV						
			Marine Reptiles	Marine reptiles would be expected to behave in a similar way to fish and marine mammals and would actively avoid a heated plume (Langford, 1990). Acclimation of test organisms at 15, 20 and 25°C allowed them to tolerate temperature increments of 8-9°C without damage (UNEP, 1985). Five listed / threatened species of marine turtle may occur within the Operational Area, although there are no BIAs or critical habitats located within the PEA and all marine turtles are known to have a more northerly distribution. The Recovery Plan for Marine Turtles in Australia, 2017-2027, lists chemical discharge as a key threat, specifically long term exposure to anthropogenic contaminants. Biocides and scale inhibitors typically released with cooling water discharges will be of low concentration and have a low level of bioavailability meaning they will not accumulate within the food chain. Impacts to marine turtles are expected to be highly localised (i.e. 100m of the discharge stream), and short-term (high-energy marine environment will dissipate the discharge stream quickly, no long-term continuous discharges expected). Impacts are not expected to impact the long term survival and recovery of threatened marine turtles. Any impacts will be inconsequential or have no adverse effect.	IV						
Vessel Operations	<u>Planned Discharge - Deck Drainage & Bilge</u> Deck drainage and bilge water can be contaminated with hydrocarbons, oil, detergents, hydraulic oil, and chemicals. Bilge water is treated onboard using an oily water	<u>Change in water quality</u> A discharge of contaminated deck drainage or bilge water can lead to a change in water quality.	Ambient water quality	Discharges of deck drainage and bilge during vessel operations will lead to a change in water quality through increased turbidity and chemical toxicity. Deck drainage water and bilge water generally consists of a mixture of fresh water, sea water, oil, sludge, chemicals and various other fluids. Discharges will be highly localised and infrequent with high dilution and dispersion rates due to wave and ocean currents. Therefore, decreased turbidity is expected to be very short term, hours rather than days. Bilge water will be treated prior to discharge via an oil in water separator (OWS) with a maximum concentration of 15 ppm oil-in-water being achieved prior to discharge. The remaining oil residue will be retained onboard for onshore disposal. Modelling (Shell, 2010) indicates that chemicals and hydrocarbon discharges will disperse rapidly to below the Predicted No Effect Concentration (PNEC) within 70 m, with no long-term impacts expected. Impacts will be localised to the discharge location. As discharges will be intermittent and vessels will be moving around the operational area, impacts are expected to be short-term with water quality quickly returning to ambient levels. Cumulative impacts are not expected. Any impacts will be	IV	A	**CM9:** Class certification	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage	Acceptable

	separator (OWS).			inconsequential or have no adverse effect, and no impacts to ecological, economic, cultural or social receptors are expected.						• Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • Class certification ensures that vessels adhere to the rules of an IACS Member society, such as MARPOL requirements and Marine Orders. • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Vessel Operations	<u>Planned Discharge - Sewage and Grey water</u> Vessels typically generate around 5-15 m^3 of wastewater (consisting of sewage and grey water) per day. Discharges will be made while in transit.	<u>Change in water quality</u> Change in water quality can occur through: • Nutrient loading (e.g. ammonia, nitrite, nitrate and orthophosphate). • Chemical exposure (organics and inorganics) • Turbidity / sedimentation of particulate matter	Ambient water quality	Nutrient loading can lead to increased growth in primary producers (such as plankton), followed by oxygen depletion. Modelling (Woodside, 2008) of a 10m^3 discharge from a stationary source over a 24 hour period shows that sewage was reduced to approximately 1% of the original concentration within 50m of the discharge. Discharges from vessels will likely be made during transit, greatly decreasing the impact area. The composition of sewage and grey water may include chemicals including organics (e.g. volatile and semi-volatile organic compounds, oil and grease, phenols, endocrine disrupting compounds) and inorganics (e.g. hydrogen sulphide, metals and metalloids, surfactants, phthalates, residual chlorine). There is also the potential for biological pathogens, such as bacteria, viruses, protozoa, parasites, etc. Organic chemicals are expected to degrade; however, some persistence may occur within sediments. In open water environments such as the Bass Strait, discharges are rapidly dispersed, and any nutrient enrichment, chemical exposure or increase in turbidity will be short-term and localised with no accumulation of impacts expected. Cumulative impacts are not expected. Impacts will be inconsequential or have no adverse effect.	IV	A	**CM9:** Class certification	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • Class certification ensures that vessels adhere to the rules of an IACS Member society, such as MARPOL requirements and Marine Orders.	Acceptable
		<u>Injury / mortality to fauna</u> A change in water quality caused by sewage and greywater discharges could result in injury or mortality to fauna.	Plankton	Plankton communities have a naturally patchy distribution in both space and time (ITOPF, 2011). They are known to have naturally high mortality rates (primarily through predation); however, in favourable conditions (e.g. supply of nutrients), plankton populations can rapidly increase. Once the favourable conditions cease, plankton populations will collapse and/or return to previous conditions. Plankton populations have evolved to respond to these environmental perturbations by copious production within short generation times (ITOPF, 2011). However, any potential change in phytoplankton or zooplankton abundance and composition is expected to be localised, typically returning to background conditions within tens to a few hundred metres of the discharge location (e.g. Abdellatif, 1993; Axelrad et al., 1981; Parnell, 2003).	IV						

Activity	Aspect	Impact	Affected Receptor	Consequence Evaluation	Consequence Level	Demonstration of ALARP: ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Acceptability Outcome
				Effects on environmental receptors along the food chain, namely, fish, reptiles, birds and cetaceans are therefore not expected beyond the immediate vicinity of the discharge in open waters. In open water environments such as the Bass Strait, discharges are rapidly dispersed, and any nutrient enrichment, chemical exposure or increase in turbidity will be short-term and localised with no lasting impacts expected. Any impacts will be inconsequential or have no adverse effects.						• The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
			Commercial Fisheries	There are six Commonwealth-managed fisheries and three Victorian State-managed fisheries which may undertake fishing activities within the Operational Area. Fisheries effort data shows that relatively small numbers of vessels are likely to be encountered within the Operational Area. It is possible that seafood fished within the immediate vicinity of the discharge may not be safe for human consumption or may be tainted due to the presence of chemicals that bioaccumulate. In open water environments such as the Bass Strait, discharges will be rapidly dispersed, and chemical toxicity will be short-term and localised with no lasting impacts expected. Any impacts are expected to be limited to the Operational Area and, given the extensive operating area utilised by Commonwealth and State fisheries and the low number of vessels likely to be operating within the Operational Area, will have inconsequential or no adverse effects.	IV						
		<u>Change in aesthetic value</u> Solids found in sewage can affect the aesthetic value of an area such as ambient water colour, the presence of surface slicks/sheens and odour.	Tourism	Changes in water quality can lead to a change in aesthetic value. As described above, the intermittent discharge and high-energy marine environment means that discharges are expected to be quickly dissipated, with impacts restricted to the localised area around the discharge. Given the distance of the Operational Area from the nearest tourist site, and the low likelihood of tourism or recreation vessels within the Operational Area due to the distance from shore, presence of PSZ and lack of tourist features, no impacts to tourism from changes in aesthetic value are expected.	No impacts expected						
Vessel Operations	<u>Planned Discharge – Food waste</u> 1-2kg of food waste will be discharged per person per day. Discharges will be made while in transit.	<u>Change in fauna behaviour</u> Increased scavenging behaviour.	Fish Birds	Discharge of food waste from moving vessels may result in a localised, temporary increase in scavenging behaviour by fish and birds. In the high energy marine environment of the Bass Strait any discharges will be rapidly dispersed, therefore impacts will be limited to the Operational Area. In addition, the rapid consumption of this food waste by scavenging fauna, and physical and microbial breakdown, ensure that the impacts of food waste discharges are limited to the discharge point. The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian yellow nosed albatross and wandering albatross, antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. Changes to predator / prey dynamics are not identified as a threat in the conservation advice or recovery plans for any of these species. Impacts to fish and birds from the planned discharge of food waste are expected to be highly localised (due to the high energy marine environment, intermittent discharge and rapid consumption) and temporary (behavioural changes will cease once water quality returns to background levels).	IV	A	**CM9:** Class certification	None	ALARP	• Impact is Consequence III or less • Impact is well understood • Principals of ESD met: • No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved. • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened birds or fish and will be undertaken in accordance with all	Acceptable

6.3 Planned Discharge - Produced Formation Water

6.3.1 Produced Formation Water Discharges

Formation water is naturally occurring water found within formations of the reservoir. During platform operations, wells bring water to the surface alongside the oil and gas, then the produced formation water (PFW) is separated and treated to remove hydrocarbons prior to discharge. Separation of formation water from reservoir fluids is not completely effective, and separated PFW often contains small amounts of naturally occurring substances including dispersed oil, dissolved organic compounds (aliphatic and aromatic hydrocarbons, organic acids and phenols), inorganic compounds (e.g. soluble inorganic chemicals, dissolved metals) and residual process chemicals. A description of the existing PFW system is provided in Section 2.4.1.1.

6.3.2 Monitoring and Management Framework

This section outlines the monitoring and management framework which Esso have developed to support the monitoring of PFW discharges from offshore assets. For a full description of the monitoring and management framework refer to Volume 4, Section 2.6.5.

Environmental values are defined as particular values or uses of the environment that are important for a healthy ecosystem or for public benefit, welfare, safety or health, and which require protection from the effects of pollution, waste discharges and deposits (Australian and New Zealand Environment Conservation Council (ANZECC)/Agriculture and Resource Management Council of Australia and New Zealand (ARMCANZ) 2000a). The environmental values considered relevant are:

- Aquatic ecosystem integrity – maintaining ecosystem processes (primary production, food chains) and the quality of water, biota and sediment
- Cultural and spiritual – including commercial and recreational fisheries

Key elements to maintain ecosystem integrity have been identified as water quality, sediment quality and biological indicators (biota). By limiting the changes to these key elements to an acceptable level there is high confidence ecosystem integrity is maintained. For each element an indicator has been identified and monitoring designed to identify change. Monitoring change in water quality and sediment quality (at representative facilities) as well as investigating potential toxicity via Whole Effluent Toxicity (WET) testing and implementing management to maintain acceptable level of change is standard industry practice in Commonwealth waters. The relevant indicators to understand change in key elements and, therefore, potential for impact to ecosystem integrity, are physio-chemical stressors, toxicants in water, biological indicators and toxicants in sediment. A number of trigger values for each indicator have been defined and are monitored to detect change. Trigger values serve as an early warning that potential changes beyond the acceptable limits may occur. The acceptable limits of change from PFW discharge within and beyond the mixing zone (the mixing zone boundary for each platform is outlined in Table 6-5) are:

- no significant impacts to MNES (per Significant Impact Guidelines [DOE, 2013])
- no direct impact to benthic habitat
- no taint of fisheries stock
- no seafood is unsafe for human consumption
- no interference with commercial fishing operations

To determine if acceptable limits have been exceeded, routine monitoring of trigger values is undertaken. An approved mixing zone protects 99% of species, as calculated using the Warne et al (2018) statistical distribution methodology on the results of direct toxicity assessment using sub-lethal chronic endpoints. The protection of 99% of species maintains a high level of ecological protection and represents no detectable change from natural variation (as per ANZG (2018)).

For each platform that discharges produced formation water, the following is discussed:

- Discharge regime (i.e. Volume flow rate of the discharge),
- Composition (physical and chemical make-up including chemical additives, constituents of potential concern, ecotoxicology),
- Potentially impacted area and receptors (movement, dispersion and dilution of discharge, and in-situ research findings)
- Potential impacts to receptors within the mixing zone, considering:
- Presence/distance to sensitive receptors (exposure assessment)
- Likely impacts to sensitive receptors including any cumulative impacts, considering
- Fate and behaviour of PFW, possible impact pathways to receptors
- Composition (physical and chemical make-up including chemical additives, constituents of potential concern, ecotoxicology of the platform's whole effluent discharge).

A summary of the PFW discharge characteristics is presented for all the platforms in Table 6-5.

Table 6-5 PFW discharge characteristics per platform

Platform	Discharge depth (m)	Water depth (m)	Discharge orientation	Discharge rate (kL/d)	Meets all ANZECC 95% water quality criteria	Meets all ANZECC 99% water quality criteria	Hydrocarbons dilution*	Trend	PAH dilution*	Trend	Metals dilution*	Trend	Meets all ANZECC shellfish taint criteria	Meets whole effluent ecotoxicology 95% species protection criteria	Meets whole effluent ecotoxicology 99% species protection criteria	Meets background TOC and hydrogen sulphide levels	Mixing zone extent (m)
HLA	11	73	vertically downward	6000 - 10000	<4.3 m	<4.3 m	8 x	Stable	8 x	Stable	16 x	Stable	<4.3 m	<47 m	<160 m	<150 m	**160 m**

Trend taken from 2014-20 data. Note that WET testing was completed on all currently discharging platforms in 2020, however only data for CBA and WKF is available at the time of writing.

Mixing zone extents are based on the maximum of four criteria relative to the maximum detected chemical constituent in PFW– (1) distance to ANZECC 99% water quality criteria, (2) distance to ANZECC shellfish taint criteria, (3) distance to whole effluent ecotoxicity 99% species protection levels, (4) distance to background TOC (proxy for naphthenic acids) and hydrogen sulphide levels. Distance is calculated using the results from a dispersion model for each platform's discharge.

For more details, see Appendix F: PFW Data file. For MLB, TNA has been used as an analogue for chemical characterisation.

*Dilution as the number of times the maximum detected result (2014-20 sampling rounds) is above ANZECC 99% water quality criteria. 'Hydrocarbons' is inclusive of Benzene, 1,2,4-trichloro benzene, Naphthalene, Phenol, Pentachlorophenol, 1,1,2-trichloroethane. 'Metals' is inclusive of Cadmium, Chromium, Cobalt, Copper, Lead, Mercury, Silver, Vanadium and Zinc. 'PAHs' is Naphthalene.

These are due to the presence of [Total] Chromium in WKF and SNA discharge, which has been assumed to be the most toxic form (CrVI) to give a conservative estimate. These would be reduced to 8 times and 600 times for WKF and SNA respectively assuming that Chromium is of a lower toxicity form (CrIII).

^ Due to one sample from 2014. Results since have shown around half this value for Naphthalene as the upper 95% confidence level. Benzene is the next highest dilution factor at 18 x.

To understand potential impacts from PFW discharges, we have undertaken a suite of comprehensive testing and sampling related to PFW discharges from each relevant offshore production facility. The details of this testing and resultant understanding of potential environmental impacts from any given platform's PFW discharge are outlined below. Note: If no PFW is discharged, this impact and associated EP requirements would cease.

6.3.3 Tuna platform

6.3.3.1 Volume

A summary of historic and five-year-projected PFW discharge volume from the platform is provided in Figure 6-1 and Figure 6-2 respectively. The maximum capacity of the system is 6000 kL/d, however based on historical discharge rates the platform is expected to discharge produced water at a much lower rate of approximately 3000 kL/d until the oil system is shut in in approximately 2022/2023.

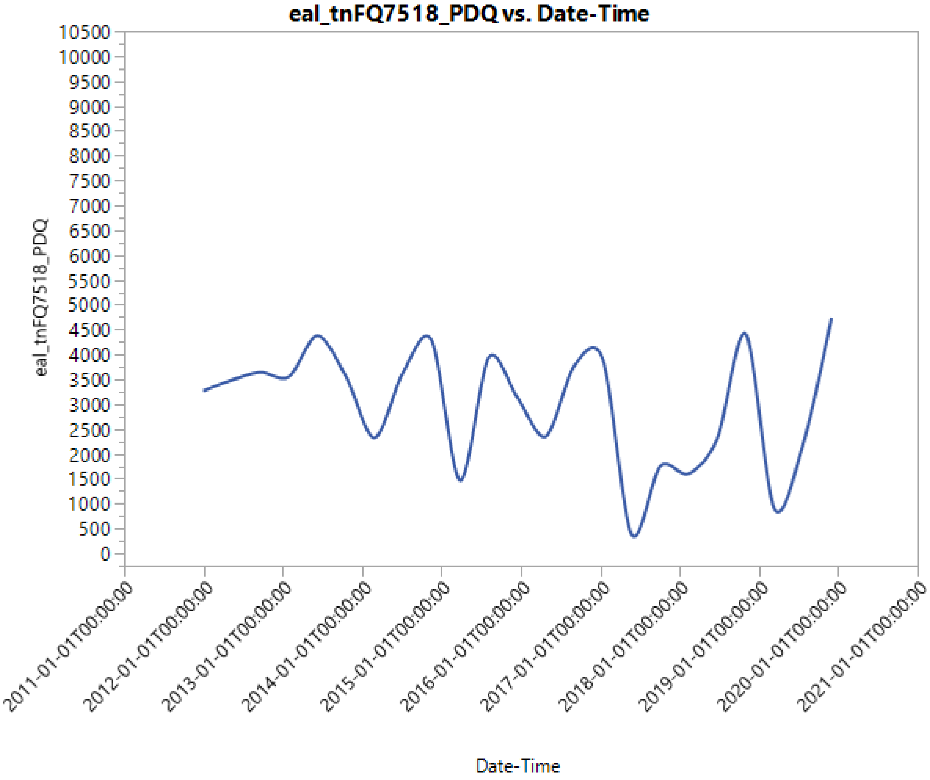

Figure 6-1 Historic TNA smoothed overboard PFW discharge volume (kL/d) (2012-2019)

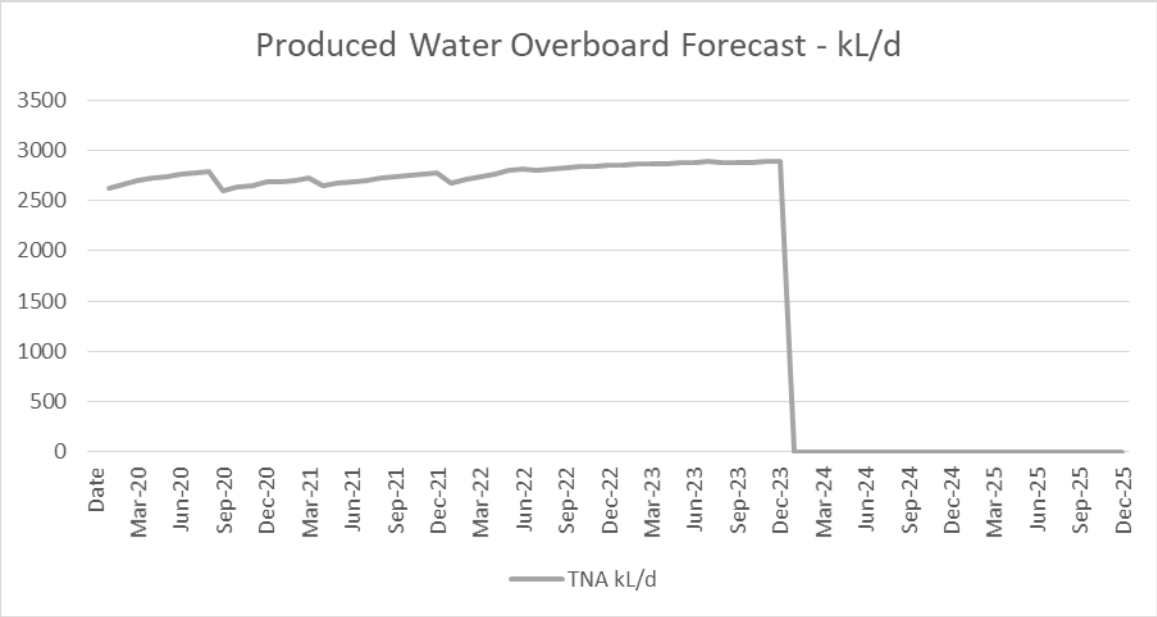

Figure 6-2 Five-year-projected maximum TNA PFW discharge volumes, kL/d.

6.3.3.2 Composition

Physical and chemical make-up

Physical and chemical make-up of TNA PFW is shown in Appendix F – PFW Data file.

Chemical additives

Chemicals in Table 6-6 are added to the platform's water handling system in order to aid oil in water treatment. Chemicals in Table 6-7 are added into the process on the platform for other reasons and could remain at residual levels in the water handling system.

Table 6-6 Chemicals added to Tuna water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Clarifier (e.g. Baker-Hughes RBW24122)	Oil phase	V-600 and V610 Production Oil Separators Inlet	Yes

Table 6-7 Chemicals added to Tuna process that could remain at residual levels in the water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Gas lift corrosion inhibitor (e.g. Baker-Hughes CGW24013)	Water phase	Gas lift into wells, upstream of water handling system	Yes

Oil in water monitoring results

Oil in water concentrations are measured on the platform using a continuous online monitor that determines the levels of oil using the way the PFW scatters light under UV fluorescence.

Data is provided in Appendix F for the platform's daily average overboard discharge levels of oil in water (in mg/L) and oil load (kg/d) since 1 Jan 2020 (reflecting the period following the NOPSEMA General Direction 740 in late 2019 where changes were made to the reporting and recording of oil in water).

Data is also provided for the same period showing the cross-check of platform online monitor readings with routine laboratory tests of oil and grease, with the alignment within a +/- 6 mg/L offset.

6.3.3.3 Ecotoxicology

To determine toxicity of the PFW discharge, whole effluent toxicity (WET) testing was performed in 2014 and 2020 across six tests (five chronic, one acute) and eight tests (seven chronic, one acute) respectively across at least 5 different species representing at least four different taxonomic groups. Further details of the ecotoxicology testing can be found in Appendix G.4 – Breakout Box 4. Chemical composition samples were taken at the same time as the samples for WET testing. Chemical additives added at the time of sampling and ecotoxicology testing on Tuna in 2014 and 2020 were Baker-Hughes RBW24122.

Summarised results of the WET testing are shown in Appendix F.

A Burrlioz model has been run with the results from the 2014 WET testing (following Warne, 2018) and modelling using ssdtools was run with the results from the 2020 WET testing with the 95% and 99% species protection level of effluent shown in Appendix F. See Appendix G.4 – Breakout Box 4 for an explanation of the model selection.

6.3.3.4 Movement, dispersion and dilution

A dispersion model was designed and calibrated to show the movement dispersion and dilution of the PFW discharge around the platform. Appendix G.6 – Breakout Box 6 shows the setup and calibration details for the model. Dispersion model inputs and outputs are summarized in Appendix G.

6.3.3.5 Fate and transport of Tuna PFW

The fate and transport of PFW in the environment are influenced by natural processes (outlined in Figure 6-3, adapted from Lee et al, 2005 and schematic from McAllister, 1997). Primarily, we deal with the potential for contaminants in the produced water to interact with the water column and water column biota through the process of dilution, dispersion and dissolution from entrained oil droplets into the water column, and the potential for contaminants in the produced water to interact with the sediment and sediment biota through the process of particulate adsorption or precipitation, followed by settling deposition onto the seabed. Biological uptake (i.e. bioaccumulation) by biota is also discussed. The remainder of transport pathways either act to reduce potential impacts on water column or sediment biota (i.e. volatilisation, photo-oxidation, degradation, dissolution in sediments) or occur in minor amounts so as to be negligible to overall impacts (i.e. solids sedimentation, particle desorption, resuspension).

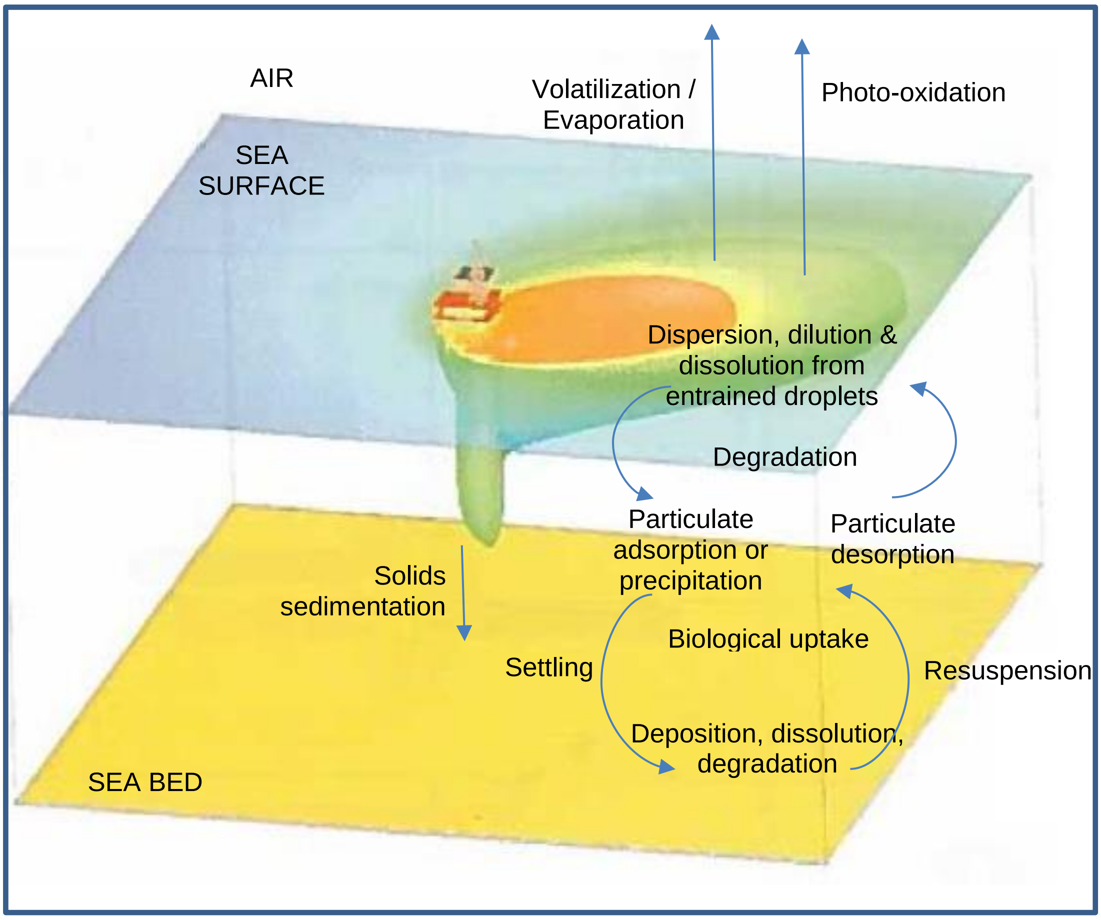

Figure 6-3 Natural processes affecting fate and transport of produced water effluent in the environment. Note: vertical scale of the initial plunge of the PFW plume is elongated for visualisation purposes.

6.3.3.6 Receptors at Tuna platform

PFW discharged to the marine environment has the potential to result in the following impacts:

- Change in water quality;
- Change in sediment quality;

As a result of change in water quality, change in sediment quality and / or habitat, further impacts may occur which include:

- Injury to fauna;
- Change in habitat;
- Change to the function, interests or activities of other users.

Receptors that could be credibly affected by the discharge of PFW are identified in Table 6-8 and Figure 6-4, with reference made to specific receptors or receptor groups per Table 5-2.

Table 6-8 Receptors affected by impacts associated with discharges of TNA PFW

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Water quality	✓ Open ocean, high energy environment, cool waters, 59 m water depth				
Sediment quality		✓ Sandy sea floor with some gravel			
Benthic habitats and communities			✓ Polychaetes, crustaceans and mollusc infauna; possible sponge, soft coral, other invertebrate filter-feeder epifauna		
Plankton			✓ Open ocean phyto- and zoo-plankton		
Fish			✓ Bony & cartilaginous fish, two vulnerable species (Great White and Whale sharks), overlaps distribution BIA for Great White shark, 29 km from Great White shark breeding BIA		
Marine Mammals - Seals			✓ Listed species the New Zealand Fur Seal and the Australian Fur Seal known to rest on the platform and swim alongside		
Marine Mammals - Cetaceans			✓ 27 cetacean species or species habitats occur, of which 5 species are listed (Sei, Blue, Fin, Southern Right and Humpback whales), facility overlaps foraging BIA for Blue whale and		

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
			distribution BIA for Southern Right whale, 33 km from Southern Right Whale migration BIA		
Australian Marine Parks and National Parks				✓ Ninety Mile Beach MNP (108 km), Point Hicks MNP (79 km), Gippsland Lakes NP (44 km)	
KEFs				✓ Overlaps with Shelf Rocky Reefs (but 26 km from South East Reef) and Upwelling East of Eden. 30 km to the Bass Cascade, 75 km to Big Horseshoe Canyon	
Commercial and recreational fisheries					✓ Likely fisheries are Bass Strait Central Zone Scallop, Small pelagic, Southern and Eastern Scalefish & Shark, Danish-seine and scalefish hook, Wrasse, and Southern Squid Jig (low intensity) Fisheries

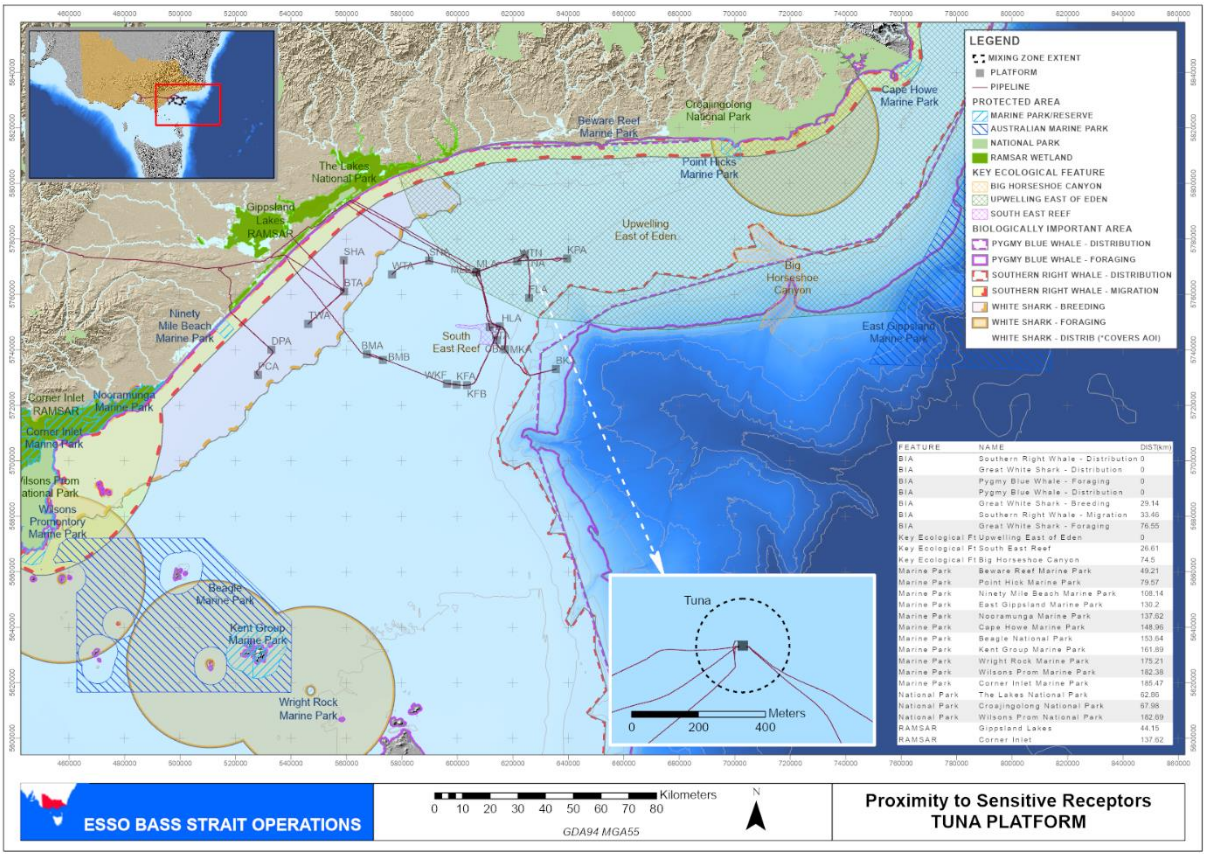

Figure 6-4 140 m mixing zone around TNA platform in relation to other environmental receptors

6.3.3.7 Tuna PFW impact assessment

Impacts to water quality

Physical properties of seawater are established within 10 m of the discharge point. Temperature changes using the RPS APASA (2016) model found that due to the turbulent mixing caused by the initial plunge and then buoyant rise of the effluent, in all cases the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location.

Chemical contaminants in PFW dilute quickly on the initial plunge, then more slowly with dispersion in the current around the platform. PFW is discharged at 16 times the ANZECC 99% species protection water quality criteria for hydrocarbons, 47 times for metals, and 91 times for inorganics; dilutes rapidly on its initial plunge to 10 times within 1 m and 50 times within 12.5 m. It reaches ANZECC 95% species protection water quality criteria within 19.4 m and ANZECC 99% species protection water quality criteria within 19.4 m of the discharge point.

PFW is discharged at between 7 and 56 times the background levels for hydrogen sulphide and up to 370 times the background levels of TOC (see Appendix F.1 – PFW data file), and gradually reduces to background levels with distance from the platform, reaching background levels within 130 m of the discharge point.

An in-situ water monitoring study found that all valid samples taken from the water column indicating the presence of the PFW plume were less than ANZECC 99% species protection water quality criteria at 59 m from the platform and beyond (see Appendix G.7 – Breakout Box 7).

Anions such as sodium, calcium, magnesium and potassium, and cations such as chloride, sulphate, bromide and bicarbonate are found in PFW however these ions (and their associated salts) are also commonly found in seawater and hence will not be discussed further (Pillard et al. 1996).

Potential Naturally Occurring Radioactive Materials (NORM) are not expected to occur in quantities that may result in significant environmental impacts and are therefore not discussed further.

Impacts to sediment quality

Some of the constituents in PFW, such as metals and hydrocarbons, may also become adsorbed onto the surface of suspended solids present in the PFW or in the receiving environment.

Accumulation of contaminants in sediments depends primarily on the volume/concentration of particulates in discharges or constituents that adsorb onto seawater particulates, the area over which those particulates could settle onto the seabed (dominated by current speeds and water depths). and the Actions of resuspension, bioturbation and microbial decay of those particulates in the water column and on the seabed will further reduce the concentration of settled sediments. Since the PFW plume is highly buoyant, and Bass Strait is a high energy environment, currents are likely to mobilise and disperse sediments around the platform, leading to lower overall concentrations in any one area.

TNA PFW contains the following chemicals which could impact marine sediments and an ANZECC (2000) or ANZECC (2013) interim sediment quality guideline value exists:

- Low molecular weight PAHs: Naphthalene, 2-methylnaphthalene, and to a lesser extent (lower number of detections): Acenapthene, Flourene, Phenanthrene
- High molecular weight PAHs: to a lesser extent (lower number of detections): Flouranthene and Pyrene
- Metals/Metalloids: Arsenic, Copper, Nickel and Zinc.

There is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment (see Appendix F – PFW Data file). There is a potential pathway for impacts to sediment through settling of constituents in the PFW plume.

An analysis of the TNA PFW discharge found that 96.2% of particles are ≤63 µm (clay or silt). Per Breakout Box 10, this silt and clay fraction (≤63 µm) is usually cited as the chemically active fraction which is associated with potential contaminants of concern (UNEP/WHO 1996). While there is potential for settling of particles in the TNA PFW plume, it is the larger particles (>63 µm) that may settle which are composed primarily of stable inorganic materials and are generally not associated with contaminants of concern (see Appendix G.10 – Breakout Box 10).

Monitoring results for offshore facilities generally show that natural dispersion processes appear to control the concentrations of potential contaminants from PFW in sediments to slightly above background concentrations (Neff et al. 2011). The results from in-situ sediment monitoring confirm this, since around TNA no PAHs were detected; and occurrences of metals/metalloids were isolated, levels remained low and detections above reference locations remained localised despite there being evidence of some gradients away from the platform (see Appendix G.8 – Breakout Box 8).

Given that at the TNA platform;

- sampling results indicate that less than 4% of particles in PFW may settle (due to their size)
- particles that settle are likely to be stable inorganic materials
- there were isolated observations of contaminants in PFW in sediments around TNA platform above ISQG “low” guideline values
- levels of contamination of copper and zinc in a gradient away from the platform remain of very low level and within a small radius

the PFW discharge is expected to have negligible impacts on sediment.

Impacts to biota

Potential impacts of PFW to biota have been assessed through WET testing and dilution modelling to establish a mixing zone. Marine biota inside the mixing zone may be exposed to chronic exposure to contaminants in PFW, however, the mixing zone is limited to a localised extent around the plume discharge point only.

Process chemicals are discharged to the sea in residual amounts if they partition into the PFW and are not removed via the available treatment processes. As WET testing was performed with samples that contained chemical additives, the WET testing results are indicative of the routinely discharged PFW and account for any potential biological impacts that could be incurred by the PFW including any chemical additives. In addition, the ecotoxicological impacts of process chemicals in PFW discharges was comprehensively investigated in a study by Henderson et al. (1999). The study tested 11 commonly used process chemicals (including biocides, corrosion inhibitors and demulsifiers) for their acute toxicity to marine bacterium, both directly in aqueous preparations and following their partitioning between oil and water phases. The study results indicated that toxicity of the PFW was not significantly altered by the presence of most process chemicals used in typical concentrations. A review of the study by Schmeichel (2017) notes that process chemicals make a small contribution to the overall acute toxicity profile of PFW discharges.

Relevant to all receptor types (ecotoxicity pathways) are the TNA WET testing results. 95% species protection criteria based on WET testing is met within 130 m of the discharge point (Appendix F – PFW data file). At this distance, 95% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of 'ecosystems in which aquatic biological diversity may have been adversely affected to a relatively small but measurable degree by human activity. The biological communities remain in a healthy condition and ecosystem integrity is largely retained' (ANZECC, 2000, p3.1-10). 99% species protection criteria based on WET testing is met within 140 m of the discharge point (Appendix F – PFW data file). At this distance, 99% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of an 'effectively unmodified, high conservation-value ecosystem' (ANZECC, 2000, p3.1-10). Outside 140 m contaminants in PFW will continue to reduce to background seawater concentrations. At these levels they are not expected to have any impact to biota.

Impacts to benthic communities and habitat

There are two pathways for potential impacts to benthic communities and habitats:

- Benthos feeding on sediments near the discharge could be subject to exposure to toxic effects of potentially higher-level contaminants of PAHs or metals if they are directly exposed to PFW for long periods; accumulate in sediments.
- Benthic Marine animals near a produced water discharge may bio-accumulate metals, phenols, and hydrocarbons from the ambient water, their food, or bottom sediments.

Direct exposure - chemical ecotoxicity effects

TNA whole effluent toxicity results (2014) show that the amphipod *Allorchestes compressa* was affected by direct exposure to more than 50% raw effluent (acute endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Allorchestes compressa* since TNA effluent is diluted 10 times within 1 m of the discharge point. The sea urchin *Heliocidaris tuberculate* was affected by exposure to more than 12.5% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Heliocidaris tuberculate* since TNA effluent is diluted 10 times within 1 m of the discharge point. The mussel *Mytilus galloprovincialis* was affected by exposure to more than 6.3% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge and possibly out to 12.5 m from the discharge point. Hence the only effect expected on *Mytilus galloprovincialis* is highly localised to within 1-12.5 m since TNA effluent is diluted by 50 times within 12.5 m of the discharge point.

Impacts from direct exposure to PAHs in PFW on fauna such as scallops, crustaceans and other molluscs within 140 m of the discharge could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size, such as was found during a study of PFW effluent exposure to sea scallops of greater than 10% raw effluent (Querbach et al. 2005, in Armsworthy et al., 2005). PFW discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). These effects are highly unlikely to occur at TNA since effluent is diluted by 10 times within 1 m of the discharge point. Also since the PFW plume is positively buoyant and does not contact the sea floor, it is expected that only fauna on the platform structure itself could be exposed and those on the sea floor are protected from direct exposure.

The range of marine acute LC50 values for arsenic (V) in water was 230-9600 µg/L for crustaceans and 330- 800 000 µg/L for molluscs (Vaughan 1996). In general, early life stages were more sensitive to arsenic than adults. The maximum arsenic level recorded in TNA undiluted PFW was 1 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence direct exposure to arsenic in TNA PFW is unlikely to have an impact on crustaceans or molluscs.

Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water. This effect could be felt by encrusting organisms on the structure (to 140 m horizontal radius of the discharge) but not seafloor organisms due to the positive buoyancy of the plume.

Bioaccumulation

A large study for the Gulf of Mexico Offshore Operators Committee examined bioaccumulation in tissues of mollusc, crustacean, and three fish species in and around 11 platforms in the Gulf of Mexico discharging over 1000 kL/d (Continental Shelf Associates, 1997). The study examined bioaccumulation of five metals (As, Cd, Hg, 226Ra and 228Ra); three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene; and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. They concluded that there is no relationship between the proximity of marine animals to offshore PFW discharges and concentrations in their edible tissues of the chemical constituents.

Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al. (2011). There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalenes and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs but not fish, from discharging than from non-discharging facilities. These PAH could have been derived from PFW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to marine animals (Neff et. al. 2011).

Effects from bioaccumulation has been primarily associated with low-molecular weight PAHs. Both BTEX and hydrogen sulphide are not bioaccumulative (Neff 2002, ANZECC, 2000 respectively). PAHs were not observed in either waters or sediments around TNA above relevant guideline criteria as part of the 2018 in-situ monitoring program, and hence the potential for bioaccumulation is low.

There were no significant differences in benthic infauna distributions observed in an in-situ study around Tuna in 2018. This study found that at both near and far zones around the platform and at reference sites, crustaceans dominated the benthic infauna, followed by polychaetes. For less than 15% of the total number of taxa, infauna abundance significantly decreased with distance from the platform, owing mostly to re-distribution of coarser sediments around the platform due to the platform presence (Appendix G.9 – Breakout Box). The change in abundance could not be correlated with increased sediment contaminants found in PFW. This is consistent with the findings in Neff et al. (1992) where distributions of benthic communities around the platform (in 8 m water depth) were explained in large part by the influence of sediment grain size on benthic community structure; and there was no correlation between faunal density and the concentration of total hydrocarbons in sediments.

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments (such as at TNA) the potential for impacts to benthic infauna would be even lower.

Copper is readily accumulated by plants and animals; bioconcentration factors ranging from 100 to 26000 have been recorded for various species of phytoplankton, zooplankton, macrophytes, macroinvertebrates and fish (Spear & Pierce 1979). Toxic effects of metals occur when the rate of uptake exceeds the rates of physiological or biochemical detoxification and excretion (Rainbow 1996, in ANZECC 2000). For benthic organisms, effects of copper on crustaceans was published as ranging between 8.5 µg/L (Callianassa australiensis, 10-14 day EC50) to 42 µg/L (Mysidiopsis bahia, from 29-

51 d MATC, reproduction) and on molluscs between 0.4 µg/L (Mytilus edulis, from 30-d EC50, reproduction of 2 µg/L) to 20000 µg/L (Ostrea edulis, 5-d LC50) (ANZECC 2000). TNA PFW copper concentrations were 14 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). As TNA PFW is diluted 10 times within 1 m of the discharge, any effects on molluscs or crustaceans from exposure to or bioaccumulation of copper in PFW would be limited to organisms within 1 m of the discharge.

In general, marine invertebrates are more sensitive to nickel than vertebrates (ANZECC 2000). Chronic effects of nickel on crustaceans was published as ranging between 141 µg/L (36-d chronic mortality, Mysidopsis bahia, Gentile et al. 1982) and 160 µg/L (Portunus pelagicus: from 42d MATC growth of 320 µg/L) to 6000 µg/L from 5-8 d LC50. Effects on echinoderms published as 2600 µg/L (Asteria forbesi from 7-d LC50) molluscs between 240 (Crassostrea virginica; from 12-d LC50 of 1200 µg/L) to 450000 µg/L from 7-12 d LC50; and algae: 1 sp, Nitzschia closterium 50 µg/L, from 5-d EC50 growth (Australian data) (all from ANZECC 2000). TNA PFW nickel concentrations were 18 µg/L or less in 5 of the 8 tests and non-detect in other years (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of nickel in TNA PFW is expected.

Zinc is adsorbed by suspended material. Zinc was found to bioaccumulate in freshwater animal tissues 50 to 1130 times but bioaccumulation is not generally considered a problem for zinc (ANZECC 2000). For benthic organisms, zinc effects on crustaceans ranged from 15 µg/L (Acanthomysis sp, growth) to 2100 µg/L (8–28 d NOEC), echinoderms (Asterias forbesi), 460 µg/L (from 7-d LC50) and molluscs: 5 spp, 7–11 d NOEC (from LC50), 15 µg/L (Crassostrea gigas) to 27500 µg/L (ANZECC 2000). Algae were affected at between 13 µg/L (Nitzschia closterium) to 796 µg/L. (Skeletonema sp) (5–10 d NOEC). TNA PFW zinc concentrations were 13 µg/L and 2 µg/L in two of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on benthic animals or plants expected as a result of the levels of zinc in TNA PFW discharge.

Some aquatic organisms may accumulate cobalt, particularly some aquatic plants and benthic organisms (Cole & Carson 1981 in ANZECC 2000). For crustaceans, published ranges of effect concentrations were 9-d LC50, 45 µg/L (Palaemon serratus) to 45 400 µg/L (Carcinus maenas). The lowest geometric mean for converted NOEC was 9 µg/L. Homarus vulgaris also had a low g.m. for NOECs of 65 µg/L; nematode Monhystera sp, 4-d LC50, 94 000 µg/L; and algae 4-5 d EC50, growth, 300 µg/L (Dytilum sp) to 23 600 µg/L (Phaeodactylium sp) (ANZECC 2000). TNA PFW cobalt concentrations were 0.14 µg/L in one of the 8 tests and non-detect in other years (Appendix F). Hence there are no effects on benthic animals or plants expected as a result of the levels of cobalt in TNA PFW discharge.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). The results from the TNA in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments is unlikely.

Given the above, benthic biota around TNA platform are highly unlikely to be affected by the PFW discharge. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform structure within 140 m of the discharge point. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

The exposure of biota to in-water contaminants is expected to be low, due to the high initial dilution of the plume, and even lower for mobile biota, accounting for multiple exposures of PFW to the same animal, that would be necessary for bioaccumulation. Filter feeders on the seafloor will experience levels of in-water contaminants well below ANZECC water quality guidelines.

Literature also supports the finding that per Neff (2011), “in well-mixed estuarine and offshore waters, elevated concentrations of saturated hydrocarbons and PAH in surficial sediments sometimes are observed out to a few hundred meters from a high-volume produced water discharge.

There were no PAHs accumulated in sediments around West Kingfish PFW discharges despite the highest naphthalene flow- and suspended sediment-weighted PFW load in Bass Strait.

There were no heavy metal toxicants systematically observed above the ANZECC sediment guideline criteria in sediments around Tuna or West Kingfish in the 2018 study despite the high metals flow-weighted load across all Bass Strait discharging platforms, and observations of sediment toxicant levels above the sediment guideline criteria around these platforms were isolated, most likely from corroding debris or structures rather than PFW, and likely to have little overall effect on benthic environments.

BTEX is known to be toxic to marine organisms and has been shown to result in developmental defects (Fucik et al. 1995) but does not significantly bio-accumulate. As such, potential bioaccumulative impacts from the decrease in water quality due to BTEX are expected to be insignificant.

Hydrogen sulphide is a by-product rapidly produced by organisms but it is non-bioaccumulative.

Impacts to plankton

There are three pathways for potential impacts to plankton:

- Exposure to temperature effects on direct exposure
- Stimulatory effects of nutrients in the plume, leading to eutrophication of waters
- Exposure to toxic effects of chemical constituents of PFW if plankton are directly exposed for long periods (i.e. directly in the plume)

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on plankton are not credible.

Stimulatory effects from nutrients in the plume

Discharges of nutrients and hydrocarbons in the PFW plume can increase the localised abundance of plankton. For example, ammonia may elicit inhibitory (toxic) and/or stimulatory (e.g. eutrophication) responses from resident biota (Neff, 2011). Plankton could be attracted to localised higher concentrations of these constituents within the mixing zone and as a result plankton populations can rapidly increase. However, increased planktonic activity and turnover mass rates within the mixing zone is not expected to have any marked change on the water quality due to the high levels of movement of water around the platform from the action of currents and waves. Levels of nitrate and phosphates are low (not unlike other produced waters, Neff, 2011) and hence are not likely to cause eutrophication. Supporting this there is anecdotal evidence that no phytoplankton blooms have ever been recorded at a Bass Strait Esso facility.

Direct exposure – chemical ecotoxicity effects

Phytoplankton are among the most sensitive organisms to both forms of arsenic. The Australian diatom Nitzschia closterium is highly sensitive to arsenic (III), with a 72-h EC50 for growth inhibition of 7 µg/L (Florence & Stauber 1991), compared to >2000 µg/L for arsenic (V). An Environmental Concern Level (ECL, see Section 8.3.4.5) of 2.3 µg/L was derived for As (III) in marine waters, using an AF of 100 (ANZECC 2000). TNA PFW arsenic concentrations were 1 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no impacts to plankton anticipated from arsenic in TNA PFW.

Plankton have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Any impacts as a result of direct exposure of planktonic communities to PFW are expected to be confined to the 140 m zone to 99% species protection. Direct exposure of planktonic communities to PFW within the 140 m zone (to 99% species protection criteria based on WET testing) is not considered to result in significant impacts at the population level of organisms that could affect broader ecological diversity or productivity of the area surrounding the facility.

Impacts to fish

There are three pathways for potential impacts to fish:

- Exposure to temperature effects on direct exposure
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed for long periods (i.e. directly in the plume)
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed to contaminated sediments

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on fish are not credible.

Direct exposure – chemical ecotoxicity effects

Early lifestages of fish (embryos, larvae) within the 140 m zone to 99% species protection criteria would be most susceptible to the exposure from chemical constituents in the PFW discharge, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011) which is not likely to be the case at TNA. Larvae entrained in the outfall may only be exposed to higher concentrations for a short period relative to the buoyancy of the organism (Querbach, et al. 2005). Outside the 140 m radius, early lifestages of fish are not expected to be affected at all.

Effects from copper in water on fish was published as ranging between 30 µg/L (2 spp, from 12-14 d EC50, hatch & mortality) to 260 µg/L (Menidia menidia, 11-d EC50, hatch) (ANZECC 2000). TNA PFW copper concentrations were 14 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of copper in TNA PFW.

Effects from zinc in water on fish was published as 10 400 µg/L (Fundulus heteroclitus, 7-d NOEC of from LC50) (ANZECC 2000). TNA PFW zinc concentrations were 13 µg/L and 2 µg/L in two of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of zinc in TNA PFW.

Effects from cobalt in water on fish was published as 52 500-227 000 µg/L (from 4-9 d LC50) (ANZECC 2000). TNA PFW cobalt concentrations were 0.14 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of cobalt in TNA PFW.

Levels of nickel (max detected 11 µg/L) in the TNA discharge are well below the concentrations that could have effects on fish (Fundulus heteroclitus, 30 000 µg/L from 7-d LC50; from ANZECC 2000).

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement. Fish also exhibit a strong avoidance reaction to hydrogen sulphide (USEPA 1986 in ANZECC 2000).

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound's volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). The dilution ratio for TNA PFW to ANZECC 99% species protection water criteria for Benzene is 12, and TNA PFW is diluted 10 times within 1 m and 50 times within 12.5 m, hence BTEX is not expected to have any toxic effects beyond 12.5 m. Many fish species can metabolise hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012).

Whole effluent ecotoxicity data from TNA PFW shows that the barramundi fish *Lates calcarifier* experienced effects above 50% raw effluent exposure (chronic endpoint). This is unlikely to occur anywhere in the mixing zone except directly at the discharge point itself. Whilst this species is not local to Bass Strait, no effect is expected on fish similar to *Lates calcarifier* since TNA effluent is diluted by 10 times within 1 m of the discharge point.

Exposure to contaminated sediments – chemical ecotoxicity effects

Effects from fish directly exposed to contaminated sediments above 22 mg/kg PAH could result in gill hyperplasia, reduced phagocytic activity of macrophages and pancreatic necrosis (spot, Hinkle-Conn et al., 1998). However this is highly unlikely to be the case as the highest level of PAHs in sediment around TNA was 0.004 mg/kg.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient fish such as great white sharks, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to fish, the limited spatial extent of the water quality (130 m radius), the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on fish particularly the great white shark from PFW discharges when assessed against the relevant criteria in the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to seals

There are three pathways for potential impacts to seals:

- Exposure to toxic effects of chemical constituents of PFW if seals are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Produced water plumes predominantly result in dissolved contaminants and they rarely cause a defined layer on the sea surface (silvery sheen is the lowest level according to the Bonn agreement and usually patchy if at all present from the PFW discharge). Hence potential impact pathways through contact of hydrocarbons with seal fur and ingestion are not credible.

Direct exposure – chemical ecotoxicity effects

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005). As such, it is highly unlikely that these potential impact pathways will be significant. In addition, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986).

Effects from inhalation of hydrocarbon vapours from PFW sheens

Inhalation of hydrocarbon vapours could cause toxic effects. However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Seals are highly mobile and active animals and do not spend all their time at the water surface, as such, it is highly unlikely that this potential impact pathways will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Exposure to on-sea hydrocarbons could cause irritation to the eyes and oral cavity. However seals are unlikely to remain swimming within the discharge plume for long periods as they are highly active animals, travel great distances and forage at various depths. As such, it is highly unlikely that this potential impact pathways will be significant so as to not have any chronic impacts to seals.

Bioaccumulation through ingestion of impacted food sources

As impacts to the predominant seal food source of fish are of very low likelihood (as above), bioaccumulation through ingestion of impacted food sources is unlikely to have any impact on seals.

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, coupled with seals being highly mobile active animals who do not spend all their time in the water or at the water surface, seals are unlikely to be exposed to elevated contamination concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as pelagic fish species). Given the potential absence of impacts to seals, the limited spatial extent of the water quality (130 m radius) the predicted short interaction duration (i.e. minutes at a time) with the PFW plume, and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

There are four pathways for potential impacts to cetaceans:

- Exposure to toxic effects of chemical constituents of PFW if cetaceans are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Direct exposure – chemical ecotoxicity effects

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathways will be significant. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013).

Effects from inhalation of hydrocarbon vapours from PFW sheens

As a result of inhaling volatile compounds when surfacing, cetaceans can experience lung congestion (Geraci & St. Aubin 1990); or irritation or damage to mucous membranes or airways (Helm et al., 2015). However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Cetaceans can be exposed through direct contact with the eyes, potentially leading to inflammation (Geraci & St. Aubin 1990). Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Bioaccumulation through ingestion of impacted food sources

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

The mixing zone overlaps the foraging BIA for the blue whale and distribution BIA for the Southern Right Whale; however, given the localised area of impact and that whales are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the Conservation Management Plan of either the Blue Whale or Southern Right Whale and the discharge activity is not inconsistent with those plans.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient cetaceans such as migrating whales, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality (130 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on cetaceans from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

There are three potential impact pathways for fisheries:

- Tainting (hydrocarbon odour in caught fish) due to tissue accumulation of hydrocarbons in PFW
- Impacts to the safety of humans through the consumption of target species tissues that are impacted by PFW.
- Reduction of fisheries stocks, through the direct impact of PFW on target species and nurseries

Tainting

Per Appendix F, ANZECC seafood taint criteria is reached within 12.5 m of the discharge point. (Note: Appendix G.3 – Breakout Box 3 applies to the detection of other phenols under the seafood taint guidelines). The total area represented by a 12.5 m radius at TNA is 490 m^2 (1/20th of a hectare), and cumulative area across all Bass Strait platform PFW discharges is <2000 m^2 (1/5th of a hectare), representing an extremely small proportion of the total fisheries area. Hence the discharge is highly unlikely to cause taint in fisheries-caught fish.

Impacts to seafood safety for humans

Since fish or shellfish are not harvested around the PFW plume or mixing zone out to at least 500 m from the platform, and the zone in which 99% species protection criteria is reached extends to only 140 m from the platform, there is no effect of the PFW discharge on humans through consumption.

Impacts to fisheries stocks

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone), where they are directly present in the PFW plume (within 140 m radius), may be exposed to chronic sub-lethal impacts (see above) however due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Stakeholder feedback confirmed that although fishers had been able to see discharges from the Bass Strait platforms from beyond the 500 m exclusion zone, the discharge did not have any effect on fisheries or fisheries equipment, or amenity for the fishers. There is general acknowledgement among fishers that Esso’s facilities provide safe habitat for juvenile fisheries species, and there have been no complaints or issues raised to date about taint, food safety or reduction of fisheries stocks due to the platform discharges. Ongoing dialogue with fishing communities is part of Esso’s stakeholder engagement plan.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Nutrient-rich sediment turnover is highest in areas of upwelling, and hence discharge of any additional nutrients also naturally found on the sea floor in PFW is therefore even less likely to have impacts on the KEF. The discharge of other contaminants in PFW is not relevant to the values of this KEF.

The Bass Cascade: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as Benthic habitats and communities applies to this KEF as described above. Given the distance from the PFW mixing zone to the reported location of the South East Reef, impacts on this reef are not anticipated.

Cumulative impacts to water from multiple discharges

Discharges of PFW from nearby platforms were modelled and shown not to interact with the PFW mixing zone (Appendix G.4 – Breakout Box 4). WTN platform is not and will not be discharging PFW over the life of this EP and hence there are no other PFW plumes within 3 km of the TNA discharge.

Other continuous discharges from the same platform are limited to discharges from pile subsea windows. These discharge at 38.5 m (ODSP) and 52.1 m (CDSP) below sea level (Table 2-5), deeper than the produced water effluent pipe depth at 28.8 m below sea level. Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window. Discharges of water containing chemicals (at discharge, all chemicals are CHARM Gold/Silver or OCNS D/E (Table 6-22)) or dissolved hydrocarbons from the pile will be intermittent or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. It is therefore expected that any exposure will be limited in duration.

Dispersion modelling for TNA PFW shows the maximum plunge depth from the discharge point under all current speeds is to 34 m below sea level, hence any cumulative impacts from the interaction with the produced water effluent plume within the mixing zone is considered unlikely.

Other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the PFW but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

Historical activities such as discharging muds and cuttings during drilling may have resulted in changes to the sea floor sediment chemical characterisation above background levels. This includes the discharge of water based muds and barite containing barium, an inert metal; and the discharge of cuttings from natural rock formations encountered during drilling, together with small amounts of residual drilling muds on cuttings. Any changes to sediment quality from historical impacts from background will be considered as part of the surrender of title process. The last drilling program on TNA was in approximately 2005, hence discharged fluids or solids from the drilling program is expected to have at least partially been dispersed or bioremediated. There is not expected to be a significant cumulative impact to sediment quality from the additive effect of discharging PFW to sediments containing higher levels of barium or residual drilling mud constituents.

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes cumulative impacts on marine fauna is unlikely.

As fishing is not carried out within 500 m of the platform, which is beyond the mixing zone of 140 m no cumulative impacts from multiple discharges is likely on commercial and recreational fishing.

Given the distance to other sensitive receptors (Table 5-2) cumulative impacts from multiple discharges are highly unlikely.

6.3.3.8 Tuna Consequence Evaluation

Impacts from TNA PFW are limited to a localised mixing zone around the discharge point, with negligible impacts to sediment. Potential impacts to biota, including benthic habitats and communities, plankton, fish, seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).

Effects could be ongoing, including through bioaccumulation of PAHs and persistent chemicals, but effects are confined to some biota on the platform structure itself (e.g. crustaceans) or dispersed in a small radius around the platform water and sediments at low and safe concentrations. Within the mixing zone, there could be sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level. The environment is highly endemic, with few endangered and rare species present, but is generally strong and resilient, and provides some ecosystem services (e.g. fisheries).

The consequence level is therefore assessed as **Consequence Level III.**

To ensure continuing confidence in the consequence level the Monitoring and Management Framework will be implemented. If routine monitoring was to detect levels in PFW above the trigger values and there was the potential to impact the ecosystem integrity, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are not realised. A sampling plan to demonstrate compliance with the approved mixing zone boundary will be developed for the sediment survey. The sampling plan outlines and justifies sampling locations and when concentration and bioavailability testing occur.

6.3.4 West Kingfish platform

6.3.4.1 Volume

A summary of historic and five-year-projected PFW discharge volume from the platform is provided in Figure 6-5 and Figure 6-6 respectively. The maximum capacity of the system is 17390 kL/d, however based on historical discharge rates the platform is expected to discharge produced water at a much lower rate of approximately 8000-10000 kL/d until oil shutdown in approximately 2022-2023.

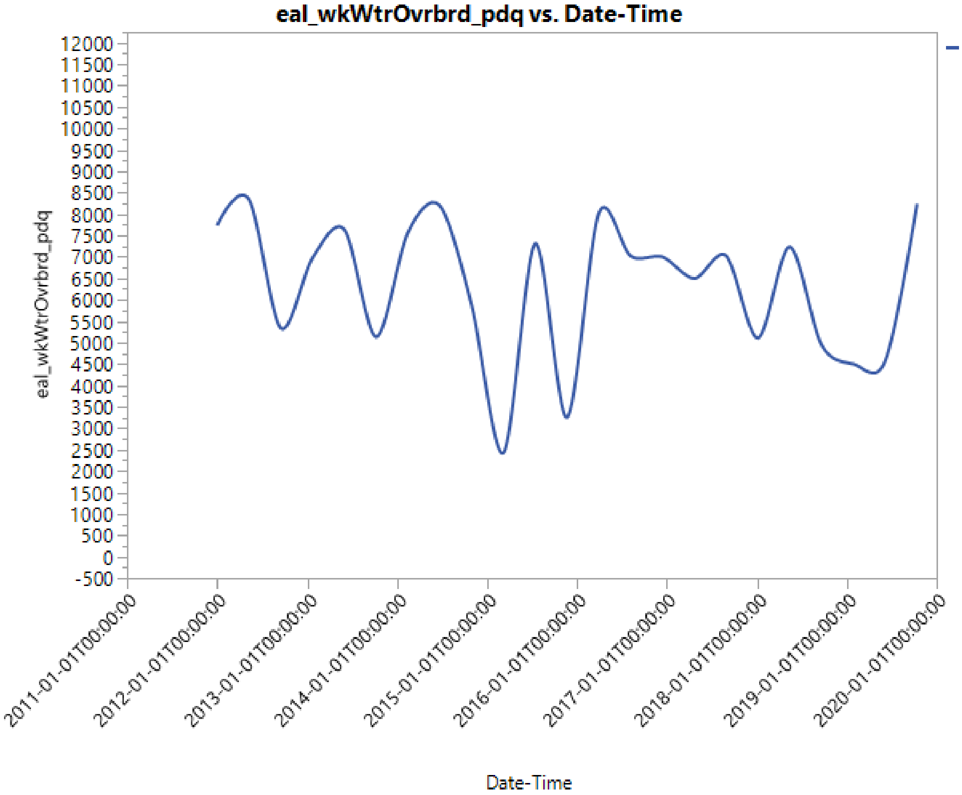

Figure 6-5 Historic smoothed overboard discharge volume (kL/d) (2012-2019)

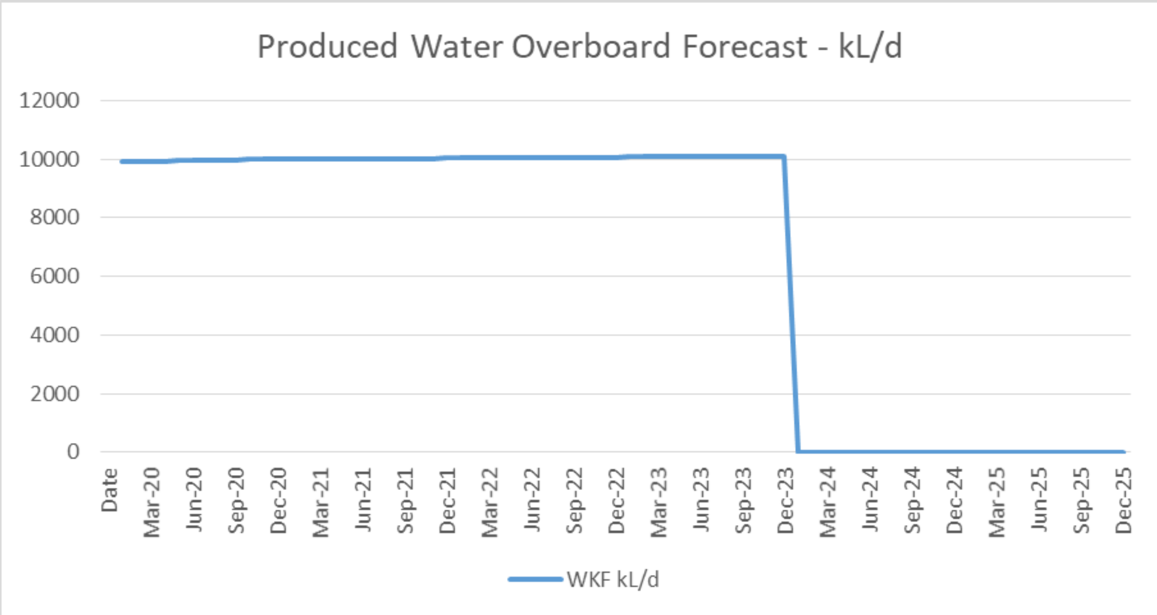

Figure 6-6 Five-year-projected maximum PFW discharge volumes, kL/d.

6.3.4.2 Composition

Physical and chemical make-up

Physical and chemical make-up of PFW is shown in Appendix F – PFW Data file.

Chemical additives

Chemicals in Table 6-9 are added to the platform's water handling system in order to aid oil in water treatment. Chemicals in Table 6-10 are added into the process on the platform for other reasons and could remain at residual levels in the water handling system.

Table 6-9 Chemicals added to West Kingfish water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
None	N/A	N/A	N/A

Table 6-10 Chemicals added to West Kingfish process that could remain at residual levels in the water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Gas lift corrosion inhibitor (e.g. Baker-Hughes CGW24013)	Water phase	Gas lift into wells, upstream of water handling system	Yes

Oil in water monitoring results

Oil in water concentrations are measured on the platform using a continuous online monitor that determines the levels of oil using the way the PFW scatters light under UV fluorescence.

Data is provided in Appendix F for the platform's daily average overboard discharge levels of oil in water (in mg/L) and oil load (kg/d) since 1 Jan 2020 (reflecting the period following the NOPSEMA General Direction 740 in late 2019 where changes were made to the reporting and recording of oil in water).

Data is also provided for the same period showing the cross-check of platform online monitor readings with routine laboratory tests of oil and grease, with the alignment within a +/- 6 mg/L offset.

6.3.4.3 Ecotoxicology

To determine toxicity of the PFW discharge, whole effluent toxicity (WET) testing was performed in 2014 and 2020 across six tests (five chronic, one acute) and eight tests (seven chronic, one acute) respectively across at least 5 different species representing at least four different taxonomic groups. Further details of the ecotoxicology testing can be found in Appendix G.4 – Breakout Box 4. Chemical composition samples were taken at the same time as the samples for WET testing.

Chemical additives added at the time of sampling and ecotoxicology testing on West Kingfish in 2014 and 2020 were Baker-Hughes CGW24013.

Summarised results of the WET testing are shown in Appendix F.

A Burrlioz model has been run with the results from the WET testing (following Warne, 2018) with the 95% and 99% species protection level of effluent shown in Appendix F.

6.3.4.4 Movement, dispersion and dilution

A dispersion model was designed and calibrated to show the movement dispersion and dilution of the PFW discharge around the platform. Appendix G.6 – Breakout Box 6 shows the setup and calibration details for the model. Dispersion model inputs and outputs are summarized in Appendix F.

6.3.4.5 Fate and transport of West Kingfish PFW

Fate and transport of WKF PFW is no different to TNA PFW as outlined in Section 5.3.2.5.

6.3.4.6 Receptors at West Kingfish platform

PFW discharged to the marine environment has the potential to result in the following impacts:

- Change in water quality;
- Change in sediment quality;

As a result of change in water quality, change in sediment quality and / or habitat, further impacts may occur which include:

- Injury to fauna;
- Change in habitat;
- Change to the function, interests or activities of other users.

Receptors that could be credibly affected by the discharge of PFW are identified in Table 6-11 and Figure 6-7, with reference made to specific receptors or receptor groups per Table 5-2

Table 6-11 Receptors affected by impacts associated with discharges of WKF PFW

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Water quality	✓ Open ocean, high energy environment, cool waters, 73 m water depth				

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Sediment quality		✓ Sandy sea floor with some gravel, possibly higher percentage of coarser-grained sand or gravel			
Benthic habitats and communities			✓ Polychaetes, crustaceans and mollusc infauna; possible sponge, soft coral, other invertebrate filter-feeder epifauna		
Plankton			✓ Open ocean phyto- and zoo-plankton		
Fish			✓ Bony & cartilaginous fish, two vulnerable species (Great White and Whale sharks), distribution BIA for Great White shark, 42 km from Great White shark breeding BIA, 66 km from Southern Right Whale migration BIA		
Marine Mammals - Seals			✓ Listed species the New Zealand Fur Seal and the Australian Fur Seal known to rest on the platform and swim alongside		
Marine Mammals - Cetaceans			✓ 27 cetacean species or species habitats occur, of which 5 species are listed (Sei, Blue, Fin, Southern Right and Humpback whales), facility overlaps foraging BIA for Blue whale and distribution BIA		

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
			for Southern Right whale		
Australian Marine National Parks and National Parks				✓ Ninety Mile Beach MNP (79 km), Point Hicks MNP (129 km), Beagle MNP (101 km), Gippsland Lakes NP (74 km)	
KEFs				✓ Overlaps with Shelf Rocky Reefs (18 km to South East Reef), 35 km to Upwelling East of Eden, 30km+ to Bass Cascade, 112 km to Big Horseshoe Canyon	
Commercial and recreational fisheries					✓ Likely fisheries are Small pelagic, Southern and Eastern Scalefish & Shark, Danish-seine and scalefish hook, Wrasse, and Southern Squid Jig (low intensity) Fisheries

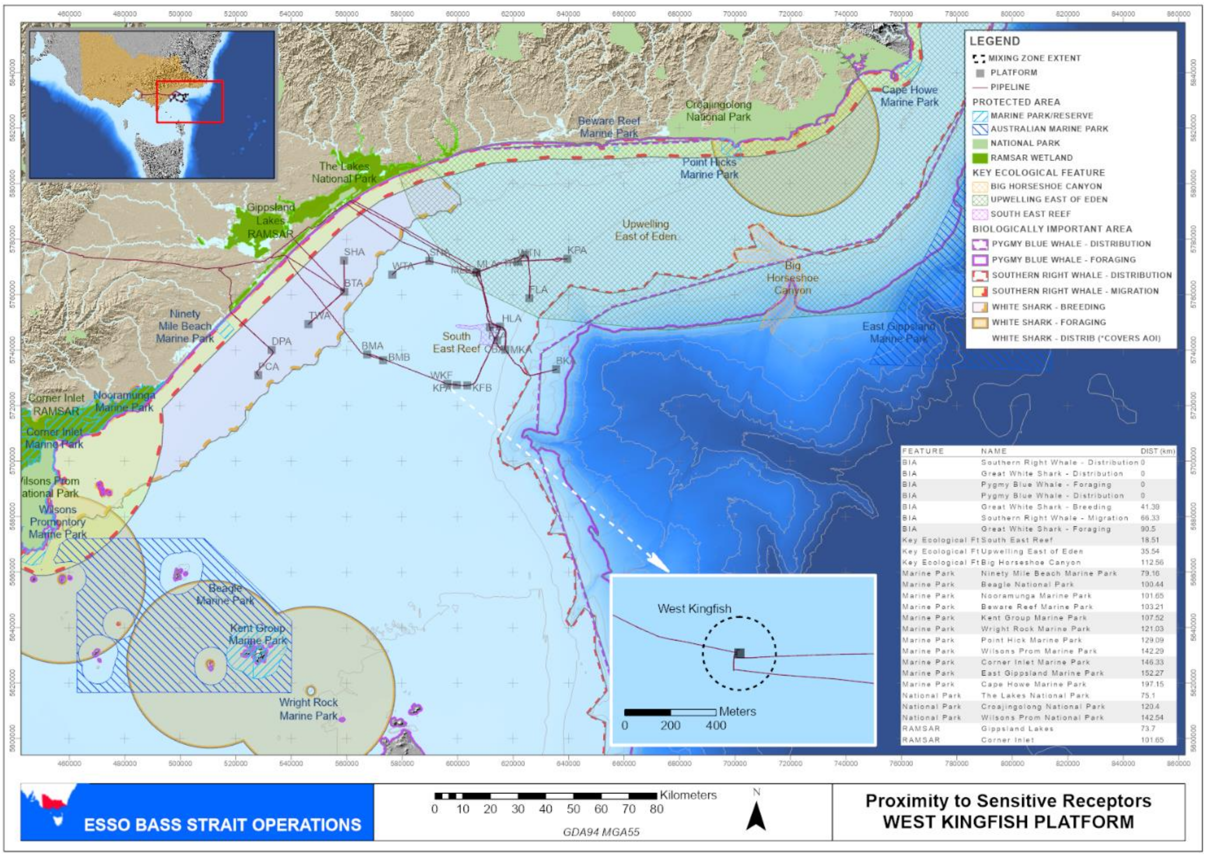

Figure 6-7 **160 m mixing zone around WKF platform in relation to other environmental receptors**

6.3.4.7 West Kingfish PFW impact assessment

Impacts to water quality

Physical properties of seawater are established within 10 m of the discharge point. Temperature changes using the RPS APASA (2016) model found that due to the turbulent mixing caused by the initial plunge and then buoyant rise of the effluent, in all cases the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location.

Chemical contaminants in PFW dilute quickly on the initial plunge, then more slowly with dispersion in the current around the platform. PFW is discharged at 7 times the ANZECC 99% species protection water quality criteria for hydrocarbons, 414 times for metals (due to Chromium where levels of Total Chromium is assumed to be all Chromium-VI, otherwise 8 times if assuming that Chromium is of a lower toxicity form (CrIII)), and 38 times for inorganics; dilutes rapidly on its initial descent, and reaches ANZECC 95% water quality criteria within 17 m; and ANZECC 99% water quality criteria within 160 m (if levels of Total Chromium is assumed to be all Chromium-VI, otherwise within 17 m).

PFW is discharged at between 28 and 224 times the background levels for hydrogen sulphide and up to 740 times the background levels of TOC (see Appendix F.4 – PFW data file) and gradually reduces to background levels with distance from the platform, reaching background levels within 160 m of the discharge point and defining the extent of the mixing zone for WKF platform.

Anions such as sodium, calcium, magnesium and potassium, and cations such as chloride, sulphate, bromide and bicarbonate are found in PFW however these ions (and their associated salts) are also commonly found in seawater and hence will not be discussed further (Pillard et al. 1996).

Potential Naturally Occurring Radioactive Materials (NORM) are not expected to occur in quantities that may result in significant environmental impacts and are therefore not discussed further.

Impacts to sediment quality

WKF PFW contains the following chemicals which could impact marine sediments and an ANZECC (2000) or ANZECC (2013) interim sediment quality guideline value exists:

- Low molecular weight PAHs: Naphthalene, 2-methylnaphthalene, and to a lesser extent (lower number of detections): Flourene, Phenanthrene
- High molecular weight PAHs: None
- Metals/Metalloids: Chromium, Copper, Nickel and Arsenic.

There is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment (see Appendix F – PFW Data file). There is a potential pathway for impacts to sediment through settling of constituents in the PFW plume.

An analysis of the WKF PFW discharge found that 99.7% of particles are ≤63 µm (clay or silt). Per Breakout Box 10, this silt and clay fraction (≤63 µm) is usually cited as the chemically active fraction which is associated with potential contaminants of concern (UNEP/WHO 1996). While there is potential for settling of particles in the WKF PFW plume, it is the larger particles (>63 µm) that may settle which are composed primarily of stable inorganic materials and are generally not associated with contaminants of concern (see Appendix G.10 – Breakout Box 10).

Monitoring results for offshore facilities generally show that natural dispersion processes appear to control the concentrations of potential contaminants from PFW in sediments to slightly above background concentrations (Neff et al. 2011). The results from in-situ sediment monitoring confirm this, and around WKF found no valid samples for PAHs, chromium, or nickel above the ANZECC (2013) ISQG "low" criteria (see Appendix G.8 – Breakout Box 8). Occurrences of metals/metalloids were isolated, levels remained low and detections above reference locations remained localised despite there being evidence of some gradients away from the platform (see Appendix G.8 – Breakout Box 8).

Given that at the WKF platform;

- sampling results indicate that less than 1% of particles in PFW may settle (due to their size)
- particles that settle are likely to be stable inorganic materials
- there were no valid observations of contaminants in PFW in sediments around WKF platform above ISQG "low" guideline values
- levels of contamination of nickel in a gradient away from the platform remains of very low level and within a small radius

the PFW discharge is expected to have negligible impacts on sediment.

Impacts to biota

Potential impacts of PFW to biota have been assessed through WET testing and dilution modelling to establish a mixing zone. Marine biota inside the mixing zone may be exposed to chronic exposure to contaminants in PFW, however, the mixing zone is limited to a localised extent around the plume discharge point only.

Process chemicals are discharged to the sea in residual amounts if they partition into the PFW and are not removed via the available treatment processes. As WET testing was performed with samples that contained chemical additives, the WET testing results are indicative of the routinely discharged PFW and account for any potential biological impacts that could be incurred by the PFW including any chemical additives. In addition, the ecotoxicological impacts of process chemicals in PFW discharges was comprehensively investigated in a study by Henderson et al. (1999). The study tested 11 commonly used process chemicals (including biocides, corrosion inhibitors and demulsifiers) for their acute toxicity to marine bacterium, both directly in aqueous preparations and following their partitioning between oil and water phases. The study results indicated that toxicity of the PFW was not significantly altered by the presence of most process chemicals used in typical concentrations. A review of the study by Schmeichel (2017) notes that process chemicals make a small contribution to the overall acute toxicity profile of PFW discharges.

Relevant to all receptor types (ecotoxicity pathways) are the WKF WET testing results. 95% species protection criteria based on WET testing is met within less than 28 m of the discharge point (Appendix F – PFW data file). At this distance, 95% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of ‘ecosystems in which aquatic biological diversity may have been adversely affected to a relatively small but measurable degree by human activity. The biological communities remain in a healthy condition and ecosystem integrity is largely retained’ (ANZECC, 2000, p3.1-10). 99% species protection criteria based on WET testing is met within less than 42 m of the discharge point (Appendix F – PFW data file). At this distance, 99% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of an ‘effectively unmodified, high conservation-value ecosystem’ (ANZECC, 2000, p3.1-10). Outside 42 m to the remainder of the boundary of the mixing zone, contaminants in PFW will continue to reduce to background seawater concentrations. At these levels they are not expected to have any impact to biota.

Impacts to benthic communities and habitat

There are two pathways for potential impacts to benthic communities and habitats:

- Benthos near the discharge could be subject to exposure to toxic effects of PAHs or metals if they are directly exposed to PFW for long periods;
- Benthic animals near a produced water discharge may bio-accumulate metals, phenols, and hydrocarbons from the ambient water, their food, or bottom sediments.

Direct exposure - chemical ecotoxicity effects

WKF whole effluent toxicity results (2014) show that the amphipod *Allorchestes compressa* was affected by exposure to more than 50% raw effluent (acute endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Allorchestes compressa* since WKF effluent is diluted 10 times within 1 m of the discharge point. The sea urchin *Heliocidaris tuberculate* was affected by exposure to more than 12.5% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Heliocidaris tuberculate* since WKF effluent is diluted 10 times within 1 m of the discharge point. The mussel *Mytilus galloprovincialis* was affected by exposure to more than 6.3% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge and possibly out to 17 m from the discharge point. Hence the only effect expected on *Mytilus galloprovincialis* is highly localised to within 1-17 m since WKF effluent is diluted by 50 times within 17 m of the discharge point.

Impacts from PAHs in PFW on fauna such as scallops, crustaceans and other molluscs within 42 m of the discharge could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size, such as was found during a study of PFW effluent exposure of greater than 10% to sea scallops (Querbach et al. 2005, in Armsworthy et al., 2005). PFW discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). These effects are highly unlikely to occur at WKF since effluent is diluted 10 times within 1 m of the discharge point. Additionally, the PFW plume is positively buoyant and does not contact the sea floor, it is expected that only fauna on the platform structure itself could be exposed and those on the sea floor are protected from direct exposure.

The range of marine acute LC50 values for arsenic (V) in water was 230-9600 µg/L for crustaceans and 330- 800 000 µg/L for molluscs (Vaughan 1996). In general, early life stages were more sensitive to arsenic than adults. The maximum arsenic level recorded in WKF undiluted PFW was 110 µg/L in 2017 with several years where arsenic was not detected and other arsenic levels detected between 3 µg/L and 10 µg/L (Appendix F). Factoring in the dilution described above, concentrations of arsenic are unlikely to have an impact on crustaceans or molluscs,

Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water. This effect could be felt by encrusting organisms on the structure (to 42 m horizontal radius of the discharge) but not seafloor organisms due to the positive buoyancy of the plume.

Bioaccumulation

A large study for the Gulf of Mexico Offshore Operators Committee examined bioaccumulation in tissues of mollusc, crustacean, and three fish species in and around 11 platforms in the Gulf of Mexico discharging over 1000 kL/d (Continental Shelf Associates, 1997). The study examined bioaccumulation of five metals (As, Cd, Hg, 226Ra and 228Ra); three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene; and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. They concluded that there is no relationship between the proximity of marine animals to offshore PFW discharges and concentrations in their edible tissues of the chemical constituents.

Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al. (2011). There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalenes and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs but not fish, from discharging than from non-discharging facilities. These PAH could have been derived from PFW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to the marine animals (Neff et. al. 2011).

Effects from bioaccumulation has been primarily associated with low-molecular weight PAHs. Both BTEX and hydrogen sulphide are not bioaccumulative (Neff 2002, ANZECC, 2000 respectively). PAHs are discharged in WKF PFW with a dilution factor of 7 for Naphthalene above the ANZECC 99% species protection level. WKF PFW is diluted 10 times within 1 m of the discharge, hence the potential for bioaccumulation from water is low. PAHs were not observed in sediments around WKF above relevant guideline criteria as part of the 2018 in-situ monitoring program, and hence the potential for bioaccumulation from sediments is low.

There were no significant differences in benthic infauna distributions observed in an in-situ study around West Kingfish in 2018. This study found that at both near and far zones around the platform and at reference sites, crustaceans dominated the benthic infauna, followed by polychaetes. For less than 12% of the total number of taxa, infauna abundance significantly increased with distance from the platform, owing mostly to the presence of barium (a major constituent of drilling muds) and re-distribution of coarser sediments around the platform (Appendix G.9 – Breakout Box). The increase at WKF with distance away from the platform for this minor percentage of taxa (rather than a decrease at TNA with distance for a majority separate fraction of taxa) can be explained by different hydrodynamic conditions present at WKF (water depth, etc.) resulting in the presence of a different set of taxa within the major taxonomic groups (only five taxa showing a distinct correlation with distance from the platform were present at both platforms, and only two of these showed a counter-gradient with distance from each platform) and the presence of barium (a major constituent of drilling muds) in a stronger gradient around the platform at WKF than at TNA, expected to be resultant from the fact that drilling on WKF was conducted more recently than at TNA The change in abundance could not be correlated with increased sediment contaminants found in PFW. This is consistent with the findings in Neff et al. (1992) where distributions of benthic communities around the platform (in 8 m water depth) were explained in large part by the influence of sediment grain size on benthic community structure; and there was no correlation between faunal density and the concentration of total hydrocarbons in sediments.

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments (such as at WKF) the potential for impacts to benthic infauna would be even lower.

For benthic organisms, effects of chromium on crustaceans was published as ranging between 4 µg/L (Cancer anthonyi, from 7-d LOEC, hatch) to 3090 µg/L (Rhithanopanopeus sp, from 20-d LC50) (ANZECC 2000). Effects on echinoderms was 2000 µg/L (from 7-d LC50, Asterias forbesi) and molluscs at 1600 µg/L (Mya arenaria, from 7-d LC50) to 10 000 µg/L (Macoma balthica, from 8-16 d LC50). WKF PFW chromium concentrations were 58 µg/L, 3 µg/L, 6 µg/L and 2 µg/L in 4 of the 8 tests and non-detect in other years (Appendix F). As WKF PFW is diluted 10 times within 1 m of the discharge and 50 times within 17 m of the discharge, any effects on molluscs or crustaceans from bioaccumulation of chromium in PFW would be limited to organisms within 17 m of the discharge. It should also be noted that in marine and estuarine conditions, the high sulphate concentrations make chromium toxicity unlikely (ANZECC 2000).

Copper is readily accumulated by plants and animals; bioconcentration factors ranging from 100 to 26000 have been recorded for various species of phytoplankton, zooplankton, macrophytes, macroinvertebrates and fish (Spear & Pierce 1979). Toxic effects of metals occur when the rate of uptake exceeds the rates of physiological or biochemical detoxification and excretion (Rainbow 1996, in ANZECC 2000). For benthic organisms, effects of copper on crustaceans was published as ranging between 8.5 µg/L (Callianassa australiensis, 10-14 day EC50) to 42 µg/L (Mysidiopsis bahia, from 29-51 d MATC, reproduction) and on molluscs between 0.4 µg/L (Mytilus edulis, from 30-d EC50, reproduction of 2 µg/L) to 20000 µg/L (Ostrea edulis, 5-d LC50) (ANZECC 2000). WKF PFW copper concentrations were 0.3 µg/L in one of the 8 tests and non-detect in other years (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of copper in WKF PFW is expected.

In general, marine invertebrates are more sensitive to nickel than vertebrates (ANZECC 2000). Chronic effects of nickel on crustaceans was published as ranging between 141 µg/L (36-d chronic mortality, Mysidopsis bahia, Gentile et al. 1982) and 160 µg/L (Portunus pelagicus: from 42d MATC growth of 320 µg/L) to 6000 µg/L from 5-8 d LC50. Effects on echinoderms published as 2600 µg/L (Asteria forbesi from 7-d LC50) molluscs between 240 (Crassostrea virginica; from 12-d LC50 of 1200 µg/L) to 450 000 µg/L from 7-12 d LC50; and algae: 1 sp, Nitzschia closterium 50 µg/L, from 5-d EC50 growth (Australian data) (all from ANZECC 2000). WKF PFW nickel concentrations were 11 µg/L and 4 µg/L in two of the 7 years tested and non-detect in other years (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of nickel in WKF PFW is expected.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). Given the results from the WKF in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments is unlikely.

Given the above, benthic biota around WKF platform are highly unlikely to be affected by the PFW discharge. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform structure within 42 m of the discharge point, within the mixing zone of 160 m. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

Impacts to plankton

There are three pathways for potential impacts to plankton:

- Exposure to temperature effects on direct exposure
- Stimulatory effects of nutrients in the plume, leading to eutrophication of waters
- Exposure to toxic effects of chemical constituents of PFW if plankton are directly exposed for long periods (i.e. directly in the plume)

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on plankton are not credible.

Stimulatory effects from nutrients in the plume

Discharges of nutrients and hydrocarbons in the PFW plume can increase the localised abundance of plankton. For example, ammonia may elicit inhibitory (toxic) and/or stimulatory (e.g. eutrophication) responses from resident biota (Neff, 2011). Plankton could be attracted to localised higher concentrations of these constituents within the mixing zone and as a result plankton populations can rapidly increase. However, increased planktonic activity and turnover mass rates within the mixing zone is not expected to have any marked change on the water quality due to the high levels of movement of water around the platform from the action of currents and waves. Levels of nitrate and phosphates are low (not unlike other produced waters, Neff, 2011) and hence are not likely to cause eutrophication. Supporting this there is anecdotal evidence that no phytoplankton blooms have ever been recorded at a Bass Strait Esso facility.

Direct exposure – chemical ecotoxicity effects

Phytoplankton are among the most sensitive organisms to both forms of arsenic. The Australian diatom Nitzschia closterium is highly sensitive to arsenic (III), with a 72-h EC50 for growth inhibition of 7 µg/L (Florence & Stauber 1991), compared to >2000 µg/L for arsenic (V). An Environmental Concern Level (ECL, see Section 8.3.4.5) of 2.3 µg/L was derived for As (III) in marine waters, using an AF of 100 (ANZECC 2000). WKF PFW arsenic concentrations were 3 µg/L, 3.2 µg/L, 10 µg/L and 110 µg/L and non-detects in the remaining years tested (Appendix F). WKF PFW dilutes 50 times within 17 m of the discharge. Hence the effects on plankton are limited to those within a 17 m radius of the discharge as a result of the levels of arsenic in WKF PFW discharge.

Plankton have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Any impacts as a result of direct exposure of planktonic communities to PFW are expected to be confined to the 42 m zone to 99% species protection, which sits within the extent of the mixing zone. Direct exposure of planktonic communities to PFW within the 42 m zone (to 99% species protection criteria based on WET testing) is not considered to result in significant impacts at the population level of organisms that could affect broader ecological diversity or productivity of the area surrounding the facility.

Impacts to fish

There are three pathways for potential impacts to fish:

- Exposure to temperature effects on direct exposure
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed for long periods (i.e. directly in the plume)
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed to contaminated sediments

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on fish are not credible.

Direct exposure – chemical ecotoxicity effects

Early lifestages of fish (embryos, larvae) within the 42 m zone to where 99% species protection criteria are met would be most susceptible to the exposure from chemical constituents in the PFW discharge, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced without liver function damage (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011) which is not likely to be the case at WKF. Larvae entrained in the outfall may only be exposed to higher concentrations for a short period relative to the buoyancy of the organism (Querbach, et al. 2005). Outside the 42 m radius, early lifestages of fish are not expected to be affected at all.

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement. Fish also exhibit a strong avoidance reaction to hydrogen sulphide (USEPA 1986 in ANZECC 2000).

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound's volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). The dilution ratio for WKF PFW to ANZECC 99% species protection water criteria for Benzene is 2, and WKF PFW is diluted 10 times within 1 m, hence BTEX is not expected to have any toxic effects outside of 1 m from the discharge point.

Levels of chromium (max detected 58 µg/L) and nickel (max detected 11 µg/L) in the WKF discharge are well below the concentrations that could have effects on fish (Chromium 776 µg/L (Citharichthys sp, from 14-21 d LC50) to 14 125 µg/L (Cyprinodon variegatus, from NOEC, growth) and Nickel Fundulus heteroclitus, 30 000 µg/L from 7-d LC50; from ANZECC 2000).

Effects from copper in water on fish was published as ranging between 30 µg/L (2 spp, from 12-14 d EC50, hatch & mortality) to 260 µg/L (Menidia menidia, 11-d EC50, hatch) (ANZECC 2000). The WKF PFW copper concentration was 0.3 µg/L in one of the 8 tests and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of copper in WKF PFW.

Whole effluent ecotoxicity data from WKF PFW shows that the barramundi fish *Lates calcarifier* experienced effects above 50% raw effluent exposure (chronic endpoint). This is unlikely to occur anywhere in the mixing zone except directly at the discharge point itself. Whilst this species is not local to Bass Strait, no effect is expected on fish similar to *Lates calcarifier* since WKF effluent is diluted by more than 10 times within 1 m of the discharge point.

Exposure to contaminated sediments – chemical ecotoxicity effects

Effects from fish directly exposed to contaminated sediments above 22 mg/kg PAH could result in gill hyperplasia, reduced phagocytic activity of macrophages and pancreatic necrosis (spot, Hinkle-Conn et al., 1998). However this is highly unlikely to be the case as PAHs were not detected in sediment around WKF.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient fish such as great white sharks, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to fish, the limited spatial extent of the water quality (160 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on fish particularly the great white shark from PFW discharges when assessed against the relevant criteria in the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to seals

There are four pathways for potential impacts to seals:

- Exposure to toxic effects of chemical constituents of PFW if seals are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Produced water plumes predominantly result in dissolved contaminants and they rarely cause a defined layer on the sea surface (silvery sheen is the lowest level according to the Bonn agreement and usually patchy if at all present from the PFW discharge). Hence potential impact pathways through contact of hydrocarbons with seal fur and ingestion are not credible.

Direct exposure – chemical ecotoxicity effects

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005). As such, it is highly unlikely that these potential impact pathways will be significant. In addition, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986).

Effects from inhalation of hydrocarbon vapours from PFW sheens

Inhalation of hydrocarbon vapours could cause toxic effects. However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Seals are highly mobile and active animals and do not spend all their time at the water surface, as such, it is highly unlikely that this potential impact pathways will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Exposure to on-sea hydrocarbons could cause irritation to the eyes and oral cavity. However seals are unlikely to remain swimming within the discharge plume for long periods as they are highly active animals, travel great distances and forage at various depths. As such, it is highly unlikely that this potential impact pathways will be significant so as to not have any chronic impacts to seals.

Bioaccumulation through ingestion of impacted food sources

As impacts to the predominant seal food source of fish are of very low likelihood (as above), bioaccumulation through ingestion of impacted food sources is unlikely to have any impact on seals.

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, coupled with seals being highly mobile active animals who do not spend all their time in the water or at the water surface, seals are unlikely to be exposed to elevated contamination concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as pelagic fish species). Given the potential absence of impacts to seals, the limited spatial extent of the water quality (160 m radius) the predicted short interaction duration (i.e. minutes at a time) with the PFW plume, and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

There are four pathways for potential impacts to cetaceans:

- Exposure to toxic effects of chemical constituents of PFW if cetaceans are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens

- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Direct exposure – chemical ecotoxicity effects

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathways will be significant. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013).

Effects from inhalation of hydrocarbon vapours from PFW sheens

As a result of inhaling volatile compounds when surfacing, cetaceans can experience lung congestion (Geraci & St. Aubin 1990); or irritation or damage to mucous membranes or airways (Helm et al., 2015). However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Cetaceans can be exposed through direct contact with the eyes, potentially leading to inflammation (Geraci & St. Aubin 1990). Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Bioaccumulation through ingestion of impacted food sources

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

The mixing zone overlaps the foraging BIA for the blue whale and distribution BIA for the Southern Right Whale; however, given the localised area of impact and that whales are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the Conservation Management Plan of either the Blue Whale or Southern Right Whale and the discharge activity is not inconsistent with those plans.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient cetaceans such as migrating whales, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality (160 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on cetaceans from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

There are three potential impact pathways for fisheries:

- Tainting (hydrocarbon odour in caught fish) due to tissue accumulation of hydrocarbons in PFW
- Impacts to the safety of humans through the consumption of target species tissues that are impacted by PFW.

- Reduction of fisheries stocks, through the direct impact of PFW on target species and nurseries

Tainting

Per Appendix F, ANZECC seafood taint criteria is reached within 17 m of the discharge point. (Note: Appendix G.3 – Breakout Box 3 applies to the detection of other phenols under the seafood taint guidelines). The total area represented by a 17 m radius at WKF is 908 m^2 (1/10th of a hectare), and cumulative area across all Bass Strait platform PFW discharges is <2000 m^2 (1/5th of a hectare) representing an extremely small proportion of the total fisheries area. Hence the discharge is highly unlikely to cause taint in fisheries-caught fish.

Impacts to seafood safety for humans

Since fish or shellfish are not harvested around the PFW plume or mixing zone out to at least 500 m from the platform, and the zone in which 99% species protection criteria is reached extends to only 42 m from the platform, there is no effect of the PFW discharge on humans through consumption.

Impacts to fisheries stocks

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone), where they are directly present in the PFW plume (within 42 m radius), may be exposed to chronic sub-lethal impacts (see above) however due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Stakeholder feedback confirmed that although fishers had been able to see discharges from the Bass Strait platforms from beyond the 500 m exclusion zone, the discharge did not have any effect on fisheries or fisheries equipment, or amenity for the fishers. There is general acknowledgement among fishers that Esso's facilities provide safe habitat for juvenile fisheries species. There were no complaints or issues brought up by fishers regarding PFW discharge. Ongoing dialogue with fishing communities is part of Esso's stakeholder engagement plan.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

The Bass Cascade: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as benthic habitats and communities applies to this KEF as described above. Given the distance from the PFW mixing zone to the reported location of the South East Reef, impacts on this reef are not anticipated.

Cumulative impacts from multiple discharges

Neither KFA or KFB platforms are discharging PFW and hence there are no other PFW plumes within 3 km of the WKF discharge.

Other continuous discharges from the same platform are limited to discharges from pile subsea windows. These discharge at 67 m (ODSP) and 69.5 m (CDSP) below sea level, deeper than the produced water effluent pipe depth at 16 m below sea level. Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window (Section 6.4.1.1). Discharges of water containing chemicals (at discharge all chemicals are CHARM Gold/Silver or OCNS D/E (Table 6-22)) or dissolved hydrocarbons from the pile will be intermittent or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. It is therefore expected that any exposure will be limited in duration.

Dispersion modelling for WKF PFW shows the maximum plunge depth from the discharge point under all current speeds is to 20 m below sea level, hence any cumulative impacts from the interaction with the produced water effluent plume within the mixing zone is considered unlikely to occur.

Other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the PFW plume but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

Historical activities such as discharging muds and cuttings during drilling may have resulted in changes to the sea floor sediment chemical characterisation above background levels. This includes the discharge of water based muds and barite containing barium, an inert metal; and the discharge of cuttings from natural rock formations encountered during drilling, together with small amounts of residual drilling muds on cuttings. Any changes to sediment quality from historical impacts from background will be considered as part of the surrender of title process. The last drilling program on WKF was in approximately 2010, hence discharged fluids or solids from the drilling program is expected to have at least partially been dispersed or bioremediated. There is not expected to be a significant cumulative impact to sediment quality from the additive effect of discharging PFW to sediments containing higher levels of barium or residual drilling mud constituents.

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes, cumulative impacts on marine fauna is unlikely.

As fishing is not carried out within 500 m of the platform, which is beyond the mixing zone of 160 m no cumulative impacts from multiple discharges is likely on commercial and recreational fishing.

Given the distance to other sensitive receptors (Table 5-2) cumulative impacts from multiple discharges are highly unlikely.

6.3.4.8 West Kingfish PFW consequence evaluation

Impacts from WKF PFW are limited to a localised mixing zone around the discharge point, with negligible impacts to sediment. Potential impacts to biota, including benthic habitats and communities, plankton, fish, and seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).

Effects could be ongoing, including through bioaccumulation of PAHs and persistent chemicals, but effects are confined to some biota on the platform structure itself (e.g. crustaceans) or dispersed in a small radius around the platform water and sediments at low and safe concentrations. Within the mixing zone, there could be sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level. The environment is highly endemic, with few endangered and rare species present, but is generally strong and resilient, and provides some ecosystem services (predominantly fisheries).

The consequence level is therefore assessed as **Consequence Level III.**

To ensure continuing confidence in the consequence level the Monitoring and Management Framework will be implemented. If routine monitoring was to detect levels in PFW above the trigger values and there was the potential to impact the ecosystem integrity, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are not realised. A sampling plan to demonstrate compliance with the approved mixing zone boundary will be developed for the sediment survey. The sampling plan outlines and justifies sampling locations and when concentration and bioavailability testing occur.

6.3.5 Halibut platform

6.3.5.1 Volume

A summary of historic and five-year-projected PFW discharge volume from the platform is provided in Figure 6-8 and Figure 6-9 respectively. The maximum capacity of the system is 13000 kL/d, however based on historical discharge rates the platform is expected to discharge produced water at a much lower rate of approximately 10000 kL/d until oil shutdown in approximately 2022/2023.

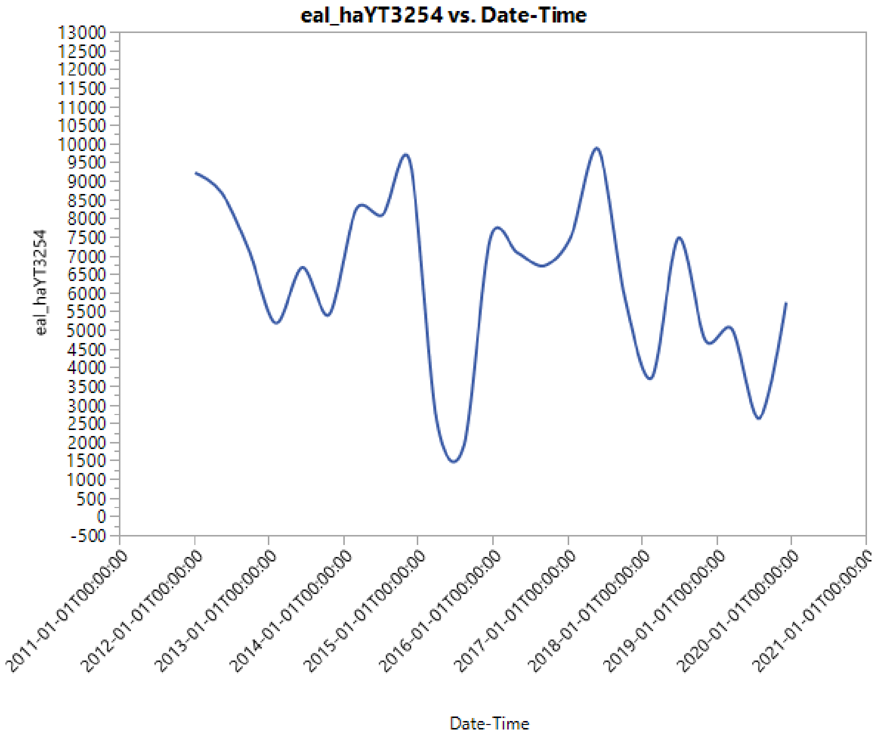

Figure 6-8 Historic HLA smoothed PFW overboard discharge volume (kL/d) (2012-2019)

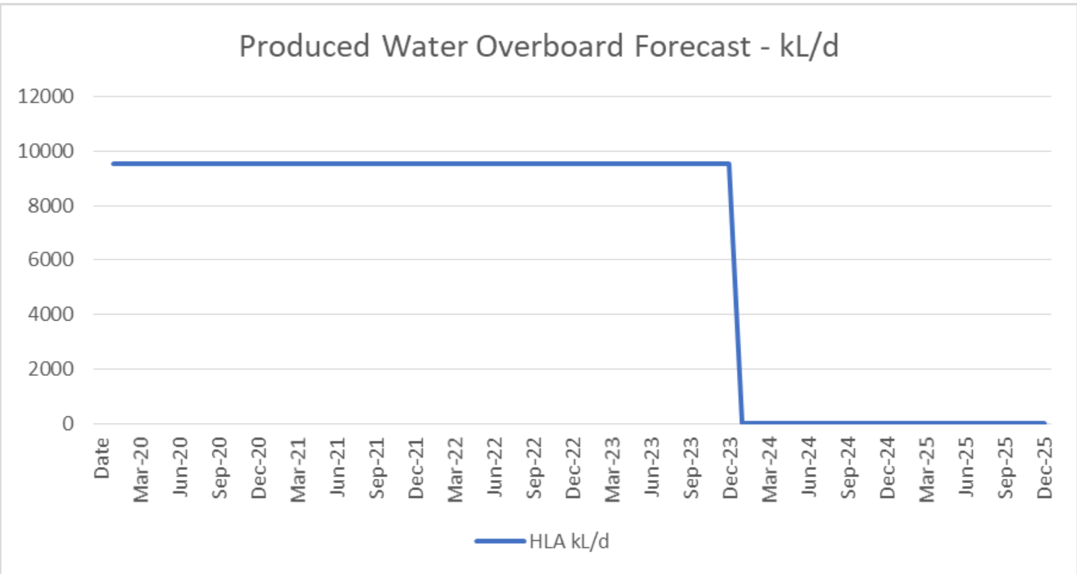

Figure 6-9 Five-year-projected maximum HLA PFW discharge volumes, kL/d.

6.3.5.2 Composition

Physical and chemical make-up

Physical and chemical make-up of PFW is shown in Appendix F – PFW Data file.

Chemical additives

Chemicals in Table 6-12 are added to the platform's water handling system in order to aid oil in water treatment. Chemicals in Table 6-13 are added into the process on the platform for other reasons and could remain at residual levels in the water handling system.

Table 6-12 Chemicals added to Halibut water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Clarifier (e.g. Baker-Hughes RBW24980)	Water phase	V-260 and V-270 Production Oil Separators Inlet and Outlet	Yes

Table 6-13 Chemicals added to Halibut process that could remain at residual levels in the water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Gas lift corrosion inhibitor (e.g. Baker-Hughes CGW24013)	Water phase	Gas lift into wells, upstream of water handling system	Yes

Oil in water monitoring results

Oil in water concentrations are measured on the platform using a continuous online monitor that determines the levels of oil using the way the PFW scatters light under UV fluorescence.

Data is provided in Appendix F for the platform's daily average overboard discharge levels of oil in water (in mg/L) and oil load (kg/d) since 1 Jan 2020 (reflecting the period following the NOPSEMA General Direction 740 in late 2019 where changes were made to the reporting and recording of oil in water).

Data is also provided for the same period showing the cross-check of platform online monitor readings with routine laboratory tests of oil and grease, with the alignment within a +/- 6 mg/L offset.

6.3.5.3 Ecotoxicology

To determine toxicity of the PFW discharge, whole effluent toxicity (WET) testing was performed in 2014 and 2020 across six tests (five chronic, one acute) and eight tests (seven chronic, one acute) respectively across at least 5 different species representing at least four different taxonomic groups. Further details of the ecotoxicology testing can be found in Appendix G.4 – Breakout Box 4. Chemical composition samples were taken at the same time as the samples for WET testing.

Chemical additives added at the time of sampling and ecotoxicology testing on Halibut in 2014 and 2020 were Baker-Hughes RBW24980.

Summarised results of the WET testing are shown in Appendix F.

A Burrlioz model has been run with the results from the WET testing (following Warne, 2018) with the 95% and 99% species protection level of effluent shown in Appendix F.

6.3.5.4 Movement, dispersion and dilution

A dispersion model was designed and calibrated to show the movement dispersion and dilution of the PFW discharge around the platform. Appendix G.6 – Breakout Box 6 shows the setup and calibration details for the model. Dispersion model inputs and outputs are summarized in Appendix F.

6.3.5.5 Fate and transport of Halibut PFW

Fate and transport of HLA PFW is no different to TNA PFW as outlined in Section 5.3.2.5.

6.3.5.6 Receptors at Halibut platform

PFW discharged to the marine environment has the potential to result in the following impacts:

- Change in water quality;
- Change in sediment quality;

As a result of change in water quality, change in sediment quality and / or habitat, further impacts may occur which include:

- Injury to fauna;
- Change in habitat;
- Change to the function, interests or activities of other users.

Receptors that could be credibly affected by the discharge of PFW are identified in Table 6-14 and Figure 6-10, with reference made to specific receptors or receptor groups per Table 5-2.

Table 6-14 Receptors affected by impacts associated with discharges of HLA PFW

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Water quality	✓ Open ocean, high energy environment, cool waters, 73 m water depth				
Sediment quality		✓ Sandy sea floor with some gravel			
Benthic habitats and communities			✓ Likely polychaetes, crustaceans and mollusc infauna; possible sponge, soft coral, other invertebrate filter-feeder epifauna		
Plankton			✓ Open ocean phyto- and zoo-plankton		
Fish			✓ Bony & cartilaginous fish, two vulnerable species (Great White and Whale sharks), distribution BIA for Great White shark, 44 km from Great White shark breeding		

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
			BIA, 57 km from Southern Right Whale migration BIA		
Marine Mammals - Seals			✓ Listed species the New Zealand Fur Seal and the Australian Fur Seal known to rest on the platform and swim alongside		
Marine Mammals - Cetaceans			✓ 27 cetacean species or species habitats occur, of which 5 species are listed (Sei, Blue, Fin, Southern Right and Humpback whales), facility overlaps foraging BIA for Blue whale and distribution BIA for Southern Right whale		
Australian Marine National Parks and National Parks				✓ Ninety Mile Beach MNP (95 km), Point Hicks MNP (101 km), Beagle MNP (108 km), Gippsland Lakes NP (63 km)	
KEFs				✓ Overlaps with Shelf Rocky Reefs (0.1 km to South East Reef), 9 km to Upwelling East of Eden, 20 km+ to Bass Cascade, 87 km to Big Horseshoe Canyon	
Commercial and recreational fisheries					✓ Likely fisheries are Small pelagic, Southern and Eastern Scalefish & Shark, Danish-

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
					seine and scalefish hook, Wrasse, and Southern Squid Jig (low intensity) Fisheries

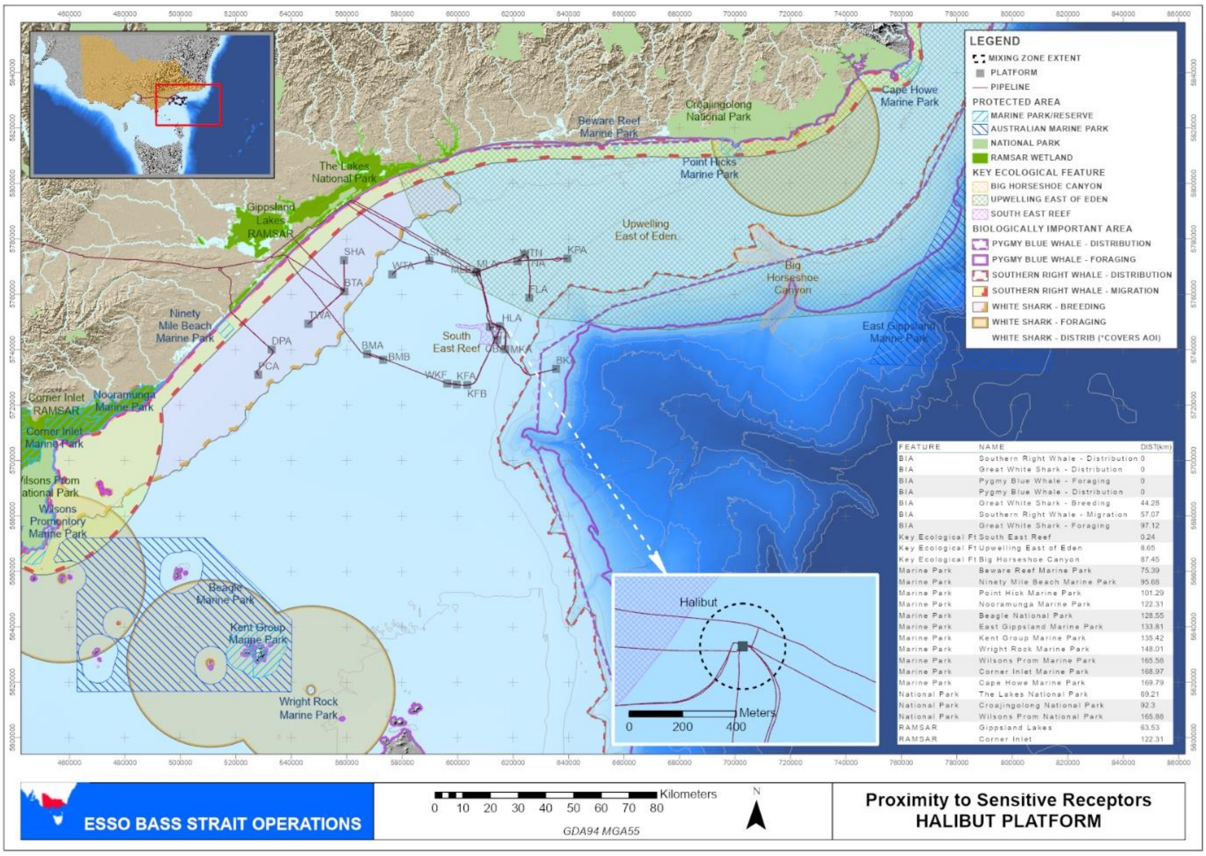

Figure 6-10 160 m mixing zone around HLA platform in relation to other environmental receptors

6.3.5.7 Halibut PFW impact assessment

Impacts to water quality

Physical properties of seawater are established within 10 m of the discharge point. Temperature changes using the RPS APASA (2016) model found that due to the turbulent mixing caused by the initial plunge and then buoyant rise of the effluent, in all cases the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location.

Chemical contaminants in PFW dilute quickly on the initial plunge, then more slowly with dispersion in the current around the platform. PFW is discharged at 8 times the ANZECC 99% species protection criteria for hydrocarbons, 16 times for metals, and 26 times for inorganics; dilutes rapidly on its initial descent, and reaches ANZECC 95% and ANZECC 99% water quality criteria within 4.3 m.

PFW is discharged at between 33 and 269 times the background levels for hydrogen sulphide and up to 78 times the background levels of TOC (see Appendix F.2 – PFW data file) and gradually reduces to background levels with distance from the platform, reaching background levels within 150 m of the discharge point.

Anions such as sodium, calcium, magnesium and potassium, and cations such as chloride, sulphate, bromide and bicarbonate are found in PFW however these ions (and their associated salts) are also commonly found in seawater and hence will not be discussed further (Pillard et al. 1996).

Potential Naturally Occurring Radioactive Materials (NORM) are not expected to occur in quantities that may result in significant environmental impacts and are therefore not discussed further.

Impacts to sediment quality

HLA PFW contains the following chemicals which could impact marine sediments and an ANZECC (2000) or ANZECC (2013) interim sediment quality guideline value exists:

- Low molecular weight PAHs: Naphthalene, 2-methylnaphthalene, and to a lesser extent (lower number of detections): Flourene, Phenanthrene and acenapthene
- High molecular weight PAHs: None
- Metals/Metalloids: Arsenic and Zinc.

There is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment (see Appendix F – PFW Data file). There is a potential pathway for impacts to sediment through settling of constituents in the PFW plume.

Particle size data is not available for HLA, however comparisons of the particle size distribution (PSD) in the produced water from TNA, WKF, CBA and SNA showed that at least 96% of the particles are very small, of the size of clay or silt (≤63 µm) This fraction is usually cited as the chemically active fraction which is associated with potential contaminants of concern (UNEP/WHO 1996). Assuming the PSD from the other platforms in Bass Strait are representative of the HLA PFW PSD, there may be potential for settling of particles in the HLA PFW plume. However, it is expected that there will be minimal larger particles (>63 µm) that may settle and these are likely composed primarily of stable inorganic materials and are generally not associated with contaminants of concern (see Appendix G.10 – Breakout Box 10). Particle size in HLA PFW will be monitored and managed in accordance with the Monitoring and Management Framework (see Volume 4 Section 2.6.5).

Monitoring results for offshore facilities generally show that natural dispersion processes appear to control the concentrations of potential contaminants from PFW in sediments to slightly above background concentrations (Neff et al. 2011). The results from in-situ sediment monitoring of a nearby platform with similar discharge characteristics (WKF) confirms this.

Around WKF the study found no valid samples for PAHs or metals that co-occur in the platform's PFW discharge above the ANZECC (2013) ISQG "low" criteria. (see Appendix G.8 – Breakout Box 8). Occurrences of metals/metalloids were isolated, levels remained low and detections above reference locations remained localised despite there being evidence of some gradients away from the platform (see Appendix G.8 – Breakout Box 8).

WKF is a suitable proxy for predicting the potential for sediment contamination around HLA as the PFW discharge rate, water depth, discharge depth, and range of contaminants in PFW is similar (Table 6-5). In addition, WKF has higher suspended solid loads than HLA (Appendix F – PFW data file), meaning that if metals were to precipitate, they would be more likely to do so in the WKF PFW plume than in the HLA PFW plume and be observed in the sediments close to the discharge point.

As a result the HLA PFW discharge is not expected to have significant impacts on sediment.

Impacts to biota

Potential impacts of PFW to biota have been assessed through WET testing and dilution modelling to establish a mixing zone. Marine biota inside the mixing zone may be exposed to chronic exposure to contaminants in PFW, however, the mixing zone is limited to a localised extent around the plume discharge point only.

Process chemicals are discharged to the sea in residual amounts if they partition into the PFW and are not removed via the available treatment processes. As WET testing was performed with samples that contained chemical additives, the WET testing results are indicative of the routinely discharged PFW and account for any potential biological impacts that could be incurred by the PFW including any chemical additives. In addition, the ecotoxicological impacts of process chemicals in PFW discharges was comprehensively investigated in a study by Henderson et al. (1999). The study tested 11 commonly used process chemicals (including biocides, corrosion inhibitors and demulsifiers) for their acute toxicity to marine bacterium, both directly in aqueous preparations and following their partitioning between oil and water phases. The study results indicated that toxicity of the PFW was not significantly altered by the presence of most process chemicals used in typical concentrations. A review of the study by Schmeichel (2017) notes that process chemicals make a small contribution to the overall acute toxicity profile of PFW discharges.

Relevant to all receptor types (ecotoxicity pathways) are the HLA WET testing results. 95% species protection criteria based on WET testing are met within 47 m of the discharge point (Appendix F – PFW data file). At this distance, 95% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of 'ecosystems in which aquatic biological diversity may have been adversely affected to a relatively small but measurable degree by human activity. The biological communities remain in a healthy condition and ecosystem integrity is largely retained' (ANZECC, 2000, p3.1-10). 99% species protection criteria based on WET testing are met within 160 m of the discharge point (Appendix F – PFW data file). At this distance, 99% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of an 'effectively unmodified, high conservation-value ecosystem' (ANZECC, 2000, p3.1-10). Outside 160 m contaminants in PFW will continue to reduce to background seawater concentrations. At these levels they are not expected to have any impact to biota.

Impacts to benthic communities and habitat

There are two pathways for potential impacts to benthic communities and habitats:

- Benthos near the discharge could be subject to exposure to toxic effects of PAHs or metals if they are directly exposed to PFW for long periods;
- Benthic animals near a produced water discharge may bio-accumulate metals, phenols, and hydrocarbons from the ambient water, their food, or bottom sediments.

Direct exposure - chemical ecotoxicity effects

HLA whole effluent toxicity results (2014) show that the amphipod *Allorchestes compressa* was affected by exposure to more than 12.5% raw effluent (acute endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Allorchestes compressa* since HLA effluent is diluted by 10 times within 0.6 m of the discharge point. The sea urchin *Heliocidaris tuberculate* was affected by exposure to more than 12.5% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Heliocidaris tuberculate* since HLA effluent is diluted by 10 times within 0.6 m of the discharge point. The mussel *Mytilus galloprovincialis* was affected by exposure to more than 12.5% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Mytilus galloprovincialis* since HLA effluent is diluted by 10 times within 0.6 m of the discharge point.

Impacts from PAHs in PFW on fauna such as scallops, crustaceans and other molluscs within 160 m of the discharge could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size, as was found during a study of PFW effluent exposure to sea scallops of greater than 10% (Querbach et al. 2005, in Armsworthy et al., 2005). PFW discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). These effects are highly unlikely to occur at HLA since effluent is diluted by 10 times within 0.6 m of the discharge point. Also since the PFW plume is positively buoyant and does not contact the sea floor, it is expected that only fauna on the platform structure itself could be exposed and those on the sea floor are protected from direct exposure.

The range of marine acute LC50 values for arsenic (V) in water was 230-9600 µg/L for crustaceans and 330- 800 000 µg/L for molluscs (Vaughan 1996). In general, early life stages were more sensitive to arsenic than adults. The maximum arsenic level recorded in HLA undiluted PFW was 1 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence direct exposure to arsenic in HLA PFW is unlikely to have an impact on crustaceans or molluscs, Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water. This effect could be felt by encrusting organisms on the structure (to 160 m horizontal radius of the discharge) but not seafloor organisms due to the positive buoyancy of the plume.

Bioaccumulation

A large study for the Gulf of Mexico Offshore Operators Committee examined bioaccumulation in tissues of mollusc, crustacean, and three fish species in and around 11 platforms in the Gulf of Mexico discharging over 1000 kL/d (Continental Shelf Associates, 1997). The study examined bioaccumulation of five metals (As, Cd, Hg, 226Ra and 228Ra); three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene; and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. They concluded that there is no relationship between the proximity of marine animals to offshore PFW discharges and concentrations in their edible tissues of the chemical constituents.

Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al. (2011). There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalenes and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs but not fish, from discharging than from non-discharging facilities. These PAH could have been derived from PFW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to the marine animals (Neff et. al. 2011).

Effects from bioaccumulation has been primarily associated with low-molecular weight PAHs. Both BTEX and hydrogen sulphide are not bioaccumulative (Neff 2002, ANZECC, 2000 respectively). PAHs are discharged in HLA PFW with a dilution factor of 8 for Naphthalene above the ANZECC 99% species protection level. HLA PFW is diluted 10 times within 0.6 m of the discharge, hence the potential for bioaccumulation from water is low. PAHs were not observed in sediments around WKF above relevant guideline criteria as part of the 2018 in-situ monitoring program, and hence the potential for bioaccumulation is low.

The potential for bioaccumulation in benthic organisms around HLA can be predicted from the WKF in-situ monitoring results, as the PFW discharge rate, water depth, discharge depth, and range of contaminants in PFW is similar (Table 6-5). In addition, the sediment profile around HLA is similar to WKF (Figure 5-3).

There were no significant differences in benthic infauna distributions observed in an in-situ study around WKF in 2018. This study found that at both near and far zones around the platform and at reference sites, crustaceans dominated the benthic infauna, followed by polychaetes. For less than 12% of the total number of taxa, infauna abundance significantly increased with distance from the platform, owing mostly to the presence of barium (a major constituent of drilling muds) and re-distribution of coarser sediments around the platform (Appendix G.9 – Breakout Box). The change in abundance could not be correlated with increased sediment contaminants found in PFW. This is consistent with the findings in Neff et al. (1992) where distributions of benthic communities around the platform (in 8 m water depth) were explained in large part by the influence of sediment grain size on benthic community structure; and there was no correlation between faunal density and the concentration of total hydrocarbons in sediments.

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments (such as at HLA) the potential for impacts to benthic infauna would be even lower.

Zinc is adsorbed by suspended material. Zinc was found to bioaccumulate in freshwater animal tissues 50 to 1130 times but bioaccumulation is not generally considered a problem for zinc (ANZECC 2000). For benthic organisms, zinc effects on crustaceans ranged from 15 µg/L (Acanthomysis sp, growth) to

2100 µg/L (8–28 d NOEC), echinoderms (Asterias forbesi), 460 µg/L (from 7-d LC50) and molluscs: 5 spp, 7–11 d NOEC (from LC50), 15 µg/L (Crassostrea gigas) to 27500 µg/L (ANZECC 2000). Algae were affected at between 13 µg/L (Nitzschia closterium) to 796 µg/L. (Skeletonema sp) (5–10 d NOEC). HLA PFW zinc concentrations were 110 µg/L or lower in 6 of the 8 tests and non-detect in other years (Appendix F). As HLA PFW is diluted to 10 times within 0.6 m of the discharge, there are no effects on benthic animals or plants expected as a result of the levels of zinc in HLA PFW discharge.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). Given the results from the WKF in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments around HLA (if present) is unlikely.

Given the above, benthic biota around HLA platform are highly unlikely to be affected by the PFW discharge. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform structure within 160 m of the discharge point. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

Impacts to plankton

There are three pathways for potential impacts to plankton:

- Exposure to temperature effects on direct exposure
- Stimulatory effects of nutrients in the plume, leading to eutrophication of waters
- Exposure to toxic effects of chemical constituents of PFW if plankton are directly exposed for long periods (i.e. directly in the plume)

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on plankton are not credible.

Stimulatory effects from nutrients in the plume

Discharges of nutrients and hydrocarbons in the PFW plume can increase the localised abundance of plankton. For example, ammonia may elicit inhibitory (toxic) and/or stimulatory (e.g. eutrophication) responses from resident biota (Neff, 2011). Plankton could be attracted to localised higher concentrations of these constituents within the mixing zone and as a result plankton populations can rapidly increase. However, increased planktonic activity and turnover mass rates within the mixing zone is not expected to have any marked change on the water quality due to the high levels of movement of water around the platform from the action of currents and waves. Levels of nitrate and phosphates are low (not unlike other produced waters, Neff, 2011) and hence are not likely to cause eutrophication. Supporting this there is anecdotal evidence that no phytoplankton blooms have ever been recorded at a Bass Strait Esso facility.

Direct exposure – chemical ecotoxicity effects

Phytoplankton are among the most sensitive organisms to both forms of arsenic. The Australian diatom Nitzschia closterium is highly sensitive to arsenic (III), with a 72-h EC50 for growth inhibition of 7 µg/L (Florence & Stauber 1991), compared to >2000 µg/L for arsenic (V). An Environmental Concern Level (ECL, see Section 8.3.4.5) of 2.3 µg/L was derived for As (III) in marine waters, using an AF of 100 (ANZECC 2000). HLA PFW arsenic concentrations were 1 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no impacts to plankton anticipated from arsenic in HLA PFW.

Plankton have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Any impacts as a result of direct exposure of planktonic communities to PFW are expected to be confined to the 160 m zone to 99% species protection. Direct exposure of planktonic communities to PFW within the 160 m zone (to 99% species protection criteria based on WET testing) is not considered to result in significant impacts at the population level of organisms that could affect broader ecological diversity or productivity of the area surrounding the facility.

Impacts to fish

There are three pathways for potential impacts to fish:

- Exposure to temperature effects on direct exposure
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed for long periods (i.e. directly in the plume)
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed to contaminated sediments

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on fish are not credible.

Direct exposure – chemical ecotoxicity effects

Early lifestages of fish (embryos, larvae) within the 160 m zone to 99% species protection criteria would be most susceptible to the exposure from chemical constituents in the PFW discharge, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced without liver function damage (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011) which is not likely to be the case at HLA. Larvae entrained in the outfall may only be exposed to higher concentrations for a short period relative to the buoyancy of the organism (Querbach, et al. 2005). Outside the 160 m radius, early lifestages of fish are not expected to be affected at all.

Effects from zinc in water on fish was published as 10 400 µg/L (Fundulus heteroclitus, 7-d NOEC of from LC50) (ANZECC 2000). HLA PFW zinc concentrations were 110 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of zinc in HLA PFW.

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement. Fish also exhibit a strong avoidance reaction to hydrogen sulphide (USEPA 1986 in ANZECC 2000).

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound's volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). The dilution ratio for HLA PFW to ANZECC 99% species protection water criteria for Benzene is 3, and HLA PFW is diluted 10 times within 0.6 m, hence BTEX is not expected to have any toxic effects.

Whole effluent ecotoxicity data from HLA PFW shows that the barramundi fish *Lates calcarifier* experienced effects above 50% raw effluent exposure (chronic endpoint). This is unlikely to occur anywhere in the mixing zone except directly at the discharge point itself. Whilst this species is not local to Bass Strait, no effect is expected on fish similar to *Lates calcarifier* since HLA effluent is diluted by more than 10 times within 0.6 m of the discharge point.

Exposure to contaminated sediments – chemical ecotoxicity effects

Effects from fish directly exposed to contaminated sediments above 22 mg/kg PAH could result in gill hyperplasia, reduced phagocytic activity of macrophages and pancreatic necrosis (spot, Hinkle-Conn et al., 1998). However this is highly unlikely to be the case as PAHs were not detected in sediment around WKF.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient fish such as great white sharks, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to fish, the limited spatial extent of the water quality (150 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on fish particularly the great white shark from PFW discharges when assessed against the relevant criteria in the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to seals

There are three pathways for potential impacts to seals:

- Exposure to toxic effects of chemical constituents of PFW if seals are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Produced water plumes predominantly result in dissolved contaminants and they rarely cause a defined layer on the sea surface (silvery sheen is the lowest level according to the Bonn agreement and usually patchy if at all present from the PFW discharge). Hence potential impact pathways through contact of hydrocarbons with seal fur and ingestion are not credible.

Direct exposure – chemical ecotoxicity effects

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005). As such, it is highly unlikely that these potential impact pathways will be significant. In addition, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986).

Effects from inhalation of hydrocarbon vapours from PFW sheens

Inhalation of hydrocarbon vapours could cause toxic effects. However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Seals are highly mobile and active animals and do not spend all their time at the water surface, as such, it is highly unlikely that this potential impact pathways will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Exposure to on-sea hydrocarbons could cause irritation to the eyes and oral cavity. However seals are unlikely to remain swimming within the discharge plume for long periods as they are highly active animals, travel great distances and forage at various depths. As such, it is highly unlikely that this potential impact pathways will be significant so as to not have any chronic impacts to seals.

Bioaccumulation through ingestion of impacted food sources

As impacts to the predominant seal food source of fish are of very low likelihood (as above), bioaccumulation through ingestion of impacted food sources is unlikely to have any impact on seals.

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, coupled with seals being highly mobile active animals who do not spend all their time in the water or at the water surface, seals are unlikely to be exposed to elevated contamination concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as pelagic fish species). Given the potential absence of impacts to seals, the limited spatial extent of the water quality (150 m radius) the predicted short interaction duration (i.e. minutes at a time) with the PFW plume, and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, destroy, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

There are four pathways for potential impacts to cetaceans:

- Exposure to toxic effects of chemical constituents of PFW if cetaceans are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Direct exposure – chemical ecotoxicity effects

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathways will be significant. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013).

Effects from inhalation of hydrocarbon vapours from PFW sheens

As a result of inhaling volatile compounds when surfacing, cetaceans can experience lung congestion (Geraci & St. Aubin 1990); or irritation or damage to mucous membranes or airways (Helm et al., 2015). However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Cetaceans can be exposed through direct contact with the eyes, potentially leading to inflammation (Geraci & St. Aubin 1990). Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Bioaccumulation through ingestion of impacted food sources

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

The mixing zone overlaps the foraging BIA for the blue whale and distribution BIA for the Southern Right Whale; however, given the localised area of impact and that whales are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the Conservation Management Plan of either the Blue Whale or Southern Right Whale and the discharge activity is not inconsistent with those plans.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient cetaceans such as migrating whales, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality (150 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on cetaceans from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, destroy, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

There are three potential impact pathways for fisheries:

- Tainting (hydrocarbon odour in caught fish) due to tissue accumulation of hydrocarbons in PFW
- Impacts to the safety of humans through the consumption of target species tissues that are impacted by PFW.
- Reduction of fisheries stocks, through the direct impact of PFW on target species and nurseries

Tainting

Per Appendix F, ANZECC seafood taint criteria is reached within 4.3 m of the discharge point. (Note: Appendix G.3 – Breakout Box 3 applies to the detection of other phenols under the seafood taint guidelines). The total area represented by a 4.3 m radius at HLA is 58 m^2 (<1/100th of a hectare), and cumulative area across all Bass Strait platform PFW discharges is <2000 m^2 (1/5th of a hectare), representing an extremely small proportion of the total fisheries area. Hence the discharge is highly unlikely to cause taint in fisheries-caught fish.

Impacts to seafood safety for humans

Since fish or shellfish are not harvested around the PFW plume or mixing zone out to at least 500 m from the platform, and the zone in which 99% species protection criteria is reached extends to only 160 m from the platform, there is no effect of the PFW discharge on humans through consumption.

Impacts to fisheries stocks

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone), where they are directly present in the PFW plume (within 160 m radius), may be exposed to chronic sub-lethal impacts (see above) however due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Stakeholder feedback confirmed that although fishers had been able to see discharges from the Bass Strait platforms from beyond the 500 m exclusion zone, the discharge did not have any effect on fisheries or fisheries equipment, or amenity for the fishers. There is general acknowledgement among fishers that Esso's facilities provide safe habitat for juvenile fisheries species. There were no complaints or issues brought up by fishers regarding PFW discharge. Ongoing dialogue with fishing communities is part of Esso's stakeholder engagement plan.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

The Bass Cascade: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as benthic habitats and communities applies to this KEF as described above. The platform's PFW mixing zone extends approximately to the edge of the reported location of the South-East Reef. Any impacts are limited to the mixing zone. If ANZECC 99% water quality criteria at the edge of the mixing zone are not exceeded (i.e. criteria suitable for high conservation value systems), there can be high confidence that ecological protection is achieved at the KEF.

Cumulative impacts from multiple discharges

Neither MKA or FTA platforms are discharging PFW and hence there are no other PFW plumes within 3 km of the HLA discharge. The next closest discharge is at CBA which is 5 km away from the HLA discharge point and the plumes are not expected to overlap (see Appendix G.6 – Breakout Box 6).

Other continuous discharges from the same platform are limited to discharges from pile subsea windows. These discharge at 46.5 m (ODSP) and 50 m (CDSP) below sea level, deeper than the produced water effluent pipe depth at 11 m below sea level. Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window (Section 6.4.1.1). Discharges of water containing chemicals (at discharge all chemicals are CHARM Gold/Silver or OCNS D/E (Table 6-22)) or dissolved hydrocarbons from the pile will be intermittent or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. It is therefore expected that any exposure will be limited in duration.

Dispersion modelling for HLA PFW shows the maximum plunge depth from the discharge point under all current speeds is to 22.6 m below sea level, hence any cumulative impacts from the interaction with the produced water effluent plume within the mixing zone is considered unlikely.

Other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the PFW plume but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

Historical activities such as discharging muds and cuttings during drilling may have resulted in changes to the sea floor sediment chemical characterisation above background levels. This includes the discharge of water based muds and barite containing barium, an inert metal; and the discharge of cuttings from natural rock formations encountered during drilling, together with small amounts of residual drilling muds on cuttings. Any changes to sediment quality from historical impacts from background will be considered as part of the surrender of title process. The last drilling program on HLA was in approximately 2007, hence discharged fluids or solids from the drilling program is expected to have at least partially been dispersed or bioremediated. There is not expected to be a significant cumulative impact to sediment quality from the additive effect of discharging PFW to sediments containing higher levels of barium or residual drilling mud constituents.

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes cumulative impacts on marine fauna is unlikely.

As fishing is not carried out within 500 m of the platform, which is beyond the mixing zone of 160 m no cumulative impacts from multiple discharges is likely on commercial and recreational fishing.

Given the distance to other sensitive receptors (Table 5-2) cumulative impacts from multiple discharges are highly unlikely.

6.3.5.8 Halibut PFW consequence evaluation

Impacts from HLA PFW are limited to a localised mixing zone around the discharge point, with negligible impacts to sediment. Potential impacts to biota, including benthic habitats and communities, plankton, fish, and seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).

Effects could be ongoing, including through bioaccumulation of PAHs and persistent chemicals, but effects are confined to some biota on the platform structure itself (e.g. crustaceans) or dispersed in a small radius around the platform water and sediments at low and safe concentrations. Within the mixing zone, there could be sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level. The environment is highly endemic, with few endangered and rare species present, but is generally strong and resilient, and provides some ecosystem services (predominantly fisheries).

The consequence level is therefore assessed as **Consequence Level III.**

To ensure continuing confidence in the consequence level the Monitoring and Management Framework will be implemented. If routine monitoring was to detect levels in PFW above the trigger values and there was the potential to impact the ecosystem integrity, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are not realised. A sampling plan to demonstrate compliance with the approved mixing zone boundary will be developed for the sediment survey. The sampling plan outlines and justifies sampling locations and when concentration and bioavailability testing occur.

6.3.6 Cobia platform

6.3.6.1 Volume

A summary of historic and five-year-projected PFW discharge volume from the platform is provided in Figure 6-11 and Figure 6-12 respectively. In late 2014 the platform was shut in for replacement of the main oil pipeline. The maximum capacity of the system is 13000 kL/d, and based on historical discharge rates the platform is expected to discharge produced water at around 12000 kL/d or less until oil shutdown in approximately 2022-2023.

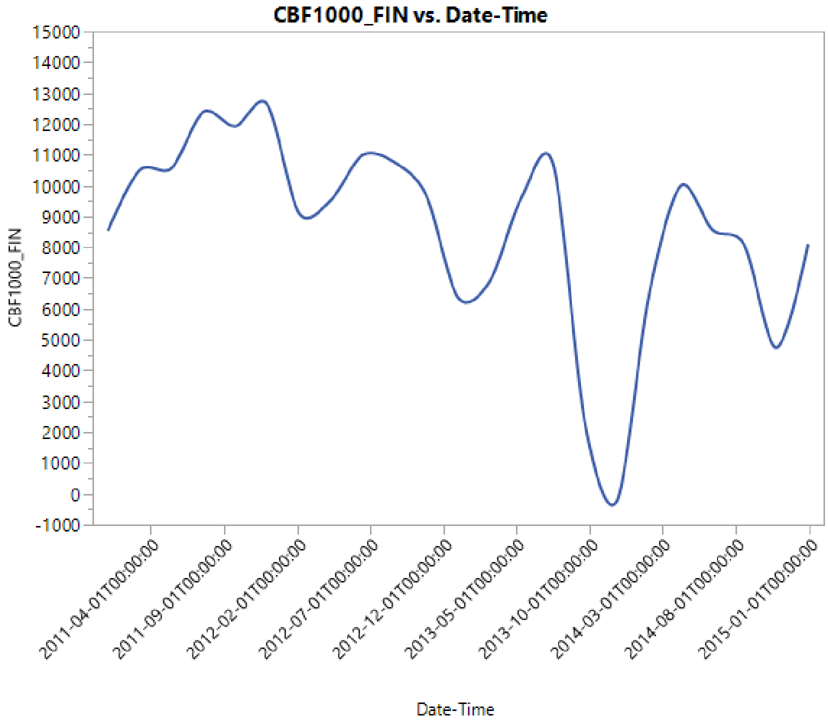

Figure 6-11 Historic CBA smoothed overboard PFW discharge volume (kL/d) (2012-2019)

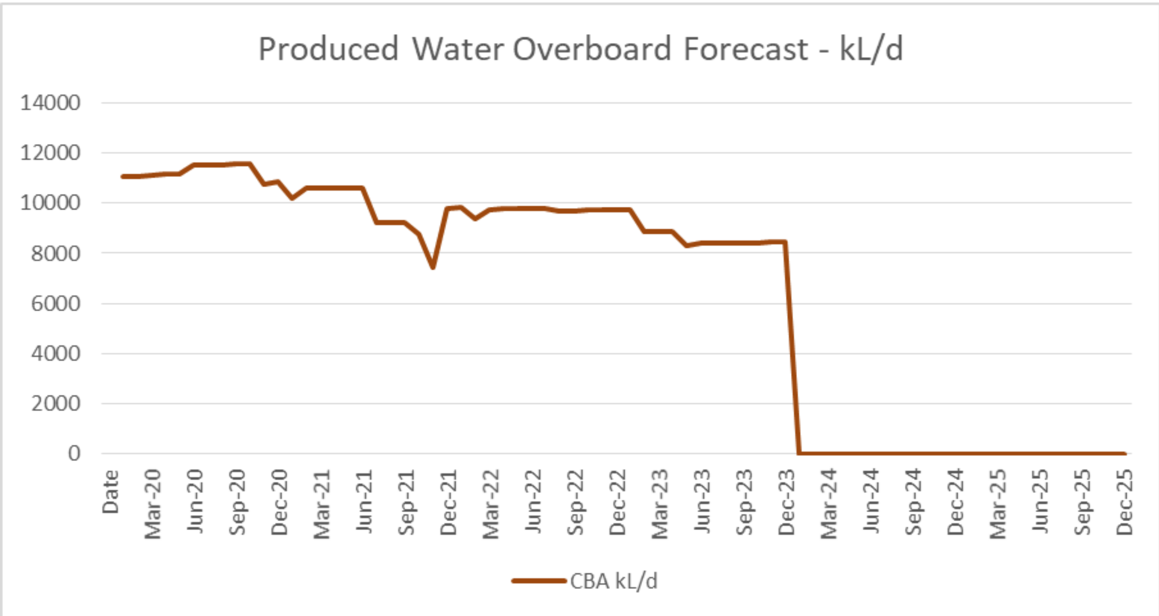

Figure 6-12 Five-year-projected maximum CBA PFW discharge volumes, kL/d.

6.3.6.2 Composition

Physical and chemical make-up

Physical and chemical make-up of PFW is shown in Appendix F – PFW Data file.

Chemical additives

Chemicals in Table 6-15 are added to the platform's water handling system in order to aid oil in water treatment. Chemicals in Table 6-16 are added into the process on the platform for other reasons and could remain at residual levels in the water handling system.

Table 6-15 Chemicals added to Cobia water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Demulsifier (e.g. Baker-Hughes DMO24586)	Oil phase	V-600 and V-620 Production Oil Separators Inlet	Yes

Table 6-16 Chemicals added to Cobia process that could remain at residual levels in the water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Gas lift corrosion inhibitor (e.g. Baker-Hughes CGW24013)	Water phase	Gas lift into wells, upstream of water handling system	Yes

Oil in water monitoring results

Oil in water concentrations are measured on the platform using a continuous online monitor that determines the levels of oil using the way the PFW scatters light under UV fluorescence.

Data is provided in Appendix F for the platform's daily average overboard discharge levels of oil in water (in mg/L) and oil load (kg/d) since 1 Jan 2020 (reflecting the period following the NOPSEMA General Direction 740 in late 2019 where changes were made to the reporting and recording of oil in water).

Data is also provided for the same period showing the cross-check of platform online monitor readings with routine laboratory tests of oil and grease, with the alignment within a +/- 6 mg/L offset.

6.3.6.3 Ecotoxicology

To determine toxicity of the PFW discharge, whole effluent toxicity (WET) testing was performed in 2014 and 2020 across six tests (five chronic, one acute) and eight tests (seven chronic, one acute) respectively across at least 5 different species representing at least four different taxonomic groups. Further details of the ecotoxicology testing can be found in Appendix G.4 – Breakout Box 4. Chemical composition samples were taken at the same time as the samples for WET testing.

Chemical additives added at the time of sampling and ecotoxicology testing on Cobia in 2014 were Baker-Hughes CRO24506 and Baker-Hughes DMO24586 in 2020.

Summarised results of the WET testing are shown in Appendix F.

A Burrlioz model has been run with the results from the WET testing (following Warne, 2018) with the 95% and 99% species protection level of effluent shown in Appendix F.

6.3.6.4 Movement, dispersion and dilution

A dispersion model was designed and calibrated to show the movement dispersion and dilution of the PFW discharge around the platform. Appendix G.6 – Breakout Box 6 shows the setup and calibration details for the model. Dispersion model inputs and outputs are summarized in Appendix F.

6.3.6.5 Fate and transport of Cobia PFW

Fate and transport of CBA PFW is no different to TNA PFW as outlined in Section 5.3.2.5.

6.3.6.6 Receptors at Cobia platform

PFW discharged to the marine environment has the potential to result in the following impacts:

- Change in water quality;
- Change in sediment quality;

As a result of change in water quality, change in sediment quality and / or habitat, further impacts may occur which include:

- Injury to fauna;
- Change in habitat;
- Change to the function, interests or activities of other users.

Receptors that could be credibly affected by the discharge of PFW are identified in Table 6-17 and Figure 6-13, with reference made to specific receptors or receptor groups per Table 5-2.

Table 6-17 Receptors affected by impacts associated with discharges of CBA PFW

Receptors	**Impacts**				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Water quality	✓ Open ocean, high energy environment, cool waters, 78 m water depth				
Sediment quality		✓ Sandy sea floor with some gravel			
Benthic habitats and communities			✓ Likely polychaetes, crustaceans and mollusc infauna; possible sponge, soft coral, other invertebrate filter-feeder epifauna		
Plankton			✓ Open ocean phyto- and zoo-plankton		
Fish			✓ Bony & cartilaginous fish, two vulnerable species (Great White and Whale sharks), distribution BIA for Great White shark, 49 km from Great White shark breeding BIA, 82 km from Southern Right Whale migration BIA		

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Marine Mammals - Seals			✓ Listed species the New Zealand Fur Seal and the Australian Fur Seal known to rest on the platform and swim alongside		
Marine Mammals - Cetaceans			✓ 27 cetacean species or species habitats occur, of which 5 species are listed (Sei, Blue, Fin, Southern Right and Humpback whales), facility overlaps foraging BIA for Blue whale and distribution BIA for Southern Right whale		
Australian Marine National Parks and National Parks				✓ Ninety Mile Beach MNP (95 km), Point Hicks MNP (105 km), Beagle MNP (124 km), Gippsland Lakes NP (68 km)	
KEFs				✓ Overlaps with Shelf Rocky Reefs (0.1 km to South East Reef), 14 km to Upwelling East of Eden, 20 km+ to Bass Cascade, 90 km to Big Horseshoe Canyon	
Commercial and recreational fisheries					✓ Likely fisheries are Small pelagic, Southern and Eastern Scalefish & Shark, Danish-seine and scalefish hook, Wrasse, and Southern Squid

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
					Jig (low intensity) Fisheries

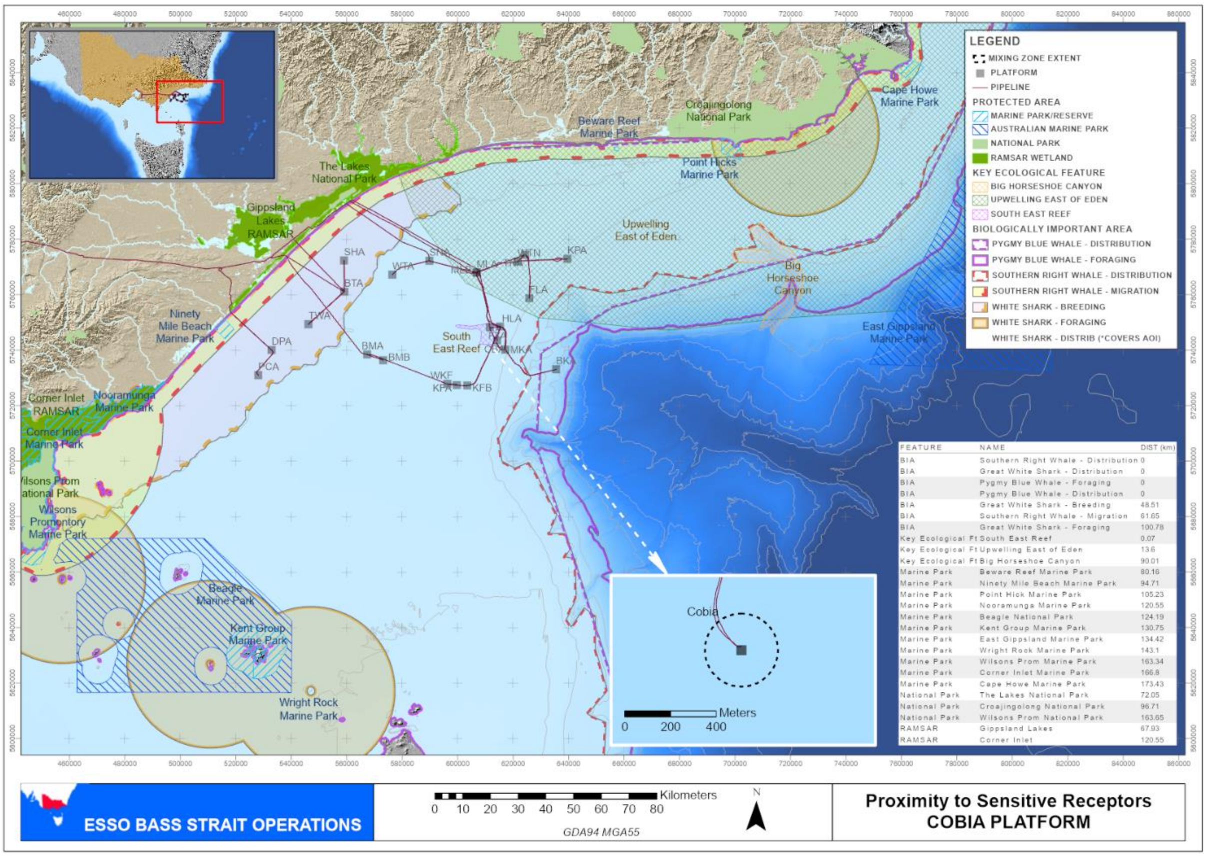

Figure 6-13 160 m mixing zone around CBA platform in relation to other environmental receptors

6.3.6.7 Cobia PFW impact assessment

Impacts to water quality

Physical properties of seawater are established within 10 m of the discharge point. Temperature changes using the RPS APASA (2016) model found that due to the turbulent mixing caused by the initial plunge and then buoyant rise of the effluent, in all cases the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location.

Chemical contaminants in PFW dilute quickly on the initial plunge, then more slowly with dispersion in the current around the platform. PFW is discharged at 7 times the ANZECC 99% species protection criteria for hydrocarbons, 12 times for metals, and 28 times for inorganics; dilutes rapidly on its initial descent, and reaches ANZECC 95% water quality criteria within 10 m; and ANZECC 99% water quality criteria within 10 m.

PFW is discharged at between 33 and 269 times the background levels for hydrogen sulphide and up to 170 times the background levels of TOC (see Appendix F.5 – PFW data file) and gradually reduces to background levels with distance from the platform, reaching background levels within 160 m of the discharge point and defining the extent of the mixing zone for CBA platform.

Anions such as sodium, calcium, magnesium and potassium, and cations such as chloride, sulphate, bromide and bicarbonate are found in PFW however these ions (and their associated salts) are also commonly found in seawater and hence will not be discussed further (Pillard et al. 1996).

Potential Naturally Occurring Radioactive Materials (NORM) are not expected to occur in quantities that may result in significant environmental impacts and are therefore not discussed further.

Impacts to sediment quality

CBA PFW contains the following chemicals which could impact marine sediments and an ANZECC (2000) or ANZECC (2013) interim sediment quality guideline value exists:

- Low molecular weight PAHs: Naphthalene, 2-methylnaphthalene, Flourene, and Phenanthrene
- High molecular weight PAHs: None
- Metals/Metalloids: Chromium, Copper, Nickel and Zinc.

There is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment (see Appendix F – PFW Data file). There is a potential pathway for impacts to sediment through settling of constituents in the PFW plume.

An analysis of the CBA PFW discharge found that 100% of particles are ≤63 µm (clay or silt). Per Breakout Box 10, this silt and clay fraction (≤63 µm) is usually cited as the chemically active fraction which is associated with potential contaminants of concern (UNEP/WHO 1996). It is unlikely that there will be settling of particles in the CBA PFW plume as it is the larger particles (>63 µm) that typically settle.

Monitoring results for offshore facilities generally show that natural dispersion processes appear to control the concentrations of potential contaminants from PFW in sediments to slightly above background concentrations (Neff et al. 2011). The results from in-situ sediment monitoring of a nearby platform with similar discharge characteristics (WKF) confirms this.

Around WKF the study found no valid samples for PAHs, or metals that co-occur in the platform's PFW discharge above the ANZECC (2013) ISQG "low" criteria. (see Appendix G.8 – Breakout Box 8). Occurrences of metals/metalloids were isolated, levels remained low and detections above reference locations remained localised despite there being evidence of some gradients away from the platform (see Appendix G.8 – Breakout Box 8).

WKF is a suitable proxy for predicting the potential for sediment contamination around CBA as the PFW discharge rate, water depth, discharge depth, and range of contaminants in PFW is similar (Table 6-5). In addition, WKF has higher suspended solid loads than CBA (Appendix E – PFW data file), meaning that if metals were to precipitate, they would be more likely to do so in the WKF PFW plume than in the CBA PFW plume and be observed in the sediments close to the discharge point.

Given that;

- sampling results at CBA indicate that a negligible portion of particles in PFW may settle (due to 100% of particles being smaller than 63 µm)
- any larger particles that do settle are likely to be stable inorganic materials
- there were no valid observations of contaminants in PFW in sediments around WKF platform (which is a suitable proxy for CBA) above ISQG "low" guideline values
- levels of contamination of nickel in a gradient away from WKF platform (which is a suitable proxy for CBA) remains of very low level and within a small radius

the PFW discharge is expected to have negligible impacts on sediment.

Impacts to biota

Potential impacts of PFW to biota have been assessed through WET testing and dilution modelling to establish a mixing zone. Marine biota inside the mixing zone may be exposed to chronic exposure to contaminants in PFW, however, the mixing zone is limited to a localised extent around the plume discharge point only.

Process chemicals are discharged to the sea in residual amounts if they partition into the PFW and are not removed via the available treatment processes. As WET testing was performed with samples that contained chemical additives, the WET testing results are indicative of the routinely discharged PFW and account for any potential biological impacts that could be incurred by the PFW including any chemical additives. In addition, the ecotoxicological impacts of process chemicals in PFW discharges was comprehensively investigated in a study by Henderson et al. (1999). The study tested 11 commonly used process chemicals (including biocides, corrosion inhibitors and demulsifiers) for their acute toxicity to marine bacterium, both directly in aqueous preparations and following their partitioning between oil and water phases. The study results indicated that toxicity of the PFW was not significantly altered by the presence of most process chemicals used in typical concentrations. A review of the study by Schmeichel (2017) notes that process chemicals make a small contribution to the overall acute toxicity profile of PFW discharges.

Relevant to all receptor types (ecotoxicity pathways) are the CBA WET testing results. 95% species protection criteria based on WET testing is met within less than 60 m of the discharge point (Appendix F – PFW data file). At this distance, 95% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of 'ecosystems in which aquatic biological diversity may have been adversely affected to a relatively small but measurable degree by human activity. The biological communities remain in a healthy condition and ecosystem integrity is largely retained' (ANZECC, 2000, p3.1-10). 99% species protection criteria based on WET testing is met within 60 m of the discharge point (Appendix F – PFW data file). At this distance, 99% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of an 'effectively unmodified, high conservation-value ecosystem' (ANZECC, 2000, p3.1-10). Outside 60 m to the remainder of the boundary of the mixing zone, contaminants in PFW will continue to reduce to background seawater concentrations. At these levels they are not expected to have any impact to biota.

Impacts to benthic communities and habitat

There are two pathways for potential impacts to benthic communities and habitats:

- Benthos near the discharge could be subject to exposure to toxic effects of PAHs or metals if they are directly exposed to PFW for long periods;
- Benthic animals near a produced water discharge may bio-accumulate metals, phenols, and hydrocarbons from the ambient water, their food, or bottom sediments.

Direct exposure - chemical ecotoxicity effects

CBA whole effluent toxicity results (2014) show that the amphipod *Allorchestes compressa* was affected by exposure to more than 25% raw effluent (acute endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Allorchestes compressa* since CBA effluent is diluted by 10 times within 0.9 m of the discharge point. The sea urchin *Heliocidaris tuberculate* was affected by exposure to more than 3.1% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Heliocidaris tuberculate* since CBA effluent is diluted by 50 times within 10 m of the discharge point. The mussel *Mytilus galloprovincialis* was affected by exposure to more than 12.5% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Mytilus galloprovincialis* since CBA effluent is diluted by 10 times within 0.9 m of the discharge point.

Impacts from PAHs in PFW on fauna such as scallops, crustaceans and other molluscs within 60 m of the discharge could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size, such as was found during a study of PFW effluent exposure to sea scallops of greater than 10% (Querbach et al. 2005, in Armsworthy et al., 2005). PFW discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). These effects are highly unlikely to occur at CBA since effluent is diluted by 10 times within 0.9 m of the discharge point. Also since the PFW plume is positively buoyant and does not contact the sea floor, it is expected that only fauna on the platform structure itself could be exposed and those on the sea floor are protected from direct exposure.

Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water. This effect could be felt by encrusting organisms on the structure (to 60 m horizontal radius of the discharge) but not seafloor organisms due to the positive buoyancy of the plume.

Bioaccumulation

A large study for the Gulf of Mexico Offshore Operators Committee examined bioaccumulation in tissues of mollusc, crustacean, and three fish species in and around 11 platforms in the Gulf of Mexico discharging over 1000 kL/d (Continental Shelf Associates, 1997). The study examined bioaccumulation of five metals (As, Cd, Hg, 226Ra and 228Ra); three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene; and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. They concluded that there is no relationship between the proximity of marine animals to offshore PFW discharges and concentrations in their edible tissues of the chemical constituents.

Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al. (2011). There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalenes and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs but not fish, from discharging than from non-discharging facilities. These PAH could have been derived from PW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to the marine animals (Neff et. al. 2011).

Effects from bioaccumulation has been primarily associated with low-molecular weight PAHs. Both BTEX and hydrogen sulphide are not bioaccumulative (Neff 2002, ANZECC, 2000 respectively). The level of PAHs in CBA PFW were 7 times higher than ANZECC 99% criteria (Naphthalene) and the CBA PFW effluent dilutes 10 times within 0.9 m from the discharge point. In addition, PAHs were not observed in sediments around WKF above relevant guideline criteria as part of the 2018 in-situ monitoring program. Hence the potential for bioaccumulation is low.

The potential for bioaccumulation in benthic organisms around CBA can be predicted from the WKF in-situ monitoring results, as as the PFW discharge rate, water depth, discharge depth, and range of contaminants in PFW is similar (Table 6-5). In addition, the sediment profile around CBA is similar to WKF (Figure 5-3).

There were no significant differences in benthic infauna distributions observed in an in-situ study around WKF in 2018. This study found that at both near and far zones around the platform and at reference sites, crustaceans dominated the benthic infauna, followed by polychaetes. For less than 12% of the total number of taxa, infauna abundance significantly increased with distance from the platform, owing mostly to the presence of barium (a major constituent of drilling muds) and re-distribution of coarser sediments around the platform (Appendix G.9 – Breakout Box 9). The change in abundance could not be correlated with increased sediment contaminants found in PFW. This is consistent with the findings in Neff et al. (1992) where distributions of benthic communities around the platform (in 8 m water depth) were explained in large part by the influence of sediment grain size on benthic community structure; and there was no correlation between faunal density and the concentration of total hydrocarbons in sediments.

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments (such as at CBA) the potential for impacts to benthic infauna would be even lower.

For benthic organisms, effects of chromium on crustaceans was published as ranging between 4 µg/L (Cancer anthonyi, from 7-d LOEC, hatch) to 3090 µg/L (Rhithanopanopeus sp, from 20-d LC50) (ANZECC 2000). Effects on echinoderms was 2000 µg/L (from 7-d LC50, Asterias forbesi) and molluscs at 1600 µg/L (Mya arenaria, from 7-d LC50) to 10 000 µg/L (Macoma balthica, from 8-16 d LC50). CBA

PFW chromium concentrations were 0.6 µg/L in one of the 3 tests and non-detect in the remaining tests (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of chromium in CBA PFW is expected. It should also be noted that in marine and estuarine conditions, the high sulphate concentrations make chromium toxicity unlikely (ANZECC 2000).

Copper is readily accumulated by plants and animals; bioconcentration factors ranging from 100 to 26000 have been recorded for various species of phytoplankton, zooplankton, macrophytes, macroinvertebrates and fish (Spear & Pierce 1979). Toxic effects of metals occur when the rate of uptake exceeds the rates of physiological or biochemical detoxification and excretion (Rainbow 1996, in ANZECC 2000). For benthic organisms, effects of copper on crustaceans was published as ranging between 8.5 µg/L (Callianassa australiensis, 10-14 day EC50) to 42 µg/L (Mysidiopsis bahia, from 29-51 d MATC, reproduction) and on molluscs between 0.4 µg/L (Mytilus edulis, from 30-d EC50, reproduction of 2 µg/L) to 20000 µg/L (Ostrea edulis, 5-d LC50) (ANZECC 2000). CBA PFW copper concentrations were 0.3 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of copper in CBA PFW is expected.

In general, marine invertebrates are more sensitive to nickel than vertebrates (ANZECC 2000). Chronic effects of nickel on crustaceans was published as ranging between 141 µg/L (36-d chronic mortality, Mysidopsis bahia, Gentile et al. 1982) and 160 µg/L (Portunus pelagicus: from 42d MATC growth of 320 µg/L) to 6000 µg/L from 5-8 d LC50. Effects on echinoderms published as 2600 µg/L (Asteria forbesi from 7-d LC50) molluscs between 240 (Crassostrea virginica; from 12-d LC50 of 1200 µg/L) to 450 000 µg/L from 7-12 d LC50; and algae: 1 sp, Nitzschia closterium 50 µg/L, from 5-d EC50 growth (Australian data) (all from ANZECC 2000). CBA PFW nickel concentrations were 1.9 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of nickel in CBA PFW is expected.

Zinc is adsorbed by suspended material. Zinc was found to bioaccumulate in freshwater animal tissues 50 to 1130 times but bioaccumulation is not generally considered a problem for zinc (ANZECC 2000). For benthic organisms, zinc effects on crustaceans ranged from 15 µg/L (Acanthomysis sp, growth) to 2100 µg/L (8–28 d NOEC), echinoderms (Asterias forbesi), 460 µg/L (from 7-d LC50) and molluscs: 5 spp, 7–11 d NOEC (from LC50), 15 µg/L (Crassostrea gigas) to 27500 µg/L (ANZECC 2000). Algae were affected at between 13 µg/L (Nitzschia closterium) to 796 µg/L. (Skeletonema sp) (5–10 d NOEC). CBA PFW zinc concentrations were 1 µg/L in one of the 3 tests and non-detect in other years (Appendix F) and hence is not expected to result in any impacts to benthic organisms.

Some aquatic organisms may accumulate cobalt, particularly some aquatic plants and benthic organisms (Cole & Carson 1981 in ANZECC 2000). For crustaceans, published ranges of effect concentrations were 9-d LC50, 45 µg/L (Palaemon serratus) to 45 400 µg/L (Carcinus maenas). The lowest geometric mean for converted NOEC was 9 µg/L. Homarus vulgaris also had a low g.m. for NOECs of 65 µg/L; nematode Monhystera sp, 4-d LC50, 94 000 µg/L; and algae 4-5 d EC50, growth, 300 µg/L (Dytilum sp) to 23 600 µg/L (Phaeodactylium sp) (ANZECC 2000). CBA PFW cobalt concentrations were 0.06 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence there are no effects on benthic animals or plants expected as a result of the levels of cobalt in CBA PFW discharge.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). Given the results from the WKF in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments is unlikely.

Given the above, benthic biota around CBA platform are highly unlikely to be affected by the PFW discharge. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform structure within 60 m of the discharge point, within the mixing zone extent of 160 m. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

Impacts to plankton

There are three pathways for potential impacts to plankton:

- Exposure to temperature effects on direct exposure
- Stimulatory effects of nutrients in the plume, leading to eutrophication of waters
- Exposure to toxic effects of chemical constituents of PFW if plankton are directly exposed for long periods (i.e. directly in the plume)

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on plankton are not credible.

Stimulatory effects from nutrients in the plume

Discharges of nutrients and hydrocarbons in the PFW plume can increase the localised abundance of plankton. For example, ammonia may elicit inhibitory (toxic) and/or stimulatory (e.g. eutrophication) responses from resident biota (Neff, 2011). Plankton could be attracted to localised higher concentrations of these constituents within the mixing zone and as a result plankton populations can rapidly increase. However, increased planktonic activity and turnover mass rates within the mixing zone is not expected to have any marked change on the water quality due to the high levels of movement of water around the platform from the action of currents and waves. Levels of nitrate and phosphates are low (not unlike other produced waters, Neff, 2011) and hence are not likely to cause eutrophication. Supporting this there is anecdotal evidence that no phytoplankton blooms have ever been recorded at a Bass Strait Esso facility.

Direct exposure – chemical ecotoxicity effects

Plankton have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Any impacts as a result of direct exposure of planktonic communities to PFW are expected to be confined to the 60 m zone to 99% species protection, which sits within the extent of the mixing zone. Direct exposure of planktonic communities to PFW within the 60 m zone (to 99% species protection criteria based on WET testing) is not considered to result in significant impacts at the population level of organisms that could affect broader ecological diversity or productivity of the area surrounding the facility.

Impacts to fish

There are three pathways for potential impacts to fish:

- Exposure to temperature effects on direct exposure
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed for long periods (i.e. directly in the plume)
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed to contaminated sediments

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on fish are not credible.

Direct exposure – chemical ecotoxicity effects

Early lifestages of fish (embryos, larvae) within the 60 m zone to where 99% species protection criteria is met would be most susceptible to the exposure from chemical constituents in the PFW discharge, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced without liver function damage (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011) which is not likely to be the case at CBA. Larvae entrained in the outfall may only be exposed to higher concentrations for a short period relative to the buoyancy of the organism (Querbach, et al. 2005). Outside the 60 m radius, early lifestages of fish are not expected to be affected at all.

Effects from zinc in water on fish was published as 10 400 µg/L (Fundulus heteroclitus, 7-d NOEC of from LC50) (ANZECC 2000). CBA PFW zinc concentrations were 1 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of zinc in CBA PFW.

Effects from cobalt in water on fish was published as 52 500-227 000 µg/L (from 4-9 d LC50) (ANZECC 2000). CBA PFW cobalt concentrations were 0.06 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of cobalt in CBA PFW.

Levels of chromium (max detected 0.6 µg/L) and nickel (max detected 1.9 µg/L) in the CBA discharge are well below the concentrations that could have effects on fish (Chromium 776 µg/L (Citharichthys sp, from 14-21 d LC50) to 14 125 µg/L (Cyprinodon variegatus, from NOEC, growth) and Nickel Fundulus heteroclitus, 30 000 µg/L from 7-d LC50; from ANZECC 2000).

Effects from copper in water on fish was published as ranging between 30 µg/L (2 spp, from 12-14 d EC50, hatch & mortality) to 260 µg/L (Menidia menidia, 11-d EC50, hatch) (ANZECC 2000). The CBA PFW copper concentration was 0.3 µg/L in one of the 3 tests and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of copper in CBA PFW.

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement. Fish also exhibit a strong avoidance reaction to hydrogen sulphide (USEPA 1986 in ANZECC 2000).

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound's volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). The dilution ratio for CBA PFW to ANZECC 99% species protection water criteria for Benzene is 2, and CBA PFW is diluted 10 times within 0.9 m, hence BTEX is not expected to have any toxic effects. Whole effluent ecotoxicity data from CBA PFW shows that the barramundi fish *Lates calcarifier* experienced effects above 50% raw effluent exposure (chronic endpoint). This is unlikely to occur anywhere in the mixing zone except directly at the discharge point itself. Whilst this species is not local to Bass Strait, no effect is expected on fish similar to *Lates calcarifier* since CBA effluent is diluted by more than 10 times within 0.9 m of the discharge point.

Exposure to contaminated sediments – chemical ecotoxicity effects

Effects from fish directly exposed to contaminated sediments above 22 mg/kg PAH could result in gill hyperplasia, reduced phagocytic activity of macrophages and pancreatic necrosis (spot, Hinkle-Conn et al., 1998). However this is highly unlikely to be the case as the PAHs were not detected in sediment around WKF.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient fish such as great white sharks, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to fish, the limited spatial extent of the water quality (160 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on fish particularly the great white shark from PFW discharges when assessed against the relevant criteria in the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to seals

There are three pathways for potential impacts to seals:

- Exposure to toxic effects of chemical constituents of PFW if seals are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Produced water plumes predominantly result in dissolved contaminants and they rarely cause a defined layer on the sea surface (silvery sheen is the lowest level according to the Bonn agreement and usually patchy if at all present from the PFW discharge). Hence potential impact pathways through contact of hydrocarbons with seal fur and ingestion are not credible.

Direct exposure – chemical ecotoxicity effects

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005). As such, it is highly unlikely that these potential impact pathways will be significant. In addition, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986).

Effects from inhalation of hydrocarbon vapours from PFW sheens

Inhalation of hydrocarbon vapours could cause toxic effects. However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Seals are highly mobile and active animals and do not spend all their time at the water surface, as such, it is highly unlikely that this potential impact pathways will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Exposure to on-sea hydrocarbons could cause irritation to the eyes and oral cavity. However seals are unlikely to remain swimming within the discharge plume for long periods as they are highly active animals, travel great distances and forage at various depths. As such, it is highly unlikely that this potential impact pathways will be significant so as to not have any chronic impacts to seals.

Bioaccumulation through ingestion of impacted food sources

As impacts to the predominant seal food source of fish are of very low likelihood (as above), bioaccumulation through ingestion of impacted food sources is unlikely to have any impact on seals.

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, coupled with seals being highly mobile active animals who do not spend all their time in the water or at the water surface, seals are unlikely to be exposed to elevated contamination concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as pelagic fish species). Given the potential absence of impacts to seals, the limited spatial extent of the water quality (160 m radius) the predicted short interaction duration (i.e. minutes at a time) with the PFW plume, and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

There are four pathways for potential impacts to cetaceans:

- Exposure to toxic effects of chemical constituents of PFW if cetaceans are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Direct exposure – chemical ecotoxicity effects

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathways will be significant. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013).

Effects from inhalation of hydrocarbon vapours from PFW sheens

As a result of inhaling volatile compounds when surfacing, cetaceans can experience lung congestion (Geraci & St. Aubin 1990); or irritation or damage to mucous membranes or airways (Helm et al., 2015). However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Cetaceans can be exposed through direct contact with the eyes, potentially leading to inflammation (Geraci & St. Aubin 1990). Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Bioaccumulation through ingestion of impacted food sources

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

The mixing zone overlaps the foraging BIA for the blue whale and distribution BIA for the Southern Right Whale; however, given the localised area of impact and that whales are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the Conservation Management Plan of either the Blue Whale or Southern Right Whale and the discharge activity is not inconsistent with those plans.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient cetaceans such as migrating whales, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality (160 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on cetaceans from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

There are three potential impact pathways for fisheries:

- Tainting (hydrocarbon odour in caught fish) due to tissue accumulation of hydrocarbons in PFW
- Impacts to the safety of humans through the consumption of target species tissues that are impacted by PFW.
- Reduction of fisheries stocks, through the direct impact of PFW on target species and nurseries

Tainting

Per Appendix F, ANZECC seafood taint criteria is reached within 0.9 m of the discharge point. (Note: Appendix G.3 – Breakout Box 3 applies to the detection of other phenols under the seafood taint guidelines). The total area represented by a 0.9 m radius at CBA is 3 m^2 (1/300th of a hectare), and cumulative area across all Bass Strait platform PFW discharges is <2000 m^2 (1/5th of a hectare), representing an extremely small proportion of the total fisheries area. Hence the discharge is highly unlikely to cause taint in fisheries-caught fish.

Impacts to seafood safety for humans

Since fish or shellfish are not harvested around the PFW plume or mixing zone out to at least 500 m from the platform, and the zone in which 99% species protection criteria is reached extends to only 60 m from the platform, there is no effect of the PFW discharge on humans through consumption.

Impacts to fisheries stocks

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone), where they are directly present in the PFW plume (within 60 m radius), may be exposed to chronic sub-lethal impacts (see above) however due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Stakeholder feedback confirmed that although fishers had been able to see discharges from the Bass Strait platforms from beyond the 500 m exclusion zone, the discharge did not have any effect on fisheries or fisheries equipment, or amenity for the fishers. There is general acknowledgement among fishers that Esso's facilities provide safe habitat for juvenile fisheries species. There were no complaints or issues brought up by fishers regarding PFW discharge. Ongoing dialogue with fishing communities is part of Esso's stakeholder engagement plan.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

The Bass Cascade: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as benthic habitats and communities applies to this KEF as described above. The platform's PFW mixing zone extends approximately to the edge of the reported location of the South-East Reef. Any impacts are limited to the mixing zone. If ANZECC 99% water quality criteria at the edge of the mixing zone are not exceeded (i.e. criteria suitable for high conservation value systems), there can be high confidence that ecological protection is achieved at the KEF.

Cumulative impacts from multiple discharges

Neither MKA or FTA platforms are discharging PFW and hence there are no other PFW plumes within 3 km of the CBA discharge. The next closest discharge is at HLA which is 5 km away from the HLA discharge point and the plumes are not expected to overlap (see Appendix G.6 – Breakout Box 6).

Other continuous discharges from the same platform are limited to discharges from pile subsea windows. These discharge at 56.7 m (ODSP) and 56.7 m (CDSP) below sea level, deeper than the produced water effluent pipe depth at 27.7 m below sea level. Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window (Section 6.4.1.1). Discharges of water containing chemicals (at discharge all chemicals are CHARM Gold/Silver or OCNS D/E (Table 6-22) or dissolved hydrocarbons from the pile will be intermittent or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. It is therefore expected that any exposure will be limited in duration.

Dispersion modelling for CBA PFW shows the maximum plunge depth from the discharge point under all current speeds is to 36.4 m below sea level, hence any cumulative impacts from the interaction with the produced water effluent plume within the mixing zone is considered unlikely.

Other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the PFW plume but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

Historical activities such as discharging muds and cuttings during drilling may have resulted in changes to the sea floor sediment chemical characterisation above background levels. This includes the discharge of water based muds and barite containing barium, an inert metal; and the discharge of cuttings from natural rock formations encountered during drilling, together with small amounts of residual drilling muds on cuttings. Any changes to sediment quality from historical impacts from background will be considered as part of the surrender of title process. The last drilling program on CBA was in approximately 2009, hence discharged fluids or solids from the drilling program is expected to have at least partially been dispersed or bioremediated. There is not expected to be a significant cumulative impact to sediment quality from the additive effect of discharging PFW to sediments containing higher levels of barium or residual drilling mud constituents.

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes cumulative impacts on marine fauna is unlikely.

As fishing is not carried out within 500 m of the platform, which is beyond the mixing zone of 160 m no cumulative impacts from multiple discharges is likely on commercial and recreational fishing.

Given the distance to other sensitive receptors (Table 5-2) cumulative impacts from multiple discharges are highly unlikely.

6.3.6.8 CBA PFW Consequence Evaluation

Impacts from CBA PFW are limited to a localised mixing zone around the discharge point, with negligible impacts to sediment. Potential impacts to biota, including benthic habitats and communities, plankton, fish, and seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).

Effects could be ongoing, including through bioaccumulation of PAHs and persistent chemicals, but effects are confined to some biota on the platform structure itself (e.g. crustaceans) or dispersed in a small radius around the platform water and sediments at low and safe concentrations. Within the mixing zone, there could be sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level. The environment is highly endemic, with few endangered and rare species present, but is generally strong and resilient, and provides some ecosystem services (predominantly fisheries).

The consequence level is therefore assessed as **Consequence Level III.**

To ensure continuing confidence in the consequence level the Monitoring and Management Framework will be implemented. If routine monitoring was to detect levels in PFW above the trigger values and there was the potential to impact the ecosystem integrity, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are not realised. A sampling plan to demonstrate compliance with the approved mixing zone boundary will be developed for the sediment survey. The sampling plan outlines and justifies sampling locations and when concentration and bioavailability testing occur.

6.3.7 Snapper platform

6.3.7.1 Volume

A summary of historic and five-year-projected PFW discharge volume from the platform is provided in Figure 6-14 and Figure 6-15 respectively. The maximum capacity of the system is 3500kL/d, however based on historical discharge rates the platform is expected to discharge produced water at a much lower rate of approximately 1500-2000kL/d until oil shutdown in approximately 2022-2023.

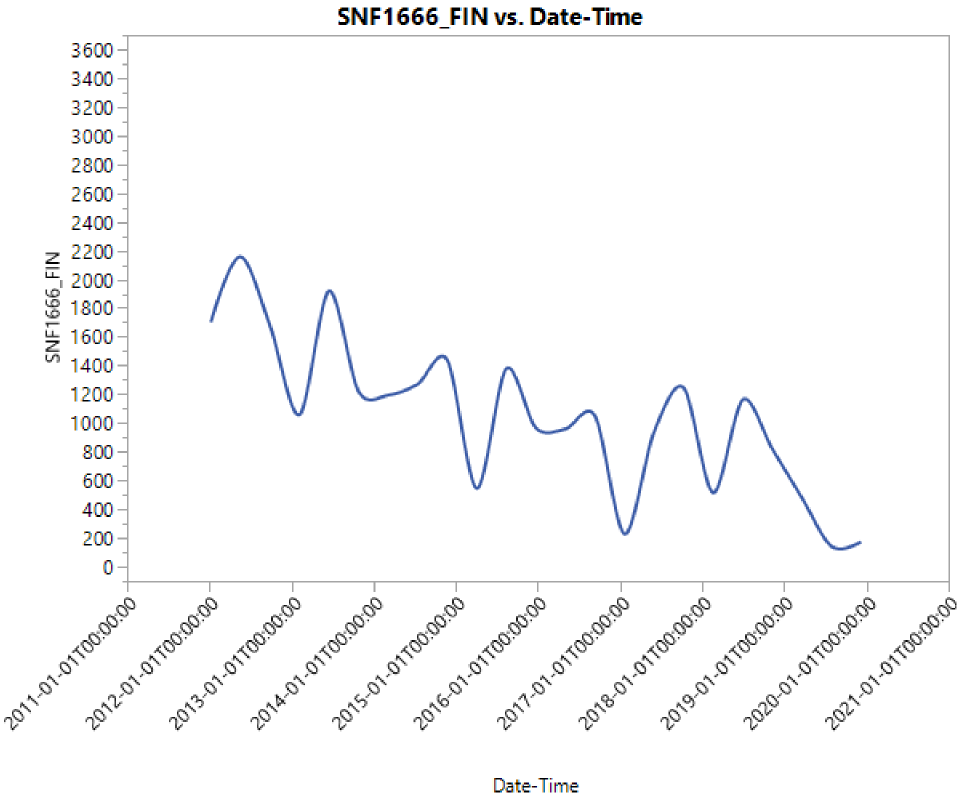

Figure 6-14 Historic smoothed SNA overboard PFW discharge volume (kL/d) (2012-2019)

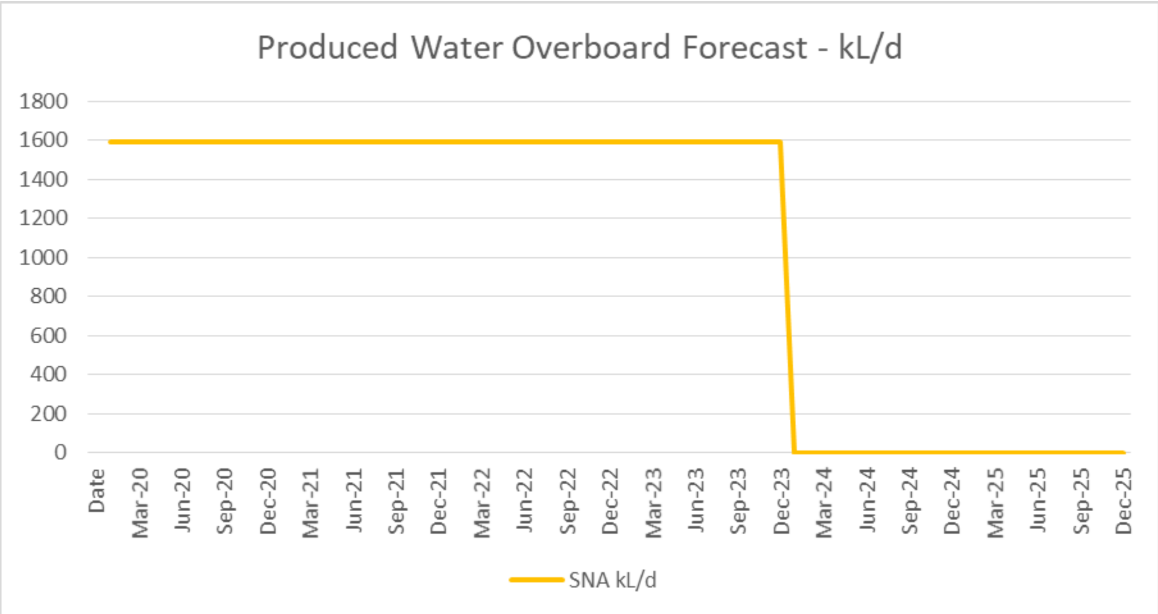

Figure 6-15 Five-year-projected maximum SNA PFW discharge volumes, kL/d.

6.3.7.2 Composition

Physical and chemical make-up

Physical and chemical make-up of PFW is shown in Appendix F – PFW Data file.

Chemical additives

Chemicals in Table 6-18 are added to the platform's water handling system in order to aid oil in water treatment. Chemicals in Table 6-19 are added into the process on the platform for other reasons and could remain at residual levels in the water handling system.

Table 6-18 Chemicals added to Snapper water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Demulsifier (e.g. Baker-Hughes DMO24586)	Oil phase	V-805 Production Oil Separator Inlet	Yes

Table 6-19 Chemicals added to Snapper process that could remain at residual levels in the water handling system.

Description	Predominant phase solubility	Additive injection point	Potentially present in PFW discharge
Gas lift corrosion inhibitor (e.g. Baker-Hughes CGW24013)	Water phase	Gas lift into wells, upstream of water handling system	Yes
Gas well corrosion inhibitor (e.g. Baker-Hughes CRO24014)	Oil phase	Gas wells, upstream of water handling system	Yes

Oil in water monitoring results

Oil in water concentrations are measured on the platform using a continuous online monitor that determines the levels of oil using the way the PFW scatters light under UV fluorescence.

Data is provided in Appendix E for the platform's daily average overboard discharge levels of oil in water (in mg/L) and oil load (kg/d) since 1 Jan 2020 (reflecting the period following the NOPSEMA General Direction 740 in late 2019 where changes were made to the reporting and recording of oil in water).

Data is also provided for the same period showing the cross-check of platform online monitor readings with routine laboratory tests of oil and grease, with the alignment within a +/- 6 mg/L offset.

6.3.7.3 Ecotoxicology

To determine toxicity of the PFW discharge, whole effluent toxicity (WET) testing was performed in 2014 and 2020 across six tests (five chronic, one acute) and eight tests (seven chronic, one acute) respectively across at least 5 different species representing at least four different taxonomic groups. Further details of the ecotoxicology testing can be found in Appendix G.4 - Breakout Box 4. Chemical composition samples were taken at the same time as the samples for WET testing.

Chemical additives added at the time of sampling and ecotoxicology testing on Snapper in 2014 were Baker-Hughes SCW24050 and Baker-Hughes DMO24586 and in 2020 were Baker-Hughes SCW24050, Baker-Hughes DMO24586 and Baker-Hughes CGW24013.

Summarised results of the WET testing are shown in Appendix F.

A Burrlioz model has been run with the results from the 2014 WET testing (following Warne, 2018) and modelling using ssdtools was run with the results from the 2020 WET testing with the 95% and 99% species protection level of effluent shown in Appendix F. See Appendix G.4 – Breakout Box 4 for an explanation of the model selection.

6.3.7.4 Movement, dispersion and dilution

A dispersion model was designed and calibrated to show the movement dispersion and dilution of the PFW discharge around the platform. Appendix G.6 – Breakout Box 6 shows the setup and calibration details for the model. Dispersion model inputs and outputs are summarized in Appendix F.

6.3.7.5 Fate and transport of Snapper PFW

Fate and transport of SNA PFW is no different to TNA PFW as outlined in Section 5.3.2.5.

6.3.7.6 Receptors at Snapper platform

PFW discharged to the marine environment has the potential to result in the following impacts:

- Change in water quality;
- Change in sediment quality;

As a result of change in water quality, change in sediment quality and / or habitat, further impacts may occur which include:

- Injury to fauna;
- Change in habitat;
- Change to the function, interests or activities of other users.

Receptors that could be credibly affected by the discharge of PFW are identified in Table 6-20 and Figure 6-16, with reference made to specific receptors or receptor groups per Table 5-2.

Table 6-20 Receptors affected by impacts associated with discharges of SNA PFW

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Water quality	✓ Open ocean, high energy environment, cool waters, 55 m water depth				
Sediment quality		✓ Sandy sea floor with some gravel			
Benthic habitats and communities			✓ Likely polychaetes, crustaceans and mollusc infauna; possible sponge, soft coral, other invertebrate filter-feeder epifauna		
Plankton			✓ Open ocean phyto- and zoo-plankton		
Fish			✓ Bony & cartilaginous fish, two vulnerable species (Great White and Whale sharks), distribution BIA for Great White shark, 13 km from Great White shark breeding		

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
			BIA, 27 km from Southern Right Whale migration BIA		
Marine Mammals - Seals			✓ Listed species the New Zealand Fur Seal and the Australian Fur Seal known to rest on the platform and swim alongside		
Marine Mammals - Cetaceans			✓ 27 cetacean species or species habitats occur, of which 5 species are listed (Sei, Blue, Fin, Southern Right and Humpback whales), facility overlaps foraging BIA for Blue whale and distribution BIA for Southern Right whale		
Australian Marine Parks and National Parks				✓ Ninety Mile Beach MNP (74 km), Point Hicks MNP (112 km), Gippsland Lakes NP (33 km)	
KEFs				✓ Overlaps with Shelf Rocky Reefs (25 km to South East Reef), 6 km to Upwelling East of Eden, 40 km+ to Bass Cascade, 109 km to Big Horseshoe Canyon	
Commercial and recreational fisheries					✓ Likely fisheries are Bass Strait Central Zone Scallop, Small pelagic, Southern and Eastern Scalefish &

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
					Shark, Danish-seine and scalefish hook, Wrasse, and Southern Squid Jig (low intensity) Fisheries

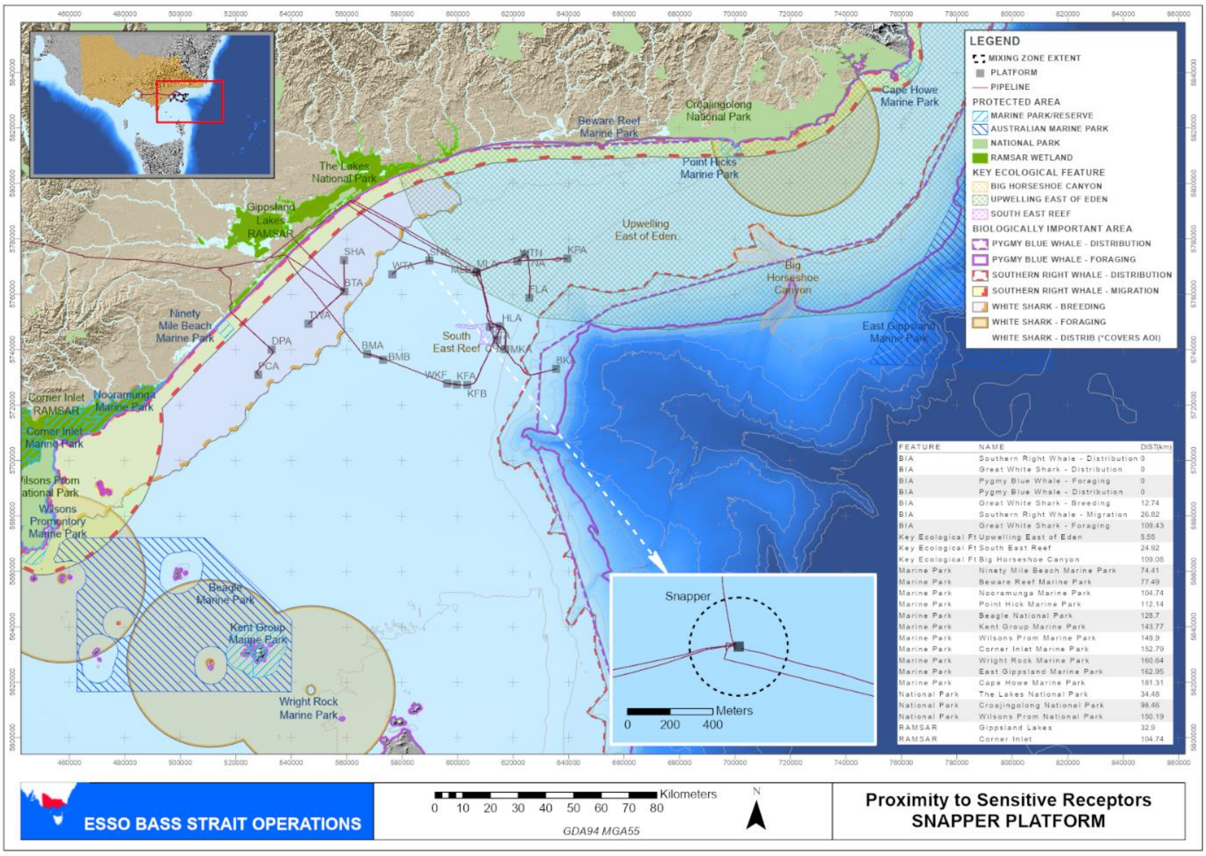

Figure 6-16 230 m mixing zone around SNA platform in relation to other environmental receptors

6.3.7.7 Snapper PFW impact assessment

Impacts to water quality

Physical properties of seawater are established within 10 m of the discharge point. Temperature changes using the RPS APASA (2016) model found that due to the turbulent mixing caused by the initial plunge and then buoyant rise of the effluent, in all cases the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location.

Chemical contaminants in PFW dilute quickly on the initial plunge, then more slowly with dispersion in the current around the platform. PFW is discharged at 30 times the ANZECC 99% species protection criteria for hydrocarbons, 3286 times for metals, and 82 times for inorganics; dilutes rapidly on its initial descent, and reaches ANZECC 95% water quality criteria within 80 m; and ANZECC 99% water quality criteria within 230 m which defines the extent of the mixing zone for the SNA platform. The large dilution factor for metals is driven by the 2019 sampling which indicated the presence of a number of metals that had not been detected before (or detected in very small concentrations) including Cadmium, Chromium, Cobalt, Copper, Nickel and Silver. In the 2020 samples taken roughly 6 months later (with the same well mix plus one additional well), none of these metals were detected. It is suspected that the 2019 results are an outlier, however SNA PFW compositional results will continue to be monitored and managed through the Monitoring and Management Framework (see Volume 4 Section 2.6.5).

PFW is discharged at between 39 and 314 times the background levels for hydrogen sulphide and up to 820 times the background levels of TOC (see Appendix F.3 – PFW data file) and gradually reduces to background levels with distance from the platform, reaching background levels within 120 m of the discharge point.

Anions such as sodium, calcium, magnesium and potassium, and cations such as chloride, sulphate, bromide and bicarbonate are found in PFW however these ions (and their associated salts) are also commonly found in seawater and hence will not be discussed further (Pillard et al. 1996).

Potential Naturally Occurring Radioactive Materials (NORM) are not expected to occur in quantities that may result in significant environmental impacts and are therefore not discussed further.

Impacts to sediment quality

SNA PFW contains the following chemicals which could impact marine sediments and an ANZECC (2000) or ANZECC (2013) interim sediment quality guideline value exists:

- Low molecular weight PAHs: Naphthalene, 2-methylnaphthalene, Fluorene, Phenanthrene and to a lesser extent (lower number of detections): Acenapthene
- High molecular weight PAHs: None
- Metals/Metalloids: Chromium, Cobalt, Copper, Silver, Zinc, Nickel and Arsenic.

There is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment (see Appendix F – PFW Data file). There is a potential pathway for impacts to sediment through settling of constituents in the PFW plume.

An analysis of the SNA PFW discharge found that 97.9% of particles are ≤63 µm (clay or silt). Per Breakout Box 10, this silt and clay fraction (≤63 µm) is usually cited as the chemically active fraction which is associated with potential contaminants of concern (UNEP/WHO 1996). While there is potential for settling of particles in the SNA PFW plume, it is the larger particles (>63 µm) that may settle which are composed primarily of stable inorganic materials and are generally not associated with contaminants of concern (see Appendix G.10 – Breakout Box 10).

Monitoring results for offshore facilities generally show that natural dispersion processes appear to control the concentrations of potential contaminants from PFW in sediments to slightly above background concentrations (Neff et al. 2011). The results from in-situ sediment monitoring of a nearby platform with similar discharge characteristics (TNA) confirms this. Around TNA the study found no valid samples for PAHs, or metals that co-occur in the platform's PFW discharge above the ANZECC (2013) ISQG "low" criteria. (see Appendix G.8 – Breakout Box 8). Occurrences of metals/metalloids were isolated, levels remained low and detections above reference locations remained localised despite there being evidence of some gradients away from the platform (see Appendix G.8 – Breakout Box 8).

TNA is a suitable proxy for predicting the potential for sediment contamination around SNA as the PFW discharge rate, discharge depth, and range of contaminants in PFW is similar (Table 6-5). The water depth at TNA is greater, allowing more chance for metals to precipitate as they move through the water column, and hence precipitation rates at SNA should be lower. In addition, TNA has higher suspended solid loads than SNA (Appendix F – PFW data file), meaning that if metals were to precipitate, they would be more likely to do so in the TNA PFW plume than in the SNA PFW plume and be observed in the sediments close to the discharge point.

Given that;

- sampling results at SNA indicate that less than 3% of particles in PFW may settle (due to their size)
- particles that settle are likely to be stable inorganic materials
- there were no valid observations of contaminants in PFW in sediments around WKF platform (which is a suitable proxy for CBA) above ISQG "low" guideline values

- levels of contamination of nickel in a gradient away from WKF platform (which is a suitable proxy for CBA) remains of very low level and within a small radius

the PFW discharge is expected to have negligible impacts on sediment.

Impacts to biota

Potential impacts of PFW to biota have been assessed through WET testing and dilution modelling to establish a mixing zone. Marine biota inside the mixing zone may be exposed to chronic exposure to contaminants in PFW, however, the mixing zone is limited to a localised extent around the plume discharge point only.

Process chemicals are discharged to the sea in residual amounts if they partition into the PFW and are not removed via the available treatment processes. As WET testing was performed with samples that contained chemical additives, the WET testing results are indicative of the routinely discharged PFW and account for any potential biological impacts that could be incurred by the PFW including any chemical additives. In addition, the ecotoxicological impacts of process chemicals in PFW discharges was comprehensively investigated in a study by Henderson et al. (1999). The study tested 11 commonly used process chemicals (including biocides, corrosion inhibitors and demulsifiers) for their acute toxicity to marine bacterium, both directly in aqueous preparations and following their partitioning between oil and water phases. The study results indicated that toxicity of the PFW was not significantly altered by the presence of most process chemicals used in typical concentrations. A review of the study by Schmeichel (2017) notes that process chemicals make a small contribution to the overall acute toxicity profile of PFW discharges.

Relevant to all receptor types (ecotoxicity pathways) are the SNA WET testing results. 95% species protection criteria based on WET testing occurs within 80 m of the discharge point (Appendix F – PFW data file). At this distance, 95% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of 'ecosystems in which aquatic biological diversity may have been adversely affected to a relatively small but measurable degree by human activity. The biological communities remain in a healthy condition and ecosystem integrity is largely retained' (ANZECC, 2000, p3.1-10). 99% species protection criteria based on WET testing is met within 110 m of the discharge point (Appendix F – PFW data file). At this distance, 99% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of an 'effectively unmodified, high conservation-value ecosystem' (ANZECC, 2000, p3.1-10). Outside 110 m to the remainder of the boundary of the mixing zone, contaminants in PFW will continue to reduce to background seawater concentrations. At these levels they are not expected to have any impact to biota.

Impacts to benthic communities and habitat

There are two pathways for potential impacts to benthic communities and habitats:

- Benthos near the discharge could be subject to exposure to toxic effects of PAHs or metals if they are directly exposed to PFW for long periods;
- Benthic animals near a produced water discharge may bio-accumulate metals, phenols, and hydrocarbons from the ambient water, their food, or bottom sediments.

Direct exposure - chemical ecotoxicity effects

SNA whole effluent toxicity results (2014) show that the amphipod *Allorchestes compressa* was affected by exposure to more than 12.5% raw effluent (acute endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Allorchestes compressa* since SNA effluent is diluted by 10 times within 1.6 m of the discharge point. The sea urchin *Heliocidaris tuberculate* was affected by exposure to more than 3.1% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Heliocidaris tuberculate* since SNA effluent is diluted by 50 times within 5 m of the discharge point. The mussel *Mytilus galloprovincialis* was affected by exposure to more than 6.3% raw effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. Hence no effect is expected on *Mytilus galloprovincialis* since SNA effluent is diluted by 50 times within 5 m of the discharge point.

Impacts from PAHs in PFW on fauna such as scallops, crustaceans and other molluscs within 110 m of the discharge could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size, such as was found during a study of PFW effluent exposure to sea scallops of greater than 10% (Querbach et al. 2005, in Armsworthy et al., 2005). PFW discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). These effects are highly unlikely to occur at SNA since effluent is diluted by 10 times within 1.6 m of the discharge point. Also since the PFW plume is positively buoyant and does not contact the sea floor, it is expected that only fauna on the platform structure itself could be exposed and those on the sea floor are protected from direct exposure.

The range of marine acute LC50 values for arsenic (V) in water was 230-9600 µg/L for crustaceans and 330- 800 000 µg/L for molluscs (Vaughan 1996). In general, early life stages were more sensitive to arsenic than adults. The maximum arsenic level recorded in SNA undiluted PFW was 3 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence direct exposure to arsenic in SNA PFW is unlikely to have an impact on crustaceans or molluscs,

Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water. This effect could be felt by encrusting organisms on the structure (to 110 m horizontal radius of the discharge) but not seafloor organisms due to the positive buoyancy of the plume.

Bioaccumulation

A large study for the Gulf of Mexico Offshore Operators Committee examined bioaccumulation in tissues of mollusc, crustacean, and three fish species in and around 11 platforms in the Gulf of Mexico discharging over 1000 kL/d (Continental Shelf Associates, 1997). The study examined bioaccumulation of five metals (As, Cd, Hg, 226Ra and 228Ra); three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene; and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. They concluded that there is no relationship between the proximity of marine animals to offshore PFW discharges and concentrations in their edible tissues of the chemical constituents.

Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al. (2011). There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalenes and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs but not fish, from discharging than from non-discharging facilities. These PAH could have been derived from PFW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to the marine animals (Neff et. al. 2011).

Effects from bioaccumulation has been primarily associated with low-molecular weight PAHs. Both BTEX and hydrogen sulphide are not bioaccumulative (Neff 2002, ANZECC, 2000 respectively). PAHs are discharged in SNA PFW with a dilution factor of 30 for Naphthalene above the ANZECC 99% species protection level. SNA PFW is diluted 50 times within 5 m of the discharge, hence the potential for bioaccumulation from water is low. PAHs were not observed in sediments around TNA above relevant guideline criteria as part of the 2018 in-situ monitoring program, and hence the potential for bioaccumulation from sediments is low.

There were no significant differences in benthic infauna distributions observed in an in-situ study around Tuna in 2018. This study found that at both near and far zones around the platform and at reference sites, crustaceans dominated the benthic infauna, followed by polychaetes. For less than 15% of the total number of taxa, infauna abundance significantly decreased with distance from the platform, owing mostly to re-distribution of coarser sediments around the platform due to the platform presence (Appendix G.9 – Breakout Box). The change in abundance could not be correlated with increased sediment contaminants found in PFW. This is consistent with the findings in Neff et al. (1992) where distributions of benthic communities around the platform (in 8 m water depth) were explained in large part by the influence of sediment grain size on benthic community structure; and there was no correlation between faunal density and the concentration of total hydrocarbons in sediments.

The potential for bioaccumulation in benthic organisms around SNA can be predicted from the TNA in-situ monitoring results, as as the PFW discharge rate, discharge depth, and range of contaminants in PFW is similar (Table 6-5). The water depth at TNA is greater than SNA which would favour greater chance for precipitation of potential contaminants. In addition, the sediment profile around SNA is similar to TNA (Figure 5-3).

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments (such as at SNA) the potential for impacts to benthic infauna would be even lower.

Copper is readily accumulated by plants and animals; bioconcentration factors ranging from 100 to 26000 have been recorded for various species of phytoplankton, zooplankton, macrophytes, macroinvertebrates and fish (Spear & Pierce 1979). Toxic effects of metals occur when the rate of uptake exceeds the rates of physiological or biochemical detoxification and excretion (Rainbow 1996, in ANZECC 2000). For benthic organisms, effects of copper on crustaceans was published as ranging between 8.5 µg/L (Callianassa australiensis, 10-14 day EC50) to 42 µg/L (Mysidiopsis bahia, from 29-51 d MATC, reproduction) and on molluscs between 0.4 µg/L (Mytilus edulis, from 30-d EC50, reproduction of 2 µg/L) to 20000 µg/L (Ostrea edulis, 5-d LC50) (ANZECC 2000). SNA PFW copper concentrations were 2 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). As SNA PFW is diluted 10 times within 1.6 m of the discharge, any effects on molluscs or crustaceans from exposure to or bioaccumulation of copper in PFW would be limited to organisms within 1.6 m of the discharge.

Zinc is adsorbed by suspended material. Zinc was found to bioaccumulate in freshwater animal tissues 50 to 1130 times but bioaccumulation is not generally considered a problem for zinc (ANZECC 2000). For benthic organisms, zinc effects on crustaceans ranged from 15 µg/L (Acanthomysis sp, growth) to 2100 µg/L (8–28 d NOEC), echinoderms (Asterias forbesi), 460 µg/L (from 7-d LC50) and molluscs: 5 spp, 7–11 d NOEC (from LC50), 15 µg/L (Crassostrea gigas) to 27500 µg/L (ANZECC 2000). Algae were affected at between 13 µg/L (Nitzschia closterium) to 796 µg/L. (Skeletonema sp) (5–10 d NOEC). SNA PFW zinc concentrations were 18 µg/L, 5 µg/L and 2 µg/L in three of the 7 years tested and non-detect in other years (Appendix F). SNA PFW dilutes 10 times within 1.6 m of the discharge. Hence there are effects on benthic animals or plants are limited to those within a 1.6 m radius of the discharge as a result of the levels of zinc in SNA PFW discharge.

Some aquatic organisms may accumulate cobalt, particularly some aquatic plants and benthic organisms (Cole & Carson 1981 in ANZECC 2000). For crustaceans, published ranges of effect concentrations were 9-d LC50, 45 µg/L (Palaemon serratus) to 45 400 µg/L (Carcinus maenas). The lowest geometric mean for converted NOEC was 9 µg/L. Homarus vulgaris also had a low g.m. for NOECs of 65 µg/L; nematode Monhystera sp, 4-d LC50, 94 000 µg/L; and algae 4-5 d EC50, growth, 300 µg/L (Dytilum sp) to 23 600 µg/L (Phaeodactylium sp) (ANZECC 2000). SNA PFW cobalt concentrations were 3 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on benthic animals or plants expected as a result of the levels of cobalt in SNA PFW discharge.

Silver is one of the most toxic metals to aquatic life in laboratory experiments. However, it is important to note that in the natural environment, silver is often found in less bioavailable complexes with chloride, dissolved organic carbon and sulphur-containing ligands and hence laboratory data may overestimate the toxicity of silver (Gorsuch & Purcell 1999 in ANZECC 2000). For crustaceans, the published ecotoxicity data is 2.5-42 µg/L (Mysidopsis bahia, 28-38 d NOEC, from MATC, reproduction and mortality); for molluscs it is 5-42 µg/L (8-28 d NOEC from LC50 and MATC, growth, reproduction) (ANZECC 2000). Effect concentrations for alga are 0.8-3.5 µg/L (5-14 d NOEC Champia parvula (red macroalgae) and Ditylum (diatom), from MATC, reproduction and LC50, growth) (ANZECC 2000). SNA PFW silver concentrations were 17 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). SNA PFW dilutes 10 times in approximately 1.6 m and 50 times in 5 m from the discharge point. Hence any effects on benthic animals or plants expected as a result of the levels of silver in SNA PFW discharge are limited to within 5 m of the discharge.

For benthic organisms, effects of chromium on crustaceans was published as ranging between 4 µg/L (Cancer anthonyi, from 7-d LOEC, hatch) to 3090 µg/L (Rhithanopanopeus sp, from 20-d LC50) (ANZECC 2000). Effects on echinoderms was 2000 µg/L (from 7-d LC50, Asterias forbesi) and molluscs at 1600 µg/L (Mya arenaria, from 7-d LC50) to 10 000 µg/L (Macoma balthica, from 8-16 d LC50). SNA PFW chromium concentrations were 460 µg/L in one year and 1 µg/L in another, out of the 7 years tested and non-detect in other years (Appendix F). As SNA PFW is diluted 10 times within 1.6 m, 50 times within 5 m and 100 times within 8 m of the discharge, any effects on molluscs or crustaceans from bioaccumulation of chromium in PFW would be limited to organisms within 8 m of the discharge. It should also be noted that In marine and estuarine conditions, the high sulphate concentrations make chromium toxicity unlikely (ANZECC 2000).

In general, marine invertebrates are more sensitive to nickel than vertebrates (ANZECC 2000). Chronic effects of nickel on crustaceans was published as ranging between 141 µg/L (36-d chronic mortality, Mysidopsis bahia, Gentile et al. 1982) and 160 µg/L (Portunus pelagicus: from 42d MATC growth of 320 µg/L) to 6000 µg/L from 5-8 d LC50. Effects on echinoderms published as 2600 µg/L (Asteria forbesi from 7-d LC50) molluscs between 240 (Crassostrea virginica; from 12-d LC50 of 1200 µg/L) to 450 000 µg/L from 7-12 d LC50; and algae: 1 sp, Nitzschia closterium 50 µg/L, from 5-d EC50 growth (Australian data) (all from ANZECC 2000). SNA PFW nickel concentrations were 140 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence no impacts to benthic organisms from bioaccumulation of nickel in SNA PFW is expected.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). Given the results from the TNA in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments is unlikely.

Given the above, benthic biota around SNA platform are highly unlikely to be affected by the PFW discharge. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform structure within 110 m of the discharge point, within the mixing zone extent of 230 m. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

Impacts to plankton

There are three pathways for potential impacts to plankton:

- Exposure to temperature effects on direct exposure
- Stimulatory effects of nutrients in the plume, leading to eutrophication of waters
- Exposure to toxic effects of chemical constituents of PFW if plankton are directly exposed for long periods (i.e. directly in the plume)

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on plankton are not credible.

Stimulatory effects from nutrients in the plume

Discharges of nutrients and hydrocarbons in the PFW plume can increase the localised abundance of plankton. For example, ammonia may elicit inhibitory (toxic) and/or stimulatory (e.g. eutrophication) responses from resident biota (Neff, 2011). Plankton could be attracted to localised higher concentrations of these constituents within the mixing zone and as a result plankton populations can rapidly increase. However, increased planktonic activity and turnover mass rates within the mixing zone is not expected to have any marked change on the water quality due to the high levels of movement of water around the platform from the action of currents and waves. Levels of nitrate and phosphates are low (not unlike other produced waters, Neff, 2011) and hence are not likely to cause eutrophication. Supporting this there is anecdotal evidence that no phytoplankton blooms have ever been recorded at a Bass Strait Esso facility.

Direct exposure – chemical ecotoxicity effects

Phytoplankton are among the most sensitive organisms to both forms of arsenic. The Australian diatom Nitzschia closterium is highly sensitive to arsenic (III), with a 72-h EC50 for growth inhibition of 7 µg/L (Florence & Stauber 1991), compared to >2000 µg/L for arsenic (V). An Environmental Concern Level (ECL, see Section 8.3.4.5) of 2.3 µg/L was derived for As (III) in marine waters, using an AF of 100 (ANZECC 2000). SNA PFW arsenic concentrations were 3 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no impacts to plankton anticipated from arsenic in SNA PFW.

Plankton have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Any impacts as a result of direct exposure of planktonic communities to PFW are expected to be confined to the 110 m zone to 99% species protection, which sits within the extent of the mixing zone. Direct exposure of planktonic communities to PFW within the 110 m zone (to 99% species protection criteria based on WET testing) is not considered to result in significant impacts at the population level of organisms that could affect broader ecological diversity or productivity of the area surrounding the facility.

Impacts to fish

There are three pathways for potential impacts to fish:

- Exposure to temperature effects on direct exposure
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed for long periods (i.e. directly in the plume)
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed to contaminated sediments

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on fish are not credible.

Direct exposure – chemical ecotoxicity effects

Early lifestages of fish (embryos, larvae) within the 110 m zone to where 99% species protection criteria are met would be most susceptible to the exposure from chemical constituents in the PFW discharge, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced without liver function damage (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011) which is not likely to be the case at HLA. Larvae entrained in the outfall may only be exposed to higher concentrations for a short period relative to the buoyancy of the organism (Querbach, et al. 2005). Outside the 110 m radius, early lifestages of fish are not expected to be affected at all.

Effects from copper in water on fish was published as ranging between 30 µg/L (2 spp, from 12-14 d EC50, hatch & mortality) to 260 µg/L (Menidia menidia, 11-d EC50, hatch) (ANZECC 2000). SNA PFW copper concentrations were 2 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of copper in SNA PFW.

Effects from zinc in water on fish was published as 10 400 µg/L (Fundulus heteroclitus, 7-d NOEC of from LC50) (ANZECC 2000). SNA PFW zinc concentrations were 18 µg/L or less in three of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of zinc in SNA PFW.

Effects from cobalt in water on fish was published as 52 500-227 000 µg/L (from 4-9 d LC50) (ANZECC 2000). SNA PFW cobalt concentrations were 3 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of cobalt in SNA PFW.

Levels of chromium (max detected 460 µg/L) and nickel (max detected 140 µg/L) in the SNA discharge are well below the concentrations that could have effects on fish (Chromium 776 µg/L (Citharichthys sp, from 14-21 d LC50) to 14 125 µg/L (Cyprinodon variegatus, from NOEC, growth) and Nickel Fundulus heteroclitus, 30 000 µg/L from 7-d LC50; from ANZECC 2000).

Salinity and organic carbon in marine waters tend to reduce toxicity to silver versus freshwaters and laboratory conditions. The acute toxicity of silver to marine fish was published as 330–2700 µg/L (96-h LC50), and no chronic test results were published in ANZECC 2000. SNA PFW silver concentrations were 17 µg/L in one of the 7 years tested and non-detect in other years (Appendix F). Hence there are no effects on fish expected as a result of the levels of silver in SNA PFW.

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement. Fish also exhibit a strong avoidance reaction to hydrogen sulphide (USEPA 1986 in ANZECC 2000).

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound's volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). The dilution ratio for SNA PFW to ANZECC 99% species protection water criteria for Benzene is 18, and SNA PFW is diluted 50 times within 5 m, hence BTEX is not expected to have any toxic effects beyond a 5 m radius from the discharge point.

Whole effluent ecotoxicity data from SNA PFW shows that the barramundi fish *Lates calcarifier* experienced effects above 12.5% raw effluent exposure (chronic endpoint). This is unlikely to occur anywhere in the mixing zone except directly at the discharge point itself. Whilst this species is not local to Bass Strait, no effect is expected on fish similar to *Lates calcarifier* since SNA effluent is diluted by more than 10 times within 1.6 m of the discharge point.

Exposure to contaminated sediments – chemical ecotoxicity effects

Effects from fish directly exposed to contaminated sediments above 22 mg/kg PAH could result in gill hyperplasia, reduced phagocytic activity of macrophages and pancreatic necrosis (spot, Hinkle-Conn et al., 1998). However this is highly unlikely to be the case as the highest level of PAHs in sediment around TNA was 0.004 mg/kg.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient fish such as great white sharks, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to fish, the limited spatial extent of the water quality (230 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on fish particularly the great white shark from PFW discharges when assessed against the relevant criteria in the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to seals

There are three pathways for potential impacts to seals:

- Exposure to toxic effects of chemical constituents of PFW if seals are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Produced water plumes predominantly result in dissolved contaminants and they rarely cause a defined layer on the sea surface (silvery sheen is the lowest level according to the Bonn agreement and usually patchy if at all present from the PFW discharge). Hence potential impact pathways through contact of hydrocarbons with seal fur and ingestion are not credible.

Direct exposure – chemical ecotoxicity effects

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005). As such, it is highly unlikely that these potential impact pathways will be significant. In addition, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986).

Effects from inhalation of hydrocarbon vapours from PFW sheens

Inhalation of hydrocarbon vapours could cause toxic effects. However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Seals are highly mobile and active animals and do not spend all their time at the water surface, as such, it is highly unlikely that this potential impact pathways will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Exposure to on-sea hydrocarbons could cause irritation to the eyes and oral cavity. However seals are unlikely to remain swimming within the discharge plume for long periods as they are highly active animals, travel great distances and forage at various depths. As such, it is highly unlikely that this potential impact pathways will be significant so as to not have any chronic impacts to seals.

Bioaccumulation through ingestion of impacted food sources

As impacts to the predominant seal food source of fish are of very low likelihood (as above), bioaccumulation through ingestion of impacted food sources is unlikely to have any impact on seals.

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, coupled with seals being highly mobile active animals who do not spend all their time in the water or at the water surface, seals are unlikely to be exposed to elevated contamination concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as pelagic fish species). Given the potential absence of impacts to seals, the limited spatial extent of the water quality (230 m radius) the predicted short interaction duration (i.e. minutes at a time) with the PFW plume, and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance.

Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

There are four pathways for potential impacts to cetaceans:

- Exposure to toxic effects of chemical constituents of PFW if cetaceans are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Direct exposure – chemical ecotoxicity effects

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathways will be significant. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013).

Effects from inhalation of hydrocarbon vapours from PFW sheens

As a result of inhaling volatile compounds when surfacing, cetaceans can experience lung congestion (Geraci & St. Aubin 1990); or irritation or damage to mucous membranes or airways (Helm et al., 2015). However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Cetaceans can be exposed through direct contact with the eyes, potentially leading to inflammation (Geraci & St. Aubin 1990). Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Bioaccumulation through ingestion of impacted food sources

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

The mixing zone overlaps the foraging BIA for the blue whale and distribution BIA for the Southern Right Whale; however, given the localised area of impact and that whales are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the Conservation Management Plan of either the Blue Whale or Southern Right Whale and the discharge activity is not inconsistent with those plans.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient cetaceans such as migrating whales, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality (230 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on cetaceans from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

There are three potential impact pathways for fisheries:

- Tainting (hydrocarbon odour in caught fish) due to tissue accumulation of hydrocarbons in PFW
- Impacts to the safety of humans through the consumption of target species tissues that are impacted by PFW.
- Reduction of fisheries stocks, through the direct impact of PFW on target species and nurseries

Tainting

Per Appendix F, ANZECC seafood taint criteria is reached within 8 m of the discharge point. (Note: Appendix G.3 – Breakout Box 3 applies to the detection of other phenols under the seafood taint guidelines). The total area represented by a 8 m radius at SNA is 201 m^2 (1/50th of a hectare), and cumulative area across all Bass Strait platform PFW discharges is <2000 m^2 (1/5th of a hectare), representing an extremely small proportion of the total fisheries area. Hence the discharge is highly unlikely to cause taint in fisheries-caught fish.

Impacts to seafood safety for humans

Since fish or shellfish are not harvested around the PFW plume or mixing zone out to at least 500 m from the platform, and the zone in which 99% species protection criteria is reached extends to only 110 m from the platform, there is no effect of the PFW discharge on humans through consumption.

Impacts to fisheries stocks

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone), where they are directly present in the PFW plume (within 110 m radius), may be exposed to chronic sub-lethal impacts (see above) however due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Stakeholder feedback confirmed that although fishers had been able to see discharges from the Bass Strait platforms from beyond the 500 m exclusion zone, the discharge did not have any effect on fisheries or fisheries equipment, or amenity for the fishers. There is general acknowledgement among fishers that Esso's facilities provide safe habitat for juvenile fisheries species. There were no complaints or issues brought up by fishers regarding PFW discharge. Ongoing dialogue with fishing communities is part of Esso's stakeholder engagement plan.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

The Bass Cascade: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as Benthic habitats and communities applies to this KEF as described above. Given the distance from the PFW mixing zone to the reported location of the South East Reef, impacts on this reef are not anticipated.

Cumulative impacts from multiple discharges

There are no other PFW plumes within 3 km of the SNA discharge. The next closest discharge is at TNA which is over 10 km away from the SNA discharge point and the plumes do not overlap (see Appendix G.6 – Breakout Box 6).

Other continuous discharges from the same platform are limited to discharges from pile subsea windows. These discharge at 35.8 m (ODSP) and 49 m (CDSP) below sea level, deeper than the produced water effluent pipe depth at 8.2 m below sea level. Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window (Section 6.4.1.1). Discharges of water containing chemicals (at discharge all chemicals are CHARM Gold/Silver or OCNS D/E (Table 6-22) or dissolved hydrocarbons from the pile will be intermittent or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. It is therefore expected that any exposure will be limited in duration.

Dispersion modelling for SNA PFW shows the maximum plunge depth from the discharge point under all current speeds is to 8.6 m below sea level, hence any cumulative impacts from the interaction with the produced water effluent plume within the mixing zone is considered unlikely.

Other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the PFW plume but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

Historical activities such as discharging muds and cuttings during drilling may have resulted in changes to the sea floor sediment chemical characterisation above background levels. This includes the discharge of water based muds and barite containing barium, an inert metal; and the discharge of cuttings from natural rock formations encountered during drilling, together with small amounts of residual drilling muds on cuttings. Any changes to sediment quality from historical impacts from background will be considered as part of the surrender of title process. The last drilling program on SNA was in approximately 2010, hence discharged fluids or solids from the drilling program is expected to have at least partially been dispersed or bioremediated. There is not expected to be a significant cumulative impact to sediment quality from the additive effect of discharging PFW to sediments containing higher levels of barium or residual drilling mud constituents.

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes cumulative impacts on marine fauna is unlikely.

As fishing is not carried out within 500 m of the platform, which is beyond the mixing zone of 230 m no cumulative impacts from multiple discharges is likely on commercial and recreational fishing.

Given the distance to other sensitive receptors (Table 5-2) cumulative impacts from multiple discharges are highly unlikely.

6.3.7.8 Snapper PFW consequence evaluation

Impacts from SNA PFW are limited to a localised mixing zone around the discharge point, with negligible impacts to sediment. Potential impacts to biota, including benthic habitats and communities, plankton, fish, and seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).

Effects could be ongoing, including through bioaccumulation of PAHs and persistent chemicals, but effects are confined to some biota on the platform structure itself (e.g. crustaceans) or dispersed in a small radius around the platform water and sediments at low and safe concentrations. Within the mixing zone, there could be sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level. The environment is highly endemic, with few endangered and rare species present, but is generally strong and resilient, and provides some ecosystem services (e.g. fisheries).

The consequence level is therefore assessed as **Consequence Level III.**

To ensure continuing confidence in the consequence level the Monitoring and Management Framework will be implemented. If routine monitoring was to detect levels in PFW above the trigger values and there was the potential to impact the ecosystem integrity, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are not realised. A sampling plan to demonstrate compliance with the approved mixing zone boundary will be developed for the sediment survey. The sampling plan outlines and justifies sampling locations and when concentration and bioavailability testing occur.

6.3.8 Marlin B platform

6.3.8.1 Volume

MLB is expected to discharge PFW overboard in approximately 2022. The maximum capacity of the system is 2450 kL/d.

6.3.8.2 Composition

There are no samples available at the present time in order to characterise the physical and chemical make-up of PFW from MLB. However, it is expected that an analogue for composition is the TNA platform discharge.

Chemical additives to the water handling system are currently unknown and will depend on the results from commissioning the equipment, and may involve a water clarifier or demulsifier chemical. Chemicals added to the MLB process that could remain at residual levels in the water handling system will likely be gaslift corrosion inhibitor (e.g. Baker-Hughes CGW24013, water soluble) and fin-fan corrosion inhibitor (e.g. Baker-Hughes CRO24037, oil soluble).

Oil in water concentrations will be measured on the platform using an online monitor that determines the levels of oil using the way the PFW scatters light under UV fluorescence.

6.3.8.3 Ecotoxicology

There are no results available currently for the ecotoxicology of MLB PFW. However, it is expected that an analogue for composition and therefore ecotoxicology is the TNA platform discharge.

6.3.8.4 Movement, dispersion and dilution

A dispersion model was designed and calibrated to show the movement dispersion and dilution of the PFW discharge around the platform. . Appendix G.6 – Breakout Box 6 shows the setup and calibration details for the model. Dispersion model inputs and outputs are summarized in Appendix F.

6.3.8.5 Fate and transport of Marlin B PFW

Fate and transport of WKF PFW is no different to TNA PFW as outlined in Section 5.3.2.5.

6.3.8.6 Receptors at Marlin B platform

PFW discharged to the marine environment has the potential to result in the following impacts:

- Change in water quality;
- Change in sediment quality;

As a result of change in water quality, change in sediment quality and / or habitat, further impacts may occur which include:

- Injury to fauna;
- Change in habitat;
- Change to the function, interests or activities of other users.

Receptors that could be credibly affected by the discharge of PFW are identified in Table 6-21, and Figure 6-17, with reference made to specific receptors or receptor groups per Table 5-2.

Table 6-21 Receptors affected by impacts associated with discharges of MLB PFW

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
Water quality	✓ Open ocean, high energy environment, cool waters, 59 m water depth				
Sediment quality		✓ Sandy sea floor with some gravel, possible calcified scallop beds			
Benthic habitats and communities			✓ Likely polychaetes, crustaceans and mollusc infauna; possible sponge, soft coral, other invertebrate filter-feeder epifauna		
Plankton			✓ Open ocean phyto- and zoo-plankton		
Fish			✓ Bony & cartilaginous fish, two vulnerable species (Great White and Whale sharks), distribution BIA for Great White shark, 23 km from Great White shark breeding BIA, 36 km from Southern Right Whale migration BIA		
Marine Mammals - Seals			✓ Listed species the New Zealand Fur Seal and the Australian Fur Seal known to rest on the		

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users
			platform and swim alongside		
Marine Mammals - Cetaceans			✓ 27 cetacean species or species habitats occur, of which 5 species are listed (Sei, Blue, Fin, Southern Right and Humpback whales), facility overlaps foraging BIA for Blue whale and distribution BIA for Southern Right whale		
Australian Marine Parks and National Parks				✓ Ninety Mile Beach MNP (90 km), Point Hicks MNP (98 km), Gippsland Lakes NP (42 km)	
KEFs				✓ Overlaps with Shelf Rocky Reefs (19 km to South East Reef), and Upwelling East of Eden, 40 km+ to Bass Cascade, 92 km to Big Horseshoe Canyon	
Commercial and recreational fisheries					✓ Likely fisheries are Bass Strait Central Zone Scallop, Small pelagic, Southern and Eastern Scalefish & Shark, Danish-seine and scalefish hook, Wrasse, and Southern Squid Jig (low intensity) Fisheries

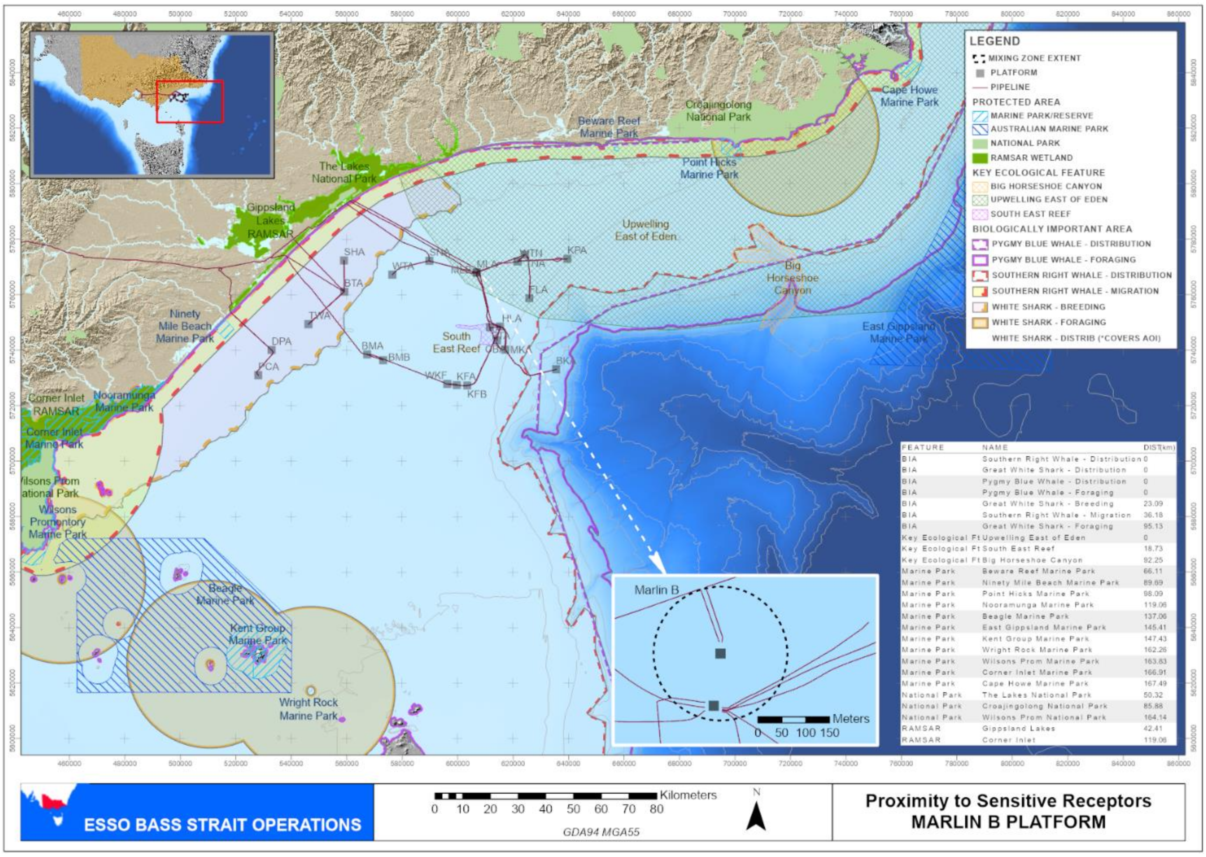

Figure 6-17 140 m mixing zone around MLB platform in relation to other environmental receptors

6.3.8.7 Marlin B PFW impact assessment

This section assumes an analogue for composition and ecotoxicology of the discharge is TNA platform PFW discharge, with dispersion occurring at MLB in accordance with the dispersion modelling results.

Impacts to water quality

Physical properties of seawater are established within 10 m of the discharge point. Temperature changes using the RPS APASA (2016) model found that due to the turbulent mixing caused by the initial plunge and then buoyant rise of the effluent, in all cases the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location.

Chemical contaminants in PFW dilute quickly on the initial plunge, then more slowly with dispersion in the current around the platform. PFW is discharged at 16 times the ANZECC 99% species protection water quality criteria for hydrocarbons, 47 times for metals, and 91 times for inorganics; dilutes rapidly on its initial plunge to 10 times within 2.4 m and 50 times within 7.8 m. It reaches ANZECC 95% species protection water quality criteria within 12 m and ANZECC 99% species protection water quality criteria within 12 m of the discharge point.

PFW is discharged at between 7 and 56 times the background levels for hydrogen sulphide and up to 370 times the background levels of TOC (see Appendix F.6 – PFW data file), and gradually reduces to background levels with distance from the platform, reaching background levels within 90 m of the discharge point and defining the extent of the mixing zone for TNA platform.

Anions such as sodium, calcium, magnesium and potassium, and cations such as chloride, sulphate, bromide and bicarbonate are found in PFW however these ions (and their associated salts) are also commonly found in seawater and hence will not be discussed further (Pillard et al. 1996).

Potential Naturally Occurring Radioactive Materials (NORM) are not expected to occur in quantities that may result in significant environmental impacts and are therefore not discussed further.

Impacts to sediment quality

TNA PFW in particular contains some PAHs and metals/metalloids that could be chemicals of concern for marine sediments where an ANZECC (2000) interim sediment quality guideline value exists. The precise chemicals of concern and their concentrations found in MLB PFW will be determined as part of the commissioning and start-up of the MLB water handling system.

There is no physical interaction of the plume with the seabed and hence no direct exposure of the constituents of PFW with the sediment (see Appendix F – PFW Data file). There is a potential pathway for impacts to sediment through settling of constituents in the PFW plume.

An analysis of the TNA PFW discharge found that 96.2% of particles are ≤63 µm (clay or silt). Per Breakout Box 10, this silt and clay fraction (≤63 µm) is usually cited as the chemically active fraction which is associated with potential contaminants of concern (UNEP/WHO 1996). While there is potential for settling of particles in the TNA PFW plume, it is the larger particles (>63 µm) that may settle which are composed primarily of stable inorganic materials and are generally not associated with contaminants of concern (see Appendix G.10 – Breakout Box 10).

Monitoring results for offshore facilities generally show that natural dispersion processes appear to control the concentrations of potential contaminants from PFW in sediments to slightly above background concentrations (Neff et al. 2011). The results from in-situ sediment monitoring of a nearby platform with similar discharge characteristics (TNA) confirms this.

Around TNA the study found no valid samples for PAHs, or metals that co-occur in the platform's PFW discharge above the ANZECC (2013) ISQG "low" criteria. (see Appendix G.8 – Breakout Box 8). Occurrences of metals/metalloids were isolated, levels remained low and detections above reference locations remained localised despite there being evidence of some gradients away from the platform (see Appendix G.8 – Breakout Box 8).

TNA is a suitable proxy for predicting the potential for sediment contamination around MLB as the PFW discharge rate, discharge depth, and range of contaminants in PFW is similar (Table 6-5). The water depth at TNA is greater, allowing more chance for metals to precipitate as they move through the water column, and hence precipitation rates at MLB should be lower. As a result the MLB PFW discharge is not expected to have significant impacts on sediment.

Impacts to biota

Potential impacts of PFW to biota have been assessed through WET testing and dilution modelling to establish a mixing zone. Marine biota inside the mixing zone may be exposed to chronic exposure to contaminants in PFW, however, the mixing zone is limited to a localised extent around the plume discharge point only.

Process chemicals are discharged to the sea in residual amounts if they partition into the PFW and are not removed via the available treatment processes. As WET testing was performed with samples that contained chemical additives, the WET testing results are indicative of the routinely discharged PFW and account for any potential biological impacts that could be incurred by the PFW including any chemical additives. In addition, the ecotoxicological impacts of process chemicals in PFW discharges was comprehensively investigated in a study by Henderson et al. (1999). The study tested 11 commonly used process chemicals (including biocides, corrosion inhibitors and demulsifiers) for their acute toxicity to marine bacterium, both directly in aqueous preparations and following their partitioning between oil and water phases. The study results indicated that toxicity of the PFW was not significantly altered by the presence of most process chemicals used in typical concentrations. A review of the study by Schmeichel (2017) notes that process chemicals make a small contribution to the overall acute toxicity profile of PFW discharges.

Relevant to all receptor types (ecotoxicity pathways) are the TNA WET testing results, which can be used as an analogue for the MLB discharge. 95% species protection criteria based on WET testing is met within 90 m of the discharge point at MLB (Appendix F – PFW data file). At this distance, 95% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of 'ecosystems in which aquatic biological diversity may have been adversely affected to a relatively small but measurable degree by human activity. The biological communities remain in a healthy condition and ecosystem integrity is largely retained' (ANZECC, 2000, p3.1-10). 99% species protection criteria based on WET testing are met within 140 m of the discharge point at MLB (Appendix F – PFW data file). At this distance, 99% species will be protected from adverse ecotoxicity effects of the discharge, and water quality is reflective of an 'effectively unmodified, high conservation-value ecosystem' (ANZECC, 2000, p3.1-10). Outside 140 contaminants in PFW will continue to reduce to background seawater concentrations. At these levels they are not expected to have any impact to biota.

Impacts to benthic communities and habitat

There are two pathways for potential impacts to benthic communities and habitats:

- Benthos near the discharge could be subject to exposure to toxic effects of PAHs or metals if they are directly exposed to PFW for long periods;
- Benthic animals near a produced water discharge may bio-accumulate metals, phenols, and hydrocarbons from the ambient water, their food, or bottom sediments.

Direct exposure - chemical ecotoxicity effects

TNA whole effluent toxicity results (2014) show that the amphipod *Allorchestes compressa* was affected by direct exposure to more than 50% raw effluent (acute endpoint). This is unlikely to occur anywhere within the mixing zone except immediately at the point of discharge. If MLB PFW can be approximated by TNA PFW, no effect is expected on *Allorchestes compressa* since MLB effluent is diluted by more than 10 times within 2.4 m of the discharge point. The sea urchin *Heliocidaris tuberculate* was affected by exposure to more than 12.5% raw TNA PFW effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone at MLB except immediately at the point of discharge. Hence no effect is expected on *Heliocidaris tuberculate* since MLB effluent is diluted by more than 10 times within 2.4 m of the discharge point. The mussel *Mytilus galloprovincialis* was affected by exposure to more than 6.3% raw TNA PFW effluent (chronic endpoint). This is unlikely to occur anywhere within the mixing zone at MLB except immediately at the point of discharge and possibly out to 7.8 m from the discharge point. Hence the only effect expected on *Mytilus galloprovincialis* is highly localised to within 1 - 7.8 m since MLB effluent is diluted by 50 times within 7.8 m of the discharge point.

Impacts from direct exposure to PAHs in PFW on fauna such as scallops, crustaceans and other molluscs within 140 m of the discharge could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size, such as was found during a study of PFW effluent exposure to sea scallops of greater than 10% raw effluent (Querbach et al. 2005, in Armsworthy et al., 2005). PFW discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). These effects are highly unlikely to occur at MLB since effluent is diluted by more than 10 times within 2.4 m of the discharge point. Also since the PFW plume is positively buoyant and does not contact the sea floor, it is expected that only fauna on the platform structure itself could be exposed and those on the sea floor are protected from direct exposure.

Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water. This effect could be felt by encrusting organisms on the structure (to 140 m horizontal radius of the discharge) but not seafloor organisms due to the positive buoyancy of the plume.

Bioaccumulation

A large study for the Gulf of Mexico Offshore Operators Committee examined bioaccumulation in tissues of mollusc, crustacean, and three fish species in and around 11 platforms in the Gulf of Mexico discharging over 1000 kL/d (Continental Shelf Associates, 1997). The study examined bioaccumulation of five metals (As, Cd, Hg, 226Ra and 228Ra); three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene; and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. They concluded that there is no relationship between the proximity of marine animals to offshore PFW discharges and concentrations in their edible tissues of the chemical constituents.

Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al. (2011). There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalenes and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs but not fish, from discharging than from non-discharging facilities. These PAH could have been derived from PFW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to marine animals (Neff et. al. 2011).

Effects from bioaccumulation has been primarily associated with low-molecular weight PAHs. Both BTEX and hydrogen sulphide are not bioaccumulative (Neff 2002, ANZECC, 2000 respectively). PAHs were not observed in either waters or sediments around TNA above relevant guideline criteria as part of the 2018 in-situ monitoring program, and hence the potential for bioaccumulation is low.

There were no significant differences in benthic infauna distributions observed in an in-situ study around Tuna in 2018. This study found that at both near and far zones around the platform and at reference sites, crustaceans dominated the benthic infauna, followed by polychaetes. For less than 15% of the total number of taxa, infauna abundance significantly decreased with distance from the platform, owing mostly to re-distribution of coarser sediments around the platform due to the platform presence (Appendix G.9 – Breakout Box). The change in abundance could not be correlated with increased sediment contaminants found in PFW. This is consistent with the findings in Neff et al. (1992) where distributions of benthic communities around the platform (in 8 m water depth) were explained in large part by the influence of sediment grain size on benthic community structure; and there was no correlation between faunal density and the concentration of total hydrocarbons in sediments.

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments (such as at MLB) the potential for impacts to benthic infauna would be even lower.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). Given the results from the TNA in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments is unlikely.

Given the above, benthic biota around MLB platform are highly unlikely to be affected by the PFW discharge. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform structure within 140 m of the discharge point. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

Impacts to plankton

There are three pathways for potential impacts to plankton:

- Exposure to temperature effects on direct exposure
- Stimulatory effects of nutrients in the plume, leading to eutrophication of waters
- Exposure to toxic effects of chemical constituents of PFW if plankton are directly exposed for long periods (i.e. directly in the plume)

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on plankton are not credible.

Stimulatory effects from nutrients in the plume

Discharges of nutrients and hydrocarbons in the PFW plume can increase the localised abundance of plankton. For example, ammonia may elicit inhibitory (toxic) and/or stimulatory (e.g. eutrophication) responses from resident biota (Neff, 2011). Plankton could be attracted to localised higher concentrations of these constituents within the mixing zone and as a result plankton populations can rapidly increase. However, increased planktonic activity and turnover mass rates within the mixing zone is not expected to have any marked change on the water quality due to the high levels of movement of water around the platform from the action of currents and waves. Levels of nitrate and phosphates are low (not unlike other produced waters, Neff, 2011) and hence are not likely to cause eutrophication. Supporting this there is anecdotal evidence that no phytoplankton blooms have ever been recorded at a Bass Strait Esso facility.

Direct exposure – chemical ecotoxicity effects

Plankton have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Any impacts as a result of direct exposure of planktonic communities to PFW are expected to be confined to the 140 m zone to 99% species protection, which sits within the extent of the mixing zone. Direct exposure of planktonic communities to PFW within the 140 m zone (to 99% species protection criteria based on WET testing) is not considered to result in significant impacts at the population level of organisms that could affect broader ecological diversity or productivity of the area surrounding the facility.

Impacts to fish

There are three pathways for potential impacts to fish:

- Exposure to temperature effects on direct exposure
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed for long periods (i.e. directly in the plume)
- Exposure to toxic effects of chemical constituents of PFW if fish are directly exposed to contaminated sediments

Direct exposure – temperature effects

As the average temperature of the produced water plume returns to within 3°C above ambient temperatures within 10 m of the discharge location, potential temperature effects on fish are not credible.

Direct exposure – chemical ecotoxicity effects

Early lifestages of fish (embryos, larvae) within the 140 m zone to where 99% species protection criteria are met would be most susceptible to the exposure from chemical constituents in the PFW discharge, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced without liver function damage (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011) which is not likely to be the case at MLB. Larvae entrained in the outfall may only be exposed to higher concentrations for a short period relative to the buoyancy of the organism (Querbach, et al. 2005). Outside the 140 m radius, early lifestages of fish are not expected to be affected at all.

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement. Fish also exhibit a strong avoidance reaction to hydrogen sulphide (USEPA 1986 in ANZECC 2000).

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound’s volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). The dilution ratio for TNA PFW to ANZECC 99% species protection water criteria for Benzene is 12, and MLB PFW is diluted 10 times within 2.4 m, hence (using TNA composition as an analogue), BTEX is not expected to have any toxic effects. Many fish species can metabolise hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012).

Whole effluent ecotoxicity data from TNA PFW shows that the barramundi fish *Lates calcarifier* experienced effects above 50% raw effluent exposure (chronic endpoint). This is unlikely to occur anywhere in the mixing zone except directly at the discharge point itself. Whilst this species is not local to Bass Strait, no effect is expected on fish similar to *Lates calcarifier* since MLB effluent is diluted by more than 10 times within 2.4 m of the discharge point.

Exposure to contaminated sediments – chemical ecotoxicity effects

Effects from fish directly exposed to contaminated sediments above 22 mg/kg PAH could result in gill hyperplasia, reduced phagocytic activity of macrophages and pancreatic necrosis (spot, Hinkle-Conn et al., 1998). However this is highly unlikely to be the case as the highest PAHs in sediment around TNA was 0.004 mg/kg.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient fish such as great white sharks, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to fish, the limited spatial extent of the water quality (90 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on fish particularly the great white shark from PFW discharges when assessed against the relevant criteria in the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to seals

There are three pathways for potential impacts to seals:

- Exposure to toxic effects of chemical constituents of PFW if seals are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Produced water plumes predominantly result in dissolved contaminants and they rarely cause a defined layer on the sea surface (silvery sheen is the lowest level according to the Bonn agreement and usually patchy if at all present from the PFW discharge). Hence potential impact pathways through contact of hydrocarbons with seal fur and ingestion are not credible.

Direct exposure – chemical ecotoxicity effects

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005). As such, it is highly unlikely that these potential impact pathways will be significant. In addition, pinnipeds have been found to have the enzyme systems necessary to convert absorbed hydrocarbons into polar metabolites, which can be excreted in urine (Engelhardt, 1982; Addison & Brodie, 1984; Addison et al., 1986).

Effects from inhalation of hydrocarbon vapours from PFW sheens

Inhalation of hydrocarbon vapours could cause toxic effects. However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Seals are highly mobile and active animals and do not spend all their time at the water surface, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Exposure to on-sea hydrocarbons could cause irritation to the eyes and oral cavity. However seals are unlikely to remain swimming within the discharge plume for long periods as they are highly active animals, travel great distances and forage at various depths. As such, it is highly unlikely that this potential impact pathway will be significant so as to not have any chronic impacts to seals.

Bioaccumulation through ingestion of impacted food sources

As impacts to the predominant seal food source of fish are of very low likelihood (as above), bioaccumulation through ingestion of impacted food sources is unlikely to have any impact on seals.

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, coupled with seals being highly mobile active animals who do not spend all their time in the water or at the water surface, seals are unlikely to be exposed to elevated contamination concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as pelagic fish species). Given the potential absence of impacts to seals, the limited spatial extent of the water quality (90 m radius) the predicted short interaction duration (i.e. minutes at a time) with the PFW plume, and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

There are four pathways for potential impacts to cetaceans:

- Exposure to toxic effects of chemical constituents of PFW if cetaceans are directly exposed for long periods (i.e. directly in the plume)
- Effects from inhalation of hydrocarbon vapours from PFW sheens
- Irritation effects from physical contact with hydrocarbons in PFW
- Bioaccumulation through the ingestion of impacted food sources

Direct exposure – chemical ecotoxicity effects

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathways will be significant. Note also, many marine mammals appear to have the necessary liver enzymes to metabolise hydrocarbons and excrete them as polar derivatives (Ball and Truskewycz, 2013).

Effects from inhalation of hydrocarbon vapours from PFW sheens

As a result of inhaling volatile compounds when surfacing, cetaceans can experience lung congestion (Geraci & St. Aubin 1990); or irritation or damage to mucous membranes or airways (Helm et al., 2015). However, the level of oil on water (i.e. sheens) from produced water plumes rarely cause silvery sheens (the lowest level according to the Bonn agreement), and hence will have extremely low levels of vapour. Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Irritation effects from physical contact with hydrocarbons in PFW

Cetaceans can be exposed through direct contact with the eyes, potentially leading to inflammation (Geraci & St. Aubin 1990). Cetaceans are highly mobile and only transit the area, as such, it is highly unlikely that this potential impact pathway will be significant.

Bioaccumulation through ingestion of impacted food sources

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

The mixing zone overlaps the foraging BIA for the blue whale and distribution BIA for the Southern Right Whale; however, given the localised area of impact and that whales are transiting the area, no impacts are expected. The discharge does not constitute a threat listed in the Conservation Management Plan of either the Blue Whale or Southern Right Whale and the discharge activity is not inconsistent with those plans.

In summary as the PFW plume is dynamic and moving constantly depending on the tides, currents, winds and internal waves, transient cetaceans such as migrating whales, are unlikely to be exposed to elevated contaminant concentrations for extended durations. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by PFW and the nature and scale of impacts to the marine ecosystem within the PFW discharge plume (i.e. slight impacts to food sources such as plankton and pelagic fish species). Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality (90 m radius) the predicted intermittent and short interaction duration (i.e. minutes at a time) with the PFW plume, it is considered that there will not be a significant impact on cetaceans from PFW discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

There are three potential impact pathways for fisheries:

- Tainting (hydrocarbon odour in caught fish) due to tissue accumulation of hydrocarbons in PFW
- Impacts to the safety of humans through the consumption of target species tissues that are impacted by PFW.
- Reduction of fisheries stocks, through the direct impact of PFW on target species and nurseries

Tainting

Per Appendix F, ANZECC seafood taint criteria of MLB PFW (using TNA composition as an analogue) is expected to be reached within 7.8 m of the discharge point. (Note: Appendix G.3 – Breakout Box 3 applies to the detection of other phenols under the seafood taint guidelines). The total area represented by a 7.8 m radius at MLB is 191 m^2 (1/50th of a hectare), and cumulative area across all Bass Strait platform PFW discharges is <2000 m^2 (1/5th of a hectare), representing an extremely small proportion of the total fisheries area. Hence, if TNA is used as an analogue for the MLB PFW discharge, the discharge is highly unlikely to cause taint in fisheries-caught fish.

Impacts to seafood safety for humans

Since fish or shellfish are not harvested around the PFW plume or mixing zone out to at least 500 m from the platform, and the zone in which 99% species protection criteria are reached extends to only 140 m from the platform, there is no effect of the PFW discharge on humans through consumption.

Impacts to fisheries stocks

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone), where they are directly present in the PFW plume (within 140 m radius), may be exposed to chronic sub-lethal impacts (see above) however due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Stakeholder feedback confirmed that although fishers had been able to see discharges from the Bass Strait platforms from beyond the 500 m exclusion zone, the discharge did not have any effect on fisheries or fisheries equipment, or amenity for the fishers. There is general acknowledgement among fishers that Esso's facilities provide safe habitat for juvenile fisheries species, and there have been no complaints or issues raised to date about taint, food safety or reduction of fisheries stocks due to the platform discharges. Ongoing dialogue with fishing communities is part of Esso's stakeholder engagement plan.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

The Bass Cascade: Given the distance from the mixing zone to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as Benthic habitats and communities applies to this KEF as described above. Given the distance from the PFW mixing zone to the reported location of the South East Reef, impacts on this reef are not anticipated.

Cumulative impacts from multiple discharges

There are no other PFW plumes within 3 km of the MLB discharge.

Other continuous discharges from the same platform are limited to discharges from pile subsea windows. These discharge at 16.9 m (ODSP) and 16.9 m (CDSP) below sea level (Table 2-5), deeper than the produced water effluent pipe depth at 11 m below sea level. Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window (Section 6.4.1.1). Discharges of water containing chemicals (at discharge all chemicals are OCNS Gold or Silver (Table 6-22) or dissolved hydrocarbons from the pile will be intermittent or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. It is therefore expected that any exposure will be limited in duration.

Dispersion modelling for MLB PFW shows the maximum plunge depth from the discharge point under all current speeds is to 12.5 m below sea level, hence any cumulative impacts from the interaction with the produced water effluent plume within the mixing zone is considered unlikely.

Other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the PFW plume but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

Historical activities such as discharging muds and cuttings during drilling may have resulted in changes to the sea floor sediment chemical characterisation above background levels. This includes the discharge of water based muds and barite containing barium, an inert metal; and the discharge of cuttings from natural rock formations encountered during drilling, together with small amounts of residual drilling muds on cuttings. Any changes to sediment quality from historical impacts from background will be considered as part of the surrender of title process. The last drilling program on MLB was in approximately 2014, hence discharged fluids or solids from the drilling program is expected to have at least partially been dispersed or bioremediated. There is not expected to be a significant cumulative impact to sediment quality from the additive effect of discharging PFW to sediments containing higher levels of barium or residual drilling mud constituents.

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes cumulative impacts on marine fauna is unlikely.

As fishing is not carried out within 500 m of the platform, which is beyond the mixing zone of 140 m no cumulative impacts from multiple discharges is likely on commercial and recreational fishing.

Given the distance to other sensitive receptors (Table 5-2) cumulative impacts from multiple discharges are highly unlikely.

6.3.8.8 Marlin B Consequence Evaluation

Impacts from MLB PFW are limited to a localised mixing zone around the discharge point, with negligible impacts to sediment. Potential impacts to biota, including benthic habitats and communities, plankton, fish, seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).

Effects could be ongoing, including through bioaccumulation of PAHs and persistent chemicals, but effects are confined to some biota on the platform structure itself (e.g. crustaceans) or dispersed in a small radius around the platform water and sediments at low and safe concentrations. Within the mixing zone, there could be sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level. The environment is highly endemic, with few endangered and rare species present, but is generally strong and resilient, and provides some ecosystem services (e.g. fisheries).

The consequence level is therefore assessed as **Consequence Level III.**

Should PFW discharge commence on MLB, the Monitoring and Management Framework will be implemented to ensure continuing confidence in the consequence level. If routine monitoring was to detect levels in PFW above the trigger values and there was the potential to impact the ecosystem integrity, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are not realised. Should PFW discharge commence on MLB, a sampling plan to demonstrate compliance with the approved mixing zone boundary will be developed for the sediment survey. The sampling plan outlines and justifies sampling locations and when concentration and bioavailability testing occur.

6.3.9 Controls

Good Practice	Adopted	Control	Rationale
Secondary separation treatment	✓	**CM43:** PFW processed though secondary separation equipment	Crude/water separation equipment is online and maintained.
	✓	**CM67:** Surveillance of the treatment system	Surveillance of water handling trends and abnormalities. This allows for response actions taken to address abnormalities as required, as well as potential improvement opportunities.
Chemical injection to aid separation	✓	**CM3:** Chemical Discharge Assessment Process	Chemicals can change the surface tension of molecules at the oil-water interface to aid separation. Pre-use assessment of a chemical additive ensures that the chemical is approved prior to adding to the water handling system.
Oil content in discharged PFW is monitored using ultraviolet fluorescence	✓	**CM10a:** The discharge stream is continuously monitored and maintained at concentrations below 30mg/L daily average.	Monitoring identifies the absolute level of oil in water and trends on the platform on a continuous basis. Early warning triggers help flag when close to the daily limit for mitigative action.
	✓	**CM10b:** Online monitor is calibrated	Maintenance and calibration is performed to ensure readings are accurate.
	✓	**CM10c:** Online monitor is serviced	
Alarms and shutdowns prevent off-spec discharge of PFW	✓	**CM38:** Sigrist alarm and shutdown functionality is tested	Alarms are functional in order to initiate water handling shutdown if required based on the OIW monitor reading.
During startup, oil in water content is carefully handled	✓	**CM10d:** Discharge of water on start-up is controlled	Operators establish control of the process on the platform during start-up of the water handling system.
Changes to the chemical content and ecotoxicity of PFW is monitored and corrective actions put in place if they exceed specified limits	✓	**CM11:** Apply the PFW monitoring and management framework procedure	Regular detailed compositional samples are collected and analysed in order to understand each individual platform's PFW composition and its potential for ecotoxicity. Results that exceed certain trigger points have specific corresponding corrective actions.

6.3.10 Demonstration of ALARP

ALARP Decision Context and Justification	**Decision Context B** The planned discharge of PFW to the marine environment is a well understood and practised activity both nationally and internationally. The impacts associated with planned PFW discharges are well managed via control measures that are considered industry best practice. These are well understood and implemented by the industry. The consequence of any impact associated with these discharges was assessed as **Level III**. Esso acknowledges that the consequence assessment of PFW to the marine environment is based on multiple lines of evidence, each with some inherent uncertainty (i.e. full composition is not available at all times over the discharge, WET testing is not available across all years, dispersion models have inherent assumptions built-in). However, risks from PFW are well-established and similar methods are generally applied (such as dispersion modelling) in order to establish the impact of the discharge. ExxonMobil has been involved in PFW impact assessment in Bass Strait since the early 1990's and has published several journal papers on the topic. Fishing stakeholders noted that they could occasionally see produced water discharges but that it did not interfere with their fishing activities. No specific stakeholder objections or claims were raised concerning PFW discharges, and it has never generated media interest to date despite Esso's long operating history in Bass Strait; nor has this type of discharge in particular generated media interest or stakeholder objection across Australia. Hence Esso believes **ALARP Decision Context B** should apply. An 'Engineering Risk Assessment' has been undertaken to ensure that any additional controls meriting additional environmental benefits have been identified and evaluated.

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
Disposal of PFW onshore via pipelines	Eliminate disposal of produced formation water offshore.	- Increased water to pipe could have implications for equipment and pipeline integrity (corrosion management) and therefore water limitations may change - Increased water to oil pipeline can cause operability issues at LFD. Water settling in the pipeline gets pushed through causing large water slugs during pigging. As these come through it is common for vapour compression to fail which increases LFD air and greenhouse emissions - All water received at LFD needs to be heated from ambient conditions to ~100°C which involves the use of fuel and greenhouse/air emissions and increases safety concerns during operation of heaters. - Water discharges from LFD to a water processing plant are limited and constraints for that discharge itself may change over time. There would be major restrictions on crude and condensate production into pipelines should additional PFW be	Not adopted

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
		transported to shore, and hence large financial losses would be imposed. Hence other than as decided on a day-to-day basis where LFD operations approves the pipeline transport of PFW from particular platforms (for example, during process upsets), the risks of blanket PFW piping onshore outweigh the benefits.	
Reinjection of PFW	Eliminate disposal of produced formation water offshore.	PFW reinjection into productive or disused wells has been trialled but was unsuccessful on a number of platforms due to technical difficulties, such as insufficient reservoir drink rate and blockages across the reservoir perforations due to sand.	Not adopted
Redesign of clean-up line to accept full PFW stream when results show discharge OIW greater than 30mg/L	Reduce likelihood of disposal of produced formation water offshore with higher than acceptable OIW	Clean up line rates are limited in order to minimise the amount of disturbance within the closed pile. By accommodating the full PFW rates, the inventory of the pile will increase in cases up to 10 times or higher. This increases the probability of pushing hydrocarbons out of the pile window. Hence the overall environmental outcome of such a modification would be worse than the existing PFW discharge.	Not adopted
Storage and re-treatment of off-spec PFW prior to discharge	Reduce likelihood of disposal of produced formation water offshore with higher than acceptable OIW	If a platform is producing 10ML/D of water then it would fill a typical platform vessel within 2-3 mins (i.e. inflow rate is 7 m^3/min into vessel volume of ~15 m^3). Given the fast inflow it is likely it would need a new separate vent line up the flare boom. In addition to space constraints on the platform, the cost implications of a separate vent line as well as a large new vessel are grossly disproportionate to the environmental benefit gained.	Not adopted
Install additional separation equipment or technologies, e.g. membranes	Reduce oil in discharged PFW	A detailed review of current offshore water handling processes with findings summarised from the reviews of each platform was performed in December 2019. On TNA, it concluded the system was operating within design. On HLA, SNA and WKF, it concluded the system could experience marginal subpar performance, all of which can be addressed by optimisation of existing systems. On no platforms did it conclude that the system was ineffective for treating PFW, or that	Not adopted

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
		additional equipment or large-scale performance improvement was required in order to have a functional water handling system. The cost of retrofitting additional separation equipment as well as the lack of sufficient deck space limits the feasibility and cost-effectiveness of this alternative. Surveillance and optimisation of existing systems is a control measure for the continuous reduction of potential impacts from PFW to ALARP levels.	
Install additional/ change oil in water monitoring equipment or technologies Use of other oil-in-water measurements versus UV fluorescence methods, such as Total Recoverable Hydrocarbons (TRH)	Enhanced oil in water monitoring accuracy, reliability, or certification of results	All Esso platforms are either fitted with a Sigrist Oil Guard online oil in water analyser (TNA, SNA) whilst others have a Sigrist Sipro online oil in water analyser installed. Quantitative GCMS analysis showed the oil in Fortescue produced water contained more aromatic than aliphatic hydrocarbon compounds to which the Sigrist will respond accordingly to its calibration. The fluorescence response of the Sigrist for OIW below 100 ppm is within the linear range of the detector. A detailed assessment was completed of the current OIW monitor against other technologies using laser-induced fluorescence and an alternative UV-fluorescence based technology. The Sigrist was confirmed as a valid continuous measure of OIW on the platform, and hence the installation of new equipment poses additional costs that do not have proportional benefits. Recommendations for improving operation of these units to achieve more reliable OIW measurement results, and recommendations to improve measurement methods to ensure that they are accurately recorded were summarised in a detailed report in December 2019 and have been incorporated as adopted controls. TRH is not the same measure as oil in water using UV fluorescence and would not be appropriate to equate the two or use TRH<30 mg/L as a standard, given:	Not adopted

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
		OIW analysis using UV fluorescence and not TRH/TPH is the one deployed around the world which is acknowledged in the 'standard' of 30 mg/L oil in PFW discharge. Sigrist technology was shown in GD report to be technology suitable to analyse oil in water for oils with certain aromatic/aliphatic balance that is present in Bass Strait; TRH without silica gel clean up also picks up naturally occurring non-petroleum hydrocarbon substances such as organic acids, as with TOC (see for example, NEPM 2013) TRH is not directly relevant to impact assessment as are certain analytes/fractions (e.g. Benzene, Naphthalene) (see for example, API Manual 4709). It is not possible to continuously monitor TRH/TPH with silica gel clean up. TPH/TRH is monitored annually during chemical characterisation.	
Reduce daily average OIW limit from 30 mg/L per day and/or reducing daily oil load from 330 kg/day	Reduced oil content to sea	The achievement of 30 mg/L oil-in-water is consistent with industry standards as well as Australian and international practice. The 30 mg/L limit proposed is a legacy of the former OPGGS Environment Regulations 29 and 29A repealed in 2014, and is consistent with monthly average regulatory standards applied globally (Neff et. al, 2011). It also exceeds the performance recommended by the IFC EHS guidelines for Offshore Oil and Gas Development (2015) where discharge to sea is allowed if oil and grease content does not exceed 42 mg/L daily maximum, i.e. mean level for any given day in the month assessed does not exceed 42 mg/L. The current infrastructure on the platforms was designed to meet what was limits of the time. Daily oil load limits are implemented to minimise total oil discharged to ocean and are highly dependent on volumes of PFW discharged. As a result of this, daily oil load limits have been determined on a platform by platform basis to reflect the wide range of predicted discharge volumes across Bass Strait. The daily oil loads (shown	Partially adopted

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
		in Appendix F.7) have been determined based on the 30 mg/L OIW discharge limit and the maximum predicted discharge volumes for each platform which has resulted in significant reductions for some facilities. As demonstrated in Figure 3-1, platforms WKF, CBA and HLA are expected to cease production by 2022 when PFW discharge will cease. On other facilities, there is limited space on the platforms to allow for retrofitting further treatment infrastructure and high capital cost associated with lowering the limit. Hence, further reductions in daily oil load limits are not practicable.	
More frequent routine WET testing	Greater frequency to assess and potentially determine if a trigger point has been reached	Routine WET testing is proposed to be conducted on a 3 yearly basis. The frequency of WET testing is guided by ANZECC (2000) Section 8.3.6.8, which states, “If the discharge is known to be of constant composition, and the receiving water characteristics are well documented and understood, one-off testing may be appropriate. Alternatively, if the discharge composition varies considerably and unpredictably, testing will be required on a more frequent basis (e.g. monthly). If a discharge varies according to the process being undertaken, but is constant within that process, or if the receiving water varies seasonally, but is relatively constant within seasons, testing can be carried out whenever such a change is known to occur.” The composition of PFW for platforms in Bass Strait is relatively constant, as demonstrated by similar toxicants being detected in sampling over time, and the development of an established mean (see Appendix F - PFW Data File). Each discharge is known to vary depending on the degree of treatment through the water handling system, however with surveillance and optimisation this is bounded within operational limits. A further potential drawback of WET testing is the lower relative precision of PFW toxicity tests compared to routine chemical analysis and the larger volumes of samples that need to be collected and shipped from offshore facilities for WET testing, for which,	Partially adopted. Frequency reduced from 5 yearly to 3 yearly. **CM11**: Apply the PFW monitoring and management framework procedure

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
		detailed compositional analysis and theoretical calculation of toxicity can be substituted for actual WET testing as an initial screening tool. Therefore, one-off to periodic (multiple-year) WET testing frequency is deemed appropriate. ANZECC also states, “water managers would only resort to DTA in cases where there is a complex mixture of chemicals entering the specific waterbody and where either the resultant toxicity cannot be easily estimated or the prediction of toxicity needs to be checked” (ANZECC 2000, Vol. 8, p185). The chemicals in PFW are well understood and stable, with more than 5 years of analytical chemistry and toxicity of the mixture has also been validated through WET testing in 2014 and 2020, hence water managers would be opting for ongoing monitoring without the need for more frequent WET testing. The time and cost of more frequent routine WET testing, and the frequent use and death of test animals and financial costs, does not outweigh the potential for only minor additional environmental information being gained by more frequent routine testing. Additionally, non-routine WET testing may be triggered outside of the 3 yearly cycle in accordance with the PFW Adaptive Monitoring and Management Framework, described in Section 2.7.5.1 of Volume 4, where there is uncertainty about the toxicity of the PFW discharge.	
Sediment and water sampling around other platforms than TNA/WKF	Greater certainty about contaminant levels in sediment around other platforms Greater certainty regarding levels of contaminants in sediments and water around other platforms and their potential to affect biota Possible finer distinction of a cause for contaminant	A multiple lines of evidence approach has been considered for the potential impacts from PFW discharge. That is, multi-year composition sampling, a dispersion model that has used actual current measurements to set up and been validated against prior models and in-sea dye monitoring; as well as in-sea water monitoring, WET testing, and finally multiple in-sea water testing monitoring programs (first conducted in 1994 and last of which was in 2018) and sediment testing (2018), all designed to determine the potential for impact to the environment from PFW. The 2018 in-sea monitoring program was conducted around Tuna and West	Adopted **CM68**: Environmental Sampling

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
	gradients around the platform	Kingfish as these platforms had the highest weighted potential for contamination from PFW around the platform (combination of discharge volume, together with TOC, suspended sediments load and PAH and metals levels). The potential for contaminants from PFW entering the water column and seabed sediments has been critically evaluated for all platforms including their receiving environments, using this data where applicable and relevant, and noting assumptions. Further, particle size distribution samples indicated the majority of particles in PFW discharge are small and unlikely to settle into sediment. The results from these monitoring programs has indicated that the likelihood for significant adverse environmental impacts from such discharges, when managed with on-board treatment systems, is low. The use of ANZECC (2000) criteria in the assessment of impacts from the PFW discharge provide suitable guidance of the levels of protection needed based on the environmental values to be protected. By monitoring and managing to the 99% species protection levels at the edge of and beyond the mixing zone (high level of ecological protection, suitable application to unmodified environments), there can be high confidence that any potential for impacts is mitigated. Esso has also used maximum toxicant levels observed in PFW in order to reduce the level of uncertainty over the total possible extent of potential impacts from the discharge. In addition, in-sea and other types of non-routine monitoring or modelling, are proposed to be triggered if required, based on certain trigger factors (see Volume 4 Section 2.6.5). Despite evidence and literature to suggest that impacts to sediment and seawater are likely to be negligible, in field verification of these assumptions have not been completed. Therefore, environmental sampling will be undertaken to verify that discharge	

Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
		from facilities is low as described in this Environment Plan. To gain further confidence that PFW discharges are not having a significant adverse environmental impact, a sediment and water sampling and analysis programme will be completed. Sampling will occur within 2 years from acceptance of this Environment Plan at the following facilities: • HLA • CBA • SNA Sampling will occur within 2 years from commissioning of the water handling system at the following facilities: • MLB	

6.3.11 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Impact Consequence level	Impact is Consequence III or less	✓	
Principles of Ecologically Sustainable Development (ESD)	No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved.	✓	The potential impact associated with this aspect is limited to a localised impact within a designated mixing zone. The mixing zone is small in scale, limited to the immediate area of the platform discharge out to within a radius encompassed by the existing petroleum safety zone (i.e. < 500 m), an area already gazetted in law for the rights of the petroleum industry to conduct operations. The impacts of PFW may be longer-term acting (as it is generally an ongoing discharge, and contains low levels of bioaccumulative PAHs and some metals) however its effects are limited predominantly to the water and biota in immediate proximity to the discharge (e.g. living on or near the platform structure), and possibly the sediment in immediate proximity to the discharge. Habitat and biota that could be impacted does not represent a large proportion of the biota that could make up a species or a food source. While there are some listed species in the operating area, these are all mobile, and for mobile biota, the discharge does

Factor	Demonstration Criteria	Criteria Met	Rationale
			not represent a large proportion of the overall environment (the discharge is quickly diluted due to the large dispersion rates in the Bass Strait high energy environment). The PFW discharge is considered as not resulting in a substantial change that could have a significant adverse impact on biodiversity, ecological integrity, social amenity or human health.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The activities were evaluated as having the potential to result in a Level III consequence thus are not considered as having the potential to result in serious or irreversible environmental damage.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	As above, the discharge does not result in a substantial change to water quality or sediment quality that could have a significant adverse impact on biodiversity, ecological integrity, social amenity or human health. The PFW discharge is not expected to result in the significant accumulation of potentially harmful chemicals, nor expected to have any significant adverse effect on threatened or migratory listed species nor hinder the recovery of White Shark. The PFW discharge is expected to have a negligible effect at the population level of any marine species, nor any broader impacts on habitat since the mixing zone is highly localised. An adaptive monitoring and management program has been developed for liquid discharges as described in Volume 2 Section 6.3. This program will seek to demonstrate that the actual levels of recorded impacts for key discharges do not exceed those which were predicted within the impact assessment presented in this EP. If recorded impact levels do exceed those described, this would trigger the adaptive management process including an ALARP/Acceptability study.
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"
	Meets ExxonMobil Environmental Standards	✓	There is no standard related to the discharge of PFW, but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed activities meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements;

Factor	Demonstration Criteria	Criteria Met	Rationale
			• OIMS System 7-1 objective to evaluate change against an established set of criteria and establish endorsement / approval levels; and • OIMS System 8-1 objective to clearly define and communicate operations integrity requirements to contractors.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	Fishing stakeholders noted that they could occasionally see produced water discharges but that it did not interfere with their fishing activities. No other specific stakeholder concerns have been raised concerning PFW discharges.

6.4 Planned Discharge – Operational Fluids

6.4.1 Causes of Planned Discharge – Operational Fluids

Water, residual production fluids and residual chemicals may be discharged to the marine environment during Operations, IMR and Wellwork activities.

6.4.1.1 Pile Discharges

As described in Section 2.4.1.1, residual fluids from platform decks and operation are directed to the drain and pile systems. The pile system acts as a separation vessel allowing hydrocarbons to separate from the water phase. Hydrocarbon vapours and liquids migrate to the top of the pile and settle out on top of the water (see Figure 2-3) and are either recycled to the process or sent to the liquids export pipeline via pile pumps. The water phase of the pile system interfaces with the sea via the pile window. Residual fluids which remain in the water phase may be discharged via the pile windows during operation, wellwork, IMR, care and preservation and decommissioning preparation activities.

As described in Section 2.4.1.1, discharge rates from the pile are estimated to be between 3 m^3 and 8 m^3 per hour during stable production. The majority of product directed to the drain system separates out as hydrocarbon and is recycled to the process via pile pumps. Only low concentrations of water soluble chemicals may separate into the water phase. These are further diluted throughout the large volume of seawater within the pile meaning that any discharges from the pile system will be largely seawater and highly diluted. A list of typical production chemicals that may be discharged from the pile system and their CHARM/OCNS ranking is provided in Table 6-22

Of the fluids directed to the pile system, the following may result in discharges to ocean via the pile window:

- Water soluble chemicals dosed into the production system
- Water containing cleaning detergents;
- Chemicals used during cleaning, flushing, leak detection, hydrate inhibition;
- Chemicals such as corrosion inhibitors, oxygen scavengers;
- Produced water clean-up;

Direct sampling of pile discharges has not been completed however, modelling has been completed to better understand the potential discharges and impacts.

Table 6-22 Typical production chemicals and rankings

Purpose	Chemical	Application	Ranking
Production	CGW24013	Fin Fan Inhibitor Gaslift Corrosion Inhibitor Fuel Gas Pipeline Inhibitor	CHARM Silver
Production	CLW24242	General Purpose Rig Wash	CHARM Silver
Production	CRO24037	Fin-Fan Corrosion Inhibitor	CHARM Gold
Production	CRW24266	Fuel Gas Heater Inhibitor	CHARM Gold
Production	CRW24340	Oxy Scavenger/ Biocide/ Corrosion Inhibitor	CHARM Silver
Production	DMO24586	Demulsifier / Pipeline Demulsifier	CHARM Gold
Production	PFR23 MeOH	Hydrate Inhibition/Mitigation	PLONOR
Production	RBW24122	Water Clarifier	CHARM Gold
Production	RBW24980	Upstream and Downstream Water Clarifier	CHARM Gold
Production	SCW24050	Scale Inhibitor	CHARM Gold

Modelling of Discharges from the piles

Modelling of discharges from the West Tuna and Marlin B pile systems was completed in 2013 to understand the rates of dispersion in the environment from pile discharges.

The mixing dilution rate and advection of the discharge plumes was predicted using near-field dispersion modelling. The method predicts the turbulent mixing and dispersion of the plume under the influence of initial momentum of discharge, buoyancy, and the ambient currents. It does not take into account mixing from turbulence in the receiving waters due to waves, decay or speciation of contaminants, or eddy shedding from the platform legs. Thus it is generally conservative, i.e. underestimates actual mixing and over-predicts concentrations.

The methodology adopted for this modelling is that of a highly conservative nature, with parameters defined to simulate a “worst case” scenario. The worst possible scenario for the transport of a concentrated plume away from an outlet has the following features:

- Current is maintained in a constant direction
- Sensitivity testing to deduce that the current speed that results in the worst case scenario are maximum currents
- A current direction that does not allow for obstacles to interact with plume (Eddy shedding from structures is neglected)
- Presence of a thermocline to trap plume and minimise buoyancy-driven mixing (this occurs mainly in summer)
- Salinity of discharge water assumed to be identical to the receiving waters. This is a strongly conservative assumption as any dilution with fresh water would reduce the density of the discharge and lead to increased buoyancy-driven mixing
- Calm conditions – effect of waves and ambient turbulence is neglected

The following parameters were input to the model and are summarised in Table 6-23.

- The closed skimmer pile discharge has the same value for salinity as the receiving water.
- Discharge temperature is assumed to be similar to receiving water temperature. Three temperatures (10°C, 15°C, and 20°C) were modelled to allow for possible variations.
- The rate of the discharge is 8.2 m^3/hr for West Tuna (WTN) , and 2.7 m^3/hr for Marlin B (MLB)

The near-field model was run for a combination of cases that comprised of the two discharges (WTN and MLB) at three discharge temperatures (10°C, 15°C, 20°C), and receiving waters exhibiting both median and maximum currents.

Table 6-23 Pile Discharge Modelling Parameters (Worley, 2013)

Parameter	WTN Closed Skimmer Pile	MLB Closed Skimmer Pile
Outfall Configuration		
Total Water Depth	61.1 m	60 m
Pipe Diameter	0.45 m	0.25 m
Depth of Discharge	-44.1 m MSL (17.1 m from seabed)	-16.9 m MSL (43.1 m from seabed)
Orientation of Discharge	Horizontal to pile	Facing downwards, parallel to pile
Graphical Representation		Discharge Properties		
Temperature	10°C 15°C 20°C	10°C 15°C 20°C
Flow Rate	8.2 m^3/hr	2.7 m^3/hr
Salinity	33.2 ppt	33.2 ppt
Receiving Water		
Maximum Current Speed (Surface)	1.4 m/s	
Maximum Current Speed (Seabed)	0.74 m/s	
Medium Current Speed (Surface)	0.27 m/s	
Medium Current Speed (Seabed)	0.16 m/s	
Salinity	33.2 ppt	
Thermocline Depth	30 m	

Parameter	WTN Closed Skimmer Pile	MLB Closed Skimmer Pile
Temperature Above Thermocline	20.9°C	
Temperature Below Thermocline	14.5°C	

Modelling results

The outlet at Marlin B is located at a depth of 16.9 metres, and is therefore in the warmer section of the water column above the thermocline. Discharge temperatures are always lower than the receiving waters and therefore the plume is negatively buoyant and dispersion increases in relation to temperature difference. This is demonstrated in Figure 6-18.

The West Tuna outlet is below the thermocline at a depth of -44.1 metres and located in the deeper, cooler receiving waters. The results show that the when the discharge temperature is similar to the temperatures found in the thermocline (between 14.9 and 20.9) the plume becomes trapped in this layer which inhibits the dispersion. This is demonstrated in Figure 6-19.

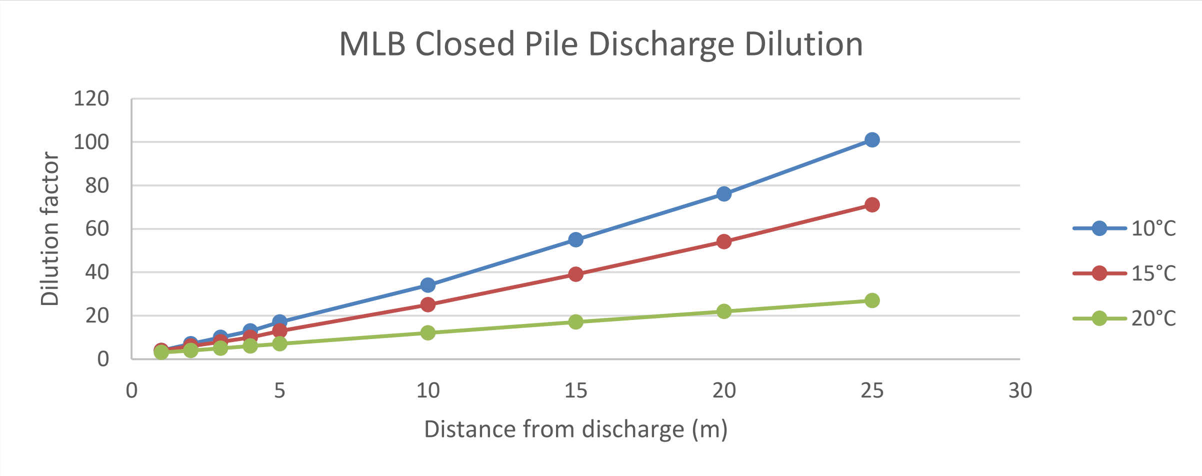

Figure 6-18 MLB Closed Pile Discharge Dilution

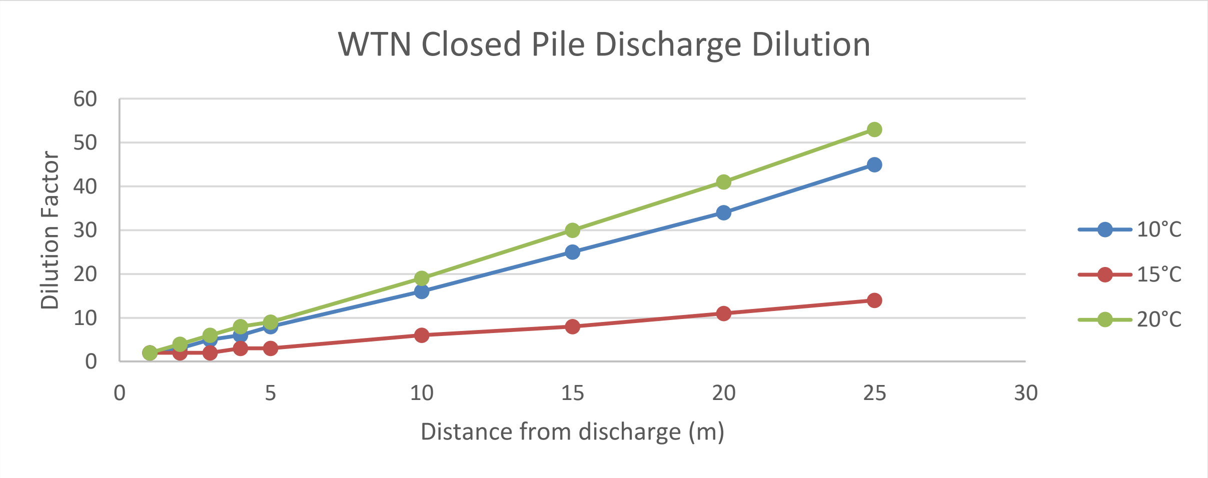

Figure 6-19 WTN Closed Pile Discharge Dilution

Per the information provided in Table 2-4, with the exception of Marlin B, all open and closed pile windows in the Bass Strait discharge deeper than 30 m meaning they discharge below the thermocline which is present during the summer months. Therefore, it has been assumed that the modelling prepared for the WTN closed pile is applicable to these facilities as an indication of dispersion rates from the open and closed pile windows.

Mercury Discharges

During the Kipper Field development drilling in 2010, reservoir sampling results indicated mercury is likely to be present in the KPA reservoir. Detailed analysis and engineering design was undertaken to ensure that mercury present was managed appropriately taking into account workforce health and safety, equipment integrity, protection of the environment and product quality.

As a result, the Kipper production process (located on the WTN Platform) has been designed to direct liquids to shore for further treatment. Kipper process equipment does not routinely direct fluids to the drain system.

Sampling of KPA Gas occurs offshore on a bi-monthly basis, to assist with the detection of mercury as it travels from the reservoir to Longford.

Sampling also occurs at Longford, at the processing plant inlet and outlet. In addition mercury levels of LFD wastewater streams are routinely analysed as part of the EAPL environmental monitoring program. Since the field was started in 2017, mercury testing on WTN and LFD has not detected levels of mercury above the specification of 1 µg/m³.

In the event that a sample records results above specification, then increased sampling protocols, including water, gas and LPG streams, would be enacted, in accordance with the Kipper Mercury Removal Project document.

Although there is no routine discharge of liquids to the drain system, maintenance activities which involve draining or depressuring may result in infrequent volumes of process fluids containing mercury entering the drain system. Examples are provided below:

- As a result of each KPA wells draining activity (approximately once every year or two years), cleaning and inspection of the internals of the Kipper separator, removal of any sand build-up, or from the KPA-WTN pig launcher/receiver vessels, small volumes of liquids (approximately 7 cubic metres, of which approximately 15% is MEG and 85% water) with low mercury concentrations (estimated at 80 ppb) will be infrequently discharged to the closed pile on WTN, then diluted in the pile before being discharged to sea.
- Production from KPA flows over the MLB facility en-route to Longford for onshore processing. The WTN pig receiver could be a pathway for discharge of mercury at the MLB facility. Concentrations at the MLB facility are expected to be orders of magnitude lower than what would be detected at the WTN facility.

Dispersion modelling completed for the WTN platform (Worley, 2013) indicated that mercury concentrations return to the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC 2000) ambient water quality guideline for 99% species protection (0.1 ppb) within 1.6 to 5.6 metres of the discharge point with a median current speed (0.27 m/s at surface – 0.16 m/s at seabed) and between 4.6 and 18.2 metres under 'worst case' conditions with a maximum current speed (1.4 m/s at surface - 0.17 m/s at seabed). The initial concentration of mercury in the Kipper separator was conservatively based on the water / MEG being fully saturated with mercury at 80 ppb (mercury solubility in water is 52 ppb) (Sabri et al 2012).

Similarly, modelling completed for the MLB platform indicates that mercury concentrations are expected to return to the ANZECC ambient water quality guideline for 99% species protection (0.1 ppb) within 0.6 to 2.7 metres of the discharge point with a median current speed (0.27 m/s at surface – 0.16 m/s at seabed) and between 1.9 and 8 metres under 'worst case' conditions with a maximum current speed

(1.4 m/s at surface - 0.17 m/s at seabed). The initial concentration of mercury at WTN also assumed a mercury concentration of 80ppb, consistent with WTN.

Downhole sampling and studies indicate that mercury concentrations are not expected to exceed the 80ppm limit modelled by Worley, 2013.

6.4.1.2 Subsea discharges

Fluids that may be routinely discharged during platform and subsea facility operations include those listed in Table 6-24.

- Hydraulic fluids from subsea valve actuation
- Chemicals discharged during production at subsea facilities

In preparation for decommissioning, equipment and pipelines may be flushed to remove residual hydrocarbons or production chemicals and sections of pipelines, pipeline risers, umbilicals and flying leads may be cut. Residual chemicals which meet criteria for discharge may be discharged to ocean in preparation for decommissioning. Table 6-25 lists residual chemicals that be non-routinely discharged during these activities.

Table 6-24 Routine subsea discharges during production

Activity	Nature of discharge	Indicative Volume
Hydraulic fluid from subsea valve actuation	Subsea valves are present at the following locations: • West Kingfish - Fuel gas pipeline SSIV • Kingfish A - Fuel gas pipeline SSIV • Kingfish B - Fuel gas pipeline SSIV • Kipper Subsea facility • West Barracouta Subsea Facility • Bream - BMA350 SSIV • Snapper - MLB450 SSIV	Up to 1000 L of hydraulic fluid could be released per week (on average) due to routine subsea equipment discharges through valve operations and during valve scheduled leak testing. Hydraulic fluid in use is Oceanic HW443R and Aqualink 300, both OCNS Ranking E.
MEG Discharge from KPA A2 well	A fault in the annular access valve (AAV) on the KPA A2 well has resulted in a continuous release of methanol to ocean during stable production.	~5 L per day

Hydraulic fluid from subsea valve actuation	Subsea valves are present at the following locations: • West Kingfish - Fuel gas pipeline SSIV • Kingfish A - Fuel gas pipeline SSIV • Kingfish B - Fuel gas pipeline SSIV • Bream - BMA350 SSIV	Up to 1000 L of hydraulic fluid could be released per week (on average) due to routine subsea equipment discharges through valve operations from CoP facilities. Hydraulic fluid in use is Oceanic HW443R and Aqualink 300, both OCNS Ranking E.

Activity	Nature of discharge	Indicative Volume One off discharges unless otherwise noted
Umbilicals	Umbilicals connect from the surface facility to the subsea development through an Umbilical Termination Assembly (UTA). From the UTA, power, electrical signals and umbilical fluids are often delivered to the various items of subsea equipment via cables and hoses, known as Electrical Flying Leads (EFLs) and Hydraulic Flying Leads (HFLs). Umbilicals which carry both electrical cables and hoses for fluids are called electro-hydraulic umbilicals (EHUs). Umbilicals at the following locations are no longer required for production: • TWA – Tied back to BTA facility. Previously cut subsea near BTA and removed from the BTA J-Tube. • SHA – Tied back to BTA facility. • BKA– Tied back to MKA facility. • CBA2 – Separate electrical and fluids umbilicals originally tied back to MKA facility. Previously cut subsea near MKA platform. Umbilicals are also present at: • KPA – separate electrical and fluids umbilicals are tied back to WTN facility. Expected to remain in operation for the lifetime of this EP. • BTW – tied back to BTA facility. Expected to be installed in 2021 and remain in operation for the lifetime of this EP. • BMB – Electrical umbilical from BMA facility to supply power and communications to BMB facility. • MLA150 subsea UV umbilical at KFB – tied back to KFB facility • MLA150 subsea UV umbilical at KFA – tied back to KFA facility • MLA150 subsea UV umbilical at WKF – tied back to WKF facility • BMA350 SSIV umbilical at BMA – tied back to BMA facility • MLB450 SSIV umbilical at SNA – tied back to SNA facility Wherever possible, fluids within the umbilical will be flushed back to the platform and sent to shore for disposal, normally via the pipeline. However, if flushing is not technically feasible, the contents of the umbilical may be discharged. During preparations for decommissioning, sections of umbilicals no longer required for production may be cut and part of the contents discharged.	BKA EHU – 15 L silicon oil, 50 L hydraulic fluid and 300 L inhibited seawater BMB Elec Umbilical – 20 L silicon oil MLA150 subsea UVs & BMA350 SSIV umbilicals – 200 L hydraulic fluid
Flying leads	Flying leads provide electrical, hydraulic and chemical service to subsea facilities. Flying leads are connected to umbilicals and hence are 'tied back' to platforms where chemical injection and electrical and hydraulic supply is managed and monitored. Once subsea facilities reach cessation of production, services are no longer required and flying leads can be removed. For removal, flying leads may be cut and the contents discharged. Where possible, flying leads will be removed without discharging the contents. However, the length and weight of	40L of silicon oil 110 L hydraulic fluid 150 L methanol 60 L inhibited seawater 25 L of pour point depressant 25 L of corrosion inhibitor

Activity	Nature of discharge	Indicative Volume One off discharges unless otherwise noted
	leads may result in unplanned release of contents during the removal process. Flying leads are located at the Blackback location and are expected to be removed during the lifetime of this EP. Flying leads are also located at BTW and KPA although are expected to remain in use throughout the lifetime of this EP.	
Pipelines	In preparation for decommissioning, pipeline and pipeline riser sections will be cut during the lifetime of this EP. The following pipelines are expected to be cut in order to separate the pipeline from the facility: • MKA • PCA/DPA • WTA • FTA • FLA • BMA • BMB • WKF • KFA • KFB Prior to separation of pipeline from facility, the contents of pipelines will be displaced with inhibited or plain seawater. Displaced pipeline contents will be sent to shore for further processing and disposal. Severing pipelines or pipeline risers will result in the once off release of small volumes of inhibited seawater from each section.	1 – 10 m^3 of inhibited seawater per pipeline

6.4.1.3 Other Surface Discharges

Wellwork

As described in Section 2.4.2, during wellwork, fluids contained within the well such as residual packer fluid, completion brine, residual drilling muds etc. will be circulated out of the well and returned to the platform. Hydrocarbon and solids are separated from the process and returned to shore for discharge. Whole NAF will be returned to shore, whilst the remaining fluid will be discharged to the pile(s). Chemicals may have been added to the well more than 30 years ago, therefore the constituents are mostly unknown.

Operational fluids which have been added to the well during completion / commissioning will also be discharged during production start-up. The use and discharge of these chemicals will be subject to the Esso Chemical Assessment Process. A list of typical production chemicals that may be discharged from the pile system and their CHARM/OCNS ranking is provided in Table 6-28

Table 6-26 Frequency of wellwork activities

Producing platforms	COP platforms
At producing platforms (TNA, WKF, HLA, CBA, SNA, MLA, MLB, BTA, WTN) wellwork activities are expected to take place approximately once per year. Wellwork campaigns last for 1 – 3 months and can involve working ~20 wells during this period.	On COP platforms, P&A activities are expected to take place as per the schedule in Figure 3-1 Platforms are expected to have two wellwork campaigns. One to plug and secure the wells and one to plug and abandon the wells.

Producing platforms	COP platforms
	A plug and secure campaign will last 1 – 3 months and can involve working on up to 20 wells A plug and abandonment campaign will last up to 24 months and will abandon all platform wells (per the number of wells listed in Appendix A, Table 1). Once all wells are plugged and abandoned, no further wellwork activities (and hence, no further wellwork discharges) will occur.

Table 6-27 Surface discharges during wellwork

Activity	Nature of discharge	Indicative Volume
Conductor cutting	The final stages of conductor cutting will result in a once off discharges of the contents of the conductor. If possible, fluids may be directed back to the platform for onshore disposal.	~42bbl inhibited sea water per well
Well circulation	Workover fluids used during well circulation consist of a brine solution (typically seawater) with a dilute concentration of chemical additives and will be discharged as part of workover operations. Fluids with hydrocarbon returns are monitored such that hydrocarbon is not discharged overboard.	From 10 bbl. (e.g. in circulating fluids in a sand-wash operation) up to 100 bbl. (e.g. for a conductor clean-out).per well
Sand washing	Sand discharge during conductor clean-out operations.	100 bbl. of entrained sand in brine per well.

6.4.2 Impact Assessment

Planned discharge of operational fluids has the potential to result in effects to marine ecosystems due to:

- Change in water quality
- Change in sediment quality
- Injury / mortality to fauna

Receptors that could be affected by the planned discharge of operational fluids are identified in Table 6-29.

Table 6-29 Receptors potentially affected by impacts associated with planned discharge of operational fluids

Receptors	Impacts				
	Change in water quality	Change in sediment quality	Injury to fauna	Change in habitat	Change to the function, interests or activities of other users

Impacts to water quality

Operational fluids discharged during operations, wellwork and IMR activities may contain chemical additives, resulting in a localised change in water quality.

Modelling indicates that discharges from the pile are diluted 5 – 20 times within 10m of the platform (or 12 – 35 times at MLB). Typical chemicals discharges, as listed in Table 6-22, are assessed to be CHARM Gold or Silver or OCNS D or E which are already considered low environmental impact at the point of discharge and are expected to dilute further in close proximity to the platform. In-situ water sampling completed at the TNA platform supports this assumption as it found that all valid samples taken from the water column indicating the presence of platform discharges were less than ANZECC 99% species protection water quality criteria at 59 m from the platform and beyond (see Appendix G.7 – Breakout Box 7).

Other subsea discharges may occur throughout the operational area at locations listed in Section 6.4.1.2 while surface discharges from wellwork may occur intermittently at platforms as described in Section 6.4.1.3. Discharges will be one-off or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area.

Other surface discharges may have the potential to expose ecological receptors which use the surface water for transit or foraging such as whales, turtles, fish and plankton. The operational area is within a foraging BIA for the Pygmy blue whale. Given the transient nature of these species, any impacts are expected to be localized and short term.

Water-soluble chemical MEG is readily biodegradable in the marine environment in aerobic and anaerobic conditions through microbial action, with studies showing degradation to < 10% of the initial concentration occurring with 1 to 21 days (Staples et al. 2001). MEG will not persist in the environment once discharged. Microbial degradation will account for the fate of almost all MEG discharged. It has been shown to be practically non-toxic (based on US EPA definitions) in relation to aquatic organisms (Staples et al. 2001) and is entirely miscible in water and has low potential to combine with lipids and therefore has very low potential for bioaccumulation (Dobson 2000, Staples et al. 2001). The Oslo Paris Convention (OSPAR) Commission lists MEG as a substance considered to Pose Little Or No Risk to the environment (PLONOR).

Brine water will sink through the water column where it will be rapidly mixed with receiving waters and dispersed by ocean currents. As such, any potential impacts are expected to be limited to the source of the discharge where concentrations are highest. This is confirmed by studies that indicate effects from increased salinity on planktonic communities in areas of high mixing and dispersion are generally limited to the point of discharge only (Azis *et al*., 2003).

The receptors with the potential to be exposed to an increase in salinity include pelagic fish species and plankton found in surface waters within the operational area. Changes in salinity can affect the ecophysiology of marine organisms. Most marine species are able to tolerate short-term fluctuations in salinity in the order of 20% to 30% (Walker and McComb, 1990). However, larval stages, which are crucial transition periods for marine species, are known to be more susceptible to impacts of increased salinity (Neuparth *et al*., 2002). Mobile pelagic species may be subjected to slightly elevated salinity levels (approximately 10-15% higher than seawater) for a very short period which they are expected to be able to tolerate.

Prior to discharge the chemical constituents of all fluids will be assessed using the Esso Chemical Discharge Assessment Procedure (described as part of the Implementation Strategy in Volume 4) which uses the OCNS ranking in conjunction with toxicity, biodegradation and bioaccumulation data to determine potential impacts to the environment and acceptability of planned discharges.

<u>Mercury</u>

As discussed in Section 6.4.1.1, modelling of mercury discharge demonstrates that concentrations in water meet ANZECC 99% species protection criteria within 18.2 m at WTN and 8 m at MLB in worst case scenarios (and less than this in median case scenarios).

Infrequent discharge of small quantities of low concentration mercury-containing fluids via the closed pile does not have the potential for bioaccumulation in marine mammals, seabirds, fish and other marine organisms because the elimination half-life for mercury (worst case as published in the U.S. Department of Health and Human Services, Toxicology Profile for Mercury 1999) is 2 months.

Given the infrequent, small volume, low concentration and short duration discharges, the mercury-containing water will be rapidly dispersed in the high energy Bass Strait marine environment. Consequently the impact of the discharge of mercury-containing water on the receiving environment is considered to be low.

As a result, any impacts from the discharge of brine and other operational fluids will be localised and short-term and the consequence level of increased salinity and potential chemical toxicity are considered to be unlikely and of low impact.

Impacts to sediment quality

Small discharges of solid-laden water were observed exiting the WTN closed pile window in 2017 as the closed pile was being pumped, expected to be reservoir sand or silty scale accumulated in the bottom of the pile (e.g. due to draining of separators or produced water directed to the pile on start-up) that was traversing out the pile window due to small changes in the pile pressure. This can be seen in Figure 6-20 over a 30 second period. While not previously observed elsewhere, this phenomenon is expected to occur at all platform closed piles intermittently.

Since sediment discharges from the pile systems are intermittent and infrequent, and Bass Strait is a high energy environment, currents are likely to mobilise and disperse sediments around the platform, leading to lower overall concentrations in any one area. There were no mounds of sand visible at the base of the pile, and encrusting marine fauna are present at the pile window, hence any smothering is likely to have an overall negligible, temporary, and localised effect.

Figure 6-20 ROV Footage from WTN Closed Pile Window (2017)

(1) 0 sec

(2) +10 sec

(3) +20 sec

(4) +30 sec

In-sea sediment monitoring results conducted to determine potential impacts to sediment at TNA and WKF from PFW and/or all other historical or active discharges (Appendix G.8 – Breakout Box 8) showed that natural dispersion processes appear to control the concentrations of potential contaminants from platforms in sediments to slightly above background concentrations and below levels known to cause deleterious effects (Neff et al. 2011; Barnes et al. 2019).

Given the homogenous seafloor environment within the operational area, comprising soft sediment benthic communities, the small volume of solid discharge which may settle on the seabed is not expected to result in an impact to those communities.

The disturbance may result in the mortality of flora and sessile fauna within this footprint through smothering and potentially the mortality of benthic infauna associated with the habitat. However the area that will be impacted is small compared with the overall extent of this habitat in the region and consequently, there will be no long-term impact on the diversity and abundance of benthic fauna.

Impacts to biota

Marine biota may be exposed to contaminants discharged from the pile. Given the results of modelling provided in Section 6.4.1.1, this is expected to be limited to a localised extent around the plume discharge point only.

Other subsea discharges may occur throughout the operational area at locations listed in Section 6.4.1.2. These discharges will be one-off or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area.

Mobile invertebrates exposed to operational discharges could experience acute or chronic exposure to toxicants in the discharge. This will be localised to biota within close proximity to the discharge location or growing on the platform structure (such as sponges, corals, and crustaceans) and is unlikely to have population-level effects. Potential bioaccumulation of sediment-derived metals or PAHs in fish biota is considered localised or negligible given hydrocarbons are removed from the discharge streams in the pile through separation prior to discharge.

Prior to discharge the chemical constituents of all fluids will be assessed using the Esso Chemical Discharge Assessment Procedure (described as part of the Implementation Strategy in Volume 4) which uses the OCNS ranking in conjunction with toxicity, biodegradation and bioaccumulation data to determine potential impacts to the environment and acceptability of planned discharges. As a result, species will be protected from adverse ecotoxicity effects of the discharge such that the biological communities are expected to remain in a healthy condition and ecosystem integrity is largely retained.

Impacts to benthic communities and habitat

Studies have found that provided the water depth is greater than the discharge depth, benthic organisms will not be affected by PFW, as the concentration of any oil or adhered/adsorbed components will be extremely low (Furuholt, 1996). Studies that have reported changes to benthic distributions were in shallow, moderate-to-poorly flushed waters of 1-8 m or continental shelf waters of up to 12 m (e.g. Osenberg et al (1992) and Rabalais et al. (1992)). It can be expected that in deeper, well-mixed ocean environments the potential for impacts to benthic infauna would be even lower. All pile and surface discharges will occur above the sea floor which is expected to minimise impacts to benthic fauna from operational discharges. Therefore, it is expected that only fauna on the platform structure itself could be exposed and those on the seafloor are protected from direct exposure.

Impacts from direct exposure to PAHs on fauna such as scallops, crustaceans and other molluscs could pose chronic developmental or growth impacts, such as reduced survival of juveniles and reduced size (Querbach et al. 2005, in Armsworthy et al., 2005). Discharge can also affect larvae viability (abalone, Raimondi and Schmitt, 1992). Sponges and soft corals localised to the discharge point could experience reduced ability to settle and metamorphose, such as was found in Luter et al (2019) on larvae of the sponge *R. odorabile* when exposed to hydrocarbons in water.

With respect to pile discharges, impacts from direct exposure to PAHs are considered highly unlikely as hydrocarbons are separated prior to discharge and any residual chemicals in the discharge are highly diluted within the pile and dispersed further once discharged.

Effects on benthic flora and fauna are primarily attributed either to uptake of contaminants from water or the presence of accumulated hydrocarbons (such as PAH) in sediments. Ecotoxicity impacts to biota from metals in sediment is more complicated, owing to the many forms that metals can take, reduction-oxidation states and overall bioavailability of the metal. While there have been a large number of studies where the chemical concentrations of contaminants have been measured in sediments, very few have been related to biological effects, either in the nature of descriptions of the natural benthic populations or laboratory-based bioassays (ANZECC 2000, p8.4-26). Given the results from the TNA in-situ sediment monitoring that found occurrences of metals/metalloids were isolated, levels remained low (for the most part, well below sediment guideline criteria) and detections above reference locations remained localised (see Appendix G.8 – Breakout Box 8), effects on benthos from accumulated metals in sediments is unlikely.

Given the above, benthic biota around the platforms in Bass Strait are highly unlikely to be affected by the pile and other discharges. Any effects would be confined to chronic impacts (such as changes in growth, metamorphosis or reproduction) for flora and fauna such as sponges and crustaceans on the platform within close proximity to the discharge locations. As the area and depth ranges of a potential, but highly unlikely impact, are small and localised, effects at a population level are not credible.

Impacts to plankton

Plankton could be susceptible to chemicals in the discharges, as they are less mobile and therefore can become exposed to the plume at the discharge point. However, plankton are expected to rapidly recover once the activity ceases, as they are known to have high levels of natural mortality and a rapid replacement rate UNEP (1985). As such, exposure of planktonic communities is not considered to result in significant impacts on population level of organisms that would affect ecological diversity or productivity and therefore is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action.

Impacts to fish

Early lifestages of fish (embryos, larvae) would be most susceptible to the exposure from chemical constituents, as they are less mobile and therefore can become exposed to the plume at the outfall. These effects can range from no effects (Mathieu et al 2011), to gill damage (turbot larvae, Brown et al. 1998). Hormonal effects could be experienced (cod, Meier et al, 2002), however this occurs at very high exposure concentration or where immune systems are already compromised by other stressors (Hamoutene et al, 2011; Burridge et al, 2011). This is unlikely to occur as pile discharges will be highly diluted in the pile and other discharges will be at low concentrations which meet environmental discharges criteria.

Later-life pelagic species are generally highly mobile and as such are not likely to be exposed at concentrations that would lead to chronic effects due to their patterns of movement.

BTEX is known to be toxic to fish and invertebrate eggs and larvae and has been shown to result in developmental defects (Fucik et al. 1995). However, due to the compound's volatility, the residence time in waters is brief; rapid active and passive excretion of these compounds from tissues will also limit in-tissue concentrations in the field; and BTEX does not bio-accumulate (Neff et al., 1996). Many fish species can metabolise hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Potential impacts from BTEX are further reduced as hydrocarbons are removed from the discharge streams through separation prior to discharge.

The mixing zone overlaps the distribution BIA for the Great White Shark; however, given the localised area of impact and that sharks are transiting the area, no impacts are expected. The discharges do not constitute a threat listed in the recovery plan of the White Shark, and the discharge activity is not inconsistent with that plan.

Impacts to seals

Seals do not spend all their time in the water, and when they do, they are highly active, travel great distances and forage at various depths (Arnould et al., 2005).

Given the depth of pile discharges, it is unlikely that seals would spend extended periods of time in close proximity to the discharge. Therefore, impacts to seals from pile discharges are highly unlikely.

Surface and other discharges will be one-off or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. Given the high mobility of seals, it is unlikely they will spend an extended period of time in these one off / intermittent discharges.

As this area potentially exposed to the discharge is small in comparison to the overall distribution of plankton and fish in the area, and the area does not represent a large proportion of the overall marine mammal feeding area (seals) or specifically a feeding area (whales and dolphins), it is unlikely these interactions will have a significant impact on marine mammals. Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by discharges and the nature and scale of impacts to the marine ecosystem within the discharge plumes (i.e. slight impacts to food sources such as pelagic fish species).

Listed Australian Fur Seals and New Zealand Fur Seals occur at the platform, however no seal breeding occurs on or around the platform, and the area is not identified as critical habitat or BIA. According to IUCN, the Australian Fur Seal is listed as Least Concern and its population is increasing (IUCN, 2015).

There is no relevant Conservation Advice or Threat Abatement Plan for Australian Fur Seals or New Zealand Fur Seals.

Given the potential absence of impacts to seals, the limited spatial extent of the discharge plumes, the predicted short interaction duration of exposure (i.e. minutes at a time), and that breeding does not occur within the OA it is considered that there will not be a significant impact on seals from operational discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to cetaceans

Cetaceans are highly mobile and transitory animals, as such, it is highly unlikely that this potential impact pathway will be significant.

Given the depth of pile discharges, it is unlikely that cetaceans would be able to approach the platform close enough to be exposed. Any potential exposures would be for a short duration.

Surface and other discharges will be one-off or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. Given the high mobility of cetaceans, it is unlikely they will spend an extended period of time in these one off / intermittent discharges.

As impacts to cetacean food source predominantly of fish and plankton is of very low likelihood (as above), and the area does not represent a large proportion of the overall cetacean feeding area therefore it is unlikely to have any impact on cetaceans.

Indirect impacts, such as altered prey abundance or ingestion of bioaccumulated toxic compounds is considered to be of no effect given the localised area predicted to be impacted by operational discharges.

Given the potential absence of impacts to cetaceans, the limited spatial extent of the water quality the predicted intermittent and short interaction duration of exposure (i.e. minutes at a time), it is considered that there will not be a significant impact on cetaceans from operational discharges when assessed against the relevant criteria from the Matters of National Environmental Significance. Significant impact guidelines 1.1. (DoE, 2013), including that there will be no long-term decrease in the size of the population, the area of occupancy of the species or an important population, the existing population will not be fragmented into two or more populations, there will be no adverse effect on habitat critical to the survival of a species, there will be no disruption to the breeding cycle of an important population, the availability or quality of habitat will not be destroyed, removed, isolated or decreased to the extent that the species is likely to decline and the recovery of the species will not be substantially interfered with.

Impacts to Fisheries – Commercial and Recreational

Since fish or shellfish are not harvested in close proximity to the platform, and modelling suggests that discharge from the piles are dispersed within close proximity to the facility, no impacts to fisheries are expected.

Other subsea discharges may occur throughout the operational area at locations listed in Section 6.4.1.2. These discharges will be one-off or infrequent, and of small volumes which will disperse rapidly in the open ocean currents within the operational area. Notification is provided to local stakeholders when subsea maintenance activities are taking place so fishing does not occur in close proximity to subsea maintenance activities while they are occurring.

Individual fish and other non-fish target species, (i.e. invertebrates of value, including squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone)), may be exposed to chronic sub-lethal impacts where they are directly present in the discharge plume. However, due to the small range and depths that this applies, population level impacts are considered highly unlikely. Whilst offshore structures may play a role in enhancing fish stocks due to the presence of hard substrate and the level of protection from fishing that they provide, fish nurseries known to be notable prolific producers are close to shore (such as Gippsland Lakes RAMSAR site) and these are expected to contribute to fisheries stocks in much greater numbers. Therefore there are no anticipated impacts to fisheries stocks.

Impacts to other receptors

Australian Marine Parks, National Parks and Reserves

Given the distance of marine parks, national parks and reserves from the mixing zone, impacts to these receptors are not considered credible.

Key Ecological Features

Upwelling East of Eden: Nutrient-rich sediment turnover is highest in areas of upwelling, and hence discharge of any additional nutrients also naturally found on the sea floor is therefore unlikely to have impacts on the KEF. The discharge of other contaminants is not relevant to the values of this KEF

The Bass Cascade: Given the distance from the facilities to the likely location of this KEF, impacts are not anticipated.

Shelf rocky reefs and hard substrates (South-East Marine Region), including the South East Reef: The same assessment as Benthic habitats and communities applies to this KEF as described above. At the CBA location, the mapped presence of South East Reef in the area including beneath the platform does not appear to coincide with increased abundance of biota in the area and therefore any potential impacts to biota are not expected to impact the South East Reef.

Cumulative impacts with other discharges

Piles are expected to be exchanging predominantly sea water, hence any discharge from the piles will be close to neutrally buoyant at the subsea window.

As described in Table 2-4, all PFW discharge points are located above the depth of the thermocline (30 m). For all platforms (with the exception of MLB) the pile discharge points are located below the thermocline. Therefore, during summer months, discharges are not expected to interact with the pile. See summary in Table 6-30. Dispersion modelling as presented in Section 6.3, shows the maximum PFW plunge depth from the discharge point under all current speeds remains above the depth of pile window discharges, hence any cumulative impacts from the interaction with the produced water effluent plume when the thermocline does not appear is considered unlikely.

On Marlin B, the modelled maximum plunge depth from PFW remains above the pile window depths. Interaction of discharges is considered unlikely, despite both discharges occurring above the thermocline.

Table 6-30 PFW discharge depth compared to pile discharge depths

Platform	PFW Discharge depth (m)	Modelled maximum plunge depth from PFW (m)	Open pile window depth (m)	Closed pile window depth (m)
TNA	29	34	52.1	38.5
WKF	16	20	69.5	67
HLA	11	22.6	50	46.5
CBA	28	36.4	55.7 – 57.7	55.7 – 57.7
SNA	8.2	8.6	49	35.8
MLB	11	12.5	16.9	16.9

Given the varying buoyancy of the plumes, the mobile nature of marine mammals and the tendency of fish to avoid plumes, cumulative impacts on marine fauna is unlikely. As fishing is not carried out within 500 m of the platform, no cumulative impacts from multiple discharges are likely on commercial and recreational fishing.

Plumes from other non-continuous discharges (such as desalination brine, sewage, grey water, food waste, liquid discharges from vessel operations, and wellwork discharges) could overlap with the plume but are short in duration and hence any cumulative impacts are unlikely to occur.

Any suspended solids in the pile contents will settle out within the pile, or if finer and suspended in the pile, then they will gradually settle out at far distances from the platform as they are carried by the current and result in no noticeable impacts to sediments. Hence any cumulative impact of the pile discharges to sediment is considered highly unlikely.

6.4.2.1 Consequence evaluation

In summary

- Modelling suggests that operational discharges are dispersed within close proximity to the discharge location and therefore, impacts will be limited to a localised area close to the discharge location
- Chemicals will be assess to be low environmental impact prior to discharge
- Potential impacts to biota, including benthic habitats and communities, plankton, fish, seals and cetaceans, including through bioaccumulation, is localised in nature to the mixing zone or negligible and is not considered significant (per Significant Impact Guidelines [DOE, 2013]).
- Discharges could result in sub-lethal, direct or indirect effects on organisms, but this would likely only apply to non-mobile receptors, such as fish embryos/juveniles, and would not apply at a population level.
- Mercury concentrations will be monitored, expected to be low and dispersed to ANZECC 99% species protection criteria in close proximity to the platform

Therefore, intermittent and small volumes of ongoing discharge of operational fluids will discharge rapidly in the high energy marine environment and therefore any impacts will be restricted to the Operational Area. Any impacts are expected to be inconsequential and no adverse effects to identified receptors. Any effects will be localised and of low to moderate intensity, resulting in a **Level IV** consequence.

6.4.3 Controls

Good Practice	Adopted	Control	Rationale
Discharge of low impact chemicals	✓	**CM3:** Chemical Discharge Assessment Process	Any chemicals planned to be discharged will be subject to the Chemical Discharge Assessment Process to ensure they are low environmental impact chemical and are approved for discharge. This includes subsea hydraulic fluids, Wellwork chemicals and production chemicals.
Monitoring of chemical use	✓	**CM47:** Monitoring of chemical use in accordance with Corrosion Control & Chemical Injection program	As part of the Corrosion Control & Chemical Injection FIMS program, oil field chemical use is monitored to ensure volumes and concentrations used are optimised. Results of monitoring (including identification of overuse) is monitored and documented in the Oil Field Chemicals Exception Report.
Routine Maintenance and testing	✓	**CM46:** Maintenance and testing of Open and Closed Skimmer Piles	Maintenance and inspection of pile equipment is conducted to ensure equipment is functioning as designed, level readings are accurate and pumps and triggers are operational so as to prevent

Good Practice	Adopted	Control	Rationale
			unplanned discharges caused by equipment failure.
Notification to stakeholders	✓	**CM36:** Pre Start notifications	Notifications to stakeholders are completed prior to subsea maintenance activities which may result in discharges. This aims to minimise impacts to fishers during short term, intermittent discharges until discharges have dispersed.
Validation of assumptions from pile discharge systems	✓	**CM68:** Environmental Sampling	Information about discharges from pile systems is limited. A sediment and water sampling program will be completed to verify impacts from production activities, including the piles.
Kipper Mercury Sampling	✓	**CM69:** Sampling of KPA Gas to monitor mercury concentrations	KPA gas is sampled bi-monthly to monitor mercury concentrations and sample results are below spec. of 1 µg/m³. In the event that a sample records results above specification, then increased sampling protocols, would be enacted to confirm that discharges remain below modelled concentrations (see 6.4.1.1) Should concentrations be measured greater than modelled concentrations (>80ppb), offshore discharge will cease until further analysis and sampling is completed to ensure that future discharges are acceptable and reduced to ALARP.

6.4.4 Demonstration of ALARP

ALARP Decision Context and Justification	Decision Context B		
	Planned discharges from offshore operations are common practice. Discharges are not managed by national regulations however industry best practice has been applied through the application of chemical assessment and selection processes. Given the small volumes, rapid dispersion in the marine environment and controls in place to manage potential impacts, there is potential for Consequence Level IV impacts. Both planned and unplanned discharges were discussed with stakeholders and no stakeholder objections or claims were raised with regards to impacts from planned operational discharges. Facilities in the Bass Strait were designed and constructed prior to the introduction of OPPGS (Environment) Regulations. Engineering design may not reflect current industry best practice. Given the design of the platforms and the opportunity for continual improvement, Esso believes ALARP Decision Context B should apply. Engineering Risk Assessment has been undertaken to assess the costs and benefits associated with additional, alternative and/or improved controls to ensure impacts from planned discharge of operational fluids continue to be reduced to ALARP.		
Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**

Collection of fluids for alternative disposal onshore	Collection and onshore disposal of fluids could minimise the volume of chemicals and operational fluids discharged to the marine environment.	In the pile systems, hydrocarbons are recycled into the process via pile pumps. Collection and onshore disposal of these fluids would reduce the net environmental benefit as recycling would not be able to occur. Directing the drained Kipper well fluids back into the pipeline is not feasible due to the cost of the equipment required to re-pressure the liquids (up to 15,000 kPa). The degree of risk reduction from manual collection of the drained liquids from the separator for treatment and disposal onshore is disproportionately small to the additional safety and environmental risks associated with manual handling, storage and crane transfers of multiple IBC volumes of recovered liquid from platform to vessel and again handling of that volume onshore. Given the increased safety risks and the reduction in net environmental benefit, collection of fluids for onshore disposal is not recommended.	Not Adopted
Re-design and construction of facilities to eliminate discharges	Re-design and construction of new drain and sump systems would eliminate discharges of residual chemicals to the marine environment.	Engineering design and construction is highly expensive and would take many years to execute. Construction activities result in a variety of impacts to the environment and stakeholders. Given the remaining lifespan of the facilities and the low environmental impacts expected from discharges, the extensive cost and net environmental benefit of reconstruction of the drains system is not considered to outweigh the impacts from planned discharges.	Not adopted
Monitor ongoing subsea hydraulic fluid discharges	Subsea hydraulic fluids may be discharged during valve actuation.	Costs associated with vessel hire, ROV and monitoring programs in order to monitor discharges are highly expensive. Fluids intended for subsea discharge are chosen to be of low environmental impact and volumes discharged are infrequent and <10L per event. Given the small volumes released, the plume will be highly localised and is expected to cause little to no adverse effects. Monitoring volume of discharges is not considered to provide any change to the environmental consequence.	Not adopted
Removal of mercury from KPA facility on WTN	Removal of mercury from the Kipper fluids on the platform would prevent the discharge of mercury-containing water from the closed pile	The technology for reliable and consistent removal of mercury from three-phase fluids is not currently available. The installation of additional treatment equipment, a separation plant and three mercury removal skids, is not	Not adopted

		practicable due to platform space constraints. Hazards associated with mercury handling are also able to be better managed onshore, however there are implications and risks associated with transporting the mercury to shore including increased likelihood of vessel collision, transporting spills, and onshore handling and disposal implications. The cost of transporting the small volumes of low concentration mercury to shore is grossly disproportionate to the reduction in risk. Modelling indicates that the small discharge of mercury poses no real impact on the environment. The infrequent, small volume discharges of mercury-containing water will be rapidly dispersed in the high energy marine environment. Consequently the impact of the discharge of mercury-containing water on the receiving environment is considered to be ALARP.	
Ongoing monitoring of fluids discharged to the drain systems	Monitoring of fluids discharged to the drain system could allow for improved management of discharges	Discharges to the open drain systems are predominantly seawater and deck cleaning detergent. Discharges to the closed drain system are predominantly production fluids which are recycled to the process with residual production chemicals. Although the volumes discharged to the closed drain systems are not directly monitored, chemical use (including identification of overuse) of these chemicals is monitored. There are several hundred drainage points on each facility therefore, it is not possible to install flow meters or monitor all the feeds to the drains.	Partially adopted. Chemical use is monitored. **CM47**: Monitoring of chemical use in accordance with Corrosion Control & Chemical Injection program **CM3**: Chemical Discharge Assessment Process
Sampling of pile fluid discharges	Greater certainty about contaminant levels in water around plie windows.	On most platforms, piles are located beneath the main platform structure. The minimum safe distance to platforms available for sampling is 10 m meaning water from the pile window is not able to be sampled. Given these limitations in safely completing water sampling, it is proposed that sediment sampling is completed to better understand the potential impacts to receptors from pile discharges.	Partially adopted **CM68:** Environmental Sampling
Remove flying leads / umbilicals full of product	Removal of flying leads containing product could minimise release of chemicals	Where possible, flying leads and umbilicals will be removed while containing product. However, this may not be possible in all occasions.	Not adopted

	to the environment and reduce potential impacts to receptors.	Due to the length of the flying leads / umbilicals and their weight when containing product, available vessels are unable to remove them without prior draining. Further, due to the weight of the flying leads / umbilicals when containing product, it is likely that they could break upon removal, which would also result in discharge of the contents.	

6.4.5 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Impact Consequence Level	Impact Consequence is III or less	✓	
Principles of Ecologically Sustainable Development (ESD)	No significant impacts to relevant receptors so that biological diversity and ecological integrity is conserved.	✓	The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The activities were evaluated as having the potential to result in a Level IV consequence thus are not considered as having the potential to result in serious or irreversible environmental damage.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	No environmental legislation or other requirements were deemed relevant.
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"
	Meets ExxonMobil Environmental Standards	✓	The use of piles for management of waste hydrocarbons meets the Upstream Waste Management Standards which calls for consideration of the waste hierarchy. Use of piles allows for waste hydrocarbon to be 'recycled' and returned back to the process. Further, the use of piles meets expectations of the Upstream Water Management Standards and standards for appropriate disposal of uncontaminated deck drainage.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed activities meet: OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements;

Factor	Demonstration Criteria	Criteria Met	Rationale
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised concerning the risk of introduction and establishment of IMS.

7 Environmental Risk Assessment

7.1 Overview

The purpose of the risk assessment is to ensure that all risks associated with the petroleum activity are identified and evaluated, and the resulting risks are demonstrated to be ALARP and Acceptable in accordance with the Esso impact and risk assessment methodology (Section 0).

The assessment of risks been undertaken in two stages:

- Risk Scoping (Section 7.2)
- Detailed Evaluation (Sections 7.3 to 7.6)

7.2 Risk Scoping

Scoping of the risks relevant to the activity ensures that a systematic assessment can be undertaken. The context of the risk assessment has been set through a description of the activity (Section 2.4) and identification of potential environmental receptors within the Operational Area and the PEA (Section 2.4.4.3). By considering the relationship between environmental aspects and the activity (Table 4-2), Esso has identified all risks to affected receptors which could potentially occur as a result of the petroleum activity.

A series of workshops was held to identify environmental impacts and risks associated with the petroleum activity and assess controls to ensure impacts and risks are managed to ALARP and an acceptable level. The workshops were attended by environment and asset personnel. Impacts and risks were evaluated using the impact assessment methodology (Section 4) to determine consequence to receptors, ALARP decision context, and likelihood and residual level of risks. Control measures were identified, and an assessment of acceptability was undertaken against the Esso Acceptability Criteria and the defined acceptable levels of environmental performance (Table 4-8).

For most risks identified, the workshop was able to determine that the adopted controls lowered risks to ALARP and to an acceptable level. These risks, and the outcomes of the assessment, are described in Table 7-3, Table 7-4, Table 7-5 and Table 7-6.

In some cases, it was not possible to finalise the risk evaluation during the workshops. This was typically due to the need for an in-depth literature review to support the evaluation and assessment of potential risks to receptors. Such as that for:

- Unplanned Introduction of IMS (Section 7.3)
- Accidental Release – LOC from drain system (Section 7.4)

Or for discharge scenarios considered as worst case scenarios and hence modelling and further analysis was required;

- Accidental Release – LOC from a vessel (Section 7.5)
- Accidental Release – LOC from a pipeline (Section 7.6)
- Accidental Release – Loss of Well Control (Section 7.6)

For all risks, control measures have been considered as described in Section 4.7. Controls are applied where a reduction in the consequence or the likelihood of the risk will occur as a result of their adoption. They may also be required by legislation, or by internal Esso requirements. Where the assessment of the risk identified that there were no suitable Good Practice control measures, and additional controls considered would not lower the risk assessment outcomes, no controls have been adopted. This is identified in the table and assessed as part of the demonstration of acceptability.

Environmental Performance Outcomes and Standards relevant to risks associated with the petroleum activity are provided in Volume 4.

7.2.1 Worst case discharge scenarios

During the risk workshops, worst case discharge scenarios were considered. These were determined using the AMSA Technical Guideline for contingency planning (AMSA, 2015), the IPIECA Finding 6 - Oil spill risk assessment and response planning for offshore installations (IPIECA & OGP (2013)), and experienced input from environment and asset personnel in attendance.

AMSA (2015) recommends that risk scenarios should consider the worst-case scenarios, the maximum credible case scenario and the most likely case scenario, in order to determine the overall resource levels for response capabilities required. This assessment focuses on two types of risk scenario (definitions from AMSA, 2015):

Worst-case scenario (WCS) - The largest volume that could be spilled as a result of any event or combination of events. The results of a catastrophic event or failure.

Most likely case scenario (MLCS) - The most likely spill over 10 m^3 for the facility or activity. The largest spill likely to occur within the life span of the facility and/or activity.

The worst case scenario for accidental discharge of hydrocarbons was identified in accordance with IPIECA & OGP (2013) and AMSA (2015) as described in Table 7-1.

Modelling of the selected worst case scenarios is used to inform the consequence assessment and establish the overall ranking of the risk.

Further detail about the worst case for each discharge scenario can be found in the relevant Risk Assessment Section.

Table 7-1 Process for determining worst case discharge scenarios

Process	Description
Identify potential discharge scenarios	Potential incidents and discharge scenarios were identified during the development of this Environment Plan. Discharge scenarios were identified based on activities that could result in releases and type of hydrocarbons that could be released. Potential discharge scenarios which could occur as a result of activities described in this Environment Plan were identified to be: • Accidental Release – LOC from vessel (Section 7.5) • Accidental Release – LOC from pipeline (Section 7.6) • Accidental Release – Loss of well control (Section 7.7)
Identification of potential pollutants	For each discharge scenario identified, analysis should include consideration of the composition of hydrocarbons released and their chemical and physical characteristics.
Determine characteristics of the discharge scenario (including the location and calculation of potential spill volumes)	Analysis of scenarios included consideration of flow rates, location, quantity and composition of hydrocarbons released.
Determine likelihood of the discharge scenario	Likelihood of hazardous event was determined in accordance with Section 4.6.2.
Selection of worst case scenarios based on risk	Once potential discharge scenarios have been identified, an assessment should be undertaken to select which scenarios are taken forward to be modelled. The likelihood of an event, and the potential quantity of discharged hydrocarbons, are the two main parameters contributing to the selection of a worst case scenario. At this stage, an initial estimation of the potential environmental consequences can be identified (a detailed assessment of environmental

Process	Description
	consequence is completed once modelling results are available). As a general rule, the closer the release location to sensitive receptors and the greater the persistence of the oil, the higher the potential contribution to the risk from releases. ***<u>Aggregation of worst case discharge scenarios</u>*** Hazardous events may be aggregated to define the oil discharge scenarios. The aggregation process can be necessary to reduce the number of scenarios to be modelled, due to modelling capacity and time restraints. Events that are aggregated should have identical, or very similar, characteristics in terms of: the release location and duration; the quantity of oil released; and the weathering characteristics of the oil. In the case of a qualitative risk assessment, one approach is to use the highest likelihood of the hazardous events representing the single scenario with the highest risk IPIECA & OGP (2013).

7.2.1.1 Oil Spill Modelling

Acknowledging the potential large scale of an oil spill, further analysis is undertaken for unplanned oil spill consequence assessment. Modelling is completed to understand behaviour of the oil and/or chemicals, in particular weathering processes and its potential pathways, travel times, areal distribution and associated volumes under the prevailing climate.

Spill modelling is performed using an advanced three-dimensional trajectory and fates model, SIMAP (Spill Impact Mapping Analysis Program). The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types.

The modelling uses:

- a five-year dataset of currents that includes the combined influence of ocean currents and tidal currents;
- high-resolution local winds from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR) model;
- detailed hydrocarbon characteristics relevant to the risk scenario being modelled;
- hydrocarbon density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges

The output is a three-dimensional oil spill model (SIMAP) which simulates the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling is conducted using a stochastic (random or non-deterministic) approach, which involves running 100 spill simulations for the scenario, initiated at random start times. This ensures that each simulation is subject to different wind and current conditions and, in turn, movement and weathering of the oil.

Results from the simulations then are combined and statistically analysed to assist with understanding the potential impacts of an oil spill as discussed below.

Oil spill modelling is used to determine the total area that could be exposed to hydrocarbon, including trace concentrations of oil in the water column, as a result of <u>any</u> spill. This is known as the Potentially Exposed Area (PEA) and is used for planning purposes to ensure that all social and environmental sensitivities are acknowledged, described and considered in the development of the Environment Plan. Thresholds, or exposure levels used to define the PEA are shown in Table 7-2.

Table 7-2 Thresholds used to define the PEA

Exposure Level	Threshold	Description
Surface – Low Exposure	1 g/m^2	Approximates range of socio-economic effects and establishes planning area for scientific monitoring (NOPSEMA 2019)
Shoreline – Low Exposure	10 g/m^2	Predicts potential for some socio-economic impact (NOPSEMA 2019)
In-water (dissolved) – Low Exposure	10 ppb (instantaneous)	Establishes planning area which may be considered for scientific monitoring based on potential for exceedance of water quality triggers (NOPSEMA 2019).
In-water (entrained) – Low Exposure	10 ppb (instantaneous)	Establishes planning area which may be considered for scientific monitoring based on potential for exceedance of water quality triggers (NOPSEMA 2019).

Modelling is also used to inform specific impact assessments by understanding the location and extent of oil at concentrations likely to result in environmental consequences. There is no agreed exposure level below which environmental impacts will not occur, so outputs should not be interpreted as a boundary. However, mapping areas which could be moderately impacted by a spill is a useful tool for impact or consequence assessment.

Note that the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that might be in place during the operations. The modelling makes no allowance for intervention following a spill to reduce volumes and/or prevent hydrocarbons from reaching sensitive areas.

Fate and weathering characteristics of spilled oil are also useful inputs for impact assessment as these provide insight into which environmental sensitivities are most likely to be affected (e.g. surface oil effects on wildlife vs. water quality effects on aquatic species) as well as the persistence and duration of exposure to oil as it weathers. Prediction of the fate and weathering of spilled oil is completed using deterministic modelling, that is, one of the 100 simulations used to complete stochastic modelling is selected for further analysis. Selection is based on the ‘worst case’ considering the fate of modelled oil.

Oil spill response operations are typically confined to those areas where oil is present in sufficient quantities to enable them to be effective. Spill modelling enables maps to be generated which define these areas to enable effective response planning and capability assessment. Further details can be found in Volume 3 and the OPEP.

Table 7-3 Operations Activities –Risk Scoping

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP				Demonstration of Acceptability	
								ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Platform Operations	Accidental Release - Dropped Objects Dropped objects can occur from lifting / crane operations.	Change in habitat Dropped objects can change habitat through the presence of a foreign object, and through dragging of equipment across the seabed. Risks are restricted to the Operational Area	Benthic habitats and communities	Alteration to benthic habitats, including destruction of habitat, as a result of a dropped object on the seabed can affect benthic habitats and communities. Benthic habitats and communities within the Bass Strait show natural small scale variation; however, the area is mostly considered homogenous. Studies conducted by Esso (Cardno, 2019) demonstrate similarities in taxa but variation in composition between different sites. High rates of disturbance to benthic communities, such as long term disturbance from dredging or trawl fishing, can lead to reduced habitat structure. This results in homogenous, low diversity communities and loss of large and long-lived sedentary species that create habitat structure and leads to reductions in primary production and ecosystem function (Handley et al., 2014). Disturbance from dropped objects during platform operations is not expected to result in high rates of disturbance at this scale, however it is possible that small scale disturbance will lead to similar outcomes. Change in habitat from dropped objects will be limited to close proximity to existing infrastructure. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be	IV	C	4	A	**CM41**: Crane maintenance and inspection programs developed and actioned per FIMS process **CM42**: Crane Operations, Maintenance and Inspection Manual (COMI) - Lifting Procedures **CM6:** Temporary Storage Assessment	None	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable

				inconsequential or have no adverse effects.									
Platform Operations Subsea facilities Operations Pipeline Operations	<u>Accidental Release – LOC (chemicals / hydraulic fluids)</u> Chemical or oil spills resulting from a single-point failure typically occur because of: equipment failure incorrect storage incorrect handling Includes drips and drops, water soluble chemicals released from the piles, oil & chemical storage and handling scenarios, and firefighting foam used during a fire. Volumes typically 80 L.	<u>Change in water quality</u> Accidental release can lead to toxicity impacts near the spill location.	Ambient water quality	Minor spill volumes can lead to a change in water quality through toxicity. The aqueous film forming foam (AFFF) contain some PFAS (per- and poly-fluoroalkyl substances) – based products. A release of AFFF will result in a change in water quality due to chemical toxicity. Due to the high energy marine environment, impacts will be limited to the discharge location and will be quickly dissipated. Any impacts will be inconsequential or have no adverse effects.	IV	B	4	A	**CM66:** PTW system **CM44:** Bunding **CM13:** Platform Induction Process (GreenCard) **CM3:** Chemical Discharge Assessment Process (Fire Fighting Foams) **CM12:** OPEP	None	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened marine mammals, marine reptiles and birds and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives which outlines what defines a significant spill. • No stakeholder objections or claims have been raised	Acceptable
		<u>Injury / mortality to fauna</u> Accidental release can lead to toxicity impacts near the spill location, however due to the high-energy nature of the receiving water column, impacts are expected to be localised and temporary.	Plankton	Early lifestages of fish (embryos, larvae) and other plankton would be most susceptible to the toxic exposure from an unplanned release of chemicals / hydraulic fluids, as they are less mobile and therefore can become exposed to the plume at the outfall. Phytoplankton are typically not sensitive to the impacts of oil, though they do accumulate it rapidly, whilst zooplankton are known to be vulnerable to hydrocarbons (Hook et al., 2016). Water column organisms that come into contact with oil risk exposure through ingestion, inhalation and dermal contact (NRDA, 2012), which can cause immediate mortality or declines in egg production and hatching rates along with a decline in swimming speeds (Hook et al., 2016). Firefighting foams are a mixture of chemicals. Fluorochemical containing foams such as AFFF have the potential to cause long lasting (chronic) effects if continuous exposure occurs due to high bioaccumulation potential. Marine fauna known to bioaccumulate fluorochemicals, such as plankton, are the most affected (Klein, 2009). Plankton is generally abundant in the upper layers of the water column and are expected to rapidly recover once									

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP: ALARP Decision Context	Demonstration of ALARP: Good Practice Control Measures	Demonstration of ALARP: Additional Control Measures Considered	Demonstration of ALARP: ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Demonstration of Acceptability: Acceptability Outcome
				the releases ceases as they are known to have high levels of natural mortality and a rapid replacement rate (UNEP 1985). Reproduction by survivors or migration from unaffected areas is likely to rapidly replenish losses (Volkman et al., 2004). As such, exposure of planktonic communities to accidental chemical and hydraulic fluid discharges is not considered to result in significant impacts on these organisms at population levels that would affect ecological diversity or productivity within Commonwealth marine areas. Rather it is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action. Once background water quality is re-established, plankton takes weeks to months to recover (ITOPF, 2011). Any impacts will be inconsequential or have no adverse effects.									
			Fish	Toxic exposure from small volumes of released chemicals and hydrocarbons can affect fish in close vicinity to the discharge through dermal contact, ingestion and inhalation. Pelagic species are generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Fish communities in the Operational Area are typical of the region. Listed threatened species which may occur; however, any impacts will be localised to the release site and temporary, with hydrocarbon /

				chemical releases dissipating quickly in the high energy marine environment and fish species not expected to suffer extended exposure. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.									
Platform Operations	Accidental Release - Waste Non-hazardous waste can be accidentally released through inappropriate storage and handling.	Change in habitat Non-hazardous waste can become marine debris, changing the habitat for marine fauna.	Benthic habitats and communities	Some waste materials released may sink to the seabed in close proximity to the release site. These materials will rest on the seabed, resulting in smothering to benthic fauna and a localised change in habitat. Change in habitat from accidental release of waste will be limited to the Operational Area. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. 				whale. Marine turtles are not expected to occur regularly within the Operational Area, although their presence is possible. Non-hazardous pollution of this kind is not listed as a threat to any marine fauna. Listed threatened species of marine fauna may occur within the Operational Area; however, any impacts will be localised to the release site and affect individual fauna only. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.									
Platform Operations	<u>Accidental Release - Bulk Transfer</u> Bulk transfer of glycol, methanol, brine, workover fluids or diesel fuel from vessel to platform is conducted using flexible hoses. Accidental release may occur with hose failure. Maximum release <1000 litres.	<u>Injury / mortality to fauna</u> Spills of hydrocarbons and chemicals can lead to toxicity impacts near the spill location.	Plankton	Early lifestages of fish (embryos, larvae) and other plankton would be most susceptible to the toxic exposure from an unplanned release of chemicals / hydrocarbons, as they are less mobile and therefore can become exposed to the plume at the outfall. However, these are expected to rapidly recover once the activity ceases, as they are known to have high levels of natural mortality and a rapid replacement rate (UNEP, 1985). As such, exposure of planktonic communities to accidental chemical and hydrocarbon discharges is not considered to result in significant impacts on these organisms at a population level that would affect ecological diversity or productivity within Commonwealth marine areas. Rather, it is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action. 				Given the maximum release volume, surface and entrained oil concentrations are possible. Fish are at risk from dissolved hydrocarbons and entrained hydrocarbons in the water column. Some fish are attracted to floating objects at sea and may congregate under slicks. Pelagic species are generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Fish are most vulnerable to water column toxicity in shallow nearshore waters, bays and estuaries, where the toxicity concentration can significantly rise. In the open marine environment, dilution is likely, and impacts are significantly reduced. The Operational Area is within a distribution BIA for great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Fish communities in the Operational Area are typical of the region. Listed threatened species may occur; however, any impacts will be localised to the release site and temporary, with hydrocarbon / chemical releases dissipating quickly in the high energy marine environment and fish species are not expected to suffer extended exposure. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.								• No stakeholder objections or claims have been raised	
Pipeline Operations	Accidental Release – LOC (pipeline) •	• Detailed Evaluation in Section 6.5											

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP				Demonstration of Acceptability	
								ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
Platform Operations	<u>Accidental Release - LOC (bulk storage, topside)</u> IBCs located on the main deck store fuel and chemicals. IBC volumes are typically 1250 L. Bulk storage occurs in the jacket legs on several platforms. An accidental release would be a pinhole leak only. An IBC represents the worst-case discharge scenario, and therefore pinhole leaks from jacket bulk storage are not discussed further.	<u>Change in water quality</u> Spills of hydrocarbons and chemicals can lead to toxicity impacts near the spill location.	Ambient water quality	IBCs are typically 1250 Litres in volume. When stored on the main deck, a spill from an IBC would go to the open drain. A release of chemical of hydrocarbons (diesel) from bulk storage via the open drains would lead to a change in water quality through toxicity. Due to the high energy marine environment, impacts will be limited to the discharge location and will be quickly dissipated. Any impacts will be inconsequential or have no adverse effects.	IV	D	4	A	**CM39:** Equipment strategies for pressure equipment developed and actioned per FIMS process **CM54:** Change out of IBC operating procedures **CM12:** OPEP	None	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened fish species and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	• Acceptable
		<u>Injury / mortality to fauna</u>	Plankton	Early lifestages of fish (embryos, larvae) and other plankton would be most susceptible to the toxic exposure from an unplanned release of chemicals / hydrocarbons, as they are less mobile and therefore can become exposed to the plume at the outfall. However, these are expected to rapidly recover once the activity ceases, as they are known to have high levels of natural mortality and a rapid replacement rate (UNEP, 1985). As such, exposure of planktonic communities to accidental chemical and hydrocarbon discharges is not considered to result in significant impacts on these organisms at a population level that would affect ecological diversity or productivity within Commonwealth marine areas. Rather, it is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action. Any impacts will be inconsequential or have no adverse effects.									
			Fish	Toxic exposure can affect fish through dermal contact, ingestion and inhalation. Given the maximum release volume, surface and entrained oil concentrations are possible. Fish are at risk from dissolved hydrocarbons and entrained hydrocarbons in the water column. Some fish are attracted to floating									

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP				Demonstration of Acceptability	
								ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				objects at sea and may congregate under slicks. Pelagic species are generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). Fish are most vulnerable to water column toxicity in shallow nearshore waters, bays and estuaries, where the toxicity concentration can significantly rise. In the open marine environment, dilution is likely, and impacts are significantly reduced. The Operational Area is within a distribution BIA for great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Fish communities in the Operational Area are typical of the region. Listed threatened species which may occur; however, any impacts will be localised to the release site and temporary, with hydrocarbon / chemical releases dissipating quickly in the high energy marine environment and fish species not expected to suffer extended exposure. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.

Wireline / Workover Activities (general) Conductor cutting and pulling	Accidental Release - Dropped Objects During wellwork activities, objects could be accidentally dropped onto the seabed.	Change in habitat Dropped objects can change habitat through the presence of a foreign object, and through dragging of equipment across the seabed. Risks are restricted to the Operational Area	Benthic habitats and communities	Alteration to benthic habitats, including destruction of habitat, as a result of a dropped object on the seabed can affect benthic habitats and communities. Benthic habitats and communities within the Bass Strait show natural small scale variation; however, the area is mostly considered homogenous. Studies conducted by Esso (Cardno, 2019) demonstrate similarities in taxa but variation in composition between different sites. High rates of disturbance to benthic communities, such as long term disturbance from dredging or trawl fishing, can lead to reduced habitat structure. This results in homogenous, low diversity communities and loss of large and long-lived sedentary species that create habitat structure and leads to reductions in primary production and ecosystem function (Handley et al., 2014). Disturbance from dropped objects during wellwork activities is not expected to result in high rates of disturbance at this scale, however it is possible that small scale disturbance will lead to similar outcomes. Change in habitat from dropped objects will be limited to close proximity to existing infrastructure. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be inconsequential or have no adverse effects. Table 7-5 IMR Activities – Risk Scoping

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP: ALARP Decision Context	Demonstration of ALARP: Good Practice Control Measures	Demonstration of ALARP: Additional Control Measures Considered	Demonstration of ALARP: ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Demonstration of Acceptability: Acceptability Outcome
Facility IMR	<u>Unplanned interaction with fauna</u> Interaction with fauna could occur through: Personnel accessing areas where wildlife is present Dropped objects Use of UAVs / drones. Deliberate harm from personnel acting against Esso policies	<u>Change in fauna behaviour, injury or death</u> Disruption to marine fauna could lead to a change in fauna behaviour, including startle response, injury or death. Risks are restricted to the Operational Area.	Birds	Although birds may use the facility for nesting, they are typically found high up on structures which are unable to be accessed by personnel (such as the flare boom) therefore interactions are unlikely. Birds are able to move freely away from personnel or noisy / moving equipment and startle responses such as flying away from a disturbance are unlikely to be detrimental, and birds will return to their nest / roost once the disturbance has passed. Occasionally, personnel may inadvertently come in contact with birds if they have landed on deck and are unable to fly away (e.g. injured or exhausted), in which case personnel are directed not to interact with the wildlife wherever practicable. Birds may also be disturbed by the use of UAVs. Drones are widely used in ornithological research, allowing data collection with minimal disturbance. Approach studies (e.g. Vas *et al.,* 2015) demonstrated that no visible change in behaviour occurred within 4 m of approach. The Operational Area is within foraging BIAs for black browed albatross, Campbell albatross, Indian yellow nosed albatross and wandering albatross, antipodean albatross, Buller's albatross, shy albatross, common diving petrel, white-faced storm petrel, and short-tailed shearwater. There are no specific areas of roosting or nesting within the Operational Area. Disturbance / disruption during roosting or nesting is not identified as a threat in the conservation advice or recovery plans for any of these species. Impacts will be short-term and temporary, with individuals returning to natural behaviours following disturbance. Any impacts will be inconsequential or have no adverse effects.	IV	B	4	B	**CM13:** Platform Induction Process (Greencard) **CM16:** SWP 50.139.A1 – Drone Operation Offshore **CM17:** SWP 50.313 – Sea Deck Access **CM53:** Onboarding process	NOT ADOPTED: Restricting access to all areas of the platform. Restricting access to all areas of the platform could minimise potential for personnel to come in contact with or interact with wildlife when not completing work activities, and hence, reduce the likelihood of deliberate or accidental harm to wildlife occurring on the platform. Access to all areas of the platform is required for safe operation of the platform, emergency escape routes, and safe access around the platform. Certain areas of the platform are restricted such as the helideck, sea deck, WTN RAT, MLB. It is not practical or realistic to confine personnel to the quarters for anything other than work based activities. NOT ADOPTED: Constant surveillance of all personnel. Constant surveillance may reduce the likelihood of personnel acting unlawfully on platforms and hence, reduce the likelihood of deliberate or accidental harm to wildlife occurring on the platform. Constant surveillance of personnel is not considered practical or reasonable. Screening of personnel prior to travelling offshore is considered sufficient to	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened bird or marine mammal species and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • Stakeholder concerns were raised following an incident on a platform in 2018, these have been taken into account by Esso and have been addressed through the incident investigation and actions taken in response.	Acceptable
			Marine mammals	Marine mammals are known to occur within the Operational Area. Pinnipeds, specifically fur seal, have been sighted using the lower level sea deck as a haul-out site for resting. If an interaction occurs, pinnipeds are likely to startle quickly, moving away from the disturbance, therefore limiting impacts. Disturbance will be limited where possible i.e. through avoidance of areas where fauna is known to be resting. Seals may be inadvertently disturbed by personnel needing to go to sea deck for maintenance and inspections. Access to sea deck does not occur regularly and is restricted. Approval from the platform supervisor must be sought prior to accessing the area and the usual practice is for work to be deferred if seals are present in the work area. Personnel are generally not required to work in areas where seals are present and as a result the opportunity for personnel to intentionally interact with, or harm, seals is limited.									

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP: ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Acceptability Outcome
				Occasionally objects may be accidentally dropped from the platform subsequently resulting in inadvertent injury of seals hauled out on lower decks or in the waters around the platform. Potential impacts of dropped objects and the associated controls are discussed further below in Accidental Release – Dropped Objects. Marine mammals can be affected by UAVs in two ways: noise disturbance, and disturbance of visual cues caused by the UAV shadow. Recordings of in-water noise from UAVs indicate that they will only be detected above background noise levels up to 1 m below the surface and will likely be undetected against vessel / platform noise (Christiansen *et al.*, 2016). Evidence suggests that marine mammals residing near the sea surface do not typically display changes in behaviour in response to close flying UAVs (Christiansen *et al.,* 2016). Conversely, evidence suggests that pinnipeds in-air may be disturbed by UAVs. Studies show various reactions to UAV presence, with pinnipeds often returning to the water from haul-out sites as a result of UAV presence (Pomeroy *et al*., 2015). Returning to the water is a common reaction for pinnipeds, and could be caused by a number of factors, however disturbance from UAV presence cannot be ruled out. Australian and New Zealand fur seals known to be present within the Operational Area, although no BIAs have been identified. If accidental or deliberate harm occurred and resulted in death, it is not expected that it would have a detrimental effect on the overall population. Consequently, the potential consequence level is considered to be Consequence Level IV as this type of event may result in a localised, short-term impact to species of recognised conservation value but is not expected to affect the population or local ecosystem function. Given the limited number of listed species that have been observed on, or around, offshore facilities and the limited opportunities for personnel to interact with these species the likelihood of death or injury of an individual is considered Highly Unlikely (D) however given an incident of similar nature has occurred at site before, the probability of occurrence has been assessed to be Somewhat Likely (B).						manage the risk of criminal incidents occurring offshore. In addition, the Esso Standards of Business Conduct stipulate Esso's Environment and Ethics policies. All staff and contractors are expected to act in accordance with these policies and all applicable laws. Any breach of these policies will be investigated and managed in accordance with Esso's existing incident investigation processes. Persons found to have breached Esso Standards of Business Conduct may face consequences up to and including loss of employment at Esso facilities.			
Facility IMR Pipeline and Subsea IMR	<u>Accidental Release - Dropped Objects</u> Objects may be dropped during mechanical repairs,	<u>Change in habitat</u> Dropped objects can change habitat through the presence of a foreign object, and through	Benthic habitats and communities	Alteration to benthic habitats, including destruction of habitat, as a result of a dropped object on the seabed can affect benthic habitats and communities. 			Fish	Toxic exposure from small volumes of released chemicals and hydrocarbons can affect fish in close vicinity to the discharge through dermal contact, ingestion and inhalation. Pelagic species are generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their patterns of movement. Many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Fish communities in the Operational Area are typical of the region. Listed threatened species which may occur; however, any impacts will be localised to the release site and temporary, with hydrocarbon / chemical releases dissipating quickly in the high energy marine environment and fish species not expected to suffer extended exposure. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.									

Table 7-6 Support Operations Activities – Risk Scoping

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP: ALARP Decision Context	Demonstration of ALARP: Good Practice Control Measures	Demonstration of ALARP: Additional Control Measures Considered	Demonstration of ALARP: ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Demonstration of Acceptability: Acceptability Outcome
Vessel Operations	<u>Unplanned Interaction with Fauna</u> The presence of moving or stationary vessels may result in interaction with marine fauna such as collision	<u>Injury / mortality to fauna</u> Vessel strike can lead to injury or death. Risks are restricted to the Operational Area	Marine mammals - cetaceans	Cetaceans are naturally inquisitive animals that are often attracted to offshore vessels and facilities. Collisions between larger vessels with reduced manoeuvrability and large, slow-moving cetaceans occur more frequently where high vessel traffic and cetacean habitat co-exist (Whale and Dolphin Conservation Society, 2006). Laist et al. (2001) identifies that larger vessels with reduced manoeuvrability moving in excess of 10 knots may cause fatal or severe injuries to cetaceans, with the most severe injuries caused by vessels travelling faster than 14 knots. Vessels typically used to undertake petroleum activities do not have the same limitations on manoeuvrability and would not be moving at these speeds when conducting activities within the scope of this EP, inside the Operational Area. The Operational Area is within a foraging BIA for the pygmy blue whale. Vessel strike is identified as a key threat in the following: • Approved Conservation Advice for Balaenoptera borealis (Sei Whale) • Conservation Management Plan for the Blue Whale, 2015-2025 • Approved Conservation Advice for Balaenoptera physalus (Fin Whale) • Conservation Management Plan for the Southern Right Whale, 2011-2021 • Approved Conservation Advice for Megaptera novaeangliae (Humpback Whale) Given the potential presence of sensitive species, potential short-term, minor adverse effects are possible.	III	D	4	B	**CM8:** Vessel Master **CMP25:** Tunnel thruster guards	NOT ADOPTED (other than for cetaceans): Vessel Masters to implement interaction management actions consistent with Australian National Guidelines for Whale and Dolphin Watching 2017. Although these guidelines are more relevant for tourism activities, they provide a list of requirements that are generally adopted by the oil and gas industry to minimise the risk of cetacean strike occurring. Both the lack of visibility of seals in the water and number of seals in close proximity to oil and gas offshore installations, make applicability of these guidelines to seals impracticable. Furthermore fauna interaction management actions as described in the guidelines will not prevent seals approaching / playing with vessels.	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened fish or marine mammals and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented • No control measures which could further lower the consequence or likelihood have been identified • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	Acceptable
			Fish	Large slow-moving marine fauna, such as the whale shark, are most susceptible to vessel strike. There is limited data regarding strikes to whale sharks, possibly due to lack of collisions being noticed and lack of reporting; however, marks observed on animals show that strikes have occurred (Peel *et al*. (2016; cited in DoE, 2015a). The Approved Conservation Advice for Rhincodon typus (Whale Shark) identifies boat strike from large vessels as a threat. Whale sharks inhabit tropical and warm temperate waters, and in Australia occur mainly off the Northern territory, Queensland and northern Western Australia (DoE, 2015a). Only isolated records exist of Whale sharks off NSW, Victoria and South Australia (Last & Stevens, 2009). As the Operational Area is located outside of a BIA, any impacts will be to an individual only with no population or ecosystem-level impacts expected. Any impacts will be inconsequential or have no adverse effects.									

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP: ALARP Decision Context	Demonstration of ALARP: Good Practice Control Measures	Demonstration of ALARP: Additional Control Measures Considered	Demonstration of ALARP: ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Demonstration of Acceptability: Acceptability Outcome
			Marine mammals - pinnipeds	Pinnipeds are not listed as a species vulnerable to vessel strike. This is likely due to their high level of activity within the water column, and their highly mobile nature. Peel *et al*. (2016) reviewed vessel strike data (1997-2015) and identified no vessel interaction reports during the period for either the Australian or New Zealand fur seal. There have been incidents of seals being injured by boat propellers around areas where they rest or congregate including oil and gas platform structures, however all indications are rather than 'boat strike' these can be attributed to be the seal interacting/playing with a boat, with experts indicating the incidence of boat strike for seals is very low. Pinnipeds are commonly seen on and around Esso platforms although there have only been 3 incidents reported in the last 10 years relating to interactions with vessels. Any potential impacts to pinnipeds would be on individuals, with no population or ecosystem level impacts expected.									
			Marine reptiles	Marine turtles are vulnerable to vessel collision, although collision is more likely in slow moving vessels (Hazel, 2007). There is limited data regarding marine turtle vessel strikes, however marks observed on animals show that strikes have occurred (Peel *et al*., 2016, cited in Commonwealth of Australia, 2016). Marine turtles are also vulnerable to entrainment in propellers or water intakes. Five listed / threatened species of marine turtle may occur within the Operational Area, however no BIAs or critical habitats have been identified and all marine turtles are known to have a more northerly distribution. Vessel disturbance is listed as a key threat in the Recovery Plan for Marine Turtles in Australia, 2017-2027; however, this is in reference to shallow coastal foraging and nesting sites where there is a high number of commercial and recreational vessels. As the Operational Area is located outside of a BIA / critical habitat, any impacts will be to an individual only with no population or ecosystem-level impacts expected. Any impacts will be inconsequential or have no adverse effects									
Vessel Operations	Unplanned Introduction of IMS	**Detailed Evaluation Section 7.3**											
Vessel Operations ROV Operations	Accidental Release - Dropped Objects Potential dropped objects may include personnel protective	Change in habitat Dropped objects can change habitat through the presence of a foreign object. Risks are restricted to the Operational Area	Benthic habitats and communities	Dropped objects can occur due to ineffective use of handling procedures, or storm / inclement weather conditions. The impact energy of an object free falling overboard as it hits the seafloor is influenced by several factors, including mass, shape of the object, water depth and prevailing currents (Sari et al. 2016). The mass of small objects such as glasses, gloves, hard hats, small tools and hardware fixtures is unlikely to contribute to impact energies with the potential to cause damage to benthic habitat.	IV	E	4	A	**CM18:** Preventative Maintenance System (PMS) **CM19:** Cargo	None	ALARP	• Risk is well understood • Level of Environmental Risk is below 1 • No potential to affect biological diversity or ecological integrity	• Acceptable

	gear, small tools and hardware fixtures (e.g. clamps).			Where objects are dropped and remain on the seabed, colonisation by epifauna is expected. By providing a hard substrate on bare substrate, this will result in a localised change in biodiversity with fouling communities settling on the object. Dropped objects will eventually degrade but may take years. Change in habitat from dropped objects will be limited to the Operational Area. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be inconsequential or have no adverse effects.					Securing Manual **CM40**: Flag State lifting requirements			• Activity will not result in serious or irreversible damage • Good practice control measures have been defined and implemented • Control measures are consistent with Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Vessel Operations ROV Operations	<u>Accidental Release – LOC (chemicals / hydraulic fluids)</u> Chemical or hydraulic fluid spills resulting from a single-point failure typically occur because of: equipment failure incorrect storage incorrect handling Includes drips and drops, and oil & chemical storage and handling scenarios. Volumes typically 80 L.	<u>Change in water quality</u> Accidental release can lead to toxicity impacts near the spill location.	Ambient water quality	Minor spill volumes can lead to a change in water quality through toxicity. Due to the high energy marine environment, impacts will be limited to the discharge location and will be quickly dissipated. Any impacts will be inconsequential or have no adverse effects.	IV	C	4	A	<u>Vessel Operations</u> **CM20:** SMPEP <u>ROV Operations</u> **CM21:** ROV pre-post dive checks **CM22:** ROV IMCA Audit	None	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened fish species and will be undertaken in accordance with all applicable management actions. • Good practice control measures have been defined and implemented • Control measures are consistent with	• Acceptable
		<u>Injury / mortality to fauna</u> Minor spill volumes can lead to toxicity impacts near the spill location, however due to the high-energy nature of the receiving water column, impacts are expected to be localised and temporary.	Plankton	Early lifestages of fish (embryos, larvae) and other plankton would be most susceptible to the toxic exposure from an unplanned release of chemicals / hydraulic fluids, as they are less mobile and therefore can become exposed to the plume at the outfall. However, these are expected to rapidly recover once the activity ceases, as they are known to have high levels of natural mortality and a rapid replacement rate (UNEP 1985). As such, exposure of planktonic communities to accidental chemical and hydraulic fluid discharges is not considered to result in significant impacts on these organisms at population levels that would affect ecological diversity or productivity within Commonwealth marine areas. Rather it is considered to result in an undetectable or limited local degradation of the environment, rapidly returning to original state by natural action. Any impacts will be inconsequential or have no adverse effects.									
			Fish	Toxic exposure from small volumes of released chemicals and hydrocarbons can affect fish in close vicinity to the discharge through dermal contact, ingestion and inhalation. Pelagic species are generally highly mobile and as such are not likely to suffer extended exposure (e.g. >96 hours) at concentrations that would lead to chronic effects due to their

								ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Acceptability Assessment	Acceptability Outcome
				patterns of movement. Many fish species can metabolise toxic hydrocarbons, which reduces the risk of bioaccumulation (NRDA, 2012). The Operational Area is within a distribution BIA for the great white shark; however, no threats have been identified in the Recovery Plan for the White Shark (*Carcharodon carcharias*). Fish communities in the Operational Area are typical of the region. Listed threatened species which may occur; however, any impacts will be localised to the release site and temporary, with hydrocarbon / chemical releases dissipating quickly in the high energy marine environment and fish species not expected to suffer extended exposure. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.								Esso's Environment Policy • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Vessel Operations	<u>Accidental Release - Waste</u> Non-hazardous waste can be accidentally released through inappropriate storage and handling.	<u>Change in habitat</u> Non-hazardous waste can become marine debris, changing the habitat for marine fauna.	Benthic habitats and communities	Some waste materials released may sink to the seabed in close proximity to the release site. These materials will rest on the seabed, resulting in smothering to benthic fauna and a localised change in habitat. Change in habitat from accidental release of waste will be limited to the Operational Area. Benthic habitats and communities within the Operational Area show natural small scale variation, however, are mostly homogenous, with no particular areas of value or sensitivity. It is possible that activities will produce a slight alteration of the local habitat and community structure due to the small amount of changed substrate in an area of uniform soft sediments; however the naturally homogenous nature of the habitats and communities in the Operational Area will result in quick recovery, and no long-term changes to ecosystem are expected. Any impacts will be inconsequential or have no adverse effects.	IV	E	4	A	**CM9:** Class Certification	None	ALARP	• Risk is well understood • Level of Environmental Risk is below 1. • No potential to affect biological diversity or ecological integrity • Activity will not result in serious or irreversible damage • Activity will not impact the long term survival and recovery of listed and threatened birds, marine reptiles or marine mammals and will be undertaken in accordance with all applicable management actions. • Activity will be undertaken in accordance with the management actions provided in the Threat Abatement Plan (2018). • Good practice control measures	• Acceptable
		<u>Injury / mortality to fauna</u> Non-hazardous waste can cause physical harm to marine fauna through ingestion or entanglement.	Birds Marine reptiles Marine mammals	Marine fauna most at risk from marine pollution include marine mammals, marine reptiles and seabirds through ingestion or entanglement. Impact will occur to species on the sea surface or in the surface waters. The ingestion or entanglement of marine fauna has the potential to limit feeding / foraging behaviours and thus can result in mortalities. The Operational Area is within a number of seabird foraging BIAs, and a foraging BIA for pygmy blue whale. Marine turtles are not expected to occur regularly within the Operational Area, although their presence is possible. Non-hazardous pollution of this kind is not listed as a threat to any marine fauna. The Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans (DoEE 2018) lists vessel-sourced, solid, non-biodegradable floating material as a threat to marine fauna.									

Activity	Aspect	Risk	Affected Receptor	Consequence Evaluation	Consequence Level	Likelihood	Risk Ranking	Demonstration of ALARP: ALARP Decision Context	Good Practice Control Measures	Additional Control Measures Considered	ALARP Outcome	Demonstration of Acceptability: Acceptability Assessment	Acceptability Outcome
				Listed threatened species of marine fauna may occur within the Operational Area; however, any impacts will be localised to the release site and affect individual fauna only. Impacts are not expected to result in population or ecosystem level effects and will not affect the long-term survival or recovery of listed threatened species. Any impacts will be inconsequential or have no adverse effects.								have been defined and implemented • Control measures are consistent with Esso's Environment Policy • Class certification ensures that vessels adhere to the rules of an IACS Member society, such as MARPOL requirements and Marine Orders. • The activity meets ExxonMobil Environmental Standards and ExxonMobil OIMS objectives • No stakeholder objections or claims have been raised	
Vessel Operations	Accidental Release - LOC (vessels)	**Detailed Evaluation Section 6.6**											

7.3 Unplanned Introduction of IMS

7.3.1 Causes of introduction of IMS

An invasive marine species (IMS) is a species occurring, as a result of human activities, beyond its accepted normal distribution and which threatens the environment, human health or economic values by the damage it causes (DoEE, 2019). Not all non-indigenous marine species introduced into new environments will cause demonstrable effects and become IMS; some are relatively benign, and few have spread widely beyond ports and harbours.

The following pathways have the potential to result in the introduction of IMS:

- discharge of ballast water from vessels containing IMS; and
- biofouling of the vessel hull and niches (e.g. sea chests, bilges, strainers) Risk Assessment

The translocation and establishment of IMS through biofouling or ballast water discharge has the potential to result in effects to seabed habitat and marine ecosystems due to:

- Changes in ecosystem dynamics.
- Changes in the functions, interests or activities of other users

Receptors that could be affected by the introduction and establishment of IMS are identified in Table 7-7.

Table 7-7 Receptors potentially affected by impacts associated with introduction of IMS

Impacts	Receptors	
	Benthic habitats and communities	Commercial Fisheries
Change in ecosystem dynamics	✓	
Changes in the functions, interests or activities of other users		✓

7.3.1.1 Change in ecosystem dynamics

Successful IMS establishment requires the following three steps:

- Colonisation and establishment of the marine pest on a vector (e.g., vessel hull) in a donor region (e.g., home port).
- Survival of the settled marine species on the vector during the voyage from the donor to the recipient region (e.g., project area).
- Colonisation (e.g., dislodgement or reproduction) of the marine species in the recipient region, followed by successful establishment of a viable new local population.

It is estimated that there are more than 250 exotic species in the Australian marine environment and that about one in six to one in ten introduced marine species become ‘pests’ (i.e. the effects of the introduced organisms are sufficiently severe) (McDonald, 2008).

IMS are likely to have little or no natural competition or predators, thus potentially outcompeting native species for food or space, preying on native species, or changing the nature of the environment.

The benthic habitat within the PEA is characterised by a soft sediment and shell/rubble seabed, infauna communities, and sparse epibiotic communities (typically sponges). The nearest area of higher value or sensitivity, the Ninety Mile Beach Marine National Park on the Victorian coast, is located between 12 km (Seahorse) and 87 km (Blackback) inshore from the operational area. The Beware Reef Marine Sanctuary and Point Hicks Marine National Park (Figure 7-1) are located more than 40 km inshore from the operational area, with the Kipper and Tuna facilities nearest to these sites of conservation significance.

…

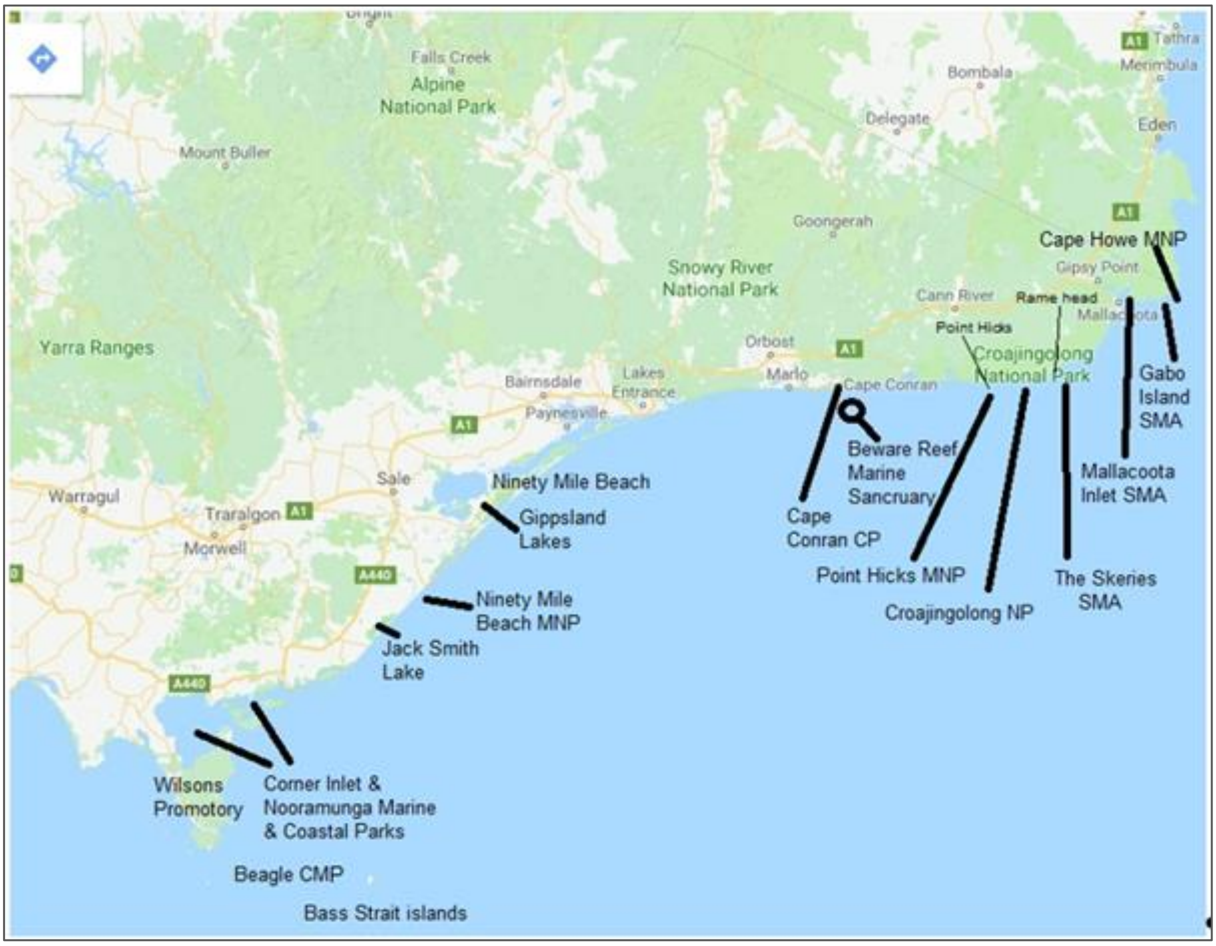

Figure 7-1 Sites of conservation significance along Gippsland Coastline

Once established, some pests can be difficult to eradicate (Hewitt, 2002) and therefore there is potential for a long-term or persistent change in habitat structure. It has been found that highly disturbed environments (such as marinas) are more susceptible to colonisation than open-water environments, where the number of dilutions and the degree of dispersal are high (Paulay *et al*., 2002). Given that the habitat found within the PEA is mostly soft sediment, potential for settlement of IMS within the PEA is limited.

7.3.1.2 Change in the functions, interests or activities of other users

Marine pest species can also deplete fishing grounds and aquaculture stock, with between 10% and 40% of Australia's fishing industry being potentially vulnerable to marine pest incursion. For example, the introduction of the Northern Pacific seastar (*Asterias amurensis*) in Victorian and Tasmanian waters was linked to a decline in scallop fisheries (DSE, 2004). Similarly, the New Zealand screw shell (*Maoricolpus roseus*), thought to have been introduced on dry ballast or through the live oyster trade, may threaten other mollusc species, including scallops. The New Zealand screw shell can densely blanket the sea floor with live and dead shells and faecal pellets and therefore smother other seafloor species (ABC Science, 2000).

Marine pests can also damage marine and industrial infrastructure, such as encrusting jetties and marinas or blocking industrial water intake pipes. By building up on vessel hulls, they can slow the vessels down and increase fuel consumption.

7.3.1.3 Consequence evaluation

If an introduced IMS successfully established within an offshore area, it is expected that any colony would remain fragmented and isolated, and only within the vicinity of the facilities (i.e. it would not be able to propagate to nearshore environments, and protected marine areas present in the wider region). Therefore, there is the potential for a localised, but irreversible, impact to habitat that is not formally managed resulting in a **Level III** consequence.

7.3.1.4 Likelihood evaluation

Vessel movement, including support and supply vessels, workover rigs and well intervention vessels as well as submersible equipment and ROVs (especially those entering the Operational Area from interstate or internationally) may pose a risk of introducing IMS. The introduction of IMS is less likely for submersible equipment and workover rigs that are transported to site out of water, meaning that any biofouling generally dehydrates and dies (and may dislodge) between locations and is therefore less likely to survive in a new location (when the equipment is lowered into the water).

Compliance with regulatory requirements for the management of ballast water and ensuring all vessels are assessed as posing a low biofouling risk in accordance with national guidelines will significantly reduce the likelihood of translocation of an IMS. Successful colonisation in the recipient region would be difficult given the nature of the benthic habitats near the Operational Area (i.e. predominantly bare sands with patchy occurrences of hard substrate) and location outside of coastal waters where the risk of IMS establishment is considered greatest (Australian Government Bureau of Resource Sciences (BRS), 2007).

IMS management areas are typically defined as all nearshore waters, extending from the lowest astronomical tide mark to at least 12 nm from land and in all waters less than 50 m deep. Most platforms and facilities are outside of this management area, however BTA, BTW, SHA and TWA are close to the nearshore boundary and in water depths of less than 50 m. DPA and PCA are also within the potential management area, however vessel traffic is significantly reduced to these locations.

While the 12 nm / 50 metre depth boundary has a very clear legal basis, it also provides a natural buffer area between offshore areas and the nearshore habitats that are susceptible to IMS establishment. Many of the IMS have a planktonic larval stage. By maintaining the 12 nm / 50 m depth criteria, the effects of dispersal and dilution of IMS larvae significantly reduces the risk of successful establishment in susceptible nearshore environments. For example, BRS established that the relative risk of an IMS incursion decreases with distance from the shoreline. It is estimated that for Bass Strait, the IMS risk is reduced to a third at 3 NM from the nearest shore and to about 1% at 24 nm offshore.

For these reasons, it is considered **Very Unlikely (D)** that this activity would result in the introduction and establishment of an IMS and any subsequent impact to receptors.

7.3.2 Risk Ranking

Consequence	Likelihood	Risk Ranking
III	D	4

7.3.3 Controls

Good Practice	Adopted	Control	Rationale
Ballast Water Management	Yes	**CM23:** Ballast Water Management Plan **CM24:** Ballast Water Certificate	The Biosecurity Act 2015 requires that vessels have a Ballast Water Management Certificate (BWMC) and Ballast Water Management Plan (BWMP), and undertake reporting and management of ballast in accordance with the Act. The BWMP must: • be vessel specific (vessel name and International Maritime Organization (IMO) number) • be approved by a survey authority, recognised organisation, or the vessel's flag administration

Good Practice	Adopted	Control	Rationale
			• nominate the rank(s) of the responsible officer and crew • contain the ballast water management method and pumping rates. BWMPs should be consistent with the Ballast Water Convention's Guidelines for Ballast Water Management and Development of Ballast Water Management Plans (G4 Guidelines). A valid BWMC must be issued by either a survey authority, classification society, or the administration of the vessel, and be in accordance with Regulation E-1 of the Ballast Water Convention.
	Yes	**CM8:** Vessel Master	The Vessel Master has responsibility for ensuring these Requirements are followed ensuring Ballast water records show location of ballast water uptake and discharge.
	Yes	**CM25:** Biosecurity clearance when entering Australian territory	Vessels that are intending to discharge internationally sourced ballast water within Australian waters must submit a Ballast Water Report through Maritime Arrivals Reporting System (MARS) at least 12 hours prior to arrival to gain biosecurity clearance. The acceptable area for a ballast water exchange between an offshore oil and gas installation and an Australian port is in areas that are no closer than 500 m from the offshore installation and no closer than 12 NM from the nearest land and in water at least 50 m deep. Ballast tank sediment must be disposed of in an area outside 200 nautical miles from the nearest land, and in at least a depth of 200 metres, or at an approved land-based reception facility.
Biofouling Management	Yes	**CM26**: IMS Risk Assessment Procedure (IMS-RAP).	Biofouling risk is assessed in accordance with the National Biofouling Management Guidelines and documented through the IMS Risk Assessment Procedure (IMS-RAP). The IMS-RAP is to be applied to all contracted non-trading vessels undertaking petroleum activities in the Gippsland Basin. Consistent with the 'best practice' approach set out in the IMO Guidelines for the Management of Ships Biofouling (IMO Guidelines) (IMO, 2012) the risk assessment considers many parameters of the vessel or rig including (where relevant): • Transport method (dry versus wet haulage) • Presence and age of antifouling coating (AFC) • Evidence of in-water inspection by divers or inspection in dry dock and cleaning of hull • Presence and operation of internal seawater treatment systems if applicable • Duration of stay in overseas or interstate coastal waters • Location of operations (operational area), timings and durations. Where the initial indicative assessment (conducted by an IMS Expert and/or via the online Vessel Check portal

Good Practice	Adopted	Control	Rationale
			(www.vessel-check.com)) results in ‘Low Risk’, the risk assessment is provided to the Principal Officer Invasive Marine Species, DJPR. If the Principal Officer is satisfied that no further action is necessary following this consultation the vessel or rig is deemed acceptable for use. If the risk assessment result is uncertain or high risk, or further action is recommended by the Principal Officer, an IMS Expert is consulted to determine whether additional controls can be implemented to reduce the vessel risk status to ‘Low Risk’. Examples of potential control/mitigation measures to reduce risk that may be proposed are consistent with the NBMG and the IMO Guidelines. The control measures proposed must meet the standard of performance described in IMS-RAP. Following implementation of these mitigation measures, the IMS Expert is consulted to reassess the level of risk for the activity and determine whether the level of risk for the activity is ‘Low Risk’ and meets the ALARP and Acceptability criteria (Sections 3.7 and 3.8). If this process still results in an uncertain or high risk then an alternative vessel or rig must be sought for the activity.

7.3.4 Demonstration of ALARP

ALARP Decision Context and Justification	**Decision Context B** The causes resulting in an introduction of IMS from ballast water discharge or biofouling are well understood and well managed by national and international regulations and industry guidance. Esso is experienced in the implementation of industry requirements through their existing ongoing operations. Given the potential for an irreversible effect on the benthic habitat, there is the potential for **Consequence Level III** impacts. No stakeholder objections or claims were raised with regards to the risk of introduction and establishment of IMS. Based on the Level III consequence rating, Esso believes **ALARP Decision Context B** should apply. An Engineering Risk Assessment has been undertaken to assess the costs and benefits associated with additional, alternative and/or improved controls.		
Engineering Risk Assessment			
Additional, Alternative, Improved Controls	**Benefit**	**Cost / Feasibility**	**Adopted**
Use of freshwater ballast	By using freshwater ballast, the likelihood of introducing an IMS can be reduced. However, because the likelihood of the consequence is already low (see above), there is limited environmental benefit associated with implementing this measure.	Costs associated with this measure are high, and disproportionate to the benefit.	Not adopted

Use only support vessels that are currently operating in Bass Strait to reduce the potential for introduction of IMS.	By only using vessels that are currently operating in Bass Strait, the likelihood of introducing an IMS can be reduced. However, because the likelihood of the consequences is already low (see above), there is limited environmental benefit associated with implementing this measure.	Limiting support vessel selection to use of those currently operating in Bass Strait could potentially pose a significant risk in terms of time and duration for sourcing a vessel, as well as the ability of those chosen to perform the required tasks. Likewise, a specialist well intervention vessel would likely be sourced from international markets. This potential cost is grossly disproportionate to the minor environmental gain (of reducing the potential likelihood of IMS introduction) achieved and is not reasonably practicable.	Not adopted
Inspect and clean all vessels	By dry docking and cleaning all wetted surfaces on all vessels the likelihood of a pest relocation is considerably lowered.	Inspection and cleaning require highly specialist facilities and must to be completed at specific locations, immediately prior to vessels commencing work. The risk already has a low likelihood so the substantial cost (and time required) to inspect and clean all vessels outweighs the environmental benefit.	Not adopted

7.3.5 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Risk Assessment Process for Unplanned Events	The risk ranking is lower than Category 1	✓	The risk ranking is Category 4 (the lowest category) and therefore considered acceptable.
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	There is potential for a localised, but irreversible, impact to benthic communities resulting in a Level III consequence. This impact is limited in extent (i.e. localised) and is not considered as having the potential to affect biological diversity and ecological integrity.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The habitat with the potential to be impacted is characterised by soft sediment communities which are scarce in the Operational Area. However, in the event that soft sediment communities do occur, there is low potential for serious or irreversible environmental damage. As described in Section 4.8, further evaluation is therefore required against the remaining Principles of ESD, as follows: *Where the activity has the potential to result in serious or irreversible environmental damage, further assessment is undertaken to determine if there is significant uncertainty in the evaluation.* There is little uncertainty associated with this aspect as the activities are well

Factor	Demonstration Criteria	Criteria Met	Rationale
			practised, the cause pathways are well known, and activities are well regulated and managed. It is not considered that there is significant scientific uncertainty associated with this aspect, and Principles of ESD are therefore met.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	The following legislative and other requirements are considered relevant as they apply to the implementation of the Ballast Water Management Convention in Australia: • Biosecurity Act 2015; and • Australian Ballast Water Management Requirements (DAWR, 2017). Vessel biofouling management aligns with: • Protection of the Sea (Harmful Anti-fouling Systems) Act 2006; and • Marine Order 98 (Marine pollution prevention - anti-fouling systems) 2013. Biofouling risk is assessed, and mitigated, in accordance with the National Biofouling Guidelines for the Petroleum Production and Exploration Industry (DAWR, 2009).
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed activities are consistent with Esso's Environment Policy, in particular, to "comply with all applicable environmental laws and regulations and apply responsible standards where laws and regulations do not exist"
	Meets ExxonMobil Environmental Standards	✓	There is no specific Environmental Standard which addresses the introduction of IMS but the activities proposed meet the strategic objectives of the Upstream Environmental Standards.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed activities meet: • OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and • OIMS System 8-1 objective to qualify, evaluate and select contractors based on their ability to perform work in a safe, secure and environmentally sound manner.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised concerning the risk of introduction and establishment of IMS.

7.4 Accidental Release – LOC from drain system

7.4.1 Causes of LOC from drain system

Skimmer piles are used to separate hydrocarbons from water in liquids directed to the open and closed drain systems. Hydrocarbon vapours migrate to the top of the pile, hydrocarbon liquids settle out on top of the water in the pile, and water at the very bottom of the pile discharging to sea via the pile window.

Hydrocarbon liquid from the piles is monitored by level monitoring equipment which is connected to alarms which prompt pump out of hydrocarbons back to the process system before hydrocarbons reach the subsea window.

Closed piles have pressure alarms to manage high pressure levels which lead to a platform shutdown. This is both for safety reasons (to manage the risk of backpressure through the drain system) and to manage the risk of pushing hydrocarbons out of the subsea window.

LOC from the drain system could occur if hydrocarbons migrate to the subsea window of the skimmer pile. This could be caused by:

- Formation of emulsion which is not detected by level instrumentation. Emulsions could be formed due to chemicals disposed to the piles or from agitation.
- Failure of pumps to pump out hydrocarbon phase.
- Over pressure of pile
- Excess flow of liquids into pile.

LOC from the drain system could occur at all platforms, apart from BMB, DPA, PCA and WTN which do not have drain systems. Maximum volumes contained within the drain systems range from 13 m^3 (at BTA platform) to 240 m^3 (at platforms CBA and SNA). The subsea window, where discharges occur, are between 18 m (at FTA platform) and 49 m (at SNA platform) below the sea surface.

The volume of hydrocarbon liquid inadvertently released from the drain systems is likely to be less than the volume of the pile system. A highly conservative estimate of loss of containment of 240 m^3 of hydrocarbons has been used to assess the risk of LOC from drain system, based on the complete loss of the largest pile system volume at 100% hydrocarbon content. This volume is an overestimate as level alarms and regular monitoring ensures piles do not operate at 100% hydrocarbon content. In addition, the. Hydrostatic pressure within the pile system would limit the release and restrict the amount lost, and fluid contained within the pile system is unlikely to be 100% hydrocarbon.

7.4.2 Risk Assessment

A loss of containment from the drain system will lead to a change in water quality, which could lead to injury / mortality in fauna.

Receptors that could be affected by a LOC from drain system are identified in Table 7-8.

Table 7-8 Receptors potentially affected by impacts associated with LOC from the drain system

Receptors	Impacts

Recreation and Tourism				✓

7.4.2.1 Consequence Evaluation

A spill of hydrocarbons to the marine environment can lead to a change in water quality through toxicity. Hydrocarbon in the piles is likely to be mainly diesel, as this is the hydrocarbon type most commonly discharged to the drain system.

The maximum release volume described as the Worst-case scenario is similar to the discharge volumes modelled for the loss of containment due to Vessel Collision (Section 7.5). A detailed description of modelling is provided in Section 7.5.2. Note that modelling scenarios are based on surface release, whereas hydrocarbons from the drain system would be released from the subsea window. Diesel is naturally buoyant and would be expected to rise quickly through the water column to the surface. Modelling undertaken for a surface release is considered appropriate to understand the potential consequences to receptors. Environmental risks to receptors are expected to be similar to those described in Section 7.5.3.

Given the moderate spill area and the potential for impacts to sensitive receptors, a loss of containment from the drain system would have possible minor, short-term effects on receptors, **Consequence Level III.**

7.4.2.2 Likelihood Evaluation

Loss of containment from the drain system is an accidental release event which has happened previously within the Bass Strait Operations. Considering the volume of hydrocarbons associated with a LOC from the drain system, together with the control measures in place, the probability of a LOC from the drain system resulting in the impacts described above is considered **Likely (C).**

7.4.3 Risk Ranking

Consequence	Likelihood	Risk Ranking
III	C	3

7.4.4 Controls

Good Practice	Adopted	Control	Rationale

Pile management system	✓	**CM46:** Maintenance and testing of Open and Closed Skimmer Piles **CM50:** Closed Drain and Open Drain Piles procedures.	Maintenance and inspection of pile equipment is conducted to ensure equipment is functioning as designed, level readings are accurate and pumps and triggers are operational so as to prevent discharges caused by equipment failure. A functional pile pump allows the hydrocarbon phase in the piles to be pumped down on a regular basis. Pumps are maintained as per the applicable OIMS 6-2 FIMS equipment strategy which calls for demonstration that pumps are functional (i.e. are able to pump out the contents of the pile). The equipment strategy also defines the criticality of the equipment. Pile pumps have been defined as criticality A, the highest level. Platforms have at minimum one pump installed. Platforms have access to a contingency pump (in the event that the primary pump is OOS or fails) either on the platform or in the LFD warehouse. Location and access to a spare pile pump is determined using the FIMS risk assessment processes. Level monitoring instrumentation is also maintained as per the applicable OIMS 6-2 FIMS equipment strategy which calls for instrumentation to be cleaned and calibrated on a recurring basis.
	✓	**CM30**: Offshore Technical Monitoring Program	Pile 'health' is monitored regularly to identify and assess abnormalities in pile level trends. Surveillance Engineers monitor pile levels on a quarterly basis against expected level trends. Abnormalities will be assessed for their significance and appropriate action taken to address the cause. This process allows for issues with level instrumentation, pile pumps or general pile health to be identified and managed.
Dosing of piles with emulsion breaker	✓	**CM71:** Dosing of piles with emulsion breaker	Where potential for emulsion in piles is identified (either through Offshore Technical Monitoring Program or Testing of Pile systems), application of emulsion breaker can be implemented to break down emulsions. This can improve accuracy of level instrumentation and assist pump function. Procedure GEN-110-201 is in place to provide guidance on when emulsion breaker should be used and how to safely apply it to open and closed drain systems. GEN-100-201 requires pile levels to be monitored every hour for 4 hours post dosing to monitor effectiveness of emulsion breaker.

7.4.5 Demonstration of ALARP

ALARP Decision Context and Justification	**Decision Context B** Loss of containment of hydrocarbon from the open drain systems can have a number of causes. There is a good understanding of potential spill sources, and the control measures required to manage these. These control measures are not regulated but are guided by OIMS management systems. There is little uncertainty associated with the potential environmental impacts which have been evaluated as **Consequence Level III**. Despite this, the likelihood of LOC from pile systems has assessed to be Likelihood B as it has happened several times at site over the past 10 years. No stakeholder objections or were claims raised during consultation for this campaign. Based on the likelihood rating, Esso believes **ALARP Decision Context B** should apply.
Engineering Risk Assessment	

Additional, Alternative, Improved Controls	Benefit	Cost / Feasibility	Adopted
Install secondary pile pump for redundancy.	Having two pile pumps would allow for contingency should the primary pump fail or be out of service.	Engineering design of piles on HLA, WKF for open piles and BTA, MLA, HLA, KFA, KFB, MKA, TNA, & SNA, for closed piles does not allow for retrospective installation of two pumps. In these cases, significant structural modifications to the pile and the platform would be required.	Adopted on BTA, KFA, KFB, MKA, TNA, SNA, CBA, FLA, FTA, BMA, MLA, MLB & WTN for open piles. Adopted on WKF, CBA, FLA, FTA, BMA, MLB & WTN closed piles. Not adopted on remaining facilities **CM46:** Maintenance and testing of Open and Closed Skimmer Piles
Store spare pile pumps at LFD warehouse.	Storing spare pile pumps at the LFD warehouse enables rapid replacement of faulty pumps.	Warehouse sparing methodology has been developed based on the type of pumps and the commonality of pumps between platforms (i.e. pumps that are common between platforms have more spares available)	Adopted. **CM46:** Maintenance and testing of Open and Closed Skimmer Piles
Dose with emulsion breaking chemicals	Emulsion breakers help to manage pile levels by breaking down emulsions that may form in piles. Use of emulsion breakers has the benefits of: Assisting pumps to function by pumping liquid (not emulsion) Assisting in accuracy of level instrumentation which uses density to differentiate between oil and water. Procedure GEN-110-201 is in place to provide guidance on when emulsion breaker should be used and how to safely apply it to open and closed drain systems.	Only a limited number of emulsion breakers are assessed as suitable for use using the Chemical Selection Assessment Process	Adopted **CM71:** Dosing of piles with emulsion breaker
Alternative disposal options for waste hydrocarbons	Reduced volume of hydrocarbons directed to drains and piles.	Significant safety risks associated with alternative disposal methods. Waste will not be returned to the process (i.e. will not be recycled)	Not adopted

7.4.6 Demonstration of Acceptability

Factor	Demonstration Criteria	Criteria Met	Rationale
Risk Assessment Process for Unplanned Events	The risk ranking is lower than Category 1	✓	The risk ranking is Category 3 and therefore considered acceptable.
Principles of Ecologically Sustainable Development (ESD)	No potential to affect biological diversity and ecological integrity.	✓	The potential impact associated with this aspect is limited to a localised short-term impact, which is not considered as having the potential to affect biological diversity and ecological integrity.
	Activity does not have the potential to result in serious or irreversible environmental damage.	✓	The activities were evaluated as having the potential to result in a Level IV consequence thus are not considered as having the potential to result in serious or irreversible environmental damage.
Legislative and Other Requirements	Legislative and other requirements have been identified and met.	✓	Activity will not impact the long term survival and recovery of listed and threatened fish, marine mammals or marine reptiles and will be undertaken in accordance with all applicable management actions.
Internal Context	Consistent with Esso's Environment Policy.	✓	Proposed control measures are consistent with Esso's Environment Policy, in particular, to "manage business with the goal of preventing incidents and of controlling emissions and wastes to below harmful levels; design, operate, and maintain facilities to this end"
	Meets ExxonMobil Environmental Standards	✓	The use of piles for management of waste hydrocarbons meets the Upstream Waste Management Standards which calls for consideration of the waste hierarchy. Use of piles allows for waste hydrocarbon to be 'recycled' and returned back to the process. Further, the use of piles meets expectations of the Upstream Water Management Standard The Upstream Water Management Standards and standards for appropriate disposal of uncontaminated deck drainage.
	Meets ExxonMobil Operations Integrity Management System (OIMS) Objectives	✓	Proposed control measures meet: OIMS System 6-5 objective to identify and assess environmental aspects; significant aspects are addressed and controlled consistent with policy and regulatory requirements; and OIMS System 6-2 objectives ensure equipment is maintained over the operating life of the equipment preventing or mitigating a significant event that could result in significant and environment consequences.
External Context	Stakeholder concerns have been considered / addressed through the consultation process.	✓	No specific stakeholder concerns have been raised concerning the accidental LOC from pile systems.

7.5 Accidental Release – LOC from a vessel

7.5.1 Causes of LOC from a vessel

Use of vessels will occur frequently as part of Bass Strait Operations (as described in Section 2.4.3) and a loss of containment relating to vessel activities has been considered as a potential discharge scenario.

Table 7-9 Selection of worst case discharge scenario - LOC from a vessel

Process	Description
Identify potential discharge scenarios	During Bass Strait Operations, potential unplanned incidents that could result in a spill include: • Collision with platform that results in tank rupture and marine diesel loss. Vessel drift or powered grounding is not considered credible given the distance from shore of the Operational Area and the lack of emergent features in the Operational Area. Vessel to vessel collisions causing multiple tank rupture during SIMOPS operations are not considered credible for the following reasons Activity Specific Operating Guidelines (ASOG) are required to consider SIMOPS, therefore activity specific procedures control and are used to prevent the possibility of collisions ASOG details include limitations for vessel speed inside the PSZ Vessels operating in close proximity are normally on DP and also have manual controls and emergency stops as backup DNV Clean class vessels (DNVGL-RU-SHIP) or similar, are used preferentially where possible. These are constructed to protect oil tanks on vessels and therefore further limit the risk of tank rupture in the unlikely case of collision
Identification of potential pollutants	Common fuel used in larger vessels servicing the oil and gas industry is Marine Diesel – MDO Group II.
Determine characteristics of the discharge scenario (including calculation of potential spill volumes)	Based on the type of support vessel usually in service, the largest fuel tank volume considered is 280 m^3. * At time of writing the contracted PSV, Skandi Feistein's largest fuel tank was 220 m^3. Largest tank sizes for other vessels types which may be used during operations (refer Section 2.4.3.1) supplied by the same operator (DOF Group) are listed below, supporting that the considered volume is appropriate for the spill scenario: Skandi Singapore DSV – largest capacity FO tank: 166.9 m^3 Skandi Darwin MPSV – largest capacity FO tank: 240 m^3 Skandi Feinstein PSV – largest capacity FO tank: 219.6 m^3 Similarly, the largest tank size for the Subsea Seven – Sea Eagle, construction/dive support vessel contracted for the BTW installation work is 190m^3. The loss of a full tank of fuel is most likely an overestimate as hydrostatic pressure would limit the release and pumping of fuel oil in a ruptured tank to another tank could also restrict the amount lost.
Determine likelihood of the discharge scenario	There have been no incidents of collision leading to tank rupture from PSVs in Bass Strait Operations over the past 10 years.
Selection of worst case scenario based on risk	Given there have been no incidents of vessel collision with platforms leading to tank rupture and LOC, modelling of a spill of MDO has been completed at a selection of facilities. This selection gives a representation of spills:

Process	Description
	• close to shore (BTA, PCA) • furthest north facility (KPA) • furthest south facility (WKF) • central fields facility (HLA)

* Representative spill volumes are based on known vessel tank sizes that have been used for the activity. These are selected for modelling and are used to assess potential impacts to the environment from MDO spills. The volume does not represent a limitation on spill response capability and does not limit the size of vessels that may be used in the future. Subsea IMR works and market availability of vessels may potentially require vessels with larger individual tank sizes to be used.

The NERA Environment Plan Reference Case for consequence analysis of an accidental release of diesel (DIIS, 2018) shows that diesel spills up to 700 m^3 will have surface impacts (10 g/m^2) occur within a 150 km boundary around the petroleum activity and that titleholders describing the environment to that boundary distance are not required to conduct additional spill modelling if their largest diesel tank size is less than 700 m^3. The PEA for this activity scope is defined in Section 5.1 and describes an area well beyond the 150 km boundary.

As demonstrated through Section 7.6 and Section 7.7, impacts of much larger spill volumes from heavier and more persistent hydrocarbons are described beyond the 150 km boundary and the spill response capability is described through volume 3. Therefore if a vessel with a larger individual tank size than 280 m^3 were to be used and in the unlikely event that a collision causing a full tank rupture occurred, the impact would be less than that described in Section 7.6 and 7.7 and spill response capability described in Volume 3 would cover the required response measures.

7.5.2 Spill Modelling

7.5.2.1 Modelling Methodology

To understand the potential consequences of a marine diesel spill and the response preparedness required, stochastic and deterministic modelling was undertaken in accordance with Section 7.2.1.1 (RPS, 2019a). Model inputs and parameters are summarised Table 7-10. The modelling was based on 100 spill simulations and annual analysis (i.e. over all seasons).

Table 7-10 Vessel collision MDO spill modelling inputs and parameters
